double precision	$\text{abs}(a[i]) < \text{sqrt}(\text{DBL_MAX})$ $\text{abs}(b[i]) < \text{sqrt}(\text{DBL_MAX})$

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vshypot DOUBLE PRECISION for vdhypot Fortran 90: REAL, INTENT(OUT) for vshypot DOUBLE PRECISION, INTENT(OUT) for vdhypot C: float* for vsHypot double* for vdHypot	FORTRAN: Array, specifies the output vector y. C: Pointer to an array that contains the output vector y.

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function computes a square root of sum of two squared elements.

Special values for Real Function v?Hypot(x)

Argument 1	Argument 2	Result	Exception
+0	+0	+0	
-0	-0	+0	
$+\infty$	any value	$+\infty$	
any value	$+\infty$	$+\infty$	
SNAN	any value	QNAN	INVALID
any value	SNAN	QNAN	INVALID
QNAN	any value	QNAN	
any value	QNAN	QNAN	

Exponential and Logarithmic Functions

v?Exp

Computes an exponential of vector elements.

Syntax

Fortran:

```
call vsexp( n, a, y )
call vdexp( n, a, y )
call vcexp( n, a, y )
call vzexp( n, a, y )
```

C:

```
vsExp( n, a, y );
vdExp( n, a, y );
vcExp( n, a, y );
vzExp( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsexp DOUBLE PRECISION for vdexp COMPLEX for vcexp DOUBLE COMPLEX for vzexp Fortran 90: REAL, INTENT (IN) for vsexp DOUBLE PRECISION, INTENT (IN) for vdexp COMPLEX, INTENT (IN) for vcexp DOUBLE COMPLEX, INTENT (IN) for vzexp C: const float* for vsExp const double* for vdExp const MKL_Complex8* for vcExp const MKL_Complex16* for vz- Exp	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Table 9-8 Precision Overflow Thresholds for Exp Real Function

Data Type	Threshold Limitations on Input Parameters
single precision	$a[i] < \text{Ln}(\text{FLT_MAX})$
double precision	$a[i] < \text{Ln}(\text{DBL_MAX})$

NOTE. Overflow can occur also in `Exp` complex function, but the exact formula is beyond the scope of this document.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for <code>vsexp</code> DOUBLE PRECISION for <code>vdexp</code> COMPLEX for <code>vcexp</code> DOUBLE COMPLEX for <code>vzexp</code> Fortran 90: REAL, INTENT (OUT) for <code>vsexp</code> DOUBLE PRECISION, INTENT (OUT) for <code>vdexp</code> COMPLEX, INTENT (OUT) for <code>vcexp</code> DOUBLE COMPLEX, INTENT (OUT) for <code>vzexp</code> C: float* for <code>vsExp</code> double* for <code>vdExp</code> MKL_Complex8* for <code>vcExp</code> MKL_Complex16* for <code>vzExp</code>	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function computes an exponential of vector elements.

Special Values for Real Function v?Exp(x)

Argument	Result	Error Code	Exception
+0	+1		
-0	+1		

Argument	Result	Error Code	Exception
$X > \text{overflow}$	$+\infty$	VML_STATUS_OVERFLOW	OVERFLOW
$X < \text{underflow}$	$+0$	VML_STATUS_UNDERFLOW	UNDERFLOW
$+\infty$	$+\infty$		
$-\infty$	$+0$		
QNAN	QNAN		
SNAN	QNAN		INVALID

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function $v?\text{Exp}(z)$

RE(z) IM(z)	$-\infty$	-X	-0	+0	+X	$+\infty$	NAN
$+i\cdot\infty$	$+0+i\cdot 0$	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	$+\infty+i\cdot\text{QNAN}$ INVALID	QNAN+i·QNAN INVALID
$+i\cdot Y$	$+0\cdot\text{CIS}(Y)$					$+\infty\cdot\text{CIS}(Y)$	QNAN+i·QNAN
$+i\cdot 0$	$+0\cdot\text{CIS}(0)$		$+1+i\cdot 0$	$+1+i\cdot 0$		$+\infty+i\cdot 0$	QNAN+i·0
$-i\cdot 0$	$+0\cdot\text{CIS}(0)$		$+1-i\cdot 0$	$+1-i\cdot 0$		$+\infty-i\cdot 0$	QNAN-i·0
$-i\cdot Y$	$+0\cdot\text{CIS}(Y)$					$+\infty\cdot\text{CIS}(Y)$	QNAN+i·QNAN
$-i\cdot\infty$	$+0-i\cdot 0$	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	$+\infty+i\cdot\text{QNAN}$ INVALID	QNAN+i·QNAN
$+i\cdot\text{NAN}$	$+0+i\cdot 0$	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	$+\infty+i\cdot\text{QNAN}$	QNAN+i·QNAN

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- raises `INVALID` exception on argument $z=-\infty+i\cdot\text{QNAN}$
- does not change `ERROR CODE`.

v?Expm1

Computes an exponential of vector elements decreased by 1.

Syntax

Fortran:

```
call vsexpm1( n, a, y )
call vdexpm1( n, a, y )
```

C:

```
vsExpm1( n, a, y );
vdExpm1( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsexpm1 DOUBLE PRECISION for vdexpm1 Fortran 90: REAL, INTENT (IN) for vsexpm1 DOUBLE PRECISION, INTENT (IN) for vdexpm1 C: const float* for vsExpm1 const double* for vdExpm1	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Table 9-9 Precision Overflow Thresholds for Expm1 Function

Data Type	Threshold Limitations on Input Parameters
single precision	$a[i] < \text{Ln}(\text{FLT_MAX})$
double precision	$a[i] < \text{Ln}(\text{DBL_MAX})$

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vsexpm1 DOUBLE PRECISION for vdexpm1 Fortran 90: REAL, INTENT(OUT) for vsexpm1 DOUBLE PRECISION, INTENT(OUT) for vdexpm1 C: float* for vsExpml double* for vdExpml	FORTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function computes an exponential of vector elements decreased by 1.

Special Values for Real Function v?Expm1(x)

Argument	Result	Error Code	Exception
+0	+0		
-0	+0		
$X > \text{overflow}$	$+\infty$	VML_STATUS_OVERFLOW	OVERFLOW
$+\infty$	$+\infty$		
$-\infty$	-1		
QNAN	QNAN		
SNAN	QNAN		INVALID

v?Ln

Computes natural logarithm of vector elements.

Syntax

Fortran:

```
call vsln( n, a, y )
call vdlm( n, a, y )
call vcLn( n, a, y )
call vzLn( n, a, y )
```

C:

```
vsLn( n, a, y );
vdLn( n, a, y );
vcLn( n, a, y );
vzLn( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsln DOUBLE PRECISION for vdlm COMPLEX for vcLn DOUBLE COMPLEX for vzLn Fortran 90: REAL, INTENT (IN) for vsln	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT (IN) for vdlN	
	COMPLEX, INTENT (IN) for vcLn	
	DOUBLE COMPLEX, INTENT (IN) for vzLn	
	C: const float* for vsLn	
	const double* for vdLn	
	const MKL_Complex8* for vcLn	
	const MKL_Complex16* for vzLn	

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vsLn DOUBLE PRECISION for vdlN COMPLEX for vcLn DOUBLE COMPLEX for vzLn	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .
	Fortran 90: REAL, INTENT (OUT) for vsLn DOUBLE PRECISION, INTENT (OUT) for vdlN COMPLEX, INTENT (OUT) for vcLn DOUBLE COMPLEX, INTENT (OUT) for vzLn	
	C: float* for vsLn double* for vdLn MKL_Complex8* for vcLn MKL_Complex16* for vzLn	

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function computes natural logarithm of vector elements.

Special Values for Real Function $v?Ln(x)$

Argument	Result	Error Code	Exception
+1	+0		
$X < +0$	QNAN	VML_STATUS_ERRDOM	INVALID
+0	$-\infty$	VML_STATUS_SING	ZERODRIVE
-0	$-\infty$	VML_STATUS_SING	ZERODRIVE
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$+\infty$	$+\infty$		
QNAN	QNAN		
SNAN	QNAN		INVALID

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function $v?Ln(z)$

RE(z) IM(z)	$-\infty$	-X	-0	+0	+X	$+\infty$	NAN

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- does not change `ERROR CODE`.

v?Log10

Computes denary logarithm of vector elements.

Syntax

Fortran:

```
call vslog10( n, a, y )
call vdlog10( n, a, y )
call vclog10( n, a, y )
call vzlog10( n, a, y )
```

C:

```
vsLog10( n, a, y );
vdLog10( n, a, y );
vcLog10( n, a, y );
vzLog10( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTTRAN 77: REAL for vslog10 DOUBLE PRECISION for vdlog10 COMPLEX for vclog10 DOUBLE COMPLEX for vzlog10 Fortran 90: REAL, INTENT (IN) for vslog10 DOUBLE PRECISION, INTENT (IN) for vdlog10 COMPLEX, INTENT (IN) for vclog10 DOUBLE COMPLEX, INTENT (IN) for vzlog10 C: const float* for vsLog10 const double* for vdLog10 const MKL_Complex8* for vcLog10 const MKL_Complex16* for vzLog10	FORTTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vslog10 DOUBLE PRECISION for vdlog10 COMPLEX for vclog10 DOUBLE COMPLEX for vzlog10 Fortran 90: REAL, INTENT(OUT) for vslog10 DOUBLE PRECISION, INTENT(OUT) for vdlog10 COMPLEX, INTENT(OUT) for vclog10 DOUBLE COMPLEX, INTENT(OUT) for vzlog10 C: float* for vsLog10 double* for vdLog10 MKL_Complex8* for vcLog10 MKL_Complex16* for vzLog10	FORTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function computes a denary logarithm of vector elements.

Special Values for Real Function $v?Log10(x)$

Argument	Result	Error Code	Exception

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- does not change `ERROR_CODE`

v?Log1p

Computes a natural logarithm of vector elements that are increased by 1.

Syntax

Fortran:

```
call vslog1p( n, a, y )  
call vdlog1p( n, a, y )
```

C:

```
vsLog1p( n, a, y );  
vdLog1p( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vslog1p DOUBLE PRECISION for vdlog1p Fortran 90: REAL, INTENT (IN) for vslog1p DOUBLE PRECISION, INTENT (IN) for vdlog1p C: const float* for vsLog1p const double* for vdLog1p	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vslog1p DOUBLE PRECISION for vdlog1p Fortran 90: REAL, INTENT (OUT) for vslog1p DOUBLE PRECISION, INTENT (OUT) for vdlog1p C: float* for vsLog1p double* for vdLog1p	FORTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function computes a natural logarithm of vector elements that are increased by 1.

Special Values for Real Function $v?Log1p(x)$

Argument	Result	Error Code	Exception
-1	$-\infty$	VML_STATUS_SING	ZERODIVIDE
$X < -1$	QNAN	VML_STATUS_ERRDOM	INVALID
+0	+0		
-0	-0		
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$+\infty$	$+\infty$		
QNAN	QNAN		
SNAN	QNAN		INVALID

Trigonometric Functions

v?Cos

Computes cosine of vector elements.

Syntax

Fortran:

```
call vscos( n, a, y )
call vdcos( n, a, y )
call vccos( n, a, y )
call vzcoss( n, a, y )
```

C:

```
vsCos( n, a, y );
vdCos( n, a, y );
vcCos( n, a, y );
vzCos( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTTRAN 77: REAL for vscos DOUBLE PRECISION for vdcos COMPLEX for vccos DOUBLE PRECISION for vzcoss	FORTTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	Fortran 90: REAL, INTENT (IN) for vscos	
	DOUBLE PRECISION, INTENT (IN) for vdcos	
	COMPLEX, INTENT (IN) for vccos	
	DOUBLE PRECISION, INTENT (IN) for vzcoss	
	C: const float* for vsCos	
	const double* for vdCos	
	const MKL_Complex8* for vcCos	
	const MKL_Complex16* for vz-	
	Cos	

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN 77: REAL for vscos	FORTTRAN: Array, specifies the output vector <i>y</i> .
	DOUBLE PRECISION for vdcos	
	COMPLEX for vccos	C: Pointer to an array that contains the output vector <i>y</i> .
	DOUBLE COMPLEX for vzcoss	
	Fortran 90: REAL, INTENT (OUT) for vscos	
	DOUBLE PRECISION, INTENT (OUT) for vdcos	
	COMPLEX, INTENT (OUT) for vccos	
	DOUBLE COMPLEX, INTENT (OUT) for vzcoss	
	C: float* for vsCos	
	double* for vdCos	

Name	Type	Description
	MKL_Complex8*	for vcCos
	MKL_Complex16*	for vzCos

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function computes cosine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trig function arguments for which VML provides the best possible performance. For performance reasons, avoid arguments that do not belong to the fast computational path in the VML High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VML Enhanced Performance (EP) functions that are fast on the entire function domain at the cost of accuracy.

Special Values for Real Function v?Cos(x)

Argument	Result	Error Code	Exception
+0	+1		
-0	+1		
$+\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are found according to the formula

$$\text{Cos}(z) = \text{Cosh}(i*z).$$

v?Sin

Computes sine of vector elements.

Syntax

Fortran:

```
call vssin( n, a, y )
```

```
call vdsin( n, a, y )
call vcsin( n, a, y )
call vzsine( n, a, y )
```

C:

```
vsSin( n, a, y );
vdSin( n, a, y );
vcSin( n, a, y );
vzSin( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTTRAN 77: REAL for vssin DOUBLE PRECISION for vdsin COMPLEX for vcsin DOUBLE PRECISION for vzsine Fortran 90: REAL, INTENT (IN) for vssin DOUBLE PRECISION, INTENT (IN) for vdsin COMPLEX, INTENT (IN) for vcsin DOUBLE PRECISION, INTENT (IN) for vzsine C: const float* for vsSin const double* for vdSin	FORTTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	const MKL_Complex8* for vcSin	
	const MKL_Complex16* for vzSin	

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vssin DOUBLE PRECISION for vdsin COMPLEX for vcsin DOUBLE COMPLEX for vzsine Fortran 90: REAL, INTENT(OUT) for vssin DOUBLE PRECISION, INTENT(OUT) for vdsin COMPLEX, INTENT(OUT) for vcsin DOUBLE COMPLEX, INTENT(OUT) for vzsine C: float* for vsSin double* for vdSin MKL_Complex8* for vcSin MKL_Complex16* for vzSin	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function computes sine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trig function arguments for which VML provides the best possible performance. For performance reasons, avoid arguments that do not belong to the fast computational path in the VML High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VML Enhanced Performance (EP) functions that are fast on the entire function domain at the cost of accuracy.

Special Values for Real Function v?Sin(x)

Argument	Result	Error Code	Exception
+0	+0		
-0	-0		
$+\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are found according to the formula $\text{Sin}(z) = -i * \text{Sinh}(i * z)$.

v?SinCos

Computes sine and cosine of vector elements.

Syntax

Fortran:

```
call vssincos( n, a, y, z )
call vdsincos( n, a, y, z )
```

C:

```
vsSinCos( n, a, y, z );
vdSinCos( n, a, y, z );
```

Input Parameters

Name	Type	Description
n	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
a	FORTRAN 77: REAL for vssincos DOUBLE PRECISION for vdsincos Fortran 90: REAL, INTENT (IN) for vssincos DOUBLE PRECISION, INTENT (IN) for vdsincos C: const float* for vsSinCos const double* for vdSinCos	FORTRAN: Array, specifies the input vector a . C: Pointer to an array that contains the input vector a .

Output Parameters

Name	Type	Description
y, z	FORTRAN 77: REAL for vssincos DOUBLE PRECISION for vdsincos Fortran 90: REAL, INTENT (OUT) for vssincos DOUBLE PRECISION, INTENT (OUT) for vdsincos C: float* for vsSinCos double* for vdSinCos	FORTRAN: Arrays, specify the output vectors y (for sine values) and z (for cosine values). C: Pointers to arrays that contain the output vectors y (for sinevalues) and z (for cosine values).

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function computes sine and cosine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trig function arguments for which VML provides the best possible performance. For performance reasons, avoid arguments that do not belong to the fast computational path in the VML High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VML Enhanced Performance (EP) functions that are fast on the entire function domain at the cost of accuracy.

Special Values for Real Function v?SinCos(x)

Argument	Result 1	Result 2	Error Code	Exception
+0	+0	+1		
-0	-0	+1		
$+\infty$	QNAN	QNAN	VML_STATUS_ERRDOM	INVALID
$-\infty$	QNAN	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN	QNAN		
SNAN	QNAN	QNAN		INVALID

Specifications for special values of the complex functions are found according to the formula

$$\text{Sin}(z) = -i * \text{Sinh}(i * z).$$

v?CIS

Computes complex exponent of real vector elements (cosine and sine of real vector elements combined to complex value).

Syntax

Fortran:

```
call vccis( n, a, y )
call vzcis( n, a, y )
```

C:

```
vcCIS( n, a, y );  
vzCIS( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vccis DOUBLE PRECISION for vzcis Fortran 90: REAL, INTENT (IN) for vccis DOUBLE PRECISION, INTENT (IN) for vzcis C: const float* for vcCIS const double* for vzCIS	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: COMPLEX for vccis DOUBLE COMPLEX for vzcis Fortran 90: COMPLEX, INTENT (OUT) for vccis DOUBLE COMPLEX, INTENT (OUT) for vzcis C: MKL_Complex8* for vcCIS	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name

Type

Description

MKL_Complex16* for vzCIS

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function computes complex exponent of real vector elements (cosine and sine of real vector elements combined to complex value).

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function v?CIS(x)

x	CIS(x)
+ ∞	QNAN+i·QNAN INVALID
+ 0	+1+i·0
- 0	+1-i·0
- ∞	QNAN+i·QNAN INVALID
NAN	QNAN+i·QNAN

Notes:

- raises `INVALID` exception when the argument is `SNAN`
- raises `INVALID` exception and sets `ERROR CODE` to `VML_STATUS_ERRDOM` for `x=+∞`, `x=-∞`

v?Tan

Computes tangent of vector elements.

Syntax

Fortran:

```
call vstan( n, a, y )
call vdtan( n, a, y )
call vctan( n, a, y )
call vztan( n, a, y )
```

C:

```
vsTan( n, a, y );
vdTan( n, a, y );
vcTan( n, a, y );
vzTan( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL, INTENT(IN) for vstan DOUBLE PRECISION, INTENT(IN) for vdtan COMPLEX, INTENT(IN) for vctan DOUBLE COMPLEX, INTENT(IN) for vztan	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	Fortran 90: REAL, INTENT (IN) for vstan	
	DOUBLE PRECISION, INTENT (IN) for vdtan	
	COMPLEX, INTENT (IN) for vctan	
	DOUBLE COMPLEX, INTENT (IN) for vztan	
	C: const float* for vsTan	
	const double* for vdTan	
	const MKL_Complex8* for vcTan	
	const MKL_Complex16* for vz- Tan	

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vstan DOUBLE PRECISION for vdtan COMPLEX for vctan DOUBLE COMPLEX for vztan Fortran 90: REAL, INTENT (OUT) for vstan DOUBLE PRECISION, INTENT (OUT) for vdtan COMPLEX, INTENT (OUT) for vctan DOUBLE COMPLEX, INTENT (OUT) for vztan C: float* for vsTan double* for vdTan	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
------	------	-------------

	MKL_Complex8* for vcTan	
	MKL_Complex16* for vzTan	

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function computes tangent of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trig function arguments for which VML provides the best possible performance. For performance reasons, avoid arguments that do not belong to the fast computational path in the VML High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VML Enhanced Performance (EP) functions that are fast on the entire function domain at the cost of accuracy.

Special Values for Real Function v?Tan(x)

Argument	Result	Error Code	Exception
+0	+0		
-0	-0		
$+\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are found according to the formula

$$\text{Tan}(z) = -i * \text{Tanh}(i * z).$$

v?Acos

Computes inverse cosine of vector elements.

Syntax

Fortran:

```
call vsacos( n, a, y )
```

```
call vdacos( n, a, y )
call vcacos( n, a, y )
call vzacos( n, a, y )
```

C:

```
vsAcos( n, a, y );
vdAcos( n, a, y );
vcAcos( n, a, y );
vzAcos( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsacos DOUBLE PRECISION for vdacos COMPLEX for vcacos DOUBLE COMPLEX for vzacos Fortran 90: REAL, INTENT (IN) for vsacos DOUBLE PRECISION, INTENT (IN) for vdacos COMPLEX, INTENT (IN) for vcacos DOUBLE COMPLEX, INTENT (IN) for vzacos C: const float* for vsAcos const double* for vdAcos	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	const MKL_Complex8* for vca-	
	cos	
	const MKL_Complex16* for vza-	
	cos	

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vsacos	FORTRAN: Array, specifies the output vector <i>y</i> .
	DOUBLE PRECISION for vdacos	
	COMPLEX for vcacos	C: Pointer to an array that contains the output vector <i>y</i> .
	DOUBLE COMPLEX for vzaacos	
	Fortran 90: REAL, INTENT (OUT) for vsacos	
	DOUBLE PRECISION, INTENT (OUT) for vdacos	
	COMPLEX, INTENT (OUT) for vca-	
	cos	
	DOUBLE COMPLEX, INTENT (OUT) for vza-	
	cos	
	C: float* for vsAcos	
	double* for vdAcos	
	MKL_Complex8* for vcAcos	
	MKL_Complex16* for vzAcos	

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function computes inverse cosine of vector elements.

Special Values for Real Function v?Acos(x)

Argument	Result	Error Code	Exception
+0	$+\pi/2$		
-0	$+\pi/2$		
+1	+0		
-1	$+\pi$		
$ X > 1$	QNAN	VML_STATUS_ERRDOM	INVALID
$+\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function v?Acos(z)

RE(z) IM(z)	$-\infty$	-X	-0	+0	+X	$+\infty$	NAN
$+i\cdot\infty$	$+\frac{3\pi}{4} - i\cdot\infty$	$+\frac{\pi}{2} - i\cdot\infty$	$+\frac{\pi}{2} - i\cdot\infty$	$+\frac{\pi}{2} - i\cdot\infty$	$+\frac{\pi}{2} - i\cdot\infty$	$+\frac{\pi}{4} - i\cdot\infty$	QNAN- $i\cdot\infty$
$+i\cdot Y$	$+\pi - i\cdot\infty$					$+0 - i\cdot\infty$	QNAN+ $i\cdot$ QNAN
$+i\cdot 0$	$+\pi - i\cdot\infty$		$+\frac{\pi}{2} - i\cdot 0$	$+\frac{\pi}{2} - i\cdot 0$		$+0 - i\cdot\infty$	QNAN+ $i\cdot$ QNAN
$-i\cdot 0$	$+\pi + i\cdot\infty$		$+\frac{\pi}{2} + i\cdot\infty$	$+\frac{\pi}{2} + i\cdot\infty$		$+0 + i\cdot\infty$	QNAN+ $i\cdot$ QNAN
$-i\cdot Y$	$+\pi + i\cdot\infty$					$+0 + i\cdot\infty$	QNAN+ $i\cdot$ QNAN
$-i\cdot\infty$	$+\frac{3\pi}{4} + i\cdot\infty$	$+\frac{\pi}{2} + i\cdot\infty$	$+\frac{\pi}{2} + i\cdot\infty$	$+\frac{\pi}{2} + i\cdot\infty$	$+\frac{\pi}{2} + i\cdot\infty$	$+\frac{\pi}{4} + i\cdot\infty$	QNAN+ $i\cdot\infty$
$+i\cdot$ NAN	QNAN+ $i\cdot\infty$	QNAN+ $i\cdot$ QNAN	$+\frac{\pi}{2} + i\cdot$ QNAN	$+\frac{\pi}{2} + i\cdot$ QNAN	QNAN+ $i\cdot$ QNAN	QNAN+ $i\cdot\infty$	QNAN+ $i\cdot$ QNAN

Notes:

- raises INVALID exception when real or imaginary part of the argument is SNAN
- does not change ERROR CODE

- $\text{Acos}(\text{CONJ}(z)) = \text{CONJ}(\text{Acos}(z))$.

v?Asin

Computes inverse sine of vector elements.

Syntax

Fortran:

```
call vsasin( n, a, y )
call vdasin( n, a, y )
call vcasin( n, a, y )
call vzasin( n, a, y )
```

C:

```
vsAsin( n, a, y );
vdAsin( n, a, y );
vcAsin( n, a, y );
vzAsin( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsasin DOUBLE PRECISION for vdasin COMPLEX for vcasin DOUBLE COMPLEX for vzasin	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	Fortran 90: REAL, INTENT (IN) for vsasin	
	DOUBLE PRECISION, INTENT (IN) for vdasin	
	COMPLEX, INTENT (IN) for vcasin	
	DOUBLE COMPLEX, INTENT (IN) for vzasin	
	C: const float* for vsAsin	
	const double* for vdAsin	
	const MKL_Complex8* for vcAsin	
	const MKL_Complex16* for vzAsin	

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN 77: REAL for vsasin DOUBLE PRECISION for vdasin COMPLEX for vcasin DOUBLE COMPLEX for vzasin Fortran 90: REAL, INTENT (OUT) for vsasin DOUBLE PRECISION, INTENT (OUT) for vdasin COMPLEX, INTENT (OUT) for vcasin DOUBLE COMPLEX, INTENT (OUT) for vzasin	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
------	------	-------------

	C: float* for vsAsin	
	double* for vdAsin	
	MKL_Complex8* for vcAsin	
	MKL_Complex16* for vzAsin	

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function computes inverse sine of vector elements.

Special Values for Real Function v?Asin(x)

Argument	Result	Error Code	Exception
+0	+0		
-0	-0		
+1	$+\pi/2$		
-1	$-\pi/2$		
$ X > 1$	QNAN	VML_STATUS_ERRDOM	INVALID
$+\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are found according to the formula

$$\text{Asin}(z) = -i * \text{Asinh}(i * z).$$

v?Atan

Computes inverse tangent of vector elements.

Syntax

Fortran:

```
call vsatan( n, a, y )
```

```
call vdatan( n, a, y )
call vcatan( n, a, y )
call vzatan( n, a, y )
```

C:

```
vsAtan( n, a, y );
vdAtan( n, a, y );
vcAtan( n, a, y );
vzAtan( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsatan DOUBLE PRECISION for vdatan COMPLEX for vcatan DOUBLE COMPLEX for vzatan Fortran 90: REAL, INTENT (IN) for vsatan DOUBLE PRECISION, INTENT (IN) for vdatan COMPLEX, INTENT (IN) for vcatan DOUBLE COMPLEX, INTENT (IN) for vzatan C: const float* for vsAtan const double* for vdAsin	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	const MKL_Complex8* for vcAtan	
	const MKL_Complex16* for vzAsin	

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsatan	FORTRAN: Array, specifies the output vector <i>y</i> .
	DOUBLE PRECISION for vdatan	
	COMPLEX for vcatan	C: Pointer to an array that contains the output vector <i>y</i> .
	DOUBLE COMPLEX for vzatan	
	Fortran 90: REAL, INTENT(OUT) for vsatan	
	DOUBLE PRECISION, INTENT(OUT) for vdatan	
	COMPLEX, INTENT(OUT) for vcatan	
	DOUBLE COMPLEX, INTENT(OUT) for vzatan	
	C: float* for vsAtan	
	double* for vdAtan	
	MKL_Complex8* for vcAtan	
	MKL_Complex16* for vzAtan	

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function computes inverse tangent of vector elements.

Special Values for Real Function v?Atan(x)

Argument	Result	Error Code	Exception
+0	+0		
-0	-0		
+∞	+ $\pi/2$		
-∞	- $\pi/2$		
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are found according to the formula

$$\text{Atan}(z) = -i \cdot \text{Atanh}(i \cdot z).$$

v?Atan2

Computes four-quadrant inverse tangent of elements of two vectors.

Syntax

Fortran:

```
call vsatan2( n, a, b, y )
call vdatan2( n, a, b, y )
```

C:

```
vsAtan2( n, a, b, y );
vdAtan2( n, a, b, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.

Name	Type	Description
a, b	FORTRAN 77: REAL for vsatan2 DOUBLE PRECISION for vdatan2 Fortran 90: REAL, INTENT(IN) for vsatan2 DOUBLE PRECISION, INTENT(IN) for vdatan2 C: const float* for vsAtan2 const double* for vdAtan2	FORTRAN: Arrays, specify the input vectors a and b . C: Pointers to arrays that contain the input vectors a and b .

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vsatan2 DOUBLE PRECISION for vdatan2 Fortran 90: REAL, INTENT(OUT) for vsatan2 DOUBLE PRECISION, INTENT(OUT) for vdatan2 C: float* for vsAtan2 double* for vdAtan2	FORTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function computes four-quadrant inverse tangent of elements of two vectors.

The elements of the output vector y are computed as the four-quadrant arctangent of $a[i] / b[i]$.

Special values for Real Function v?Atan2(x)

Argument 1	Argument 2	Result	Exception
$-\infty$	$-\infty$	$-3*\pi/4$

SNAN	SNAN	QNAN	INVALID

Hyperbolic Functions

v?Cosh

Computes hyperbolic cosine of vector elements.

Syntax

Fortran:

```
call vscosh( n, a, y )
call vdcosh( n, a, y )
call vccosh( n, a, y )
call vzcosh( n, a, y )
```

C:

```
vsCosh( n, a, y );
vdCosh( n, a, y );
vcCosh( n, a, y );
```

```

vzCosh( n, a, y );

```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vscosh DOUBLE PRECISION for vdcosh COMPLEX for vccosh DOUBLE COMPLEX for vzcosh Fortran 90: REAL, INTENT (IN) for vscosh DOUBLE PRECISION, INTENT (IN) for vdcosh COMPLEX, INTENT (IN) for vccosh DOUBLE COMPLEX, INTENT (IN) for vzcosh C: const float* for vsCosh const double* for vdCosh const MKL_Complex8* for vc-Cosh const MKL_Complex16* for vz-Cosh	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Table 9-10 Precision Overflow Thresholds for Cosh Real Function

Data Type	Threshold Limitations on Input Parameters
single precision	$-\ln(\text{FLT_MAX}) - \ln 2 < a[i] < \ln(\text{FLT_MAX}) + \ln 2$
double precision	$-\ln(\text{DBL_MAX}) - \ln 2 < a[i] < \ln(\text{DBL_MAX}) + \ln 2$

NOTE. Overflow can occur also in `Cosh` complex function, but the exact formula is beyond the scope of this document.

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for <code>vscosh</code> DOUBLE PRECISION for <code>vdcosh</code> COMPLEX for <code>vccosh</code> DOUBLE COMPLEX for <code>vzcosh</code> Fortran 90: REAL, INTENT (OUT) for <code>vscosh</code> DOUBLE PRECISION, INTENT (OUT) for <code>vdcosh</code> COMPLEX, INTENT (OUT) for <code>vc-cosh</code> DOUBLE COMPLEX, INTENT (OUT) for <code>vzcosh</code> C: float* for <code>vsCosh</code> double* for <code>vdCosh</code> MKL_Complex8* for <code>vcCosh</code> MKL_Complex16* for <code>vzCosh</code>	FORTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function computes hyperbolic cosine of vector elements.

Special Values for Real Function `v?Cosh(x)`

Argument	Result	Error Code	Exception
+0	+1		

Argument	Result	Error Code	Exception
-0	+1		
X > overflow	$+\infty$	VML_STATUS_OVERFLOW	OVERFLOW

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- does not change `ERROR CODE`
- $Cosh(CONJ(z)) = CONJ(Cosh(z))$

- $\text{Cosh}(-z) = \text{Cosh}(z)$.

v?Sinh

Computes hyperbolic sine of vector elements.

Syntax

Fortran:

```
call vssinh( n, a, y )
call vdsinh( n, a, y )
call vcsinh( n, a, y )
call vzsinh( n, a, y )
```

C:

```
vsSinh( n, a, y );
vdSinh( n, a, y );
vcSinh( n, a, y );
vzSinh( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vssinh DOUBLE PRECISION for vdsinh COMPLEX for vcsinh DOUBLE COMPLEX for vzsinh	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	Fortran 90: REAL, INTENT (IN) for vssinh	
	DOUBLE PRECISION, INTENT (IN) for vdsinh	
	COMPLEX, INTENT (IN) for vcsinh	
	DOUBLE COMPLEX, INTENT (IN) for vzsinh	
	C: const float* for vsSinh	
	const double* for vdSinh	
	const MKL_Complex8* for vc- Sinh	
	const MKL_Complex16* for vzS- inh	

Table 9-11 Precision Overflow Thresholds for Sinh Real Function

Data Type	Threshold Limitations on Input Parameters
single precision	$-\ln(\text{FLT_MAX}) - \ln 2 < a[i] < \ln(\text{FLT_MAX}) + \ln 2$
double precision	$-\ln(\text{DBL_MAX}) - \ln 2 < a[i] < \ln(\text{DBL_MAX}) + \ln 2$

NOTE. Overflow can occur also in `Sinh` complex function, but the exact formula is beyond the scope of this document.

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN 77: REAL for vssinh DOUBLE PRECISION for vdsinh COMPLEX for vcsinh DOUBLE COMPLEX for vzsinh	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
------	------	-------------

	Fortran 90: REAL, INTENT (OUT) for vssinh DOUBLE PRECISION, INTENT (OUT) for vdsinh COMPLEX, INTENT (OUT) for vc- sinh DOUBLE COMPLEX, INTENT (OUT) for vzsinh C: float* for vsSinh double* for vdSinh MKL_Complex8* for vcSinh MKL_Complex16* for vzSinh	
--	--	--

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function computes hyperbolic sine of vector elements.

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- does not change `ERROR_CODE`
- $\text{Sinh}(\text{CONJ}(z)) = \text{CONJ}(\text{Sinh}(z))$
- $\text{Sinh}(-z) = -\text{Sinh}(z)$.

v?Tanh

Computes hyperbolic tangent of vector elements.

Syntax

Fortran:

```
call vstanh( n, a, y )
```

```
call vdtanh( n, a, y )
call vctanh( n, a, y )
call vztanh( n, a, y )
```

C:

```
vsTanh( n, a, y );
vdTanh( n, a, y );
vcTanh( n, a, y );
vzTanh( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vstanh DOUBLE PRECISION for vdtanh COMPLEX for vctanh DOUBLE COMPLEX for vztanh Fortran 90: REAL, INTENT(IN) for vstanh DOUBLE PRECISION, INTENT(IN) for vdtanh COMPLEX, INTENT(IN) for vctanh DOUBLE COMPLEX, INTENT(IN) for vztanh C: const float* for vsTanh const double* for vdTanh	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	const MKL_Complex8* for vc-Tanh	
	const MKL_Complex16* for vz-Tanh	

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vstanh DOUBLE PRECISION for vdtanh COMPLEX for cstanh DOUBLE COMPLEX for zdtanh Fortran 90: REAL, INTENT (OUT) for vstanh DOUBLE PRECISION, INTENT (OUT) for vdtanh COMPLEX, INTENT (OUT) for cstanh DOUBLE COMPLEX, INTENT (OUT) for zdtanh C: float* for vsTanh double* for vdTanh MKL_Complex8* for vcTanh MKL_Complex16* for vzTanh	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function computes hyperbolic tangent of vector elements.

- $\text{Tanh}(-z) = -\text{Tanh}(z)$.

v?Acosh

Computes inverse hyperbolic cosine (nonnegative) of vector elements.

Syntax

Fortran:

```
call vsacosh( n, a, y )
call vdacosh( n, a, y )
call vcacosh( n, a, y )
call vzacosh( n, a, y )
```

C:

```
vsAcosh( n, a, y );
vdAcosh( n, a, y );
vcAcosh( n, a, y );
vzAcosh( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- does not change `ERROR CODE`
- `Acosh(CONJ(z))=CONJ(Acosh(z))`.

v?Asinh

Computes inverse hyperbolic sine of vector elements.

Syntax

Fortran:

```
call vsasinh( n, a, y )
call vdasinh( n, a, y )
call vcasinh( n, a, y )
call vzasinh( n, a, y )
```

C:

```
vsAsinh( n, a, y );
vdAsinh( n, a, y );
vcAsinh( n, a, y );
vzAsinh( n, a, y );
```

Input Parameters

Name	Type	Description

Notes:

- $Atanh(+ -1 + -i \cdot 0) = + -\infty + -i \cdot 0$, and **ZERODIVIDE** exception is raised
- raises **INVALID** exception when real or imaginary part of the argument is **SNAN**
- does not change **ERROR CODE**
- $Atanh(CONJ(z)) = CONJ(Atanh(z))$
- $Atanh(-z) = -Atanh(z)$.

Special Functions

v?Erf

Computes the error function value of vector elements.

Syntax

Fortran:

```
call vserf( n, a, y )
call vderf( n, a, y )
```

C:

```
vsErf( n, a, y );
vdErf( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vserf DOUBLE PRECISION for vderf Fortran 90: REAL, INTENT (IN) for vserf DOUBLE PRECISION, INTENT (IN) for vderf C: const float* for vsErf const double* for vdErf	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for <code>vserf</code> DOUBLE PRECISION for <code>vderf</code> Fortran 90: REAL, INTENT(OUT) for <code>vserf</code> DOUBLE PRECISION, INTENT(OUT) for <code>vderf</code> C: float* for <code>vsErf</code> double* for <code>vdErf</code>	FORTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function `Erf` computes the error function values for elements of the input vector a and writes them to the output vector y .

The error function is defined as given by:

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt .$$

Useful relations:

$$1. \quad \text{erfc}(x) = 1 - \text{erf}(x) ,$$

where `erfc` is the complementary error function.

$$2. \quad \Phi(x) = \frac{1}{2} \text{erf} (x/\sqrt{2}) ,$$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

is the cumulative normal distribution function.

$$3. \quad \Phi^{-1}(x) = \sqrt{2} \operatorname{erf}^{-1}(2x - 1),$$

where $\Phi^{-1}(x)$ and $\operatorname{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\operatorname{erf}(x)$ respectively.

Figure 9-1 illustrates the relationships among Erf family functions (Erf, Erfc, CdfNorm).

Figure 9-1 Erf Family Functions Relationship

Useful relations for these functions:

$$\text{erf}(x) + \text{erfc}(x) = 1$$

$$\text{cdfnorm}(x) = \frac{1}{2} \left(1 + \text{erf} \left(\frac{x}{\sqrt{2}} \right) \right) = 1 - \frac{1}{2} \text{erfc} \left(\frac{x}{\sqrt{2}} \right)$$

v?Erfc

Computes the complementary error function value of vector elements.

Syntax

Fortran:

```
call vserfc( n, a, y )
call vderfc( n, a, y )
```

C:

```
vsErfc( n, a, y );
vdErfc( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vserfc DOUBLE PRECISION for vderfc	FORTRAN: Array, specifies the input vector <i>a</i> .

Name	Type	Description
	Fortran 90: REAL, INTENT(IN) for <code>vserfc</code>	C: Pointer to an array that contains the input vector <i>a</i> .
	DOUBLE PRECISION, INTENT(IN) for <code>vderfc</code>	
	C: <code>const float*</code> for <code>vsErfc</code> <code>const double*</code> for <code>vdErfc</code>	

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for <code>vserfc</code> DOUBLE PRECISION for <code>vderfc</code>	FORTRAN: Array, specifies the output vector <i>y</i> .
	Fortran 90: REAL, INTENT(OUT) for <code>vserfc</code>	C: Pointer to an array that contains the output vector <i>y</i> .
	DOUBLE PRECISION, INTENT(OUT) for <code>vderfc</code>	
	C: <code>float*</code> for <code>vsErfc</code> <code>double*</code> for <code>vdErfc</code>	

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function `Erfc` computes the complementary error function values for elements of the input vector *a* and writes them to the output vector *y*.

The complementary error function is defined as given by:

$$\text{erfc}(x) = \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt .$$

Useful relations:

$$1. \text{erfc}(x) = 1 - \text{erf}(x).$$

$$2. \Phi(x) = \frac{1}{2} \text{erf}(x/\sqrt{2}),$$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

is the cumulative normal distribution function.

$$3. \Phi^{-1}(x) = \sqrt{2} \text{erf}^{-1}(2x - 1),$$

where $\Phi^{-1}(x)$ and $\text{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\text{erf}(x)$ respectively.

See also [Figure 9-1](#) in [Erf](#) function description for [Erfc](#) function relationship with the other functions of [Erf](#) family.

Special Values for Real Function v?Erfc(x)

Argument	Result	Error Code	Exception
X > underflow	+0	VML_STATUS_UNDERFLOW	UNDERFLOW
$+\infty$	+0		
$-\infty$	+2		
QNAN	QNAN		
SNAN	QNAN		INVALID

v?CdfNorm

Computes the cumulative normal distribution function values of vector elements.

Syntax

Fortran:

```
call vscdfnorm( n, a, y )
```

```
call vdcdfnorm( n, a, y )
```

C:

```
vsCdfNorm( n, a, y );
```

```
vdCdfNorm( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vscdfnorm DOUBLE PRECISION for vd- cdfnorm Fortran 90: REAL, INTENT(IN) for vscdfnorm DOUBLE PRECISION, INTENT(IN) for vdcdfnorm C: const float* for vsCdfNorm const double* for vdCdfNorm	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vscdfnorm DOUBLE PRECISION for vd- cdfnorm	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
	Fortran 90: REAL, INTENT (OUT) for vscdfnorm	
	DOUBLE PRECISION, INTENT (OUT) for vdcdfnorm	
	C: float* for vsCdfNorm double* for vdCdfNorm	

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function `CdfNorm` computes the cumulative normal distribution function values for elements of the input vector *a* and writes them to the output vector *y*.

The cumulative normal distribution function is defined as given by:

$$\text{CdfNorm}(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{t^2}{2}} dt .$$

Useful relations:

$$\text{cdfnorm}(x) = \frac{1}{2} \left(1 + \text{erf} \left(\frac{x}{\sqrt{2}} \right) \right) = 1 - \frac{1}{2} \text{erfc} \left(\frac{x}{\sqrt{2}} \right)$$

where `Erf` and `Erfc` are the error and complementary error functions.

See also [Figure 9-1](#) in `Erf` function description for `CdfNorm` function relationship with the other functions of `Erf` family.

Special Values for Real Function v?CdfNorm(x)

Argument	Result	Error Code	Exception
X < underflow	+0	VML_STATUS_UNDERFLOW	UNDERFLOW

Argument	Result	Error Code	Exception
$+\infty$	+1		
$-\infty$	+0		
QNAN	QNAN		
SNAN	QNAN		INVALID

v?ErfInv

Computes inverse error function value of vector elements.

Syntax

Fortran:

```
call vserfinv( n, a, y )
call vderfinv( n, a, y )
```

C:

```
vsErfInv( n, a, y );
vdErfInv( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vserfinv DOUBLE PRECISION for vderfinv Fortran 90: REAL, INTENT(IN) for vserfinv	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT(IN) for vderfinv	
	C: const float* for vsErfInv const double* for vdErfInv	

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vserfinv DOUBLE PRECISION for vderfinv Fortran 90: REAL, INTENT(OUT) for vserfinv DOUBLE PRECISION, INTENT(OUT) for vderfinv C: float* for vsErfInv double* for vdErfInv	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function `ErfInv` computes the inverse error function values for elements of the input vector *a* and writes them to the output vector *y*

$$y = \operatorname{erf}^{-1}(a),$$

where `erf(x)` is the error function defined as given by:

$$\operatorname{erfc}(x) = \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt \; .$$

Useful relations:

$$1. \operatorname{erf}^{-1}(x) = \operatorname{erfc}^{-1}(1 - x),$$

where erfc is the complementary error function.

$$2. \Phi(x) = \frac{1}{2} \operatorname{erf}(x/\sqrt{2}),$$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

is the cumulative normal distribution function.

$$3. \Phi^{-1}(x) = \sqrt{2} \operatorname{erf}^{-1}(2x - 1),$$

where $\Phi^{-1}(x)$ and $\operatorname{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\operatorname{erf}(x)$ respectively.

Figure 9-2 illustrates the relationships among ErfInv family functions (ErfInv, ErfcInv, CdfNormInv).

Figure 9-2 ErfInv Family Functions Relationship

Useful relations for these functions:

$$\text{erfcinv}(x) = \text{erfinv}(1 - x)$$

$$\text{cdfnorminv}(x) = \sqrt{2}\text{erfinv}(2x - 1) = \sqrt{2}\text{erfcinv}(2 - 2x)$$

Special Values for Real Function v?ErfInv(x)

v?ErfcInv

Computes the inverse complementary error function value of vector elements.

Syntax

Fortran:

```
call vserfcinv( n, a, y )
call vderfcinv( n, a, y )
```

C:

```
vsErfcInv( n, a, y );
vdErfcInv( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN)	Specifies the number of elements to be calculated.

Name	Type	Description
	C: const int	
<i>a</i>	FORTRAN 77: REAL for vserfcinv DOUBLE PRECISION for vderfcinv Fortran 90: REAL, INTENT (IN) for vserfcinv DOUBLE PRECISION, INTENT (IN) for vderfcinv C: const float* for vsErfcInv const double* for vdErfcInv	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vserfcinv DOUBLE PRECISION for vderfcinv Fortran 90: REAL, INTENT (OUT) for vserfcinv DOUBLE PRECISION, INTENT (OUT) for vderfcinv C: float* for vsErfcInv double* for vdErfcInv	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function `ErfcInv` computes the inverse complimentary error function values for elements of the input vector *a* and writes them to the output vector *y*.

The inverse complimentary error function is defined as given by:

$$\text{erfcinv}(x) = \text{erfinv}(1 - x)$$

$$\text{erfinv}(x) = \text{erf}^{-1}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt,$$

where `erf(x)` denotes the error function and `erfinv(x)` denotes the inverse error function.

See also [Figure 9-2](#) in `ErfInv` function description for `ErfcInv` function relationship with the other functions of `ErfInv` family.

Special Values for Real Function `v?ErfcInv(x)`

Argument	Result	Error Code	Exception

SNAN	QNAN		INVALID

v?CdfNormInv

Computes the inverse cumulative normal distribution function values of vector elements.

Syntax

Fortran:

```
call vscdfnorminv( n, a, y )
call vdcdfnorminv( n, a, y )
```

C:

```
vsCdfNormInv( n, a, y );
vdCdfNormInv( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	<p>FORTRAN 77: INTEGER</p> <p>Fortran 90: INTEGER, INTENT (IN)</p> <p>C: const int</p>	Specifies the number of elements to be calculated.

Name	Type	Description
	<code>const double*</code> for <code>vdCdfNormInv</code>	

Output Parameters

Name	Type	Description
<code>y</code>	FORTRAN 77: REAL for <code>vsCDFnorm</code> DOUBLE PRECISION for <code>vd-cdfnorminv</code> Fortran 90: REAL, INTENT(OUT) for <code>vsCDFnorm</code> DOUBLE PRECISION, INTENT(OUT) for <code>vdCDFnorminv</code> C: <code>float*</code> for <code>vsCdfNormInv</code> <code>double*</code> for <code>vdCdfNormInv</code>	FORTRAN: Array, specifies the output vector <code>y</code> . C: Pointer to an array that contains the output vector <code>y</code> .

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function `CdfNormInv` computes the inverse cumulative normal distribution function values for elements of the input vector `a` and writes them to the output vector `y`.

The inverse cumulative normal distribution function is defined as given by:

$$\text{CdfNormInv}(x) = \text{CdfNorm}^{-1}(x) ,$$

where `CdfNorm(x)` denotes the cumulative normal distribution function.

Useful relations:

$$\text{cdfnorminv}(x) = \sqrt{2}\text{erfinv}(2x - 1) = \sqrt{2}\text{erfcinv}(2 - 2x)$$

where `erfinv(x)` denotes the inverse error function and `erfcinv(x)` denotes the inverse complementary error functions.

See also [Figure 9-2](#) in `ErfInv` function description for `CdfNormInv` function relationship with the other functions of `ErfInv` family.

Rounding Functions

v?Floor

Computes an integer value rounded towards minus infinity for each vector element.

Syntax

Fortran:

```
call vsfloor( n, a, y )
call vdfloor( n, a, y )
```

C:

```
vsFloor( n, a, y );  
vdFloor( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsfloor DOUBLE PRECISION for vdfloor Fortran 90: REAL, INTENT (IN) for vsfloor DOUBLE PRECISION, INTENT (IN) for vdfloor C: const float* for vsFloor const double* for vdFloor	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsfloor DOUBLE PRECISION for vdfloor Fortran 90: REAL, INTENT (OUT) for vsfloor DOUBLE PRECISION, INTENT (OUT) for vdfloor C: float* for vsFloor	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
	double* for vdFloor	

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function computes an integer value rounded towards minus infinity for each vector element.

Special Values for Real Function v?Floor(x)

Argument	Result	Exception
+0	+0	
-0	-0	
$+\infty$	$+\infty$	
$-\infty$	$-\infty$	
SNAN	QNAN	INVALID
QNAN	QNAN	

v?Ceil

Computes an integer value rounded towards plus infinity for each vector element.

Syntax

Fortran:

```
call vsceil( n, a, y )
call vdceil( n, a, y )
```

C:

```
vsCeil( n, a, y );
vdCeil( n, a, y );
```

Input Parameters

Name	Type	Description
n	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
a	FORTTRAN 77: REAL for vsceil DOUBLE PRECISION for vdceil Fortran 90: REAL, INTENT (IN) for vsceil DOUBLE PRECISION, INTENT (IN) for vdceil C: const float* for vsCeil const double* for vdCeil	FORTTRAN: Array, specifies the input vector a . C: Pointer to an array that contains the input vector a .

Output Parameters

Name	Type	Description
y	FORTTRAN 77: REAL for vsceil DOUBLE PRECISION for vdceil Fortran 90: REAL, INTENT (OUT) for vsceil DOUBLE PRECISION, INTENT (OUT) for vdceil C: float* for vsCeil double* for vdCeil	FORTTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function computes an integer value rounded towards plus infinity for each vector element.

Special Values for Real Function v?Ceil(x)

Argument	Result	Exception
+0	+0	
-0	-0	
$+\infty$	$+\infty$	
$-\infty$	$-\infty$	
SNAN	QNAN	INVALID
QNAN	QNAN	

v?Trunc

Computes an integer value rounded towards zero for each vector element.

Syntax

Fortran:

```
call vstrunc( n, a, y )
call vdtrunc( n, a, y )
```

C:

```
vsTrunc( n, a, y );
vdTrunc( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN)	Specifies the number of elements to be calculated.

Name	Type	Description
	C: const int	
<i>a</i>	FORTRAN 77: REAL for vstrunc DOUBLE PRECISION for vdtrunc Fortran 90: REAL, INTENT (IN) for vstrunc DOUBLE PRECISION, INTENT (IN) for vdtrunc C: const float* for vsTrunc const double* for vdTrunc	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vstrunc DOUBLE PRECISION for vdtrunc Fortran 90: REAL, INTENT (OUT) for vstrunc DOUBLE PRECISION, INTENT (OUT) for vdtrunc C: float* for vsTrunc double* for vdTrunc	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

This function is declared in `mk1_vml.f77` for FORTRAN 77 interface, in `mk1_vml.fi` for Fortran 90 interface, and in `mk1_vml_functions.h` for C interface.

The function computes an integer value rounded towards zero for each vector element.

Special Values for Real Function v?Trunc(x)

Argument	Result	Exception
+0	+0	

Argument	Result	Exception
-0	-0	
$+\infty$	$+\infty$	
$-\infty$	$-\infty$	
SNAN	QNAN	INVALID
QNAN	QNAN	

v?Round

Computes an integer value rounded to nearest for each vector element.

Syntax

Fortran:

```
call vsround( n, a, y )
call vdround( n, a, y )
```

C:

```
vsRound( n, a, y );
vdRound( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsround DOUBLE PRECISION for vdround Fortran 90: REAL, INTENT (IN) for vsround	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT(IN) for vdround	
	C: const float* for vsRound const double* for vdRound	

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsround DOUBLE PRECISION for vdround Fortran 90: REAL, INTENT(OUT) for vsround DOUBLE PRECISION, INTENT(OUT) for vdround C: float* for vsRound double* for vdRound	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function computes an integer value rounded to nearest for each vector element.

Halfway values, that is, 0.5, -1.5, and the like, are rounded off away from zero. That is, 0.5 -> 1, -1.5 -> -2, etc.

Special Values for Real Function v?Round(x)

Argument	Result	Exception
+0	+0	
-0	-0	
+∞	+∞	
-∞	-∞	
SNAN	QNaN	INVALID

Argument	Result	Exception
QNaN	QNaN	

v?NearbyInt

Computes a rounded integer value in a current rounding mode for each vector element.

Syntax

Fortran:

```
call vsnearbyint( n, a, y )
call vdnearbyint( n, a, y )
```

C:

```
vsNearbyInt( n, a, y );
vdNearbyInt( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsnearbyint DOUBLE PRECISION for vdnearbyint Fortran 90: REAL, INTENT (IN) for vsnearbyint DOUBLE PRECISION, INTENT (IN) for vdnearbyint	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	C: <code>const float*</code> for <code>vsNearbyInt</code>	
	<code>const double*</code> for <code>vdNearbyInt</code>	

Output Parameters

Name	Type	Description
<code>y</code>	FORTRAN 77: <code>REAL</code> for <code>vsnearbyint</code>	FORTRAN: Array, specifies the output vector <code>y</code> .
	<code>DOUBLE PRECISION</code> for <code>vdnearbyint</code>	C: Pointer to an array that contains the output vector <code>y</code> .
	Fortran 90: <code>REAL, INTENT(OUT)</code> for <code>vsnearbyint</code>	
	<code>DOUBLE PRECISION, INTENT(OUT)</code> for <code>vdnearbyint</code>	
	C: <code>float*</code> for <code>vsNearbyInt</code>	
	<code>double*</code> for <code>vdNearbyInt</code>	

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function computes a rounded integer value in a current rounding mode for each vector element.

Halfway values, that is, 0.5, -1.5, and the like, are rounded off towards even values.

Special Values for Real Function `v?NearbyInt(x)`

Argument	Result	Exception
<code>+0</code>	<code>+0</code>	
<code>-0</code>	<code>-0</code>	
<code>+∞</code>	<code>+∞</code>	
<code>-∞</code>	<code>-∞</code>	

Argument	Result	Exception
SNAN	QNAN	INVALID
QNAN	QNAN	

v?Rint

Computes a rounded integer value in a current rounding mode for each vector element with inexact result exception raised for each changed value.

Syntax

Fortran:

```
call vsrint( n, a, y )
call vdrint( n, a, y )
```

C:

```
vsRint( n, a, y );
vdRint( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsrint DOUBLE PRECISION for vdrint Fortran 90: REAL, INTENT (IN) for vsrint DOUBLE PRECISION, INTENT (IN) for vdrint	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	C: <code>const float*</code> for <code>vsRint</code>	
	<code>const double*</code> for <code>vdRint</code>	

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: <code>REAL</code> for <code>vsrint</code> <code>DOUBLE PRECISION</code> for <code>vdrint</code> Fortran 90: <code>REAL, INTENT(OUT)</code> for <code>vsrint</code> <code>DOUBLE PRECISION, INTENT(OUT)</code> for <code>vdrint</code> C: <code>float*</code> for <code>vsRint</code> <code>double*</code> for <code>vdRint</code>	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function computes a rounded integer value in a current rounding mode for each vector element with inexact result exception raised for each changed value.

Halfway values, that is, 0.5, -1.5, and the like, are rounded off towards even values. For each changed value, inexact result exception is raised.

Argument	Result	Exception
+0	+0	
-0	-0	
$+\infty$	$+\infty$	
$-\infty$	$-\infty$	
SNAN	QNAN	INVALID
QNAN	QNAN	

v?Modf

Computes a truncated integer value and remaining fraction part for each vector element.

Syntax

Fortran:

```
call vsmodf( n, a, y, z )
call vdmodf( n, a, y, z )
```

C:

```
vsModf( n, a, y, z );
vdModf( n, a, y, z );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsmodf DOUBLE PRECISION for vdmodf Fortran 90: REAL, INTENT (IN) for vsmodf DOUBLE PRECISION, INTENT (IN) for vdmodf C: const float* for vsModf const double* for vdModf	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i> , <i>z</i>	FORTRAN 77: REAL for vsmodf	FORTRAN: Array, specifies the output vector <i>y</i> and <i>z</i> .
	DOUBLE PRECISION for vdmodf	
	Fortran 90: REAL, INTENT(OUT) for vsmodf	C: Pointer to an array that contains the output vector <i>y</i> and <i>z</i> .
	DOUBLE PRECISION, INTENT(OUT) for vdmodf	
	C: float* for vsModf	
	double* for vdModf	

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function computes a truncated integer value and remaining fraction part for each vector element.

Halfway values, that is, 0.5, -1.5, and the like, are rounded off towards even values. For each changed value, `inexact result` exception is raised.

VML Pack/Unpack Functions

This section describes VML functions which convert vectors with unit increment to and from vectors with positive increment indexing, vector indexing and mask indexing (see [Appendix B](#) for details on vector indexing methods).

[Table 9-12](#) lists available VML Pack/Unpack functions, together with data types and indexing methods associated with them.

Table 9-12 VML Pack/Unpack Functions

Function Short Name	Data Types	Indexing Methods	Description
v?Pack	s, d	I, V, M	Gathers elements of arrays, indexed by different methods.
v?Unpack	s, d	I, V, M	Scatters vector elements to arrays with different indexing.

v?Pack

Copies elements of an array with specified indexing to a vector with unit increment.

Syntax

Fortran:

```
call vspacki( n, a, inca, y )
call vspackv( n, a, ia, y )
call vspackm( n, a, ma, y )
call vdpacki( n, a, inca, y )
call vdpackv( n, a, ia, y )
call vdpackm( n, a, ma, y )
```

C:

```
vsPackI( n, a, inca, y );
vsPackV( n, a, ia, y );
vsPackM( n, a, ma, y );
vdPackI( n, a, inca, y );
```

```
vdPackV( n, a, ia, y );
vdPackM( n, a, ma, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vspacki, vspackv, vspackm DOUBLE PRECISION for vdpacki, vdpackv, vdpackm Fortran 90: REAL, INTENT(IN) for vspacki, vspackv, vspackm DOUBLE PRECISION, INTENT(IN) for vdpacki, vdpackv, vdpackm C: const float* for vsPackI, vsPackV, vsPackM const double* for vdPackI, vdPackV, vdPackM	FORTRAN: Array, DIMENSION at least (1 + (n-1)*inca) for vspacki/vdpacki, Array, DIMENSION at least max(n, max(ia[j])), j=0, ..., n-1 for vspackv/vdpackv , Array, DIMENSION at least n for vspackm/vdpackm. Specifies the input vector <i>a</i> . C: Specifies pointer to an array that contains the input vector <i>a</i> . Size of the array must be: at least (1 + (n-1)*inca) for vsPackI/vdPackI, at least max(n, max(ia[j])), j=0, ..., n-1 for vsPackV/vdPackV , at least n for vsPackM/vdPackM.
<i>inca</i>	FORTRAN 77: INTEGER for vspacki, vdpacki Fortran 90: INTEGER, INTENT(IN) for vspacki, vdpacki	Specifies the increment for the elements of <i>a</i> .

Name	Type	Description
	C: <code>const int</code> for <code>vsPackI</code> , <code>vdPackI</code>	
<i>ia</i>	FORTRAN 77: <code>INTEGER</code> for <code>vs-packv</code> , <code>vdpackv</code> Fortran 90: <code>INTEGER</code> , <code>INTENT (IN)</code> for <code>vspackv</code> , <code>vd-packv</code> C: <code>const int*</code> for <code>vsPackV</code> , <code>vdPackV</code>	FORTRAN: Array, <code>DIMENSION</code> at least <i>n</i> . Specifies the index vector for the elements of <i>a</i> . C: Specifies the pointer to an array of size at least <i>n</i> that contains the index vector for the elements of <i>a</i> .
<i>ma</i>	FORTRAN 77: <code>INTEGER</code> for <code>vs-packm</code> , <code>vdpackm</code> Fortran 90: <code>INTEGER</code> , <code>INTENT (IN)</code> for <code>vspackm</code> , <code>vd-packm</code> C: <code>const int*</code> for <code>vsPackM</code> , <code>vdPackM</code>	FORTRAN: Array, <code>DIMENSION</code> at least <i>n</i> , Specifies the mask vector for the elements of <i>a</i> . C: Specifies the pointer to an array of size at least <i>n</i> that contains the mask vector for the elements of <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: <code>REAL</code> for <code>vspacki</code> , <code>vspackv</code> , <code>vspackm</code> <code>DOUBLE PRECISION</code> for <code>vdpacki</code> , <code>vdpackv</code> , <code>vdpackm</code> Fortran 90: <code>REAL</code> , <code>INTENT (OUT)</code> for <code>vspacki</code> , <code>vspackv</code> , <code>vspackm</code> <code>DOUBLE PRECISION</code> , <code>INTENT (OUT)</code> for <code>vdpacki</code> , <code>vd-packv</code> , <code>vdpackm</code> C: <code>float*</code> for <code>vsPackI</code> , <code>vsPackV</code> , <code>vsPackM</code>	FORTRAN: Array, <code>DIMENSION</code> at least <i>n</i> . Specifies the output vector <i>y</i> . C: Pointer to an array of size at least <i>n</i> that contains the output vector <i>y</i> .

Name	Type	Description
	double*	for vdPackI, vdPackV, vdPackM

v?Unpack

Copies elements of a vector with unit increment to an array with specified indexing.

Syntax

Fortran:

```
call vsunpacki( n, a, y, incy )
call vsunpackv( n, a, y, iy )
call vsunpackm( n, a, y, my )
call vdunpacki( n, a, y, incy )
call vdunpackv( n, a, y, iy )
call vdunpackm( n, a, y, my )
```

C:

```
vsUnpackI( n, a, y, incy );
vsUnpackV( n, a, y, iy );
vsUnpackM( n, a, y, my );
vdUnpackI( n, a, y, incy );
vdUnpackV( n, a, y, iy );
vdUnpackM( n, a, y, my );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsunpac- ki, vsunpackv, vsunpackm DOUBLE PRECISION for vdunpac- ki, vdunpackv, vdunpackm. Fortran 90: REAL, INTENT (IN) for vsunpacki, vsunpackv, vsunpackm DOUBLE PRECISION, INTENT (IN) for vdunpacki, vdunpackv, vdunpackm. C: const float* for vsUnpackI, vsUnpackV, vsUnpackM const double* for vdUnpackI, vdUnpackV, vdUnpackM	FORTRAN: Array, DIMENSION at least <i>n</i> . Specifies the input vector <i>a</i> . C: Specifies the pointer to an array of size at least <i>n</i> that contains the input vector <i>a</i> .
<i>incy</i>	FORTRAN 77: INTEGER for vsunpacki, vdunpacki. Fortran 90: INTEGER, INTENT (IN) for vsunpacki, vdunpacki. C: const int for vsUnpackI, vdUnpackI.	Specifies the increment for the elements of <i>y</i> .
<i>iy</i>	FORTRAN 77: INTEGER for vsunpackv, vdunpackv	FORTRAN: Array, DIMENSION at least <i>n</i> . Specifies the index vector for the elements of <i>y</i> .

Name	Type	Description
	Fortran 90: INTEGER, INTENT (IN) for vsunpackv, vdunpackv C: const int* for vsUnpackV, vdUnpackV	C: Specifies the pointer to an array of size at least n that contains the index vector for the elements of a .
my	FORTTRAN 77: INTEGER for vsunpackm, vdunpackm Fortran 90: INTEGER, INTENT (IN) for vsunpackm, vdunpackm C: const int* for vsUnpackM, vdUnpackM	FORTTRAN: Array, DIMENSION at least n , Specifies the mask vector for the elements of y . C: Specifies the pointer to an array of size at least n that contains the mask vector for the elements of a .

Output Parameters

Name	Type	Description
y	FORTTRAN 77: REAL for vsunpack- ki, vsunpackv, vsunpackm DOUBLE PRECISION for vdunpack- ki, vdunpackv, vdunpackm Fortran 90: REAL, INTENT (OUT) for vsunpacki, vsunpackv, vsunpackm DOUBLE PRECISION, INTENT (OUT) for vdunpacki, vdunpackv, vdunpackm C: float* for vsUnpackI, vsUn- packV, vsUnpackM double* for vdUnpackI, vdUn- packV, vdUnpackM	FORTTRAN: Array, DIMENSION at least $(1 + (n-1)*incy)$ for vsunpack- ki, at least $\max(n, \max(iy[j]))$, $j=0, \dots,$ $n-1$, for vsunpackv, at least n for vsunpackm/vdunpackm C: Specifies the pointer to an array that contains the output vector y . Size of the array must be: at least $(1 + (n-1)*incy)$ for vsUn- PackI, at least $\max(n, \max(ia[j]))$, $j=0, \dots, n-1$, for vsUnPackV, at least n for vsUnPackM.

VML Service Functions

VML Service functions allow the user to set /get the accuracy mode, and set/get the error code. All these functions are available both in Fortran- and C- interfaces. [Table 9-13](#) lists available VML Service functions and their short description.

Table 9-13 VML Service Functions

Function Short Name	Description
SetMode	Sets the VML mode
GetMode	Gets the VML mode
SetErrStatus	Sets the VML error status
GetErrStatus	Gets the VML error status
ClearErrStatus	Clears the VML error status
SetErrorCallback	Sets the additional error handler callback function
GetErrorCallback	Gets the additional error handler callback function
ClearErrorCallback	Deletes the additional error handler callback function

SetMode

Sets a new mode for VML functions according to mode parameter and stores the previous VML mode to oldmode.

Syntax

Fortran:

```
oldmode = vmlsetmode( mode )
```

C:

```
oldmode = vmlSetMode( mode );
```

Input Parameters

Name	Type	Description
<i>mode</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN)	Specifies the VML mode to be set.

Name	Type	Description
	C: <code>const unsigned int</code>	

Output Parameters

Name	Type	Description
<i>oldmode</i>	FORTRAN: <code>INTEGER</code> C: <code>int</code>	Specifies the former VML mode.

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The *mode* parameter is designed to control accuracy, FPU, error handling and threading options. [Table 9-14](#) lists values of the *mode* parameter. All other possible values of the *mode* parameter may be obtained from these values by using bitwise OR (`|`) operation to combine one value for accuracy, one for FPU, and one for error control options. The default value of the *mode* parameter is `VML_HA | VML_ERRMODE_DEFAULT | VML_NUM_THREADES_OMP_AUTO`. Thus, the current FPU control word (FPU precision and the rounding method) is used by default.

If any VML mathematical function requires different FPU precision, or rounding method, it changes these options automatically and then restores the former values. The *mode* parameter enables you to minimize switching the internal FPU mode inside each VML mathematical function that works with similar precision and accuracy settings. To accomplish this, set the *mode* parameter to `VML_FLOAT_CONSISTENT` for single precision real and complex functions, or to `VML_DOUBLE_CONSISTENT` for double precision real and complex functions. These values of the *mode* parameter are the optimal choice for the respective function groups, as they are required for most of the VML mathematical functions. After the execution is over, set the *mode* to `VML_RESTORE` if you need to restore the previous FPU mode.

Table 9-14 Values of the *mode* Parameter

Value of <i>mode</i>	Description
Accuracy Control	
<code>VML_HA</code>	High accuracy versions of VML functions will be used.
<code>VML_LA</code>	Low accuracy versions of VML functions will be used.
<code>VML_EP</code>	Enhanced Performance accuracy versions of VML functions will be used.

Value of <i>mode</i>	Description
Additional FPU Mode Control	
VML_FLOAT_CONSISTENT	The optimal FPU mode (control word) for single precision functions is set, and the previous FPU mode is saved.
VML_DOUBLE_CONSISTENT	The optimal FPU mode (control word) for double precision functions is set, and the previous FPU mode is saved.
VML_RESTORE	The previously saved FPU mode is restored.
Error Mode Control	
VML_ERRMODE_IGNORE	No action is set for computation errors.
VML_ERRMODE_ERRNO	On error, the <i>errno</i> variable is set.
VML_ERRMODE_STDERR	On error, the error text information is written to <i>stderr</i> .
VML_ERRMODE_EXCEPT	On error, an exception is raised.
VML_ERRMODE_CALLBACK	On error, an additional error handler function is called.
VML_ERRMODE_DEFAULT	On error, the <i>errno</i> variable is set, an exception is raised, and an additional error handler function is called.
Threading Mode Control	
VML_NUM_THREADS_OMP_AUTO	This is default behavior. Maximum number of threads is determined by environmental variable OMP_NUM_THREADS and can be overridden by OpenMP* function <code>omp_set_num_threads()</code> . For performance reasons VML threading logic can use fewer number of threads.
VML_NUM_THREADS_OMP_FIXED	Number of threads is determined by environmental variable OMP_NUM_THREADS and can be overridden by OpenMP* function <code>omp_set_num_threads()</code> . Use this mode to disable VML threading logic.

Examples

Several examples of calling the function `vmlSetMode()` with different values of the *mode* parameter are given below:

Fortran:

```
oldmode = vmlsetmode( VML_LA )

call vmlsetmode( IOR(VML_LA, IOR(VML_FLOAT_CONSISTENT,
VML_ERRMODE_IGNORE )))

call vmlsetmode( VML_RESTORE)

call vmlsetmode( VML_NUM_THREADS_OMP_FIXED)
```

C:

```
vmlSetMode( VML_LA );  
vmlSetMode( VML_LA | VML_FLOAT_CONSISTENT | VML_ERRMODE_IGNORE  
);  
vmlSetMode( VML_RESTORE);  
vmlSetMode( VML_NUM_THREADS_OMP_FIXED);
```

GetMode

Gets the VML mode.

Syntax

Fortran:

```
mod = vmlgetmode()
```

C:

```
mod = vmlGetMode( void );
```

Output Parameters

Name	Type	Description
<i>mod</i>	FORTTRAN: INTEGER C: int	Specifies the packed <i>mode</i> parameter.

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function `vmlGetMode()` returns the VML *mode* parameter that controls accuracy, FPU, and error handling options. The *mod* variable value is some combination of the values listed in the [Table 9-14](#). You can obtain some of these values using the respective mask from the [Table 9-15](#).

Table 9-15 Values of Mask for the *mode* Parameter

Value of mask	Description
VML_ACCURACY_MASK	Specifies mask for accuracy <i>mode</i> selection.
VML_FPUMODE_MASK	Specifies mask for FPU <i>mode</i> selection.
VML_ERRMODE_MASK	Specifies mask for error <i>mode</i> selection.

See example below:

Examples

Fortran:

```
mod = vmlgetmode()
accm = IAND(mod, VML_ACCURACY_MASK)
fpum = IAND(mod, VML_FPUMODE_MASK)
errm = IAND(mod, VML_ERRMODE_MASK)
```

C:

```
accm = vmlGetMode(void ) & VML_ACCURACY_MASK;
fpum = vmlGetMode(void ) & VML_FPUMODE_MASK;
errm = vmlGetMode(void ) & VML_ERRMODE_MASK;
```

SetErrStatus

Sets the new VML error status according to `err` and stores the previous VML error status to `olderr`.

Syntax

Fortran:

```
olderr = vmlseterrstatus( err )
```

C:

```
olderr = vmlSetErrStatus( err );
```

Input Parameters

Name	Type	Description
<i>err</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the VML error status to be set.

Output Parameters

Name	Type	Description
<i>olderr</i>	FORTRAN: INTEGER C: int	Specifies the former VML error status.

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.fi` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

Table 9-16 lists possible values of the *err* parameter.

Table 9-16 Values of the VML Error Status

Error Status	Description
VML_STATUS_OK	The execution was completed successfully.
VML_STATUS_BADSIZE	The array dimension is not positive.
VML_STATUS_BADMEM	NULL pointer is passed.
VML_STATUS_ERRDOM	At least one of array values is out of a range of definition.
VML_STATUS_SING	At least one of array values caused a singularity.
VML_STATUS_OVERFLOW	An overflow has happened during the calculation process.
VML_STATUS_UNDERFLOW	An underflow has happened during the calculation process.

Examples

```
vmlSetErrStatus( VML_STATUS_OK );

vmlSetErrStatus( VML_STATUS_ERRDOM );

vmlSetErrStatus( VML_STATUS_UNDERFLOW );
```

GetErrStatus

Gets the VML error status.

Syntax

Fortran:

```
err = vmlgeterrstatus( )
```

C:

```
err = vmlGetErrStatus( void );
```

Output Parameters

Name	Type	Description
<i>err</i>	FORTTRAN: INTEGER C: int	Specifies the VML error status.

ClearErrStatus

Sets the VML error status to VML_STATUS_OK and stores the previous VML error status to olderr.

Syntax

Fortran:

```
olderr = vmlclearerrstatus( )
```

C:

```
olderr = vmlClearErrStatus( void );
```

Output Parameters

Name	Type	Description
<i>olderr</i>	FORTRAN: INTEGER C: int	Specifies the former VML error status.

SetErrorCallback

Sets the additional error handler callback function and gets the old callback function.

Syntax

Fortran:

```
oldcallback = vmlseterrorcallback( callback )
```

C:

```
oldcallback = vmlSetErrorCallBack( callback );
```

Input Parameters

Name	Description
FORTRAN: Address of the callback function. <i>callback</i>	<p>The callback function has the following format:</p> <pre> INTEGER FUNCTION ERRFUNC(par) TYPE (ERROR_STRUCTURE) par ! ... ! user error processing ! ... ERRFUNC = 0 ! if ERRFUNC= 0 - standard VML error handler ! is called after the callback ! if ERRFUNC != 0 - standard VML error handler ! is not called END </pre> <p>The passed error structure is defined as follows:</p> <pre> TYPE ERROR_STRUCTURE SEQUENCE INTEGER*4 ICODE INTEGER*4 IINDEX REAL*8 DBA1 REAL*8 DBA2 REAL*8 DBR1 REAL*8 DBR2 CHARACTER(64) CFUNCNAME INTEGER*4 IFUNCNAMELEN END TYPE ERROR_STRUCTURE </pre>

Name	Description
C: <i>callback</i> Pointer to the callback function.	<p data-bbox="867 314 1362 373">The callback function has the following format:</p> <pre data-bbox="867 390 1234 621">static int __stdcall MyHandler(DefVmlErrorContext* pContext) { /* Handler body */ };</pre> <p data-bbox="867 644 1362 703">The passed error structure is defined as follows:</p> <pre data-bbox="867 720 1362 1362">typedef struct _DefVmlErrorContext { int iCode; /* Error status value */ int iIndex; /* Index for bad array element, or bad array dimension, or bad array pointer */ double dbA1; /* Error argument 1 */ double dbA2; /* Error argument 2 */ double dbR1; /* Error result 1 */ double dbR2; /* Error result 2 */ char cFuncName[64]; /* Function name */ int iFuncNameLen; /* Length of functionname*/ } DefVmlErrorContext;</pre>

Output Parameters

Name	Type	Description
<i>oldcallback</i>	Fortran 90: INTEGER C: int	FORTTRAN: Address of the former callback function. C: Pointer to the former callback function.

NOTE. FORTRAN 77 support is unavailable for this function.

Description

This function is declared in `mkl_vml.fi` for Fortran 90 interface and in `mkl_vml_functions.h` for C interface.

The callback function is called on each VML mathematical function error if `VML_ERRMODE_CALLBACK` error mode is set (see [Table 9-14](#)).

Use the `vmlSetErrorCallBack()` function if you need to define your own callback function instead of default empty callback function.

The input structure for a callback function contains the following information about the error encountered:

- the input value that caused an error
- location (array index) of this value
- the computed result value
- error code
- name of the function in which the error occurred.

You can insert your own error processing into the callback function. This may include correcting the passed result values in order to pass them back and resume computation. The standard error handler is called after the callback function only if it returns `0`.

GetErrorCallBack

Gets the additional error handler callback function.

Syntax

Fortran:

```
callback = vmlgeterrorcallback( )
```

C:

```
callback = vmlGetErrorCallBack( void );
```

Output Parameters

Name	Description
<i>callback</i>	Fortran 90: Address of the callback function C: Pointer to the callback function

NOTE. FORTRAN 77 support is unavailable for this function.

ClearErrorCallBack

Deletes the additional error handler callback function and retrieves the former callback function.

Syntax

Fortran:

```
oldcallback = vmlclearerrorcallback( )
```

C:

```
oldcallback = vmlClearErrorCallBack( void );
```

Output Parameters

Name	Type	Description
<i>oldcallback</i>	Fortran 90: INTEGER C: int	FORTTRAN: Address of the former callback function C: Pointer to the former callback function

NOTE. FORTRAN 77 support is unavailable for this function.

Statistical Functions

Statistical functions in Intel® MKL are known as Vector Statistical Library (VSL) that is designed for the purpose of

- generating vectors of pseudorandom and quasi-random numbers
- performing mathematical operations of convolution and correlation.

The corresponding functionality is described in the respective [Random Number Generators](#) and [Convolution and Correlation](#) sections.

Random Number Generators

VSL provides a set of routines implementing commonly used pseudo- or quasi-random number generators with continuous and discrete distribution. To improve performance, all these routines were developed using the calls to the highly optimized *Basic Random Number Generators* (BRNGs) and the library of vector mathematical functions (VML, see [Chapter 9, “Vector Mathematical Functions”](#)).

VSL provides interfaces both for FORTRAN and C languages. For users of the C and C++ languages the `mkl_vsl.h` header file is provided. For users of the Fortran 90 or Fortran 95 language the `mkl_vsl.fi` header file is provided. For users of the FORTRAN 77 language the `mkl_vsl.f77` header file is provided. All header files are found in the following directory:

```
${MKL}/include
```

The `mkl_vsl.fi` header is intended for using via the Fortran `include` clause and is compatible with both standard forms of F90/F95 sources — the free and 72-columns fixed forms. If you need to use the VSL interface with 80- or 132-columns fixed form sources, you may add a new file to your project. That file is formatted as a 72-columns fixed-form source and consists of a single `include` clause as follows:

```
include 'mkl_vsl.fi'
```

This `include` clause causes the compiler to generate the module files `mkl_vsl.mod` and `mkl_vsl_type.mod`, which are used to process the Fortran use clauses referencing to the VSL interface:

```
use mkl_vsl_type
```

```
use mkl_vsl
```

Because of this specific feature, you do not need to include the `mkl_vsl.fi` header into each source of your project. You only need to include the header into some of the sources. In any case, make sure that the sources that depend on the VSL interface are compiled after those that include the header so that the module files `mkl_vsl.mod` and `mkl_vsl_type.mod` are generated prior to using them.

The `mkl_vsl.f77` header is intended for using via the Fortran `include` clause as follows:

```
include 'mkl_vsl.f77'
```

NOTE. For Fortran 90 interface, VSL provides both subroutine-style interface and function-style interface. Default interface in this case is a function-style interface. Function-style interface, unlike subroutine-style interface, allows the user to get error status of each routine. Subroutine-style interface is provided for backward compatibility only. To use subroutine-style interface, manually include `mkl_vsl_subroutine.fi` file instead of `mkl_vsl.fi` by changing the line `include 'mkl_vsl.fi'` in `include\mkl.fi` with the line `include 'mkl_vsl_subroutine.fi'`.

For FORTRAN 77 interface, VSL provides only function-style interface.

All VSL routines can be classified into three major categories:

- Transformation routines for different types of statistical distributions, for example, uniform, normal (Gaussian), binomial, etc. These routines indirectly call basic random number generators, which are either pseudorandom number generators or quasi-random number generators. Detailed description of the generators can be found in [Distribution Generators](#) section.
- Service routines to handle random number streams: create, initialize, delete, copy, save to a binary file, load from a binary file, get the index of a basic generator. The description of these routines can be found in [Service Routines](#) section.
- Registration routines for basic pseudorandom generators and routines that obtain properties of the registered generators (see [Advanced Service Routines](#) section).

The last two categories are referred to as service routines.

Conventions

This document makes no specific differentiation between random, pseudorandom, and quasi-random numbers, nor between random, pseudorandom, and quasi-random number generators unless the context requires otherwise. For details, refer to 'Random Numbers' section in [VSL Notes](#) document provided with Intel® MKL.

All generators of nonuniform distributions, both discrete and continuous, are built on the basis of the uniform distribution generators, called Basic Random Number Generators (BRNGs). The pseudorandom numbers with nonuniform distribution are obtained through an appropriate transformation of the uniformly distributed pseudorandom numbers. Such transformations are referred to as *generation methods*. For a given distribution, several generation methods can be used. See [VSL Notes](#) for the description of methods available for each generator.

The *stream descriptor* specifies which BRNG should be used in a given transformation method. See 'Random Streams and RNGs in Parallel Computation' section of [VSL Notes](#).

The term *computational node* means a logical or physical unit that can process data in parallel.

Mathematical Notation

The following notation is used throughout the text:

N	The set of natural numbers $N = \{1, 2, 3 \dots\}$.
Z	The set of integers $Z = \{\dots -3, -2, -1, 0, 1, 2, 3 \dots\}$.
R	The set of real numbers.
$\lfloor a \rfloor$	The floor of a (the largest integer less than or equal to a).
\oplus or xor	Bitwise exclusive OR.
C_{α}^{κ} or $\binom{\alpha}{\kappa}$	Binomial coefficient or combination ($\alpha \in R, \alpha \geq 0; \kappa \in N \cup \{0\}$).
	$C_{\alpha}^{\kappa} = 1$
	For $\alpha \geq \kappa$ binomial coefficient is defined as
	$C_{\alpha}^{\kappa} = \frac{\alpha(\alpha - 1) \dots (\alpha - \kappa + 1)}{\kappa!}$
	If $\alpha < \kappa$, then
	$C_{\alpha}^{\kappa} = 0$
$\Phi(x)$	Cumulative Gaussian distribution function

$$\Phi(x) = \int_{-\infty}^x \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{y^2}{2}\right) dy$$

defined over $-\infty < x < +\infty$.

$\Phi(-\infty) = 0$, $\Phi(+\infty) = 1$.

$\Gamma(\alpha)$

The complete gamma function

$$\Gamma(\alpha) = \int_0^{\infty} t^{\alpha-1} e^{-t} dt$$

where $\alpha > 0$.

$B(p, q)$

The complete beta function

$$B(p, q) = \int_0^1 t^{p-1} (1-t)^{q-1} dt$$

where $p > 0$ and $q > 0$.

$LCG(a, c, m)$

Linear Congruential Generator $x_{n+1} = (ax_n + c) \bmod m$, where a is called the *multiplier*, c is called the *increment*, and m is called the *modulus* of the generator.

$MCG(a, m)$

Multiplicative Congruential Generator $x_{n+1} = (ax_n) \bmod m$ is a special case of Linear Congruential Generator, where the increment c is taken to be 0.

$GFSR(p, q)$

Generalized Feedback Shift Register Generator

$$x_n = x_{n-p} \oplus x_{n-q}.$$

Naming Conventions

The names of all VSL functions in FORTRAN are lowercase; names in C may contain both lowercase and uppercase letters.

The names of generator routines have the following structure:

`v<type of result>rng<distribution>` for FORTRAN-interface

`v<type of result>Rng<distribution>` for C-interface,

where `v` is the prefix of a VSL vector function, and the field `<type of result>` is either `s`, `d`, or `i` and specifies one of the following types:

<code>s</code>	REAL for FORTRAN-interface float for C-interface
<code>d</code>	DOUBLE PRECISION for FORTRAN-interface double for C-interface
<code>i</code>	INTEGER for FORTRAN-interface int for C-interface

Prefixes `s` and `d` apply to continuous distributions only, prefix `i` applies only to discrete case. The prefix `rng` indicates that the routine is a random generator, and the `<distribution>` field specifies the type of statistical distribution.

Names of service routines follow the template below:

`vsl<name>`,

where `vsl` is the prefix of a VSL service function. The field `<name>` contains a short function name. For a more detailed description of service routines refer to [Service Routines](#) and [Advanced Service Routines](#) sections.

Prototype of each generator routine corresponding to a given probability distribution fits the following structure:

```
status = <function name>( method, stream, n, r, [<distribution parameters>] ),
```

where

- `method` defines the method of generation. A detailed description of this parameter can be found in [Table 10-1](#). See the next page, where the structure of the `method` parameter name is explained.
- `stream` defines the descriptor of the random stream and must have a non-zero value. Random streams, descriptors, and their usage are discussed further in [Random Streams](#) and [Service Routines](#).
- `n` defines the number of random values to be generated. If `n` is less than or equal to zero, no values are generated. Furthermore, if `n` is negative, an error condition is set.
- `r` defines the destination array for the generated numbers. The dimension of the array must be large enough to store at least `n` random numbers.
- `status` defines the error status of a VSL routine. See [Error Reporting](#) section for a detailed description of error status values.

Additional parameters included into `<distribution parameters>` field are individual for each generator routine and are described in detail in [Distribution Generators](#) section.

To invoke a distribution generator, use a call to the respective VSL routine. For example, to obtain a vector r , composed of n independent and identically distributed random numbers with normal (Gaussian) distribution, that have the mean value a and standard deviation σ , write the following:

for FORTRAN-interface

```
status = vsrnggaussian( method, stream, n, r, a, sigma )
```

for C-interface

```
status = vsRngGaussian( method,  
stream, n, r, a, sigma )
```

The name of a `method` parameter has the following structure:

```
VSL_METHOD_<precision><distribution>_<method>,
```

```
VSL_METHOD_<precision><distribution>_<method>_ACCURATE,
```

where

<code><precision></code>	s	for single precision continuous distribution
	D	for double precision continuous distribution
	I	for discrete distribution
<code><distribution></code>	probability distribution	
<code><method></code>	method name.	

Type of name structure for `method` parameter corresponds to fast and accurate modes of random number generation (see ["Distribution Generators"](#) section and [VSL Notes](#) for details).

Method names `VSL_METHOD_<precision><distribution>_<method>` and `VSL_METHOD_<precision><distribution>_<method>_ACCURATE` should be used with `vsl<precision>Rng<distribution>` function only, where

<code><precision></code>	s	for single precision continuous distribution
	d	for double precision continuous distribution
	i	for discrete distribution
<code><distribution></code>	probability distribution.	

[Table 10-1](#) provides specific predefined values of the `method` name. The third column contains names of the functions that use the given method.

Table 10-1 Values of `<method>` in `method` parameter

Method	Short Description	Functions
STD	Standard method. Currently there is only one method for these functions.	Uniform (<code>continuous</code>), Uni- form (<code>dis- crete</code>), Uni- formBits
BOXMULLER	BOXMULLER generates normally distributed random number x thru the pair of uniformly distributed numbers u_1 and u_2 according to the formula: $x = \sqrt{-2 \ln u_1} \sin 2\pi u_2$	Gaussian, GaussianMV
BOXMULLER2	BOXMULLER2 generates normally distributed random numbers x_1 and x_2 thru the pair of uniformly distributed numbers u_1 and u_2 according to the formulas: $x_1 = \sqrt{-2 \ln u_1} \sin 2\pi u_2$ $x_2 = \sqrt{-2 \ln u_1} \cos 2\pi u_2$	Gaussian, GaussianMV, Lognormal
ICDF	Inverse cumulative distribution function method.	Exponen- tial, Laplace, Weibull, Cauchy, Rayleigh, Gumbel, Bernoulli, Geometric, Gaussian, GaussianMV

Method	Short Description	Functions
GNORM	For $\alpha > 1$, a gamma distributed random number is generated as a cube of properly scaled normal random number; for $0.6 \leq \alpha < 1$, a gamma distributed random number is generated using rejection from Weibull distribution; for $\alpha < 0.6$, a gamma distributed random number is obtained using transformation of exponential power distribution; for $\alpha = 1$, gamma distribution is reduced to exponential distribution.	Gamma
CJA	For $\min(p, q) > 1$, Cheng method is used; for $\min(p, q) < 1$, Jöhnk method is used, if $q + K \cdot p^2 + C \leq 0$ ($K = 0.852...$, $C = -0.956...$) otherwise, Atkinson switching algorithm is used; for $\max(p, q) < 1$, method of Jöhnk is used; for $\min(p, q) < 1$, $\max(p, q) > 1$, Atkinson switching algorithm is used (CJA stands for the first letters of Cheng, Jöhnk, Atkinson); for $p = 1$ or $q = 1$, inverse cumulative distribution function method is used; for $p = 1$ and $q = 1$, beta distribution is reduced to uniform distribution.	Beta
BTPE	Acceptance/rejection method for $n_{trial} \cdot \min(p, 1 - p) \geq 30$ with decomposition into 4 regions: <ul style="list-style-type: none"> – 2 parallelograms – triangle – left exponential tail – right exponential tail 	Binomial
H2PE	Acceptance/rejection method for large mode of distribution with decomposition into 3 regions: <ul style="list-style-type: none"> – rectangular – left exponential tail – right exponential tail 	Hypergeometric

Method	Short Description	Functions
PTPE	Acceptance/rejection method for $\lambda \geq 27$ with decomposition into 4 regions: <ul style="list-style-type: none">– 2 parallelograms– triangle– left exponential tail– right exponential tail; otherwise, table lookup method is used.	<a>Poisson
POISNORM	for $\lambda \geq 1$, method based on Poisson inverse CDF approximation by Gaussian inverse CDF; for $\lambda < 1$, table lookup method is used.	<a>Poisson , <a>PoissonV
NBAR	Acceptance/rejection method for , <div>$\frac{(a-1) \cdot (1-p)}{p} \geq 100$</div> with decomposition into 5 regions: <ul style="list-style-type: none">– rectangular– 2 trapezoid– left exponential tail– right exponential tail	<a>NegBinomial

Basic Generators

- VSL provides the following BRNGs, which differ in speed and other properties:
- the 32-bit multiplicative congruential pseudorandom number generator $MCG(1132489760, 2^{31}-1)$ [L’Ecuyer99]
 - the 32-bit generalized feedback shift register pseudorandom number generator $GFSR(250,103)$ [Kirkpatrick81]

- the combined multiple recursive pseudorandom number generator *MRG-32k3a* [[L'Ecuyer99a](#)]
- the 59-bit multiplicative congruential pseudorandom number generator *MCG(13¹³, 2⁵⁹)* from NAG Numerical Libraries [[NAG](#)]
- Wichmann-Hill pseudorandom number generator (a set of 273 basic generators) from NAG Numerical Libraries [[NAG](#)]
- Mersenne Twister pseudorandom number generator *MT19937* [[Matsumoto98](#)] with period length $2^{19937}-1$ of the produced sequence
- Set of 1024 Mersenne Twister pseudorandom number generators *MT2203* [[Matsumoto98](#)], [[Matsumoto00](#)]. Each of them generates a sequence of period length equal to $2^{2203}-1$. Parameters of the generators provide mutual independence of the corresponding sequences.

Besides these pseudorandom number generators, VSL provides two basic quasi-random number generators:

- Sobol quasi-random number generator [[Sobol76](#)], [[Bratley88](#)], which works in arbitrary dimension. For dimensions greater than 40 the user should supply initialization parameters (initial direction numbers and primitive polynomials or direction numbers) by using `vslNewStreamEx` function. See additional details on interface for registration of the parameters in the library in [VSL Notes](#).
- Niederreiter quasi-random number generator [[Bratley92](#)], which works in arbitrary dimension. For dimensions greater than 318 the user should supply initialization parameters (irreducible polynomials or direction numbers) by using `vslNewStreamEx` function. See additional details on interface for registration of the parameters in the library in [VSL Notes](#).

See some testing results for the generators in [VSL Notes](#) and comparative performance data at http://www.intel.com/software/products/mkl/data/vsl/vsl_performance_data.htm.

VSL provides means of registration of such user-designed generators through the steps described in [Advanced Service Routines](#) section.

For some basic generators, VSL provides two methods of creating independent random streams in multiprocessor computations, which are the leapfrog method and the block-splitting method. These sequence splitting methods are also useful in sequential Monte Carlo.

In addition, MT2203 pseudorandom number generator is a set of 1024 generators designed to create up to 1024 independent random sequences, which might be used in parallel Monte Carlo simulations. Another generator that has the same feature is Wichmann-Hill. It allows creating up to 273 independent random streams. The properties of the generators designed for parallel computations are discussed in detail in [[Coddington94](#)].

You may want to design and use your own basic generators. VSL provides means of registration of such user-designed generators through the steps described in [Advanced Service Routines](#) section.

There is also an option to utilize externally generated random numbers in VSL distribution generator routines. For this purpose VSL provides three additional basic random number generators:

- for external random data packed in 32-bit integer array
- for external random data stored in double precision floating-point array; data is supposed to be uniformly distributed over (a,b) interval
- for external random data stored in single precision floating-point array; data is supposed to be uniformly distributed over (a,b) interval.

Such basic generators are called the abstract basic random number generators.
See [VSL Notes](#) for a more detailed description of the generator properties.

BRNG Parameter Definition

Predefined values for the *brng* input parameter are as follows:

Table 10-2 Values of *brng* parameter

Value	Short Description
VSL_BRNG_MCG31	A 31-bit multiplicative congruential generator.
VSL_BRNG_R250	A generalized feedback shift register generator.
VSL_BRNG_MRG32K3A	A combined multiple recursive generator with two components of order 3.
VSL_BRNG_MCG59	A 59-bit multiplicative congruential generator.
VSL_BRNG_WH	A set of 273 Wichmann-Hill combined multiplicative congruential generators.
VSL_BRNG_MT19937	A Mersenne Twister pseudorandom number generator.
VSL_BRNG_MT2203	A set of 1024 Mersenne Twister pseudorandom number generators.
VSL_BRNG_SOBOL	A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \leq s \leq 40$; user-defined dimensions are also available.

Value	Short Description
VSL_BRNG_NIEDERR	A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \leq s \leq 318$; user-defined dimensions are also available.
VSL_BRNG_IABSTRACT	An abstract random number generator for integer arrays.
VSL_BRNG_DABSTRACT	An abstract random number generator for double precision floating-point arrays.
VSL_BRNG_SABSTRACT	An abstract random number generator for single precision floating-point arrays.

See [VSL Notes](#) for detailed description.

Random Streams

Random stream (or *stream*) is an abstract source of pseudo- and quasi-random sequences of uniform distribution. Users have no direct access to these sequences and operate with stream state descriptors only. A stream state descriptor, which holds state descriptive information for a particular BRNG, is a necessary parameter in each routine of a distribution generator. Only the distribution generator routines operate with random streams directly. See [VSL Notes](#) for details.

NOTE. Random streams associated with abstract basic random number generator are called the abstract random streams. See [VSL Notes](#) for detailed description of abstract streams and their use.

User can create unlimited number of random streams by VSL [Service Routines](#) like [NewStream](#) and utilize them in any distribution generator to get the sequence of numbers of given probability distribution. When they are no longer needed, the streams should be deleted calling service routine [DeleteStream](#).

VSL provides service functions [SaveStreamF](#) and [LoadStreamF](#) to save random stream descriptive data to a binary file and to read this data from a binary file respectively. See [VSL Notes](#) for detailed description.

Data Types

FORTRAN 77:
INTEGER*4 vslstreamstate(2)

Fortran 90:
TYPE
 VSL_STREAM_STATE
INTEGER*4 descriptor1
INTEGER*4 descriptor2
END
 TYPE VSL_STREAM_STATE

C:
typedef (void*) VSLStreamStatePtr;

See [Advanced Service Routines](#) for the format of the stream state structure for user-designed generators.

Error Reporting

VSL routines return status codes of the performed operation to report errors and warnings to the calling program. Thus, it is up to the application to perform error-related actions and/or recover from the error. The status codes are of integer type and have the following format:

VSL_ERROR_<ERROR_NAME> - indicates VSL errors
VSL_WARNING_<WARNING_NAME> - indicates VSL warnings.

VSL errors are of negative values while warnings are of positive values. The status code of zero value indicates that the operation is completed successfully: VSL_ERROR_OK (or synonymic VSL_STATUS_OK).

Table 10-3 Status Codes and Messages

Status Code	Message
VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BAD_ARG	Input argument value is not valid.
VSL_ERROR_NULL_PTR	Input pointer argument is NULL.

Status Code	Message
VSL_ERROR_MEM_FAILURE	System cannot allocate memory.
VSL_ERROR_INVALID_BRNG_INDEX	BRNG index is not valid.
VSL_ERROR_BRNGS_INCOMPATIBLE	Two BRNGs are not compatible for the operation.
VSL_ERROR_LEAPFROG_UNSUPPORTED	BRNG does not support Leapfrog method.
VSL_ERROR_SKIPAHEAD_UNSUPPORTED	BRNG does not support Skip-Ahead method.
VSL_ERROR_BAD_STREAM	The random stream is invalid.
VSL_ERROR_FILE_OPEN	Indicates an error in opening the file.
VSL_ERROR_FILE_READ	Indicates an error in reading the file.
VSL_ERROR_FILE_WRITE	Indicates an error in writing the file.
VSL_ERROR_FILE_CLOSE	Indicates an error in closing the file.
VSL_ERROR_BAD_FILE_FORMAT	File format is unknown.
VSL_ERROR_UNSUPPORTED_FILE_VER	File format version is not supported.
VSL_ERROR_BRNG_TABLE_FULL	Registration cannot be completed due to lack of free entries in the table of registered BRNGs.
VSL_ERROR_BAD_STREAM_STATE_SIZE	The value in <code>StreamStateSize</code> field is bad.
VSL_ERROR_BAD_WORD_SIZE	The value in <code>WordSize</code> field is bad.
VSL_ERROR_BAD_NSEEDS	The value in <code>NSeeds</code> field is bad.
VSL_ERROR_BAD_NBITS	The value in <code>NBits</code> field is bad.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns zero as the number of updated entries in a buffer.

Status Code	Message
VSL_ERROR_INVALID_ABSTRACT_STREAM	The abstract random stream is invalid.

VSL Usage Model

A typical algorithm for VSL random number generators is as follows:

1. Create and initialize stream/streams. Functions `vslNewStream`, `vslNewStreamEx`, `vslCopyStream`, `vslCopyStreamState`, `vslLeapfrogStream`, `vslSkipAheadStream`.
2. Call one or more RNGs.
3. Process the output.
4. Delete the stream/streams. Function `vslDeleteStream`.

NOTE. You may reiterate steps 2-3. Random number streams may be generated for different threads.

The following C example demonstrates generation of a random stream that is output of basic generator MT19937. The seed is equal to 777. The stream is used to generate 10,000 normally distributed random numbers in blocks of 1,000 random numbers with parameters $\mu = 5$ and $\sigma = 2$. Delete the streams after completing the generation. The purpose of the example is to calculate the sample mean for normal distribution with the given parameters.

C Example of VSL Usage

```
#include <stdio.h>
#include "mkl_vsl.h"

int main();
{
    double r[1000]; /* buffer for random numbers */
    double s; /* average */
    VSLStreamStatePtr stream;
    int i, j;

    /* Initializing */
    s = 0.0;
    vslNewStream( &stream, VSL_BRNG_MT19937, 777 );

    /* Generating */
    for ( i=0; i<10; i++ );
    {
```

```

    vdRngGaussian( VSL_METHOD_DGAUSSIAN_ICDF, stream, 1000, r, 5.0, 2.0 );
    for ( j=0; j<1000; j++ );
    {
        s += r[j];
    }
}
s /= 10000.0;

/* Deleting the stream */
vslDeleteStream( &stream );

/* Printing results */
printf( "Sample mean of normal distribution = %f\n", s );

return 0;
}

```

The Fortran version of the same example is below:

Fortran Example of VSL Usage

```

include 'mkl_vsl.fi'

program MKL_VSL_GAUSSIAN

USE MKL_VSL_TYPE
USE MKL_VSL

real(kind=8) r(1000) ! buffer for random numbers
real(kind=8) s      ! average
real(kind=8) a, sigma ! parameters of normal distribution

TYPE (VSL_STREAM_STATE) :: stream

integer(kind=4) errcode
integer(kind=4) i,j
integer brng,method,seed,n

n = 1000
s = 0.0
a = 5.0
sigma = 2.0
brng=VSL_BRNG_MT19937
method=VSL_METHOD_DGAUSSIAN_ICDF
seed=777

!      ***** Initializing *****
errcode=vslnewstream( stream, brng, seed )

!      ***** Generating *****

```

```
do i = 1,10
  errcode=vdrnggaussian( method, stream, n, r, a, sigma )
  do j = 1, 1000
    s = s + r(j)
  end do
end do

s = s / 10000.0

! ***** Deinitialize *****
errcode=vsldeltestream( stream )

! ***** Printing results *****
print *, "Sample mean of normal distribution = ", s

end
```

Additionally, examples that demonstrate usage of VSL random number generators are available in the following directories:

```
${MKL}/examples/vslc/source
${MKL}/examples/vslf/source.
```

Service Routines

Stream handling comprises routines for creating, deleting, or copying the streams and getting the index of a basic generator. A random stream can also be saved to and then read from a binary file. [Table 10-4](#) lists all available service routines

Table 10-4 Service Routines

Routine	Short Description
NewStream	Creates and initializes a random stream.
NewStreamEx	Creates and initializes a random stream for the generators with multiple initial conditions.
iNewAbstractStream	Creates and initializes an abstract random stream for integer arrays.
dNewAbstractStream	Creates and initializes an abstract random stream for double precision floating-point arrays.
sNewAbstractStream	Creates and initializes an abstract random stream for single precision floating-point arrays.

Routine	Short Description
DeleteStream	Deletes previously created stream.
CopyStream	Copies a stream to another stream.
CopyStreamState	Creates a copy of a random stream state.
SaveStreamF	Writes a stream to a binary file.
LoadStreamF	Reads a stream from a binary file.
LeapfrogStream	Initializes the stream by the leapfrog method to generate a subsequence of the original sequence.
SkipAheadStream	Initializes the stream by the skip-ahead method.
GetStreamStateBrng	Obtains the index of the basic generator responsible for the generation of a given random stream.
GetNumRegBrngs	Obtains the number of currently registered basic generators.

NOTE. In the above table, the `vsl` prefix in the function names is omitted. In the function reference this prefix is always used in function prototypes and code examples.

Most of the generator-based work comprises three basic steps:

1. Creating and initializing a stream ([NewStream](#), [NewStreamEx](#), [CopyStream](#), [CopyStreamState](#), [LeapfrogStream](#), [SkipAheadStream](#)).
2. Generating random numbers with given distribution, see [Distribution Generators](#).
3. Deleting the stream ([DeleteStream](#)).

Note that you can concurrently create multiple streams and obtain random data from one or several generators by using the stream state. You must use the [DeleteStream](#) function to delete all the streams afterwards.

NewStream

Creates and initializes a random stream.

Syntax

Fortran:

```
status = vslnewstream( stream, brng, seed )
```

C:

```
status = vslNewStream( &stream, brng, seed );
```

Input Parameters

Name	Type	Description
<i>brng</i>	FORTRAN 77: INTEGER	Index of the basic generator to initialize the stream. See Table 10-2 for specific value.
	Fortran 90: INTEGER, INTENT (IN)	
	C: const int	
<i>seed</i>	FORTRAN 77: INTEGER	Initial condition of the stream. In the case of a quasi-random number generator seed parameter is used to set the dimension. If the dimension is greater than the dimension that brng can support or is less than 1, then the dimension is assumed to be equal to 1.
	Fortran 90: INTEGER, INTENT (IN)	
	C: const unsigned int	

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4	Stream state descriptor
	stream(2)	
	Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (OUT)	
	C: VSLStreamStatePtr*	

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

For a basic generator with number *brng*, this function creates a new stream and initializes it with a 32-bit seed. The seed is an initial value used to select a particular sequence generated by the basic generator *brng*. The function is also applicable for generators with multiple initial conditions. See [VSL Notes](#) for a more detailed description of stream initialization for different basic generators.

NOTE. This function is not applicable for abstract basic random number generators. Please use [vslNewAbstractStream](#), [vslsNewAbstractStream](#) or [vsldNewAbstractStream](#) to utilize integer, single-precision or double-precision external random data respectively.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .

NewStreamEx

Creates and initializes a random stream for generators with multiple initial conditions.

Syntax

Fortran:

```
status = vslnewstreamex( stream, brng, n, params )
```

C:

```
status = vslNewStreamEx( &stream, brng, n, params );
```

Input Parameters

Name	Type	Description
<i>brng</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Index of the basic generator to initialize the stream. See Table 10-2 for specific value.
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of initial conditions contained in <i>params</i>
<i>params</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const unsigned int	Array of initial conditions necessary for the basic generator <i>brng</i> to initialize the stream. In the case of a quasi-random number generator only the first element in <i>params</i> parameter is used to set the dimension. If the dimension is greater than the dimension that <i>brng</i> can support or is less than 1, then the dimension is assumed to be equal to 1.

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (OUT) C: VSLStreamStatePtr*	Stream state descriptor

Description

This function is declared in `mk1_vsl.f77` for FORTRAN 77 interface, in `mk1_vsl.fi` for Fortran 90 interface, and in `mk1_vsl_functions.h` for C interface.

The function provides an advanced tool to set the initial conditions for a basic generator if its input arguments imply several initialization parameters. Initial values are used to select a particular sequence generated by the basic generator *brng*. Whenever possible, use [NewStream](#), which is analogous to [vslNewStreamEx](#) except that it takes only one 32-bit initial condition. In particular, [vslNewStreamEx](#) may be used to initialize the state table in Generalized Feedback Shift Register Generators (GFSRs). A more detailed description of this issue can be found in [VSL Notes](#).

This function is also used to pass user-defined initialization parameters of quasi-random number generators into the library. See [VSL Notes](#) for the format for their passing and registration in VSL.

NOTE. This function is not applicable for abstract basic random number generators. Please use [vslNewAbstractStream](#), [vslsNewAbstractStream](#) or [vslldNewAbstractStream](#) to utilize integer, single-precision or double-precision external random data respectively.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .

iNewAbstractStream

Creates and initializes an abstract random stream for integer arrays.

Syntax

Fortran:

```
status = vslnewabstractstream( stream, n, ibuf, icallback )
```

C:

```
status = vslNewAbstractStream( &stream, n, ibuf, icallback );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Size of the array <i>ibuf</i>
<i>ibuf</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const unsigned int	Array of <i>n</i> 32-bit integers
<i>icallback</i>	See <i>Note</i> below	FORTRAN: Address of the callback function used for <i>ibuf</i> update C: Pointer to the callback function used for <i>ibuf</i> update

NOTE. Format of the callback function in FORTRAN 77:

```
INTEGER FUNCTION IUPDATEFUNC( stream, n, ibuf, nmin, nmax, idx )  
  
INTEGER*4 stream(2)  
  
INTEGER n  
  
INTEGER*4 ibuf(n)  
  
INTEGER nmin  
  
INTEGER nmax  
  
INTEGER idx
```

Format of the callback function in Fortran 90:

```

INTEGER FUNCTION IUPDATEFUNC(C)( stream, n, ibuf, nmin, nmax, idx )

TYPE(VSL_STREAM_STATE), POINTER :: stream[reference]

INTEGER(KIND=4), INTENT(IN)      :: n[reference]

INTEGER(KIND=4), INTENT(OUT)    :: ibuf[reference](0:n-1)

INTEGER(KIND=4), INTENT(IN)     :: nmin[reference]

INTEGER(KIND=4), INTENT(IN)     :: nmax[reference]

INTEGER(KIND=4), INTENT(IN)     :: idx[reference]

```

Format of the callback function in C:

```

int iUpdateFunc( VSLStreamStatePtr stream, int* n, unsigned int ibuf[], int* nmin,
int* nmax, int* idx );

```

The callback function returns the number of elements in the array actually updated by the function. [Table 10-5](#) gives the description of the callback function parameters.

Table 10-5 icallback Callback Function Parameters

Parameters	Short Description
<i>stream</i>	Abstract stream descriptor
<i>n</i>	Size of <i>ibuf</i>
<i>ibuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>ibuf</i> to start update $0 \leq idx < n$.

Output Parameters

Name	Type	Description
<i>stream</i>	FORTTRAN 77: INTEGER*4 <code>stream(2)</code> Fortran 90: <code>TYPE (VSL_STREAM_STATE),</code> <code>TINTENT (OUT)</code> C: <code>VSLStreamStatePtr*</code>	Descriptor of the stream state structure

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function creates a new abstract stream and associates it with an integer array *ibuf* and user's callback function *icallback* that is intended for updating of *ibuf* content.

Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_BAD_ARG</code>	Parameter <i>n</i> is not positive.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory for <i>stream</i> .
<code>VSL_ERROR_NULL_PTR</code>	Either buffer or callback function parameter is a NULL pointer.

dNewAbstractStream

Creates and initializes an abstract random stream for double precision floating-point arrays.

Syntax

Fortran:

```
status = vsldnewabstractstream( stream, n, dbuf, a, b, dcallback )
```

C:

```
status = vsldNewAbstractStream( &stream, n, dbuf, a, b, dcallback );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Size of the array <i>dbuf</i>
<i>dbuf</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: DOUBLE PRECISION, INTENT (IN) C: const double	Array of <i>n</i> double precision floating-point random numbers with uniform distribution over interval (a,b)
<i>a</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: DOUBLE PRECISION, INTENT (IN) C: const double	Left boundary a
<i>b</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: DOUBLE PRECISION, INTENT (IN) C: const double	Right boundary b
<i>dcallback</i>	See <i>Note</i> below	FORTRAN: Address of the callback function used for update of the array <i>dbuf</i> C: Pointer to the callback function used for update of the array <i>dbuf</i>

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (OUT) C: VSLStreamStatePtr*	Descriptor of the stream state structure

NOTE. Format of the callback function in FORTRAN 77:

```
INTEGER FUNCTION DUPDATEFUNC( stream, n, dbuf, nmin, nmax, idx )  
  
INTEGER*4 stream(2)  
  
INTEGER n  
  
DOUBLE PRECISION dbuf(n)  
  
INTEGER nmin  
  
INTEGER nmax  
  
INTEGER idx
```

Format of the callback function in Fortran 90:

```
INTEGER FUNCTION DUPDATEFUNC[C]( stream, n, dbuf, nmin, nmax, idx )  
  
TYPE (VSL_STREAM_STATE), POINTER :: stream[reference]  
INTEGER (KIND=4), INTENT (IN) :: n[reference]  
REAL (KIND=8), INTENT (OUT) :: dbuf[reference] (0:n-1)  
INTEGER (KIND=4), INTENT (IN) :: nmin[reference]  
INTEGER (KIND=4), INTENT (IN) :: nmax[reference]  
INTEGER (KIND=4), INTENT (IN) :: idx[reference]
```

Format of the callback function in C:

```
int dUpdateFunc( VSLStreamStatePtr stream, int* n, double dbuf[], int* nmin, int*  
nmax, int* idx );
```

The callback function returns the number of elements in the array actually updated by the function. [Table 10-6](#) gives the description of the callback function parameters.

dcallback Callback Function Parameters

Parameters	Short Description
<i>stream</i>	Abstract stream descriptor
<i>n</i>	Size of <i>dbuf</i>
<i>dbuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>dbuf</i> to start update $0 \leq idx < n$.

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function creates a new abstract stream for double precision floating-point arrays with random numbers of the uniform distribution over interval (a,b) . The function associates the stream with a double precision array *dbuf* and user's callback function *dcallback* that is intended for updating of *dbuf* content.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BAD_ARG	Parameter <i>n</i> is not positive.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .
VSL_ERROR_NULL_PTR	Either buffer or callback function parameter is a NULL pointer.

sNewAbstractStream

Creates and initializes an abstract random stream for single precision floating-point arrays.

Syntax

Fortran:

```
status = vslsnewabstractstream( stream, n, sbuf, a, b, scallback )
```

C:

```
status = vslsNewAbstractStream( &stream, n, sbuf, a, b, scallback );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Size of the array <i>sbuf</i>
<i>sbuf</i>	FORTTRAN 77: REAL Fortran 90: REAL, INTENT (IN) C: const float	Array of <i>n</i> single precision floating-point random numbers with uniform distribution over interval (<i>a</i> , <i>b</i>)
<i>a</i>	FORTTRAN 77: REAL Fortran 90: REAL, INTENT (IN) C: const float	Left boundary <i>a</i>
<i>b</i>	FORTTRAN 77: REAL Fortran 90: REAL, INTENT (IN) C: const float	Right boundary <i>b</i>

Name	Type	Description
<i>scallback</i>	See Note below	FORTRAN: Address of the callback function used for update of the array <i>sbuf</i> C: Pointer to the callback function used for update of the array <i>sbuf</i>

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (OUT) C: VSLStreamStatePtr*	Descriptor of the stream state structure

NOTE. Format of the callback function in FORTRAN 77:

```
INTEGER FUNCTION SUPDATEFUNC( stream, n, ibuf, nmin, nmax, idx )  
  
INTEGER*4 stream(2)  
  
INTEGER n  
  
REAL sbuf(n)  
  
INTEGER nmin  
  
INTEGER nmax  
  
INTEGER idx
```

Format of the callback function in Fortran 90:

```
INTEGER FUNCTION SUPDATEFUNC[C]( stream, n, sbuf, nmin, nmax, idx )  
  
TYPE(VSL_STREAM_STATE), POINTER :: stream[reference]  
  
INTEGER(KIND=4), INTENT(IN)      :: n[reference]  
  
REAL(KIND=4),   INTENT(OUT)      :: sbuf[reference](0:n-1)  
  
INTEGER(KIND=4), INTENT(IN)      :: nmin[reference]  
  
INTEGER(KIND=4), INTENT(IN)      :: nmax[reference]  
  
INTEGER(KIND=4), INTENT(IN)      :: idx[reference]
```

Format of the callback function in C:

```
int sUpdateFunc( VSLStreamStatePtr stream, int* n, float sbuf[], int* nmin, int*  
nmax, int* idx );
```

The callback function returns the number of elements in the array actually updated by the function. [Table 10-7](#) gives the description of the callback function parameters.

Table 10-7 **scallback** Callback Function Parameters

Parameters	Short Description
<i>stream</i>	Abstract stream descriptor
<i>n</i>	Size of <i>sbuf</i>
<i>sbuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>sbuf</i> to start update $0 \leq idx < n$.

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function creates a new abstract stream for single precision floating-point arrays with random numbers of the uniform distribution over interval (a,b) . The function associates the stream with a single precision array *sbuf* and user's callback function *callback* that is intended for updating of *sbuf* content.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BAD_ARG	Parameter <i>n</i> is not positive.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .
VSL_ERROR_NULL_PTR	Either buffer or callback function parameter is a NULL pointer.

DeleteStream

Deletes a random stream.

Syntax

Fortran:

```
status = vsldeletestream( stream )
```

C:

```
status = vslDeleteStream( &stream );
```

Input/Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (OUT) C: VSLStreamStatePtr*	FORTRAN: Stream state descriptor. Must have non-zero value. After the stream is successfully deleted, the descriptor becomes invalid. C: Stream state descriptor. Must have non-zero value. After the stream is successfully deleted, the pointer is set to NULL.

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function deletes the random stream created by one of the initialization functions.

Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<code>srcstream</code> parameter is a NULL pointer.
<code>VSL_ERROR_BAD_STREAM</code>	<code>srcstream</code> is not a valid random stream.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory for <code>newstream</code> .

CopyStream

Creates a copy of a random stream.

Syntax

Fortran:

```
status = vslcopystream( newstream, srcstream )
```

C:

```
status = vslCopyStream( &newstream, srcstream );
```

Input Parameters

Name	Type	Description
<code>srcstream</code>	FORTTRAN 77: <code>INTEGER*4</code> <code>srcstream(2)</code> Fortran 90: <code>TYPE(VSL_STREAM_STATE),</code> <code>INTENT(IN)</code> C: <code>const</code> <code>VSLStreamStatePtr</code>	FORTTRAN: Descriptor of the stream to be copied C: Pointer to the stream state structure to be copied

Output Parameters

Name	Type	Description
<i>newstream</i>	FORTRAN 77: INTEGER*4 newstream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (OUT) C: VSLStreamStatePtr*	Copied stream descriptor

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function creates an exact copy of *srcstream* and stores its descriptor to *newstream*.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>srcstream</i> parameter is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>srcstream</i> is not a valid random stream.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>newstream</i> .

CopyStreamState

Creates a copy of a random stream state.

Syntax

Fortran:

```
status = vslcopystreamstate( deststream, srcstream )
```

C:

```
status = vslCopyStreamState( deststream, srcstream );
```

Input Parameters

Name	Type	Description
<i>srcstream</i>	FORTRAN 77: INTEGER*4 srcstream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: const VSLStreamStatePtr	FORTRAN: Descriptor of the destination stream where the state of <i>srcstream</i> stream is copied C: Pointer to the stream state structure, from which the state structure is copied

Output Parameters

Name	Type	Description
<i>deststream</i>	FORTRAN 77: INTEGER*4 deststream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (OUT) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream with the state to be copied C: Pointer to the stream state structure where the stream state is copied

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function copies a stream state from *srcstream* to the existing *deststream* stream. Both the streams should be generated by the same basic generator. An error message is generated when the index of the BRNG that produced *deststream* stream differs from the index of the BRNG that generated *srcstream* stream.

Unlike [CopyStream](#) function, which creates a new stream and copies both the stream state and other data from *srcstream*, the function `CopyStreamState` copies only *srcstream* stream state data to the generated *deststream* stream.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	Either <i>srcstream</i> or <i>deststream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	Either <i>srcstream</i> or <i>deststream</i> is not a valid random stream.
VSL_ERROR_BRNGS_INCOMPATIBLE	BRNG associated with <i>srcstream</i> is not compatible with BRNG associated with <i>deststream</i> .

SaveStreamF

Writes random stream descriptive data to binary file.

Syntax

Fortran:

```
errstatus = vslsavestreamf( stream, fname )
```

C:

```
errstatus = vslSaveStreamF( stream, fname );
```

Input Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(IN) C: const VSLStreamStatePtr	Random stream to be written to the file
<i>fname</i>	FORTRAN 77: CHARACTER(*) Fortran 90: CHARACTER(*), INTENT(IN)	FORTRAN: File name specified as a C-style null-terminated string C: File name specified as a Fortran-style character string

Name	Type	Description
	C: <code>const char*</code>	

Output Parameters

Name	Type	Description
<i>errstatus</i>	FORTRAN: <code>INTEGER</code> C: <code>int</code>	Error status of the operation

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function writes the random stream descriptive data to the binary file. Random stream descriptive data is saved to the binary file with the name *fname*. Random stream *stream* must be a valid stream created by [NewStream](#)-like or [CopyStream](#)-like service routines. If the stream cannot be saved to the file, *errstatus* has a non-zero value. Random stream can be read from the binary file using [LoadStreamF](#) function.

Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	Either <i>fname</i> or <i>stream</i> is a NULL pointer.
<code>VSL_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.
<code>VSL_ERROR_FILE_OPEN</code>	Indicates an error in opening the file.
<code>VSL_ERROR_FILE_WRITE</code>	Indicates an error in writing the file.
<code>VSL_ERROR_FILE_CLOSE</code>	Indicates an error in closing the file.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory for internal needs.

LoadStreamF

Creates new stream and reads stream descriptive data from binary file.

Syntax

Fortran:

```
errstatus = vslloadstreamf( stream, fname )
```

C:

```
errstatus = vslLoadStreamF( &stream, fname );
```

Input Parameters

Name	Type	Description
<i>fname</i>	FORTRAN 77: CHARACTER(*)	FORTRAN: File name specified as a C-style null-terminated string
	Fortran 90: CHARACTER(*), INTENT(IN)	C: File name specified as a Fortran-style character string
	C: const char*	

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2)	FORTRAN: Descriptor of a new random stream
	Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(OUT)	C: Pointer to a new random stream
	C: VSLStreamStatePtr*	
<i>errstatus</i>	FORTRAN: INTEGER C: int	Error status of the operation

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function creates a new stream and reads stream descriptive data from the binary file. A new random stream is created using the stream descriptive data from the binary file with the name *fname*. If the stream cannot be read (for example, an I/O error occurs or the file format is invalid), *errstatus* has a non-zero value. To save random stream to the file, use [SaveStreamF](#) function.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>fname</i> is a NULL pointer.
VSL_ERROR_FILE_OPEN	Indicates an error in opening the file.
VSL_ERROR_FILE_WRITE	Indicates an error in writing the file.
VSL_ERROR_FILE_CLOSE	Indicates an error in closing the file.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for internal needs.
VSL_ERROR_BAD_FILE_FORMAT	Unknown file format.
VSL_ERROR_UNSUPPORTED_FILE_VER	File format version is unsupported.

LeapfrogStream

Initializes a stream using the leapfrog method.

Syntax

Fortran:

```
status = vslleapfrogstream( stream, k, nstreams )
```

C:

```
status = vslLeapfrogStream( stream, k, nstreams );
```

Input Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream to which leapfrog method is applied C: Pointer to the stream state structure to which leapfrog method is applied
<i>k</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Index of the computational node, or stream number
<i>nstreams</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Largest number of computational nodes, or stride

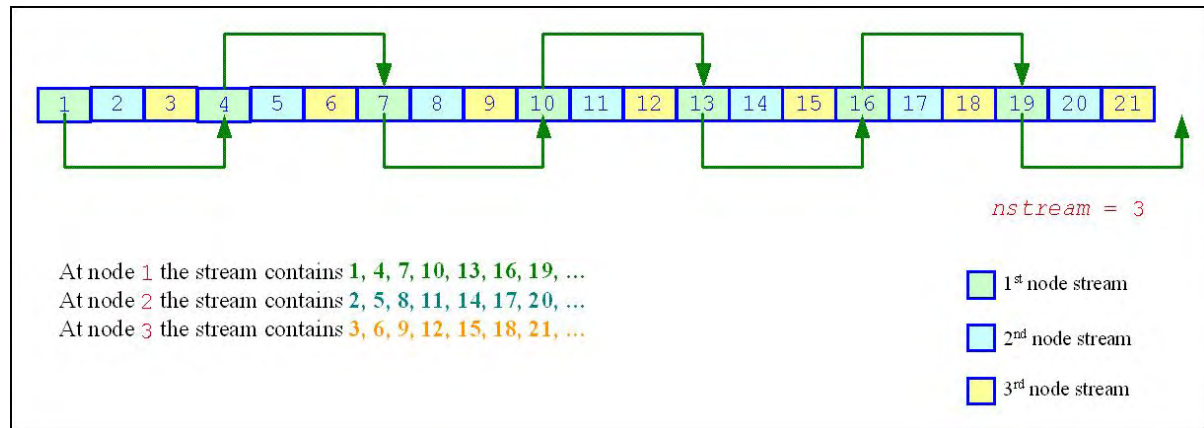

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function function allows generating random numbers in a random stream with non-unit stride. This feature is particularly useful in distributing random numbers from original stream across *nstreams* buffers without generating the original random sequence with subsequent manual distribution. One of the important applications of the leapfrog method is splitting the original sequence into non-overlapping subsequences across *nstreams* computational nodes.

The function initializes the original random stream (see [Figure 10-1](#)) to generate random numbers for the computational node k , $0 \leq k < nstreams$, where $nstreams$ is the largest number of computational nodes used.

Figure 10-1 Leapfrog Method

The leapfrog method is supported only for those basic generators that allow splitting elements by the leapfrog method, which is more efficient than simply generating them by a generator with subsequent manual distribution across computational nodes. See [VSL Notes](#) for details.

For quasi-random basic generators the leapfrog method allows generating individual components of quasi-random vectors instead of whole quasi-random vectors. In this case $nstreams$ parameter should be equal to the dimension of the quasi-random vector while k parameter should be the index of a component to be generated ($0 \leq k < nstreams$). Other parameters values are not allowed.

The following code examples illustrate the initialization of three independent streams using the leapfrog method:

Example 10-1 Fortran 90 Code for Leapfrog Method

```
...  
TYPE(VSL_STREAM_STATE)    ::stream1  
TYPE(VSL_STREAM_STATE)    ::stream2  
TYPE(VSL_STREAM_STATE)    ::stream3  
! Creating 3 identical streams  
status = vslnewstream(stream1, VSL_BRNG_MCG31, 174)  
status = vslcopystream(stream2, stream1)  
status = vslcopystream(stream3, stream1)  
! Leapfrogging the streams  
  
status = vslleapfrogstream(stream1, 0, 3)  
status = vslleapfrogstream(stream2, 1, 3)  
status = vslleapfrogstream(stream3, 2, 3)  
! Generating random numbers  
  
...  
! Deleting the streams  
  
status = vsldeletestream(stream1)  
status = vsldeletestream(stream2)  
status = vsldeletestream(stream3)  
...
```

Example 10-2 C Code for Leapfrog Method

```
...
VSLStreamStatePtr stream1;
VSLStreamStatePtr stream2;
VSLStreamStatePtr stream3;
/* Creating 3 identical streams */
status = vslNewStream(&stream1, VSL_BRNG_MCG31, 174);
status = vslCopyStream(&stream2, stream1);
status = vslCopyStream(&stream3, stream1);
/* Leapfrogging the streams
*/
status = vslLeapfrogStream(stream1, 0, 3);
status = vslLeapfrogStream(stream2, 1, 3);
status = vslLeapfrogStream(stream3, 2, 3);
/* Generating random numbers
*/
...
/* Deleting the streams
*/
status = vslDeleteStream(&stream1);
status = vslDeleteStream(&stream2);
status = vslDeleteStream(&stream3);
...
```

Return Values

VSL_ERROR_OK, VSL_STATUS_OK
VSL_ERROR_NULL_PTR
VSL_ERROR_BAD_STREAM
VSL_ERROR_LEAPFROG_UNSUPPORTED

Indicates no error, execution is successful.
stream is a NULL pointer.
stream is not a valid random stream.
BRNG does not support Leapfrog method.

SkipAheadStream

Initializes a stream using the block-splitting method.

Syntax

Fortran:

```
status = vslskipaheadstream( stream, nskip )
```

C:

```
status = vslSkipAheadStream( stream, nskip);
```

Input Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2)	FORTRAN: Descriptor of the stream to which block-splitting method is applied
	Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN)	C: Pointer to the stream state structure to which block-splitting method is applied
	C: VSLStreamStatePtr	
<i>nskip</i>	FORTRAN 77: INTEGER*4 nskip(2)	Number of skipped elements
	Fortran 90: INTEGER (KIND=8), INTENT (IN)	
	C: const long long int	

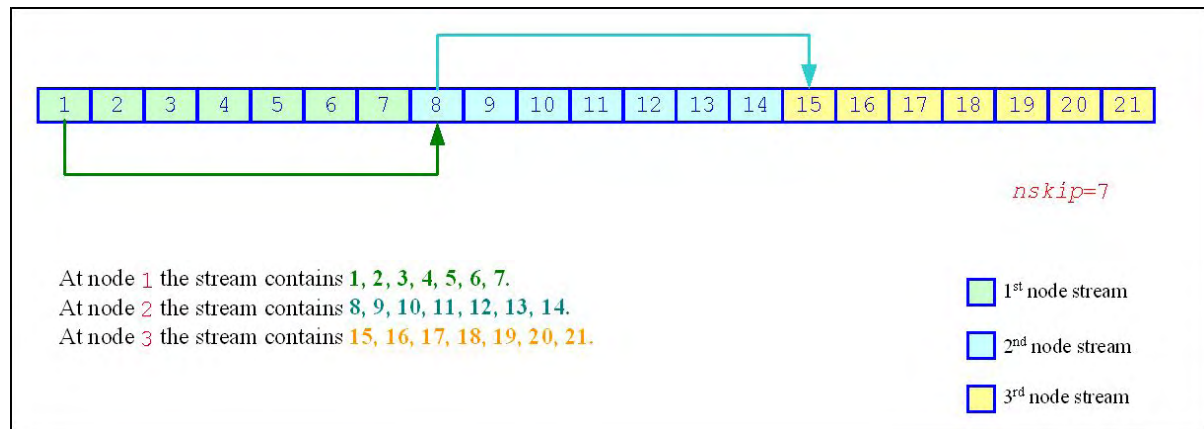

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function skips a given number of elements in a random stream. This feature is particularly useful in distributing random numbers from original random stream across different computational nodes. If the largest number of random numbers used by a computational node

is *nskip*, then the original random sequence may be split by `SkipAheadStream` into non-overlapping blocks of *nskip* size so that each block corresponds to the respective computational node. The number of computational nodes is unlimited. This method is known as the block-splitting method or as the skip-ahead method. (see [Figure 10-2](#)).

Figure 10-2 Block-Splitting Method

The skip-ahead method is supported only for those basic generators that allow skipping elements by the skip-ahead method, which is more efficient than simply generating them by generator with subsequent manual skipping. See [VSL Notes](#) for details.

Please note that for quasi-random basic generators the skip-ahead method works with components of quasi-random vectors rather than with whole quasi-random vectors. Therefore, to skip *NS* quasi-random vectors, set the *nskip* parameter equal to the *NS*DIMEN*, where *DIMEN* is the dimension of the quasi-random vector. If this operation results in exceeding the period of the quasi-random number generator, which is $2^{32}-1$, the library returns the `VSL_ERROR_SKIPAHEAD_UNSUPPORTED` error code.

The following code examples illustrate how to initialize three independent streams using the `SkipAheadStream` function:

Example 10-3 Fortran 90 Code for Block-Splitting Method

```
...
type(VSL_STREAM_STATE)  ::stream1
type(VSL_STREAM_STATE)  ::stream2
type(VSL_STREAM_STATE)  ::stream3
! Creating the 1st stream
status = vslnewstream(stream1, VSL_BRNG_MCG31, 174)
! Skipping ahead by 7 elements the 2nd stream

status = vslcopystream(stream2, stream1);
status = vslskipaheadstream(stream2, 7);
! Skipping ahead by 7 elements the 3rd stream

status = vslcopystream(stream3, stream2);
status = vslskipaheadstream(stream3, 7);
! Generating random numbers

...
! Deleting the streams

status = vsldeletestream(stream1)
status = vsldeletestream(stream2)
status = vsldeletestream(stream3)
...
```

Example 10-4 C Code for Block-Splitting Method

```
VSLStreamStatePtr stream1;
VSLStreamStatePtr stream2;
VSLStreamStatePtr stream3;
/* Creating the 1st stream
*/
status = vslNewStream(&stream1, VSL_BRNG_MCG31, 174);
/* Skipping ahead by 7 elements the 2nd stream */
status = vslCopyStream(&stream2, stream1);
status = vslSkipAheadStream(stream2, 7);
/* Skipping ahead by 7 elements the 3rd stream */
status = vslCopyStream(&stream3, stream2);
status = vslSkipAheadStream(stream3, 7);
/* Generating random numbers
*/
...
/* Deleting the streams
*/
status = vslDeleteStream(&stream1);
status = vslDeleteStream(&stream2);
status = vslDeleteStream(&stream3);
...
```

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_SKIPAHEAD_UNSUPPORTED	BRNG does not support the Skip-Ahead method.

GetStreamStateBrng

Returns index of a basic generator used for generation of a given random stream.

Syntax

Fortran:

```
brng = vslgetstreamstatebrng( stream )
```

C:

```
brng = vslGetStreamStateBrng( stream );
```

Input Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), TINTENT (IN) C: const VSLStreamStatePtr	FORTRAN: Descriptor of the stream state C: Pointer to the stream state structure

Output Parameters

Name	Type	Description
<i>brng</i>	FORTRAN: INTEGER C: int	Index of the basic generator assigned for the generation of <i>stream</i> ; negative in case of an error

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function retrieves the index of a basic generator used for generation of a given random stream.

Return Values

VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.

GetNumRegBrngs

Obtains the number of currently registered basic generators.

Syntax

Fortran:

```
nregbrngs = vslgetnumregbrngs( )
```

C:

```
nregbrngs = vslGetNumRegBrngs( void );
```

Output Parameters

Name	Type	Description
<i>nregbrngs</i>	FORTTRAN: INTEGER C: int	Number of basic generators registered at the moment of the function call

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function obtains the number of currently registered basic generators. Whenever user registers a user-designed basic generator, the number of registered basic generators is incremented. The maximum number of basic generators that can be registered is determined by `VSL_MAX_REG_BRNGS` parameter.

Distribution Generators

VSL routines are used to generate random numbers with different types of distribution. Each function group is introduced below by the type of underlying distribution and contains a short description of its functionality, as well as specifications of the call sequence for both FORTRAN

and C-interface and the explanation of input and output parameters. [Table 10-8](#) and [Table 10-9](#) list the random number generator routines, together with used data types, output distributions, and sets correspondence between data types of the generator routines and called basic random number generators.

Table 10-8 Continuous Distribution Generators

Type of Distribution	Data Types	BRNG Data Type	Description
Uniform	s, d	s, d	Uniform continuous distribution on the interval $[a, b]$.
Gaussian	s, d	s, d	Normal (Gaussian) distribution.
GaussianMV	s, d	s, d	Multivariate normal (Gaussian) distribution.
Exponential	s, d	s, d	Exponential distribution.
Laplace	s, d	s, d	Laplace distribution (double exponential distribution).
Weibull	s, d	s, d	Weibull distribution.
Cauchy	s, d	s, d	Cauchy distribution.
Rayleigh	s, d	s, d	Rayleigh distribution.
Lognormal	s, d	s, d	Lognormal distribution.
Gumbel	s, d	s, d	Gumbel (extreme value) distribution.
Gamma	s, d	s, d	Gamma distribution.
Beta	s, d	s, d	Beta distribution.

Table 10-9 Discrete Distribution Generators

Type of Distribution	Data Types	BRNG Data Type	Description
Uniform	i	d	Uniform discrete distribution on the interval $[a, b]$.

Type of Distribution	Data Types	BRNG Data Type	Description
UniformBits	i	i	Generator of integer random values with uniform bit distribution.
Bernoulli	i	s	Bernoulli distribution.
Geometric	i	s	Geometric distribution.
Binomial	i	d	Binomial distribution.
Hypergeometric	i	d	Hypergeometric distribution.
Poisson	i	s (for VSL_METHOD_IPOISSON_POISNORM) s (for distribution parameter $\lambda \geq 27$) and d (for $\lambda < 27$) (for VSL_METHOD_IPOISSON_PTPE)	Poisson distribution.
PoissonV	i	s	Poisson distribution with varying mean.
NegBinomial	i	d	Negative binomial distribution, or Pascal distribution.

The library provides two modes of random number generation, accurate and fast. Accurate generation mode is intended for the applications that are highly demanding to accuracy of calculations. When used in this mode, the generators produce random numbers lying completely within definitional domain for all values of the distribution parameters. For example, random numbers obtained from the generator of continuous distribution that is uniform on interval $[a,b]$ belong to this interval irrespective of what a and b values may be. Fast mode provides high performance of generation and also guaranties that generated random numbers belong to the definitional domain except for some specific values of distribution parameters. The generation mode is set by specifying relevant value of the method parameter in generator routines. List of distributions that support accurate mode of generation is given in the table below.

Table 10-10 Distribution Generators Supporting Accurate Mode

Type of Distribution	Data Types
Uniform	s, d
Exponential	s, d
Weibull	s, d
Rayleigh	s, d
Lognormal	s, d

Continuous Distributions

This section describes routines for generating random numbers with continuous distribution.

Uniform

Generates random numbers with uniform distribution.

Syntax

Fortran:

```
status = vsrnguniform( method, stream, n, r, a, b )
status = vdrnguniform( method, stream, n, r, a, b )
```

C:

```
status = vsRngUniform( method, stream, n, r, a, b );
status = vdRngUniform( method, stream, n, r, a, b );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method; the specific values are as follows: VSL_METHOD_SUNIFORM_STD VSL_METHOD_DUNIFORM_STD VSL_METHOD_SUNIFORM_STD_ACCURATE VSL_METHOD_DUNIFORM_STD_ACCURATE Standard method.
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated
<i>a</i>	FORTRAN 77: REAL for vsrnguniform DOUBLE PRECISION for vdrnguniform Fortran 90: REAL, INTENT (IN) for vsrnguniform DOUBLE PRECISION, INTENT (IN) for vdrnguniform	Left bound a

Name	Type	Description
	C: const float for vsRngUniform const double for vdRngUniform	
<i>b</i>	FORTTRAN 77: REAL for vsrnguniform DOUBLE PRECISION for vdrnguniform Fortran 90: REAL, INTENT(IN) for vsrnguniform DOUBLE PRECISION, INTENT(IN) for vdrnguniform C: const float for vsRngUniform const double for vdRngUniform	Right bound <i>b</i>

Output Parameters

Name	Type	Description
<i>r</i>	FORTTRAN 77: REAL for vsrnguniform DOUBLE PRECISION for vdrnguniform Fortran 90: REAL, INTENT(OUT) for vsrnguniform	Vector of <i>n</i> random numbers uniformly distributed over the interval $[a, b]$

Name	Type	Description
------	------	-------------

	DOUBLE PRECISION, INTENT (OUT) for vdrnguniform	
--	---	--

C: float* for vsRngUniform		
--------------------------------------	--	--

double* for vdRngUniform		
--------------------------	--	--

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates random numbers uniformly distributed over the interval $[a, b]$, where a, b are the left and right bounds of the interval, respectively, and $a, b \in \mathbb{R}$; $a > b$.

The probability density function is given by:

$$f_{a,b}(x) = \begin{cases} \frac{1}{b-a}, & x \in [a, b] \\ 0, & x \notin [a, b] \end{cases}, \quad -\infty < x < +\infty$$

The cumulative distribution function is as follows:

$$f_{a,b}(x) = \begin{cases} 0, & x < a \\ \frac{x-a}{b-a}, & a \leq x \leq b, \\ 1, & x \geq b \end{cases}, \quad -\infty < x < +\infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_ERROR_SKIPAHEAD_UNSUPPORTED	Period of the generator has been exceeded.

Gaussian

Generates normally distributed random numbers.

Syntax

Fortran:

```
status = vsrnggaussian( method, stream, n, r, a, sigma )
status = vdrnggaussian( method, stream, n, r, a, sigma )
```

C:

```
status = vsRngGaussian( method, stream, n, r, a, sigma );
status = vdRngGaussian( method, stream, n, r, a, sigma );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method. The specific values are as follows: VSL_METHOD_SGAUSSIAN_BOXMULLER VSL_METHOD_SGAUSSIAN_BOXMULLER2 VSL_METHOD_SGAUSSIAN_ICDF VSL_METHOD_DGAUSSIAN_BOXMULLER VSL_METHOD_DGAUSSIAN_BOXMULLER2 VSL_METHOD_DGAUSSIAN_ICDF See brief description of the methods BOXMULLER, BOXMULLER2, and ICDF in Table 10-1
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated
<i>a</i>	FORTRAN 77: REAL for vsrnggaussian DOUBLE PRECISION for vdrnggaussian Fortran 90: REAL, INTENT (IN) for vsrnggaussian	Mean value <i>a</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT(IN) for vdrnggaussian C: const float for vsRngGaussian const double for vdRngGaussian	
<i>sigma</i>	FORTRAN 77: REAL for vsrnggaussian DOUBLE PRECISION for vdrnggaussian Fortran 90: REAL, INTENT(IN) for vsrnggaussian DOUBLE PRECISION, INTENT(IN) for vdrnggaussian C: const float for vsRngGaussian const double for vdRngGaussian	Standard deviation σ .

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: REAL for vsrnggaussian DOUBLE PRECISION for vdrnggaussian	Vector of <i>n</i> normally distributed random numbers

Name	Type	Description
	Fortran 90: REAL, INTENT(OUT) for vsrnggaussian	
	DOUBLE PRECISION, INTENT(OUT) for vdrnggaussian	
	C: float* for vsRngGaussian	
	double* for vdRngGaussian	

Description

This function is declared in `mk1_vsl.f77` for FORTRAN 77 interface, in `mk1_vsl.fi` for Fortran 90 interface, and in `mk1_vsl_functions.h` for C interface.

The function generates random numbers with normal (Gaussian) distribution with mean value a and standard deviation σ , where

$a, \sigma \in \mathbb{R} ; \sigma > 0$.

The probability density function is given by:

$$f_{a, \sigma}(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-a)^2}{2\sigma^2}\right), \quad -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a, \sigma}(x) = \int_{-\infty}^x \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(y-a)^2}{2\sigma^2}\right) dy, \quad -\infty < x < +\infty.$$

The cumulative distribution function $F_{a,\sigma}(x)$ can be expressed in terms of standard normal distribution $\Phi(x)$ as

$$F_{a,\sigma}(x) = \Phi((x - a)/\sigma)$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

VSL_ERROR_SKIPAHEAD_UNSUPPORTED

Period of the generator has been exceeded.

GaussianMV

Generates random numbers from multivariate normal distribution.

Syntax

Fortran:

```
status = vsrnggaussianmv( method, stream, n, r, dimen, mstorage, a, t )
```

```
status = vdrnggaussianmv( method, stream, n, r, dimen, mstorage, a, t )
```

C:

```
status = vsRngGaussianMV( method, stream, n, r, dimen, mstorage, a, t );
```

```
status = vdRngGaussianMV( method, stream, n, r, dimen, mstorage, a, t );
```

Input Parameters

Name	Type	Description

C: Elements of the lower triangular matrix passed according to the matrix T storage scheme <i>mstorage</i> .

Output Parameters

Name	Type	Description
r	FORTRAN 77: REAL for vsrnggaussianmv DOUBLE PRECISION for vdrnggaussianmv	Array of n random vectors of dimension <i>dimen</i>

Name	Type	Description
	Fortran 90: REAL, INTENT(OUT) for vsrnggaussianmv DOUBLE PRECISION, INTENT(OUT) for vdrnggaussianmv C: float* for vsRngGaussianMV double* for vdRngGaussianMV	

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates random numbers with d -variate normal (Gaussian) distribution with mean value a and variance-covariance matrix C , where $a \in R^d$; C is a $d \times d$ symmetric positive-definite matrix.

The probability density function is given by:

$$f_{a,C}(x) = \frac{1}{\sqrt{\det(2\pi C)}} \exp(-1/2(x-a)^T C^{-1}(x-a)),$$

where $x \in R^d$.

Matrix C can be represented as $C = TT^T$, where T is a lower triangular matrix - Cholesky factor of C .

Instead of variance-covariance matrix C the generation routines require Cholesky factor of C in input. To compute Cholesky factor of matrix C , the user may call MKL LAPACK routines for matrix factorization: `?potrf` or `?pptrf` for `v?RngGaussianMV`/`v?rnggaussianmv` routines (`?` means either `s` or `d` for single and double precision respectively). See [Application Notes](#) for more details.

Application Notes

Since matrices are stored in Fortran by columns, while in C they are stored by rows, the usage of MKL factorization routines (assuming Fortran matrices storage) in combination with multivariate normal RNG (assuming C matrix storage) is slightly different in C and Fortran. The following tables help in using these routines in C and Fortran. For further information please refer to the appropriate VSL example file.

Table 10-11 Using Cholesky Factorization Routines in Fortran

Matrix Storage Scheme	Variance-Covariance Matrix Argument	Factorization Routine	UPLO Parameter in Factorization Routine	Result of Factorization as Input Argument for RNG
VSL_MATRIX_STORAGE_FULL	C in Fortran two-dimensional array	spotrf for vsrnggaussianmv dpotrf for vdrnggaussianmv	'U'	Upper triangle of T^T . Lower triangle is not used.
VSL_MATRIX_STORAGE_PACKED	Lower triangle of C packed by columns into one-dimensional array	spptrf for vsrnggaussianmv dpptrf for vdrnggaussianmv	'L'	Upper triangle of T^T packed by rows into one-dimensional array.

Table 10-12 Using Cholesky Factorization Routines in C

Matrix Storage Scheme	Variance-Covariance Matrix Argument	Factorization Routine	UPLO Parameter in Factorization Routine	Result of Factorization as Input Argument for RNG
VSL_MATRIX_STORAGE_FULL	C in C two-dimensional array	spotrf for vsRngGaussianMV dpotrf for vdRngGaussianMV	'U'	Upper triangle of T^T . Lower triangle is not used.
VSL_MATRIX_STORAGE_PACKED	Lower triangle of C packed by columns into one-dimensional array	spptrf for vsRngGaussianMV dpptrf for vdRngGaussianMV	'L'	Upper triangle of T^T packed by rows into one-dimensional array.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_ERROR_SKIPAHEAD_UNSUPPORTED	Period of the generator has been exceeded.

Exponential

Generates exponentially distributed random numbers.

Syntax

Fortran:

```
status = vsrngexponential( method, stream, n, r, a, beta )
status = vdrngexponential( method, stream, n, r, a, beta )
```

C:

```
status = vsRngExponential( method, stream, n, r, a, beta );
status = vdRngExponential( method, stream, n, r, a, beta );
```

Input Parameters

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates random numbers with exponential distribution that has displacement a and scalefactor β , where $a, \beta \in \mathbb{R} ; \beta > 0$.

The probability density function is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{1}{\beta} \exp(-(x-a)/\beta), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp(-(x-a)/\beta), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

VSL_ERROR_SKIPAHEAD_UNSUPPORTED

Period of the generator has been exceeded.

Laplace

Generates random numbers with Laplace distribution.

Syntax

Fortran:

```
status = vsrnglaplace( method, stream, n, r, a, beta )
```

```
status = vdrnglaplace( method, stream, n, r, a, beta )
```

C:

```
status = vsRngLaplace( method, stream, n, r, a, beta );  
status = vdRngLaplace( method, stream, n, r, a, beta );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method. The specific values are as follows: VSL_METHOD_SLAPLACE_ICDF VSL_METHOD_DLAPLACE_ICDF Inverse cumulative distribution function method
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: REAL for vsrnglaplace DOUBLE PRECISION for vdrnglaplace	Vector of n Laplace distributed random numbers

Name	Type	Description
	Fortran 90: REAL, INTENT (OUT) for vsrnglaplace	
	DOUBLE PRECISION, INTENT (OUT) for vdrnglaplace	
	C: float* for vsRngLaplace	
	double* for vdrngLaplace	

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates random numbers with Laplace distribution with mean value (or average) a and scalefactor β , where $a, \beta \in R ; \beta > 0$. The scalefactor value determines the standard deviation as

$$\sigma = \beta\sqrt{2}$$

The probability density function is given by:

$$f_{a,\beta}(x) = \frac{1}{\sqrt{2\beta}} \exp\left(-\frac{|x - a|}{\beta}\right), -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$f_{a,\beta}(x) = \begin{cases} \frac{1}{2} \exp\left(-\frac{|x-a|}{\beta}\right), & x \geq a \\ 1 - \frac{1}{2} \exp\left(-\frac{|x-a|}{\beta}\right), & x < a \end{cases}, -\infty < x < +\infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

VSL_ERROR_SKIPAHEAD_UNSUPPORTED

Period of the generator has been exceeded.

Weibull

Generates Weibull distributed random numbers.

Syntax

Fortran:

```
status = vsrngweibull( method, stream, n, r, alpha, a, beta )
```

```
status = vdrngweibull( method, stream, n, r, alpha, a, beta )
```

C:

```
status = vsRngWeibull( method, stream, n, r, alpha, a, beta );
```

```
status = vdRngWeibull( method, stream, n, r, alpha, a, beta );
```

Input Parameters

Name	Type	Description

Name	Type	Description
	<code>const double</code> for <code>vdRngWeibull</code>	

Output Parameters

Name	Type	Description
r	FORTRAN 77: <code>REAL</code> for <code>vsrngweibull</code> <code>DOUBLE PRECISION</code> for <code>vdrngweibull</code> Fortran 90: <code>REAL</code> , <code>INTENT(OUT)</code> for <code>vsrngweibull</code> <code>DOUBLE PRECISION</code> , <code>INTENT(OUT)</code> for <code>vdrngweibull</code> C: <code>float*</code> for <code>vsRngWeibull</code> <code>double*</code> for <code>vdRngWeibull</code>	Vector of n Weibull distributed random numbers

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates Weibull distributed random numbers with displacement a , scalefactor β , and shape α , where $\alpha, \beta, a \in \mathbb{R}$; $\alpha > 0, \beta > 0$.

The probability density function is given by:

$$f_{a,\alpha,\beta}(x) = \begin{cases} \frac{\alpha}{\beta^\alpha} (x - a)^{\alpha-1} \exp\left(-\left(\frac{x - a}{\beta}\right)^\alpha\right), & x \geq a \\ 0, & x < a \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\alpha,\beta}(x) = \begin{cases} 1 - \exp\left(-\left(\frac{x - a}{\beta}\right)^\alpha\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

VSL_ERROR_SKIPAHEAD_UNSUPPORTED

Period of the generator has been exceeded.

Cauchy

Generates Cauchy distributed random values.

Syntax

Fortran:

```
status = vsrngcauchy( method, stream, n, r, a, beta )
status = vdrngcauchy( method, stream, n, r, a, beta )
```

C:

```
status = vsRngCauchy( method, stream, n, r, a, beta );
status = vdRngCauchy( method, stream, n, r, a, beta );
```

Input Parameters

Name	Type	Description

Output Parameters

Name	Type	Description
r	FORTRAN 77: REAL for vsrngcauchy DOUBLE PRECISION for vdrngcauchy Fortran 90: REAL, INTENT (OUT) for vsrngcauchy DOUBLE PRECISION, INTENT (OUT) for vdrngcauchy C: float* for vsRngCauchy double* for vdRngCauchy	Vector of n Cauchy distributed random numbers

Description

This function is declared in `mk1_vs1.f77` for FORTRAN 77 interface, in `mk1_vs1.fi`

The function generates Cauchy distributed random numbers with displacement a and scalefactor β , where $a, \beta \in R ; \beta > 0$.

The probability density function is given by:

$$f_{a,\beta}(x) = \frac{1}{\pi\beta \left(1 + \left(\frac{x - a}{\beta}\right)^2\right)}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \frac{1}{2} + \frac{1}{\pi} \arctan \left(\frac{x - a}{\beta} \right), -\infty < x < +\infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_ERROR_SKIPAHEAD_UNSUPPORTED	Period of the generator has been exceeded.

Rayleigh

Generates Rayleigh distributed random values.

Syntax

Fortran:

```
status = vsrngrayleigh( method, stream, n, r, a, beta )
status = vdrnggrayleigh( method, stream, n, r, a, beta )
```

C:

```
status = vsRngRayleigh( method, stream, n, r, a, beta );
status = vdRngRayleigh( method, stream, n, r, a, beta );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method. The specific values are as follows: VSL_METHOD_SRAYLEIGH_ICDF VSL_METHOD_DRAYLEIGH_ICDF VSL_METHOD_SRAYLEIGH_ICDF_ACCURATE VSL_METHOD_DRAYLEIGH_ICDF_ACCURATE Inverse cumulative distribution function method
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated
<i>a</i>	FORTRAN 77: REAL for vsrngrayleigh DOUBLE PRECISION for vdrngrayleigh Fortran 90: REAL, INTENT (IN) for vsrngrayleigh DOUBLE PRECISION, INTENT (IN) for vdrngrayleigh	Displacement <i>a</i>

Name	Type	Description
	C: const float for vsRngRayleigh const double for vdRngRayleigh	
<i>beta</i>	FORTRAN 77: REAL for vsrnggrayleigh DOUBLE PRECISION for vdrngrayleigh Fortran 90: REAL, INTENT(IN) for vsrnggrayleigh DOUBLE PRECISION, INTENT(IN) for vdrngrayleigh C: const float for vsRngRayleigh const double for vdRngRayleigh	Scalefactor β .

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: REAL for vsrnggrayleigh DOUBLE PRECISION for vdrngrayleigh Fortran 90: REAL, INTENT(OUT) for vsrnggrayleigh	Vector of n Rayleigh distributed random numbers

Name	Type	Description
------	------	-------------

	DOUBLE PRECISION, INTENT (OUT) for vdrngrayleigh	
C:	float* for vsRngRayleigh double* for vdRngRayleigh	

Description

This function is declared in `mk1_vsl.f77` for FORTRAN 77 interface, in `mk1_vsl.fi` for Fortran 90 interface, and in `mk1_vsl_functions.h` for C interface.

The function generates Rayleigh distributed random numbers with displacement a and scalefactor β , where $a, \beta \in \mathbb{R} ; \beta > 0$.

Rayleigh distribution is a special case of [Weibull](#) distribution, where the shape parameter $\alpha = 2$.

The probability density function is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{2(x-a)}{\beta^2} \exp\left(-\frac{(x-a)^2}{\beta^2}\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp\left(-\frac{(x-a)^2}{\beta^2}\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_ERROR_SKIPAHEAD_UNSUPPORTED	Period of the generator has been exceeded.

Lognormal

Generates lognormally distributed random numbers.

Syntax

Fortran:

```
status = vsrnglognormal( method, stream, n, r, a, sigma, b, beta )
status = vdrnglognormal( method, stream, n, r, a, sigma, b, beta )
```

C:

```
status = vsRngLognormal( method, stream, n, r, a, sigma, b, beta );
status = vdRngLognormal( method, stream, n, r, a, sigma, b, beta );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method. The specific values are as follows: VSL_METHOD_SLOGNORMAL_BOXMULLER2 VSL_METHOD_DLOGNORMAL_BOXMULLER2 VSL_METHOD_SLOGNORMAL_BOXMULLER2_ACCURATE VSL_METHOD_DLOGNORMAL_BOXMULLER2_ACCURATE Inverse cumulative distribution function method
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure

<i>beta</i>	FORTRAN 77: REAL for vsrnglognormal DOUBLE PRECISION for vdrnglognormal Fortran 90: REAL, INTENT (IN) for vsrnglognormal DOUBLE PRECISION, INTENT (IN) for vdrnglognormal C: const float for vsRngLognormal const double for vdRngLognormal	Scalefactor β .

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: REAL for vsrnglognormal DOUBLE PRECISION for vdrnglognormal Fortran 90: REAL, INTENT (OUT) for vsrnglognormal DOUBLE PRECISION, INTENT (OUT) for vdrnglognormal	Vector of n lognormally distributed random numbers

Name	Type	Description
------	------	-------------

	C: float* for vsRngLognormal	
	double* for vdRngLognormal	

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates lognormally distributed random numbers with average of distribution a and standard deviation σ of subject normal distribution, displacement b , and scalefactor β , where $a, \sigma, b, \beta \in \mathbb{R}$; $\sigma > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{a,\sigma,b,\beta}(x) = \begin{cases} \frac{1}{\sigma(x-b)\sqrt{2\pi}} \exp\left(-\frac{[\ln((x-b)/\beta) - a]^2}{2\sigma^2}\right), & x > b \\ 0, & x \leq b \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\sigma,b,\beta}(x) = \begin{cases} \Phi((\ln((x-b)/\beta) - a)/\sigma), & x > b \\ 0, & x \leq b \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK
VSL_ERROR_NULL_PTR
VSL_ERROR_BAD_STREAM

Indicates no error, execution is successful.
stream is a NULL pointer.
stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_ERROR_SKIPAHEAD_UNSUPPORTED	Period of the generator has been exceeded.

Gumbel

Generates Gumbel distributed random values.

Syntax

Fortran:

```
status = vsrnggumbel( method, stream, n, r, a, beta )
status = vdrnggumbel( method, stream, n, r, a, beta )
```

C:

```
status = vsRngGumbel( method, stream, n, r, a, beta );
status = vdRngGumbel( method, stream, n, r, a, beta );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER	Generation method. The specific values are as follows: VSL_METHOD_SGUMBEL_ICDF VSL_METHOD_DGUMBEL_ICDF Inverse cumulative distribution function method
	Fortran 90: INTEGER, INTENT (IN)	
	C: const int

	C: const float for vsRngGumbel	
	const double for vdRngGumbel	

Output Parameters

Name	Type	Description
r	FORTRAN 77: REAL for vsrnggumbel DOUBLE PRECISION for vdrnggumbel Fortran 90: REAL, INTENT(OUT) for vsrnggumbel DOUBLE PRECISION, INTENT(OUT) for vdrnggumbel C: float* for vsRngGumbel double* for vdRngGumbel	Vector of n random numbers with Gumbel distribution

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates Gumbel distributed random numbers with displacement a and scalefactor β , where $a, \beta \in R$; $\beta > 0$.

The probability density function is given by:

$$f_{a,\beta}(x) = \left\{ \frac{1}{\beta} \exp\left(\frac{x-a}{\beta}\right) \exp(-\exp((x-a)/\beta)), -\infty < x < +\infty \right.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = 1 - \exp(-\exp((x-a)/\beta)), -\infty < x < +\infty$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_ERROR_SKIPAHEAD_UNSUPPORTED	Period of the generator has been exceeded.

Gamma

Generates gamma distributed random values.

Syntax

Fortran:

```
status = vsrnggamma( method, stream, n, r, alpha, a, beta )
status = vdrnggamma( method, stream, n, r, alpha, a, beta )
```

C:

```
status = vsRngGamma( method, stream, n, r, alpha, a, beta );
status = vdRngGamma( method, stream, n, r, alpha, a, beta );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method. The specific values are as follows: VSL_METHOD_SGAMMA_GNORM VSL_METHOD_DGAMMA_GNORM VSL_METHOD_SGAMMA_GNORM_ACCURATE VSL_METHOD_DGAMMA_GNORM_ACCURATE Acceptance/rejection method using random numbers with Gaussian distribution. See brief description of the method GNORM in Table 10-1
<i>stream</i>	FORTTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTTRAN: Descriptor of the stream state structure C: Pointer to the stream state structure

Output Parameters

Name	Type	Description
r	FORTRAN 77: REAL for vsrnggamma DOUBLE PRECISION for vdrnggamma Fortran 90: REAL, INTENT (OUT) for vsrnggamma DOUBLE PRECISION, INTENT (OUT) for vdrnggamma C: float* for vsRngGamma double* for vdRngGamma	Vector of n random numbers with gamma distribution

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates random numbers with gamma distribution that has shape parameter α , displacement a , and scale parameter β , where α, β , and $a \in R$; $\alpha > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{\alpha,a,\beta}(x) = \begin{cases} \frac{1}{\Gamma(\alpha)\beta^\alpha} (x - a)^{\alpha-1} e^{-(x-a)/\beta}, & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty$$

where $\Gamma(\alpha)$ is the complete gamma function.
The cumulative distribution function is as follows:

$$F_{\alpha, \beta}(x) = \begin{cases} \int_a^x \frac{1}{\Gamma(\alpha)\beta^\alpha} (y - a)^{\alpha-1} e^{-(y-a)/\beta} dy, & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_ERROR_SKIPAHEAD_UNSUPPORTED	Period of the generator has been exceeded.

Beta

Generates beta distributed random values.

Syntax

Fortran:

```
status = vsrngbeta( method, stream, n, r, p, q, a, beta )
status = vdrngbeta( method, stream, n, r, p, q, a, beta )
```

C:

```
status = vsRngBeta( method, stream, n, r, p, q, a, beta );
status = vdRngBeta( method, stream, n, r, p, q, a, beta );
```

Input Parameters

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: REAL for vsrngbeta DOUBLE PRECISION for vdrngbeta Fortran 90: REAL, INTENT(OUT) for vsrngbeta DOUBLE PRECISION, INTENT(OUT) for vdrngbeta C: float* for vsRngBeta double* for vdRngBeta	Vector of n random numbers with beta distribution

Description

This function is declared in `mk1_vs1.f77` for FORTRAN 77 interface, in `mk1_vs1.fi`

The function generates random numbers with beta distribution that has shape parameters p and q , displacement a , and scale parameter β , where p, q, a , and $\beta \in \mathbb{R}$; $p > 0$, $q > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{p,q,a,\beta}(x) = \begin{cases} \frac{1}{B(p, q)\beta^{p+q-1}} (x - a)^{p-1} (\beta + a - x)^{q-1}, & a \leq x < a + \beta \\ 0, & x < a, x \geq a + \beta \end{cases}, -\infty < x < \infty,$$

where $B(p, q)$ is the complete beta function.

The cumulative distribution function is as follows:

$$F_{p,q,a,\beta}(x) = \begin{cases} 0, & x < a \\ \int_a^x \frac{1}{B(p, q)\beta^{p+q-1}} (y - a)^{p-1} (\beta + a - y)^{q-1} dy, & a \leq x < a + \beta \\ 1, & x \geq a + \beta \end{cases}, -\infty < x < \infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_ERROR_SKIPAHEAD_UNSUPPORTED	Period of the generator has been exceeded.

Discrete Distributions

This section describes routines for generating random numbers with discrete distribution.

Uniform

Generates random numbers uniformly distributed over the interval $[a, b)$.

Syntax

Fortran:

```
status = virnguniform( method, stream, n, r, a, b )
```

C:

```
status = viRngUniform( method, stream, n, r, a, b );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER	Generation method; dummy and set to 0 in case of uniform distribution. The specific value is as follows: VSL_METHOD_IUNIFORM_STD
	Fortran 90: INTEGER, INTENT (IN)	
	C: const int	Standard method. Currently there is only one method for this distribution generator.
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2)	FORTRAN: Descriptor of the stream state structure.
	Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN)	C: Pointer to the stream state structure
	C: VSLStreamStatePtr	
<i>n</i>	FORTRAN 77: INTEGER	Number of random values to be generated
	Fortran 90: INTEGER, INTENT (IN)	
	C: const int	

Name	Type	Description
<i>a</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Left interval bound <i>a</i>
<i>b</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Right interval bound <i>b</i>

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (OUT) C: int*	Vector of <i>n</i> random numbers uniformly distributed over the interval $[a, b)$

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates random numbers uniformly distributed over the interval $[a, b)$, where *a*, *b* are the left and right bounds of the interval respectively, and $a, b \in \mathbb{Z}; a < b$.

The probability distribution is given by:

$$P(X = k) = \frac{1}{b - a}, k \in \{a, a + 1, \dots, b - 1\}.$$

The cumulative distribution function is as follows:

$$F_{a,b}(x) = \begin{cases} 0, & x < a \\ \frac{\lfloor x - a + 1 \rfloor}{b - a}, & a \leq x < b, x \in R. \\ 1, & x \geq b \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_ERROR_SKIPAHEAD_UNSUPPORTED	Period of the generator has been exceeded.

UniformBits

Generates integer random values with uniform bit distribution.

Syntax

Fortran:

```
status = virnguniformbits( method, stream, n, r )
```

C:

```
status = viRngUniformBits( method, stream, n, r );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method; dummy and set to 0. The specific value is as follows: VSL_METHOD_IUNIFORMBITS_STD Standard method. Currently there is only one method for this distribution generator.
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (OUT) C: unsigned int*	FORTRAN: Vector of <i>n</i> random integer numbers. If the <i>stream</i> was generated by a 64 or a 128-bit generator, each integer value is represented by two or four elements of <i>r</i> respectively. The number of bytes occupied by each integer is contained in the field <i>wordsize</i> of the structure VSL_BRNG_PROPERTIES. The total number of bits that are actually used to store the value are contained in the field <i>nbits</i> of the same structure. See Advanced Service Routines for a more detailed discussion of VSLBRngProperties.

Name	Type	Description
		C: Vector of n random integer numbers. If the <i>stream</i> was generated by a 64 or a 128-bit generator, each integer value is represented by two or four elements of r respectively. The number of bytes occupied by each integer is contained in the field <i>WordSize</i> of the structure <code>VSLBRngProperties</code> . The total number of bits that are actually used to store the value are contained in the field <i>NBits</i> of the same structure. See Advanced Service Routines for a more detailed discussion of <code>VSLBRngProperties</code> .

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates integer random values with uniform bit distribution. The generators of uniformly distributed numbers can be represented as recurrence relations over integer values in modular arithmetic. Apparently, each integer can be treated as a vector of several bits. In a truly random generator, these bits are random, while in pseudorandom generators this randomness can be violated. For example, a well known drawback of linear congruential generators is that lower bits are less random than higher bits (for example, see [Knuth81]). For this reason, care should be taken when using this function. Typically, in a 32-bit *LCG* only 24 higher bits of an integer value can be considered random. See [VSL Notes](#) for details.

Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<i>stream</i> is a NULL pointer.
<code>VSL_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.
<code>VSL_ERROR_BAD_UPDATE</code>	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
<code>VSL_ERROR_NO_NUMBERS</code>	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
<code>VSL_ERROR_SKIPAHEAD_UNSUPPORTED</code>	Period of the generator has been exceeded.

Bernoulli

Generates Bernoulli distributed random values.

Syntax

Fortran:

```
status = virngbernoulli( method, stream, n, r, p )
```

C:

```
status = viRngBernoulli( method, stream, n, r, p );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method. The specific value is as follows: VSL_METHOD_IBERNOULLI_ICDF Inverse cumulative distribution function method.
<i>stream</i>	FORTTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated
<i>p</i>	FORTTRAN 77: DOUBLE PRECISION Fortran 90: DOUBLE PRECISION, INTENT (IN)	Success probability p of a trial

Name	Type	Description
	C: <code>const double</code>	

Output Parameters

Name	Type	Description
r	FORTRAN 77: <code>INTEGER</code> Fortran 90: <code>INTEGER,</code> <code>INTENT (OUT)</code> C: <code>int*</code>	Vector of n Bernoulli distributed random values

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates Bernoulli distributed random numbers with probability p of a single trial success, where

$$p \in R; \; 0 \leq p \leq 1.$$

A variate is called Bernoulli distributed, if after a trial it is equal to 1 with probability of success p , and to 0 with probability $1 - p$.

The probability distribution is given by:

$$P(X = 1) = p$$

$$P(X = 0) = 1 - p$$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - p, & 0 \leq x < 1, x \in R. \\ 1, & x \geq 1 \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_ERROR_SKIPAHEAD_UNSUPPORTED	Period of the generator has been exceeded.

Geometric

Generates geometrically distributed random values.

Syntax

Fortran:

```
status = virnggeometric( method, stream, n, r, p )
```

C:

```
status = viRngGeometric( method, stream, n, r, p );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER	Generation method. The specific value is as follows: VSL_METHOD_IGEOMETRIC_ICDF Inverse cumulative distribution function method.
	Fortran 90: INTEGER, INTENT (IN)	
	C: const int	
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2)	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure

Name	Type	Description
	Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	
n	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated
p	FORTTRAN 77: DOUBLE PRECISION Fortran 90: DOUBLE PRECISION, INTENT (IN) C: const double	Success probability p of a trial

Output Parameters

Name	Type	Description
r	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (OUT) C: int*	Vector of n geometrically distributed random values

Description

This function is declared in `mk1_vsl.f77` for FORTRAN 77 interface, in `mk1_vsl.fi` for Fortran 90 interface, and in `mk1_vsl_functions.h` for C interface.

The function generates geometrically distributed random numbers with probability p of a single trial success, where $p \in R$; $0 < p < 1$.

A geometrically distributed variate represents the number of independent Bernoulli trials preceding the first success. The probability of a single Bernoulli trial success is p .

The probability distribution is given by:

$$P(X = k) = p \cdot (1 - p)^k, \quad k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - (1 - p)^{\lfloor x+1 \rfloor}, & 0 \leq x \end{cases} \quad x \in \mathbb{R}.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

VSL_ERROR_SKIPAHEAD_UNSUPPORTED

Period of the generator has been exceeded.

Binomial

Generates binomially distributed random numbers.

Syntax

Fortran:

```
status = virngbinomial( method, stream, n, r, ntrial, p )
```

C:

```
status = viRngBinomial( method, stream, n, r, ntrial, p );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method. The specific value is as follows: VSL_METHOD_IBINOMIAL_BTPE See brief description of the BTPE method in Table 10-1 .
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated
<i>ntrials</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of independent trials m
<i>p</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: DOUBLE PRECISION, INTENT (IN) C: const double	Success probability p of a single trial

Output Parameters

Name	Type	Description
r	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (OUT) C: int*	Vector of n binomially distributed random values

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates binomially distributed random numbers with number of independent Bernoulli trials m , and with probability p of a single trial success, where $p \in R$; $0 \leq p \leq 1$, $m \in N$.

A binomially distributed variate represents the number of successes in m independent Bernoulli trials with probability of a single trial success p .

The probability distribution is given by:

$$P(X = k) = C_m^k p^k (1 - p)^{m-k}, k \in \{0, 1, \dots, m\}.$$

The cumulative distribution function is as follows:

$$F_{m,p}(x) = \begin{cases} 0, & x < 0 \\ \sum_{k=0}^{\lfloor x \rfloor} C_m^k p^k (1 - p)^{m-k}, & 0 \leq x < m, x \in R \\ 1, & x \geq m \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_ERROR_SKIPAHEAD_UNSUPPORTED	Period of the generator has been exceeded.

Hypergeometric

Generates hypergeometrically distributed random values.

Syntax

Fortran:

```
status = virnghypergeometric( method, stream, n, r, l, s, m )
```

C:

```
status = viRngHypergeometric( method, stream, n, r, l, s, m );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method. The specific value is as follows: VSL_METHOD_IHYPERGEOMETRIC_H2PE See brief description of the H2PE method in Table 10-1
<i>stream</i>	FORTTRAN 77: INTEGER*4 stream(2)	FORTTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure

Name	Type	Description
	Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	
<i>n</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated
<i>l</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Lot size <i>l</i>
<i>s</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Size of sampling without replacement <i>s</i>
<i>m</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of marked elements <i>m</i>

Output Parameters

Name	Type	Description
<i>r</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (OUT) C: int*	Vector of <i>n</i> hypergeometrically distributed random values

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates hypergeometrically distributed random values with lot size l , size of sampling s , and number of marked elements in the lot m , where $l, m, s \in \mathbb{N} \setminus \{0\}$; $l \geq \max(s, m)$.

Consider a lot of l elements comprising m "marked" and $l-m$ "unmarked" elements. A trial sampling without replacement of exactly s elements from this lot helps to define the hypergeometric distribution, which is the probability that the group of s elements contains exactly k marked elements.

The probability distribution is given by:)

$$P(X = k) = \frac{C_m^k C_{l-m}^{s-k}}{C_l^s}$$

, $k \in \{\max(0, s + m - l), \dots, \min(s, m)\}$

The cumulative distribution function is as follows:

$$F_{l,s,m}(X) = \begin{cases} 0, & x < \max(0, s + m - l) \\ \sum_{k=\max(0, s+m-l)}^{\lfloor x \rfloor} \frac{C_m^k C_{l-m}^{s-k}}{C_l^s}, & \max(0, s + m - l) \leq x \leq \min(s, m) \\ 1, & x > \min(s, m) \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

VSL_ERROR_NULL_PTR

VSL_ERROR_BAD_STREAM

Indicates no error, execution is successful.

stream is a NULL pointer.

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_ERROR_SKIPAHEAD_UNSUPPORTED	Period of the generator has been exceeded.

Poisson

Generates Poisson distributed random values.

Syntax

Fortran:

```
status = virngpoisson( method, stream, n, r, lambda )
```

C:

```
status = viRngPoisson( method, stream, n, r, lambda );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method. The specific values are as follows: VSL_METHOD_IPOISSON_PTPE VSL_METHOD_IPOISSON_POISNORM See brief description of the PTPE and POISNORM methods in Table 10-1 .
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated
<i>lambda</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: DOUBLE PRECISION, INTENT (IN) C: const double	Distribution parameter λ .

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (OUT) C: int*	Vector of <i>n</i> Poisson distributed random values

Description

This function is declared in `mk1_vsl.f77` for FORTRAN 77 interface, in `mk1_vsl.fi` for Fortran 90 interface, and in `mk1_vsl_functions.h` for C interface.

The function generates Poisson distributed random numbers with distribution parameter λ , where $\lambda \in R; \lambda > 0$.

The probability distribution is given by:

$$P(X = k) = \frac{\lambda^k e^{-\lambda}}{k!},$$

$k \in \{0, 1, 2, \dots\}$.

The cumulative distribution function is as follows:

$$F_{\lambda}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda^k e^{-\lambda}}{k!}, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in \mathbb{R}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

VSL_ERROR_SKIPAHEAD_UNSUPPORTED

Period of the generator has been exceeded.

PoissonV

Generates Poisson distributed random values with varying mean.

Syntax

Fortran:

```
status = virngpoissonv( method, stream, n, r, lambda )
```

C:

```
status = viRngPoissonV( method, stream, n, r, lambda );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method. The specific value is as follows: VSL_METHOD_IPOISSONV_POISNORM See brief description of the POISNORM method in Table 10-1
<i>stream</i>	FORTTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated
<i>lambda</i>	FORTTRAN 77: DOUBLE PRECISION Fortran 90: DOUBLE PRECISION, INTENT (IN) C: const double*	Array of <i>n</i> distribution parameters λ_i .

Output Parameters

Name	Type	Description
<i>r</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (OUT) C: int*	Vector of <i>n</i> Poisson distributed random values

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates n Poisson distributed random numbers $x_i (i = 1, \dots, n)$ with distribution parameter λ_i , where $\lambda_i \in R; \lambda_i > 0$.

The probability distribution is given by:

$$P(X_i = k) = \frac{\lambda_i^k \exp(-\lambda_i)}{k!}, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_{\lambda_i}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda_i^k e^{-\lambda_i}}{k!}, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in R$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

VSL_ERROR_SKIPAHEAD_UNSUPPORTED

Period of the generator has been exceeded.

NegBinomial

Generates random numbers with negative binomial distribution.

Syntax

Fortran:

```
status = virngnegbinomial( method, stream, n, r, a, p )
```

C:

```
status = viRngNegbinomial( method, stream, n, r, a, p );
```

Input Parameters

Name	Type	Description
<i>method</i>	FORTTRAN 77: INTEGER	Generation method. The specific value is: VSL_METHOD_INEGBINOMIAL_NBAR See brief description of the NBAR method in Table 10-1
	Fortran 90: INTEGER, INTENT (IN)	
	C: const int	
<i>stream</i>	FORTTRAN 77: INTEGER*4 stream(2)	FORTTRAN: descriptor of the stream state structure. C: pointer to the stream state structure
	Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN)	
	C: VSLStreamStatePtr	
<i>n</i>	FORTTRAN 77: INTEGER	Number of random values to be generated
	Fortran 90: INTEGER, INTENT (IN)	
	C: const int	
<i>a</i>	FORTTRAN 77: DOUBLE PRECISION	The first distribution parameter <i>a</i>

Name	Type	Description
	Fortran 90: DOUBLE PRECISION, INTENT(IN) C: const double	
p	FORTTRAN 77: DOUBLE PRECISION Fortran 90: DOUBLE PRECISION, INTENT(IN) C: const double	The second distribution parameter p

Output Parameters

Name	Type	Description
r	FORTTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(OUT) C: int*	Vector of n random values with negative binomial distribution.

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function generates random numbers with negative binomial distribution and distribution parameters a and p , where $p, a \in R$; $0 < p < 1$; $a > 0$.

If the first distribution parameter $a \in N$, this distribution is the same as Pascal distribution. If $a \in N$, the distribution can be interpreted as the expected time of a -th success in a sequence of Bernoulli trials, when the probability of success is p .

The probability distribution is given by:

$$P(X = k) = C_{a+k-1}^k p^a (1 - p)^k, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_{a,p}(X) = \begin{cases} \sum_{k=0}^{\lfloor X \rfloor} C_{a+k-1}^k p^a (1-p)^k, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in R$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_ERROR_SKIPAHEAD_UNSUPPORTED	Period of the generator has been exceeded.

Advanced Service Routines

This section describes service routines for registering a user-designed basic generator ([RegisterBrng](#)) and for obtaining properties of the previously registered basic generators ([GetBrngProperties](#)). See [VSL Notes](#) ("Basic Generators" section of VSL Structure chapter) for substantiation of the need for several basic generators including user-defined BRNGs.

Data types

The Advanced Service routines refer to a structure defining the properties of the basic generator. This structure is described in Fortran 90 as follows:

```
TYPE VSL_BRNG_PROPERTIES
    INTEGER streamstatesize
    INTEGER nseeds
    INTEGER includeszero
    INTEGER wordsize
    INTEGER nbits
    INTEGER nitstream
    INTEGER sbrng
    INTEGER dbrng
    INTEGER ibrng
END TYPE VSL_BRNG_PROPERTIES
```

The C version is as follows:

```
typedef struct _VSLBRngProperties {
    int StreamStateSize;
    int NSeeds;
    int IncludesZero;
    int WordSize;
    int NBits;
    InitStreamPtr InitStream;
    sBRngPtr sBRng;
    dBRngPtr dBRng;
    iBRngPtr iBRng;
} VSLBRngProperties;
```

The following table provides brief descriptions of the fields engaged in the above structure:

Table 10-13 Field Descriptions

Field	Short Description
FORTRAN: streamstatesize C: StreamStateSize	The size, in bytes, of the stream state structure for a given basic generator.
FORTRAN: nseeds C: NSeeds	The number of 32-bit initial conditions (seeds) necessary to initialize the stream state structure for a given basic generator.
FORTRAN: includeszero C: IncludesZero	Flag value indicating whether the generator can produce a random 0.
FORTRAN: wordsize C: WordSize	Machine word size, in bytes, used in integer-value computations. Possible values: 4, 8, and 16 for 32, 64, and 128-bit generators, respectively.
FORTRAN: nbits C: NBits	The number of bits required to represent a random value in integer arithmetic. Note that, for instance, 48-bit random values are stored to 64-bit (8 byte) memory locations. In this case, wordsize/WordSize is equal to 8 (number of bytes used to store the random value), while nbits/NBits contains the actual number of bits occupied by the value (in this example, 48).
FORTRAN: initstream C: InitStream	Contains the pointer to the initialization routine of a given basic generator.
FORTRAN: sbrng C: sBRng	Contains the pointer to the basic generator of single precision real numbers uniformly distributed over the interval (a,b) (real in FORTRAN and float in C).
FORTRAN: dbrng C: dBRng	Contains the pointer to the basic generator of double precision real numbers uniformly distributed over the interval (a,b) (double PRECISION in FORTRAN and double in C).
FORTRAN: ibrng C: iBRng	Contains the pointer to the basic generator of integer numbers with uniform bit distribution ¹ (INTEGER in FORTRAN and unsigned int in C).

¹A specific generator that permits operations over single bits and bit groups of random numbers.

RegisterBrng

Registers user-defined basic generator.

Syntax

Fortran:

```
brng = vslregisterbrng( properties )
```

C:

```
brng = vslRegisterBrng( &properties );
```

Input Parameters

Name	Type	Description
<i>properties</i>	FORTRAN: TYPE (VSL_BRNG_PROPERTIES), INTENT (IN) C: const VSLBRngProperties*	Pointer to the structure containing properties of the basic generator to be registered

NOTE. FORTRAN 77 support is unavailable for this function.

Output Parameters

Name	Type	Description
<i>brng</i>	FORTRAN: INTEGER, INTENT (OUT) C: int	Number (index) of the registered basic generator; used for identification. Negative values indicate the registration error.

Description

This function is declared in `mkl_vsl.fi` for Fortran 90 interface and in `mkl_vsl_functions.h` for C interface.

An example of a registration procedure can be found in the respective directory of VSL examples.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BRNG_TABLE_FULL	Registration cannot be completed due to lack of free entries in the table of registered BRNGs.
VSL_ERROR_BAD_STREAM_STATE_SIZE	Bad value in StreamStateSize field.
VSL_ERROR_BAD_WORD_SIZE	Bad value in WordSize field.
VSL_ERROR_BAD_NSEEDS	Bad value in NSeeds field.
VSL_ERROR_BAD_NBITS	Bad value in NBits field.
VSL_ERROR_NULL_PTR	At least one of the fields iBrng, dBrng, sBrng or InitStream is a NULL pointer.

GetBrngProperties

Returns structure with properties of a given basic generator.

Syntax

Fortran:

```
status = vslgetbrngproperties( brng, properties )
```

C:

```
status = vslGetBrngProperties( brng, &properties );
```

Input Parameters

Name	Type	Description
brng	FORTRAN: INTEGER, INTENT (IN) C: const int	Number (index) of the registered basic generator; used for identification. See specific values in Table 10-2 . Negative values indicate the registration error.

NOTE. FORTRAN 77 support is unavailable for this function.

Output Parameters

Name	Type	Description
<i>properties</i>	FORTRAN: TYPE(VSL_BRNG_PROPERTIES), INTENT(OUT) C: VSLBRngProperties*	Pointer to the structure containing properties of the generator with number <i>brng</i>

Description

This function is declared in `mkl_vsl.fi` for Fortran 90 interface and in `mkl_vsl_functions.h` for C interface.

The function returns a structure with properties of a given basic generator.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.

Formats for User-Designed Generators

To register a user-designed basic generator using [RegisterBrng](#) function, you need to pass the pointer `iBrng` to the integer-value implementation of the generator; the pointers `sBrng` and `dBrng` to the generator implementations for single and double precision values, respectively; and pass the pointer `InitStream` to the stream initialization routine. See below recommendations on defining such functions with input and output arguments. An example of the registration procedure for a user-designed generator can be found in the respective directory of VSL examples.

The respective pointers are defined as follows:

```
typedef int(*InitStreamPtr)( int method, VSLStreamStatePtr stream, int n, const unsigned
int params[] );

typedef int(*sBrngPtr)( VSLStreamStatePtr stream, int n, float r[], float a, float b );

typedef int(*dBrngPtr)( VSLStreamStatePtr stream, int n, double r[], double a, double b );

typedef int(*iBrngPtr)( VSLStreamStatePtr stream, int n, unsigned int r[] );
```

InitStream

C:

```
int MyBrngInitStream( int method, VSLStreamStatePtr stream, int n, const unsigned int
params[] )
{
    /* Initialize the stream */

    ...

} /* MyBrngInitStream */
```

Description

The initialization routine of a user-designed generator must initialize *stream* according to the specified initialization *method*, initial conditions *params* and the argument *n*. The value of *method* determines the initialization method to be used.

- If *method* is equal to 1, the initialization is by the standard generation method, which must be supported by all basic generators. In this case the function assumes that the *stream* structure was not previously initialized. The value of *n* is used as the actual number of 32-bit values passed as initial conditions through *params*. Note, that the situation when the actual number of initial conditions passed to the function is not sufficient to initialize the generator is not an error. Whenever it occurs, the basic generator must initialize the missing conditions using default settings.
- If *method* is equal to 2, the generation is by the leapfrog method, where *n* specifies the number of computational nodes (independent streams). Here the function assumes that the *stream* was previously initialized by the standard generation method. In this case *params* contains only one element, which identifies the computational node. If the generator does not support the leapfrog method, the function must return the error code `VSL_ERROR_LEAPFROG_UNSUPPORTED`.
- If *method* is equal to 3, the generation is by the block-splitting method. Same as above, the *stream* is assumed to be previously initialized by the standard generation method; *params* is not used, *n* identifies the number of skipped elements. If the generator does not support the block-splitting method, the function must return the error code `VSL_ERROR_SKIPAHEAD_UNSUPPORTED`.

For a more detailed description of the leapfrog and the block-splitting methods, refer to the description of [LeapfrogStream](#) and [SkipAheadStream](#), respectively.

Stream state structure is individual for every generator. However, each structure has a number of fields that are the same for all the generators:

C:

```
typedef struct
{
    unsigned int Reserved1[2];
    unsigned int Reserved2[2];
    [fields specific for the given generator]
} MyStreamState;
```

The fields *Reserved1* and *Reserved2* are reserved for private needs only, and must not be modified by the user. When including specific fields into the structure, follow the rules below:

- The fields must fully describe the current state of the generator. For example, the state of a linear congruential generator can be identified by only one initial condition;
- If the generator can use both the leapfrog and the block-splitting methods, additional fields should be introduced to identify the independent streams. For example, in $LCG(a, c, m)$, apart from the initial conditions, two more fields should be specified: the value of the multiplier a^k and the value of the increment $(a^k - 1) c / (a - 1)$.

For a more detailed discussion, refer to [Knuth81], and [Gentle98]. An example of the registration procedure can be found in the respective directory of VSL examples.

iBRng

C:

```
int iMyBrng( VSLStreamStatePtr stream, int n, unsigned int r[] )
{
    int i; /* Loop variable */
    /* Generating integer random numbers */
    /* Pay attention to word size needed to
       store only random number */
    for( i = 0; i < n; i++)
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* iMyBrng */
```

NOTE. When using 64 and 128-bit generators, consider digit capacity to store the numbers to the random vector x correctly. For example, storing one 64-bit value requires two elements of x , the first to store the lower 32 bits and the second to store the higher 32 bits. Similarly, use 4 elements of x to store a 128-bit value.

sBRng

C:

```
int sMyBrng( VSLStreamStatePtr stream, int n, float r[], float a, float b )
{
    int i;    /* Loop variable */
    /* Generating float (a,b) random numbers */
    for ( i = 0; i < n; i++ )
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* sMyBrng */
```

dBRng

C:

```
int dMyBrng( VSLStreamStatePtr stream, int n, double r[], double a, double b )
{
    int i;    /* Loop variable */
    /* Generating double (a,b) random numbers */
    for ( i = 0; i < n; i++ )
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* dMyBrng */
```

Convolution and Correlation

Overview

VSL provides a set of routines intended to perform linear convolution and correlation transformations for single and double precision real and complex data.

For correct definition of implemented operations, see [Mathematical Notation and Definitions](#) section.

The current implementation provides:

- Fourier algorithms for one-dimensional single and double precision real and complex data
- Fourier algorithms for multi-dimensional single and double precision real and complex data
- Direct algorithms for one-dimensional single and double precision real and complex data
- Direct algorithms for multi-dimensional single and double precision real and complex data

One-dimensional algorithms cover the following functions from the IBM* ESSL library:

SCONF, SCORF

SCOND, SCORD

SDCON, SDCOR

DDCON, DDCOR

SDDCON, SDDCOR.

Special wrappers are designed to simulate these ESSL functions. The wrappers are provided as sample sources for FORTRAN and C. To reuse them, use the following directories:

`${MKL}/examples/vslc/essl/vsl_wrappers`

`${MKL}/examples/vslf/essl/vsl_wrappers`

Additionally, you can browse the examples demonstrating the calculation of the ESSL functions through the wrappers. You can find the examples in the following directories:

`${MKL}/examples/vslc/essl`

`${MKL}/examples/vslf/essl`

Convolution and correlation API provides interfaces for FORTRAN 77, Fortran 90 and C/89 languages. You may use the C/89 interface also with later versions of C or C++, or Fortran 90 interface with programs written in Fortran 95.

For users of the C/C++ and FORTRAN languages, the `mk1_vs1.h`, `mk1_vs1.fi`, and `mk1_vs1.f77` headers are provided. All header files are found under the directory:

```
${MKL}/include
```

See more details about the FORTRAN header in [Random Number Generators](#) section of this chapter.

Convolution and correlation API is implemented through task objects, or tasks. Task object is a data structure, or descriptor, which holds parameters that determine the specific convolution or correlation operation. Such parameters may be precision, type, and number of dimensions of user data, an identifier of the computation algorithm to be used, shapes of data arrays, and so on.

All Intel MKL convolution and correlation routines process task objects in one way or another: either create a new task descriptor, change the parameter settings, compute mathematical results of the convolution or correlation using the stored parameters, or perform other operations. Accordingly, all routines are split into the following groups:

Task Constructors - routines that create a new task object descriptor and set up most common parameters.

Task Editors - routines that can set or modify some parameter settings in the existing task descriptor.

Task Execution Routines - compute results of the convolution or correlation operation over the actual input data, using the operation parameters held in the task descriptor.

Task Copy - routines used to make several copies of the task descriptor.

Task Destructors - routines that delete task objects and free the memory.

When the task is executed or copied for the first time, a special process runs which is called task commitment. During this process, consistency of task parameters is checked and the required work data are prepared. If the parameters are consistent, the task is tagged as committed successfully. The task remains committed until you edit its parameters. Hence, the task can be executed multiple times after a single commitment process. Since the task commitment process may include costly intermediate calculations such as preparation of Fourier transform of input data, launching the process only once can help speed up overall performance.

Naming Conventions

The names of FORTRAN routines in the convolution and correlation API are written in lowercase, while the names of FORTRAN types and constants are written in uppercase. The names are not case-sensitive.

In C, the names of routines, types, and constants are case-sensitive and can be lowercase and uppercase.

The names of routines have the following structure:

`vsl[datatype]{Conv|Corr}<base name>` for C-interface

`vsl[datatype]{conv|corr}<base name>` for FORTRAN-interface

where `vsl` is a prefix indicating that the routine belongs to Vector Statistical Library of Intel® MKL.

The field `[datatype]` is optional. If present, the symbol specifies the type of the input and output data and can be `s` (for single precision real type), `d` (for double precision real type), `c` (for single precision complex type), or `z` (for double precision complex type).

The prefix `Conv` or `Corr` specifies whether the routine refers to convolution or correlation task, respectively.

The `<base name>` field specifies a particular functionality that the routine is designed for, for example, `NewTask`, `DeleteTask`.

NOTE. In this document, routines are often referred to by their base name when this does not lead to ambiguity. In the routine reference, the full name is always used in prototypes and code examples.

Data Types

All convolution or correlation routines use the following types for specifying data objects:

Type	Data Object
FORTTRAN 77: <code>INTEGER*4</code> <code>task (2)</code>	Pointer to a task descriptor for convolution
Fortran 90: <code>TYPE (VSL_CONV_TASK)</code> C: <code>VSLConvTaskPtr</code>	
FORTTRAN 77: <code>INTEGER*4</code> <code>task (2)</code>	Pointer to a task descriptor for correlation
Fortran 90: <code>TYPE (VSL_CORR_TASK)</code> C: <code>VSLCorrTaskPtr</code>	

Type	Data Object
FORTRAN 77: REAL*4 Fortran 90: REAL (KIND=4) C: float	Input/output user real data in single precision
FORTRAN 77: REAL*8 Fortran 90: REAL (KIND=8) C: double	Input/output user real data in double precision
FORTRAN 77: COMLEX*8 Fortran 90: COMPLEX (KIND=4) C: MKL_Complex8	Input/output user complex data in single precision
FORTRAN 77: COMPLEX*16 Fortran 90: COMPLEX (KIND=8) C: MKL_Complex16	Input/output user complex data in double precision
FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	All other data

Generic integer type (without specifying the byte size) is used for all integer data.

NOTE. The actual size of the generic integer type is platform-dependent. The appropriate byte size for integers must be chosen at the stage of compiling your software.

Parameters

Basic parameters held by the task descriptor are assigned values when the task object is created, copied, or modified by task editors. Parameters of the correlation or convolution task are initially set up by task constructors when the task object is created. Parameter changes or additional settings are made by task editors. More parameters which define location of the data being convolved need to be specified when the task execution routine is invoked.

According to how the parameters are passed or assigned values, all of them can be categorized as either explicit (directly passed as routine parameters when a task object is created or executed) or optional (assigned some default or implicit values during task construction).

The following table lists all applicable parameters used in the Intel MKL convolution and correlation API.

Table 10-14 Convolution and Correlation Task Parameters

Name	Category	Type	Default Value Label	Description
<i>job</i>	explicit	integer	Implied by the constructor name	Specifies whether the task relates to convolution or correlation
<i>type</i>	explicit	integer	Implied by the constructor name	Specifies the type (real or complex) of the input/output data. Set to real in the current version.
<i>precision</i>	explicit	integer	Implied by the constructor name	Specifies precision (single or double) of the input/output data to be provided in arrays <i>x</i> , <i>y</i> , <i>z</i> .
<i>kind</i>	optional	integer	"linear"	Specifies whether the task relates to computing linear or circular convolution/correlation. Note that currently only the linear type is supported.
<i>mode</i>	explicit	integer	None	Specifies whether the convolution/correlation computation should be done via Fourier transforms, or by a direct method, or by automatically choosing between the two. See SetMode for the list of named constants for this parameter.
<i>method</i>	optional	integer	"auto"	Hints at a particular computation method if several methods are available for the given <i>mode</i> . Setting this parameter to "auto" means that software will choose the best available method.

Name	Category	Type	Default Value Label	Description
<i>internal_precision</i>	optional	integer	Set equal to the value of <i>precision</i>	Specifies precision of internal calculations. Can enforce double precision calculations even when input/output data are single precision. See SetInternalPrecision for the list of named constants for this parameter.
<i>dims</i>	explicit	integer	None	Specifies the rank (number of dimensions) of the user data provided in arrays <i>x, y, z</i> . Can be in the range from 1 to 7.
<i>x, y</i>	explicit	real arrays	None	Specify input data arrays. See Data Allocation for more information.
<i>z</i>	explicit	real array	None	Specifies output data array. See Data Allocation for more information.
<i>xshape, yshape, zshape</i>	explicit	integer arrays	None	Define shapes of the arrays <i>x, y, z</i> . See Data Allocation for more information.
<i>xstride, ystride, zstride</i>	explicit	integer arrays	None	Define strides within arrays <i>x, y, z</i> , that is specify the physical location of the input and output data in these arrays. See Data Allocation for more information.
<i>start</i>	optional	integer array	Undefined	Defines the first element of the mathematical result that will be stored to output array <i>z</i> . See SetStart and Data Allocation for more information.
<i>decimation</i>	optional	integer array	Undefined	Defines how to thin out the mathematical result that will be stored to output array <i>z</i> . See SetDecimation and Data Allocation for more information.

Users of the C or C++ language may pass the NULL pointer instead of either or all of the parameters *xstride*, *ystride*, or *zstride* for multi-dimensional calculations. In this case, the software assumes the dense data allocation for the arrays *x*, *y*, or *z* due to the FORTRAN-style “by columns” representation of multi-dimensional arrays.

Task Status and Error Reporting

Task status is an integer value which is zero if no error has been detected while processing the task, or a specific non-zero error code otherwise. Negative status values are used for errors, and positive values are reserved for warnings.

An error can be caused by bad parameter values, system fault like memory allocation failure, or can be an internal error self-detected by the software.

Each task descriptor contains the current status of the task. When creating a task object, constructor assigns the `VSL_STATUS_OK` status to the task. When processing the task afterwards, other routines such as editors or executors can change the task status if an error occurs and write a corresponding error code into the task status field.

Note that at the stage of creating a task or editing its parameters, the set of parameters may be inconsistent. The parameter consistency check is only performed during the task commitment operation which is implicitly invoked before task execution or task copying. If an error is detected at this stage, task execution or task copying is terminated and the task descriptor saves the corresponding error code. Once an error occurs, any further attempts to process that task descriptor will be terminated and the task will keep the same error code.

Normally, every convolution or correlation function (except `DeleteTask`) returns the status assigned to the task while performing the function operation.

The status codes are given symbolic names defined in the respective header files. For C/C++, these names are defined as macros via `#define` statements, and for FORTRAN as integer constants via `PARAMETER` operators.

If there is no error, the `VSL_STATUS_OK` is returned, which is defined as zero:

```
C/C++:           #define VSL_STATUS_OK 0
F90/F95:          INTEGER(KIND=4) VSL_STATUS_OK
                  PARAMETER(VSL_STATUS_OK = 0)

F77:              INTEGER*4 VSL_STATUS_OK
                  PARAMETER(VSL_STATUS_OK = 0)
```

In case of an error, a non-zero error code is returned, which signals about the origin of the failure. The following status codes for the convolution/correlation error codes are pre-defined in the header files for both C/C++ and FORTRAN languages.

Table 10-15 Convolution/Correlation Status Codes and Messages

Status Code	Message
VSL_CC_ERROR_NOT_IMPLEMENTED,	Requested functionality is not implemented.
VSL_CC_ERROR_ALLOCATION_FAILURE	Memory allocation failure.
VSL_CC_ERROR_BAD_DESCRIPTOR	Task descriptor is corrupted.
VSL_CC_ERROR_SERVICE_FAILURE	A service function has failed.
VSL_CC_ERROR_EDIT_FAILURE	Failure while editing the task.
VSL_CC_ERROR_EDIT_PROHIBITED	You cannot edit this parameter.
VSL_CC_ERROR_COMMIT_FAILURE	Task commitment has failed.
VSL_CC_ERROR_COPY_FAILURE	Failure while copying the task.
VSL_CC_ERROR_DELETE_FAILURE	Failure while deleting the task.
VSL_CC_ERROR_BAD_ARGUMENT	Bad argument or task parameter.
VSL_CC_ERROR_JOB	Bad parameter: <i>job</i> .
SL_CC_ERROR_KIND	Bad parameter: <i>kind</i> .
VSL_CC_ERROR_MODE	Bad parameter: <i>mode</i> .
VSL_CC_ERROR_METHOD	Bad parameter: <i>method</i> .
VSL_CC_ERROR_TYPE	Bad parameter: <i>type</i> .
VSL_CC_ERROR_EXTERNAL_PRECISION	Bad parameter: <i>external_precision</i> .
VSL_CC_ERROR_INTERNAL_PRECISION	Bad parameter: <i>internal_precision</i> .
VSL_CC_ERROR_PRECISION	Incompatible external/internal precisions.
VSL_CC_ERROR_DIMS	Bad parameter: <i>dims</i> .
VSL_CC_ERROR_XSHAPE	Bad parameter: <i>xshape</i> .

Status Code	Message
VSL_CC_ERROR_YSHAPE	Bad parameter: <i>yshape</i> . Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or >nmax.
VSL_CC_ERROR_ZSHAPE	Bad parameter: <i>zshape</i> .
VSL_CC_ERROR_XSTRIDE	Bad parameter: <i>xstride</i> .
VSL_CC_ERROR_YSTRIDE	Bad parameter: <i>ystride</i> .
VSL_CC_ERROR_ZSTRIDE	Bad parameter: <i>zstride</i> .
VSL_CC_ERROR_X	Bad parameter: <i>x</i> .
VSL_CC_ERROR_Y	Bad parameter: <i>y</i> .
VSL_CC_ERROR_Z	Bad parameter: <i>z</i> .
VSL_CC_ERROR_START	Bad parameter: <i>start</i> .
VSL_CC_ERROR_DECIMATION	Bad parameter: <i>decimation</i> .
VSL_CC_ERROR_OTHER	Some other error.

Task Constructors

Task constructors are routines intended for creating a new task descriptor and setting up basic parameters. This means that no additional parameter adjustment is typically required and other routines can use the task object.

Intel® MKL implementation of the convolution and correlation API provides two different forms of constructors: a general form and an X-form. X-form constructors work in the same way as the general form but also assign particular data to the first operand vector used in convolution or correlation operation (stored in array *x*).

Using X-form constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector held in array *x* against different vectors held in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

For each constructor routine there is also an associated one-dimensional version which exploits the algorithmic and computational benefits provided by the simplicity of the data structures for one-dimensional case.

NOTE. If constructor fails to create a task descriptor, it returns `NULL` task pointer.

The [Table 10-16](#) lists available task constructors:

Table 10-16 Task Constructors

Routine	Description
NewTask	Creates a new convolution or correlation task descriptor for a multidimensional case.
NewTask1D	Creates a new convolution or correlation task descriptor for a one-dimensional case.
NewTaskX	Creates a new convolution or correlation task descriptor as an X-form for a multidimensional case.
NewTaskX1D	Creates a new convolution or correlation task descriptor as an X-form for a one-dimensional case.

NewTask

Creates a new convolution or correlation task descriptor for multidimensional case.

Syntax

Fortran:

```
status = vslsconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vsldconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslcconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslzconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vsiscorrnewtask(task, mode, dims, xshape, yshape, zshape)
status = vsldcorrnewtask(task, mode, dims, xshape, yshape, zshape)
```

```
status = vsllccornewtask(task, mode, dims, xshape, yshape, zshape)
status = vsllzcornewtask(task, mode, dims, xshape, yshape, zshape)
```

C:

```
status = vsllsConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslldConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vsllcConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vsllzConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vsllsCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslldCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vsllcCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vsllzCorrNewTask(task, mode, dims, xshape, yshape, zshape);
```

Input Parameters

Name	Type	Description
<i>mode</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See Table 10-18 for a list of possible values.
<i>dims</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	Rank of user data. Specifies number of dimensions for the input and output arrays <i>x</i> , <i>y</i> , and <i>z</i> used during the execution stage. Must be in the range from 1 to 7. The value is explicitly assigned by the constructor.
<i>xshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION(*) C: const int[]	Defines the shape of the input data for the source array <i>x</i> . See Data Allocation for more information.

Name	Type	Description
<i>yshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION(*) C: const int[]	Defines the shape of the input data for the source array <i>y</i> . See Data Allocation for more information.
<i>zshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION(*) C: const int[]	Defines the shape of the output data to be stored in array <i>z</i> . See Data Allocation for more information.

Output Parameters

Name	Type	Description
<i>task</i>	FORTRAN 77: INTEGER*4 task(2) for vslsconvnewtask, vsldconvnewtask, vslcconvnewtask, vslzconvnewtask INTEGER*4 task(2) for vslscorrnewtask, vsldcorrnewtask, vslccorrnewtask, vslzcorrnewtask Fortran 90: TYPE(VSL_CONV_TASK) for vslsconvnewtask, vsldconvnewtask, vslcconvnewtask, vslzconvnewtask	Pointer to the task descriptor if created successfully or NULL pointer otherwise.

Name	Type	Description
	TYPE (VSL_CORR_TASK) for vslscorrnewtask, vsldcorrnewtask, vslccorrnewtask, vslzcorrnewtask C: VSLConvTaskPtr* for vslsConvNewTask, vsldConvNewTask, vslcConvNewTask, vslzConvNewTask VSLCorrTaskPtr* for vslsCorrNewTask, vsldCorrNewTask, vslcConvNewTask, vslzConvNewTask	
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

Description

This routine is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

Each `NewTask` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table 10-14](#)).

The parameters `xshape`, `yshape`, and `zshape` define the shapes of the input and output data provided by the arrays `x`, `y`, and `z`, respectively. Each shape parameter is an array of integers with its length equal to the value of `dims`. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter `dims` is 1, then `xshape`, `yshape`, `zshape` are equal to the number of elements read from the arrays `x` and `y` or stored to the array `z`. Note that values of shape parameters may differ from physical shapes of arrays `x`, `y`, and `z` if non-trivial strides are assigned.

If the constructor fails to create a task descriptor, it returns a `NULL` task pointer.

NewTask1D

Creates a new convolution or correlation task descriptor for one-dimensional case.

Syntax

Fortran:

```
status = vslsconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vsldconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vsllconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vsllzconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vsllscorrnewtask1d(task, mode, xshape, yshape, zshape)
status = vsldcorrnewtask1d(task, mode, xshape, yshape, zshape)
status = vsllccorrnewtask1d(task, mode, xshape, yshape, zshape)
status = vsllzcorrnewtask1d(task, mode, xshape, yshape, zshape)
```

C:

```
status = vslsConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vsldConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vsllConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vsllzConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vsllsCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vsldCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vsllCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vsllzCorrNewTask1D(task, mode, xshape, yshape, zshape);
```

Input Parameters

Name	Type	Description
<i>mode</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See Table 10-18 for a list of possible values.
<i>xshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	Defines the length of the input data sequence for the source array <i>x</i> . See Data Allocation for more information.
<i>yshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	Defines the length of the input data sequence for the source array <i>y</i> . See Data Allocation for more information.
<i>zshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	Defines the length of the output data sequence to be stored in array <i>z</i> . See Data Allocation for more information.

Output Parameters

Name	Type	Description
<i>task</i>	FORTRAN 77: INTEGER*4 task(2) for vslsconvnewtaskld, vsldconvnewtaskld, vslcconvnewtaskld, vslzconvnewtaskld INTEGER*4 task(2) for vsldcorrnewtaskld, vsldcorrnewtaskld, vslccorrnewtaskld, vslzcorrnewtaskld	Pointer to the task descriptor if created successfully or NULL pointer otherwise.

Name	Type	Description
	Fortran 90: TYPE(VSL_CONV_TASK) for vslsconvnewtask1d, vsldconvnewtask1d, vslcconvnewtask1d, vslzconvnewtask1d TYPE(VSL_CORR_TASK) for vslscorrnewtask1d, vsldcorrnewtask1d, vslccorrnewtask1d, vslzcorrnewtask1d C: VSLConvTaskPtr* for vslsConvNewTask1D, vsldConvNewTask1D, vslcConvNewTask1D, vslzConvNewTask1D VSLCorrTaskPtr* for vslsCorrNewTask1D, vsldCorrNewTask1D, vslcCorrNewTask1D, vslzCorrNewTask1D	
<i>status</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

Description

This routine is declared in `mk1_vsl.f77` for FORTRAN 77 interface, in `mk1_vsl.fi` for Fortran 90 interface, and in `mk1_vsl_functions.h` for C interface.

Each `NewTask1D` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table 10-14](#)). Unlike `NewTask`, these routines represent a special one-dimensional version of the constructor which assumes that the value of the parameter *dims* is 1. The

parameters *xshape*, *yshape*, and *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. You explicitly assign the shape parameters when calling the constructor.

NewTaskX

Creates a new convolution or correlation task descriptor for multidimensional case and assigns source data to the first operand vector.

Syntax

Fortran:

```
status = vslsconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vsldconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslcconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vsllzconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslsconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vsldconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslccorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vsllzcorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
```

C:

```
status = vslsConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);

status = vsldConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);

status = vslcConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);

status = vsllzConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);

status = vslsCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);
```

```
status = vsldCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);

status = vslcCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);

status = vslzCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);
```

Input Parameters

Output Parameters

Name	Type	Description
<i>task</i>	FORTRAN 77: INTEGER*4 task(2) for vslsconvnewtaskx, vsldconvnewtaskx, vslcconvnewtaskx, vslzconvnewtaskx INTEGER*4 task(2) for vslscorrnewtaskx, vsldcorrnewtaskx, vslccorrnewtaskx, vslzcorrnewtaskx Fortran 90: TYPE(VSL_CONV_TASK) for vslsconvnewtaskx, vsldconvnewtaskx, vslcconvnewtaskx, vslzconvnewtaskx	Pointer to the task descriptor if created successfully or NULL pointer otherwise.

Name	Type	Description
	TYPE (VSL_CORR_TASK) for vslscorrnewtaskx, vsldcorrnewtaskx, vslccorrnewtaskx, vslzcorrnewtaskx C: VSLConvTaskPtr* for vslsConvNewTaskX, vsldConvNewTaskX, vslcConvNewTaskX, vslzConvNewTaskX VSLCorrTaskPtr* for vslsCorrNewTaskX, vsldCorrNewTaskX, vslcCorrNewTaskX, vslzCorrNewTaskX	
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

Each `NewTaskX` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table 10-14](#)).

Unlike `NewTask`, these routines represent the so called X-form version of the constructor, which means that in addition to creating the task descriptor they assign particular data to the first operand vector in array `x` used in convolution or correlation operation. The task descriptor created by the `NewTaskX` constructor keeps the pointer to the array `x` all the time, that is, until the task object is deleted by one of the destructor routines (see [DeleteTask](#)).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array *x* against different vectors in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters *xshape*, *yshape*, and *zshape* define the shapes of the input and output data provided by the arrays *x*, *y*, and *z*, respectively. Each shape parameter is an array of integers with its length equal to the value of *dims*. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter *dims* is 1, then *xshape*, *yshape*, and *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. Note that values of shape parameters may differ from physical shapes of arrays *x*, *y*, and *z* if non-trivial strides are assigned.

The stride parameter *xstride* specifies the physical location of the input data in the array *x*. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter *xstride* is *s*, then only every *s*th element of the array *x* will be used to form the input sequence. The stride value must be positive or negative but not zero.

NewTaskX1D

Creates a new convolution or correlation task descriptor for one-dimensional case and assigns source data to the first operand vector.

Syntax

Fortran:

```
status = vs1sconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vs1dconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vs1cconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vs1zconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vs1scorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vs1dcorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vs1ccorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vs1zcorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
```

C:

```
status = vslsConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vsldConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslcConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslzConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslsCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vsldCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslcCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslzCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
```

Input Parameters

Name	Type	Description
<i>mode</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See Table 10-18 for a list of possible values.
<i>xshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	Defines the length of the input data sequence for the source array <i>x</i> . See Data Allocation for more information.
<i>yshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	Defines the length of the input data sequence for the source array <i>y</i> . See Data Allocation for more information.
<i>zshape</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	Defines the length of the output data sequence to be stored in array <i>z</i> . See Data Allocation for more information.

<i>task</i>	FORTTRAN 77: <code>INTEGER*4</code> <code>task(2)</code> for <code>vslsconvnewtaskxld</code> , <code>vsldconvnewtaskxld</code> , <code>vslcconvnewtaskxld</code> , <code>vslzconvnewtaskxld</code> <code>INTEGER*4 task(2)</code> for <code>vslscorrnewtaskxld</code> , <code>vsldcorrnewtaskxld</code> , <code>vslccorrnewtaskxld</code> , <code>vslzcorrnewtaskxld</code> Fortran 90: <code>TYPE(VSL_CONV_TASK)</code> for <code>vslsconvnewtaskxld</code> , <code>vsldconvnewtaskxld</code> , <code>vslcconvnewtaskxld</code> , <code>vslzconvnewtaskxld</code>	Pointer to the task descriptor if created successfully or NULL pointer otherwise.

Name	Type	Description
	TYPE(VSL_CORR_TASK) for vslscorrnewtaskx1d, vsldcorrnewtaskx1d, vslccorrnewtaskx1d, vslzcorrnewtaskx1d C: VSLConvTaskPtr* for vslsConvNewTaskX1D, vsldConvNewTaskX1D, vslcConvNewTaskX1D, vslzConvNewTaskX1D VSLCorrTaskPtr* for vslsCorrNewTaskX1D, vsldCorrNewTaskX1D, vslcCorrNewTaskX1D, vslzCorrNewTaskX1D	
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

Each `NewTaskX1D` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table 10-14](#)).

These routines represent a special one-dimensional version of the so called X-form of the constructor. This assumes that the value of the parameter *dims* is 1 and that in addition to creating the task descriptor, constructor routines assign particular data to the first operand vector in array *x* used in convolution or correlation operation. The task descriptor created by the `NewTaskX1D` constructor keeps the pointer to the array *x* all the time, that is, until the task object is deleted by one of the destructor routines (see [DeleteTask](#)).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array x against different vectors in array y . This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters $xshape$, $yshape$, and $zshape$ are equal to the number of elements read from the arrays x and y or stored to the array z . You explicitly assign the shape parameters when calling the constructor.

The [stride parameters](#) $xstride$ specifies the physical location of the input data in the array x and is an interval between locations of consecutive elements of the array. For example, if the value of the parameter $xstride$ is s , then only every s^{th} element of the array x will be used to form the input sequence. The stride value must be positive or negative but not zero.

Task Editors

Task editors in convolution and correlation API of the Intel MKL are routines intended for setting up or changing the following task parameters (see [Table 10-14](#)):

- *mode*
- *internal_precision*
- *start*
- *decimation*.

For setting up or changing each of the above parameters, a separate routine exists.

NOTE. Fields of the task descriptor structure are accessible only through the set of task editor routines provided with the software.

After applying any of the editor routines to change the task descriptor settings, the task loses its commitment status and will go through the full commitment process again during the next execution or copy operation. This is motivated by the fact that the currently stored work data computed during the last commitment process may become invalid with respect to new parameter settings. For more information about task commitment, see [Overview](#).

[Table 10-17](#) lists available task editors.

Table 10-17 Task Editors

Routine	Description
SetMode	Changes the value of the parameter <i>mode</i> for the operation of convolution or correlation.
SetInternalPrecision	Changes the value of the parameter <i>internal_precision</i> for the operation of convolution or correlation.
SetStart	Sets the value of the parameter <i>start</i> for the operation of convolution or correlation.
SetDecimation	Sets the value of the parameter <i>decimation</i> for the operation of convolution or correlation.

NOTE. You can use the `NULL` task pointer in calls to editor routines. In this case, the routine will be terminated and no system crash will occur.

SetMode

Changes the value of the parameter `mode` in the convolution or correlation task descriptor.

Syntax

Fortran:

```
status = vslconvsetmode(task, newmode)
status = vslcorrsetmode(task, newmode)
```

C:

```
status = vslConvSetMode(task, newmode);
status = vslCorrSetMode(task, newmode);
```

Input Parameters

Name	Type	Description
<i>task</i>	FORTRAN 77: INTEGER*4 task(2) for vslconvsetmode INTEGER*4 task(2) for vslcorrsetmode Fortran 90: TYPE(VSL_CONV_TASK) for vslconvsetmode TYPE(VSL_CORR_TASK) for vslcorrsetmode C: VSLConvTaskPtr for vslConvSetMode VSLCorrTaskPtr for vslCorrSetMode	Pointer to the task descriptor.
<i>newmode</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	New value of the parameter mode.

Output Parameters

Name	Type	Description
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Current status of the task.

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function routine changes the value of the parameter `mode` for the operation of convolution or correlation. This parameter defines whether the computation should be done via Fourier transforms of the input/output data or using a direct algorithm. Initial value for `mode` is assigned by a task constructor.

Predefined values for the `mode` parameter are as follows:

Table 10-18 Values of `mode` parameter

Value	Purpose
VSL_CONV_MODE_FFT	Compute convolution by using fast Fourier transform.
VSL_CORR_MODE_FFT	Compute correlation by using fast Fourier transform.
VSL_CONV_MODE_DIRECT	Compute convolution directly.
VSL_CORR_MODE_DIRECT	Compute correlation directly.
VSL_CONV_MODE_AUTO	Automatically choose direct or Fourier mode for convolution.
VSL_CORR_MODE_AUTO	Automatically choose direct or Fourier mode for correlation.

SetInternalPrecision

Changes the value of the parameter `internal_precision` in the convolution or correlation task descriptor.

Syntax

Fortran:

```
status = vslconvsetinternalprecision(task, precision)
status = vslcorrsetinternalprecision(task, precision)
```

C:

```
status = vslConvSetInternalPrecision(task, precision);
status = vslCorrSetInternalPrecision(task, precision);
```

Input Parameters

Name	Type	Description
<i>task</i>	FORTRAN 77: INTEGER*4 task(2) for vslconvsetinternalprecision INTEGER*4 task(2) for vslcorrsetinternalprecision Fortran 90: TYPE(VSL_CONV_TASK) for vslconvsetinternalprecision TYPE(VSL_CORR_TASK) for vslcorrsetinternalprecision C: VSLConvTaskPtr for vslConvSetInternalPrecision VSLCorrTaskPtr for vslCorrSetInternalPrecision	Pointer to the task descriptor.
<i>precision</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	New value of the parameter <i>internal_precision</i> .

Output Parameters

Name	Type	Description
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Current status of the task.

Description

This routine is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The routine changes the value of the parameter *internal_precision* for the operation of convolution or correlation. This parameter defines whether the internal computations of the convolution or correlation result should be done in single or double precision. Initial value for *internal_precision* is assigned by a task constructor and set to either “single” or “double” according to the particular flavor of the constructor used.

Changing the *internal_precision* can be useful if the default setting of this parameter was “single” but you want to calculate the result with double precision even if input and output data are represented in single precision.

Predefined values for the *internal_precision* input parameter are as follows:

Table 10-19 Values of *internal_precision* Parameter

Value	Purpose
VSL_CONV_PRECISION_SINGLE	Compute convolution with single precision.
VSL_CORR_PRECISION_SINGLE	Compute correlation with single precision.
VSL_CONV_PRECISION_DOUBLE	Compute convolution with double precision.
VSL_CORR_PRECISION_DOUBLE	Compute correlation with double precision.

SetStart

*Changes the value of the parameter *start* in the convolution or correlation task descriptor.*

Syntax

Fortran:

```
status = vslconvsetstart(task, start)
status = vslcorrsetstart(task, start)
```

C:

```
status = vslConvSetStart(task, start);
status = vslCorrSetStart(task, start);
```

Input Parameters

Name	Type	Description
<i>task</i>	FORTRAN 77: INTEGER*4 task(2) for vslconvsetstart INTEGER*4 task(2) for vslcorrsetstart Fortran 90: TYPE (VSL_CONV_TASK) for vslconvsetstart TYPE (VSL_CORR_TASK) for vslcorrsetstart C: VSLConvTaskPtr for vslConvSetStart VSLCorrTaskPtr for vslCorrSetStart	Pointer to the task descriptor.
<i>start</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION (*) C: const int[]	New value of the parameter <i>start</i> .

Output Parameters

Name	Type	Description
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Current status of the task.

Description

This routine is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The routine sets the value of the parameter *start* for the operation of convolution or correlation. In a one-dimensional case, this parameter points to the first element in the mathematical result that should be stored in the output array. In a multidimensional case, *start* is an array of indices and its length is equal to the number of dimensions specified by the parameter *dims*. For more information about the definition and effect of this parameter, see [Data Allocation](#).

During the initial task descriptor construction, the default value for *start* is undefined and this parameter is not used. Therefore the only way to set and use the *start* parameter is via assigning it some value by one of the `SetStart` routines.

SetDecimation

*Changes the value of the parameter *decimation* in the convolution or correlation task descriptor.*

Syntax

Fortran:

```
status = vslconvsetdecimation(task, decimation)
status = vslcorrsetdecimation(task, decimation)
```

C:

```
status = vslConvSetDecimation(task, decimation);
status = vslCorrSetDecimation(task, decimation);
```

Input Parameters

Name	Type	Description
<i>task</i>	Fortran 77: INTEGER*4 task(2) for vslconvsetdecimation INTEGER*4 task(2) for vslcorrsetdecimation Fortran 90: TYPE(VSL_CONV_TASK) for vslconvsetdecimation	Pointer to the task descriptor.

Name	Type	Description
	TYPE (VSL_CORR_TASK) for vslcorrsetdecimation	
	C: VSLConvTaskPtr for vslConvSetDecimation	
	VSLCorrTaskPtr for vslCorrSetDecimation	
<i>decimation</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION (*) C: const int[]	New value of the parameter <i>decimation</i> .

Output Parameters

Name	Type	Description
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Current status of the task.

Description

This routine is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The routine sets the value of the parameter *decimation* for the operation of convolution or correlation. This parameter determines how to thin out the mathematical result of convolution or correlation before writing it into the output data array. For example, in a one-dimensional case, if $decimation = d > 1$, only every d -th element of the mathematical result is written to the output array *z*. In a multidimensional case, *decimation* is an array of indices and its length is equal to the number of dimensions specified by the parameter *dims*. For more information about the definition and effect of this parameter, see [Data Allocation](#).

During the initial task descriptor construction, the default value for *decimation* is undefined and this parameter is not used. Therefore the only way to set and use the *decimation* parameter is via assigning it some value by one of the `SetDecimation` routines.

Task Execution Routines

Task execution routines compute convolution or correlation results based on parameters held by the task descriptor and on the supplied user data for input vectors.

Once created and adjusted, the task can be executed multiple times by applying to different input/output data of the same type, precision, and shape.

Intel MKL implementation of the convolution and correlation API provides two different forms of execution routines: a general form and an X-form. General form executors use the task descriptor created by the general form constructor and expect to get two source data arrays x and y on input. Alternatively, X-form executors use the task descriptor created by the X-form constructor and expect to get only one source data array y on input because the first array x has been already specified on the construction stage.

When the task is executed for the first time, the execution routine includes task commitment operation, which involves two basic steps: parameters consistency check and preparation of auxiliary data (for example, this might be the calculation of Fourier transform for input data).

For each execution routine there is also an associated one-dimensional version which exploits the algorithmic and computational benefits provided by the simplicity of the data structures for one-dimensional case.

NOTE. You can use the `NULL` task pointer in calls to execution routines. In this case, the routine will be terminated and no system crash will occur.

If the task is executed successfully, the execution routine returns zero status code. If an error is detected, the execution routine returns an error code which signals that a specific error has occurred. In particular, an error status code is returned in the following cases:

- if the task pointer is `NULL`,
- if the task descriptor is corrupted,
- if calculation has failed for some other reason.

NOTE. Intel® MKL does not control floating-point errors, like overflow or gradual underflow, or operations with NaNs, etc.

If an error occurs, the task descriptor stores the error code.

The table below lists all task execution routines.

Table 10-20 Task Execution Routines

Routine	Description
Exec	Computes convolution or correlation for a multidimensional case.
Exec1D	Computes convolution or correlation for a one-dimensional case.
ExecX	Computes convolution or correlation as X-form for a multidimensional case.
ExecX1D	Computes convolution or correlation as X-form for a one-dimensional case.

Exec

Computes convolution or correlation for multidimensional case.

Syntax

Fortran:

```
status = vslsconvexec(task, x, xstride, y, ystride, z, zstride)
status = vsldconvexec(task, x, xstride, y, ystride, z, zstride)
status = vslcconvexec(task, x, xstride, y, ystride, z, zstride)
status = vslzconvexec(task, x, xstride, y, ystride, z, zstride)
status = vslscorrexec(task, x, xstride, y, ystride, z, zstride)
status = vsldcorrexec(task, x, xstride, y, ystride, z, zstride)
status = vslccorrexec(task, x, xstride, y, ystride, z, zstride)
status = vslzcorrexec(task, x, xstride, y, ystride, z, zstride)
```

C:

```
status = vslsConvExec(task, x, xstride, y, ystride, z, zstride);
status = vsldConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslcConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslzConvExec(task, x, xstride, y, ystride, z, zstride);
```

```

status = vsIsCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vsldCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vslcCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vslzCorrExec(task, x, xstride, y, ystride, z, zstride);

```

<i>status</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

This routine is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

Each of the `Exec` routines computes convolution or correlation of the data provided by the arrays `x` and `y` and then stores the results in the array `z`. Parameters of the operation are read from the task descriptor created previously by a corresponding `NewTask` constructor and pointed to by `task`. If `task` is `NULL`, no operation is done.

The stride parameters `xstride`, `ystride`, and `zstride` specify the physical location of the input and output data in the arrays `x`, `y`, and `z`, respectively. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter `zstride` is `s`, then only every s^{th} element of the array `z` will be used to store the output data. The stride value must be positive or negative but not zero.

Exec1D

Computes convolution or correlation for one-dimensional case.

Syntax

Fortran:

```
status = vslsconvexeclD(task, x, xstride, y, ystride, z, zstride)
status = vsldconvexeclD(task, x, xstride, y, ystride, z, zstride)
status = vslcconvexeclD(task, x, xstride, y, ystride, z, zstride)
status = vslzconvexeclD(task, x, xstride, y, ystride, z, zstride)
status = vslscorrexeclD(task, x, xstride, y, ystride, z, zstride)
status = vsldcorrexeclD(task, x, xstride, y, ystride, z, zstride)
status = vslccorrexeclD(task, x, xstride, y, ystride, z, zstride)
status = vslzcorrexeclD(task, x, xstride, y, ystride, z, zstride)
```

C:

```
status = vslsConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vsldConvExec1D(task, x, xstride, y, ystride, z, zstride);
```

```
status = vslcConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslzConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslsCorrExec1D(task, x, xstride, y, ystride, z, zstride);
status = vsldCorrExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslcCorrExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslzCorrExec1D(task, x, xstride, y, ystride, z, zstride);
```

<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to <code>VSL_STATUS_OK</code> if the task is executed successfully or set to non-zero error code otherwise.

Description

This routine is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

Each of the `Exec1D` routines computes convolution or correlation of the data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special one-dimensional version of the operation, assuming that the value of the parameter `dims` is 1. Using this version of execution routines can help speed up performance in case of one-dimensional data.

Parameters of the operation are read from the task descriptor created previously by a corresponding `NewTask1D` constructor and pointed to by `task`. If `task` is `NULL`, no operation is done.

ExecX

Computes convolution or correlation for multidimensional case with the fixed first operand vector.

Syntax

Fortran:

```
status = vslsconvexec(task, y, ystride, z, zstride)
status = vsldconvexec(task, y, ystride, z, zstride)
status = vslcconvexec(task, y, ystride, z, zstride)
status = vslzconvexec(task, y, ystride, z, zstride)
```

```

status = vslscorrexecx(task, y, ystride, z, zstride)
status = vsldcorrexecx(task, y, ystride, z, zstride)
status = vslccorrexecx(task, y, ystride, z, zstride)
status = vslzcorrexecx(task, y, ystride, z, zstride)

```

C:

```

status = vslsConvExecX(task, y, ystride, z, zstride);
status = vsldConvExecX(task, y, ystride, z, zstride);
status = vslcConvExecX(task, y, ystride, z, zstride);
status = vslzConvExecX(task, y, ystride, z, zstride);
status = vslsCorrExecX(task, y, ystride, z, zstride);
status = vslcCorrExecX(task, y, ystride, z, zstride);
status = vslzCorrExecX(task, y, ystride, z, zstride);
status = vsldCorrExecX(task, y, ystride, z, zstride);

```

Name	Type	Description
	C: const float[] for vslsConvExecX and vslsCorrExecX, const double[] for vsldConvExecX and vsldCorrExecX, const MKL_Complex8[] for vslcConvExecX and vslcCorrExecX, const MKL_Complex16[] for vslzConvExecX and vslzCorrExecX	
<i>status</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

This routine is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

Each of the `ExecX` routines computes convolution or correlation of the data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special version of the operation, which assumes that the first operand vector was set on the task construction stage and the task object keeps the pointer to the array `x`.

Parameters of the operation are read from the task descriptor created previously by a corresponding `NewTaskX` constructor and pointed to by `task`. If `task` is `NULL`, no operation is done.

Using this form of execution routines is recommended when you need to compute multiple convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

ExecX1D

Computes convolution or correlation for one-dimensional case with the fixed first operand vector.

Syntax

Fortran:

```
status = vslsconvexecx1d(task, y, ystride, z, zstride)
status = vsldconvexecx1d(task, y, ystride, z, zstride)
status = vslcconvexecx1d(task, y, ystride, z, zstride)
status = vslzconvexecx1d(task, y, ystride, z, zstride)
status = vslscorrexecx1d(task, y, ystride, z, zstride)
status = vsldcorrexecx1d(task, y, ystride, z, zstride)
status = vslccorrexecx1d(task, y, ystride, z, zstride)
status = vslzcorrexecx1d(task, y, ystride, z, zstride)
```

C:

```
status = vslsConvExecX1D(task, y, ystride, z, zstride);
status = vsldConvExecX1D(task, y, ystride, z, zstride);
status = vslcConvExecX1D(task, y, ystride, z, zstride);
status = vslzConvExecX1D(task, y, ystride, z, zstride);
status = vslsCorrExecX1D(task, y, ystride, z, zstride);
status = vslcCorrExecX1D(task, y, ystride, z, zstride);
status = vslzCorrExecX1D(task, y, ystride, z, zstride);
status = vsldCorrExecX1D(task, y, ystride, z, zstride);
```

Input Parameters

Name	Type	Description
	Fortran 90: REAL (KIND=4) , DIMENSION (*) for vslsconvexecx1d and vslscorreexecx1d, REAL (KIND=8) , DIMENSION (*) for vsldconvexecx1d and vsldcorreexecx1d, COMPLEX (KIND=4) , DIMENSION (*) forvslcconvexecx1d and vslccorreexecx1d, COMPLEX (KIND=8) , DIMENSION (*) for vslzconvexecx1d and vslzcorreexecx1d C: const float[] for vslsConvExecX1D and vslsCorrExecX1D, const double[] for vsldConvExecX1D and vsldCorrExecX1D, const MKL_Complex8[] for vslcConvExecX1D and vslcCorrExecX1D, const MKL_Complex16[] for vslzConvExecX1D and vslzCorrExecX1D	
<i>status</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

This routine is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

Each of the `ExecX1D` routines computes convolution or correlation of one-dimensional (assuming that `dims = 1`) data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special version of the operation, which expects that the first operand vector was set on the task construction stage.

Parameters of the operation are read from the task descriptor created previously by a corresponding `NewTaskX1D` constructor and pointed to by `task`. If `task` is `NULL`, no operation is done.

Using this form of execution routines is recommended when you need to compute multiple one-dimensional convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

Task Destructors

Task destructors are routines designed for deleting task objects and deallocating memory.

DeleteTask

Destroys the task object and frees the memory.

Syntax

Fortran:

```
errcode = vslconvdeletetask(task)
```

```
errcode = vslcorrdeletetask(task)
```

C:

```
errcode = vslConvDeleteTask(task);
```

```
errcode = vslCorrDeleteTask(task);
```

Input Parameters

Name	Type	Description
<i>task</i>	FORTTRAN 77: INTEGER*4 task(2) for vslconvdeletetask INTEGER*4 task(2) for vslcorrdeletetask Fortran 90: TYPE(VSL_CONV_TASK) for vslconvdeletetask TYPE(VSL_CORR_TASK) for vslcorrdeletetask C: VSLConvTaskPtr* for vslConvDeleteTask VSLCorrTaskPtr* for vslCorrDeleteTask	Pointer to the task descriptor.

Output Parameters

Name	Type	Description
<i>errcode</i>	FORTTRAN 77: INTEGER Fortran 90: INTEGER C: int	Contains 0 if the task object is deleted successfully. Contains error code if an error occurred.

Description

This routine is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

Given a pointer to a task descriptor, this routine deletes the task descriptor object and frees the memory allocated for the data structure. If the task holds a work memory, the latter is also freed. The task pointer is set to `NULL`.

Note that if by some reason the task was not deleted successfully, the routine returns an error code. This error code has no relation to the task status code and does not change it.

NOTE. You can use the `NULL` task pointer in calls to destructor routines. In this case, the routine will be terminated and no system crash will occur.

Task Copy

The routines are designed for copying convolution and correlation task descriptors.

CopyTask

Copies a descriptor for convolution or correlation task.

Syntax

Fortran:

```
status = vslconvcopytask(newtask, srctask)
status = vslcorrcopytask(newtask, srctask)
```

C:

```
status = vslConvCopyTask(newtask, srctask);
status = vslCorrCopyTask(newtask, srctask);
```

Input Parameters

Name	Type	Description
<i>srctask</i>	FORTRAN 77: INTEGER*4 srctask(2) for vslconvcopytask INTEGER*4 srctask(2) for vslcorrcopytask Fortran 90: TYPE(VSL_CONV_TASK) for vslconvcopytask	Pointer to the source task descriptor.

Name	Type	Description
	TYPE (VSL_CORR_TASK) for vslcorrcopytask	
	C: const VSLConvTaskPtr for vslConvCopyTask	
	const VSLCorrTaskPtr for vslCorrCopyTask	

Output Parameters

Name	Type	Description
<i>newtask</i>	FORTRAN 77: INTEGER*4 srctask(2) for vslconvcopytask INTEGER*4 srctask(2) for vslcorrcopytask Fortran 90: TYPE (VSL_CONV_TASK) for vslconvcopytask TYPE (VSL_CORR_TASK) for vslcorrcopytask C: VSLConvTaskPtr* for vslConvCopyTask VSLCorrTaskPtr* for vslCorrCopyTask	Pointer to the new task descriptor.
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Current status of the source task.

Description

This routine is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.fi` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

If a task object `srcTask` already exists, you can use an appropriate `CopyTask` routine to make its copy in `newTask`. After the copy operation, both source and new task objects will become committed (see [Overview](#) for information about task commitment). If the source task was not previously committed, the commitment operation for this task is implicitly invoked before copying starts. If an error occurs during source task commitment, the task stores the error code in the status field. If an error occurs during copy operation, the routine returns a `NULL` pointer instead of a reference to a new task object.

Usage Examples

This section demonstrates how you can use the Intel MKL routines to perform some common convolution and correlation operations both for single threaded and multiple threaded calculations. The following two sample functions `scond1` and `sconf1` simulate the convolution and correlation functions `SCOND` and `SCONF` found in IBM ESSL* library. The functions assume single threaded calculations and can be used with C or C++ compilers.

Example 10-5 Function `scond1` for Single Threaded Calculations

```
#include "mkl_vsl.h"

int acond1(
    float h[], int inch,
    float x[], int incx,
    float y[], int incy,
    int nh, int nx, int iy0, int ny)
{
    int status;
    VSLConvTaskPtr task;
    vslsConvNewTask1D(&task,VSL_CONV_MODE_DIRECT,nh,nx,ny);
    vslConvSetStart(task, &iy0);
    status = vslsConvExec1D(task, h,inch, x,incx, y,incy);
    vslConvDeleteTask(&task);
    return status;
}
```

Example 10-6 Function `sconf1` for Single Threaded Calculations

```
#include "mkl_vsl.h"

int sconf1(
    int init,
    float h[], int inclh,
    float x[], int inclx, int inc2x,
    float y[], int incly, int inc2y,
    int nh, int nx, int m, int iy0, int ny,
    void* aux1, int naux1, void* aux2, int naux2)
{
    int status;

    /* assume that aux1!=0 and naux1 is big enough */
```

```
VSLConvTaskPtr* task = (VSLConvTaskPtr*)aux1;

if (init != 0)

    /* initialization: */

    status = vslsConvNewTaskX1D(task, VSL_CONV_MODE_FFT,
        nh, nx, ny, h, inclh);
if (init == 0) {
    /* calculations: */

    int i;

    vslConvSetStart(*task, &iy0);

    for (i=0; i<m; i++) {
        float* xi = &x[inc2x * i];
        float* yi = &y[inc2y * i];

        /* task is implicitly committed at i==0 */

        status = vslsConvExecX1D(*task, xi, inclx, yi, incly);
    };
};

vslConvDeleteTask(task);

return status;
}
```

Using Multiple Threads

For functions such as `sconf1` described in the previous example, parallel calculations may be more preferable instead of cycling. If $m > 1$, you can use multiple threads for invoking the task execution against different data sequences. For such cases, use task copy routines to create m copies of the task object before the calculations stage and then run these copies with different threads. Ensure that you make all necessary parameter adjustments for the task (using [Task Editors](#)) before copying it.

The sample code for that can look like following:

```
if (init == 0) {
    int i, status, ss[M];
    VSLConvTaskPtr tasks[M];
    /* assume that M is big enough */
    . . .
    vslConvSetStart(*task, &iy0);
    . . .
    for (i=0; i<m; i++)
        /* implicit commitment at i==0 */
        vslConvCopyTask(&tasks[i],*task);
    . . .
```

Then, m threads may be started to execute different copies of the task:

```
. . .
    float* xi = &x[inc2x * i];
    float* yi = &y[inc2y * i];
    ss[i]=vslsConvExecX1D(tasks[i], xi,inc1x, yi,inc1y);
    . . .
```

And finally, after all threads have finished the calculations, overall status ought to be collected from all task objects. The following code assumes signaling the first error found, if any:

```
. . .
for (i=0; i<m; i++) {
    status = ss[i];
    if (status != 0) /* 0 means "OK" */
        break;
};
return status;
}; /* end if init==0 */
```

Execution routines modify the task internal state (fields of the task structure). Such modifications may conflict with each other if different threads work with the same task object simultaneously. This is the reason why different threads must use different copies of the task.

Mathematical Notation and Definitions

The following notation is necessary to explain the underlying mathematical definitions used in the text:

$\mathbf{R} = (-\infty, +\infty)$	The set of real numbers.
$\mathbf{Z} = \{0, \pm 1, \pm 2, \dots\}$	The set of integer numbers.
$\mathbf{Z}^N = \mathbf{Z} \times \dots \times \mathbf{Z}$	The set of N-dimensional series of integer numbers.
$p = (p_1, \dots, p_N) \in \mathbf{Z}^N$	N-dimensional series of integers.
$u: \mathbf{Z}^N \rightarrow \mathbf{R}$	Function u with arguments from \mathbf{Z}^N and values from \mathbf{R} .
$u(p) = u(p_1, \dots, p_N)$	The value of the function u for the argument (p_1, \dots, p_N) .
$w = u * v$	Function w is the convolution of the functions u, v .
$w = u \bullet v$	Function w is the correlation of the functions u, v .

Given series $p, q \in \mathbf{Z}^N$:

- series $r = p + q$ is defined as $r^n = p^n + q^n$ for every $n=1, \dots, N$
- series $r = p - q$ is defined as $r^n = p^n - q^n$ for every $n=1, \dots, N$
- series $r = \sup\{p, q\}$ is defines as $r^n = \max\{p^n, q^n\}$ for every $n=1, \dots, N$
- series $r = \inf\{p, q\}$ is defined as $r^n = \min\{p^n, q^n\}$ for every $n=1, \dots, N$
- inequality $p \leq q$ means that $p^n \leq q^n$ for every $n=1, \dots, N$.

A function $u(p)$ is called a finite function if there exist series $p^{\min}, p^{\max} \in \mathbf{Z}^N$ such that:

$$u(p) \neq 0$$

implies

$$p^{\min} \leq p \leq p^{\max}.$$

Operations of convolution and correlation are only defined for finite functions.

Consider functions u, v and series $p^{\min}, p^{\max}, q^{\min}, q^{\max} \in \mathbf{Z}^N$ such that:

$$u(p) \neq 0 \text{ implies } p^{\min} \leq p \leq p^{\max}.$$

$v(q) \neq 0$ implies $Q^{\min} \leq q \leq Q^{\max}$.

Definitions of linear correlation and linear convolution for functions u and v are given below.

Linear Convolution

If function $w = u * v$ is the convolution of u and v , then:

$w(r) \neq 0$ implies $R^{\min} \leq r \leq R^{\max}$,
where $R^{\min} = P^{\min} + Q^{\min}$ and $R^{\max} = P^{\max} + Q^{\max}$.

If $R^{\min} \leq r \leq R^{\max}$, then:

$w(r) = \sum u(t) \cdot v(r-t)$ is the sum for all $t \in \mathbf{Z}^N$ such that $T^{\min} \leq t \leq T^{\max}$,
where $T^{\min} = \sup\{P^{\min}, r - Q^{\max}\}$ and $T^{\max} = \inf\{P^{\max}, r - Q^{\min}\}$.

Linear Correlation

If function $w = u \bullet v$ is the correlation of u and v , then:

$w(r) \neq 0$ implies $R^{\min} \leq r \leq R^{\max}$,
where $R^{\min} = Q^{\min} - P^{\max}$ and $R^{\max} = Q^{\max} - P^{\min}$.

If $R^{\min} \leq r \leq R^{\max}$, then:

$w(r) = \sum u(t) \cdot v(r+t)$ is the sum for all $t \in \mathbf{Z}^N$ such that $T^{\min} \leq t \leq T^{\max}$,
where $T^{\min} = \sup\{P^{\min}, Q^{\min} - r\}$ and $T^{\max} = \inf\{P^{\max}, Q^{\max} - r\}$.

Representation of the functions u, v, w as the input/output data for the Intel MKL convolution and correlation functions is described in the [Data Allocation](#) section below.

Data Allocation

This section explains the relation between:

- mathematical finite functions u, v, w introduced in the section [Mathematical Notation and Definitions](#);
- multi-dimensional input and output data vectors representing the functions u, v, w ;
- arrays u, v, w used to store the input and output data vectors in computer memory

The convolution and correlation routine parameters that determine the allocation of input and output data are the following:

- Data arrays x, y, z
- Shape arrays $xshape, yshape, zshape$
- Strides within arrays $xstride, ystride, zstride$
- Parameters $start, decimation$

Finite Functions and Data Vectors

The finite functions $u(p)$, $v(q)$, and $w(r)$ introduced above are represented as multi-dimensional vectors of input and output data:

`inputu(i1, ..., idims)` for $u(p_1, \dots, p_N)$

`inputv(j1, ..., jdims)` for $v(q_1, \dots, q_N)$

`output(k1, ..., kdims)` for $w(r_1, \dots, r_N)$.

Parameter *dims* represents the number of dimensions and is equal to N.

The parameters *xshape*, *yshape*, and *zshape* define the shapes of input/output vectors:

`inputu(i1, ..., idims)` is defined if $1 \leq i_n \leq xshape(n)$ for every $n=1, \dots, dims$

`inputv(j1, ..., jdims)` is defined if $1 \leq j_n \leq yshape(n)$ for every $n=1, \dots, dims$

`output(k1, ..., kdims)` is defined if $1 \leq k_n \leq zshape(n)$ for every $n=1, \dots, dims$.

Relation between the input vectors and the functions u and v is defined by the following formulas:

`inputu(i1, ..., idims)` = $u(p_1, \dots, p_N)$, where $p_n = p_n^{\min} + (i_n - 1)$ for every n

`inputv(j1, ..., jdims)` = $v(q_1, \dots, q_N)$, where $q_n = q_n^{\min} + (j_n - 1)$ for every n .

Relation between the output vector and the function $w(r)$ is similar (but only in the case when parameters *start* and *decimation* are not defined):

`output(k1, ..., kdims)` = $w(r_1, \dots, r_N)$, where $r_n = r_n^{\min} + (k_n - 1)$ for every n .

If the parameter *start* is defined, it must belong to the interval $R_n^{\min} \leq start(n) \leq R_n^{\max}$.

If defined, the *start* parameter replaces R^{\min} in the formula:

`output(k1, ..., kdims)` = $w(r_1, \dots, r_N)$, where $r_n = start(n) + (k_n - 1)$

If the parameter *decimation* is defined, it changes the relation according to the following formula:

$\text{output}(k_1, \dots, k_{\text{dims}}) = w(r_1, \dots, r_N)$, where $r_n = R_n^{\min} + (k_n - 1) \cdot \text{decimation}(n)$

If both parameters *start* and *decimation* are defined, the formula is as follows:

$\text{output}(k_1, \dots, k_{\text{dims}}) = w(r_1, \dots, r_N)$, where $r_n = \text{start}(n) + (k_n - 1) \cdot \text{decimation}(n)$

The convolution and correlation software checks the values of *zshape*, *start*, and *decimation* during task commitment. If r_n exceeds R_n^{\max} for some $k_n, n=1, \dots, \text{dims}$, an error is raised.

Allocation of Data Vectors

Both parameter arrays *x* and *y* contain input data vectors in memory, while array *z* is intended for storing output data vector. To access the memory, the convolution and correlation software uses only pointers to these arrays and ignores the array shapes.

For parameters *x*, *y*, and *z*, you can provide one-dimensional arrays with the requirement that actual length of these arrays be sufficient to store the data vectors.

The allocation of the input and output data inside the arrays *x*, *y*, and *z* is described below assuming that the arrays are one-dimensional. Given multi-dimensional indices $i, j, k \in \mathbf{Z}^N$, one-dimensional indices $e, f, g \in \mathbf{Z}$ are defined such that:

$\text{inputu}(i_1, \dots, i_{\text{dims}})$ is allocated at $x(e)$

$\text{inputv}(j_1, \dots, j_{\text{dims}})$ is allocated at $y(f)$

$\text{output}(k_1, \dots, k_{\text{dims}})$ is allocated at $z(g)$.

The indices *e*, *f*, and *g* are defined as follows:

$e = 1 + \sum x_{\text{stride}}(n) \cdot dx(n)$ (the sum is for all $n=1, \dots, \text{dims}$)

$f = 1 + \sum y_{\text{stride}}(n) \cdot dy(n)$ (the sum is for all $n=1, \dots, \text{dims}$)

$g = 1 + \sum z_{\text{stride}}(n) \cdot dz(n)$ (the sum is for all $n=1, \dots, \text{dims}$)

The distances $dx(n)$, $dy(n)$, and $dz(n)$ depend on the signum of the stride:

$dx(n) = i_n - 1$ if $x_{\text{stride}}(n) > 0$, or $dx(n) = i_n - x_{\text{shape}}(n)$ if $x_{\text{stride}}(n) < 0$

$dy(n) = j_n - 1$ if $y_{\text{stride}}(n) > 0$, or $dy(n) = j_n - y_{\text{shape}}(n)$ if $y_{\text{stride}}(n) < 0$

$dz(n) = k_n - 1$ if $z_{\text{stride}}(n) > 0$, or $dz(n) = k_n - z_{\text{shape}}(n)$ if $z_{\text{stride}}(n) < 0$

The definitions of indices e , f , and g assume that indexes for arrays x , y , and z are started from unity:

$x(e)$ is defined for $e=1, \dots, \text{length}(x)$

$y(f)$ is defined for $f=1, \dots, \text{length}(y)$

$z(g)$ is defined for $g=1, \dots, \text{length}(z)$

Below is a detailed explanation about how elements of the multi-dimensional output vector are stored in the array z for one-dimensional and two-dimensional cases.

One-dimensional case. If $\text{dims}=1$, then zshape is the number of the output values to be stored in the array z . The actual length of array z may be greater than zshape elements.

If $\text{zstride}>1$, output values are stored with the stride: $\text{output}(1)$ is stored to $z(1)$, $\text{output}(2)$ is stored to $z(1+\text{zstride})$, and so on. Hence, the actual length of z must be at least $1+\text{zstride}*(\text{zshape}-1)$ elements or more.

If $\text{zstride}<0$, it still defines the stride between elements of array z . However, the order of the used elements is the opposite. For the k -th output value, $\text{output}(k)$ is stored in $z(1+|\text{zstride}|*(\text{zshape}-k))$, where $|\text{zstride}|$ is the absolute value of zstride . The actual length of the array z must be at least $1+|\text{zstride}|*(\text{zshape} - 1)$ elements.

Two-dimensional case. If $\text{dims}=2$, the output data is a two-dimensional matrix. The value $\text{zstride}(1)$ defines the stride inside matrix columns, that is, the stride between the $\text{output}(k_1, k_2)$ and $\text{output}(k_1+1, k_2)$ for every pair of indices k_1, k_2 . On the other hand, $\text{zstride}(2)$ defines the stride between columns, that is, the stride between $\text{output}(k_1, k_2)$ and $\text{output}(k_1, k_2+1)$.

If $\text{zstride}(2)$ is greater than $\text{zshape}(1)$, this causes sparse allocation of columns. If the value of $\text{zstride}(2)$ is smaller than $\text{zshape}(1)$, this may result in the transposition of the output matrix. For example, if $\text{zshape} = (2, 3)$, you can define $\text{zstride} = (3, 1)$ to allocate output values like transposed matrix of the shape 3×2 .

Whether zstride assumes this kind of transformations or not, you need to ensure that different elements $\text{output}(k_1, \dots, k_{\text{dims}})$ will be stored in different locations $z(g)$.

Fourier Transform Functions

This chapter describes the following implementations of the fast Fourier transform functions available in Intel® MKL:

- Fast Fourier transform (FFT) functions for single-processor or shared-memory systems (see [FFT Functions](#) below)
- [Cluster FFT functions](#) for distributed-memory architectures (available with Intel® MKL for the Linux* and Windows* operating systems only).

The general form of the discrete Fourier transform is

$$Z_{k_1, k_2, \dots, k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \dots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1, j_2, \dots, j_d} \exp \left(\delta i 2\pi \sum_{l=1}^d j_l k_l / n_l \right)$$

for $k_l = 0, \dots, n_l-1$ ($l = 1, \dots, d$), where σ is an arbitrary real-valued scale factor, and the sign in the exponent is $\delta = -1$ for the forward transform and $\delta = +1$ for the backward transform. In most common situations, the domain of the forward transform, that is, the set where the input (periodic) sequence $\{w_{j_1, j_2, \dots, j_d}\}$ belongs, can be the set of complex-valued sequences and real-valued sequences. Respective domains for the backward transform, or backward domains, are represented by complex-valued sequences and complex-valued conjugate-even sequences.

Both groups of FFT functions above present a uniform and easy-to-use application programmer interface providing fast computation of a discrete Fourier transform through the fast Fourier transform algorithm.

Both FFT and Cluster FFT functions support a five-stage usage model for computing an FFT:

1. Allocate a fresh descriptor for the problem with a call to the [DftiCreateDescriptor](#) or [DftiCreateDescriptorDM](#) function. The descriptor captures the configuration of the transform, namely, the dimensionality (or rank), sizes, number of transforms, memory layout of the input/output data (defined by strides), scaling factors, and so on. Many of the configuration settings are assigned default values in this call and may need modification depending on your application.
2. Optionally adjust the descriptor configuration with a call to the [DftiSetValue](#) or [DftiSetValueDM](#) function as needed. Typically, you must carefully define the data storage layout for an FFT or the data distribution among processes for a Cluster FFT. The configuration settings of the descriptor, such as the default values, can be obtained with the [DftiGetValue](#) or [DftiGetValueDM](#) function.

3. Commit the descriptor with a call to the [DftiCommitDescriptor](#) or [DftiCommitDescriptorDM](#) function, that is, make the descriptor ready for the transform computation. Once the descriptor is committed, the parameters of the transform, such as the type and number of transforms, strides and distances, the type and storage layout of the data, and so on, are "frozen" in the descriptor.
4. Compute the transform with a call to the [DftiComputeForward](#)/[DftiComputeBackward](#) or [DftiComputeForwardDM](#)/[DftiComputeBackwardDM](#) functions as many times as needed. With the committed descriptor, the compute functions only accept pointers to the input/output data and compute the transform as defined. To modify any configuration parameters later on, use [DftiSetValue](#) followed by [DftiCommitDescriptor](#) ([DftiSetValueDM](#) followed by [DftiCommitDescriptorDM](#)) or create and commit another descriptor.
5. Deallocate the descriptor with a call to the [DftiFreeDescriptor](#) or [DftiFreeDescriptorDM](#) function. This will return the memory internally consumed by the descriptor to the operating system.

All the above functions return an integer status value, which is zero upon successful completion of the operation. You can interpret a non-zero status with the help of the [DftiErrorClass](#) or [DftiErrorMessage](#) function.

The FFT functions support lengths with arbitrary factors. See the *Intel MKL User's Guide* for specific radices supported efficiently and the length constraints.

NOTE. The FFT functions assume the Cartesian representation of complex data (that is, the real and imaginary parts define a complex number). The Intel MKL Vector Mathematical Functions provide an efficient tool for conversion to and from the polar representation (see [Example C-30a in Appendix C](#) and [Example C-30b in Appendix C](#)).

FFT Functions

The fast Fourier transform function library of Intel MKL provides one-dimensional, two-dimensional, and multi-dimensional (up to rank 7) transforms and both Fortran and C interfaces for all transform functions.

[Table 11-1](#) lists FFT functions implemented in Intel MKL:

Table 11-1 FFT Functions in Intel MKL

Function Name	Operation
Descriptor Manipulation Functions	

Function Name	Operation
DftiCreateDescriptor	Allocates memory for the descriptor data structure and preliminarily initializes it.
DftiCommitDescriptor	Performs all initialization for the actual FFT computation.
DftiCopyDescriptor	Copies an existing descriptor.
DftiFreeDescriptor	Frees memory allocated for a descriptor.
FFT Computation Functions	
DftiComputeForward	Computes the forward FFT.
DftiComputeBackward	Computes the backward FFT.
Descriptor Configuration Functions	
DftiSetValue	Sets one particular configuration parameter with the specified configuration value.
DftiGetValue	Gets the value of one particular configuration parameter.
Status Checking Functions	
DftiErrorClass	Checks if the status reflects an error of a predefined class.
DftiErrorMessage	Generates an error message.

Description of the FFT functions is followed by discussion of configuration settings (see [Configuration Settings](#)) and various configuration parameters used.

Computing FFT

The FFT functions described later in this chapter are provided with the Fortran and C interfaces. Fortran stands for Fortran 95. The FFT interface relies critically on many modern features offered in Fortran 95 that have no counterpart in FORTRAN 77.

NOTE. Following the explicit function interface in Fortran, data array must be defined as one-dimensional for any transformation type.

The materials presented in this chapter assume the availability of native complex types in C as they are specified in C9X.

You can find code examples that use FFT interface functions to compute transform results in [Fourier Transform Functions Code Examples](#) section in the Appendix C.

For most common situations, an FFT computation can be effected by four function calls. The approach adopted in Intel MKL for FFT computation uses one single data structure, the descriptor, to record flexible configuration whose parameters can be changed independently. This results in enhanced functionality and ease of use.

The descriptor data structure, when created, contains information about the length and domain of the FFT to be computed, as well as the setting of rather a large number of configuration parameters. The default settings for all of these parameters include, for example, the following:

- the FFT to be computed does not have a scale factor;
- there is only one set of data to be transformed;
- the data is stored contiguously in memory;
- the computed result overwrites (in place) the input data; etc.

Should any one of these many default settings be inappropriate, they can be changed one-at-a-time through the function [DftiSetValue](#) as illustrated in the [Example C-20](#) and [Example C-21](#).

FFT Interface

To use the FFT functions, you need to access the module `MKL_DFTI` through the "use" statement in Fortran; or access the header file `mkl_dfti.h` through "include" in C.

The Fortran interface provides a derived type `DFTI_DESCRIPTOR`; a number of named constants representing various names of configuration parameters and their possible values; and a number of overloaded functions through the generic functionality of Fortran 95.

The C interface provides the `DFTI_DESCRIPTOR_HANDLE` type, a number of named constants of two enumeration types `DFTI_CONFIG_PARAM` and `DFTI_CONFIG_VALUE`, and a number of functions, some of which accept different number of input arguments.

NOTE. Some of the FFT functions and/or functionality described in the subsequent sections of this chapter may not be supported by the currently available implementation of the library. You can find the complete list of the implementation-specific exceptions in the release notes to your version of the library.

There are four main categories of FFT functions in Intel MKL:

- 1. Descriptor Manipulation.** There are four functions in this category. The first one, `DftiCreateDescriptor`, creates an FFT descriptor whose storage is allocated dynamically. This function configures the descriptor with default settings corresponding to a few input values supplied by the user.

The second, `DftiCommitDescriptor`, "commits" the descriptor to all its setting. In practice, this usually means that all the necessary precomputation will be performed. This may include factorization of the input length and computation of all the required twiddle factors. The third function, `DftiCopyDescriptor`, makes an extra copy of a descriptor, and the fourth function, `DftiFreeDescriptor`, frees up all the memory allocated for the descriptor information.
- 2. FFT Computation.** There are two functions in this category. The first, `DftiComputeForward`, performs the forward FFT computation, and the second function, `DftiComputeBackward`, performs a backward FFT computation.
- 3. Descriptor configuration.** There are two functions in this category. One function, `DftiSetValue`, sets one specific value to one of the many configuration parameters that are changeable (a few are not); the other, `DftiGetValue`, gets the current value of any one of these configuration parameters (all are readable). These parameters, though many, are handled one-at-a-time.
- 4. Status Checking.** The functions described in the three categories above return an integer value denoting the status of the operation. In particular, a non-zero return value always indicates a problem of some sort. Envisioned to be further enhanced in later releases of Intel MKL, FFT interface at present provides for one logical status class function, `DftiErrorClass`, and a simple status message generation function, `DftiErrorMessage`.

Status Checking Functions

All of the descriptor manipulation, FFT computation, and descriptor configuration functions return an integer value denoting the status of the operation. Two functions serve to check the status. The first function is a logical function that checks if the status reflects an error of a predefined class, and the second is an error message function that returns a character string.

ErrorClass

Checks if the status reflects an error of a predefined class.

Syntax

Fortran:

```
Predicate = DftiErrorClass( Status, Error_Class )
```

C:

```
predicate = DftiErrorClass( status, error_class );
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and `mkl_dfti.f90` header file for the Fortran interface. The FFT interface in Intel MKL provides a set of predefined error classes listed in [Table 11-2](#). They are named constants and have the type `INTEGER` in Fortran and `MKL_LONG` in C.

Table 11-2 Predefined Error Classes

Named Constants	Comments
<code>DFTI_NO_ERROR</code>	No error. The zero status belongs to this class.
<code>DFTI_MEMORY_ERROR</code>	Usually associated with memory allocation
<code>DFTI_INVALID_CONFIGURATION</code>	Invalid settings of one or more configuration parameters
<code>DFTI_INCONSISTENT_CONFIGURATION</code>	Inconsistent configuration or input parameters
<code>DFTI_NUMBER_OF_THREADS_ERROR</code>	Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function)
<code>DFTI_MULTITHREADED_ERROR</code>	Usually associated with a value that OMP routines return in case of errors
<code>DFTI_BAD_DESCRIPTOR</code>	Descriptor is unusable for computation

Named Constants	Comments
DFTI_UNIMPLEMENTED	Unimplemented legitimate settings; implementation dependent
DFTI_MKL_INTERNAL_ERROR	Internal library error
DFTI_1D_LENGTH_EXCEEDS_INT32	Length of one of dimensions exceeds $2^{32} - 1$ (4 bytes).

Function `DftiErrorClass` returns a nonzero value (the value of `.TRUE.` in Fortran) if the status belongs to a predefined error class. Note that direct comparison of a status with a predefined class is an incorrect usage. The correct way to check if a function call was successful is through the use of `DftiErrorClass` with a specific error class. However, the zero value of the status belongs to the `DFTI_NO_ERROR` class and thus the zero status indicates successful completion of an operation. See [Example C-22](#) on a correct use of the status checking functions.

Interface and Prototype

```
//Fortran interface
INTERFACE DftiErrorClass
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
  FUNCTION some_actual_function_8( Status, Error_Class )
    LOGICAL some_actual_function_8
    INTEGER, INTENT(IN) :: Status, Error_Class
  END FUNCTION some_actual_function_8
END INTERFACE DftiErrorClass
```

```
/* C prototype */  
MKL_LONG DftiErrorClass( MKL_LONG , MKL_LONG );
```

ErrorMessage

Generates an error message.

Syntax

Fortran:

```
ERROR_MESSAGE = DftiErrorMessage( Status )
```

C:

```
error_message = DftiErrorMessage( status );
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and `mkl_dfti.f90` header file for the Fortran interface. The error message function generates an error message character string. The maximum length of the string in Fortran is given by the named constant `DFTI_MAX_MESSAGE_LENGTH`. The actual error message is implementation dependent. In Fortran, the user needs to use a character string of length `DFTI_MAX_MESSAGE_LENGTH` as the target. In C, the function returns a pointer to a character string, that is, a character array with terminating `'\0'` character.

[Example C-22](#) shows how this function can be used.

Interface and Prototype

```
//Fortran interface
INTERFACE DftiErrorMessage
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
  FUNCTION some_actual_function_9( Status )
  CHARACTER(LEN=DFTI_MAX_MESSAGE_LENGTH) some_actual_function_9( Status )
  INTEGER, INTENT(IN) :: Status
  END FUNCTION some_actual_function_9
END INTERFACE DftiErrorMessage

/* C prototype */
char *DftiErrorMessage( MKL_LONG );
```

Descriptor Manipulation Functions

There are four functions in this category: create a descriptor, commit a descriptor, copy a descriptor, and free a descriptor.

CreateDescriptor

Allocates memory for the descriptor data structure and preliminarily initializes it.

Syntax

Fortran:

```
Status = DftiCreateDescriptor( Desc_Handle, Precision, Forward_Domain, &
                               Dimension, Length )
```

C:

```
status = DftiCreateDescriptor( &desc_handle, precision, forward_domain,
                               dimension, length );
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and `mkl_dfti.f90` header file for the Fortran interface. This function allocates memory for the descriptor data structure and instantiates it with all the default configuration settings with respect to the precision, domain, dimension, and length of the desired transform. The domain is understood to be the domain of the forward transform. Since memory is allocated dynamically, the result is actually a pointer to the created descriptor. This function is slightly different from the "initialization" function in more traditional software packages or libraries used for computing FFT. This function does not perform any significant computational work such as twiddle factors computation. The function [DftiCommitDescriptor](#) does this work after the function [DftiSetValue](#) has set values of all needed parameters.

The precision and (forward) domain are specified through named constants provided in the FFT interface for the configuration values. The choices for precision are `DFTI_SINGLE` and `DFTI_DOUBLE`; and the choices for (forward) domain are `DFTI_COMPLEX` and `DFTI_REAL`. See [Table 11-5](#) for the complete table of named constants for configuration values.

Dimension is a simple positive integer indicating the dimension of the transform. Length is either a simple positive integer for one-dimensional transform, or an integer array (pointer in C) containing the positive integers corresponding to the length dimensions for multi-dimensional transform.

The function returns the zero status when completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```
! Fortran interface.
! Note that the body provided below only illustrates the list of different
! parameters and the types of dummy parameters. You can rely only on the function
! name following keyword INTERFACE. For the precise definition of the
! interface, see the include/mkl_dfti.f90 file in the Intel MKL directory.
```

```
INTERFACE DftiCreateDescriptor

  FUNCTION some_actual_function_1d(desc, precision, domain, dim, length)
    INTEGER :: some_actual_function_1d
    ...
    INTEGER, INTENT(IN) :: length
  END FUNCTION some_actual_function_1d

  FUNCTION some_actual_function_md(desc, precision, domain, dim, lengths)
    INTEGER :: some_actual_function_md
    ...
    INTEGER, INTENT(IN), DIMENSION(*) :: lengths
  END FUNCTION some_actual_function_md

  ...

END INTERFACE DftiCreateDescriptor
```

Note that the function is overloaded, because the actual parameter for the formal parameter *length* can be a scalar or a rank-one array.

The function is also overloaded with respect to the type of the *precision* parameter to provide an option of using a precision-specific function for the generic name. Using more specific functions can reduce the size of statically linked executable for the applications using only single-precision FFTs or only double-precision FFTs. To use this option, change statement "USE MKL_DFTI" in your program unit to either of the following:

```
USE MKL_DFTI, FORGET=>DFTI_SINGLE, DFTI_SINGLE=>DFTI_SINGLE_R
USE MKL_DFTI, FORGET=>DFTI_DOUBLE, DFTI_DOUBLE=>DFTI_DOUBLE_R
```

where the name "FORGET" can be replaced with any name that is not used in the program unit.

```
/* C prototype.
 * Note that the preprocessor definition provided below only illustrates
 * that the actual function called may be determined at compile time.
 * You can rely only on the declaration of the function.
 * For precise definition of the preprocessor macro, see the include/mkl_dfti.h
 * file in the Intel MKL directory.
```

```

*/
MKL_LONG DftiCreateDescriptor(DFTI_DESCRIPTOR_HANDLE * pHandle,
    enum DFTI_CONFIG_VALUE precision,
    enum DFTI_CONFIG_VALUE domain,
    MKL_LONG dimension, ... /* length(s) */ );

#define DftiCreateDescriptor(desc,prec,domain,dim,sizes) \
    ((prec)==DFTI_SINGLE && (dim)==1) ? \
    some_actual_function_sld((desc),(domain),(MKL_LONG)(sizes)) : \
    ...

```

Variable *length(s)* is interpreted as a scalar (MKL_LONG) or an array (MKL_LONG*), depending on the value of parameter *dimension*. If the value of parameter *precision* is known at compile time, then the compiler may retain, at a certain level of optimization, only the call to the respective specific function, thereby reducing the size of the statically linked application. Avoid direct calls to the specific functions used in the preprocessor macro definition, because their interface may change in future releases of the library. If the use of the macro is undesirable, you can safely undefine it after inclusion of the Intel MKL FFT header file, as follows:

```

#include "mkl_dfti.h"
#undef DftiCreateDescriptor

```

CommitDescriptor

Performs all initialization for the actual FFT computation.

Syntax

Fortran:

```
Status = DftiCommitDescriptor( Desc_Handle )
```

C:

```
status = DftiCommitDescriptor( desc_handle );
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and `mkl_dfti.f90` header file for the Fortran interface. The interface requires a function that completes initialization of a previously created descriptor before the descriptor can be used for FFT computations. Typically, this committal performs all initialization that facilitates the actual FFT computation. For a modern implementation, it may involve exploring many different factorizations of the input length to search for highly efficient computation method.

Any changes of configuration parameters of a committed descriptor via the set value function (see [Descriptor Configuration](#)) requires a re-committal of the descriptor before a computation function can be invoked. Typically, this committal function call is immediately followed by a computation function call (see [FFT Computation](#)).

The function returns the zero status when completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```
! Fortran interface
INTERFACE DftiCommitDescriptor
!Note that the body provided here is to illustrate the different
!argument list and types of dummy arguments. The interface
!does not guarantee what the actual function names are.
!Users can only rely on the function name following the
!keyword INTERFACE
  FUNCTION some_actual function_1 ( Desc_Handle )
    INTEGER :: some_actual function_1
    TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
  END FUNCTION some_actual function_1
END INTERFACE DftiCommitDescriptor

/* C prototype */
MKL_LONG DftiCommitDescriptor( DFTI_DESCRIPTOR_HANDLE );
```

CopyDescriptor

Copies an existing descriptor.

Syntax

Fortran:

```
Status = DftiCopyDescriptor( Desc_Handle_Original, Desc_Handle_Copy )
```

C:

```
status = DftiCopyDescriptor( desc_handle_original, &desc_handle_copy );
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and `mkl_dfti.f90` header file for the Fortran interface. This function makes a copy of an existing descriptor and provides a pointer to it. The purpose is that all information of the original descriptor will be maintained even if the original is destroyed via the free descriptor function

`DftiFreeDescriptor`.

The function returns the zero status when completes successfully. The function returns `DFTI_NO_ERROR` when completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```
! Fortran interface
INTERFACE DftiCopyDescriptor
! Note that the body provided here is to illustrate the different
! argument list and types of dummy arguments. The interface
! does not guarantee what the actual function names are.
! Users can only rely on the function name following the
! keyword INTERFACE
    FUNCTION some_actual_function_2( Desc_Handle_Original,
    Desc_Handle_Copy )
    INTEGER :: some_actual_function_2
    TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle_Original, Desc_Handle_Copy
    END FUNCTION some_actual_function_2
END INTERFACE DftiCopyDescriptor

/* C prototype */
MKL_LONG DftiCopyDescriptor( DFTI_DESCRIPTOR_HANDLE, DFTI_DESCRIPTOR_HANDLE * );
```

FreeDescriptor

Frees memory allocated for a descriptor.

Syntax

Fortran:

```
Status = DftiFreeDescriptor( Desc_Handle )
```

C:

```
status = DftiFreeDescriptor( &desc_handle );
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and `mkl_dfti.f90` header file for the Fortran interface. This function frees up all memory space allocated for a descriptor.

NOTE. Memory allocation/deallocation inside Intel MKL is managed by Intel MKL Memory Manager. So, even after successful completion of `FreeDescriptor`, the memory space may continue being allocated for the application because the Memory Manager sometimes does not return the memory space to the OS but considers the space free and can reuse it for future memory allocation. See [Example “MKL_FreeBuffers Usage with FFT Functions”](#) in the description of the service function `FreeBuffers` on how to use Intel MKL Memory Manager and actually release memory.

The function returns the zero status when completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```
! Fortran interface
INTERFACE DftiFreeDescriptor
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
    FUNCTION some_actual_function_3( Desc_Handle )
        INTEGER :: some_actual_function_3
        TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
    END FUNCTION some_actual_function_3
END INTERFACE DftiFreeDescriptor
```

```
/* C prototype */  
MKL_LONG DftiFreeDescriptor( DFTI_DESCRIPTOR_HANDLE * );
```

FFT Computation Functions

There are two functions in this category: compute the forward transform, and compute the backward transform.

ComputeForward

Computes the forward FFT.

Syntax

Fortran:

```
status = DftiComputeForward( desc_handle, x_inout )  
status = DftiComputeForward( desc_handle, x_in, y_out )  
status = DftiComputeForward( desc_handle, xre_inout, xim_inout )  
status = DftiComputeForward( desc_handle, xre_in, xim_in, yre_out, yim_out  
)
```

C:

```
status = DftiComputeForward( desc_handle, x_inout );  
status = DftiComputeForward( desc_handle, x_in, y_out );  
status = DftiComputeForward( desc_handle, xre_inout, xim_inout );  
status = DftiComputeForward( desc_handle, xre_in, xim_in, yre_out, yim_out  
);
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and in the `mkl_dfti.f90` module file for the Fortran interface. The function accepts the descriptor handle parameter and one or more data parameters. Provided the descriptor is configured and

committed successfully, actual computation of the FFT can be performed. Function `DftiComputeForward` computes the forward FFT, that is, the transform with the minus sign in the exponent, $\delta = -1$.

The number and types of the data parameters that the function requires may vary depending on the configuration of the descriptor. This variation is accommodated by the variable parameters in C and the generic interface in Fortran. The generic Fortran interface to the computation function is based on a set of specific functions. These functions can check for inconsistency between the required and actual number of parameters. However, the specific functions disregard the type of the actual parameters and instead use the interpretation defined in the descriptor by configuration parameters `FTI_FORWARD_DOMAIN`, `DFTI_INPUT_STRIDES`, `DFTI_INPUT_DISTANCE`, and so on.

The function returns the zero status when completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```
! Fortran interface.
! Note that the body provided below only illustrates the list of different
! parameters and the types of dummy parameters. You can rely only on the function
! name following keyword INTERFACE. For the precise definition of the
! interface, see the include/mkl_dfti.f90 file in the Intel MKL directory.
INTERFACE DftiComputeForward

    FUNCTION some_actual_function_1(desc,sSrcDst)
        INTEGER some_actual_function_1
        REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDst
        ...
    END FUNCTION some_actual_function_1

    FUNCTION some_actual_function_2(desc,cSrcDst)
        INTEGER some_actual_function_2
        COMPLEX(8), INTENT(INOUT), DIMENSION(*) :: cSrcDst
        ...
    END FUNCTION some_actual_function_2

    FUNCTION some_actual_function_3(desc,sSrcDstRe,sSrcDstIm)
        INTEGER some_actual_function_3
        REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstRe
        REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstIm
        ...
    END FUNCTION some_actual_function_3
    ...
END INTERFACE DftiComputeForward
```

Fortran interface requires that the data parameters have the type of assumed-size rank-1 array, even for multidimensional transforms. The implementations of the FFT interface require the data stored linearly in memory with a regular "stride" pattern capable to describe multidimensional array layout (discussed more fully in [Strides](#), see also [3]), and the function requires the data parameters refer to the first element of the data. Consequently, the data arrays should be specified with the `DIMENSION(*)` attribute and the storage associated with the actual multidimensional arrays via the `EQUIVALENCE` statement.

```
/* C prototype */
MKL_LONG DftiComputeForward( DFTI_DESCRIPTOR_HANDLE, void*, ... );
```

ComputeBackward

Computes the backward FFT.

Syntax

Fortran:

```
status = DftiComputeBackward( desc_handle, x_inout )
status = DftiComputeBackward( desc_handle, y_in, x_out )
status = DftiComputeBackward( desc_handle, xre_inout, xim_inout )
status = DftiComputeBackward( desc_handle, yre_in, yim_in, xre_out, xim_out )
```

C:

```
status = DftiComputeBackward( desc_handle, x_inout );
status = DftiComputeBackward( desc_handle, y_in, x_out );
status = DftiComputeBackward( desc_handle, xre_inout, xim_inout );
status = DftiComputeBackward( desc_handle, yre_in, yim_in, xre_out, xim_out );
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and `mkl_dfti.f90` module file for the Fortran interface. The function accepts the descriptor handle parameter and one or more data parameters. Provided the descriptor is configured and committed successfully, actual computation of the FFT can be performed. Function `DftiComputeBackward` computes the inverse FFT, that is, the transform with the plus sign in the exponent, $\delta = +1$.

The number and types of the data parameters that the function requires may vary depending on the configuration of the descriptor. This variation is accommodated by the variable parameters in C and the generic interface in Fortran. The generic Fortran interface to the computation function is based on a set of specific functions. These functions can check for inconsistency between the required and actual number of parameters. However, the specific functions disregard the type of the actual parameters and instead use the interpretation defined in the descriptor by configuration parameters `DFTI_FORWARD_DOMAIN`, `DFTI_INPUT_STRIDES`, `DFTI_INPUT_DISTANCE`, and so on.

The function returns the zero status when completes successfully. See [Status Checking Functions](#) for more information on the returned status.

MKL_LONG DftiComputeBackward( DFTI_DESCRIPTOR_HANDLE, void *, ... );

```

Descriptor Configuration Functions

There are two functions in this category: the value setting function [DftiSetValue](#) sets one particular configuration parameter to an appropriate value, and the value getting function [DftiGetValue](#) reads the value of one particular configuration parameter. While all configuration parameters are readable, a few of them cannot be set by user. Some of these contain fixed information of a particular implementation such as version number, or dynamic information, but nevertheless are derived by the implementation during execution of one of the functions. See [Configuration Settings](#) for details.

SetValue

Sets one particular configuration parameter with the specified configuration value.

Syntax

Fortran:

```
Status = DftiSetValue( Desc_Handle, Config_Param, Config_Val )
```

C:

```
status = DftiSetValue( desc_handle, config_param, config_val );
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and `mkl_dfti.f90` header file for the Fortran interface. This function sets one particular configuration parameter with the specified configuration value. The configuration parameter is one of the named constants listed in [Table 11-3](#), and the configuration value must have the corresponding type, which can be a named constant or a native type. See [Configuration Settings](#) for details of the meaning of the setting. Note that you can set configuration parameters `DFTI_FORWARD_DOMAIN`, `DFTI_PRECISION`, `DFTI_DIMENSION`, and `DFTI_LENGTHS` only through the [DftiCreateDescriptor](#) function. The `DftiSetValue` function does not change these parameters.

The function returns the zero status when completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```
! Fortran interface
INTERFACE DftiSetValue
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
FUNCTION some_actual_function_6_INTVAL( Desc_Handle, Config_Param, INTVAL )

END INTERFACE DftiSetValue
```

```
/* C prototype */  
MKL_LONG DftiSetValue( DFTI_DESCRIPTOR_HANDLE, DFTI_CONFIG_PARAM , ... );
```

GetValue

Gets the configuration value of one particular configuration parameter.

Syntax

Fortran:

```
Status = DftiGetValue( Desc_Handle, Config_Param, Config_Val )
```

C:

```
status = DftiGetValue( desc_handle, config_param, &config_val );
```

Description

The function is declared in the `mkl_dfti.h` header file for the C interface and `mkl_dfti.f90` header file for the Fortran interface. This function gets the configuration value of one particular configuration parameter. The configuration parameter is one of the named constants listed in [Table 11-3](#) and [Table 11-4](#), and the configuration value is the corresponding appropriate type, which can be a named constant or a native type.

The function returns the zero status when completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

END FUNCTION some_actual_function_7_CHARS
END INTERFACE DftiGetValue

/* C prototype */
MKL_LONG DftiGetValue( DFTI_DESCRIPTOR_HANDLE,
    DFTI_CONFIG_PARAM ,
    ... );

```

Configuration Settings

Each of the configuration parameters is identified by a named constant in the `MKL_DFTI` module. In C, these named constants have the enumeration type `DFTI_CONFIG_PARAM`. The list of configuration parameters whose values can be set by user is given in [Table 11-3](#); the list of configuration parameters that are read-only is given in [Table 11-4](#). All parameters are readable. Most of these parameters are self-explanatory, while some others are discussed more fully in the description of the relevant functions.

Table 11-3 Settable Configuration Parameters

Named Constants	Value Type	Comments
<i>Most common configurations, no default, must be set explicitly</i>		
<code>DFTI_FORWARD_DOMAIN</code>	Named constant	Domain for the forward transform, settable by <code>DftiCreateDescriptor</code> only
<code>DFTI_PRECISION</code>	Named constant	Precision of computation, settable by <code>DftiCreateDescriptor</code> only
<code>DFTI_DIMENSION</code>	Integer scalar	Dimension of the transform, settable by <code>DftiCreateDescriptor</code> only
<code>DFTI_LENGTHS</code>	Integer scalar/array	Lengths of each dimension, settable by <code>DftiCreateDescriptor</code> only
<i>Common configurations including multiple transform and data representation</i>		
<code>DFTI_NUMBER_OF_TRANSFORMS</code>	Integer scalar	For multiple number of transforms
<code>DFTI_FORWARD_SCALE</code>	Floating-point scalar	Scale factor for forward transform
<code>DFTI_BACKWARD_SCALE</code>	Floating-point scalar	Scale factor for backward transform

Named Constants	Value Type	Comments
DFTI_PLACEMENT	Named constant	Placement of the computation result
DFTI_COMPLEX_STORAGE	Named constant	Storage method, complex domain data
DFTI_REAL_STORAGE	Named constant	Storage method, real domain data
DFTI_CONJUGATE_EVEN_STORAGE	Named constant	Storage method, conjugate-even domain data
DFTI_DESCRIPTOR_NAME	Character string	No longer than DFTI_MAX_NAME_LENGTH
DFTI_PACKED_FORMAT	Named constant	Packed format, real domain data
DFTI_NUMBER_OF_USER_THREADS	Integer scalar	Number of user threads employing the same descriptor for FFT computation
<i>Configurations regarding stride of data</i>		
DFTI_INPUT_DISTANCE	Integer scalar	Multiple transforms, distance of first elements
DFTI_OUTPUT_DISTANCE	Integer scalar	Multiple transforms, distance of first elements
DFTI_INPUT_STRIDES	Integer array	Stride information of input data
DFTI_OUTPUT_STRIDES	Integer array	Stride information of output data
<i>Advanced configuration</i>		
DFTI_ORDERING	Named constant	Scrambling of data order
DFTI_TRANSPOSE	Named constant	Scrambling of dimensions

Table 11-4 Read-Only Configuration Parameters

Named Constants	Value Type	Comments
DFTI_COMMIT_STATUS	Name constant	Whether descriptor has been committed
DFTI_VERSION	String	Intel MKL library version number

The configuration parameters are set by various values. Some of these values are specified by native data types such as an integer value (for example, number of simultaneous transforms requested), or a single-precision number (for example, the scale factor one would like to apply on a forward transform).

Other configuration values are discrete in nature (for example, the domain of the forward transform) and are thus provided in the DFTI module as named constants. In C, these named constants have the enumeration type `DFTI_CONFIG_VALUE`. The complete list of named constants used for this kind of configuration values is given in [Table 11-5](#).

Table 11-5 Named Constant Configuration Values

Named Constant	Comments
DFTI_SINGLE	Single precision
DFTI_DOUBLE	Double precision
DFTI_COMPLEX	Complex domain
DFTI_REAL	Real domain
DFTI_INPLACE	Output overwrites input
DFTI_NOT_INPLACE	Output does not overwrite input
DFTI_COMPLEX_COMPLEX	Storage method (see Storage schemes)
DFTI_REAL_REAL	Storage method (see Storage schemes)
DFTI_COMPLEX_REAL	Storage method (see Storage schemes)
DFTI_REAL_COMPLEX	Storage method (see Storage schemes)
DFTI_COMMITTED	Committal status of a descriptor
DFTI_UNCOMMITTED	Committal status of a descriptor

Named Constant	Comments
DFTI_ORDERED	Data ordered in both forward and backward domains
DFTI_BACKWARD_SCRAMBLED	Data scrambled in backward domain (by forward transform)
DFTI_NONE	Used to specify no transposition
DFTI_ALLOW	Transposition of the result of a transform
DFTI_CCS_FORMAT	Packed format, real data (see Packed formats)
DFTI_PACKED_FORMAT	Packed format, real data (see Packed formats)
DFTI_PERM_FORMAT	Packed format, real data (see Packed formats)
DFTI_CCE_FORMAT	Packed format, real data (see Packed formats)
DFTI_VERSION_LENGTH	Number of characters for library version length
DFTI_MAX_NAME_LENGTH	Maximum descriptor name length
DFTI_MAX_MESSAGE_LENGTH	Maximum status message length

Table 11-6 lists the possible values for those configuration parameters that are discrete in nature.

Table 11-6 Settings for Discrete Configuration Parameters

Named Constant	Possible Values
DFTI_PRECISION	DFTI_SINGLE, or DFTI_DOUBLE (no default)
DFTI_FORWARD_DOMAIN	DFTI_COMPLEX, or DFTI_REAL
DFTI_PLACEMENT	DFTI_INPLACE (default), or DFTI_NOT_INPLACE
DFTI_COMPLEX_STORAGE	DFTI_COMPLEX_COMPLEX (default)

Named Constant	Possible Values
DFTI_REAL_STORAGE	DFTI_REAL_REAL (default), or DFTI_REAL_COMPLEX
DFTI_CONJUGATE_EVEN_STORAGE	DFTI_COMPLEX_COMPLEX, or DFTI_COMPLEX_REAL (default)
DFTI_PACKED_FORMAT	DFTI_CCS_FORMAT (default), or DFTI_PACK_FORMAT, or DFTI_PERM_FORMAT, or DFTI_CCE_FORMAT
DFTI_ORDERING	DFTI_ORDERED (default), or DFTI_BACKWARD_SCRAMBLED
DFTI_TRANSPOSE	DFTI_NONE (default), or DFTI_ALLOW

Table 11-7 lists the default values of the settable configuration parameters.

Table 11-7 Default Configuration Values of Settable Parameters

Named Constants	Default Value
DFTI_NUMBER_OF_TRANSFORMS	1
DFTI_NUMBER_OF_USER_THREADS	1
DFTI_FORWARD_SCALE	1.0
DFTI_BACKWARD_SCALE	1.0
DFTI_PLACEMENT	DFTI_INPLACE
DFTI_COMPLEX_STORAGE	DFTI_COMPLEX_COMPLEX
DFTI_REAL_STORAGE	DFTI_REAL_REAL
DFTI_CONJUGATE_EVEN_STORAGE	DFTI_COMPLEX_REAL

Named Constants	Default Value
DFTI_PACKED_FORMAT	DFTI_CCS_FORMAT
DFTI_DESCRIPTOR_NAME	no name, string of zero length
DFTI_INPUT_DISTANCE	0
DFTI_OUTPUT_DISTANCE	0
DFTI_INPUT_STRIDES	Tightly packed according to dimension and FFT lengths
DFTI_OUTPUT_STRIDES	Same as above. see Strides for details
DFTI_ORDERING	DFTI_ORDERED
DFTI_TRANSPOSE	DFTI_NONE

Precision of transform

The configuration parameter `DFTI_PRECISION` denotes the floating-point precision in which the transform is to be carried out. A setting of `DFTI_SINGLE` stands for single precision, and a setting of `DFTI_DOUBLE` stands for double precision. The data is meant to be presented in this precision; the computation will be carried out in this precision; and the result will be delivered in this precision. This is one of the four settable configuration parameters that do not have default values. The user must set them explicitly, most conveniently at the call to descriptor creation function [DftiCreateDescriptor](#).

Fortran module `MKL_DFTI` also defines named constants `DFTI_SINGLE_R` and `DFTI_DOUBLE_R`, with the same semantics as `DFTI_SINGLE` and `DFTI_DOUBLE`, respectively. These constants are *not recommended for direct use*. They only facilitate access to precision-specific functions for the generic name `DftiCreateDescriptor` through the modification of the "USE MKL_DFTI" statement, as described in section [CreateDescriptor](#).

Forward domain of transform

As already mentioned in the introduction to the Fourier Transform Functions chapter, the general form of the discrete Fourier transform is

$$z_{k_1, k_2, \dots, k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \dots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1, j_2, \dots, j_d} \exp \left(\delta i 2\pi \sum_{l=1}^d j_l k_l / n_l \right)$$

where w is the input sequence, z is the output sequence, both indexed by $k_l = 0, \dots, n_l-1$, for $l = 1, \dots, d$, scale factor σ is an arbitrary real number with the default value of 1.0, and the sign in the exponent is $\delta = -1$ for the forward transform and $\delta = +1$ for the backward transform.

The implementation of FFT supports forward transforms on input sequences of two domains, as specified by configuration parameter `DFTI_FORWARD_DOMAIN`: general complex-valued sequences (`DFTI_COMPLEX` domain) and general real-valued sequences (`DFTI_REAL` domain). The forward transform maps the forward domain to the corresponding backward domain, as shown in [Table 11-8](#), where the conjugate-even domain covers complex-valued sequences with the symmetry property:

$$x_{k_1, k_2, \dots, k_d} = \overline{x_{n_1-k_1, n_2-k_2, \dots, n_d-k_d}}$$

Here the overline denotes the complex conjugate, and it is assumed that

$$x_{\dots, n_l, \dots} \equiv x_{\dots, 0, \dots}$$

Due to this property of conjugate-even sequences, only a part of such sequence is stored in the computer memory, as described in [Storage schemes](#).

Table 11-8 Correspondence of Forward and Backward Domain

Forward Domain	Implied Backward Domain
Complex (<code>DFTI_COMPLEX</code>)	Complex (<code>DFTI_COMPLEX</code>)
Real (<code>DFTI_REAL</code>)	Conjugate-even

`DFTI_FORWARD_DOMAIN` is the second of four configuration parameters without a default value.

Transform dimension and lengths

The dimension of the transform is a positive integer value represented in an integer scalar of `Integer` data type in Fortran and `MKL_LONG` data type in C. For one-dimensional transform, the transform length is specified by a positive integer value represented in an integer scalar of `Integer` data type in Fortran and `MKL_LONG` data type in C. For multi-dimensional (≥ 2) transform, the lengths of each of the dimension is supplied in an integer array (`Integer` data type in Fortran and `MKL_LONG` data type in C). `DFTI_DIMENSION` and `DFTI_LENGTHS` are the remaining two of four configuration parameters without default.

As mentioned, these four configuration parameters do not have default value. They are most conveniently set at the descriptor creation function. They can only be set in the descriptor creation function, and not by the function `DftiSetValue`.

Number of transforms

In some situations, the user may need to perform a number of FFTs of the same dimension and lengths. The most common situation would be to transform a number of one-dimensional data of the same length. This parameter has the default value of 1, and can be set to positive integer value by an `Integer` data type in Fortran and `MKL_LONG` data type in C. Data sets have no common elements. The distance parameter is obligatory if multiple number is more than one.

Scale

The forward transform and backward transform are each associated with a scale factor σ of its own with default value of 1. The user can set one or both of them via the two configuration parameters `DFTI_FORWARD_SCALE` and `DFTI_BACKWARD_SCALE`. For example, for a one-dimensional transform of length n , one can use the default scale of 1 for the forward transform while setting the scale factor for backward transform to be $1/n$, making the backward transform the inverse of the forward transform.

The scale factor configuration parameter should be set by a real floating-point data type of the same precision as the value for `DFTI_PRECISION`.

Placement of result

By default, the computational functions overwrite the input data with the output result. That is, the default setting of the configuration parameter `DFTI_PLACEMENT` is `DFTI_INPLACE`. The user can change that by setting it to `DFTI_NOT_INPLACE`. Data sets have no common elements.

Packed formats

The result of the forward transform (i.e. in the frequency-domain) of real data is represented in several possible packed formats: **Pack**, **Perm**, **CCS**, or **CCE**. The data can be packed due to the symmetry property of the FFT of a real data.

The **CCE** format stores the values of the first half of the output complex conjugate-even signal resulted from the forward FFT. Note that the one-dimensional signal stored in **CCE** format is one complex element longer. For multi-dimensional real transform, $n_1 * n_2 * n_3 * \dots * n_k$ the size of complex matrix in **CCE** format is $(n_1/2+1) * n_2 * n_3 * \dots * n_k$ for Fortran and $n_1 * n_2 * \dots * (n_k/2+1)$ for C.

The **CCS** format looks like the **CCE** format. It is the same format as **CCE** for one-dimensional transform. The **CCS** format is slightly different for multi-dimensional real transform. In **CCS** format, the output samples of the FFT are arranged as shown in [Table 11-9](#) for one-dimensional FFT and in [Table 11-10](#) for two-dimensional FFT.

The **Pack** format is a compact representation of a complex conjugate-symmetric sequence. The disadvantage of this format is that it is not the natural format used by the real FFT algorithms ("natural" in the sense that array is natural for complex FFTs). In **Pack** format, the output samples of the FFT are arranged as shown in [Table 11-9](#) for one-dimensional FFT and in [Table 11-11](#) for two-dimensional FFT.

The **Perm** format is an arbitrary permutation of the **Pack** format for even lengths and one is the same as the **Pack** format for odd lengths. In **Perm** format, the output samples of the FFT are arranged as shown in [Table 11-9](#) for one-dimensional FFT and in [Table 11-12](#) for two-dimensional FFT.

Table 11-9 Packed Format Output Samples

For $n = s*2$										
FFT Real	0	1	2	3	...	n-2	n-1	n	n+1	
CCS	R_0	0	R_1	I_1	...	$R_{n/2-1}$	$I_{n/2-1}$	$R_{n/2}$	0	
Pack	R_0	R_1	I_1	R_2	...	$I_{n/2-1}$	$R_{n/2}$			
Perm	R_0	$R_{n/2}$	R_1	I_1	...	$R_{n/2-1}$	$I_{n/2-1}$			

For $n = s*2 + 1$											
FFT Real	0	1	2	3	...	n-4	n-3	n-2	n-1	n	n+1
CCS	R_0	0	R_1	I_1	...	I_{s-2}	R_{s-1}	I_{s-1}	R_s	I_s	

For $n = s*2 + 1$

Pack	R_0	R_1	I_1	R_2	...	R_{s-1}	I_{s-1}	R_s	I_s
Perm	R_0	R_1	I_1	R_2	...	R_{s-1}	I_{s-1}	R_s	I_s

Note that [Table 11-9](#) uses the following notation for complex data entries:

$$R_j = \text{Re } z_j$$

$$I_j = \text{Im } z_j$$

See also [Table 11-13](#) and [Table 11-14](#).

Note that in the [Table 11-11](#) and [Table 11-12](#), for even number of columns $n = k*2$, while for odd number of columns $n = k*2+1$ and the first row is

$z(1,1) \ REz(1,2) \ IMz(1,2) \ \dots \ REz(1,k) \ IMz(1,k)$

If m is even, the last row in `Pack` format and the second row in `Perm` format is

$z(m/2+1,1) \ REz(m/2+1,2) \ IMz(m/2+1,2) \ \dots \ REz(m/2+1,k) \ IMz(m/2+1,k)$

The tables for two-dimensional FFT use Fortran-interface conventions. For C-interface specifics in storing packed data, see [Storage schemes](#) section below. See also [Table 11-15](#) and [Table 11-16](#) for examples of Fortran-interface and C-interface formats.

Storage schemes

Depending on the value of configuration parameter `DFTI_FORWARD_DOMAIN`, the implementation of FFT supports several storage schemes for input and output data (see document [3] for the rationale behind the definition of the storage schemes). The data elements are placed within contiguous memory blocks, defined with generalized strides (see [Strides](#)). For multiple transforms an `nth` set of data (`nth` begins with zero) should be located within the same memory block, and the data sets are placed at a `distance` from each other (see [Number of transforms](#) and [Input and output distances](#)).

NOTE. In C/C++, avoid setting up multidimensional arrays with lists of pointers to one-dimensional arrays. Instead use a one-dimensional array with the explicit indexing to access the data elements.

The C/C++ notation is used to precisely describe association of mathematical entities with the data elements stored in memory. [FFT Examples](#) demonstrate the usage of storage formats in C and Fortran.

Storage schemes for complex domain. For the `DFTI_COMPLEX` forward domain, both input and output sequences belong to the complex domain. In this case, configuration parameter `DFTI_COMPLEX_STORAGE` can have one of the two values: `DFTI_COMPLEX_COMPLEX` (default) or `DFTI_REAL_REAL`.

NOTE. In the Intel MKL FFT implementation, storage schemes for a forward complex domain and the respective backward complex domain are the same.

With `DFTI_COMPLEX_COMPLEX` storage, the complex-valued data sequence is referenced by a single data parameter `z` associated with the complex type so that complex-valued element z_{k_1, k_2, \dots, k_d} of the sequence is located at `z[nth*distance + stride0 + k1*stride1 + k2*stride2 + ... kd*strided]` as a structure consisting of the real and imaginary parts.

The following example illustrates a typical usage of the `DFTI_COMPLEX_COMPLEX` storage:

```
complex :: x(n)
...
! on input, for i=1,...,N: x(i) = wi-1
status = DftiComputeForward( desc_handle, x )
! on output, for i=1,...,N: x(i) = zi-1
```

With the `DFTI_REAL_REAL` storage, the complex-valued data sequence is referenced by two data parameters `ZRe` and `ZIm`, both associated with the real type so that complex-valued element z_{k_1, k_2, \dots, k_d} of the sequence is computed as $ZRe[nth*distance + stride_0 + k_1*stride_1 + k_2*stride_2 + \dots + k_d*stride_d] + \sqrt{-1} \times ZIm[nth*distance + stride_0 + k_1*stride_1 + k_2*stride_2 + \dots + k_d*stride_d]$.

A typical usage of the `DFTI_REAL_REAL` storage is illustrated by the following example:

```
real :: xre(n), xim(n)
...
status = DftiSetValue( desc_handle, DFTI_COMPLEX_STORAGE, DFTI_REAL_REAL)
! on input, for i=1,...,N: cmplx(xre(i),xim(i)) = wi-1
status = DftiComputeForward( desc_handle, xre, xim )
! on output, for i=1,...,N: cmplx(xre(i),xim(i)) = zi-1
```

Storage scheme for the real and conjugate-even domains. This setting for the storage schemes for these domains is recorded in the configuration parameters `DFTI_REAL_STORAGE` and `DFTI_CONJUGATE_EVEN_STORAGE`. Since a forward real domain corresponds to a conjugate-even backward domain, they are considered together. The example uses [one-](#), [two-](#) and [three-dimensional](#) real to conjugate-even transforms. In-place computation is assumed whenever possible (that is, when the input data type matches the output data type).

One-Dimensional Transform

Consider a one-dimensional n -length transform of the form

$$z_k = \sum_{j=0}^{n-1} w_j e^{-i2\pi jk/n}, \quad w_j \in R, z_k \in C.$$

There is a symmetry:

For even n : $z(n/2+i) = \text{conjg}(z(n/2-i)), 1 \leq i \leq n/2-1$, and moreover $z(0)$ and $z(n/2)$ are real values.

For odd n : $z(m+i) = \text{conjg}(z(m-i+1)), 1 \leq i \leq m$, and moreover $z(0)$ is real value.

$m = \text{floor}(n/2)$.

Assume that the stride has the default value (unit stride).

This complex conjugate-symmetric vector can be stored in the complex array of size $m+1$ or in the real array of size $2m+2$ or $2m$ depending on packed format.

Two-Dimensional Transform

Each of the real-to-complex functions computes the forward FFT of a two-dimensional real matrix according to the mathematical equation

$$z_{i,j} = \sum_{k=0}^{m-1} \sum_{l=0}^{n-1} t_{k,l} * W_m^{-i*k} * W_n^{-j*l},$$

$$0 \leq i \leq m-1, 0 \leq j \leq n-1$$

$t_{k,l} = \text{cmplx}(r_{k,l}, 0)$, where $r_{k,l}$ is a real input matrix, $0 \leq k \leq m-1$, $0 \leq l \leq n-1$. The mathematical result $z_{i,j}$, $0 \leq i \leq m-1$, $0 \leq j \leq n-1$, is the complex matrix of size (m, n) . Each column is the complex conjugate-symmetric vector as follows:

For even m :

for $0 \leq j \leq n-1$,

$$z(m/2+i, j) = \text{conjg}(z(m/2-i, j)), 1 \leq i \leq m/2-1.$$

Moreover, $z(0, j)$ and $z(m/2, j)$ are real values for $j=0$ and $j=n/2$.

For odd m :

for $0 \leq j \leq n-1$,

$z(s+i, j) = \text{conjg}(z(s-i, j)), 1 \leq i \leq s-1$,

where $s = \text{floor}(m/2)$.

Moreover, $z(0, j)$ are real values for $j=0$ and $j=n/2$.

This mathematical result can be stored in the real two-dimensional array of size:

$(m+2, n+2)$ (CCS format), or

(m, n) (Pack or Perm formats), or

$(2 * (m/1+1), n)$ (CCE format, Fortran-interface),

$((m, 2 * (n/2+1)))$ (CCE format, C-interface)

or in the complex two-dimensional array of size:

$(m/2+1, n)$ (CCE format, Fortran-interface),

$(m, n/2+1)$ (CCE format, C-interface)

Since the multidimensional array data are arranged differently in Fortran and C (see [Strides](#)), the output array that holds the computational result contains complex conjugate-symmetric columns (for Fortran) or complex conjugate-symmetric rows (for C).

The following tables give examples of output data layout in `Pack` format for a forward two-dimensional real-to-complex FFT of a 6-by-4 real matrix. Note that the same layout is used for the input data of the corresponding backward complex-to-real FFT.

Table 11-15 Fortran-interface Data Layout for a 6-by-4 Matrix

$z(1,1)$	$\text{Re } z(1,2)$	$\text{Im } z(1,2)$	$z(1,3)$
$\text{Re } z(2,1)$	$\text{Re } z(2,2)$	$\text{Re } z(2,3)$	$\text{Re } z(2,4)$
$\text{Im } z(2,1)$	$\text{Im } z(2,2)$	$\text{Im } z(2,3)$	$\text{Im } z(2,4)$
$\text{Re } z(3,1)$	$\text{Re } z(3,2)$	$\text{Re } z(3,3)$	$\text{Re } z(3,4)$
$\text{Im } z(3,1)$	$\text{Im } z(3,2)$	$\text{Im } z(3,3)$	$\text{Im } z(3,4)$
$z(4,1)$	$\text{Re } z(4,2)$	$\text{Im } z(4,2)$	$z(4,3)$

For the above example, the stride array is taken to be (0, 1, 6).

Table 11-16 C-interface Data Layout for a 6-by-4 Matrix

z(1,1)	Re z(1,2)	Im z(1,2)	z(1,3)
Re z(2,1)	Re z(2,2)	Im z(2,2)	Re z(2,3)
Im z(2,1)	Re z(3,2)	Im z(3,2)	Im z(2,3)
Re z(3,1)	Re z(4,2)	Im z(4,2)	Re z(3,3)
Im z(3,1)	Re z(5,2)	Im z(5,2)	Im z(3,3)
z(4,1)	Re z(6,2)	Im z(6,2)	z(4,3)

For the second example, the stride array is taken to be (0, 4, 1).

See also [Packed formats](#).

Three-Dimensional Transform

Each of the real-to-complex functions computes the forward FFT of a three-dimensional real matrix according to the mathematical equation

$$z_{i,j,q} = \sum_{k=0}^{m-1} \sum_{l=0}^{n-1} \sum_{s=0}^{k-1} t_{p,l,s} * W_m^{-i*p} * W_n^{-j*l} * W_k^{-q*s},$$

$$0 \leq i \leq m-1, 0 \leq j \leq n-1, 0 \leq s \leq k-1$$

$t_{p,l,s} = \text{cmplx}(r_{p,l,s}, 0)$, where $r_{p,l,s}$ is a real input matrix, $0 \leq k \leq m-1$, $0 \leq l \leq n-1$, $0 \leq s \leq k-1$. The mathematical result $z_{i,j,q}$, $0 \leq i \leq m-1$, $0 \leq j \leq n-1$, $0 \leq q \leq k-1$ is the complex matrix of size (m, n, k) , which is a complex conjugate-symmetric, or conjugate-even, matrix as follows:

$z_{m1,n1,k1} = \text{conjg}(z_{m-m1,n-n1,k-k1})$, where each dimension is periodic.

This mathematical result can be stored in the real three-dimensional array of size:

$(m/2+1, n, k)$ (CCE format, Fortran-interface),

$(m, n, k/2+1)$ (CCE format, C-interface).

Since the multidimensional array data are arranged differently in Fortran and C (see [Strides](#)), the output array that holds the computational result contains complex conjugate-symmetric columns (for Fortran) or complex conjugate-symmetric rows (for C).

NOTE. There is one packed format for 3D REAL FFT - CCE format. In both in-place and out-of-place REAL FFT, for real data, the stride and distance parameters are in `REAL` units and for complex data, they are in `COMPLEX` units. So, elements of input and output data can be placed in different elements of input-output array of the in-place FFT.

1. DFTI_REAL_REAL for real domain, **DFTI_COMPLEX_REAL** for conjugate-even domain (by default). It is used for 1D and 2D REAL FFT.

- A typical usage of in-place transform is as follows:

```
// m = floor( n/2 )
REAL :: X(0:2*m+1)
...some other code...
...assuming inplace transform...
Status = DftiComputeForward( Desc_Handle, X )
```

On input,

$$X(j) = w_j, \quad j = 0, 1, \dots, n-1.$$

On output,

Output data stored in one of formats: `Pack`, `Perm` or `CCS` (see [Packed formats](#)).

CCS format: $X(2*k) = \text{Re}(z_k)$, $X(2*k+1) = \text{Im}(z_k)$, $k = 0, 1, \dots, m$.

Pack format:

even n: $X(0) = \text{Re}(z_0)$, $X(2*k-1) = \text{Re}(z_k)$, $X(2*k) = \text{Im}(z_k)$, $k = 1, \dots, m-1$,
and $X(n-1) = \text{Re}(z_m)$

odd n: $X(0) = \text{Re}(z_0)$, $X(2*k-1) = \text{Re}(z_k)$, $X(2*k) = \text{Im}(z_k)$, $k = 1, \dots, m$

Perm format:

even n: $X(0) = \text{Re}(z_0)$, $X(1) = \text{Re}(z_m)$, $X(2*k) = \text{Re}(z_k)$, $X(2*k+1) = \text{Im}(z_k)$,
 $k = 1, \dots, m-1$,

odd n: $X(0) = \text{Re}(z_0)$, $X(2*k-1) = \text{Re}(z_k)$, $X(2*k) = \text{Im}(z_k)$, $k = 1, \dots, m$.

See [Example C-16](#), [Example C-17](#), [Example C-18](#), and [Example C-19](#).

Input and output data exchange the roles in the backward transform.

- A typical usage of out-of-place transform is as follows:

```
// m = floor( n/2 )
REAL :: X(0:n-1)
REAL :: Y(0:2*m+1)
...some other code...
...assuming out-of-place transform...
Status = DftiComputeForward( Desc_Handle, X, Y )
```

On input, $X(j) = w_j$, $j = 0, 1, \dots, n-1$.

On output,

Output data stored in one of formats: `Pack`, `Perm` or `CCS` (see [Packed formats](#)).

CCS format: $Y(2*k) = \text{Re}(z_k)$, $Y(2*k+1) = \text{Im}(z_k)$, $k = 0, 1, \dots, m$.

Pack format:

even n : $Y(0) = \text{Re}(z_0)$, $Y(2*k-1) = \text{Re}(z_k)$, $Y(2*k) = \text{Im}(z_k)$, $k = 1, \dots, m-1$,
and $Y(n-1) = \text{Re}(z_m)$

odd n : $Y(0) = \text{Re}(z_0)$, $Y(2*k-1) = \text{Re}(z_k)$, $Y(2*k) = \text{Im}(z_k)$, $k = 1, \dots, m$

Perm format:

even n : $Y(0) = \text{Re}(z_0)$, $Y(1) = \text{Re}(z_m)$, $Y(2*k) = \text{Re}(z_k)$, $Y(2*k+1) = \text{Im}(z_k)$,
 $k = 1, \dots, m-1$,

odd n : $Y(0) = \text{Re}(z_0)$, $Y(2*k-1) = \text{Re}(z_k)$, $Y(2*k) = \text{Im}(z_k)$, $k = 1, \dots, m$.

Notice that if the stride of the output array is not set to the default value unit stride, the real and imaginary parts of one complex element will be placed with this stride.

For example:

CCS format: $Y(2*k*s) = \text{Re}(z_k)$, $Y((2*k+1)*s) = \text{Im}(z_k)$, $k = 0, 1, \dots, m$, s - stride.

See [Example C-16a](#) and [Example C-17a](#).

Input and output data exchange the roles in the backward transform.

2. DFTI_REAL_REAL for real domain, **DFTI_COMPLEX_COMPLEX** for conjugate-even domain. It is used for 1D, 2D and 3D REAL FFT. The CCE format is set by default. You must explicitly set the storage scheme in this case, because its value is not the default one.

- A typical usage of in-place transform is as follows:

```
// m = floor( n/2 )
REAL :: X(0:m*2)
...some other code...
...assuming in-place transform...
Status = DftiSetValue( Desc_Handle, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX)
...
Status = DftiComputeForward( Desc_Handle, X)
```

On input,

$X(j) = w_j, j = 0, 1, \dots, n-1.$

On output,

$X(2*k) = \text{Re}(z_k), X(2*k+1) = \text{Im}(z_k), k = 0, 1, \dots, m.$

See [Example C-24](#).

Input and output data exchange the roles in the backward transform.

- A typical usage of out-of-place transform is as follows:

```
// m = floor( n/2 )
REAL :: X(0:n-1)
COMPLEX :: Y(0:m)
...some other code...
...assuming out-of-place transform...
Status = DftiSetValue( Desc_Handle, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX)
...
Status = DftiComputeForward( Desc_Handle, X, Y )
```

On input,

$X(j) = w_j, j = 0, 1, \dots, n-1.$

On output,

$$Y(k) = z_k, \quad k = 0, 1, \dots, m.$$

See [Example C-24a](#) and [Example C-25](#)

Input and output data exchange the roles in the backward transform.

- 3. DFTI_REAL_COMPLEX** for real domain, **DFTI_COMPLEX_COMPLEX** for conjugate-even domain. It is not used in the current version. See [Note in the "FFT Interface" section](#) for details. A typical usage is as follows:

```
// m = floor( n/2 )
COMPLEX :: X(0:m)
...some other code...
...inplace transform...
Status = DftiComputeForward( Desc_Handle, X )
```

On input,

$$X(j) = w_j, \quad j = 0, 1, \dots, n-1.$$

That is, the imaginary parts of $X(j)$ are zero.

On output,

$$Y(k) = z_k, \quad k = 0, 1, \dots, m,$$

where m is `floor(n/2)`.

Number of user threads

Customer application can be parallelized by using the following techniques:

- a.** You do not create threads in your application but specify the parallel mode within the FFT module of Intel MKL. See *Intel MKL User's Guide* for more information on how to do this. See also [Example C-26 in Appendix C](#).
- b.** You create threads in the application yourself and have each thread perform all stages of FFT implementation, including descriptor initialization, FFT computation, and descriptor deallocation. In this case, each descriptor is used only within its corresponding thread. It is recommended to set single-threaded mode for Intel MKL. See [Example C-27 in Appendix C](#).
- c.** You create threads in the application yourself after initializing all FFT descriptors. This implies that threading is employed for parallel FFT computation only, and the descriptors are released upon return from the parallel region. In this case, each descriptor is used only within its corresponding thread. It is obligatory to explicitly set the single-threaded mode for Intel

MKL, otherwise, the actual number of threads may differ from one, because the `DftiCommitDescriptor` function is not in a parallel region. See [Example C-27a in Appendix C](#).

- d. You create threads in the application yourself after initializing the only FFT descriptor. This implies that threading is employed for parallel FFT computation only, and the descriptor is released upon return from the parallel region. In this case, each thread uses the same descriptor. See [Example C-28 in Appendix C](#).

In cases "a", "b", and "c", listed above, set the parameter `DFTI_NUMBER_OF_USER_THREADS` to 1 (its default value), since each particular descriptor instance is used only in a single thread.

In case "d", you must use the `DftiSetValue()` function to set the `DFTI_NUMBER_OF_USER_THREADS` to the actual number of FFT computation threads, because multiple threads will be using the same descriptor. If this setting is not done, your program will work incorrectly or fail, since the descriptor contains individual data for each thread.

WARNING.

- It is not recommended to simultaneously parallelize your program and employ the Intel MKL internal threading because this will slow down the performance. Note that in case "d" above, FFT computation is automatically initiated in a single-threading mode.
 - You must not change the number of threads after the `DftiCommitDescriptor()` function completed FFT initialization.
-

Input and output distances

FFT interface in Intel MKL allows the computation of multiple number of transforms. Consequently, the user needs to be able to specify the data distribution of these multiple sets of data. This is accomplished by the distance between the first data element of the consecutive data sets. This parameter is obligatory if multiple number is more than one. The parameter is a value of `Integer` data type in Fortran and `MKL_LONG` data type in C. Data sets don't have any common elements. The following example illustrates the specification. Consider computing the forward FFT on three 32-length complex sequences stored in `X(0:31, 1)`, `X(0:31, 2)`, and `X(0:31, 3)`. Suppose the results are to be stored in the locations `Y(0:31, k)`, $k = 1, 2, 3$, of the array `Y(0:63, 3)`. Thus the input distance is 32, while the output distance is 64. Notice that the data and result parameters in computation functions are all declared as

assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran. Here is the code fragment:

```
Complex :: X_2D(0:31,3), Y_2D(0:63, 3)

Complex :: X(96), Y(192)
Equivalence (X_2D, X)
Equivalence (Y_2D, Y)
.....
Status = DftiCreateDescriptor(Desc_Handle, DFTI_SINGLE,

    DFTI_COMPLEX, 1, 32)
Status = DftiSetValue(Desc_Handle, DFTI_NUMBER_OF_TRANSFORMS, 3)
Status = DftiSetValue(Desc_Handle, DFTI_INPUT_DISTANCE, 32)
Status = DftiSetValue(Desc_Handle, DFTI_OUTPUT_DISTANCE, 64)
Status = DftiSetValue(Desc_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor(Desc_Handle)
Status = DftiComputeForward(Desc_Handle, X, Y)
Status = DftiFreeDescriptor(Desc_Handle)
```

Strides

In addition to supporting transforms of multiple number of datasets, FFT interface supports non-unit stride distribution of data within each data set. The parameter is an array of values of `Integer` data type in Fortran and `MKL_LONG` data type in C.

The stride values determine the memory layout of the input and output data.

An input data element $X(n_1, n_2, \dots, n_D)$ of a D -dimensional transform is located at offset $nth * idistance + istrate[0] + n_1 * istrate[1] + \dots + n_D * istrate[D]$ from the first element (the element pointed to by X). Here $nth = 0, \dots, M - 1$ with M being the number of transforms defined by the `DFTI_NUMBER_OF_TRANSFORMS` configuration parameter, $idistance$ is the spacing between the first elements of the data for the multiple transforms, as defined by the `DFTI_INPUT_DISTANCE` configuration parameter, and $istrate$ is the array of strides defined by the `DFTI_INPUT_STRIDES` configuration parameter.

The offset is counted in sizes of the respective data type rather than bytes. The type of the elements is defined by the descriptor configuration rather than by the type of the variable passed to the computation functions.

The `DFTI_FORWARD_DOMAIN`, `DFTI_COMPLEX_STORAGE`, `DFTI_CONJUGATE_EVEN_STORAGE`, and `DFTI_PACKED_FORMAT` configuration parameters define the type of the elements as shown in [Table 11-16a](#).

The output data layout depends on the `DFTI_PLACEMENT` configuration parameter:

- For out-of-place transforms, the output data is stored similarly to the input data, with the distance and stride defined by the `DFTI_OUTPUT_DISTANCE` and `DFTI_OUTPUT_STRIDES` configuration parameters, respectively.
- For in-place transforms, `DFTI_OUTPUT_STRIDES` is disregarded unless it is a real to CCE transform, where forward and backward domains are associated with different element types. For a real to CCE transform, you must set the output strides explicitly.

Table 11-16a Assumed Element Types of the Input/Output Data

Descriptor Configuration	Element Type in the Forward Domain	Element Type in the Backward Domain
<code>DFTI_FORWARD_DOMAIN=DFTI_COMPLEX</code> <code>DFTI_COMPLEX_STORAGE=DFTI_COMPLEX_COMPLEX</code>	Complex	Complex
<code>DFTI_FORWARD_DOMAIN=DFTI_COMPLEX</code> <code>DFTI_COMPLEX_STORAGE=DFTI_REAL_REAL</code>	Real	Real
<code>DFTI_FORWARD_DOMAIN=DFTI_REAL</code> <code>DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_REAL</code> <code>DFTI_PACKED_FORMAT={DFTI_CCS_FORMAT, DFTI_PACK_FORMAT, DFTI_PERM_FORMAT}</code>	Real	Real
<code>DFTI_FORWARD_DOMAIN=DFTI_REAL</code> <code>DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX</code> <code>DFTI_PACKED_FORMAT=DFTI_CCE_FORMAT</code>	Real	Complex

Consider the following situation where a 32-length FFT is to be computed on the sequence x_j , $0 \leq j < 32$. The actual location of these values are in $x(5)$, $x(7)$, ..., $x(67)$ of an array $x(1:68)$. The stride accommodated by the FFT interface consists of a displacement from the first element of the data array $L0$, (4 in this case), and a constant distance of consecutive elements $L1$ (2 in this case). Thus for the Fortran array x

$$x_j = x(1 + L0 + L1 * j) = x(5 + L1 * j).$$

This stride vector (4,2) is provided by a length-2 rank-1 integer array:

```
COMPLEX :: X(68)
INTEGER :: Stride(2)
.....
Status = DftiCreateDescriptor(Desc_Handle, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 32)
Stride = (/ 4, 2 /)
Status = DftiSetValue(Desc_Handle, DFTI_INPUT_STRIDES, Stride)
Status = DftiSetValue(Desc_Handle, DFTI_OUTPUT_STRIDES, Stride)
Status = DftiCommitDescriptor(Desc_Handle)
Status = DftiComputeForward(Desc_Handle, X)
Status = DftiFreeDescriptor(Desc_Handle)
```

In general, for a d -dimensional transform, the stride is provided by a $d+1$ -length integer vector $(L0, L1, L2, \dots, Ld)$ with the meaning:

- $L0$ = displacement from the first array element
- $L1$ = distance between consecutive data elements in the first dimension
- $L2$ = distance between consecutive data elements in the second dimension
- ... = ...
- Ld = distance between consecutive data elements in the d -th dimension.

A d -dimensional data sequence

$$x_{j_1, j_2, \dots, j_d}, \quad 0 \leq j_i \leq J_i, \quad 1 \leq i \leq d$$

will be stored in the rank-1 array x by the mapping

$$x_{j_1, j_2, \dots, j_d} = x(\text{first index} + L0 + j_1 L1 + j_2 L2 + \dots + j_d Ld).$$

For multiple transforms, the value $L0$ applies to the first data sequence, and Lj , $j = 1, 2, \dots, d$ apply to all the data sequences.

In the case of a single one-dimensional sequence, $L1$ is simply the usual stride. The default setting of strides in the general multi-dimensional situation corresponds to the case where the sequences are distributed tightly into the array:

$$L1 = 1, L2 = J_1, L3 = J_1 J_2, \dots, Ld = \prod_{i=1}^{d-1} J_i$$

Both the input data and output data have a stride associated with it. The default is set in accordance with the data to be stored contiguously in memory in a way that is natural to the language.

Note that in case of a real FFT, where different formats are available, the default value is not the one that seems most natural for certain formats. For example, with the *CCE* format, strides are set by default to $L1 = 1$, $L2 = J1$ for a real transform regardless. However, for a complex matrix, slightly over half of the matrix is actually stored, and you should set strides to $L1 = 1$, $L2 = J1/2 + 1$. In case of an *in-place* transform with the *CCE* data format, even for a real array, you should set strides explicitly: $L1 = 1$, $L2 = (J1/2 + 1) * 2$.

See [Example C-23](#) as an illustration of how to use the configuration parameters discussed above. See [Storage schemes](#) and [Packed formats](#) on how to define arrays for different formats.

Ordering

It is well known that a number of FFT algorithms apply an explicit permutation stage that is time consuming [4]. The exclusion of this step is similar to applying FFT to input data whose order is scrambled, or allowing a scrambled order of the FFT results. In applications such as convolution and power spectrum calculation, the order of result or data is unimportant and thus permission of scrambled order is attractive if it leads to higher performance. The following options are available in Intel MKL:

- `DFTI_ORDERED`: Forward transform data ordered, backward transform data ordered (default option).
- `DFTI_BACKWARD_SCRAMBLLED`: Forward transform data ordered, backward transform data scrambled.

[Table 11-17](#) tabulates the effect on this configuration setting.

Table 11-17 Scrambled Order Transform

	DftiComputeForward	DftiComputeBackward
DFTI_ORDERING	Input → Output	Input → Output
DFTI_ORDERED	ordered → ordered	ordered → ordered
DFTI_BACKWARD_SCRAMBLED	ordered → scrambled	scrambled → ordered

Note that meaning of the latter two options are "allow scrambled order if practical." There are situations where in fact allowing out of order data gives no performance advantage, and thus an implementation may choose to ignore the suggestion. Strictly speaking, the normal order is also a scrambled order, the trivial one.

Transposition

This is an option that allows for the result of a high-dimensional transform to be presented in a transposed manner. The default setting is `DFTI_NONE` and can be set to `DFTI_ALLOW`. Similar to that of scrambled order, sometimes in higher dimension transform, performance can be gained if the result is delivered in a transposed manner. FFT interface offers an option for the output be returned in a transposed form if performance gain is possible. Since the generic stride specification is naturally suited for representation of transposition, this option allows the strides for the output to be possibly different from those originally specified by the user. Consider an example where a two-dimensional result

$$Y_{j_1, j_2}, \quad 0 \leq j_i < n_i,$$

is expected. Originally the user specified that the result be distributed in the (flat) array `y` in with generic strides $L_1 = 1$ and $L_2 = n_1$. With the transposition option, the computation may actually return the result into `y` with stride $L_1 = n_2$ and $L_2 = 1$. These strides can be obtained from an appropriate inquiry function. Note also that in dimension 3 and above, transposition means an arbitrary permutation of the dimension.

Cluster FFT Functions

This section describes the cluster Fast Fourier Transform (FFT) functions implemented in Intel® MKL.

NOTE. These functions are available only for the Linux* and Windows* operating systems.

The cluster FFT function library was designed to perform fast Fourier transforms on a cluster, that is, a group of computers interconnected via a network. Each computer (node) in the cluster has its own memory and processor(s). Data interchanges between the nodes are provided by the network.

One or more processes may be running in parallel on each cluster node. To organize communication between different processes, the cluster FFT function library uses the Message Passing Interface (MPI). To avoid dependence on a specific MPI implementation (for example, MPICH, Intel® MPI, and others), the library works with MPI via a message-passing library for linear algebra called BLACS.

Cluster FFT functions of Intel MKL provide one-dimensional, two-dimensional, and multi-dimensional (up to the order of 7) functions and both Fortran and C interfaces for all transform functions.

To develop applications using the cluster FFT functions, you should have basic skills in MPI programming.

The interfaces for the Intel MKL cluster FFT functions are similar to the corresponding interfaces for the conventional Intel MKL [FFT functions](#), described earlier in this chapter. Refer there for details not explained in this section.

[Table 11-18](#) lists cluster FFT functions implemented in Intel MKL:

Table 11-18 Cluster FFT Functions in Intel MKL

Function Name	Operation
Descriptor Manipulation Functions	
DftiCreateDescriptorDM	Allocates memory for the descriptor data structure and preliminarily initializes it.
DftiCommitDescriptorDM	Performs all initialization for the actual FFT computation.
DftiFreeDescriptorDM	Frees memory allocated for a descriptor.
FFT Computation Functions	
DftiComputeForwardDM	Computes the forward FFT.
DftiComputeBackwardDM	Computes the backward FFT.
Descriptor Configuration Functions	
DftiSetValueDM	Sets one particular configuration parameter with the specified configuration value.

Function Name	Operation
DftiGetValueDM	Gets the value of one particular configuration parameter.

Computing Cluster FFT

The cluster FFT functions described later in this section are provided with Fortran and C interfaces. Fortran stands for Fortran 95.

Cluster FFT computation is performed by [DftiComputeForwardDM](#) and [DftiComputeBackwardDM](#) functions, called in a program using MPI, which will be referred to as MPI program. After an MPI program starts, a number of processes are created. MPI identifies each process by its rank. The processes are independent of one another and communicate via MPI. A function called in an MPI program is invoked in all the processes. Each process manipulates data according to its rank. Input or output data for a cluster FFT transform is a sequence of real or complex values. A cluster FFT computation function operates local part of the input data, i.e. some part of the data to be operated in a particular process, as well as generates local part of the output data. While each process performs its part of computations, running in parallel and communicating through MPI, the processes perform the entire FFT computation. FFT computations using the Intel MKL cluster FFT functions are typically effected by a number of steps listed below:

1. Initiate MPI by calling `MPI_Init` in C/C++ or `MPI_INIT` in Fortran (the function must be called prior to calling any FFT function and any MPI function).
2. Allocate memory for the descriptor and create it by calling [DftiCreateDescriptorDM](#).
3. Specify one of several values of configuration parameters by one or more calls to [DftiSetValueDM](#).
4. Obtain values of configuration parameters needed to create local data arrays; the values are retrieved by calling [DftiGetValueDM](#).
5. Initialize the descriptor for the FFT computation by calling [DftiCommitDescriptorDM](#).
6. Create arrays for local parts of input and output data and fill the local part of input data with values. (For more information, see [Distributing Data among Processes](#).)
7. Compute the transform by calling [DftiComputeForwardDM](#) or [DftiComputeBackwardDM](#).
8. Gather local output data into the global array using MPI functions. (This step is optional because you may need to immediately employ the data differently.)
9. Release memory allocated for the descriptor by calling [DftiFreeDescriptorDM](#).
10. Finalize communication through MPI by calling `MPI_Finalize` in C/C++ or `MPI_FINALIZE` in Fortran (the function must be called after the last call to a cluster FFT function and the last call to an MPI function).

Several code examples in the “[Examples for Cluster FFT Functions](#)” section in Appendix C illustrate cluster FFT computations.

Distributing Data among Processes

The Intel MKL cluster FFT functions store all input and output multi-dimensional arrays (matrices) in one-dimensional arrays (vectors). The arrays are stored in the row-major order in C/C++ and in the column-major order in Fortran. For example, a two-dimensional matrix A of size (m, n) is stored in a vector B of size $m*n$ so that

- $B[i*n+j]=A[i][j]$ in C/C++ ($i=0, \dots, m-1, j=0, \dots, n-1$)
- $B(j*m+i)=A(i, j)$ in Fortran ($i=1, \dots, m, j=1, \dots, n$).

NOTE. Order of FFT dimensions is the same as the order of array dimensions in the programming language. For example, a 3-dimensional FFT with `Lengths=(m,n,l)` can be computed over an array `Ar[m][n][l]` in C/C++ or `AR(m,n,l)` in Fortran.

All MPI processes involved in cluster FFT computation operate their own portions of data. These local arrays make up the virtual global array that the fast Fourier transform is applied to. It is your responsibility to properly allocate local arrays (if needed), fill them with initial data and gather resulting data into an actual global array or process the resulting data differently. To be able to do this, see sections below on how the virtual global array is composed of the local ones.

Multi-dimensional transforms

If the dimension of transform is greater than one, the cluster FFT function library splits data in the dimension whose index changes most slowly, so that the parts contain all elements with several consecutive values of this index. It is the first dimension in C and the last one in Fortran. If the global array is two-dimensional, in C, it gives each process several consecutive rows. The term “rows” will be used regardless of the array dimension and programming language. Local arrays are placed in memory allocated for the virtual global array consecutively, in the order determined by process ranks. For example, in case of two processes, during the computation of a three-dimensional transform whose matrix has size $(11,15,12)$, the processes may store local arrays of sizes $(6,15,12)$ and $(5,15,12)$, respectively.

If p is the number of MPI processes and the matrix of a transform to be computed has size (m, n, l) , in C, each MPI process works with local data array of size (m_q, n, l) , where $\sum_{q=0}^{p-1} m_q = m$, $q=0, \dots, p-1$. Local input arrays must contain appropriate parts of the actual global input array, and then local output arrays will contain appropriate parts of the actual global output

array. You can figure out which particular rows of the global array the local array must contain from the following configuration parameters of the cluster FFT interface: `CDFT_LOCAL_NX`, `CDFT_LOCAL_START_X`, and `CDFT_LOCAL_SIZE`. To retrieve values of the parameters, use the `DftiGetValueDM` function:

- `CDFT_LOCAL_NX` specifies how many rows of the global array the current process receives.
- `CDFT_LOCAL_START_X` specifies which row of the global input or output array corresponds to the first row of the local input or output array. If `A` is a global array and `L` is the appropriate local array, then
 - `L[i][j][k]=A[i+cdft_local_start_x][j][k]`, where $i=0, \dots, m_q-1$, $j=0, \dots, n-1$, $k=0, \dots, l-1$ for C/C++
 - `L(i,j,k)=A(i,j,k+cdft_local_start_x-1)`, where $i=1, \dots, m$, $j=1, \dots, n$, $k=1, \dots, l_q$ for Fortran.

Example C-29 in Appendix C shows how the data is distributed among processes for a two-dimensional cluster FFT computation.

One-dimensional transforms

In this case, input and output data are distributed among processes differently and even the numbers of elements stored in a particular process before and after the transform may be different. Each local array stores a segment of consecutive elements of the appropriate global array. Such segment is determined by the number of elements and a shift with respect to the first array element. So, to specify segments of the global input and output arrays that a particular process receives, *four* configuration parameters are needed: `CDFT_LOCAL_NX`, `CDFT_LOCAL_START_X`, `CDFT_LOCAL_OUT_NX`, and `CDFT_LOCAL_OUT_START_X`. Use the `DftiGetValueDM` function to retrieve their values. The meaning of the four configuration parameters depends upon the type of the transform, as shown in Table 11-19:

Table 11-19 Data Distribution Configuration Parameters for 1D Transforms

Meaning of the Parameter	Forward Transform	Backward Transform
Number of elements in input array	CDFT_LOCAL_NX	CDFT_LOCAL_OUT_NX
Elements shift in input array	CDFT_LOCAL_START_X	CDFT_LOCAL_OUT_START_X
Number of elements in output array	CDFT_LOCAL_OUT_NX	CDFT_LOCAL_NX

Meaning of the Parameter	Forward Transform	Backward Transform
Elements shift in output array	CDFT_LOCAL_OUT_START_X	CDFT_LOCAL_START_X

Memory size for local data

The memory size needed for local arrays cannot be just calculated from `CDFT_LOCAL_NX` (`CDFT_LOCAL_OUT_NX`), because the cluster FFT functions sometimes require allocating a little bit more memory for local data than just the size of the appropriate sub-array. The configuration parameter `CDFT_LOCAL_SIZE` specifies the size of the local input and output array in data elements. Each local input and output arrays must have size not less than `CDFT_LOCAL_SIZE*size_of_element`. Note that in the current implementation of the cluster FFT interface, data elements can be real or complex values, each complex value consisting of the real and imaginary parts. If you employ a user-defined workspace for in-place transforms (for more information, refer to [Table 11-20](#)), it must have the same size as the local arrays. [Example C-30](#) in Appendix C illustrates how the cluster FFT functions distribute data among processes in case of a one-dimensional FFT computation effected with a user-defined workspace.

Available Auxiliary Functions

If a global input array is located on one MPI process and you want to obtain its local parts or you want to gather the global output array on one MPI process, you can use functions `MKL_CDFT_ScatterData` and `MKL_CDFT_GatherData` to distribute or gather data among processes, respectively. These functions are defined in a file that is delivered with Intel MKL and located in the following subdirectory of the Intel MKL installation directory:
`examples/cdftc/examples_support.c` for C/C++ and
`examples/cdftf/examples_support.f90` for Fortran.

Restriction on Lengths of Transforms

The algorithm that the Intel MKL cluster FFT functions use to distribute data among processes imposes a restriction on lengths of transforms with respect to the number of MPI processes used for the FFT computation:

- For a multi-dimensional transform, lengths of the first two dimensions in C/C++ or of the last two dimensions in Fortran must be not less than the number of MPI processes.
- Length of a one-dimensional transform must be the product of two integers each of which is not less than the number of MPI processes.

Non-compliance with the restriction causes an error `CDFT_SPREAD_ERROR` (refer to [Error Codes](#) for details). To achieve the compliance, you can change the transform lengths and/or the number of MPI processes, which is specified at start of an MPI program. MPI-2 enables changing the number of processes during execution of an MPI program.

Cluster FFT Interface

To use the cluster FFT functions, you need to access the module `MKL_CDFT` through the "use" statement in Fortran; or access the header file `mkl_cdft.h` through "include" in C/C++.

The Fortran interface provides a derived type `DFTI_DESCRIPTOR_DM`; a number of named constants representing various names of configuration parameters and their possible values; and a number of overloaded functions through the generic functionality of Fortran 95.

The C interface provides a structure type `DFTI_DESCRIPTOR_DM_HANDLE` and a number of functions, some of which accept a different number of input arguments.

To provide communication between parallel processes through MPI, the following include statement must be present in your code:

- Fortran:

```
INCLUDE "mpif.h"
```

(for some MPI versions, "mpif90.h" header may be used instead).

- C/C++:

```
#include "mpi.h"
```

There are three main categories of the cluster FFT functions in Intel MKL:

- 1. Descriptor Manipulation.** There are three functions in this category. The [DftiCreateDescriptorDM](#) function creates an FFT descriptor whose storage is allocated dynamically. The [DftiCommitDescriptorDM](#) function "commits" the descriptor to all its settings. The [DftiFreeDescriptorDM](#) function frees up the memory allocated for the descriptor.
- 2. FFT Computation.** There are two functions in this category. The [DftiComputeForwardDM](#) function performs the forward FFT computation, and the [DftiComputeBackwardDM](#) function performs the backward FFT computation.
- 3. Descriptor Configuration.** There are two functions in this category. The [DftiSetValueDM](#) function sets one specific configuration value to one of the many configuration parameters. The [DftiGetValueDM](#) function gets the current value of any of these configuration parameters, all of which are readable. These parameters, though many, are handled one at a time.

Descriptor Manipulation Functions

There are three functions in this category: create a descriptor, commit a descriptor, and free a descriptor.

CreateDescriptorDM

Allocates memory for the descriptor data structure and preliminarily initializes it.

Syntax

Fortran:

```
Status = DftiCreateDescriptorDM(comm, handle, v1, v2, dim, size)
Status = DftiCreateDescriptorDM(comm, handle, v1, v2, dim, sizes)
```

C/C++:

```
status = DftiCreateDescriptorDM(comm, &handle, v1, v2, dim, size );
status = DftiCreateDescriptorDM(comm, &handle, v1, v2, dim, sizes );
```

Input Parameters

<i>comm</i>	MPI communicator, e.g. <code>MPI_COMM_WORLD</code> .
<i>v1</i>	Precision of the transform.
<i>v2</i>	Type of the forward domain. Must be <code>DFTI_COMPLEX</code> for complex-to-complex transforms or <code>DFTI_REAL</code> for real-to-complex transforms.
<i>dim</i>	Dimension of the transform.
<i>size</i>	Length of the transform in a one-dimensional case.
<i>sizes</i>	Lengths of the transform in a multi-dimensional case.

Output Parameters

<i>handle</i>	Pointer to the descriptor handle of transform. If the function completes successfully, the pointer to the created handle is stored in the variable.
---------------	---

Description

The function is declared in the `mkl_cdft.h` header file for the C interface and `mkl_cdft.f90` header file for the Fortran interface. This function allocates memory in a particular MPI process for the descriptor data structure and instantiates it with default configuration settings with respect to the precision, domain, dimension, and length of the desired transform. The domain is understood to be the domain of the forward transform. The result is a pointer to the created descriptor. This function is slightly different from the "initialization" function `DftiCommitDescriptorDM` in a more traditional software packages or libraries used for computing the FFT. This function does not perform any significant computation work, such as twiddle factors computation, because the default configuration settings can still be changed using the function `DftiSetValueDM`.

The value of the parameter `vl` is specified through named constants `DFTI_SINGLE` and `DFTI_DOUBLE`. It corresponds to precision of input data, output data, and computation. A setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The parameter `dim` is a simple positive integer indicating the dimension of the transform.

In C/C++, for one-dimensional transforms, length is a single integer value of the parameter `size` having type `MKL_LONG`; for multi-dimensional transforms, length is supplied with the parameter `sizes`, which is an array of integers having type `MKL_LONG`. In Fortran, length is an integer or an array of integers.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. In this case, the pointer to the created descriptor handle is stored in `handle`. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiCreateDescriptorDM
    INTEGER(4) FUNCTION DftiCreateDescriptorDMn(C,H,P1,P2,D,L)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: H
        INTEGER(4) C,P1,P2,D,L(*)
    END FUNCTION
    INTEGER(4) FUNCTION DftiCreateDescriptorDM1(C,H,P1,P2,D,L)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: H
        INTEGER(4) C,P1,P2,D,L
    END FUNCTION
END INTERFACE

/* C/C++ prototype */
MKL_LONG DftiCreateDescriptorDM(MPI_Comm,DFTI_DESCRIPTOR_DM_HANDLE*,
    enum DFTI_CONFIG_VALUE,enum DFTI_CONFIG_VALUE,MKL_LONG,...);
```

CommitDescriptorDM

Performs all initialization for the actual FFT computation.

Syntax

Fortran:

```
Status = DftiCommitDescriptorDM(handle)
```

C/C++:

```
status = DftiCommitDescriptorDM(handle);
```

Input Parameters

handle The descriptor handle. Must be valid, that is, created in a call to [DftiCreateDescriptorDM](#).

Description

The function is declared in the `mkl_cdft.h` header file for the C interface and `mkl_cdft.f90` header file for the Fortran interface. The cluster FFT interface requires a function that completes initialization of a previously created descriptor before the descriptor can be used for FFT computations in a particular MPI process. The `DftiCommitDescriptorDM` function performs all initialization that facilitates the actual FFT computation. For the current implementation, it may involve exploring many different factorizations of the input length to search for highly efficient computation method.

Any changes of configuration parameters of a committed descriptor via the set value function (see [Descriptor Configuration](#)) requires a re-committal of the descriptor before a computation function can be invoked. Typically, this committal function is called right before a computation function call (see [FFT Computation](#)).

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiCommitDescriptorDM
    INTEGER(4) FUNCTION DftiCommitDescriptorDM(handle);
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: handle
    END FUNCTION
END INTERFACE

/* C/C++ prototype */
```

```
MKL_LONG DftiCommitDescriptorDM(DFTI_DESCRIPTOR_DM_HANDLE handle);
```

FreeDescriptorDM

Frees memory allocated for a descriptor.

Syntax

Fortran:

```
Status = DftiFreeDescriptorDM(handle)
```

C/C++:

```
status = DftiFreeDescriptorDM(&handle);
```

Input Parameters

handle The descriptor handle. Must be valid, that is, created in a call to [DftiCreateDescriptorDM](#).

Output Parameters

handle The descriptor handle. Memory allocated for the handle is released on output.

Description

The function is declared in the `mkl_cdft.h` header file for the C interface and `mkl_cdft.f90` header file for the Fortran interface. This function frees up all memory allocated for a descriptor in a particular MPI process. Call the `DftiFreeDescriptorDM` function to delete the descriptor handle. Upon successful completion of `DftiFreeDescriptorDM` the descriptor handle is no longer valid.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiFreeDescriptorDM
  INTEGER(4) FUNCTION DftiFreeDescriptorDM(handle)
    TYPE(DFTI_DESCRIPTOR_DM), POINTER :: handle
  END FUNCTION
END INTERFACE

/* C/C++ prototype */

MKL_LONG DftiFreeDescriptorDM(DFTI_DESCRIPTOR_DM_HANDLE *handle);
```

FFT Computation Functions

There are two functions in this category: compute the forward transform and compute the backward transform.

ComputeForwardDM

Computes the forward FFT.

Syntax

Fortran:

```
Status = DftiComputeForwardDM(handle, in_X, out_X)
Status = DftiComputeForwardDM(handle, in_out_X)
```

C/C++:

```
status = DftiComputeForwardDM(handle, in_X, out_X);
status = DftiComputeForwardDM(handle, in_out_X);
```

Input Parameters

<i>handle</i>	The descriptor handle.
<i>in_X, in_out_X</i>	Local part of input data. Array of complex values. Refer to the Distributing Data among Processes section on how to allocate and initialize the array.

Output Parameters

<i>out_X, in_out_X</i>	Local part of output data. Array of complex values. Refer to the Distributing Data among Processes section on how to allocate the array.
------------------------	---

Description

The function is declared in the `mkl_cdft.h` header file for the C interface and `mkl_cdft.f90` header file for the Fortran interface. The `DftiComputeForwardDM` function computes the forward FFT. Forward FFT is the transform using the factor $e^{-i2\pi/n}$.

Before you call the function, the valid descriptor, created by `DftiCreateDescriptorDM`, must be configured and committed using the `DftiCommitDescriptorDM` function.

The computation is carried out by calling the `DftiComputeForward` function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of `DftiComputeForward`.

Local part of input data, as well as local part of the output data, is an appropriate sequence of complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See the [Distributing Data among Processes](#) section for details.

Refer to the [Configuration Settings](#) section for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter `DFTI_PRECISION` determines the precision of input data, output data, and transform: a setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The configuration parameter `DFTI_PLACEMENT` informs the function whether the computation should be in-place. If the value of this parameter is `DFTI_INPLACE` (default), you must call the function with two parameters, otherwise you must supply three parameters. If `DFTI_PLACEMENT = DFTI_INPLACE` and three parameters are supplied, then the third parameter is ignored.

CAUTION. Even in case of an out-of-place transform, local array of input data `in_X` may be changed. To save data, make its copy before calling `DftiComputeForwardDM`.

In case of an in-place transform, `DftiComputeForwardDM` dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

NOTE. You can specify your own workspace of the same size through the configuration parameter `CDFT_WORKSPACE` to avoid redundant memory allocation.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiComputeForwardDM
    INTEGER(4) FUNCTION DftiComputeForwardDM(h, in_X, out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(8), DIMENSION(*) :: in_x, out_X
    END FUNCTION DftiComputeForwardDM
    INTEGER(4) FUNCTION DftiComputeForwardDMi(h, in_out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(8), DIMENSION(*) :: in_out_X
    END FUNCTION DftiComputeForwardDMi
    INTEGER(4) FUNCTION DftiComputeForwardDMs(h, in_X, out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(4), DIMENSION(*) :: in_x, out_X
    END FUNCTION DftiComputeForwardDMs
    INTEGER(4) FUNCTION DftiComputeForwardDMis(h, in_out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(4), DIMENSION(*) :: in_out_X
    END FUNCTION DftiComputeForwardDMis
END INTERFACE

/* C/C++ prototype */
MKL_LONG DftiComputeForwardDM(DFTI_DESCRIPTOR_DM_HANDLE handle, void *in_X,...);
```

ComputeBackwardDM

Computes the backward FFT.

Syntax

Fortran:

```
Status = DftiComputeBackwardDM(handle, in_X, out_X)
```

```
Status = DftiComputeBackwardDM(handle, in_out_X)
```

C/C++:

```
status = DftiComputeBackwardDM(handle, in_X, out_X);
```

```
status = DftiComputeBackwardDM(handle, in_out_X);
```

Input Parameters

handle

The descriptor handle.

in_X, in_out_X

Local part of input data. Array of complex values.
Refer to the [Distributing Data among Processes](#) section on how to allocate and initialize the array.

Output Parameters

out_X, in_out_X

Local part of output data. Array of complex values.
Refer to the [Distributing Data among Processes](#) section on how to allocate the array.

Description

The function is declared in the `mkl_cdft.h` header file for the C interface and `mkl_cdft.f90` header file for the Fortran interface. The `DftiComputeBackwardDM` function computes the backward FFT. Backward FFT is the transform using the factor $e^{i2\pi/n}$.

Before you call the function, the valid descriptor, created by `DftiCreateDescriptorDM`, must be configured and committed using the `DftiCommitDescriptorDM` function.

The computation is carried out by calling the `DftiComputeBackward` function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of `DftiComputeBackward`.

Local part of input data, as well as local part of the output data, is an appropriate sequence of complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See the [Distributing Data among Processes](#) section for details.

Refer to the [Configuration Settings](#) section for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter `DFTI_PRECISION` determines the precision of input data, output data, and transform: a setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The configuration parameter `DFTI_PLACEMENT` informs the function whether the computation should be in-place. If the value of this parameter is `DFTI_INPLACE` (default), you must call the function with two parameters, otherwise you must supply three parameters. If `DFTI_PLACEMENT = DFTI_INPLACE` and three parameters are supplied, then the third parameter is ignored.

CAUTION. Even in case of an out-of-place transform, local array of input data `in_X` may be changed. To save data, make its copy before calling `DftiComputeBackwardDM`.

In case of an in-place transform, `DftiComputeBackwardDM` dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

NOTE. You can specify your own workspace of the same size through the configuration parameter `CDFT_WORKSPACE` to avoid redundant memory allocation.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```

! Fortran Interface
INTERFACE DftiComputeBackwardDM
    INTEGER(4) FUNCTION DftiComputeBackwardDM(h, in_X, out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(8), DIMENSION(*) :: in_x, out_X
    END FUNCTION DftiComputeBackwardDM
    INTEGER(4) FUNCTION DftiComputeBackwardDMi(h, in_out_X)

        COMPLEX(4), DIMENSION(*) :: in_out_X
    END FUNCTION DftiComputeBackwardDMis
END INTERFACE

/* C/C++ prototype */
MKL_LONG DftiComputeBackwardDM(DFTI_DESCRIPTOR_DM_HANDLE handle, void *in_X,...);

```

Descriptor Configuration Functions

There are two functions in this category: the value setting function [DftiSetValueDM](#) sets one particular configuration parameter to an appropriate value, the value getting function [DftiGetValueDM](#) reads the value of one particular configuration parameter.

Some configuration parameters used by cluster FFT functions originate from the conventional FFT interface (see [Configuration Settings](#) subsection in the “FFT Functions” section for details).

Other configuration parameters are specific to the cluster FFT. Integer values of these parameters have type `MKL_LONG` in C/C++ and `INTEGER(4)` in Fortran. The exact type of the configuration parameters being floating-point scalars is `float` or `double` in C/C++ and `REAL(4)` or `REAL(8)` in Fortran. The configuration parameters whose values are named constants have the `enum` type in C/C++ and `INTEGER` in Fortran. They are defined in the `mk1_cdft.h` header file in C/C++ and `MKL_CDFT` module in Fortran.

Names of the configuration parameters specific to the cluster FFT interface have prefix `CDFT`.

SetValueDM

Sets one particular configuration parameter with the specified configuration value.

Syntax

Fortran:

```
Status = DftiSetValueDM (handle, param, value)
```

C/C++:

```
status = DftiSetValueDM (handle, param, value);
```

Input Parameters

<i>handle</i>	The descriptor handle. Must be valid, that is, created in a call to DftiCreateDescriptorDM .
<i>param</i>	Name of a parameter to be set up in the descriptor handle. See Table 11-20 for the list of available parameters.
<i>value</i>	Value of the parameter.

Description

The function is declared in the `mkl_cdft.h` header file for the C interface and `mkl_cdft.f90` header file for the Fortran interface. This function sets one particular configuration parameter with the specified configuration value. The configuration parameter is one of the named constants listed in the table below, and the configuration value must have the corresponding type. See [Configuration Settings](#) for details of the meaning of the setting. See [Table 11-6](#) for possible values of the parameters that are named constants.

Table 11-20 Settable Configuration Parameters

Parameter Name	Data Type	Description	Default Value
<code>DFTI_FORWARD_SCALE</code>	Floating-point scalar	Scale factor of forward transform.	1.0
<code>DFTI_BACKWARD_SCALE</code>	Floating-point scalar	Scale factor of backward transform.	1.0
<code>DFTI_PLACEMENT</code>	Named constant	Placement of the computation result.	<code>DFTI_INPLACE</code>
<code>DFTI_ORDERING</code>	Named constant	Scrambling of data order.	<code>DFTI_ORDERED</code>
<code>DFTI_WORKSPACE</code>	Array of an appropriate type	Auxiliary buffer, a user-defined workspace. Enables saving memory during in-place computations.	NULL (allocate workspace dynamically).
<code>DFTI_PACKED_FORMAT</code>	Named constant	Packed format, real data.	<ul style="list-style-type: none"> <code>DFTI_PERM_FORMAT</code> — default and the only available value for one-dimensional transforms <code>DFTI_CCE_FORMAT</code> — default and the only available

Parameter Name	Data Type	Description	Default Value
			value for multi-dimensional transforms
DFTI_TRANSPOSE	Named constant	This parameter determines how the output data is located for multi-dimensional transforms. If the parameter value is <code>DFTI_NONE</code> , the data is located in a usual manner described in this manual. If the value is <code>DFTI_ALLOW</code> , the last (first) global transposition is not performed for a forward (backward) transform.	<code>DFTI_NONE</code>

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```

    END FUNCTION
```

END INTERFACE

```
/* C/C++ prototype */
MKL_LONG DftiSetValueDM(DFTI_DESCRIPTOR_DM_HANDLE handle, int param,...);
```

GetValueDM

Gets the value of one particular configuration parameter.

Syntax

Fortran:

```
Status = DftiGetValueDM(handle, param, value)
```

C/C++:

```
status = DftiGetValueDM(handle, param, &value);
```

Input Parameters

<i>handle</i>	The descriptor handle. Must be valid, that is, created in a call to DftiCreateDescriptorDM .
<i>param</i>	Name of a parameter to be retrieved from the descriptor. See Table 11-21 for the list of available parameters.

Output Parameters

<i>value</i>	Value of the parameter.
--------------	-------------------------

Description

The function is declared in the `mkl_cdft.h` header file for the C interface and `mkl_cdft.f90` header file for the Fortran interface. This function gets the configuration value of one particular configuration parameter. The configuration parameter is one of the named constants listed in

the table below, and the configuration value is the corresponding appropriate type, which can be a named constant or a native type. Possible values of the named constants can be found in [Table 11-6](#).

Table 11-21 Retrievable Configuration Parameters

Parameter Name	Data Type	Description
DFTI_PRECISION	Named constant	Precision of computation, input data and output data.
DFTI_DIMENSION	Integer scalar	Dimension of the transform
DFTI_LENGTHS	Array of integer values	Array of lengths of the transform. Number of lengths corresponds to the dimension of the transform.
DFTI_FORWARD_SCALE	Floating-point scalar	Scale factor of forward transform.
DFTI_BACKWARD_SCALE	Floating-point scalar	Scale factor of backward transform.
DFTI_PLACEMENT	Named constant	Placement of the computation result.
DFTI_COMMIT_STATUS	Named constant	Shows whether descriptor has been committed.
DFTI_FORWARD_DOMAIN	Named constant	Forward domain of transforms, has the value of DFTI_COMPLEX or DFTI_REAL.
DFTI_ORDERING	Named constant	Scrambling of data order.
CDFT_MPI_COMM	Type of MPI communicator	MPI communicator used for transforms.
CDFT_LOCAL_SIZE	Integer scalar	Necessary size of input, output, and buffer arrays in data elements.
CDFT_LOCAL_X_START	Integer scalar	Row/element number of the global array that corresponds to the first row/element of the local array. For more information, see Distributing Data among Processes .

Parameter Name	Data Type	Description
CDFT_LOCAL_NX	Integer scalar	The number of rows/elements of the global array stored in the local array. For more information, see Distributing Data among Processes .
CDFT_LOCAL_OUT_X_START	Integer scalar	Element number of the appropriate global array that corresponds to the first element of the input or output local array in a 1D case. For details, see Distributing Data among Processes .
CDFT_LOCAL_OUT_NX	Integer scalar	The number of elements of the appropriate global array that are stored in the input or output local array in a 1D case. For details, see Distributing Data among Processes .

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```

    END FUNCTION
END INTERFACE

/* C/C++ prototype */
MKL_LONG DftiGetValueDM(DFTI_DESCRIPTOR_DM_HANDLE handle, int param,...);
```

Error Codes

All the cluster FFT functions return an integer value denoting the status of the operation. These values are identified by named constants. Each function returns `DFTI_NO_ERROR` if no errors were encountered during execution. Otherwise, a function generates an error code. In addition to FFT error codes, the cluster FFT interface has its own ones. Named constants specific to the cluster FFT interface have prefix "CDFT" in names. [Table 11-22](#) lists error codes that the cluster FFT functions may return.

Table 11-22 Error Codes that Cluster FFT Functions Return

Named Constants	Comments
<code>DFTI_NO_ERROR</code>	No error.
<code>DFTI_MEMORY_ERROR</code>	Usually associated with memory allocation.
<code>DFTI_INVALID_CONFIGURATION</code>	Invalid settings of one or more configuration parameters.
<code>DFTI_INCONSISTENT_CONFIGURATION</code>	Inconsistent configuration or input parameters.
<code>DFTI_NUMBER_OF_THREADS_ERROR</code>	Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function).
<code>DFTI_MULTITHREADED_ERROR</code>	Usually associated with a value that OMP routines return in case of errors.
<code>DFTI_BAD_DESCRIPTOR</code>	Descriptor is unusable for computation.
<code>DFTI_UNIMPLEMENTED</code>	Unimplemented legitimate settings; implementation dependent.
<code>DFTI_MKL_INTERNAL_ERROR</code>	Internal library error.
<code>DFTI_1D_LENGTH_EXCEEDS_INT32</code>	Length of one of dimensions exceeds $2^{32} - 1$ (4 bytes).
<code>CDFT_SPREAD_ERROR</code>	Data cannot be distributed (For more information, see Distributing Data among Processes.)
<code>CDFT_MPI_ERROR</code>	MPI error. Occurs when calling MPI.

PBLAS Routines

This chapter describes the Intel® Math Kernel Library implementation of the PBLAS (Parallel Basic Algebra Subprograms) routines from the ScaLAPACK package for distributed-memory architecture. PBLAS is intended for using for vector-vector, matrix-vector and matrix-matrix operations with the aim of simplifying the parallelization of linear codes. The design of PBLAS is as consistent as possible with that of the BLAS. The routine descriptions are arranged in several sections according to the PBLAS level of operation:

- [PBLAS Level 1 Routines](#) (distributed vector-vector operations)
- [PBLAS Level 2 Routines](#) (distributed matrix-vector operations)
- [PBLAS Level 3 Routines](#) (distributed matrix-matrix operations)

Each section presents the routine and function group descriptions in alphabetical order by routine group name; for example, the `p?asum` group, the `p?axpy` group. The question mark in the group name corresponds to different character indicating the data type (`s`, `d`, `c`, and `z` or their combination); see [Routine Naming Conventions](#).

NOTE. PBLAS routines are provided only with Intel® MKL versions for Linux* and Windows* OSs.

Generally, PBLAS runs on a network of computers using MPI as a message-passing layer and a set of prebuilt communication subprograms (BLACS), as well as a set of PBLAS optimized for the target architecture. Intel MKL version of PBLAS is optimized for Intel® processors. For the detailed system and environment requirements see *Intel® MKL Release Notes* and *Intel® MKL User's Guide*.

For full reference on PBLAS routines and related information see http://www.netlib.org/scalapack/html/pblas_qref.html.

Overview

The model of the computing environment for PBLAS is represented as a one-dimensional array of processes or also a two-dimensional process grid. To use PBLAS, all global matrices or vectors must be distributed on this array or grid prior to calling the PBLAS routines.

PBLAS uses the two-dimensional block-cyclic data distribution as a layout for dense matrix computations. This distribution provides good work balance between available processors, as well as gives the opportunity to use PBLAS Level 3 routines for optimal local computations. Information about the data distribution that is required to establish the mapping between each global array and

its corresponding process and memory location is contained in the so called *array descriptor* associated with each global array. An example of an array descriptor structure is given in [Table 12-1](#).

Table 12-1 Content of the array descriptor for dense matrices

Array Element #	Name	Definition
1	<i>dtype</i>	Descriptor type (=1 for dense matrices)
2	<i>ctxt</i>	BLACS context handle for the process grid
3	<i>m</i>	Number of rows in the global array
4	<i>n</i>	Number of columns in the global array
5	<i>mb</i>	Row blocking factor
6	<i>nb</i>	Column blocking factor
7	<i>rsrc</i>	Process row over which the first row of the global array is distributed
8	<i>csrc</i>	Process column over which the first column of the global array is distributed
9	<i>lld</i>	Leading dimension of the local array

The number of rows and columns of a global dense matrix that a particular process in a grid receives after data distributing is denoted by *LOCr()* and *LOCc()*, respectively. To compute these numbers, you can use the ScaLAPACK tool routine *numroc*.

After the block-cyclic distribution of global data is done, you may choose to perform an operation on a submatrix of the global matrix *A*, which is contained in the global subarray *sub(A)*, defined by the following 6 values (for dense matrices):

<i>m</i>	The number of rows of <i>sub(A)</i>
<i>n</i>	The number of columns of <i>sub(A)</i>
<i>a</i>	A pointer to the local array containing the entire global array <i>A</i>
<i>ia</i>	The row index of <i>sub(A)</i> in the global array
<i>ja</i>	The column index of <i>sub(A)</i> in the global array
<i>desca</i>	The array descriptor for the global array <i>A</i>

Intel MKL provides the PBLAS routines with interface similar to the interface used in the Netlib PBLAS (see http://www.netlib.org/scalapack/html/pblas_qref.html).

Routine Naming Conventions

The naming convention for PBLAS routines is similar to that used for BLAS routines (see [Routine Naming Conventions in Chapter 2](#)). A general rule is that each routine name in PBLAS, which has a BLAS equivalent, is simply the BLAS name prefixed by initial letter *p* that stands for "parallel".

PBLAS routine names have the following structure:

`p <character> <name> <mod> ()`

The `<character>` field indicates the Fortran data type:

<code>s</code>	real, single precision
<code>c</code>	complex, single precision
<code>d</code>	real, double precision
<code>z</code>	complex, double precision

Some routines and functions can have combined character codes, such as `sc` or `dz`.

For example, the function `pscsum` uses a complex input array and returns a real value.

The `<name>` field, in PBLAS level 1, indicates the operation type. For example, the PBLAS level 1 routines `p?dot`, `p?swap`, `p?copy` compute a vector dot product, vector swap, and copy vector, respectively.

In PBLAS level 2 and 3, `<name>` reflects the matrix argument type:

<code>ge</code>	general matrix
<code>sy</code>	symmetric matrix
<code>he</code>	Hermitian matrix
<code>tr</code>	triangular matrix

In PBLAS level 3, the `<name>=tran` indicates the transposition of the matrix.

The `<mod>` field, if present, provides additional details of the operation. PBLAS level 1 names can have the following characters in the `<mod>` field:

<code>c</code>	conjugated vector
<code>u</code>	unconjugated vector

PBLAS level 2 names can have the following additional characters in the `<mod>` field:

<code>mv</code>	matrix-vector product
<code>sv</code>	solving a system of linear equations with matrix-vector operations
<code>r</code>	rank-1 update of a matrix
<code>r2</code>	rank-2 update of a matrix.

PBLAS level 3 names can have the following additional characters in the `<mod>` field:

<code>mm</code>	matrix-matrix product
<code>sm</code>	solving a system of linear equations with matrix-matrix operations
<code>rk</code>	rank- k update of a matrix

$r2k$ rank- $2k$ update of a matrix.

The examples below illustrate how to interpret PBLAS routine names:

<code>pddot</code>	<code><p> <d> <dot></code> : double-precision real distributed vector-vector dot product
<code>pcdotc</code>	<code><p> <c> <dot> <c></code> : complex distributed vector-vector dot product, conjugated
<code>pscasum</code>	<code><p> <sc> <asum></code> : sum of magnitudes of distributed vector elements, single precision real output and single precision complex input
<code>pcdotu</code>	<code><p> <c> <dot> <u></code> : distributed vector-vector dot product, unconjugated, complex
<code>psgemv</code>	<code><p> <s> <ge> <mv></code> : distributed matrix-vector product, general matrix, single precision
<code>pztrmm</code>	<code><p> <z> <tr> <mm></code> : distributed matrix-matrix product, triangular matrix, double-precision complex.

PBLAS Level 1 Routines

PBLAS Level 1 includes routines and functions, which perform distributed vector-vector operations. [Table 12-1](#) lists the PBLAS Level 1 routine groups and the data types associated with them.

Table 12-1 PBLAS Level 1 Routine Groups and Their Data Types

Routine or Function Group	Data Types	Description
<code>p?amax</code>	s, d, c, z	Calculates an index of the distributed vector element with maximum absolute value
<code>p?asum</code>	s, d, sc, dz	Calculates sum of magnitudes of a distributed vector
<code>p?axpy</code>	s, d, c, z	Calculates distributed vector-scalar product
<code>p?copy</code>	s, d, c, z	Copies a distributed vector
<code>p?dot</code>	s, d	Calculates a dot product of two distributed real vectors
<code>p?dotc</code>	c, z	Calculates a dot product of two distributed complex vectors, one of them is conjugated

Routine or Function Group	Data Types	Description
<code>p?dotu</code>	<code>c, z</code>	Calculates a dot product of two distributed complex vectors
<code>p?nrm2</code>	<code>s, d, sc, dz</code>	Calculates the 2-norm (Euclidean norm) of a distributed vector
<code>p?scal</code>	<code>s, d, c, z, cs, zd</code>	Calculates a product of a distributed vector by a scalar
<code>p?swap</code>	<code>s, d, c, z</code>	Swaps two distributed vectors

p?amax

Computes the global index of the element of a distributed vector with maximum absolute value.

Syntax

```
call psamax(n, amax, indx, x, ix, jx, descx, incx)
call pdamax(n, amax, indx, x, ix, jx, descx, incx)
call pcamax(n, amax, indx, x, ix, jx, descx, incx)
call pzamax(n, amax, indx, x, ix, jx, descx, incx)
```

Description

The functions `p?amax` compute global index of the maximum element in absolute value of a distributed vector `sub(x)`,

where `sub(x)` denotes `X(ix, jx:jx+n-1)` if `incx=m_x`, and `X(ix: ix+n-1, jx)` if `incx=1`.

Input Parameters

`n` (global) INTEGER. The length of distributed vector `sub(x)`, $n \geq 0$.

`x` (local) REAL for `psamax`
DOUBLE PRECISION for `pdamax`

	COMPLEX for pcamax DOUBLE COMPLEX for pzamax Array, DIMENSION $(jx-1)*m_x + ix + (n-1)*abs(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>x</code> indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively.
<code>descx</code>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <code>x</code> .
<code>incx</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and <code>m_x</code> . <code>incx</code> must not be zero.

Output Parameters

<code>amax</code>	(global) REAL for psamax. DOUBLE PRECISION for pdamax. COMPLEX for pcamax. DOUBLE COMPLEX for pzamax. Maximum absolute value (magnitude) of elements of the distributed vector only in its scope.
<code>indx</code>	(global) INTEGER. The global index of the maximum element in absolute value of the distributed vector <code>sub(x)</code> only in its scope.

p?asum

Computes the sum of magnitudes of elements of a distributed vector.

Syntax

```
call psasum(n, asum, x, ix, jx, descx, incx)
call pscasum(n, asum, x, ix, jx, descx, incx)
call pdasum(n, asum, x, ix, jx, descx, incx)
call pdzasum(n, asum, x, ix, jx, descx, incx)
```

Description

The functions `p?asum` compute the sum of the magnitudes of elements of a distributed vector `sub(x)`,

where `sub(x)` denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx=1$.

Input Parameters

<code>n</code>	(global) INTEGER. The length of distributed vector <code>sub(x)</code> , $n \geq 0$.
<code>x</code>	(local) REAL for <code>psasum</code> DOUBLE PRECISION for <code>pdasum</code> COMPLEX for <code>pscasum</code> DOUBLE COMPLEX for <code>pdzasum</code> Array, DIMENSION $(jx-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>x</code> indicating the first row and the first column of the submatrix <code>sub(x)</code> , respectively.
<code>descx</code>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <code>x</code> .
<code>incx</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . $incx$ must not be zero.

Output Parameters

<code>asum</code>	(local) REAL for <code>psasum</code> and <code>pscasum</code> . DOUBLE PRECISION for <code>pdasum</code> and <code>pdzasum</code> Contains the sum of magnitudes of elements of the distributed vector only in its scope.
-------------------	---

p?axpy

Computes a distributed vector-scalar product and adds the result to a distributed vector.

Syntax

```
call psaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pdaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pcaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Description

The p?axpy routines perform the following operation with distributed vectors:

$\text{sub}(y) := \text{sub}(y) + a * \text{sub}(x)$

where:

a is a scalar;

$\text{sub}(x)$ and $\text{sub}(y)$ are n -element distributed vectors.

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;

$\text{sub}(y)$ denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

n	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
a	(local) REAL for psaxpy DOUBLE PRECISION for pdaxpy COMPLEX for pcaxpy DOUBLE COMPLEX for pzaxpy Specifies the scalar a .
x	(local) REAL for psaxpy DOUBLE PRECISION for pdaxpy COMPLEX for pcaxpy DOUBLE COMPLEX for pzaxpy Array, DIMENSION $(jx-1)*m_x + ix+(n-1)*abs(incx)$.

	This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix x indicating the first row and the first column of the submatrix $\text{sub}(X)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix x .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) REAL for psaxpy DOUBLE PRECISION for pdaxpy COMPLEX for pcaxpy DOUBLE COMPLEX for pzaxpy Array, DIMENSION $(jy-1)*m_y + iy + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix y indicating the first row and the first column of the submatrix $\text{sub}(Y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix y .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

y Overwritten by $\text{sub}(y) := \text{sub}(y) + a*\text{sub}(x)$.

p?copy

Copies one distributed vector to another vector.

Syntax

```
call pscopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

```
call pdcopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pccopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzcopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Description

The `p?copy` routines perform a copy operation with distributed vectors defined as

$\text{sub}(y) = \text{sub}(x)$,

where $\text{sub}(x)$ and $\text{sub}(y)$ are n -element distributed vectors.

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx=1$;

$\text{sub}(y)$ denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy=1$.

Input Parameters

<i>n</i>	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
<i>x</i>	(local) REAL for <code>pscopy</code> DOUBLE PRECISION for <code>pdcopy</code> COMPLEX for <code>pccopy</code> DOUBLE COMPLEX for <code>pzcopy</code> Array, DIMENSION $(jx-1)*m_x + ix + (n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(X)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix X .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) REAL for <code>pscopy</code> DOUBLE PRECISION for <code>pdcopy</code> COMPLEX for <code>pccopy</code> DOUBLE COMPLEX for <code>pzcopy</code> Array, DIMENSION $(jy-1)*m_y + iy + (n-1)*\text{abs}(incy)$.

	This array contains the entries of the distributed vector <code>sub(y)</code> .
<code>iy, jy</code>	(global) <code>INTEGER</code> . The row and column indices in the distributed matrix <code>Y</code> indicating the first row and the first column of the submatrix <code>sub(Y)</code> , respectively.
<code>descy</code>	(global and local) <code>INTEGER</code> array of dimension 8. The array descriptor of the distributed matrix <code>Y</code> .
<code>incy</code>	(global) <code>INTEGER</code> . Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and <code>m_y</code> . <code>incy</code> must not be zero.

Output Parameters

<code>y</code>	Overwritten by the distributed vector <code>sub(x)</code> .
----------------	---

p?dot

Computes the dot product of two distributed real vectors.

Syntax

```
call psdot(n, dot, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pddot(n, dot, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Description

The ?dot functions compute the dot product `dot` of two distributed real vectors defined as

$$dot = sub(x)' * sub(y)$$

where `sub(x)` and `sub(y)` are n -element distributed vectors.

`sub(x)` denotes `X(ix, jx:jx+n-1)` if `incx=m_x`, and `X(ix: ix+n-1, jx)` if `incx= 1`;

`sub(y)` denotes `Y(iy, jy:jy+n-1)` if `incy=m_y`, and `Y(iy: iy+n-1, jy)` if `incy= 1`.

Input Parameters

<code>n</code>	(global) <code>INTEGER</code> . The length of distributed vectors, $n \geq 0$.
<code>x</code>	(local) <code>REAL</code> for <code>psdot</code> <code>DOUBLE PRECISION</code> for <code>pddot</code>

	<p>Array, DIMENSION $(j_x-1)*m_x + ix + (n-1)*abs(incx)$. This array contains the entries of the distributed vector $sub(x)$.</p>
<i>ix, jx</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix x indicating the first row and the first column of the submatrix $sub(X)$, respectively.</p>
<i>descx</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix x.</p>
<i>incx</i>	<p>(global) INTEGER. Specifies the increment for the elements of $sub(x)$. Only two values are supported, namely 1 and m_x. <i>incx</i> must not be zero.</p>
<i>y</i>	<p>(local) REAL for psdot DOUBLE PRECISION for pddot Array, DIMENSION $(j_y-1)*m_y + iy + (n-1)*abs(incy)$. This array contains the entries of the distributed vector $sub(y)$.</p>
<i>iy, jy</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix y indicating the first row and the first column of the submatrix $sub(Y)$, respectively.</p>
<i>descy</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix y.</p>
<i>incy</i>	<p>(global) INTEGER. Specifies the increment for the elements of $sub(y)$. Only two values are supported, namely 1 and m_y. <i>incy</i> must not be zero.</p>

Output Parameters

<i>dot</i>	<p>(local) REAL for psdot DOUBLE PRECISION for pddot Dot product of $sub(x)$ and $sub(y)$ only in their scope.</p>
------------	--

p?dotc

Computes the dot product of two distributed complex vectors, one of them is conjugated.

Syntax

```
call pcdotc(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzdotc(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Description

The `p?dotu` functions compute the dot product `dotc` of two distributed vectors one of them is conjugated:

$$dotc = \text{conjg}(\text{sub}(x)') * \text{sub}(y)$$

where `sub(x)` and `sub(y)` are n -element distributed vectors.

`sub(x)` denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;

`sub(y)` denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

<code>n</code>	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
<code>x</code>	(local) COMPLEX for <code>pcdotc</code> DOUBLE COMPLEX for <code>pzdotc</code> Array, DIMENSION $(jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively.
<code>descx</code>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix X .
<code>incx</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . <code>incx</code> must not be zero.
<code>y</code>	(local) COMPLEX for <code>pcdotc</code> DOUBLE COMPLEX for <code>pzdotc</code>

	Array, DIMENSION $(jy-1)*m_y + iy + (n-1)*abs(incy)$. This array contains the entries of the distributed vector $sub(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix $sub(Y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $sub(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

<i>dotc</i>	(local) COMPLEX for pcdotc DOUBLE COMPLEX for pzdote Dot product of $sub(x)$ and $sub(y)$ only in their scope.
-------------	--

p?dotu

Computes the dot product of two distributed complex vectors.

Syntax

```
call pcdotu(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzdotu(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Description

The p?dotu functions compute the dot product *dotu* of two distributed vectors defined as

$dotu = sub(x)^H * sub(y)$

where $sub(x)$ and $sub(y)$ are *n*-element distributed vectors.

$sub(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;

$sub(y)$ denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

<i>n</i>	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
<i>x</i>	(local) COMPLEX for pcdotu DOUBLE COMPLEX for pzdotu Array, DIMENSION $(jx-1)*m_x + ix + (n-1)*abs(incx)$. This array contains the entries of the distributed vector $sub(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix $sub(X)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $sub(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) COMPLEX for pcdotu DOUBLE COMPLEX for pzdotu Array, DIMENSION $(jy-1)*m_y + iy + (n-1)*abs(incy)$. This array contains the entries of the distributed vector $sub(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix $sub(Y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $sub(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

<i>dotu</i>	(local) COMPLEX for pcdotu DOUBLE COMPLEX for pzdotu Dot product of $sub(x)$ and $sub(y)$ only in their scope.
-------------	--

p?nrm2

Computes the Euclidean norm of a distributed vector.

Syntax

```
call psnrm2(n, norm2, x, ix, jx, descx, incx)
call pdnrm2(n, norm2, x, ix, jx, descx, incx)
call pscnrm2(n, norm2, x, ix, jx, descx, incx)
call pdznrm2(n, norm2, x, ix, jx, descx, incx)
```

Description

The p?nrm2 functions compute the Euclidean norm of a distributed vector $\text{sub}(x)$, where $\text{sub}(x)$ is an n -element distributed vector.

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$.

Input Parameters

n	(global) INTEGER. The length of distributed vector $\text{sub}(x)$, $n \geq 0$.
x	(local) REAL for psnrm2 DOUBLE PRECISION for pdnrm2 COMPLEX for pscnrm2 DOUBLE COMPLEX for pdznrm2 Array, DIMENSION $(jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
ix, jx	(global) INTEGER. The row and column indices in the distributed matrix x indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
$descx$	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix x .
$incx$	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.

Output Parameters

norm2 (local) REAL for psnrm2 and pscnrm2.
 DOUBLE PRECISION for pdnrm2 and pdznrm2
 Contains the Euclidean norm of a distributed vector only in its scope.

p?scal

Computes a product of a distributed vector by a scalar.

Syntax

```
call psscal(n, a, x, ix, jx, descx, incx)
call pdscal(n, a, x, ix, jx, descx, incx)
call pcscal(n, a, x, ix, jx, descx, incx)
call pzscal(n, a, x, ix, jx, descx, incx)
call pcsscal(n, a, x, ix, jx, descx, incx)
call pzdscale(n, a, x, ix, jx, descx, incx)
```

Description

The p?scal routines multiplies a n -element distributed vector $\text{sub}(x)$ by the scalar a :

$\text{sub}(x) = a * \text{sub}(x),$

where $\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx=1$.

Input Parameters

n (global) INTEGER. The length of distributed vector $\text{sub}(x)$, $n \geq 0$.

a (global) REAL for psscal and pcsscal
 DOUBLE PRECISION for pdscal and pzdscale
 COMPLEX for pcscal
 DOUBLE COMPLEX for pzscal
 Specifies the scalar a .

<i>x</i>	<p>(local) REAL for psscal DOUBLE PRECISION for pdscal COMPLEX for pcscal and pcsscal DOUBLE COMPLEX for pzscal and pzdscale Array, DIMENSION (<i>jx</i>-1)*<i>m_x</i> + <i>ix</i>+(<i>n</i>-1)*abs(<i>incx</i>)). This array contains the entries of the distributed vector <i>sub(x)</i>.</p>
<i>ix, jx</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix <i>sub(X)</i>, respectively.</p>
<i>descx</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i>.</p>
<i>incx</i>	<p>(global) INTEGER. Specifies the increment for the elements of <i>sub(x)</i>. Only two values are supported, namely 1 and <i>m_x</i>. <i>incx</i> must not be zero.</p>

Output Parameters

<i>x</i>	Overwritten by the updated distributed vector <i>sub(x)</i>
----------	---

p?swap

Swaps two distributed vectors.

Syntax

```
call psswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pdswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pcswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Description

Given two distributed vectors *sub(x)* and *sub(y)*, the p?swap routines return vectors *sub(y)* and *sub(x)* swapped, each replacing the other.

Here *sub(x)* denotes *X(ix, jx:jx+n-1)* if *incx=m_x*, and *X(ix: ix+n-1, jx)* if *incx= 1*;
sub(y) denotes *Y(iy, jy:jy+n-1)* if *incy=m_y*, and *Y(iy: iy+n-1, jy)* if *incy= 1*.

Input Parameters

<i>n</i>	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
<i>x</i>	(local) REAL for psswap DOUBLE PRECISION for pdswap COMPLEX for pswap DOUBLE COMPLEX for pzswap Array, DIMENSION $(jx-1)*m_x + ix + (n-1)*abs(incx)$. This array contains the entries of the distributed vector $sub(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix $sub(X)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $sub(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) REAL for psswap DOUBLE PRECISION for pdswap COMPLEX for pswap DOUBLE COMPLEX for pzswap Array, DIMENSION $(jy-1)*m_y + iy + (n-1)*abs(incy)$. This array contains the entries of the distributed vector $sub(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix $sub(Y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $sub(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

<i>x</i>	Overwritten by distributed vector $sub(y)$.
----------	--

y Overwritten by distributed vector `sub(x)`.

PBLAS Level 2 Routines

This section describes PBLAS Level 2 routines, which perform distributed matrix-vector operations. [Table 12-2](#) lists the PBLAS Level 2 routine groups and the data types associated with them.

Table 12-2 PBLAS Level 2 Routine Groups and Their Data Types

Routine Groups	Data Types	Description
p?gemv	s, d, c, z	Matrix-vector product using a distributed general matrix
p?ger	s, d	Rank-1 update of a distributed general matrix
p?gerc	c, z	Rank-1 update (conjugated) of a distributed general matrix
p?geru	c, z	Rank-1 update (unconjugated) of a distributed general matrix
p?hemv	c, z	Matrix-vector product using a distributed Hermitian matrix
p?her	c, z	Rank-1 update of a distributed Hermitian matrix
p?her2	c, z	Rank-2 update of a distributed Hermitian matrix
p?symv	s, d	Matrix-vector product using a distributed symmetric matrix
p?syr	s, d	Rank-1 update of a distributed symmetric matrix
p?syr2	s, d	Rank-2 update of a distributed symmetric matrix
p?trmv	s, d, c, z	Distributed matrix-vector product using a triangular matrix
p?trsv	s, d, c, z	Solves a system of linear equations whose coefficients are in a distributed triangular matrix

p?gemv

Computes a distributed matrix-vector product using a general matrix

Syntax

```
call psgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx,
beta, y, iy, jy, descy, incy)

call pdgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx,
beta, y, iy, jy, descy, incy)

call pcgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx,
beta, y, iy, jy, descy, incy)

call pzgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx,
beta, y, iy, jy, descy, incy)
```

Description

The p?gemv routines perform a distributed matrix-vector operation defined as

$\text{sub}(y) := \alpha * \text{sub}(A) * \text{sub}(x) + \beta * \text{sub}(y),$

or

$\text{sub}(y) := \alpha * \text{sub}(A)' * \text{sub}(x) + \beta * \text{sub}(y),$

or

$\text{sub}(y) := \alpha * \text{conjg}(\text{sub}(A)') * \text{sub}(x) + \beta * \text{sub}(y),$

where

α and β are scalars,

$\text{sub}(A)$ is a m -by- n submatrix, $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1),$

$\text{sub}(x)$ and $\text{sub}(y)$ are subvectors.

When $\text{trans} = 'N'$ or $'n'$, $\text{sub}(x)$ denotes $X(\text{ix}, \text{jx}:\text{jx}+n-1)$ if $\text{incx} = m_x$, and $X(\text{ix}:\text{ix}+n-1, \text{jx})$ if $\text{incx} = 1$, $\text{sub}(y)$ denotes $Y(\text{iy}, \text{jy}:\text{jy}+m-1)$ if $\text{incy} = m_y$, and $Y(\text{iy}:\text{iy}+m-1, \text{jy})$ if $\text{incy} = 1$.

When $\text{trans} = 'T'$ or $'t'$, or $'C'$, or $'c'$, $\text{sub}(x)$ denotes $X(\text{ix}, \text{jx}:\text{jx}+m-1)$ if $\text{incx} = m_x$, and $X(\text{ix}:\text{ix}+m-1, \text{jx})$ if $\text{incx} = 1$, $\text{sub}(y)$ denotes $Y(\text{iy}, \text{jy}:\text{jy}+n-1)$ if $\text{incy} = m_y$, and $Y(\text{iy}:\text{iy}+m-1, \text{jy})$ if $\text{incy} = 1$.

Input Parameters

<i>trans</i>	(global) CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then $\text{sub}(y) := \alpha * \text{sub}(A) * \text{sub}(x) + \beta * \text{sub}(y)$; if <i>trans</i> = 'T' or 't', then $\text{sub}(y) := \alpha * \text{sub}(A)^T * \text{sub}(x) + \beta * \text{sub}(y)$; if <i>trans</i> = 'C' or 'c', then $\text{sub}(y) := \alpha * \text{conjg}(\text{sub}(A)) * \text{sub}(x) + \beta * \text{sub}(y)$.
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix $\text{sub}(A)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) REAL for psgemv DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) REAL for psgemv DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv Array, DIMENSION (<i>lld_a</i> , <i>LOCq(ja+n-1)</i>). Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .
<i>x</i>	(local) REAL for psgemv DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv

	<p>Array, DIMENSION $(jx-1)*m_x + ix + (n-1)*abs(incx)$ when $trans = 'N'$ or $'n'$, and $(jx-1)*m_x + ix + (m-1)*abs(incx)$ otherwise.</p> <p>This array contains the entries of the distributed vector $sub(x)$.</p>
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix x indicating the first row and the first column of the submatrix $sub(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix x .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $sub(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.
<i>beta</i>	<p>(global) REAL for psgemv DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv</p> <p>Specifies the scalar $beta$. When $beta$ is set to zero, then $sub(y)$ need not be set on input.</p>
<i>y</i>	<p>(local) REAL for psgemv DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv</p> <p>Array, DIMENSION $(jy-1)*m_y + iy + (m-1)*abs(incy)$ when $trans = 'N'$ or $'n'$, and $(jy-1)*m_y + iy + (n-1)*abs(incy)$ otherwise.</p> <p>This array contains the entries of the distributed vector $sub(y)$.</p>
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix y indicating the first row and the first column of the submatrix $sub(y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix y .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $sub(y)$. Only two values are supported, namely 1 and m_y . $incy$ must not be zero.

Output Parameters

y Overwritten by the updated distributed vector `sub(y)`.

p?ger

Performs a rank-1 update of a distributed general matrix.

Syntax

```
call psger(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a,
ia, ja, desca)
```

```
call pdger(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a,
ia, ja, desca)
```

Description

The `p?ger` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{sub}(y)' + \text{sub}(A),$$

where:

α is a scalar,

$\text{sub}(A)$ is a m -by- n distributed general matrix, $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$,

$\text{sub}(x)$ is an m -element distributed vector, $\text{sub}(y)$ is an n -element distributed vector,

$\text{sub}(x)$ denotes $X(ix, jx:jx+m-1)$ if $incx = m_x$, and $X(ix: ix+m-1, jx)$ if $incx = 1$,

$\text{sub}(y)$ denotes $Y(iy, jy:jy+n-1)$ if $incy = m_y$, and $Y(iy: iy+n-1, jy)$ if $incy = 1$.

Input Parameters

m	(global) INTEGER. Specifies the number of rows of the distributed matrix <code>sub(A)</code> , $m \geq 0$.
n	(global) INTEGER. Specifies the number of columns of the distributed matrix <code>sub(A)</code> , $n \geq 0$.
α	(global) REAL for <code>psger</code> DOUBLE REAL for <code>pdger</code> Specifies the scalar α .

<i>x</i>	<p>(local) REAL for psgcr DOUBLE REAL for pdger Array, DIMENSION at least $(j_x-1)*m_x + i_x + (m-1)*abs(incx)$. This array contains the entries of the distributed vector $sub(x)$.</p>
<i>ix, jx</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix $sub(x)$, respectively.</p>
<i>descx</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i>.</p>
<i>incx</i>	<p>(global) INTEGER. Specifies the increment for the elements of $sub(x)$. Only two values are supported, namely 1 and m_x. <i>incx</i> must not be zero.</p>
<i>y</i>	<p>(local) REAL for psgcr DOUBLE REAL for pdger Array, DIMENSION at least $(j_y-1)*m_y + i_y + (n-1)*abs(incy)$. This array contains the entries of the distributed vector $sub(y)$.</p>
<i>iy, jy</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix $sub(y)$, respectively.</p>
<i>descy</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>y</i>.</p>
<i>incy</i>	<p>(global) INTEGER. Specifies the increment for the elements of $sub(y)$. Only two values are supported, namely 1 and m_y. <i>incy</i> must not be zero.</p>
<i>a</i>	<p>(local) REAL for psgcr DOUBLE REAL for pdger Array, DIMENSION $(lld_a, LOCq(ja+n-1))$. Before entry this array contains the local pieces of the distributed matrix $sub(A)$.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $sub(A)$, respectively.</p>

desca (global and local) `INTEGER` array of dimension 8. The array descriptor of the distributed matrix *A*.

Output Parameters

a Overwritten by the updated distributed matrix `sub(A)`.

p?gerc

Performs a rank-1 update (conjugated) of a distributed general matrix.

Syntax

```
call pcgerc(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a,
ia, ja, desca)
```

```
call pzgerc(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a,
ia, ja, desca)
```

Description

The `p?gerc` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{conjg}(\text{sub}(y)') + \text{sub}(A),$$

where:

alpha is a scalar,

`sub(A)` is a *m*-by-*n* distributed general matrix, `sub(A) = A(ia:ia+m-1, ja:ja+n-1)`,

`sub(x)` is an *m*-element distributed vector, `sub(y)` is an *n*-element distributed vector,

`sub(x)` denotes `X(ix, jx:jx+m-1)` if `incx = m_x`, and `X(ix: ix+m-1, jx)` if `incx = 1`,

`sub(y)` denotes `Y(iy, jy:jy+n-1)` if `incy = m_y`, and `Y(iy: iy+n-1, jy)` if `incy = 1`.

Input Parameters

m (global) `INTEGER`. Specifies the number of rows of the distributed matrix `sub(A)`, $m \geq 0$.

n (global) `INTEGER`. Specifies the number of columns of the distributed matrix `sub(A)`, $n \geq 0$.

alpha (global) `COMPLEX` for `pcgerc`

	DOUBLE COMPLEX for pzgerc Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) COMPLEX for pcgerc DOUBLE COMPLEX for pzgerc Array, DIMENSION at least $(j_x-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector $sub(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix $sub(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $sub(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) COMPLEX for pcgerc DOUBLE COMPLEX for pzgerc Array, DIMENSION at least $(j_y-1)*m_y + iy+(n-1)*abs(incy)$. This array contains the entries of the distributed vector $sub(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix $sub(y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $sub(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.
<i>a</i>	(local) COMPLEX for pcgerc DOUBLE COMPLEX for pzgerc Array, DIMENSION at least $(lld_a, LOCq(ja+n-1))$. Before entry this array contains the local pieces of the distributed matrix $sub(A)$.

<i>ia, ja</i>	(global) <code>INTEGER</code> . The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<i>desca</i>	(global and local) <code>INTEGER</code> array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .

Output Parameters

<i>a</i>	Overwritten by the updated distributed matrix <code>sub(A)</code> .
----------	---

p?geru

Performs a rank-1 update (unconjugated) of a distributed general matrix.

Syntax

```
call pcgeru(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a,
ia, ja, desca)

call pzgeru(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a,
ia, ja, desca)
```

Description

The `p?geru` routines perform a matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{sub}(y)' + \text{sub}(A),$$

where:

alpha is a scalar,

`sub(A)` is a *m*-by-*n* distributed general matrix, `sub(A)=A(ia:ia+m-1, ja:ja+n-1)`,

`sub(x)` is an *m*-element distributed vector, `sub(y)` is an *n*-element distributed vector,

`sub(x)` denotes `X(ix, jx:jx+m-1)` if `incx = m_x`, and `X(ix: ix+m-1, jx)` if `incx = 1`,

`sub(y)` denotes `Y(iy, jy:jy+n-1)` if `incy = m_y`, and `Y(iy: iy+n-1, jy)` if `incy = 1`.

Input Parameters

<i>m</i>	(global) <code>INTEGER</code> . Specifies the number of rows of the distributed matrix <code>sub(A)</code> , $m \geq 0$.
----------	---

<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) COMPLEX for pcgeru DOUBLE COMPLEX for pzgeru Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) COMPLEX for pcgeru DOUBLE COMPLEX for pzgeru Array, DIMENSION at least $(j_x-1)*m_x + ix + (n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) COMPLEX for pcgeru DOUBLE COMPLEX for pzgeru Array, DIMENSION at least $(j_y-1)*m_y + iy + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.
<i>a</i>	(local) COMPLEX for pcgeru DOUBLE COMPLEX for pzgeru

	Array, DIMENSION at least $(lld_a, LOCq(ja+n-1))$. Before entry this array contains the local pieces of the distributed matrix $sub(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $sub(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix A .

Output Parameters

<i>a</i>	Overwritten by the updated distributed matrix $sub(A)$.
----------	--

p?hemv

Computes a distributed matrix-vector product using a Hermitian matrix.

Syntax

```
call pchemv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta,
y, iy, jy, descy, incy)

call pzhemv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta,
y, iy, jy, descy, incy)
```

Description

The p?hemv routines perform a distributed matrix-vector operation defined as

$$sub(y) := alpha * sub(A) * sub(x) + beta * sub(y),$$

where:

alpha and *beta* are scalars,

$sub(A)$ is a n -by- n Hermitian distributed matrix, $sub(A) = A(ia:ia+n-1, ja:ja+n-1)$,

$sub(x)$ and $sub(y)$ are distributed vectors.

$sub(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx = m_x$, and $X(ix: ix+n-1, jx)$ if $incx = 1$,

$sub(y)$ denotes $Y(iy, jy:jy+n-1)$ if $incy = m_y$, and $Y(iy: iy+n-1, jy)$ if $incy = 1$.

Input Parameters

<i>uplo</i>	<p>(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix $\text{sub}(A)$ is used:</p> <p>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the $\text{sub}(A)$ is used.</p> <p>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the $\text{sub}(A)$ is used.</p>
<i>n</i>	<p>(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.</p>
<i>alpha</i>	<p>(global) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Specifies the scalar <i>alpha</i>.</p>
<i>a</i>	<p>(local) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Array, DIMENSION (<i>lld_a</i>, $\text{LOCq}(ja+n-1)$). This array contains the local pieces of the distributed matrix $\text{sub}(A)$. Before entry when <i>uplo</i> = 'U' or 'u', the n-by-n upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and when <i>uplo</i> = 'L' or 'l', the n-by-n lower triangular part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i>.</p>
<i>x</i>	<p>(local) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Array, DIMENSION at least $(jx-1)*m_x + ix + (n-1)*\text{abs}(incx)$.</p>

	This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix X .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>beta</i>	(global) COMPLEX for <code>pchemv</code> DOUBLE COMPLEX for <code>pzhemv</code> Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then $\text{sub}(y)$ need not be set on input.
<i>y</i>	(local) COMPLEX for <code>pchemv</code> DOUBLE COMPLEX for <code>pzhemv</code> Array, DIMENSION at least $(jy-1)*m_y + iy + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix Y .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated distributed vector $\text{sub}(y)$.
----------	---

p?her

Performs a rank-1 update of a distributed Hermitian matrix.

Syntax

```
call pcher(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
call pzher(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
```

Description

The p?her routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{conjg}(\text{sub}(x)') + \text{sub}(A),$$

where:

α is a real scalar,

$\text{sub}(A)$ is a n -by- n distributed Hermitian matrix, $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$,

$\text{sub}(x)$ is distributed vector.

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx = m_x$, and $X(ix:ix+n-1, jx)$ if $incx = 1$.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix $\text{sub}(A)$ is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the $\text{sub}(A)$ is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the $\text{sub}(A)$ is used.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) REAL for pcher DOUBLE REAL for pzher Specifies the scalar α .
<i>x</i>	(local) COMPLEX for pcher DOUBLE COMPLEX for pzher

	<p>Array, DIMENSION at least $(j_x-1)*m_x + ix+(n-1)*abs(incx)$.</p> <p>This array contains the entries of the distributed vector $sub(x)$.</p>
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix x indicating the first row and the first column of the submatrix $sub(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix x .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $sub(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>a</i>	<p>(local) COMPLEX for <i>pcher</i> DOUBLE COMPLEX for <i>pzher</i></p> <p>Array, DIMENSION $(lld_a, LOCq(ja+n-1))$. This array contains the local pieces of the distributed matrix $sub(A)$. Before entry with <i>uplo</i> = 'U' or 'u', the n-by-n upper triangular part of the distributed matrix $sub(A)$ must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of $sub(A)$ is not referenced, and with <i>uplo</i> = 'L' or 'l', the n-by-n lower triangular part of the distributed matrix $sub(A)$ must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of $sub(A)$ is not referenced.</p>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $sub(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix A .

Output Parameters

<i>a</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of the array <i>a</i> is overwritten by the upper triangular part of the updated distributed matrix $sub(A)$.
----------	---

With `uplo = 'L' or 'l'`, the lower triangular part of the array `a` is overwritten by the lower triangular part of the updated distributed matrix `sub(A)`.

p?her2

Performs a rank-2 update of a distributed Hermitian matrix.

Syntax

```
call pcher2(uplo, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy,
a, ia, ja, desca)

call pzher2(uplo, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy,
a, ia, ja, desca)
```

Description

The `p?her2` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{conj}(\text{sub}(y)') + \text{conj}(\alpha) * \text{sub}(y) * \text{conj}(\text{sub}(x)') + \text{sub}(A),$$

where:

`alpha` is a scalar,

`sub(A)` is a n -by- n distributed Hermitian matrix, `sub(A) = A(ia:ia+n-1, ja:ja+n-1)`,

`sub(x)` and `sub(y)` are distributed vectors.

`sub(x)` denotes $X(ix, jx:jx+n-1)$ if `incx = m_x`, and $X(ix:ix+n-1, jx)$ if `incx = 1`,

`sub(y)` denotes $Y(iy, jy:jy+n-1)$ if `incy = m_y`, and $Y(iy:iy+n-1, jy)$ if `incy = 1`.

Input Parameters

`uplo` (global) CHARACTER*1. Specifies whether the upper or lower triangular part of the distributed Hermitian matrix `sub(A)` is used:
 If `uplo = 'U' or 'u'`, then the upper triangular part of the `sub(A)` is used.
 If `uplo = 'L' or 'l'`, then the low triangular part of the `sub(A)` is used.

<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) COMPLEX for pcher2 DOUBLE COMPLEX for pzher2 Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) COMPLEX for pcher2 DOUBLE COMPLEX for pzher2 Array, DIMENSION at least $(j_x-1)*m_x + ix + (n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) COMPLEX for pcher2 DOUBLE COMPLEX for pzher2 Array, DIMENSION at least $(j_y-1)*m_y + iy + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.
<i>a</i>	(local) COMPLEX for pcher2 DOUBLE COMPLEX for pzher2

Array, `DIMENSION (lld_a, LOCq(ja+n-1))`. This array contains the local pieces of the distributed matrix `sub(A)`. Before entry with `uplo = 'U' or 'u'`, the n -by- n upper triangular part of the distributed matrix `sub(A)` must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of `sub(A)` is not referenced, and with `uplo = 'L' or 'l'`, the n -by- n lower triangular part of the distributed matrix `sub(A)` must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of `sub(A)` is not referenced.

`ia, ja`

(global) `INTEGER`. The row and column indices in the distributed matrix `A` indicating the first row and the first column of the submatrix `sub(A)`, respectively.

`desca`

(global and local) `INTEGER` array of dimension 8. The array descriptor of the distributed matrix `A`.

Output Parameters

`a`

With `uplo = 'U' or 'u'`, the upper triangular part of the array `a` is overwritten by the upper triangular part of the updated distributed matrix `sub(A)`.

With `uplo = 'L' or 'l'`, the lower triangular part of the array `a` is overwritten by the lower triangular part of the updated distributed matrix `sub(A)`.

p?symv

Computes a distributed matrix-vector product using a symmetric matrix.

Syntax

```
call pssymv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta,
y, iy, jy, descy, incy)
```

```
call pdsymv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta,
y, iy, jy, descy, incy)
```

Description

The `p?symv` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(y) := \alpha * \text{sub}(A) * \text{sub}(x) + \beta * \text{sub}(y),$$

where:

alpha and *beta* are scalars,

sub(A) is a *n*-by-*n* symmetric distributed matrix, $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$,

sub(x) and *sub(y)* are distributed vectors.

sub(x) denotes $X(\text{ix}, \text{jx}:\text{jx}+n-1)$ if *incx* = *m_x*, and $X(\text{ix}:\text{ix}+n-1, \text{jx})$ if *incx* = 1,

sub(y) denotes $Y(\text{iy}, \text{jy}:\text{jy}+n-1)$ if *incy* = *m_y*, and $Y(\text{iy}:\text{iy}+n-1, \text{jy})$ if *incy* = 1.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix <i>sub(A)</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(A)</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(A)</i> is used.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix <i>sub(A)</i> , $n \geq 0$.
<i>alpha</i>	(global) REAL for <code>pssymv</code> DOUBLE REAL for <code>pdsymv</code> Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) REAL for <code>pssymv</code> DOUBLE REAL for <code>pdsymv</code> Array, DIMENSION (<i>lld_a</i> , <i>LOCq(ja+n-1)</i>). This array contains the local pieces of the distributed matrix <i>sub(A)</i> . Before entry when <i>uplo</i> = 'U' or 'u', the <i>n</i> -by- <i>n</i> upper triangular part of the distributed matrix <i>sub(A)</i> must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of <i>sub(A)</i> is not referenced, and when <i>uplo</i> = 'L' or 'l', the <i>n</i> -by- <i>n</i> lower triangular part of the distributed matrix <i>sub(A)</i> must contain

	the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of <code>sub(A)</code> is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .
<i>x</i>	(local) REAL for pssymv DOUBLE REAL for pdsymv Array, DIMENSION at least $(j_x-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix <code>sub(x)</code> , respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>beta</i>	(global) REAL for pssymv DOUBLE REAL for pdsymv Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then <code>sub(y)</code> need not be set on input.
<i>y</i>	(local) REAL for pssymv DOUBLE REAL for pdsymv Array, DIMENSION at least $(j_y-1)*m_y + iy+(n-1)*abs(incy)$. This array contains the entries of the distributed vector <code>sub(y)</code> .
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix <code>sub(y)</code> , respectively.

<i>descy</i>	(global and local) <code>INTEGER</code> array of dimension 8. The array descriptor of the distributed matrix <i>y</i> .
<i>incy</i>	(global) <code>INTEGER</code> . Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated distributed vector <code>sub(y)</code> .
----------	---

p?syr

Performs a rank-1 update of a distributed symmetric matrix.

Syntax

```
call pssyr(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
call pdsyr(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
```

Description

The `p?syr` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{sub}(x)' + \text{sub}(A),$$

where:

alpha is a scalar,

`sub(A)` is a *n*-by-*n* distributed symmetric matrix, `sub(A) = A(ia:ia+n-1, ja:ja+n-1)`,

`sub(x)` is distributed vector.

`sub(x)` denotes `X(ix, jx:jx+n-1)` if `incx = m_x`, and `X(ix: ix+n-1, jx)` if `incx = 1`,

Input Parameters

<i>uplo</i>	(global) <code>CHARACTER*1</code> . Specifies whether the upper or lower triangular part of the symmetric distributed matrix <code>sub(A)</code> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <code>sub(A)</code> is used.
-------------	--

	If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(A)</i> is used.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix <i>sub(A)</i> , $n \geq 0$.
<i>alpha</i>	(global) REAL for <i>pssyr</i> DOUBLE REAL for <i>pdsyr</i> Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) REAL for <i>pssyr</i> DOUBLE REAL for <i>pdsyr</i> Array, DIMENSION at least $(j_x-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector <i>sub(x)</i> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix <i>sub(x)</i> , respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>a</i>	(local) REAL for <i>pssyr</i> DOUBLE REAL for <i>pdsyr</i> Array, DIMENSION $(lld_a, LOCq(ja+n-1))$. This array contains the local pieces of the distributed matrix <i>sub(A)</i> . Before entry with <i>uplo</i> = 'U' or 'u', the <i>n</i> -by- <i>n</i> upper triangular part of the distributed matrix <i>sub(A)</i> must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of <i>sub(A)</i> is not referenced, and with <i>uplo</i> = 'L' or 'l', the <i>n</i> -by- <i>n</i> lower triangular part of the distributed matrix <i>sub(A)</i> must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of <i>sub(A)</i> is not referenced.

<i>ia, ja</i>	(global) <code>INTEGER</code> . The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<i>desca</i>	(global and local) <code>INTEGER</code> array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .

Output Parameters

<i>a</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of the array <i>a</i> is overwritten by the upper triangular part of the updated distributed matrix <code>sub(A)</code> . With <i>uplo</i> = 'L' or 'l', the lower triangular part of the array <i>a</i> is overwritten by the lower triangular part of the updated distributed matrix <code>sub(A)</code> .
----------	--

p?syrr2

Performs a rank-2 update of a distributed symmetric matrix.

Syntax

```
call pssyr2(uplo, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy,
a, ia, ja, desca)

call pdsyr2(uplo, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy,
a, ia, ja, desca)
```

Description

The `p?syrr2` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{sub}(y)' + \alpha * \text{sub}(y) * \text{sub}(x)' + \text{sub}(A),$$

where:

alpha is a scalar,

`sub(A)` is a *n*-by-*n* distributed symmetric matrix, `sub(A)=A(ia:ia+n-1, ja:ja+n-1)`,

`sub(x)` and `sub(y)` are distributed vectors.

`sub(x)` denotes `X(ix, jx:jx+n-1)` if `incx = m_x`, and `X(ix: ix+n-1, jx)` if `incx = 1`,

`sub(y)` denotes `Y(iy, jy:jy+n-1)` if `incy = m_y`, and `Y(iy: iy+n-1, jy)` if `incy = 1`.

Input Parameters

<i>uplo</i>	<p>(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the distributed symmetric matrix $\text{sub}(A)$ is used:</p> <p>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the $\text{sub}(A)$ is used.</p> <p>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the $\text{sub}(A)$ is used.</p>
<i>n</i>	<p>(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.</p>
<i>alpha</i>	<p>(global) REAL for pssyr2 DOUBLE REAL for pdsyr2 Specifies the scalar <i>alpha</i>.</p>
<i>x</i>	<p>(local) REAL for pssyr2 DOUBLE REAL for pdsyr2 Array, DIMENSION at least $(j_x-1)*m_x + ix + (n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.</p>
<i>ix, jx</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.</p>
<i>descx</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i>.</p>
<i>incx</i>	<p>(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x. <i>incx</i> must not be zero.</p>
<i>y</i>	<p>(local) REAL for pssyr2 DOUBLE REAL for pdsyr2 Array, DIMENSION at least $(j_y-1)*m_y + iy + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.</p>

<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <i>sub(Y)</i> , respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(Y)</i> . Only two values are supported, namely 1 and <i>m_Y.incy</i> must not be zero.
<i>a</i>	(local) REAL for <i>pssyr2</i> DOUBLE REAL for <i>pdsyr2</i> Array, DIMENSION (<i>lld_a</i> , LOCq(<i>ja+n-1</i>)). This array contains the local pieces of the distributed matrix <i>sub(A)</i> . Before entry with <i>uplo</i> = 'U' or 'u', the <i>n</i> -by- <i>n</i> upper triangular part of the distributed matrix <i>sub(A)</i> must contain the upper triangular part of the distributed symmetric matrix and the strictly lower triangular part of <i>sub(A)</i> is not referenced, and with <i>uplo</i> = 'L' or 'l', the <i>n</i> -by- <i>n</i> lower triangular part of the distributed matrix <i>sub(A)</i> must contain the lower triangular part of the distributed symmetric matrix and the strictly upper triangular part of <i>sub(A)</i> is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .

Output Parameters

<i>a</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of the array <i>a</i> is overwritten by the upper triangular part of the updated distributed matrix <i>sub(A)</i> . With <i>uplo</i> = 'L' or 'l', the lower triangular part of the array <i>a</i> is overwritten by the lower triangular part of the updated distributed matrix <i>sub(A)</i> .
----------	--

p?trmv

Computes a distributed matrix-vector product using a triangular matrix.

Syntax

```
call pstrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pdtrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pctrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pztrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
```

Description

The p?trmv routines perform one of the following distributed matrix-vector operations defined as

$\text{sub}(x) := \text{sub}(A) * \text{sub}(x)$, or $\text{sub}(x) := \text{sub}(A)^T * \text{sub}(x)$, or $\text{sub}(x) := \text{conjg}(\text{sub}(A)^T) * \text{sub}(x)$,

where:

$\text{sub}(A)$ is a n -by- n unit, or non-unit, upper or lower triangular distributed matrix, $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$,

$\text{sub}(x)$ is an n -element distributed vector.

$\text{sub}(x)$ denotes $X(\text{ix}, \text{jx}:\text{jx}+n-1)$ if $\text{incx} = m_x$, and $X(\text{ix}:\text{ix}+n-1, \text{jx})$ if $\text{incx} = 1$,

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	(global) CHARACTER*1. Specifies the form of $\text{op}(\text{sub}(A))$ used in the matrix equation: if <i>transa</i> = 'N' or 'n', then $\text{sub}(x) := \text{sub}(A) * \text{sub}(x)$; if <i>transa</i> = 'T' or 't', then $\text{sub}(x) := \text{sub}(A)^T * \text{sub}(x)$; if <i>transa</i> = 'C' or 'c', then $\text{sub}(x) := \text{conjg}(\text{sub}(A)^T) * \text{sub}(x)$.

<i>diag</i>	<p>(global) CHARACTER*1. Specifies whether the matrix $\text{sub}(A)$ is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.</p>
<i>n</i>	<p>(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.</p>
<i>a</i>	<p>(local) REAL for pstrmv DOUBLE PRECISION for pdtrmv COMPLEX for pctrmv DOUBLE COMPLEX for pztrmv Array, DIMENSION at least (<i>lld_a</i>, LOCq(1, <i>ja</i>+<i>n</i>-1)). Before entry with <i>uplo</i> = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix $\text{sub}(A)$ is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix $\text{sub}(A)$ is not referenced. When <i>diag</i> = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix $\text{sub}(A)$ are not referenced either, but are assumed to be unity.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i>.</p>
<i>x</i>	<p>(local) REAL for pstrmv DOUBLE PRECISION for pdtrmv COMPLEX for pctrmv DOUBLE COMPLEX for pztrmv Array, DIMENSION at least (<i>jx</i>-1)*<i>m_x</i> + <i>ix</i>+(<i>n</i>-1)*abs(<i>incx</i>)). This array contains the entries of the distributed vector $\text{sub}(x)$.</p>

<i>ix, jx</i>	(global) <code>INTEGER</code> . The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix <code>sub(x)</code> , respectively.
<i>descx</i>	(global and local) <code>INTEGER</code> array of dimension 8. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) <code>INTEGER</code> . Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and <code>m_x</code> . <i>incx</i> must not be zero.

Output Parameters

<i>x</i>	Overwritten by the transformed distributed vector <code>sub(x)</code> .
----------	---

p?trsv

Solves a system of linear equations whose coefficients are in a distributed triangular matrix.

Syntax

```
call pstrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pdtrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pctrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pztrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
```

Description

The `p?trsv` routines solve one of the systems of equations:

`sub(A)*sub(x) = b`, or `sub(A)'*sub(x) = b`, or `conjg(sub(A)')*sub(x) = b`,

where:

`sub(A)` is a *n*-by-*n* unit, or non-unit, upper or lower triangular distributed matrix, `sub(A) = A(ia:ia+n-1, ja:ja+n-1)`,

b and `sub(x)` are *n*-element distributed vectors,

`sub(x)` denotes `X(ix, jx:jx+n-1)` if `incx = m_x`, and `X(ix: ix+n-1, jx)` if `incx = 1`,.

The routine does not test for singularity or near-singularity. Such tests must be performed before calling this routine.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the distributed matrix <code>sub(A)</code> is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	(global) CHARACTER*1. Specifies the form of the system of equations: if <i>transa</i> = 'N' or 'n', then <code>sub(A)*sub(x) = b</code> ; if <i>transa</i> = 'T' or 't', then <code>sub(A)'*sub(x) = b</code> ; if <i>transa</i> = 'C' or 'c', then <code>conjg(sub(A)')*sub(x) = b</code> .
<i>diag</i>	(global) CHARACTER*1. Specifies whether the matrix <code>sub(A)</code> is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix <code>sub(A)</code> , $n \geq 0$.
<i>a</i>	(local) REAL for <code>pstrsv</code> DOUBLE PRECISION for <code>pdtrsv</code> COMPLEX for <code>pctrsv</code> DOUBLE COMPLEX for <code>pztrsv</code> Array, DIMENSION at least <code>(lld_a, LOCq(1, ja+n-1))</code> . Before entry with <i>uplo</i> = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix <code>sub(A)</code> , and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix <code>sub(A)</code> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix <code>sub(A)</code> , and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix <code>sub(A)</code> is not referenced. When <i>diag</i> = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix <code>sub(A)</code> are not referenced either, but are assumed to be unity.

<i>ia, ja</i>	(global) INTEGER . The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .
<i>x</i>	(local) REAL for <i>pstrsv</i> DOUBLE PRECISION for <i>pdtrsv</i> COMPLEX for <i>pctrsv</i> DOUBLE COMPLEX for <i>pztrsv</i> Array, DIMENSION at least $(jx-1)*m_x + ix + (n-1)*abs(incx)$. This array contains the entries of the distributed vector <i>sub(x)</i> . Before entry, <i>sub(x)</i> must contain the <i>n</i> -element right-hand side distributed vector <i>b</i> .
<i>ix, jx</i>	(global) INTEGER . The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix <i>sub(x)</i> , respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER . Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.

Output Parameters

<i>x</i>	Overwritten with the solution vector.
----------	---------------------------------------

PBLAS Level 3 Routines

PBLAS Level 3 routines perform distributed matrix-matrix operations. [Table 2-3](#) lists the PBLAS Level 3 routine groups and the data types associated with them.

Table 12-3 PBLAS Level 3 Routine Groups and Their Data Types

Routine Group	Data Types	Description
p?gemm	s, d, c, z	Distributed matrix-matrix product of general matrices

Routine Group	Data Types	Description
p?hemm	c, z	Distributed matrix-matrix product, one matrix is Hermitian
p?herk	c, z	Rank-k update of a distributed Hermitian matrix
p?her2k	c, z	Rank-2k update of a distributed Hermitian matrix
p?symb	s, d, c, z	Matrix-matrix product of distributed symmetric matrices
p?syrk	s, d, c, z	Rank-k update of a distributed symmetric matrix
p?syr2k	s, d, c, z	Rank-2k update of a distributed symmetric matrix
p?tran	s, d	Transposition of a real distributed matrix
p?tranc	c, z	Transposition of a complex distributed matrix (conjugated)
p?tranu	c, z	Transposition of a complex distributed matrix
p?trmm	s, d, c, z	Distributed matrix-matrix product, one matrix is triangular
p?trsm	s, d, c, z	Solution of a distributed matrix equation, one matrix is triangular

p?gemm

Computes a scalar-matrix-matrix product and adds the result to a scalar-matrix product for distributed matrices.

Syntax

```
call psgemm(transa, transb, m, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)

call pdgemm(transa, transb, m, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)
```

```
call pcgemm(transa, transb, m, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)
```

```
call pzgemm(transa, transb, m, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)
```

Description

The `p?gemm` routines perform a matrix-matrix operation with general distributed matrices. The operation is defined as

$$\text{sub}(C) := \alpha * \text{op}(\text{sub}(A)) * \text{op}(\text{sub}(B)) + \beta * \text{sub}(C),$$

where:

$\text{op}(x)$ is one of $\text{op}(x) = x$, or $\text{op}(x) = x'$,

α and β are scalars,

$\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+k-1)$, $\text{sub}(B) = B(\text{ib}:\text{ib}+k-1, \text{jb}:\text{jb}+n-1)$, and $\text{sub}(C) = C(\text{ic}:\text{ic}+m-1, \text{jc}:\text{jc}+n-1)$, are distributed matrices.

Input Parameters

<i>transa</i>	(global) CHARACTER*1. Specifies the form of $\text{op}(\text{sub}(A))$ used in the matrix multiplication: if <i>transa</i> = 'N' or 'n', then $\text{op}(\text{sub}(A)) = \text{sub}(A)$; if <i>transa</i> = 'T' or 't', then $\text{op}(\text{sub}(A)) = \text{sub}(A)'$; if <i>transa</i> = 'C' or 'c', then $\text{op}(\text{sub}(A)) = \text{sub}(A)'$.
<i>transb</i>	(global) CHARACTER*1. Specifies the form of $\text{op}(\text{sub}(B))$ used in the matrix multiplication: if <i>transb</i> = 'N' or 'n', then $\text{op}(\text{sub}(B)) = \text{sub}(B)$; if <i>transb</i> = 'T' or 't', then $\text{op}(\text{sub}(B)) = \text{sub}(B)'$; if <i>transb</i> = 'C' or 'c', then $\text{op}(\text{sub}(B)) = \text{sub}(B)'$.
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrices $\text{op}(\text{sub}(A))$ and $\text{sub}(C)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrices $\text{op}(\text{sub}(B))$ and $\text{sub}(C)$, $n \geq 0$. The value of <i>n</i> must be at least zero.
<i>k</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{op}(\text{sub}(A))$ and the number of rows of the distributed matrix $\text{op}(\text{sub}(B))$.

<i>alpha</i>	<p>The value of <i>k</i> must be greater than or equal to 0.</p> <p>(global) REAL for psgemm DOUBLE PRECISION for pdgemm COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm Specifies the scalar <i>alpha</i>. When <i>alpha</i> is equal to zero, then the local entries of the arrays <i>a</i> and <i>b</i> corresponding to the entries of the submatrices <i>sub(A)</i> and <i>sub(B)</i> respectively need not be set on input.</p>
<i>a</i>	<p>(local) REAL for psgemm DOUBLE PRECISION for pdgemm COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm Array, DIMENSION (<i>lld_a</i>, <i>kla</i>), where <i>kla</i> is LOCc(<i>ja</i>+<i>k</i>-1) when <i>transa</i> = 'N' or 'n', and is LOCq(<i>ja</i>+<i>m</i>-1) otherwise. Before entry this array must contain the local pieces of the distributed matrix <i>sub(A)</i>.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i>, respectively</p>
<i>desca</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i>.</p>
<i>b</i>	<p>(local)REAL for psgemm DOUBLE PRECISION for pdgemm COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm Array, DIMENSION (<i>lld_b</i>, <i>klb</i>), where <i>klb</i> is LOCc(<i>jb</i>+<i>n</i>-1) when <i>transb</i> = 'N' or 'n', and is LOCq(<i>jb</i>+<i>k</i>-1) otherwise. Before entry this array must contain the local pieces of the distributed matrix <i>sub(B)</i>.</p>
<i>ib, jb</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix <i>sub(B)</i>, respectively</p>
<i>descb</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>B</i>.</p>

<i>beta</i>	<p>(global) REAL for psgemm DOUBLE PRECISION for pdgemm COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm Specifies the scalar <i>beta</i>. When <i>beta</i> is equal to zero, then <code>sub(C)</code> need not be set on input.</p>
<i>c</i>	<p>(local)REAL for psgemm DOUBLE PRECISION for pdgemm COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm Array, DIMENSION (<code>lld_a</code>, <code>LOCq(jc+n-1)</code>). Before entry this array must contain the local pieces of the distributed matrix <code>sub(C)</code>.</p>
<i>ic, jc</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>c</i> indicating the first row and the first column of the submatrix <code>sub(C)</code>, respectively</p>
<i>desc</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>c</i>.</p>

Output Parameters

<i>c</i>	<p>Overwritten by the <i>m</i>-by-<i>n</i> distributed matrix $\alpha * \text{op}(\text{sub}(A)) * \text{op}(\text{sub}(B)) + \beta * \text{sub}(C)$.</p>
----------	---

p?hemm

Performs a scalar-matrix-matrix product (one matrix operand is Hermitian) and adds the result to a scalar-matrix product.

Syntax

```
call pchemm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta,
c, ic, jc, descc)

call pzhemm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta,
c, ic, jc, descc)
```

Description

The `p?hemm` routines perform a matrix-matrix operation with distributed matrices. The operation is defined as

$$\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B) + \beta * \text{sub}(C),$$

or

$$\text{sub}(C) := \alpha * \text{sub}(B) * \text{sub}(A) + \beta * \text{sub}(C),$$

where:

alpha and *beta* are scalars,

sub(A) is a Hermitian distributed matrix, *sub(A)* = *A(ia:ia+m-1, ja:ja+m-1)*, if *side* = 'L', and *sub(A)* = *A(ia:ia+n-1, ja:ja+n-1)*, if *side* = 'R'.

sub(B) and *sub(C)* are *m*-by-*n* distributed matrices.

sub(B) = *B(ib:ib+m-1, jb:jb+n-1)*, *sub(C)* = *C(ic:ic+m-1, jc:jc+n-1)*.

Input Parameters

<i>side</i>	(global) CHARACTER*1. Specifies whether the Hermitian distributed matrix <i>sub(A)</i> appears on the left or right in the operation: if <i>side</i> = 'L' or 'l', then <i>sub(C)</i> := <i>alpha</i> * <i>sub(A)</i> * <i>sub(B)</i> + <i>beta</i> * <i>sub(C)</i> ; if <i>side</i> = 'R' or 'r', then <i>sub(C)</i> := <i>alpha</i> * <i>sub(B)</i> * <i>sub(A)</i> + <i>beta</i> * <i>sub(C)</i> .
<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <i>sub(A)</i> is used: if <i>uplo</i> = 'U' or 'u', then the upper triangular part is used; if <i>uplo</i> = 'L' or 'l', then the lower triangular part is used.
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distribute submatrix <i>sub(C)</i> , <i>m</i> ≥ 0.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distribute submatrix <i>sub(C)</i> , <i>n</i> ≥ 0.
<i>alpha</i>	(global) COMPLEX for <code>pchemm</code> DOUBLE COMPLEX for <code>pzhemm</code>

	Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) COMPLEX for pchemm DOUBLE COMPLEX for pzchemm Array, DIMENSION (<i>lld_a</i> , LOCq(<i>ja+na-1</i>)). Before entry this array must contain the local pieces of the symmetric distributed matrix sub(<i>A</i>), such that when <i>uplo</i> = 'U' or 'u', the <i>na-by-na</i> upper triangular part of the distributed matrix sub(<i>A</i>) must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of sub(<i>A</i>) is not referenced, and when <i>uplo</i> = 'L' or 'l', the <i>na-by-na</i> lower triangular part of the distributed matrix sub(<i>A</i>) must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of sub(<i>A</i>) is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix sub(<i>A</i>), respectively
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .
<i>b</i>	(local) COMPLEX for pchemm DOUBLE COMPLEX for pzchemm Array, DIMENSION (<i>lld_b</i> , LOCq(<i>jb+n-1</i>)). Before entry this array must contain the local pieces of the distributed matrix sub(<i>B</i>).
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix sub(<i>B</i>), respectively.
<i>descb</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>B</i> .
<i>beta</i>	(global) COMPLEX for pchemm DOUBLE COMPLEX for pzchemm Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then sub(<i>c</i>) need not be set on input.
<i>c</i>	(local) COMPLEX for pchemm DOUBLE COMPLEX for pzchemm

	Array, DIMENSION (lld_c, LOCq(jc+n-1)). Before entry this array must contain the local pieces of the distributed matrix sub(C).
ic, jc	(global) INTEGER. The row and column indices in the distributed matrix c indicating the first row and the first column of the submatrix sub(C), respectively
descc	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix c.

Output Parameters

c	Overwritten by the m-by-n updated distributed matrix.
---	---

p?hemm

Performs a scalar-matrix-matrix product (one matrix operand is Hermitian) and adds the result to a scalar-matrix product.

Syntax

```
call pchemm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta,
c, ic, jc, descc)

call pzhemm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta,
c, ic, jc, descc)
```

Description

The p?hemm routines perform a matrix-matrix operation with distributed matrices. The operation is defined as

$\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B) + \text{beta} * \text{sub}(C),$

or

$\text{sub}(C) := \alpha * \text{sub}(B) * \text{sub}(A) + \text{beta} * \text{sub}(C),$

where:

alpha and *beta* are scalars,

sub(A) is a Hermitian distributed matrix, sub(A)=A(ia:ia+m-1, ja:ja+m-1), if side = 'L', and sub(A)=A(ia:ia+n-1, ja:ja+n-1), if side = 'R'.

$\text{sub}(B)$ and $\text{sub}(C)$ are m -by- n distributed matrices.

$\text{sub}(B) = B(ib:ib+m-1, jb:jb+n-1)$, $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$.

Input Parameters

<i>side</i>	(global) CHARACTER*1. Specifies whether the Hermitian distributed matrix $\text{sub}(A)$ appears on the left or right in the operation: if <i>side</i> = 'L' or 'l', then $\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B) + \beta * \text{sub}(C)$; if <i>side</i> = 'R' or 'r', then $\text{sub}(C) := \alpha * \text{sub}(B) * \text{sub}(A) + \beta * \text{sub}(C)$.
<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix $\text{sub}(A)$ is used: if <i>uplo</i> = 'U' or 'u', then the upper triangular part is used; if <i>uplo</i> = 'L' or 'l', then the lower triangular part is used.
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distribute submatrix $\text{sub}(C)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distribute submatrix $\text{sub}(C)$, $n \geq 0$.
<i>alpha</i>	(global) COMPLEX for pchemm DOUBLE COMPLEX for pzhemm Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) COMPLEX for pchemm DOUBLE COMPLEX for pzhemm Array, DIMENSION (<i>lld_a</i> , $\text{LOCq}(ja+na-1)$). Before entry this array must contain the local pieces of the symmetric distributed matrix $\text{sub}(A)$, such that when <i>uplo</i> = 'U' or 'u', the na -by- na upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and when <i>uplo</i> = 'L' or 'l', the na -by- na lower triangular part of

	the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .
<i>b</i>	(local) COMPLEX for pchemm DOUBLE COMPLEX for pzhemm Array, DIMENSION (<i>lld_b</i> , <i>LOCq(jb+n-1)</i>). Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(B)$.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix $\text{sub}(B)$, respectively.
<i>descb</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>B</i> .
<i>beta</i>	(global) COMPLEX for pchemm DOUBLE COMPLEX for pzhemm Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then $\text{sub}(C)$ need not be set on input.
<i>c</i>	(local) COMPLEX for pchemm DOUBLE COMPLEX for pzhemm Array, DIMENSION (<i>lld_c</i> , <i>LOCq(jc+n-1)</i>). Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(C)$.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively
<i>descc</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	Overwritten by the <i>m</i> -by- <i>n</i> updated distributed matrix.
----------	---

p?herk

Performs a rank-k update of a distributed Hermitian matrix.

Syntax

```
call pcherk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pzherk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Description

The p?herk routines perform a distributed matrix-matrix operation defined as

$\text{sub}(C) := \alpha * \text{sub}(A) * \text{conjg}(\text{sub}(A)') + \beta * \text{sub}(C),$

or

$\text{sub}(C) := \alpha * \text{conjg}(\text{sub}(A)') * \text{sub}(A) + \beta * \text{sub}(C),$

where:

α and β are scalars,

$\text{sub}(C)$ is an n -by- n Hermitian distributed matrix, $\text{sub}(C) = C(ic:ic+n-1, jc:jc+n-1)$.

$\text{sub}(A)$ is a distributed matrix, $\text{sub}(A) = A(ia:ia+n-1, ja:ja+k-1)$, if $trans = 'N'$ or $'n'$, and $\text{sub}(A) = A(ia:ia+k-1, ja:ja+n-1)$ otherwise.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix $\text{sub}(C)$ is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the $\text{sub}(C)$ is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the $\text{sub}(C)$ is used.
<i>trans</i>	(global) CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then $\text{sub}(C) := \alpha * \text{sub}(A) * \text{conjg}(\text{sub}(A)') + \beta * \text{sub}(C);$ if <i>trans</i> = 'C' or 'c', then $\text{sub}(C) := \alpha * \text{conjg}(\text{sub}(A)') * \text{sub}(A) + \beta * \text{sub}(C).$

<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix <code>sub(C)</code> , $n \geq 0$.
<i>k</i>	(global) INTEGER. On entry with <code>trans = 'N' or 'n'</code> , <i>k</i> specifies the number of columns of the distributed matrix <code>sub(A)</code> , and on entry with <code>trans = 'T' or 't' or 'C' or 'c'</code> , <i>k</i> specifies the number of rows of the distributed matrix <code>sub(A)</code> , $k \geq 0$.
<i>alpha</i>	(global) REAL for <code>pcherk</code> DOUBLE PRECISION for <code>pzherk</code> Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) COMPLEX for <code>pcherk</code> DOUBLE COMPLEX for <code>pzherk</code> Array, DIMENSION (<code>lld_a</code> , <code>kla</code>), where <code>kla</code> is <code>LOCq(ja+k-1)</code> when <code>trans = 'N' or 'n'</code> , and is <code>LOCq(ja+n-1)</code> otherwise. Before entry with <code>trans = 'N' or 'n'</code> , this array contains the local pieces of the distributed matrix <code>sub(A)</code> .
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) REAL for <code>pcherk</code> DOUBLE PRECISION for <code>pzherk</code> Specifies the scalar <i>beta</i> .
<i>c</i>	(local) COMPLEX for <code>pcherk</code> DOUBLE COMPLEX for <code>pzherk</code> Array, DIMENSION (<code>lld_c</code> , <code>LOCq(jc+n-1)</code>). Before entry with <code>uplo = 'U' or 'u'</code> , this array contains <i>n</i> -by- <i>n</i> upper triangular part of the symmetric distributed matrix <code>sub(C)</code> and its strictly lower triangular part is not referenced. Before entry with <code>uplo = 'L' or 'l'</code> , this array contains <i>n</i> -by- <i>n</i> lower triangular part of the symmetric distributed matrix <code>sub(C)</code> and its strictly upper triangular part is not referenced.

ic, jc (global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix *sub(C)*, respectively.

desc (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *C*.

Output Parameters

C With *uplo* = 'U' or 'u', the upper triangular part of *sub(C)* is overwritten by the upper triangular part of the updated distributed matrix.
 With *uplo* = 'L' or 'l', the lower triangular part of *sub(C)* is overwritten by the upper triangular part of the updated distributed matrix.

p?her2k

Performs a rank-2k update of a Hermitian distributed matrix.

Syntax

FORTRAN 77:

```
call pcher2k(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc,
             desc)
call pzher2k(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc,
             desc)
```

Description

The p?her2k routines perform a distributed matrix-matrix operation defined as

$$\text{sub}(C) := \alpha * \text{sub}(A) * \text{conjg}(\text{sub}(B)') + \text{conjg}(\alpha) * \text{sub}(B) * \text{conjg}(\text{sub}(A)') + \beta * \text{sub}(C),$$

or

$$\text{sub}(C) := \alpha * \text{conjg}(\text{sub}(A)') * \text{sub}(A) + \text{conjg}(\alpha) * \text{conjg}(\text{sub}(B)') * \text{sub}(B) + \beta * \text{sub}(C),$$

where:

alpha and *beta* are scalars,

sub(C) is an *n*-by-*n* Hermitian distributed matrix, $\text{sub}(C) = C(ic:ic+n-1, jc:jc+n-1)$.

`sub(A)` is a distributed matrix, `sub(A)=A(ia:ia+n-1, ja:ja+k-1)`, if `trans = 'N' or 'n'`, and `sub(A) = A(ia:ia+k-1, ja:ja+n-1)` otherwise.

`sub(B)` is a distributed matrix, `sub(B) = B(ib:ib+n-1, jb:jb+k-1)`, if `trans = 'N' or 'n'`, and `sub(B)=B(ib:ib+k-1, jb:jb+n-1)` otherwise.

Input Parameters

<code>uplo</code>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <code>sub(C)</code> is used: If <code>uplo = 'U' or 'u'</code> , then the upper triangular part of the <code>sub(C)</code> is used. If <code>uplo = 'L' or 'l'</code> , then the low triangular part of the <code>sub(C)</code> is used.
<code>trans</code>	(global) CHARACTER*1. Specifies the operation: if <code>trans = 'N' or 'n'</code> , then <code>sub(C) := alpha*sub(A)*conjg(sub(B)') + conjg(alpha)*sub(B)*conjg(sub(A)') + beta*sub(C)</code> ; if <code>trans = 'C' or 'c'</code> , then <code>sub(C) := alpha*conjg(sub(A)')*sub(A) + conjg(alpha)*conjg(sub(B)')*sub(A) + beta*sub(C)</code> .
<code>n</code>	(global) INTEGER. Specifies the order of the distributed matrix <code>sub(C)</code> , $n \geq 0$.
<code>k</code>	(global) INTEGER. On entry with <code>trans = 'N' or 'n'</code> , <code>k</code> specifies the number of columns of the distributed matrices <code>sub(A)</code> and <code>sub(B)</code> , and on entry with <code>trans = 'C' or 'c'</code> , <code>k</code> specifies the number of rows of the distributed matrices <code>sub(A)</code> and <code>sub(B)</code> , $k \geq 0$.
<code>alpha</code>	(global) COMPLEX for <code>pcher2k</code> DOUBLE COMPLEX for <code>pzher2k</code> Specifies the scalar <code>alpha</code> .
<code>a</code>	(local) COMPLEX for <code>pcher2k</code> DOUBLE COMPLEX for <code>pzher2k</code>

	<p>Array, DIMENSION (lld_a, kla), where kla is $LOCq(ja+k-1)$ when $trans = 'N'$ or $'n'$, and is $LOCq(ja+n-1)$ otherwise. Before entry with $trans = 'N'$ or $'n'$, this array contains the local pieces of the distributed matrix $sub(A)$.</p>
ia, ja	<p>(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $sub(A)$, respectively.</p>
$desca$	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix A.</p>
b	<p>(local) COMPLEX for pcher2k DOUBLE COMPLEX for pzher2k Array, DIMENSION (lld_b, $k1b$), where $k1b$ is $LOCq(jb+k-1)$ when $trans = 'N'$ or $'n'$, and is $LOCq(jb+n-1)$ otherwise. Before entry with $trans = 'N'$ or $'n'$, this array contains the local pieces of the distributed matrix $sub(B)$.</p>
ib, jb	<p>(global) INTEGER. The row and column indices in the distributed matrix B indicating the first row and the first column of the submatrix $sub(B)$, respectively.</p>
$descb$	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix B.</p>
$beta$	<p>(global) REAL for pcher2k DOUBLE PRECISION for pzher2k Specifies the scalar $beta$.</p>
c	<p>(local) COMPLEX for pcher2k DOUBLE COMPLEX for pzher2k Array, DIMENSION (lld_c, $LOCq(jc+n-1)$). Before entry with $uplo = 'U'$ or $'u'$, this array contains n-by-n upper triangular part of the symmetric distributed matrix $sub(C)$ and its strictly lower triangular part is not referenced. Before entry with $uplo = 'L'$ or $'l'$, this array contains n-by-n lower triangular part of the symmetric distributed matrix $sub(C)$ and its strictly upper triangular part is not referenced.</p>

<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>c</i> indicating the first row and the first column of the submatrix <i>sub(C)</i> , respectively.
<i>descc</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>c</i> .

Output Parameters

<i>c</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of <i>sub(C)</i> is overwritten by the upper triangular part of the updated distributed matrix. With <i>uplo</i> = 'L' or 'l', the lower triangular part of <i>sub(C)</i> is overwritten by the upper triangular part of the updated distributed matrix.
----------	--

p?symm

Performs a scalar-matrix-matrix product (one matrix operand is symmetric) and adds the result to a scalar-matrix product for distribute matrices.

Syntax

FORTRAN 77:

```
call pssymm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta,
c, ic, jc, descc)

call pdsymm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta,
c, ic, jc, descc)

call pcsymm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta,
c, ic, jc, descc)

call pzsymm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta,
c, ic, jc, descc)
```

Description

The `p?s`ymm routines perform a matrix-matrix operation with distributed matrices. The operation is defined as

$$\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B) + \beta * \text{sub}(C),$$

or

$\text{sub}(C) := \alpha * \text{sub}(B) * \text{sub}(A) + \beta * \text{sub}(C),$

where:

α and β are scalars,

$\text{sub}(A)$ is a symmetric distributed matrix, $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+m-1)$, if $\text{side} = 'L'$,
and $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$, if $\text{side} = 'R'$.

$\text{sub}(B)$ and $\text{sub}(C)$ are m -by- n distributed matrices.

$\text{sub}(B) = B(\text{ib}:\text{ib}+m-1, \text{jb}:\text{jb}+n-1)$, $\text{sub}(C) = C(\text{ic}:\text{ic}+m-1, \text{jc}:\text{jc}+n-1)$.

Input Parameters

<i>side</i>	(global) CHARACTER*1. Specifies whether the symmetric distributed matrix $\text{sub}(A)$ appears on the left or right in the operation: if $\text{side} = 'L'$ or $'l'$, then $\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B) + \beta * \text{sub}(C);$ if $\text{side} = 'R'$ or $'r'$, then $\text{sub}(C) := \alpha * \text{sub}(B) * \text{sub}(A) + \beta * \text{sub}(C).$
<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix $\text{sub}(A)$ is used: if $\text{uplo} = 'U'$ or $'u'$, then the upper triangular part is used; if $\text{uplo} = 'L'$ or $'l'$, then the lower triangular part is used.
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distribute submatrix $\text{sub}(C)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distribute submatrix $\text{sub}(C)$, $m \geq 0$.
<i>alpha</i>	(global) REAL for pssymm DOUBLE PRECISION for pdsymm COMPLEX for pcsymm DOUBLE COMPLEX for pzsymm Specifies the scalar α .
<i>a</i>	(local) REAL for pssymm DOUBLE PRECISION for pdsymm

	<p>COMPLEX for pcsymm DOUBLE COMPLEX for pzsymm Array, DIMENSION (lld_a, LOCq(ja+na-1)). Before entry this array must contain the local pieces of the symmetric distributed matrix sub(A), such that when uplo = 'U' or 'u', the na-by-na upper triangular part of the distributed matrix sub(A) must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of sub(A) is not referenced, and when uplo = 'L' or 'l', the na-by-na lower triangular part of the distributed matrix sub(A) must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of sub(A) is not referenced.</p>
ia, ja	<p>(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix sub(A), respectively.</p>
desca	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix A.</p>
b	<p>(local) REAL for pssymm DOUBLE PRECISION for pdsymm COMPLEX for pcsymm DOUBLE COMPLEX for pzsymm Array, DIMENSION (lld_b, LOCq(jb+n-1)). Before entry this array must contain the local pieces of the distributed matrix sub(B).</p>
ib, jb	<p>(global) INTEGER. The row and column indices in the distributed matrix B indicating the first row and the first column of the submatrix sub(B), respectively.</p>
descb	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix B.</p>
beta	<p>(global) REAL for pssymm DOUBLE PRECISION for pdsymm COMPLEX for pcsymm DOUBLE COMPLEX for pzsymm Specifies the scalar beta. When beta is set to zero, then sub(C) need not be set on input.</p>

c (local) REAL for pssymm
 DOUBLE PRECISION for pdsymm
 COMPLEX for pcsymm
 DOUBLE COMPLEX for pzsymm
 Array, DIMENSION (*lld_c*, LOCq(*jc+n-1*)). Before entry this array must contain the local pieces of the distributed matrix *sub(C)*.

ic, jc (global) INTEGER. The row and column indices in the distributed matrix *c* indicating the first row and the first column of the submatrix *sub(C)*, respectively.

desc (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *c*.

Output Parameters

c Overwritten by the *m*-by-*n* updated matrix.

p?syrk

Performs a rank-k update of a symmetric distributed matrix.

Syntax

```
call pssyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, desc)
call pdsyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, desc)
call pcsyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, desc)
call pzsyk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, desc)
```

Description

The p?syrk routines perform a distributed matrix-matrix operation defined as

$$\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(A)^T + \beta * \text{sub}(C),$$

or

$$\text{sub}(C) := \alpha * \text{sub}(A)^T * \text{sub}(A) + \beta * \text{sub}(C),$$

where:

alpha and *beta* are scalars,

$\text{sub}(C)$ is an n -by- n symmetric distributed matrix, $\text{sub}(C) = C(ic:ic+n-1, jc:jc+n-1)$.

$\text{sub}(A)$ is a distributed matrix, $\text{sub}(A) = A(ia:ia+n-1, ja:ja+k-1)$, if $trans = 'N'$ or $'n'$, and $\text{sub}(A) = A(ia:ia+k-1, ja:ja+n-1)$ otherwise.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix $\text{sub}(C)$ is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the $\text{sub}(C)$ is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the $\text{sub}(C)$ is used.
<i>trans</i>	(global) CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then $\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(A)^T + \beta * \text{sub}(C)$; if <i>trans</i> = 'T' or 't', then $\text{sub}(C) := \alpha * \text{sub}(A)^T * \text{sub}(A) + \beta * \text{sub}(C)$.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(C)$, $n \geq 0$.
<i>k</i>	(global) INTEGER. On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the distributed matrix $\text{sub}(A)$, and on entry with <i>trans</i> = 'T' or 't', <i>k</i> specifies the number of rows of the distributed matrix $\text{sub}(A)$, $k \geq 0$.
<i>alpha</i>	(global) REAL for pssyrk DOUBLE PRECISION for pdsyrk COMPLEX for pcsyrk DOUBLE COMPLEX for pzsyk Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) REAL for pssyrk DOUBLE PRECISION for pdsyrk COMPLEX for pcsyrk DOUBLE COMPLEX for pzsyk

	<p>Array, DIMENSION (<i>lld_a</i>, <i>kla</i>), where <i>kla</i> is $\text{LOCq}(ja+k-1)$ when <i>trans</i> = 'N' or 'n', and is $\text{LOCq}(ja+n-1)$ otherwise. Before entry with <i>trans</i> = 'N' or 'n', this array contains the local pieces of the distributed matrix <i>sub(A)</i>.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i>, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i>.</p>
<i>beta</i>	<p>(global) REAL for pssyrk DOUBLE PRECISION for pdsyrk COMPLEX for pcsyrk DOUBLE COMPLEX for pzsyk Specifies the scalar <i>beta</i>.</p>
<i>c</i>	<p>(local) REAL for pssyrk DOUBLE PRECISION for pdsyrk COMPLEX for pcsyrk DOUBLE COMPLEX for pzsyk Array, DIMENSION (<i>lld_c</i>, $\text{LOCq}(jc+n-1)$). Before entry with <i>uplo</i> = 'U' or 'u', this array contains <i>n</i>-by-<i>n</i> upper triangular part of the symmetric distributed matrix <i>sub(C)</i> and its strictly lower triangular part is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', this array contains <i>n</i>-by-<i>n</i> lower triangular part of the symmetric distributed matrix <i>sub(C)</i> and its strictly upper triangular part is not referenced.</p>
<i>ic, jc</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <i>sub(C)</i>, respectively.</p>
<i>descc</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>C</i>.</p>

Output Parameters

c With *uplo* = 'U' or 'u', the upper triangular part of *sub(C)* is overwritten by the upper triangular part of the updated distributed matrix.
 With *uplo* = 'L' or 'l', the lower triangular part of *sub(C)* is overwritten by the upper triangular part of the updated distributed matrix.

p?syr2k

Performs a rank-2k update of a symmetric distributed matrix.

Syntax

```
call pssyr2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)
```

```
call pdsyr2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)
```

```
call pcsyr2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)
```

```
call pzsyr2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb,
beta, c, ic, jc, descc)
```

Description

The *p?syr2k* routines perform a distributed matrix-matrix operation defined as

$$\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B)' + \alpha * \text{sub}(B) * \text{sub}(A)' + \beta * \text{sub}(C),$$

or

$$\text{sub}(C) := \alpha * \text{sub}(A)' * \text{sub}(B) + \alpha * \text{sub}(B)' * \text{sub}(A) + \beta * \text{sub}(C),$$

where:

alpha and *beta* are scalars,

sub(C) is an *n*-by-*n* symmetric distributed matrix, *sub(C)* = *C*(*ic:ic+n-1, jc:jc+n-1*).

sub(A) is a distributed matrix, *sub(A)* = *A*(*ia:ia+n-1, ja:ja+k-1*), if *trans* = 'N' or 'n', and *sub(A)* = *A*(*ia:ia+k-1, ja:ja+n-1*) otherwise.

$\text{sub}(B)$ is a distributed matrix, $\text{sub}(B)=B(ib:ib+n-1, jb:jb+k-1)$, if $trans = 'N'$ or $'n'$, and $\text{sub}(B)=B(ib:ib+k-1, jb:jb+n-1)$ otherwise.

Input Parameters

<i>uplo</i>	<p>(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix $\text{sub}(C)$ is used:</p> <p>If $uplo = 'U'$ or $'u'$, then the upper triangular part of the $\text{sub}(C)$ is used.</p> <p>If $uplo = 'L'$ or $'l'$, then the low triangular part of the $\text{sub}(C)$ is used.</p>
<i>trans</i>	<p>(global) CHARACTER*1. Specifies the operation:</p> <p>if $trans = 'N'$ or $'n'$, then $\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B) + \alpha * \text{sub}(B) * \text{sub}(A) + \beta * \text{sub}(C)$;</p> <p>if $trans = 'T'$ or $'t'$, then $\text{sub}(C) := \alpha * \text{sub}(B) * \text{sub}(A) + \alpha * \text{sub}(A) * \text{sub}(B) + \beta * \text{sub}(C)$.</p>
<i>n</i>	<p>(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(C)$, $n \geq 0$.</p>
<i>k</i>	<p>(global) INTEGER. On entry with $trans = 'N'$ or $'n'$, k specifies the number of columns of the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$, and on entry with $trans = 'T'$ or $'t'$, k specifies the number of rows of the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$, $k \geq 0$.</p>
<i>alpha</i>	<p>(global) REAL for pssyr2k DOUBLE PRECISION for pdsyr2k COMPLEX for pcsyr2k DOUBLE COMPLEX for pzsy2k Specifies the scalar <i>alpha</i>.</p>
<i>a</i>	<p>(local) REAL for pssyr2k DOUBLE PRECISION for pdsyr2k COMPLEX for pcsyr2k DOUBLE COMPLEX for pzsy2k</p>

	<p>Array, DIMENSION (<i>lld_a</i>, <i>kla</i>), where <i>kla</i> is LOCq(<i>ja</i>+<i>k</i>-1) when <i>trans</i> = 'N' or 'n', and is LOCq(<i>ja</i>+<i>n</i>-1) otherwise. Before entry with <i>trans</i> = 'N' or 'n', this array contains the local pieces of the distributed matrix sub(<i>A</i>).</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix sub(<i>A</i>), respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i>.</p>
<i>b</i>	<p>(local) REAL for pssyr2k DOUBLE PRECISION for pdsyr2k COMPLEX for pcsyr2k DOUBLE COMPLEX for pzsy2k Array, DIMENSION (<i>lld_b</i>, <i>klb</i>), where <i>klb</i> is LOCq(<i>jb</i>+<i>k</i>-1) when <i>trans</i> = 'N' or 'n', and is LOCq(<i>jb</i>+<i>n</i>-1) otherwise. Before entry with <i>trans</i> = 'N' or 'n', this array contains the local pieces of the distributed matrix sub(<i>B</i>).</p>
<i>ib, jb</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix sub(<i>B</i>), respectively.</p>
<i>descb</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>B</i>.</p>
<i>beta</i>	<p>(global) REAL for pssyr2k DOUBLE PRECISION for pdsyr2k COMPLEX for pcsyr2k DOUBLE COMPLEX for pzsy2k Specifies the scalar <i>beta</i>.</p>
<i>c</i>	<p>(local) REAL for pssyr2k DOUBLE PRECISION for pdsyr2k COMPLEX for pcsyr2k DOUBLE COMPLEX for pzsy2k Array, DIMENSION (<i>lld_c</i>, LOCq(<i>jc</i>+<i>n</i>-1)).</p>

Before entry with `uplo = 'U' or 'u'`, this array contains n -by- n upper triangular part of the symmetric distributed matrix `sub(C)` and its strictly lower triangular part is not referenced.

Before entry with `uplo = 'L' or 'l'`, this array contains n -by- n lower triangular part of the symmetric distributed matrix `sub(C)` and its strictly upper triangular part is not referenced.

`ic, jc`

(global) `INTEGER`. The row and column indices in the distributed matrix `C` indicating the first row and the first column of the submatrix `sub(C)`, respectively.

`descc`

(global and local) `INTEGER` array of dimension 8. The array descriptor of the distributed matrix `C`.

Output Parameters

`c`

With `uplo = 'U' or 'u'`, the upper triangular part of `sub(C)` is overwritten by the upper triangular part of the updated distributed matrix.

With `uplo = 'L' or 'l'`, the lower triangular part of `sub(C)` is overwritten by the upper triangular part of the updated distributed matrix.

p?tran

Transposes a real distributed matrix.

Syntax

```
call pstran(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

```
call pdtran(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Description

The `p?tran` routines transpose a real distributed matrix. The operation is defined as

$$\text{sub}(C) := \text{beta} * \text{sub}(C) + \text{alpha} * \text{sub}(A)^T,$$

where:

`alpha` and `beta` are scalars,

$\text{sub}(C)$ is an m -by- n distributed matrix, $\text{sub}(C)=C(ic:ic+m-1, jc:jc+n-1)$.

$\text{sub}(A)$ is a distributed matrix, $\text{sub}(A)=A(ia:ia+n-1, ja:ja+m-1)$.

Input Parameters

m	(global) INTEGER. Specifies the number of rows of the distributed matrix $\text{sub}(C)$, $m \geq 0$.
n	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{sub}(C)$, $n \geq 0$.
α	(global) REAL for pstran DOUBLE PRECISION for pdtran Specifies the scalar α .
a	(local) REAL for pstran DOUBLE PRECISION for pdtran Array, DIMENSION (lld_a , $LOCq(ja+m-1)$). This array contains the local pieces of the distributed matrix $\text{sub}(A)$.
ia, ja	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
$desca$	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix A .
β	(global) REAL for pstran DOUBLE PRECISION for pdtran Specifies the scalar β . When β is equal to zero, then $\text{sub}(C)$ need not be set on input.
c	(local) REAL for pstran DOUBLE PRECISION for pdtran Array, DIMENSION (lld_c , $LOCq(jc+n-1)$). This array contains the local pieces of the distributed matrix $\text{sub}(C)$.
ic, jc	(global) INTEGER. The row and column indices in the distributed matrix C indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.
$descc$	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix C .

Output Parameters

c Overwritten by the updated submatrix.

p?tranu

Transposes a distributed complex matrix.

Syntax

```
call pctranu(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

```
call pztranu(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Description

The p?tranu routines transpose a complex distributed matrix. The operation is defined as

$\text{sub}(C) := \text{beta} * \text{sub}(C) + \text{alpha} * \text{sub}(A)^T,$

where:

alpha and *beta* are scalars,

sub(C) is an *m*-by-*n* distributed matrix, $\text{sub}(C) = C(\text{ic}:\text{ic}+m-1, \text{jc}:\text{jc}+n-1).$

sub(A) is a distributed matrix, $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+m-1).$

Input Parameters

<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix <i>sub(C)</i> , $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix <i>sub(C)</i> , $n \geq 0$.
<i>alpha</i>	(global) COMPLEX for pctranu DOUBLE COMPLEX for pztranu Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) COMPLEX for pctranu DOUBLE COMPLEX for pztranu Array, DIMENSION (<i>lld_a</i> , LOCq(<i>ja</i> + <i>m</i> -1)). This array contains the local pieces of the distributed matrix <i>sub(A)</i> .

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) COMPLEX for <i>pctranu</i> DOUBLE COMPLEX for <i>pztranu</i> Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then <i>sub(C)</i> need not be set on input.
<i>c</i>	(local) COMPLEX for <i>pctranu</i> DOUBLE COMPLEX for <i>pztranu</i> Array, DIMENSION (<i>lld_c</i> , <i>LOCq(jc+n-1)</i>). This array contains the local pieces of the distributed matrix <i>sub(C)</i> .
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <i>sub(C)</i> , respectively.
<i>descc</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	Overwritten by the updated submatrix.
----------	---------------------------------------

p?tranc

Transposes a complex distributed matrix, conjugated.

Syntax

```
call pctranc(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pztranc(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Description

The *p?tranc* routines transpose a complex distributed matrix. The operation is defined as

$$\text{sub}(C) := \text{beta} * \text{sub}(C) + \text{alpha} * \text{conjg}(\text{sub}(A)'),$$

where:

alpha and *beta* are scalars,

$\text{sub}(C)$ is an m -by- n distributed matrix, $\text{sub}(C)=C(ic:ic+m-1, jc:jc+n-1)$.

$\text{sub}(A)$ is a distributed matrix, $\text{sub}(A)=A(ia:ia+n-1, ja:ja+m-1)$.

Input Parameters

<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix $\text{sub}(C)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{sub}(C)$, $n \geq 0$.
<i>alpha</i>	(global) COMPLEX for pctranc DOUBLE COMPLEX for pztranc Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) COMPLEX for pctranc DOUBLE COMPLEX for pztranc Array, DIMENSION (<i>lld_a</i> , <i>LOCq(ja+m-1)</i>). This array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) COMPLEX for pctranc DOUBLE COMPLEX for pztranc Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then $\text{sub}(C)$ need not be set on input.
<i>c</i>	(local) COMPLEX for pctranc DOUBLE COMPLEX for pztranc Array, DIMENSION (<i>lld_c</i> , <i>LOCq(jc+n-1)</i>). This array contains the local pieces of the distributed matrix $\text{sub}(C)$.

<i>ic, jc</i>	(global) <code>INTEGER</code> . The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <code>sub(C)</code> , respectively.
<i>descC</i>	(global and local) <code>INTEGER</code> array of dimension 8. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>C</i>	Overwritten by the updated submatrix.
----------	---------------------------------------

p?trmm

Computes a scalar-matrix-matrix product (one matrix operand is triangular) for distributed matrices.

Syntax

```
call pstrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib,
           jb, descb)
```

```
call pdtrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib,
           jb, descb)
```

```
call pctrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib,
           jb, descb)
```

```
call pztrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib,
           jb, descb)
```

Description

The `p?trmm` routines perform a matrix-matrix operation using triangular matrices. The operation is defined as

$$\text{sub}(B) := \alpha * \text{op}(\text{sub}(A)) * \text{sub}(B)$$

or

$$\text{sub}(B) := \alpha * \text{sub}(B) * \text{op}(\text{sub}(A))$$

where:

alpha is a scalar,

sub(B) is an *m*-by-*n* distributed matrix, $\text{sub}(B) = B(ib:ib+m-1, jb:jb+n-1)$.

A is a unit, or non-unit, upper or lower triangular distributed matrix, $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+m-1)$, if $\text{side} = 'L'$ or $'l'$, and $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$, if $\text{side} = 'R'$ or $'r'$.

$\text{op}(\text{sub}(A))$ is one of $\text{op}(\text{sub}(A)) = \text{sub}(A)$, or $\text{op}(\text{sub}(A)) = \text{sub}(A)'$, or $\text{op}(\text{sub}(A)) = \text{conjg}(\text{sub}(A)')$.

Input Parameters

<i>side</i>	(global) CHARACTER*1. Specifies whether $\text{op}(\text{sub}(A))$ appears on the left or right of $\text{sub}(B)$ in the operation: if $\text{side} = 'L'$ or $'l'$, then $\text{sub}(B) := \alpha * \text{op}(\text{sub}(A)) * \text{sub}(B)$; if $\text{side} = 'R'$ or $'r'$, then $\text{sub}(B) := \alpha * \text{sub}(B) * \text{op}(\text{sub}(A))$.
<i>uplo</i>	(global) CHARACTER*1. Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular: if $\text{uplo} = 'U'$ or $'u'$, then the matrix is upper triangular; if $\text{uplo} = 'L'$ or $'l'$, then the matrix is low triangular.
<i>transa</i>	(global) CHARACTER*1. Specifies the form of $\text{op}(\text{sub}(A))$ used in the matrix multiplication: if $\text{transa} = 'N'$ or $'n'$, then $\text{op}(\text{sub}(A)) = \text{sub}(A)$; if $\text{transa} = 'T'$ or $'t'$, then $\text{op}(\text{sub}(A)) = \text{sub}(A)'$; if $\text{transa} = 'C'$ or $'c'$, then $\text{op}(\text{sub}(A)) = \text{conjg}(\text{sub}(A)')$.
<i>diag</i>	(global) CHARACTER*1. Specifies whether the matrix $\text{sub}(A)$ is unit triangular: if $\text{diag} = 'U'$ or $'u'$ then the matrix is unit triangular; if $\text{diag} = 'N'$ or $'n'$, then the matrix is not unit triangular.
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix $\text{sub}(B)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{sub}(B)$, $n \geq 0$.
<i>alpha</i>	(global) REAL for pstrmm DOUBLE PRECISION for pdtrmm COMPLEX for pctrmm DOUBLE COMPLEX for pztrmm Specifies the scalar <i>alpha</i> .

When *alpha* is zero, then the array *b* need not be set before entry.

a

(local) REAL for pstrmm
 DOUBLE PRECISION for pdtrmm
 COMPLEX for pctrmm
 DOUBLE COMPLEX for pztrmm

Array, DIMENSION (*lld_a*, *ka*), where *ka* is at least LOCq(1, *ja+m-1*) when *side* = 'L' or 'l' and is at least LOCq(1, *ja+n-1*) when *side* = 'R' or 'r'.

Before entry with *uplo* = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix *sub(A)*, and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix *sub(A)* is not referenced.

Before entry with *uplo* = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix *sub(A)*, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix *sub(A)* is not referenced.

When *diag* = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix *sub(A)* are not referenced either, but are assumed to be unity.

ia, ja

(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix *sub(A)*, respectively.

desca

(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

b

(local) REAL for pstrmm
 DOUBLE PRECISION for pdtrmm
 COMPLEX for pctrmm
 DOUBLE COMPLEX for pztrmm

Array, DIMENSION (*lld_b*, LOCq(1, *jb+n-1*)).

Before entry, this array contains the local pieces of the distributed matrix *sub(B)*.

ib, jb

(global) INTEGER. The row and column indices in the distributed matrix *B* indicating the first row and the first column of the submatrix *sub(B)*, respectively.

descb (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *B*.

Output Parameters

b Overwritten by the transformed distributed matrix.

p?trsm

Solves a distributed matrix equation (one matrix operand is triangular).

Syntax

```
call pstrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib,
           jb, descb)
```

```
call pdtrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib,
           jb, descb)
```

```
call pctrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib,
           jb, descb)
```

```
call pztrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib,
           jb, descb)
```

Description

The p?trsm routines solve one of the following distributed matrix equations:

$\text{op}(\text{sub}(A)) * X = \alpha * \text{sub}(B),$

or

$X * \text{op}(\text{sub}(A)) = \alpha * \text{sub}(B),$

where:

alpha is a scalar,

X and *sub(B)* are *m*-by-*n* distributed matrices, $\text{sub}(B) = B(ib:ib+m-1, jb:jb+n-1);$

A is a unit, or non-unit, upper or lower triangular distributed matrix, $\text{sub}(A) = A(ia:ia+m-1, ja:ja+m-1),$ if *side* = 'L' or 'l', and $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1),$ if *side* = 'R' or 'r';

$\text{op}(\text{sub}(A))$ is one of $\text{op}(\text{sub}(A)) = \text{sub}(A)$, or $\text{op}(\text{sub}(A)) = \text{sub}(A)'$, or $\text{op}(\text{sub}(A)) = \text{conjg}(\text{sub}(A)')$.

The distributed matrix $\text{sub}(B)$ is overwritten by the solution matrix X .

Input Parameters

<i>side</i>	(global) CHARACTER*1. Specifies whether $\text{op}(\text{sub}(A))$ appears on the left or right of X in the equation: if <i>side</i> = 'L' or 'l', then $\text{op}(\text{sub}(A)) * X = \alpha * \text{sub}(B)$; if <i>side</i> = 'R' or 'r', then $X * \text{op}(\text{sub}(A)) = \alpha * \text{sub}(B)$.
<i>uplo</i>	(global) CHARACTER*1. Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>transa</i>	(global) CHARACTER*1. Specifies the form of $\text{op}(\text{sub}(A))$ used in the matrix equation: if <i>transa</i> = 'N' or 'n', then $\text{op}(\text{sub}(A)) = \text{sub}(A)$; if <i>transa</i> = 'T' or 't', then $\text{op}(\text{sub}(A)) = \text{sub}(A)'$; if <i>transa</i> = 'C' or 'c', then $\text{op}(\text{sub}(A)) = \text{conjg}(\text{sub}(A)')$.
<i>diag</i>	(global) CHARACTER*1. Specifies whether the matrix $\text{sub}(A)$ is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix $\text{sub}(B)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{sub}(B)$, $n \geq 0$.
<i>alpha</i>	(global) REAL for pstrsm DOUBLE PRECISION for pdtrsm COMPLEX for pctrsm DOUBLE COMPLEX for pztrsm Specifies the scalar <i>alpha</i> . When <i>alpha</i> is zero, then <i>a</i> is not referenced and <i>b</i> need not be set before entry.

<i>a</i>	<p>(local) REAL for pstrsm DOUBLE PRECISION for pdtrsm COMPLEX for pctrsm DOUBLE COMPLEX for pztrsm Array, DIMENSION (<i>lld_a</i>, <i>ka</i>), where <i>ka</i> is at least LOCq(1, <i>ja+m-1</i>) when <i>side</i> = 'L' or 'l' and is at least LOCq(1, <i>ja+n-1</i>) when <i>side</i> = 'R' or 'r'. Before entry with <i>uplo</i> = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix <i>sub(A)</i>, and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix <i>sub(A)</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix <i>sub(A)</i>, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix <i>sub(A)</i> is not referenced. When <i>diag</i> = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix <i>sub(A)</i> are not referenced either, but are assumed to be unity.</p>
<i>ia, ja</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i>, respectively.</p>
<i>desca</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>A</i>.</p>
<i>b</i>	<p>(local) REAL for pstrsm DOUBLE PRECISION for pdtrsm COMPLEX for pctrsm DOUBLE COMPLEX for pztrsm Array, DIMENSION (<i>lld_b</i>, LOCq(1, <i>jb+n-1</i>)). Before entry, this array contains the local pieces of the distributed matrix <i>sub(B)</i>.</p>
<i>ib, jb</i>	<p>(global) INTEGER. The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix <i>sub(B)</i>, respectively.</p>
<i>descb</i>	<p>(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix <i>B</i>.</p>

Output Parameters

b Overwritten by the solution distributed matrix x .

Partial Differential Equations Support

13

The Intel® Math Kernel Library (Intel® MKL) provides tools for solving Partial Differential Equations (PDE). These tools are Trigonometric Transform interface routines (see [Trigonometric Transform Routines](#)) and Poisson Library (see [Poisson Library Routines](#)).

Poisson Library is designed for fast solving of simple Helmholtz, Poisson, and Laplace problems. The solver is based on the Trigonometric Transform interface, which is, in turn, based on the Intel MKL Fast Fourier Transform (FFT) interface (refer to [Fourier Transform Functions](#)), optimized for Intel® processors.

Direct use of the Trigonometric Transform routines may be helpful to those who have already implemented their own solvers similar to the one that the Poisson Library provides. As it may be hard enough to modify the original code so as to make it work with Poisson Library, you are encouraged to use fast (staggered) sine/cosine transforms implemented in the Trigonometric Transform interface to improve performance of your solver.

Both Trigonometric Transform and Poisson Library routines can be called from C and Fortran 90, although the interfaces description uses C convention. Fortran 90 users can find routine calls specifics in the “[Calling PDE Support Routines from Fortran 90](#)” section.

Trigonometric Transform Routines

In addition to the Fast Fourier Transform (FFT) interface, described in chapter “[Fast Fourier Transforms](#)”, Intel® MKL supports the Real Discrete Trigonometric Transforms (sometimes called real-to-real Discrete Fourier Transforms) interface. In this manual, the interface is referred to as TT interface. It implements a group of routines (TT routines) used to compute sine/cosine, staggered sine/cosine, and twice staggered sine/cosine transforms (referred to as staggered2 sine/cosine transforms, for brevity). The TT interface provides much flexibility of use: you can adjust routines to your particular needs at the cost of manual tuning routine parameters or just call routines with default parameter values. The current Intel MKL implementation of the TT interface can be used in solving partial differential equations and contains routines that are helpful for Fast Poisson and similar solvers.

To describe the Intel MKL TT interface, the C convention is used. Fortran users should refer to [Calling PDE Support Routines from Fortran 90](#).

For the list of Trigonometric Transforms currently implemented in Intel MKL TT interface, see [Transforms Implemented](#).

If you have got used to the FFTW interface (www.fftw.org), you can call the TT interface functions through real-to-real FFTW to Intel MKL wrappers without changing FFTW function calls in your code (refer to the “[FFTW to Intel® MKL Wrappers for FFTW 3.x](#)” section in [Appendix F](#) for details). However, you are strongly encouraged to use the native TT interface for better performance. Another reason

why you should use the wrappers cautiously is that TT and the real-to-real FFTW interfaces are not fully compatible and some features of the real-to-real FFTW, such as strides and multidimensional transforms, are not available through wrappers.

Transforms Implemented

TT routines allow computing the following transforms:

Forward sine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin \frac{ki\pi}{n}, k = 1, \dots, n-1$$

Backward sine transform

$$f(i) = \sum_{k=1}^{n-1} F(k) \sin \frac{ki\pi}{n}, i = 1, \dots, n-1$$

Forward staggered sine transform

$$F(k) = \frac{1}{n} \sin \frac{(2k-1)\pi}{2} f(n) + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin \frac{(2k-1)i\pi}{2n}, k = 1, \dots, n$$

Backward staggered sine transform

$$f(i) = \sum_{k=1}^n F(k) \sin \frac{(2k-1)i\pi}{2n}, i = 1, \dots, n$$

Forward staggered2 sine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^n f(i) \sin \frac{(2k-1)(2i-1)\pi}{4n}, \quad k = 1, \dots, n$$

Backward staggered2 sine transform

$$f(i) = \sum_{k=1}^n F(k) \sin \frac{(2k-1)(2i-1)\pi}{4n}, \quad i = 1, \dots, n$$

Forward cosine transform

$$F(k) = \frac{1}{n} \left[f(0) + f(n) \cos k\pi \right] + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \cos \frac{ki\pi}{n}, \quad k = 0, \dots, n$$

Backward cosine transform

$$f(i) = \frac{1}{2} \left[F(0) + F(n) \cos i\pi \right] + \sum_{k=1}^{n-1} F(k) \cos \frac{ki\pi}{n}, \quad i = 0, \dots, n$$

Forward staggered cosine transform

$$F(k) = \frac{1}{n} f(0) + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \cos \frac{(2k+1)i\pi}{2n}, \quad k = 0, \dots, n-1$$

Backward staggered cosine transform

$$f(i) = \sum_{k=0}^{n-1} F(k) \cos \frac{(2k+1)i\pi}{2n}, i = 0, \dots, n-1$$

Forward staggered2 cosine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^n f(i) \cos \frac{(2k-1)(2i-1)\pi}{4n}, k = 1, \dots, n$$

Backward staggered2 cosine transform

$$f(i) = \sum_{k=1}^n F(k) \cos \frac{(2k-1)(2i-1)\pi}{4n}, i = 1, \dots, n$$

NOTE. The size of the transform n can be any integer greater or equal to 2.

Sequence of Invoking TT Routines

Computation of a transform using TT interface is conceptually divided into four steps, each of which is performed via a dedicated routine. [Table 13-1](#) lists the routines and briefly describes their purpose and use.

Most TT routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with "s" and "d". The wildcard "?" stands for either of these symbols in routine names.

Table 13-1 TT Interface Routines

Routine	Description
<code>?_init_trig_transform</code>	Initializes basic data structures of Trigonometric Transforms.
<code>?_commit_trig_transform</code>	Checks consistency and correctness of user-defined data as well as creates a data structure to be used by Intel MKL FFT interface ¹ .
<code>?_forward_trig_transform</code> <code>?_backward_trig_transform</code>	Computes a forward/backward Trigonometric Transform of a specified type using the appropriate formula (see Transforms Implemented).
<code>free_trig_transform</code>	Cleans the memory used by a data structure needed for calling FFT interface ¹ .

¹TT routines call Intel MKL FFT interface for better performance.

To find a transformed vector for a particular input vector only once, the Intel MKL TT interface routines are normally invoked in the order in which they are listed in [Table 13-1](#).

NOTE. Though the order of invoking TT routines may be changed, it is highly recommended to follow the above order of routine calls.

The diagram in [Figure 13-1](#) indicates the typical order in which TT interface routines can be invoked in a general case (prefixes and suffixes in routine names are omitted).

Figure 13-1 Typical Order of Invoking TT Interface Routines

A general scheme of using TT routines for double-precision computations is shown below. A similar scheme holds for single-precision computations with the only difference in the initial letter of routine names.

```

...
    d_init_trig_transform(&n, &tt_type, ipar, dpar, &ir);
/* Change parameters in ipar if necessary. */
/* Note that the result of the Transform will be in f ! If you want to preserve the data
stored in f,
save them before this place in your code */
    d_commit_trig_transform(f, &handle, ipar, dpar, &ir);
    d_forward_trig_transform(f, &handle, ipar, dpar, &ir);
    d_backward_trig_transform(f, &handle, ipar, dpar, &ir);
    free_trig_transform(&handle, ipar, &ir);
/* here the user may clean the memory used by f, dpar, ipar */
...

```

You can find examples of Fortran 90 and C code that use TT interface routines to solve one-dimensional Helmholtz problem in the “[Trigonometric Transform Code Examples](#)” section in Appendix C.

Interface Description

All types in this documentation are standard C types: `int`, `float`, and `double`. Fortran 90 users can call the routines with `INTEGER`, `REAL`, and `DOUBLE PRECISION` Fortran types, respectively (see examples in the “[Trigonometric Transform Code Examples](#)” section in Appendix C).

The interface description uses the built-in type `int` for integer values. If you employ the ILP64 interface, read this type as `long long int` (or `INTEGER*8` for Fortran). For more information, refer to the *Intel MKL User's Guide*.

Routine Options

All TT routines use parameters to pass various options to one another. These parameters are arrays `ipar`, `dpar` and `spar`. Values for these parameters should be specified very carefully (see [Common Parameters](#)). You can change these values during computations to meet your needs.

WARNING. To avoid failure or wrong results, you must provide correct and consistent parameters to the routines.

User Data Arrays

TT routines take arrays of user data as input. For example, user arrays are passed to the routine `d_forward_trig_transform` to compute a forward Trigonometric Transform. To minimize storage requirements and improve the overall run-time efficiency, Intel MKL TT routines do not make copies of user input arrays.

NOTE. If you need a copy of your input data arrays, save them yourself.

TT Routines

The section gives detailed description of TT routines, their syntax, parameters and values they return. Double-precision and single-precision versions of the same routine are described together.

TT routines call Intel MKL FFT interface (described in section “[FFT Functions](#)” in chapter “Fast Fourier Transforms”), which enhances performance of the routines.

?_init_trig_transform

Initializes basic data structures of a Trigonometric Transform.

Syntax

```
void d_init_trig_transform (int *n, int *tt_type, int ipar[], double dpar[],
int *stat);
```

```
void s_init_trig_transform (int *n, int *tt_type, int ipar[], float spar[],
int *stat);
```

Input Parameters

<i>n</i>	int*. Contains the size of the problem, which should be a positive integer greater than 1. Note that data vector of the transform, which other TT routines will use, must have size <i>n</i> +1 for all but staggered2 transforms. Staggered2 transforms require the vector of size <i>n</i> .
<i>tt_type</i>	int*. Contains the type of transform to compute, defined via a set of named constants. The following constants are available in the current implementation of TT interface: MKL_SINE_TRANSFORM, MKL_STAGGERED_SINE_TRANSFORM, MKL_STAGGERED2_SINE_TRANSFORM; MKL_COSINE_TRANSFORM, MKL_STAGGERED_COSINE_TRANSFORM, MKL_STAGGERED2_COSINE_TRANSFORM.

Output Parameters

<i>ipar</i>	int array of size 128. Contains integer data needed for Trigonometric Transform computations.
-------------	---

<code>dpar</code>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations.
<code>spar</code>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations.
<code>stat</code>	int*. Contains the routine completion status, which is also written to <code>ipar[6]</code> . The status should be 0 to proceed to other TT routines.

Description

The routine is declared in the `mkl_trig_transforms.h` header file for the C interface and `mkl_trig_transforms.f90` header file for the Fortran interface. The routine initializes basic data structures for Trigonometric Transforms of appropriate precision. After a call to `?_init_trig_transform`, all subsequently invoked TT routines use values of `ipar` and `dpar` (`spar`) array parameters returned by `?_init_trig_transform`. The routine initializes the entire array `ipar`. In the `dpar` or `spar` array, `?_init_trig_transform` initializes elements that do not depend upon the type of transform. For a detailed description of arrays `ipar`, `dpar` and `spar`, refer to the [Common Parameters](#) section. You can skip calling the initialization routine in your code. For more information, see [Caveat on Parameter Modifications](#).

Return Values

<code>stat= 0</code>	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this <code>stat</code> value.
<code>stat= -99999</code>	The routine failed to complete the task.

?_commit_trig_transform

Checks consistency and correctness of user's data as well as initializes certain data structures required to perform the Trigonometric Transform.

Syntax

```
void d_commit_trig_transform (double f[], DFTI_DESCRIPTOR_HANDLE *handle,
int ipar[], double dpar[], int *stat);

void s_commit_trig_transform (float f[], DFTI_DESCRIPTOR_HANDLE *handle, int
ipar[], float spar[], int *stat);
```

Input Parameters

<i>f</i>	<p>double for d_commit_trig_transform, float for s_commit_trig_transform, array of size n for staggered2 transforms and of size $n+1$ for all other transforms, where n is the size of the problem. Contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors:</p> <ul style="list-style-type: none"> • $f[0]$ and $f[n]$ for sine transforms • $f[n]$ for staggered cosine transforms • $f[0]$ for staggered sine transforms. <p>Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. These restrictions meet the requirements of the Poisson Library (described in the Poisson Library Routines section), which the TT interface is primarily designed for.</p>
<i>ipar</i>	int array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.
<i>spar</i>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.

Output Parameters

<i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, refer to section " FFT Functions " in chapter "Fast Fourier Transforms").
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar</i> [6] is updated with the <i>stat</i> value.
<i>dpar</i>	Contains double-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.

<i>spar</i>	Contains single-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.
<i>stat</i>	int*. Contains the routine completion status, which is also written to <i>ipar[6]</i> .

Description

The routine is declared in the `mkl_trig_transforms.h` header file for the C interface and `mkl_trig_transforms.f90` header file for the Fortran interface. The routine `?_commit_trig_transform` checks consistency and correctness of the parameters to be passed to the transform routines `?_forward_trig_transform` and/or `?_backward_trig_transform`. The routine also initializes the following data structures: *handle*, *dpar* in case of `d_commit_trig_transform`, and *spar* in case of `s_commit_trig_transform`. The `?_commit_trig_transform` routine initializes only those elements of *dpar* or *spar* that depend upon the type of transform, defined in the `?_init_trig_transform` routine and passed to `?_commit_trig_transform` with the *ipar* array. The size of the problem *n*, which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called `?_init_trig_transform` routine. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the [Common Parameters](#) section. The routine performs only a basic check for correctness and consistency of the parameters. If you are going to modify parameters of TT routines, see the [Caveat on Parameter Modifications](#) section. Unlike `?_init_trig_transform`, the `?_commit_trig_transform` routine is mandatory, and you cannot skip calling it in your code.

Return Values

stat= 11

The routine produced some warnings and made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning *ipar[6]*=0 if you are sure that the parameters are correct.

stat= 10

The routine made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning *ipar[6]*=0 if you are sure that the parameters are correct.

`stat= 1`

The routine produced some warnings. You may proceed with computations by assigning `ipar[6]=0` if you are sure that the parameters are correct.

`stat= 0`

The routine completed the task normally.

`stat= -100`

The routine stopped for any of the following reasons:

- An error in the user's data was encountered.
- Data in `ipar`, `dpar` or `spar` parameters became incorrect and/or inconsistent as a result of modifications.

`stat= -1000`

The routine stopped because of an FFT interface error.

`stat= -10000`

The routine stopped because the initialization failed to complete or the parameter `ipar[0]` was altered by mistake.

NOTE. Although positive values of `stat` usually indicate minor problems with the input data and Trigonometric Transform computations can be continued, you are highly recommended to investigate the problem first and achieve `stat=0`.

?_forward_trig_transform

Computes the forward Trigonometric Transform of type specified by the parameter.

Syntax

```
void d_forward_trig_transform (double f[], DFTI_DESCRIPTOR_HANDLE *handle,
int ipar[], double dpar[], int *stat);
```

```
void s_forward_trig_transform (float f[], DFTI_DESCRIPTOR_HANDLE *handle,
int ipar[], float spar[], int *stat);
```

Input Parameters

`f` double for `d_forward_trig_transform`,
 float for `s_forward_trig_transform`,

array of size n for staggered2 transforms and of size $n+1$ for all other transforms, where n is the size of the problem. On input, contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors:

- $f[0]$ and $f[n]$ for sine transforms
- $f[n]$ for staggered cosine transforms
- $f[0]$ for staggered sine transforms.

Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. The above restrictions meet the requirements of the Poisson Library (described in the [Poisson Library Routines](#) section), which the TT interface is primarily designed for.

<i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”).
<i>ipar</i>	int array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations.
<i>spar</i>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations.

Output Parameters

<i>f</i>	Contains the transformed vector on output.
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar</i> [6] is updated with the <i>stat</i> value.
<i>stat</i>	int*. Contains the routine completion status, which is also written to <i>ipar</i> [6].

Description

The routine is declared in the `mkl_trig_transforms.h` header file for the C interface and `mkl_trig_transforms.f90` header file for the Fortran interface. The routine computes the forward Trigonometric Transform of type defined in the `?_init_trig_transform` routine and passed to `?_forward_trig_transform` with the *ipar* array. The size of the problem n , which

determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called `?_init_trig_transform` routine. The other data that facilitates the computation is created by `?_commit_trig_transform` and supplied in *dpar* or *spar*. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the [Common Parameters](#) section. The routine has a commit step, which calls the `?_commit_trig_transform` routine. The transform is computed according to formulas given in the [Transforms Implemented](#) section. The routine replaces the input vector *f* with the transformed vector.

NOTE. If you need a copy of the data vector *f* to be transformed, make the copy before calling the `?_forward_trig_transform` routine.

Return Values

stat = 0

The routine completed the task normally.

stat = -100

The routine stopped for any of the following reasons:

- An error in the user's data was encountered.
- Data in *ipar*, *dpar* or *spar* parameters became incorrect and/or inconsistent as a result of modifications.

stat = -1000

The routine stopped because of an FFT interface error.

stat = -10000

The routine stopped because its commit step failed to complete or the parameter *ipar*[0] was altered by mistake.

?_backward_trig_transform

Computes the backward Trigonometric Transform of type specified by the parameter.

Syntax

```
void d_backward_trig_transform (double f[], DFTI_DESCRIPTOR_HANDLE *handle,
int ipar[], double dpar[], int *stat);
```

```
void s_backward_trig_transform (float f[], DFTI_DESCRIPTOR_HANDLE *handle,
int ipar[], float spar[], int *stat);
```

Input Parameters

<i>f</i>	<p>double for <code>d_backward_trig_transform</code>, float for <code>s_backward_trig_transform</code>, array of size n for <code>staggered2</code> transforms and of size $n+1$ for all other transforms, where n is the size of the problem. On input, contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors:</p> <ul style="list-style-type: none"> • $f[0]$ and $f[n]$ for sine transforms • $f[n]$ for staggered cosine transforms • $f[0]$ for staggered sine transforms. <p>Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. The above restrictions meet the requirements of the Poisson Library (described in the Poisson Library Routines section), which the TT interface is primarily designed for.</p>
<i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, refer to section " FFT Functions " in chapter "Fast Fourier Transforms").
<i>ipar</i>	int array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations.
<i>spar</i>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations.

Output Parameters

<i>f</i>	Contains the transformed vector on output.
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar</i> [6] is updated with the <i>stat</i> value.
<i>stat</i>	int*. Contains the routine completion status, which is also written to <i>ipar</i> [6].

Description

The routine is declared in the `mkl_trig_transforms.h` header file for the C interface and `mkl_trig_transforms.f90` header file for the Fortran interface. The routine computes the backward Trigonometric Transform of type defined in the `?_init_trig_transform` routine and passed to `?_backward_trig_transform` with the `ipar` array. The size of the problem n , which determines sizes of the array parameters, is also passed to the routine with the `ipar` array and defined in the previously called `?_init_trig_transform` routine. The other data that facilitates the computation is created by `?_commit_trig_transform` and supplied in `dpar` or `spar`. For a detailed description of arrays `ipar`, `dpar` and `spar`, refer to the [Common Parameters](#) section. The routine has a commit step, which calls the `?_commit_trig_transform` routine. The transform is computed according to formulas given in the [Transforms Implemented](#) section. The routine replaces the input vector f with the transformed vector.

NOTE. If you need a copy of the data vector f to be transformed, make the copy before calling the `?_backward_trig_transform` routine.

Return Values

`stat= 0`

The routine completed the task normally.

`stat= -100`

The routine stopped for any of the following reasons:

- An error in the user's data was encountered.
- Data in `ipar`, `dpar` or `spar` parameters became incorrect and/or inconsistent as a result of modifications.

`stat= -1000`

The routine stopped because of an FFT interface error.

`stat= -10000`

The routine stopped because its commit step failed to complete or the parameter `ipar[0]` was altered by mistake.

free_trig_transform

Cleans the memory allocated for the data structure used by the FFT interface.

Syntax

```
void free_trig_transform (DFTI_DESCRIPTOR_HANDLE *handle, int ipar[], int *stat);
```

Input Parameters

<i>ipar</i>	<code>int</code> array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>handle</i>	<code>DFTI_DESCRIPTOR_HANDLE*</code> . The data structure used by Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”).

Output Parameters

<i>handle</i>	The data structure used by Intel MKL FFT interface. Memory allocated for the structure is released on output.
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar</i> [6] is updated with the <i>stat</i> value.
<i>stat</i>	<code>int*</code> . Contains the routine completion status, which is also written to <i>ipar</i> [6].

Description

The routine is declared in the `mkl_trig_transforms.h` header file for the C interface and `mkl_trig_transforms.f90` header file for the Fortran interface. The routine cleans the memory used by the *handle* structure, needed for Intel MKL FFT functions. To release the memory allocated for other parameters, include cleaning of the memory in your code.

Return Values

<i>stat</i> = 0	The routine completed the task normally.
<i>stat</i> = -1000	The routine stopped because of an FFT interface error.
<i>stat</i> = -99999	The routine failed to complete the task.

Common Parameters

This section provides description of array parameters that hold TT routine options: *ipar*, *dpar* and *spar*.

NOTE. Initial values are assigned to the array parameters by the appropriate `?_init_trig_transform` and `?_commit_trig_transform` routines.

ipar `int` array of size 128, holds integer data needed for Trigonometric Transform computations. Its elements are described in [Table 13-2](#):

Table 13-2 Elements of the ipar Array

Index	Description
0	Contains the size of the problem to solve. The <code>?_init_trig_transform</code> routine sets <code>ipar[0]=n</code> , and all subsequently called TT routines use <code>ipar[0]</code> as the size of the transform.
1	<p>Contains error messaging options:</p> <ul style="list-style-type: none"> <code>ipar[1]=-1</code> indicates that all error messages will be printed to the file <code>MKL_Trig_Transforms_log.txt</code> in the folder from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. <code>ipar[1]=0</code> indicates that no error messages will be printed. <code>ipar[1]=1</code> (default) indicates that all error messages will be printed to the preconnected default output device (usually, screen). <p>In case of errors, each TT routine assigns a non-zero value to <code>stat</code> regardless of the <code>ipar[1]</code> setting.</p>
2	<p>Contains warning messaging options:</p> <ul style="list-style-type: none"> <code>ipar[2]=-1</code> indicates that all warning messages will be printed to the file <code>MKL_Trig_Transforms_log.txt</code> in the directory from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. <code>ipar[2]=0</code> indicates that no warning messages will be printed.

Index	Description
	<ul style="list-style-type: none"> <code>ipar[2]=1</code> (default) indicates that all warning messages will be printed to the preconnected default output device (usually, screen). <p>In case of warnings, the <code>stat</code> parameter will acquire a non-zero value regardless of the <code>ipar[2]</code> setting.</p>
3 through 4	Reserved for future use.
5	Contains the type of the transform. The <code>?_init_trig_transform</code> routine sets <code>ipar[5]=tt_type</code> , and all subsequently called TT routines use <code>ipar[5]</code> as the type of the transform.
6	Contains the <code>stat</code> value returned by the last completed TT routine. Used to check that the previous call to a TT routine completed with <code>stat=0</code> .
7	<p>Informs the <code>?_commit_trig_transform</code> routines whether to initialize data structures <code>dpar</code> (<code>spar</code>) and <code>handle</code>. <code>ipar[7]=0</code> indicates that the routine should skip the initialization and only check correctness and consistency of the parameters. Otherwise, the routine initializes the data structures. The default value is 1.</p> <p>The possibility to check correctness and consistency of input data without initializing data structures <code>dpar</code>, <code>spar</code> and <code>handle</code> enables avoiding performance losses in a repeated use of the same transform for different data vectors. Note that you can benefit from the opportunity that <code>ipar[7]</code> gives only if you are sure to have supplied proper tolerance value in the <code>dpar</code> or <code>spar</code> array. Otherwise, avoid tuning this parameter.</p>
8	<p>Contains message style options for TT routines. If <code>ipar[8]=0</code> then TT routines print all error and warning messages in Fortran-style notations. Otherwise, TT routines print the messages in C-style notations. The default value is 1.</p> <p>When selecting between these notations, mind that by default, numbering of elements in C arrays starts from 0 and in Fortran, it starts from 1. For example, for a C-style message "<i>parameter ipar[0]=3 should be an even integer</i>", the corresponding Fortran-style message will be "<i>parameter ipar(1)=3 should be an even integer</i>". The use of <code>ipar[8]</code> enables you to view messages in a more convenient style.</p>

Index	Description
9	Specifies the number of OpenMP threads to run TT routines in the OpenMP environment of the Poisson Library. The default value is 1. You are highly recommended not to alter this value. See also Caveat on Parameter Modifications .
10	Specifies the mode of compatibility with FFTW. The default value is 0. Set the value to 1 to invoke compatibility with FFTW. In the latter case, results will not be normalized, because FFTW does not do this. It is highly recommended not to alter this value, but rather use real-to-real FFTW to MKL wrappers, described in the "FFTW to Intel® MKL Wrappers for FFTW 3.x" section in Appendix F . See also Caveat on Parameter Modifications .
11 through 127	Reserved for future use.

NOTE. You may declare the *ipar* array in your code as `int ipar[11]`. However, for compatibility with later versions of Intel MKL TT interface, which may require more *ipar* values, it is highly recommended to declare *ipar* as `int ipar[128]`.

Arrays *dpar* and *spar* are the same except in the data precision:

<i>dpar</i>	double array of size $5n/2+2$, holds data needed for double-precision routines to perform TT computations. This array is initialized in the d_init_trig_transform and d_commit_trig_transform routines.
<i>spar</i>	float array of size $5n/2+2$, holds data needed for single-precision routines to perform TT computations. This array is initialized in the s_init_trig_transform and s_commit_trig_transform routines.

As *dpar* and *spar* have similar elements in respective positions, the elements are described together in [Table 13-3](#):

Table 13-3 Elements of the *dpar* and *spar* Arrays

Index	Description
0	Contains the first absolute tolerance used by the appropriate ?_commit_trig_transform routine. For a staggered cosine or a sine transform, $f[n]$ should be equal to 0.0 and for a staggered sine or a sine transform, $f[0]$ should be equal to 0.0. The ?_commit_trig_transform routine checks whether absolute values of these parameters are below $dpar[0]*n$

Index	Description
	or <i>spar</i> [0]* <i>n</i> , depending on the routine precision. To suppress warnings resulting from tolerance checks, set <i>dpar</i> [0] or <i>spar</i> [0] to a sufficiently large number.
1	Reserved for future use.
2 through 5 <i>n</i> /2+1	<p>Contain tabulated values of trigonometric functions. Contents of the elements depend upon the type of transform <i>tt_type</i>, set up in the ?_commit_trig_transform routine:</p> <ul style="list-style-type: none">• If <i>tt_type</i>=MKL_SINE_TRANSFORM, the transform uses only the first <i>n</i>/2 array elements, which contain tabulated sine values.• If <i>tt_type</i>=MKL_STAGGERED_SINE_TRANSFORM, the transform uses only the first 3<i>n</i>/2 array elements, which contain tabulated sine and cosine values.• If <i>tt_type</i>=MKL_STAGGERED2_SINE_TRANSFORM, the transform uses all the 5<i>n</i>/2 array elements, which contain tabulated sine and cosine values.• If <i>tt_type</i>=MKL_COSINE_TRANSFORM, the transform uses only the first <i>n</i> array elements, which contain tabulated cosine values.• If <i>tt_type</i>=MKL_STAGGERED_COSINE_TRANSFORM, the transform uses only the first 3<i>n</i>/2 elements, which contain tabulated sine and cosine values.• If <i>tt_type</i>=MKL_STAGGERED2_COSINE_TRANSFORM, the transform uses all the 5<i>n</i>/2 elements, which contain tabulated sine and cosine values.

NOTE. To save memory, you can define the array size depending upon the type of transform.

Caveat on Parameter Modifications

Flexibility of the TT interface enables you to skip calling the [?_init_trig_transform](#) routine and to initialize the basic data structures explicitly in your code. You may also need to modify the contents of *ipar*, *dpar* and *spar* arrays after initialization. When doing so, provide correct and consistent data in the arrays. Mistakenly altered arrays cause errors or wrong computation. You can perform a basic check for correctness and consistency of parameters by calling the [?_commit_trig_transform](#) routine; however, this does not ensure the correct result of a transform but only reduces the chance of errors or wrong results.

NOTE. To supply correct and consistent parameters to TT routines, you should have considerable experience in using the TT interface and good understanding of elements that the *ipar*, *spar* and *dpar* arrays contain and dependencies between values of these elements.

However, in rare occurrences, even advanced users might fail to compute a transform using TT routines after the parameter modifications. In cases like these, refer for technical support at <http://www.intel.com/software/products/support/>.

WARNING. The only way that ensures proper computation of the Trigonometric Transforms is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of *ipar*, *dpar* and *spar* arrays unless a strong need arises.

Implementation Details

Several aspects of the Intel MKL TT interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, users are provided with the TT language-specific header files to include in their code. Currently, the following of them are available:

- `mkl_trig_transforms.h`, to be used together with `mkl_dfti.h`, for C programs.
- `mkl_trig_transforms.f90`, to be used together with `mkl_dfti.f90`, for Fortran 90 programs.

NOTE. Use of the Intel MKL TT software without including one of the above header files is not supported.

C-specific Header File

The C-specific header file defines the following function prototypes:

```
void d_init_trig_transform(int *, int *, int *, double *, int *);
```

```
void d_commit_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, int *, double *, int *);
```

```
void d_forward_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, int *, double *, int *);
void d_backward_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, int *, double *, int *);

void s_init_trig_transform(int *, int *, int *, float *, int *);
void s_commit_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, int *, float *, int *);

void s_forward_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, int *, float *, int *);
void s_backward_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, int *, float *, int *);

void free_trig_transform(DFTI_DESCRIPTOR_HANDLE *, int *, int *);
```

Fortran-Specific Header File

The Fortran90-specific header file defines the following function prototypes:

```
SUBROUTINE D_INIT_TRIG_TRANSFORM(n, tt_type, ipar, dpar, stat)
```

```
    INTEGER, INTENT(IN) :: n, tt_type
```

```
    INTEGER, INTENT(INOUT) :: ipar(*)
```

```
    REAL(8), INTENT(INOUT) :: dpar(*)
```

```
    INTEGER, INTENT(OUT) :: stat
```

```
END SUBROUTINE D_INIT_TRIG_TRANSFORM
```

```
SUBROUTINE D_COMMIT_TRIG_TRANSFORM(f, handle, ipar, dpar, stat)
```

```
    REAL(8), INTENT(INOUT) :: f(*)
```

```
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
```

```
    INTEGER, INTENT(INOUT) :: ipar(*)
```

```
    REAL(8), INTENT(INOUT) :: dpar(*)
```

```
    INTEGER, INTENT(OUT) :: stat
```

```
END SUBROUTINE D_COMMIT_TRIG_TRANSFORM
```

```
SUBROUTINE D_FORWARD_TRIG_TRANSFORM(f, handle, ipar, dpar, stat)
```

```
    REAL(8), INTENT(INOUT) :: f(*)
```

```
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
```

```
    INTEGER, INTENT(INOUT) :: ipar(*)
```

```
    REAL(8), INTENT(INOUT) :: dpar(*)
```

```
    INTEGER, INTENT(OUT) :: stat
```

```
END SUBROUTINE D_FORWARD_TRIG_TRANSFORM
```

```
SUBROUTINE D_BACKWARD_TRIG_TRANSFORM(f, handle, ipar, dpar, stat)
```

```
    REAL(8), INTENT(INOUT) :: f(*)
```

```
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
```

```
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(8), INTENT(INOUT) :: dpar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE D_BACKWARD_TRIG_TRANSFORM

SUBROUTINE S_INIT_TRIG_TRANSFORM(n, tt_type, ipar, spar, stat)
    INTEGER, INTENT(IN) :: n, tt_type
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(4), INTENT(INOUT) :: spar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE S_INIT_TRIG_TRANSFORM

SUBROUTINE S_COMMIT_TRIG_TRANSFORM(f, handle, ipar, spar, stat)
    REAL(4), INTENT(INOUT) :: f(*)
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(4), INTENT(INOUT) :: spar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE S_COMMIT_TRIG_TRANSFORM

SUBROUTINE S_FORWARD_TRIG_TRANSFORM(f, handle, ipar, spar, stat)
    REAL(4), INTENT(INOUT) :: f(*)
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(4), INTENT(INOUT) :: spar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE S_FORWARD_TRIG_TRANSFORM
```

```

SUBROUTINE S_BACKWARD_TRIG_TRANSFORM(f, handle, ipar, spar, stat)
    REAL(4), INTENT(INOUT) :: f(*)
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(4), INTENT(INOUT) :: spar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE S_BACKWARD_TRIG_TRANSFORM

```

```

SUBROUTINE FREE_TRIG_TRANSFORM(handle, ipar, stat)
    INTEGER, INTENT(INOUT) :: ipar(*)
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE FREE_TRIG_TRANSFORM

```

Fortran 90 specifics of the TT routines usage are similar for all Intel MKL PDE support tools and described in the [Calling PDE Support Routines from Fortran 90](#) section.

Poisson Library Routines

In addition to Real Discrete Trigonometric Transforms (TT) interface (refer to [Trigonometric Transform Routines](#)), Intel® MKL supports the Poisson Library interface, referred to as PL interface. The interface implements a group of routines (PL routines) used to compute a solution of Laplace, Poisson, and Helmholtz problems of special kind using discrete Fourier transforms. Laplace and Poisson problems are special cases of a more general Helmholtz problem. The problems being solved are defined more exactly in the [Poisson Library Implemented](#) subsection. The PL interface provides much flexibility of use: you can adjust routines to your particular needs at the cost of manual tuning routine parameters or just call routines with default parameter values. The interface can adjust style of error and warning messages to C or Fortran notations by setting up a dedicated parameter. This adds convenience to debugging, because users can read information in the way that is natural for their code. The Intel MKL PL interface currently contains only routines that implement the following solvers:

- Fast Laplace, Poisson and Helmholtz solvers in a Cartesian coordinate system
- Fast Poisson and Helmholtz solvers in a spherical coordinate system.

To describe the Intel MKL PL interface, the C convention is used. Fortran usage specifics can be found in the [Calling PDE Support Routines from Fortran 90](#) section.

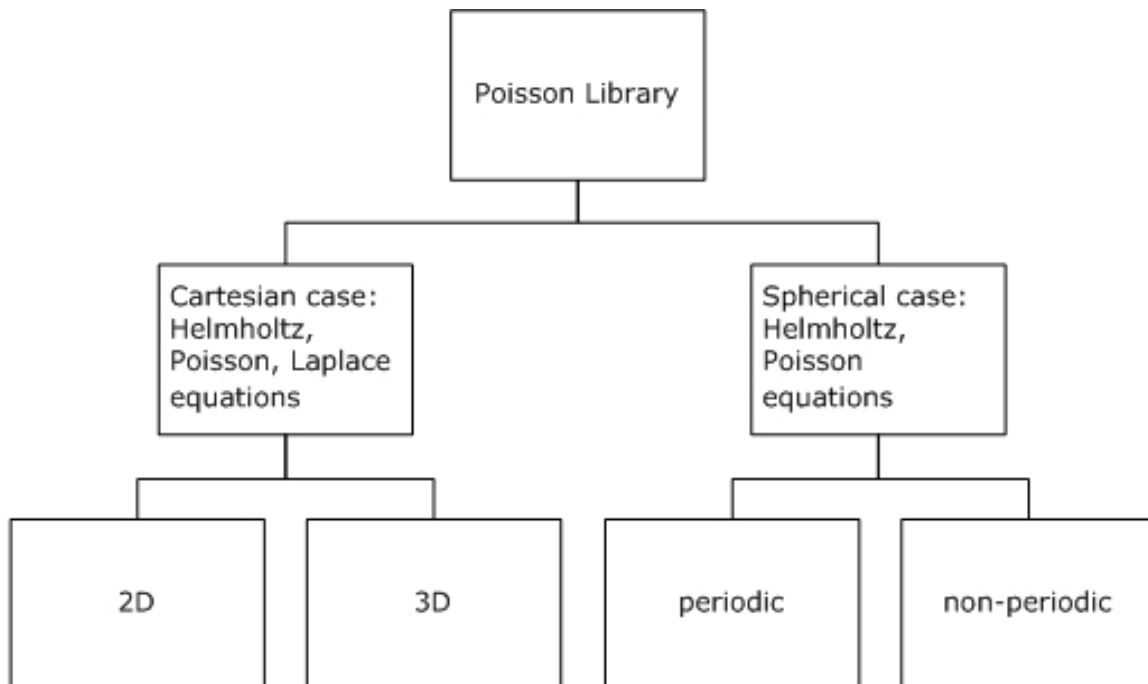

NOTE. Fortran users should mind that respective array indices in Fortran increase by 1.

Poisson Library Implemented

PL routines enable approximate solving of certain two-dimensional and three-dimensional problems. [Figure 13-2](#) shows the general structure of the Poisson Library.

Figure 13-2 Structure of the Poisson Library

Sections below provide details of the problems that can be solved using Intel MKL PL.

Two-Dimensional Problems

Notational Conventions

The PL interface description uses the following notation for boundaries of a rectangular domain $a_x < x < b_x$, $a_y < y < b_y$ on a Cartesian plane:

$$bd_a_x = \{x = a_x, a_y \leq y \leq b_y\}, bd_b_x = \{x = b_x, a_y \leq y \leq b_y\}$$

$$bd_a_y = \{a_x \leq x \leq b_x, y = a_y\}, bd_b_y = \{a_x \leq x \leq b_x, y = b_y\}.$$

The wildcard "+" may stand for any of the symbols a_x , b_x , a_y , b_y , so that bd_+ denotes any of the above boundaries.

The PL interface description uses the following notation for boundaries of a rectangular domain $a_\phi < \phi < b_\phi$, $a_\theta < \theta < b_\theta$ on a sphere $0 \leq \phi \leq 2\pi$, $0 \leq \theta \leq \pi$:

$$bd_a_\phi = \{\phi = a_\phi, a_\theta \leq \theta \leq b_\theta\}, bd_b_\phi = \{\phi = b_\phi, a_\theta \leq \theta \leq b_\theta\}$$

$$bd_a_\theta = \{a_\phi \leq \phi \leq b_\phi, \theta = a_\theta\}, bd_b_\theta = \{a_\phi \leq \phi \leq b_\phi, \theta = b_\theta\}.$$

The wildcard "~" may stand for any of the symbols a_ϕ , b_ϕ , a_θ , b_θ , so that $bd_~$ denotes any of the above boundaries.

Two-dimensional (2D) Helmholtz problem on a Cartesian plane

The 2D Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} + qu = f(x, y), q = \text{const} \geq 0$$

in a rectangle, that is, a rectangular domain $a_x < x < b_x$, $a_y < y < b_y$, with one of the following boundary conditions on each boundary bd_+ :

- The Dirichlet boundary condition

$$u(x, y) = G(x, y)$$

- The Neumann boundary condition

$$\frac{\partial u}{\partial n}(x, y) = g(x, y)$$

where

$$n = -x \text{ on } bd_a_x, \quad n = x \text{ on } bd_b_x,$$

$$n = -y \text{ on } bd_a_y, \quad n = y \text{ on } bd_b_y.$$

Two-dimensional (2D) Poisson problem on a Cartesian plane

The Poisson problem is a special case of the Helmholtz problem, when $q=0$. The 2D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} = f(x, y)$$

in a rectangle $a_x < x < b_x, a_y < y < b_y$ with the Dirichlet or Neumann boundary condition on each boundary bd_+ . In case of a problem with the Neumann boundary condition on the entire boundary, you can find the solution of the problem only up to a constant. In this case, the Poisson Library will compute the solution that provides the minimal Euclidean norm of a residual.

Two-dimensional (2D) Laplace problem on a Cartesian plane

The Laplace problem is a special case of the Helmholtz problem, when $q=0$ and $f(x, y)=0$. The 2D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$$

in a rectangle $a_x < x < b_x, a_y < y < b_y$ with the Dirichlet or Neumann boundary condition on each boundary bd_+ .

Helmholtz problem on a sphere

The Helmholtz problem on a sphere is to find an approximate solution of the Helmholtz equation

$$-\Delta_s u + qu = f, \quad q = const \geq 0,$$

$$\Delta_s = \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \varphi^2} + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial}{\partial \theta} \right)$$

in a spherical rectangle that is, a domain bounded by angles $a_\phi \leq \phi \leq b_\phi, a_\theta \leq \theta \leq b_\theta$, with boundary conditions for particular domains listed in [Table 13-4](#).

Table 13-4 Details of Helmholtz Problem on a Sphere

Domain on a sphere	Boundary condition	Periodic/non-periodic case
Rectangular, that is, $b_\phi - a_\phi < 2 \pi$ and $b_\theta - a_\theta < \pi$	Homogeneous Dirichlet boundary conditions on each boundary $bd_~$	<i>non-periodic</i>
Where $a_\phi = 0, b_\phi = 2 \pi$, and $b_\theta - a_\theta < \pi$	Homogeneous Dirichlet boundary conditions on the boundaries bd_a_θ and bd_b_θ	<i>periodic</i>
Entire sphere, that is, $a_\phi = 0, b_\phi = 2 \pi, a_\theta = 0$, and $b_\theta = \pi$	Boundary condition	<i>periodic</i>
$\left(\sin \theta \frac{\partial u}{\partial \theta} \right)_{\substack{\theta \rightarrow 0 \\ \theta \rightarrow \pi}} = 0$		
at the poles.		

Poisson problem on a sphere

The Poisson problem is a special case of the Helmholtz problem, when $q=0$. The Poisson problem on a sphere is to find an approximate solution of the Poisson equation

$$-\Delta_s u = f, \quad \Delta_s = \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \phi^2} + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial}{\partial \theta} \right)$$

in a spherical rectangle $a_\phi \leq \phi \leq b_\phi, a_\theta \leq \theta \leq b_\theta$ in cases listed in [Table 13-4](#). The solution to the Poisson problem on the entire sphere can be found up to a constant only. In this case, Poisson Library will compute the solution that provides the minimal Euclidean norm of a residual.

Approximation of 2D problems

To find an approximate solution for any of the 2D problems, a uniform mesh is built in the rectangular domain:

$$\{x_i = a_x + ih_x, y_j = a_y + jh_y\},$$

$$i = 0, \dots, n_x, j = 0, \dots, n_y, h_x = \frac{b_x - a_x}{n_x}, h_y = \frac{b_y - a_y}{n_y}$$

in the Cartesian case and

$$\{\phi_i = a_\phi + ih_\phi, \theta_j = a_\theta + jh_\theta\},$$

$$i = 0, \dots, n_\phi, j = 0, \dots, n_\theta, h_\phi = \frac{b_\phi - a_\phi}{n_\phi}, h_\theta = \frac{b_\theta - a_\theta}{n_\theta}$$

in the spherical case.

Poisson Library uses the standard five-point finite difference approximation on this mesh to compute the approximation to the solution:

- In the Cartesian case, the values of the approximate solution will be computed in the mesh points (x_i, y_j) provided that the user knows the values of the right-hand side $f(x, y)$ in these points and the values of the appropriate boundary functions $G(x, y)$ and/or $g(x, y)$ in the mesh points laying on the boundary of the rectangular domain.
- In the spherical case, the values of the approximate solution will be computed in the mesh points (ϕ_i, θ_j) provided that the user knows the values of the right-hand side $f(\phi, \theta)$ in these points.

NOTE. The number of mesh intervals n_ϕ in the ϕ direction of a spherical mesh must be even in the periodic case. The current implementation of the Poisson Library does not support meshes with the number of intervals that does not meet this condition.

Three-Dimensional Problems

Notational Conventions

The PL interface description uses the following notation for boundaries of a parallelepiped domain $a_x < x < b_x, a_y < y < b_y, a_z < z < b_z$:

$$bd_a_x = \{x = a_x, a_y \leq y \leq b_y, a_z \leq z \leq b_z\}, bd_b_x = \{x = b_x, a_y \leq y \leq b_y, a_z \leq z \leq b_z\}$$

$$bd_a_y = \{a_x \leq x \leq b_x, y = a_y, a_z \leq z \leq b_z\}, bd_b_y = \{a_x \leq x \leq b_x, y = b_y, a_z \leq z \leq b_z\}$$

$$bd_a_z = \{a_x \leq x \leq b_x, a_y \leq y \leq b_y, z = a_z\}, bd_b_z = \{a_x \leq x \leq b_x, a_y \leq y \leq b_y, z = b_z\}.$$

The wildcard "+" may stand for any of the symbols $a_x, b_x, a_y, b_y, a_z, b_z$, so that bd_+ denotes any of the above boundaries.

Three-dimensional (3D) Helmholtz problem

The 3D Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} - \frac{\partial^2 u}{\partial z^2} + qu = f(x, y, z), q = \text{const} \geq 0$$

in a parallelepiped, that is, a parallelepiped domain $a_x < x < b_x, a_y < y < b_y, a_z < z < b_z$, with one of the following boundary conditions on each boundary bd_+ :

- The Dirichlet boundary condition

$$u(x, y, z) = G(x, y, z)$$

- The Neumann boundary condition

$$\frac{\partial u}{\partial n}(x, y, z) = g(x, y, z)$$

where

$$n = -x \text{ on } bd_{-a_x}, n = x \text{ on } bd_{+b_x},$$

$$n = -y \text{ on } bd_{-a_y}, n = y \text{ on } bd_{+b_y},$$

$$n = -z \text{ on } bd_{-a_z}, n = z \text{ on } bd_{+b_z}.$$

Three-dimensional (3D) Poisson problem

The Poisson problem is a special case of the Helmholtz problem, when $q=0$. The 3D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} - \frac{\partial^2 u}{\partial z^2} = f(x, y, z)$$

in a parallelepiped $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$ with Dirichlet or Neumann boundary condition on each boundary bd_+ .

Three-dimensional (3D) Laplace problem

The Laplace problem is a special case of the Helmholtz problem, when $q=0$ and $f(x, y, z)=0$. The 3D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0$$

in a parallelepiped $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$ with the Dirichlet or Neumann boundary condition on each boundary bd_+ .

Approximation of 3D problems

To find an approximate solution for each of the 3D problems, a uniform mesh is built in the parallelepiped domain

$$\{x_i = a_x + ih_x, y_j = a_y + jh_y, z_k = a_z + kh_z\}$$

where

$$i = 0, \dots, n_x, j = 0, \dots, n_y, k = 0, \dots, n_z$$

$$h_x = \frac{b_x - a_x}{n_x}, h_y = \frac{b_y - a_y}{n_y}, h_z = \frac{b_z - a_z}{n_z}$$

The Poisson Library uses the standard seven-point finite difference approximation on this mesh to compute the approximation to the solution. The values of the approximate solution will be computed in the mesh points (x_i, y_j, z_k) , provided that the user knows the values of the right-hand side $f(x, y, z)$ in these points and the values of the appropriate boundary functions $G(x, y, z)$ and/or $g(x, y, z)$ in the mesh points laying on the boundary of the parallelepiped domain.

Sequence of Invoking PL Routines

NOTE. This description always considers the solution process for the Helmholtz problem, because Fast Poisson Solver and Fast Laplace Solver are special cases of Fast Helmholtz Solver (see [Poisson Library Implemented](#)).

Computation of a solution of the Helmholtz problem using the PL interface is conceptually divided into four steps, each of which is performed via a dedicated routine. [Table 13-5](#) lists the routines and briefly describes their purpose.

Most PL routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with “s” and “d”. The wildcard “?” stands for either of these symbols in routine names. The routines for Cartesian coordinate system have 2D and 3D versions. Their names end respectively in “2D” and “3D”. The routines for spherical coordinate system have periodic and non-periodic versions. Their names end respectively in “p” and “np”

Table 13-5 PL Interface Routines

Routine	Description
<code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/ ?_init_sph_p/?_init_sph_np</code>	Initializes basic data structures of Poisson Library for Fast Helmholtz Solver in the 2D/3D/periodic/non-periodic case, respectively.
<code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/ ?_commit_sph_p/?_commit_sph_np</code>	Checks consistency and correctness of user's data, creates and initializes data structures to be used by the Intel MKL FFT interface ¹ , as well as other data structures needed for the solver.

Routine	Description
<code>?_Helmholtz_2D/?_Helmholtz_3D/ ?_sph_p/?_sph_np</code>	Computes an approximate solution of 2D/3D/periodic/non-periodic Helmholtz problem (see Poisson Library Implemented) specified by the parameters.
<code>free_Helmholtz_2D/free_Helmholtz_3D/ free_sph_p/free_sph_np</code>	Cleans the memory used by the data structures needed for calling the Intel MKL FFT interface ¹ .

¹ PL routines call the Intel MKL FFT interface for better performance.

To find an approximate solution of Helmholtz problem only once, the Intel MKL PL interface routines are normally invoked in the order in which they are listed in [Table 13-5](#).

NOTE. Though the order of invoking PL routines may be changed, it is highly recommended to follow the above order of routine calls.

The diagram in [Figure 13-3](#) indicates the typical order in which PL routines can be invoked in a general case.

Figure 13-3 Typical Order of Invoking PL Routines

A general scheme of using PL routines for double-precision computations in a 3D Cartesian case is shown below. A similar scheme holds for single-precision computations with the only difference in the initial letter of routine names. The general scheme in a 2D Cartesian case differs from the one below in the set of routine parameters and the ending of routine names: "2D" instead of "3D".

```
...
d_init_Helmholtz_3D(&ax, &bx, &ay, &by, &az, &bz, &nx, &ny, &nz, BCtype, ipar, dpar, &stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f! If you want to keep the
data stored in f,
save it before the function call below */
d_commit_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar,
dpar, &stat);
d_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar, dpar,
&stat);
free_Helmholtz_3D (&xhandle, &yhandle, ipar, &stat);
/* here you may clean the memory used by f, dpar, ipar */
...
```

A general scheme of using PL routines for double-precision computations in a spherical periodic case is shown below. Similar scheme holds for single-precision computations with the only difference in the initial letter of routine names. The general scheme in a spherical non-periodic case differs from the one below in the set of routine parameters and the ending of routine names: "np" instead of "p".

```
...
d_init_sph_p(&ap, &bp, &at, &bt, &np, &nt, &q, ipar, dpar, &stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f! If you want to
keep the data stored in f, save it before the function call below */
d_commit_sph_p(f, &handle_s, &handle_c, ipar, dpar, &stat);
d_sph_p(f, &handle_s, &handle_c, ipar, dpar, &stat);
free_sph_p(&handle_s, &handle_c, ipar, &stat);
/* here you may clean the memory used by f, dpar, ipar */
...
```

You can find examples of Fortran 90 and C code that use PL routines to solve Helmholtz problem (in both Cartesian and spherical cases) in the “[Poisson Library Code Examples](#)” section in Appendix C.

Interface Description

All types in this documentation are standard C types: `int`, `float`, and `double`. Fortran 90 users can call the routines with `INTEGER`, `REAL`, and `DOUBLE PRECISION` Fortran types, respectively (see examples in the “[Poisson Library Code Examples](#)” section in Appendix C).

The interface description uses the built-in type `int` for integer values. If you employ the ILP64 interface, read this type as `long long int` (or `INTEGER*8` for Fortran). For more information, refer to the *Intel MKL User's Guide*.

Routine Options

All PL routines use parameters for passing various options to the routines. These parameters are arrays `ipar`, `dpar` and `spar`. Values for these parameters should be specified very carefully (see [Common Parameters](#)). You can change these values during computations to meet your needs.

WARNING. To avoid failure or wrong results, you must provide correct and consistent parameters to the routines.

User Data Arrays

PL routines take arrays of user data as input. For example, user arrays are passed to the routine `d_Helmholtz_3D` to compute an approximate solution to 3D Helmholtz problem. To minimize storage requirements and improve the overall run-time efficiency, Intel MKL PL routines do not make copies of user input arrays.

NOTE. If you need a copy of your input data arrays, save them yourself.

PL Routines for the Cartesian Solver

The section gives detailed description of Cartesian PL routines, their syntax, parameters and values they return. All flavors of the same routine, namely, double-precision and single-precision, 2D and 3D, are described together.

NOTE. Some of the routine parameters are used only in the 3D Fast Helmholtz Solver.

PL routines call the Intel MKL FFT interface (described in section “[FFT Functions](#)” in chapter “Fast Fourier Transforms”), which enhances performance of the routines.

?_init_Helmholtz_2D/?_init_Helmholtz_3D

Initializes basic data structures of the Fast 2D/3D Helmholtz Solver.

Syntax

```
void d_init_Helmholtz_2D(double* ax, double* bx, double* ay, double* by,
int* nx, int* ny, char* Bctype, double* q, int* ipar, double* dpar, int*
stat);

void s_init_Helmholtz_2D(float* ax, float* bx, float* ay, float* by, int*
nx, int* ny, char* Bctype, float* q, int* ipar, float* spar, int* stat);

void d_init_Helmholtz_3D(double* ax, double* bx, double* ay, double* by,
double* az, double* bz, int* nx, int* ny, int* nz, char* Bctype, double* q,
int* ipar, double* dpar, int* stat);

void s_init_Helmholtz_3D(float* ax, float* bx, float* ay, float* by, float*
az, float* bz, int* nx, int* ny, int* nz, char* Bctype, float* q, int* ipar,
float* spar, int* stat);
```

Input Parameters

<p><i>ax</i></p>	<p>double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the leftmost boundary of the domain along x-axis.</p>
------------------	---

<i>bx</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the rightmost boundary of the domain along x-axis.
<i>ay</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the leftmost boundary of the domain along y-axis.
<i>by</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the rightmost boundary of the domain along y-axis.
<i>az</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the leftmost boundary of the domain along z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
<i>bz</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the rightmost boundary of the domain along z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
<i>nx</i>	int*. The number of mesh intervals along x-axis.
<i>ny</i>	int*. The number of mesh intervals along y-axis.
<i>nz</i>	int*. The number of mesh intervals along z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
<i>BCTYPE</i>	char*. Contains the type of boundary conditions on each boundary. Must contain four characters for ?_init_Helmholtz_2D and six characters for ?_init_Helmholtz_3D. Each of the characters can be 'N' (Neumann boundary condition) or 'D' (Dirichlet boundary

condition). Types of boundary conditions for the boundaries should be specified in the following order: bd_a_x , bd_b_x , bd_a_y , bd_b_y , bd_a_z , bd_b_z . Boundary condition types for the last two boundaries should be specified only in the 3D case.

q double* for
`d_init_Helmholtz_2D/d_init_Helmholtz_3D,`
float* for `s_init_Helmholtz_2D/s_init_Helmholtz_3D`
.
The constant Helmholtz coefficient. Note that to solve Poisson or Laplace problem, you should set the value of q to 0.

Output Parameters

$ipar$ int array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to [Common Parameters](#)).

$dpar$ double array of size $5 \times nx/2 + 7$ in the 2D case or $5 \times (nx + ny)/2 + 9$ in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to [Common Parameters](#)).

$spar$ float array of size $5 \times nx/2 + 7$ in the 2D case or $5 \times (nx + ny)/2 + 9$ in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to [Common Parameters](#)).

$stat$ int*. Routine completion status, which is also written to $ipar[0]$. The status should be 0 to proceed to other PL routines.

Description

The routines `?_init_Helmholtz_2D/?_init_Helmholtz_3D` are declared in the `mkl_poisson.h` header file for the C interface and `mkl_poisson.f90` header file for the Fortran interface. The routines initialize basic data structures for Poisson Library computations of the appropriate precision. All routines invoked after a call to a `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine use values of the $ipar$, $dpar$ and $spar$ array parameters returned by the routine. Detailed description of the array parameters can be found in [Common Parameters](#).

WARNING. Data structures initialized and created by 2D/3D flavors of the routine cannot be used by 3D/2D flavors of any PL routines, respectively.

You can skip calling this routine in your code. However, see [Caveat on Parameter Modifications](#) before doing so.

Return Values

`stat= 0`

The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this `stat` value.

`stat= -99999`

The routine failed to complete the task because of a fatal error.

?_commit_Helmholtz_2D/?_commit_Helmholtz_3D

Checks consistency and correctness of user's data as well as initializes certain data structures required to solve 2D/3D Helmholtz problem.

Syntax

```
void d_commit_Helmholtz_2D(double* f, double* bd_ax, double* bd_bx, double*
bd_ay, double* bd_by, DFTI_DESCRIPTOR* xhandle, int* ipar, double* dpar, int*
stat);
```

```
void s_commit_Helmholtz_2D (float* f, float* bd_ax, float* bd_bx, float*
bd_ay, float* bd_by, DFTI_DESCRIPTOR* xhandle, int* ipar, float* spar, int*
stat);
```

```
void d_commit_Helmholtz_3D(double* f, double* bd_ax, double* bd_bx, double*
bd_ay, double* bd_by, double* bd_az, double* bd_bz, DFTI_DESCRIPTOR* xhandle,
DFTI_DESCRIPTOR* yhandle, int* ipar, double* dpar, int* stat);
```

```
void s_commit_Helmholtz_3D(float* f, float* bd_ax, float* bd_bx, float*
bd_ay, float* bd_by, float* bd_az, float* bd_bz, DFTI_DESCRIPTOR* xhandle,
DFTI_DESCRIPTOR* yhandle, int* ipar, float* spar, int* stat);
```

Input Parameters

<i>f</i>	<pre>double* for d_commit_Helmholtz_2D/d_com- mit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_com- mit_Helmholtz_3D.</pre> <p>Contains the right-hand side of the problem packed in a single vector.</p> <p>The size of the vector for the 2D problem is $(nx+1)*(ny+1)$. In this case, the value of the right-hand side in the mesh point (i, j) is stored in $f[i+j*(nx+1)]$.</p> <p>The size of the vector for the 3D problem is $(nx+1)*(ny+1)*(nz+1)$. In this case, value of the right-hand side in the mesh point (i, j, k) is stored in $f[i+j*(nx+1)+k*(nx+1)*(ny+1)]$.</p> <p>Note that to solve the Laplace problem, you should set all the elements of the array f to 0.</p> <p>Note also that the array f may be altered by the routine. To preserve the vector, save it in another memory location.</p>
<i>ipar</i>	<pre>int</pre> <p>array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).</p>
<i>dpar</i>	<pre>double</pre> <p>array of size $5*n_x/2+7$ in the 2D case or $5*(n_x+n_y)/2+9$ in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).</p>
<i>spar</i>	<pre>float</pre> <p>array of size $5*n_x/2+7$ in the 2D case or $5*(n_x+n_y)/2+9$ in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).</p>
<i>bd_ax</i>	<pre>double* for d_commit_Helmholtz_2D/d_com- mit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_com- mit_Helmholtz_3D.</pre> <p>Contains values of the boundary condition on the leftmost boundary of the domain along x-axis.</p>

For `?_commit_Helmholtz_2D`, the size of the array is $ny+1$. In case of the Dirichlet boundary condition (value of `BCtype[0]` is 'D'), it contains values of the function $G(ax, y_j)$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCtype[0]` is 'N'), it contains values of the function $g(ax, y_j)$, $j=0, \dots, ny$. The value corresponding to the index j is placed in `bd_ax[j]`.

For `?_commit_Helmholtz_3D`, the size of the array is $(ny+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of `BCtype[0]` is 'D'), it contains values of the function $G(ax, y_j, z_k)$, $j=0, \dots, ny, k=0, \dots, nz$. In case of the Neumann boundary condition (value of `BCtype[0]` is 'N'), it contains the values of the function $g(ax, y_j, z_k)$, $j=0, \dots, ny, k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (j, k) is placed in `bd_ax[j+k*(ny+1)]`.

`bd_bx`

`double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D,`
`float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.`

Contains values of the boundary condition on the rightmost boundary of the domain along x -axis.

For `?_commit_Helmholtz_2D`, the size of the array is $ny+1$. In case of the Dirichlet boundary condition (value of `BCtype[1]` is 'D'), it contains values of the function $G(bx, y_j)$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCtype[1]` is 'N'), it contains values of the function $g(bx, y_j)$, $j=0, \dots, ny$. The value corresponding to the index j is placed in `bd_bx[j]`.

For `?_commit_Helmholtz_3D`, the size of the array is $(ny+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of `BCtype[1]` is 'D'), it contains values of the function $G(bx, y_j, z_k)$, $j=0, \dots, ny, k=0, \dots, nz$. In case of the Neumann boundary condition (value of `BCtype[1]` is 'N'), it contains the values of the function $g(bx, y_j, z_k)$, $j=0, \dots, ny, k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (j, k) is placed in `bd_bx[j+k*(ny+1)]`.

bd_ay

```
double* for d_commit_Helmholtz_2D/d_com-
mit_Helmholtz_3D,
float* for s_commit_Helmholtz_2D/s_com-
mit_Helmholtz_3D.
```

Contains values of the boundary condition on the leftmost boundary of the domain along y -axis.

For `?_commit_Helmholtz_2D`, the size of the array is $nx+1$. In case of the Dirichlet boundary condition (value of `BCtype[2]` is 'D'), it contains values of the function $G(x_i, ay)$, $i=0, \dots, nx$. In case of the Neumann boundary condition (value of `BCtype[2]` is 'N'), it contains values of the function $g(x_i, ay)$, $i=0, \dots, nx$. The value corresponding to the index i is placed in `bd_ay[i]`.

For `?_commit_Helmholtz_3D`, the size of the array is $(nx+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of `BCtype[2]` is 'D'), it contains values of the function $G(x_i, ay, z_k)$, $i=0, \dots, nx, k=0, \dots, nz$. In case of the Neumann boundary condition (value of `BCtype[2]` is 'N'), it contains the values of the function $g(x_i, ay, z_k)$, $i=0, \dots, nx, k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (i, k) is placed in `bd_ay[i+k*(nx+1)]`.

bd_by

```
double* for d_commit_Helmholtz_2D/d_com-
mit_Helmholtz_3D,
float* for s_commit_Helmholtz_2D/s_com-
mit_Helmholtz_3D.
```

Contains values of the boundary condition on the rightmost boundary of the domain along y -axis.

For `?_commit_Helmholtz_2D`, the size of the array is $nx+1$. In case of the Dirichlet boundary condition (value of `BCtype[3]` is 'D'), it contains values of the function $G(x_i, by)$, $i=0, \dots, nx$. In case of the Neumann boundary condition (value of `BCtype[3]` is 'N'), it contains values of the function $g(x_i, by)$, $i=0, \dots, nx$. The value corresponding to the index i is placed in `bd_by[i]`.

For `?_commit_Helmholtz_3D`, the size of the array is $(nx+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of `BCtype[3]` is 'D'), it contains values of the function

$G(x_i, by, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of `BCType[3]` is 'N'), it contains the values of the function $g(x_i, by, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (i, k) is placed in `bd_by[i+k*(nx+1)]`.

`bd_az`

`double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D,`
`float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.`

This parameter is needed only for `?_commit_Helmholtz_3D`. Contains values of the boundary condition on the leftmost boundary of the domain along z -axis.

The size of the array is $(nx+1)*(ny+1)$. In case of the Dirichlet boundary condition (value of `BCType[4]` is 'D'), it contains values of the function $G(x_i, y_j, az)$, $i=0, \dots, nx$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCType[4]` is 'N'), it contains the values of the function $g(x_i, y_j, az)$, $i=0, \dots, nx$, $j=0, \dots, ny$. The values are packed in the array so that the value corresponding to indices (i, j) is placed in `bd_az[i+j*(nx+1)]`.

`bd_bz`

`double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D,`
`float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.`

This parameter is needed only for `?_commit_Helmholtz_3D`. Contains values of the boundary condition on the rightmost boundary of the domain along z -axis.

The size of the array is $(nx+1)*(ny+1)$. In case of the Dirichlet boundary condition (value of `BCType[5]` is 'D'), it contains values of the function $G(x_i, y_j, bz)$, $i=0, \dots, nx$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCType[5]` is 'N'), it contains the values of the function $g(x_i, y_j, bz)$, $i=0, \dots, nx$, $j=0, \dots, ny$. The values are packed in the array so that the value corresponding to indices (i, j) is placed in `bd_bz[i+j*(nx+1)]`.

Output Parameters

<i>f</i>	Vector of the right-hand side of the problem. Possibly, altered on output.
<i>ipar</i>	Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .
<i>dpar</i>	Contains double-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .
<i>spar</i>	Contains single-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .
<i>xhandle, yhandle</i>	DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”). <i>yhandle</i> is used only by <code>?_commit_Helmholtz_3D</code> .
<i>stat</i>	int*. Routine completion status, which is also written to <i>ipar</i> [0]. The status should be 0 to proceed to other PL routines.

Description

The routines `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` are declared in the `mkl_poisson.h` header file for the C interface and `mkl_poisson.f90` header file for the Fortran interface. The routines check consistency and correctness of the parameters to be passed to the solver routines `?_Helmholtz_2D/?_Helmholtz_3D`. They also initialize data structures *xhandle, yhandle* as well as arrays *ipar* and *dpar/spar*, depending upon the routine precision. Refer to [Common Parameters](#) to find out which particular array elements the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routines initialize and what values are written there.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of PL routines, see the [Caveat on Parameter Modifications section](#). Unlike `?_init_Helmholtz_2D/?_init_Helmholtz_3D`, the routines `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` are mandatory, and you cannot skip calling them in your code. Values of *ax, bx, ay, by, az, bz, nx, ny, nz*, and *Bctype* are passed to each of the routines with the *ipar* array and defined in a previous call to the appropriate `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine.

Return Values

The routine completed without errors and produced some warnings.

The routine successfully completed the task.

The routine stopped because an error in the user's data was found or the data in the *dpar*, *spar* or *ipar* array was altered by mistake.

The routine stopped because of an Intel MKL FFT or TT interface error.

The routine stopped because the initialization failed to complete or the parameter *ipar*[0] was altered by mistake.

The routine failed to complete the task because of a fatal error.

? Helmholtz 2D/? Helmholtz 3D

Computes the solution of 2D/3D Helmholtz problem specified by the parameters.

Syntax

```
void d_Helmholtz_2D(double* f, double* bd_ax, double* bd_bx, double* bd_ay,
double* bd_by, DFTI_DESCRIPTOR* xhandle, int* ipar, double* dpar, int* stat);
```

```
void s_Helmholtz_2D (float* f, float* bd_ax, float* bd_bx, float* bd_ay,
float* bd_by, DFTI_DESCRIPTOR* xhandle, int* ipar, float* spar, int* stat);
```

```
void d_Helmholtz_3D(double* f, double* bd_ax, double* bd_bx, double* bd_ay,
double* bd_by, double* bd_az, double* bd_bz, DFTI_DESCRIPTOR* xhandle,
DFTI_DESCRIPTOR* yhandle, int* ipar, double* dpar, int* stat);
```

```
void s_Helmholtz_3D(float* f, float* bd_ax, float* bd_bx, float* bd_ay,
float* bd_by, float* bd_az, float* bd_bz, DFTI_DESCRIPTOR* xhandle,
DFTI_DESCRIPTOR* yhandle, int* ipar, float* spar, int* stat);
```

Input Parameters

```
f      double* for d_Helmholtz_2D/d_Helmholtz_3D,  
      float* for s_Helmholtz_2D/s_Helmholtz_3D.
```

Contains the right-hand side of the problem packed in a single vector and modified by the appropriate `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine. Note that an attempt to substitute the original right-hand side vector at this point will result in a wrong solution. The size of the vector for the 2D problem is $(nx+1)*(ny+1)$. In this case, value of the right-hand side in the mesh point (i, j) is stored in `f[i+j*(nx+1)]`. The size of the vector for the 3D problem is $(nx+1)*(ny+1)*(nz+1)$. In this case, value of the right-hand side in the mesh point (i, j, k) is stored in `f[i+j*(nx+1)+k*(nx+1)*(ny+1)]`.

<code>xhandle, yhandle</code>	DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”). <code>yhandle</code> is used only by <code>?_Helmholtz_3D</code> .
<code>ipar</code>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
<code>dpar</code>	double array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
<code>spar</code>	float array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
<code>bd_ax</code>	double* for <code>d_Helmholtz_2D/d_Helmholtz_3D</code> , float* for <code>s_Helmholtz_2D/s_Helmholtz_3D</code> . Contains values of the boundary condition on the leftmost boundary of the domain along x -axis. For <code>?_Helmholtz_2D</code> , the size of the array is $ny+1$. In case of the Dirichlet boundary condition (value of <code>BCtype[0]</code> is 'D'), it contains values of the function $G(ax, y_j)$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of <code>BCtype[0]</code> is 'N'), it contains values of the function $g(ax, y_j)$, $j=0, \dots, ny$. The value corresponding to the index j is placed in <code>bd_ax[j]</code> .

For `?_Helmholtz_3D`, the size of the array is $(ny+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of `BCtype[0]` is 'D'), it contains values of the function $G(ax, y_j, z_k)$, $j=0, \dots, ny$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of `BCtype[0]` is 'N'), it contains the values of the function $g(ax, y_j, z_k)$, $j=0, \dots, ny$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (j, k) is placed in `bd_ax[j+k*(ny+1)]`.

`bd_bx`

`double* for d_Helmholtz_2D/d_Helmholtz_3D,`
`float* for s_Helmholtz_2D/s_Helmholtz_3D.`
 Contains values of the boundary condition on the rightmost boundary of the domain along x -axis.
 For `?_Helmholtz_2D`, the size of the array is $ny+1$. In case of the Dirichlet boundary condition (value of `BCtype[1]` is 'D'), it contains values of the function $G(bx, y_j)$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCtype[1]` is 'N'), it contains values of the function $g(bx, y_j)$, $j=0, \dots, ny$. The value corresponding to the index j is placed in `bd_bx[j]`.

For `?_Helmholtz_3D`, the size of the array is $(ny+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of `BCtype[1]` is 'D'), it contains values of the function $G(bx, y_j, z_k)$, $j=0, \dots, ny$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of `BCtype[1]` is 'N'), it contains the values of the function $g(bx, y_j, z_k)$, $j=0, \dots, ny$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (j, k) is placed in `bd_bx[j+k*(ny+1)]`.

`bd_ay`

`double* for d_Helmholtz_2D/d_Helmholtz_3D,`
`float* for s_Helmholtz_2D/s_Helmholtz_3D.`
 Contains values of the boundary condition on the leftmost boundary of the domain along y -axis.
 For `?_Helmholtz_2D`, the size of the array is $nx+1$. In case of the Dirichlet boundary condition (value of `BCtype[2]` is 'D'), it contains values of the function $G(x_i, ay)$, $i=0, \dots, nx$. In case of the Neumann boundary condition (value of

$BCtype[2]$ is 'N'), it contains values of the function $g(x_i, ay)$, $i=0, \dots, nx$. The value corresponding to the index i is placed in $bd_ay[i]$.

For $?_Helmholtz_3D$, the size of the array is $(nx+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of $BCtype[2]$ is 'D'), it contains values of the function $G(x_i, ay, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of $BCtype[2]$ is 'N'), it contains the values of the function $g(x_i, ay, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (i, k) is placed in $bd_ay[i+k*(nx+1)]$.

bd_by

double* for $d_Helmholtz_2D/d_Helmholtz_3D$,
float* for $s_Helmholtz_2D/s_Helmholtz_3D$.

Contains values of the boundary condition on the rightmost boundary of the domain along y -axis.

For $?_Helmholtz_2D$, the size of the array is $nx+1$. In case of the Dirichlet boundary condition (value of $BCtype[3]$ is 'D'), it contains values of the function $G(x_i, by)$, $i=0, \dots, nx$. In case of the Neumann boundary condition (value of $BCtype[3]$ is 'N'), it contains values of the function $g(x_i, by)$, $i=0, \dots, nx$. The value corresponding to the index i is placed in $bd_by[i]$.

For $?_Helmholtz_3D$, the size of the array is $(nx+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of $BCtype[3]$ is 'D'), it contains values of the function $G(x_i, by, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of $BCtype[3]$ is 'N'), it contains the values of the function $g(x_i, by, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (i, k) is placed in $bd_by[i+k*(nx+1)]$.

bd_az

double* for $d_Helmholtz_2D/d_Helmholtz_3D$,
float* for $s_Helmholtz_2D/s_Helmholtz_3D$.

This parameter is needed only for $?_Helmholtz_3D$.

Contains values of the boundary condition on the leftmost boundary of the domain along z -axis.

The size of the array is $(nx+1)*(ny+1)$. In case of the Dirichlet boundary condition (value of `BCTYPE[4]` is 'D'), it contains values of the function $G(x_i, y_j, az)$, $i=0, \dots, nx$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCTYPE[4]` is 'N'), it contains the values of the function $g(x_i, y_j, az)$, $i=0, \dots, nx$, $j=0, \dots, ny$. The values are packed in the array so that the value corresponding to indices (i, j) is placed in `bd_az[i+j*(nx+1)]`.

`bd_bz` `double*` for `d_Helmholtz_2D/d_Helmholtz_3D`, `float*` for `s_Helmholtz_2D/s_Helmholtz_3D`. This parameter is needed only for `?_Helmholtz_3D`. Contains values of the boundary condition on the rightmost boundary of the domain along z -axis. The size of the array is $(nx+1)*(ny+1)$. In case of the Dirichlet boundary condition (value of `BCTYPE[5]` is 'D'), it contains values of the function $G(x_i, y_j, bz)$, $i=0, \dots, nx$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCTYPE[5]` is 'N'), it contains the values of the function $g(x_i, y_j, bz)$, $i=0, \dots, nx$, $j=0, \dots, ny$. The values are packed in the array so that the value corresponding to indices (i, j) is placed in `bd_bz[i+j*(nx+1)]`.

NOTE. To avoid wrong computation results, do not change arrays `bd_ax`, `bd_bx`, `bd_ay`, `bd_by`, `bd_az`, `bd_bz` between a call to the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine and a subsequent call to the appropriate `?_Helmholtz_2D/?_Helmholtz_3D` routine.

Output Parameters

<code>f</code>	On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input.
<code>xhandle, yhandle</code>	Data structures used by the Intel MKL FFT interface.
<code>ipar</code>	Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .

<i>dpar</i>	Contains double-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters
<i>spar</i>	Contains single-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .
<i>stat</i>	<i>int*</i> . Routine completion status, which is also written to <i>ipar[0]</i> . The status should be 0 to proceed to other PL routines.

Description

The routines are declared in the `mkl_poisson.h` header file for the C interface and `mkl_poisson.f90` header file for the Fortran interface. The routines compute the approximate solution of Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to formulas given in the [Poisson Library Implemented](#) section. The *f* parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of *ax*, *bx*, *ay*, *by*, *az*, *bz*, *nx*, *ny*, *nz*, and *BCtype* are passed to each of the routines with the *ipar* array and defined in the previous call to the appropriate `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine.

Return Values

<i>stat</i> = 1	The routine completed without errors and produced some warnings.
<i>stat</i> = 0	The routine successfully completed the task.
<i>stat</i> = -2	The routine stopped because division by zero occurred. It usually happens if the data in the <i>dpar</i> or <i>spar</i> array was altered by mistake.
<i>stat</i> = -3	The routine stopped because the memory was insufficient to complete the computations.
<i>stat</i> = -100	The routine stopped because an error in the user's data was found or the data in the <i>dpar</i> , <i>spar</i> or <i>ipar</i> array was altered by mistake.
<i>stat</i> = -1000	The routine stopped because of the Intel MKL FFT or TT interface error.

`stat= -10000`

The routine stopped because the initialization failed to complete or the parameter `ipar[0]` was altered by mistake.

`stat= -99999`

The routine failed to complete the task because of a fatal error.

free_Helmholtz_2D/free_Helmholtz_3D

Cleans the memory allocated for the data structures used by the FFT interface.

Syntax

```
void free_Helmholtz_2D(DFTI_DESCRIPTOR* xhandle, int* ipar, int* stat);
void free_Helmholtz_3D (DFTI_DESCRIPTOR* xhandle, DFTI_DESCRIPTOR* yhandle,
int* ipar, int* stat);
```

Input Parameters

<code>xhandle, yhandle</code>	DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”). The structure <code>yhandle</code> is used only by <code>free_Helmholtz_3D</code> .
<code>ipar</code>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).

Output Parameters

<code>xhandle, yhandle</code>	Data structures used by the Intel MKL FFT interface. Memory allocated for the structures is released on output.
<code>ipar</code>	Contains integer data to be used by Fast Helmholtz Solver. Status of the routine call is written to <code>ipar[0]</code> .
<code>stat</code>	int*. Routine completion status, which is also written to <code>ipar[0]</code> .

Description

The routine is declared in the `mkl_poisson.h` header file for the C interface and `mkl_poisson.f90` header file for the Fortran interface. The routine cleans the memory used by the `xhandle` and `yhandle` structures, needed for calling the Intel MKL FFT functions. To release memory allocated for other parameters, include cleaning of the memory in your code.

Return Values

<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -1000</code>	The routine stopped because of an Intel MKL FFT or TT interface error.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

PL Routines for the Spherical Solver

The section gives detailed description of spherical PL routines, their syntax, parameters and values they return. All flavors of the same routine, namely, double-precision and single-precision, periodic (having names ending in "p") and non-periodic (having names ending in "np"), are described together.

These PL routines also call the Intel MKL FFT interface (described in section "[FFT Functions](#)" in chapter "Fast Fourier Transforms"), which enhances performance of the routines.

?_init_sph_p/?_init_sph_np

Initializes basic data structures of the Fast periodic and non-periodic Helmholtz Solver on a sphere.

Syntax

```
void d_init_sph_p(double* ap, double* at, double* bp, double* bt, int* np,
int* nt, double* q, int* ipar, double* dpar, int* stat);

void s_init_sph_p(float* ap, float* at, float* bp, float* bt, int* np, int*
nt, float* q, int* ipar, float* spar, int* stat);

void d_init_sph_np(double* ap, double* at, double* bp, double* bt, int* np,
int* nt, double* q, int* ipar, double* dpar, int* stat);

void s_init_sph_np(float* ap, float* at, float* bp, float* bt, int* np, int*
nt, float* q, int* ipar, float* spar, int* stat);
```

Input Parameters

<i>ap</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The coordinate (angle) of the leftmost boundary of the domain along ϕ -axis.
<i>bp</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The coordinate (angle) of the rightmost boundary of the domain along ϕ -axis.
<i>at</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The coordinate (angle) of the leftmost boundary of the domain along θ -axis.
<i>bt</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The coordinate (angle) of the rightmost boundary of the domain along θ -axis.
<i>np</i>	int*. The number of mesh intervals along ϕ -axis. Must be even in the periodic case.
<i>nt</i>	int*. The number of mesh intervals along θ -axis.
<i>q</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The constant Helmholtz coefficient. Note that to solve Poisson problem, you should set the value of <i>q</i> to 0.

Output Parameters

<i>ipar</i>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>dpar</i>	double array of size $5*np/2+nt+10$. Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).

<i>spar</i>	float array of size $5 \cdot n_p/2 + n_t + 10$. Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>stat</i>	int*. Routine completion status, which is also written to <i>ipar[0]</i> . The status should be 0 to proceed to other PL routines.

Description

The routines `?_init_sph_p/?_init_sph_np` are declared in the `mkl_poisson.h` header file for the C interface and `mkl_poisson.f90` header file for the Fortran interface. The routines initialize basic data structures for Poisson Library computations of the appropriate precision. All routines invoked after a call to a `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine use values of the *ipar*, *dpar* and *spar* array parameters returned by the routine. Detailed description of the array parameters can be found in [Common Parameters](#).

WARNING. Data structures initialized and created by periodic/non-periodic flavors of the routine cannot be used by non-periodic/periodic flavors of any PL routines for Helmholtz Solver on a sphere, respectively.

You can skip calling this routine in your code. However, see [Caveat on Parameter Modifications](#) before doing so.

Return Values

<i>stat</i> = 0	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this <i>stat</i> value.
<i>stat</i> = -99999	The routine failed to complete the task because of fatal error.

?_commit_sph_p/?_commit_sph_np

Checks consistency and correctness of user's data as well as initializes certain data structures required to solve periodic/non-periodic Helmholtz problem on a sphere.

Syntax

```
void d_commit_sph_p(double* f, DFTI_DESCRIPTOR* handle_s, DFTI_DESCRIPTOR*
handle_c, int* ipar, double* dpar, int* stat);

void s_commit_sph_p(float* f, DFTI_DESCRIPTOR* handle_s, DFTI_DESCRIPTOR*
handle_c, int* ipar, float* spar, int* stat);

void d_commit_sph_np(double* f, DFTI_DESCRIPTOR* handle, int* ipar, double*
dpar, int* stat);

void s_commit_sph_np(float* f, DFTI_DESCRIPTOR* handle, int* ipar, float*
spar, int* stat);
```

Input Parameters

<i>f</i>	double* for d_commit_sph_p/d_commit_sph_np, float* for s_commit_sph_p/s_commit_sph_np. Contains the right-hand side of the problem packed in a single vector. The size of the vector is $(np+1)*(nt+1)$ and value of the right-hand side in the mesh point (i, j) is stored in $f[i+j*(np+1)]$. Note that the array <i>f</i> may be altered by the routine. Please save this vector in another memory location if you want to preserve it.
<i>ipar</i>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>dpar</i>	double array of size $5*np/2+nt+10$. Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>spar</i>	float array of size $5*np/2+nt+10$. Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).

Output Parameters

<i>f</i>	Vector of the right-hand side of the problem. Possibly, altered on output.
<i>ipar</i>	Contains integer data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<i>dpar</i>	Contains double-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<i>spar</i>	Contains single-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<i>handle_s</i> , <i>handle_c</i> , <i>handle</i>	DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”). <i>handle_s</i> and <i>handle_c</i> are used only in <code>?_commit_sph_p</code> and <i>handle</i> is used only in <code>?_commit_sph_np</code> .
<i>stat</i>	int*. Routine completion status, which is also written to <i>ipar</i> [0]. The status should be 0 to proceed to other PL routines.

Description

The routines `?_commit_sph_p/?_commit_sph_np` are declared in the `mkl_poisson.h` header file for the C interface and `mkl_poisson.f90` header file for the Fortran interface. The routines check consistency and correctness of the parameters to be passed to the solver routines `?_sph_p/?_sph_np`, respectively. They also initialize certain data structures. The routine `?_commit_sph_p` initializes structures *handle_s* and *handle_c*, and `?_commit_sph_np` initializes *handle*. The routines also initialize arrays *ipar* and *dpar/spar*, depending upon the routine precision. Refer to [Common Parameters](#) to find out which particular array elements the `?_commit_sph_p/?_commit_sph_np` routines initialize and what values are written there.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of PL routines, see the [Caveat on Parameter Modifications](#) section. Unlike `?_init_sph_p/?_init_sph_np`, the routines `?_commit_sph_p/?_commit_sph_np` are mandatory, and you cannot skip calling them in your code. Values of *np* and *nt* are passed to each of the routines with the *ipar* array and defined in a previous call to the appropriate `?_init_sph_p/?_init_sph_np` routine.

Return Values

`stat= 1`

The routine completed without errors and produced some warnings.

`stat= 0`

The routine successfully completed the task.

`stat= -100`

The routine stopped because an error in the user's data was found or the data in the *dpar*, *spar* or *ipar* array was altered by mistake.

`stat= -1000`

The routine stopped because of an Intel MKL FFT or TT interface error.

`stat= -10000`

The routine stopped because the initialization failed to complete or the parameter *ipar*[0] was altered by mistake.

`stat= -99999`

The routine failed to complete the task because of a fatal error.

?_sph_p/?_sph_np

Computes the solution of a spherical Helmholtz problem specified by the parameters.

Syntax

```
void d_sph_p(double* f, DFTI_DESCRIPTOR* handle_s, DFTI_DESCRIPTOR* handle_c,
int* ipar, double* dpar, int* stat);
```

```
void s_sph_p(float* f, DFTI_DESCRIPTOR* handle_s, DFTI_DESCRIPTOR* handle_c,
int* ipar, float* spar, int* stat);
```

```
void d_sph_np(double* f, DFTI_DESCRIPTOR* handle, int* ipar, double* dpar,
int* stat);
```

```
void s_sph_np(float* f, DFTI_DESCRIPTOR* handle, int* ipar, float* spar, int*
stat);
```

Input Parameters

f double* for d_sph_p/d_sph_np,
float* for s_sph_p/s_sph_np.

Contains the right-hand side of the problem packed in a single vector and modified by the appropriate `?_commit_sph_p/?_commit_sph_np` routine. Note that an attempt to substitute the original right-hand side vector at this point will result in a wrong solution. The size of the vector is $(np+1)*(nt+1)$ and value of the right-hand side in the mesh point (i, j) is stored in $f[i+j*(np+1)]$.

<code>handle_s, handle_c, handle</code>	DESCRIPTOR_HANDLE*. Data structures used by Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”). <code>handle_s</code> and <code>handle_c</code> are used only in <code>?_sph_p</code> and <code>handle</code> is used only in <code>?_sph_np</code> .
<code>ipar</code>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<code>dpar</code>	double array of size $5*np/2+nt+10$. Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<code>spar</code>	float array of size $5*np/2+nt+10$. Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).

Output Parameters

<code>f</code>	On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input.
<code>handle_s, handle_c, handle</code>	Data structures used by the Intel MKL FFT interface.
<code>ipar</code>	Contains integer data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<code>dpar</code>	Contains double-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .

<i>spar</i>	Contains single-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<i>stat</i>	int*. Routine completion status, which is also written to <i>ipar[0]</i> . The status should be 0 to proceed to other PL routines.

Description

The routines are declared in the `mkl_poisson.h` header file for the C interface and `mkl_poisson.f90` header file for the Fortran interface. The routines compute the approximate solution on a sphere of the Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to formulas given in the [Poisson Library Implemented](#) section. The *f* parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of *np* and *nt* are passed to each of the routines with the *ipar* array and defined in the previous call to the appropriate `?_init_sph_p/?_init_sph_np` routine.

Return Values

<i>stat</i> = 1	The routine completed without errors and produced some warnings.
<i>stat</i> = 0	The routine successfully completed the task.
<i>stat</i> = -2	The routine stopped because division by zero occurred. It usually happens if the data in the <i>dpar</i> or <i>spar</i> array was altered by mistake.
<i>stat</i> = -3	The routine stopped because the memory was insufficient to complete the computations.
<i>stat</i> = -100	The routine stopped because an error in the user's data was found or the data in the <i>dpar</i> , <i>spar</i> or <i>ipar</i> array was altered by mistake.
<i>stat</i> = -1000	The routine stopped because of an Intel MKL FFT or TT interface error.
<i>stat</i> = -10000	The routine stopped because the initialization failed to complete or the parameter <i>ipar[0]</i> was altered by mistake.
<i>stat</i> = -99999	The routine failed to complete the task because of a fatal error.

free_sph_p/free_sph_np

Cleans the memory allocated for the data structures used by the FFT interface.

Syntax

```
void free_sph_p(DFTI_DESCRIPTOR* handle_s, DFTI_DESCRIPTOR* handle_c, int*
ipar, int* stat);

void free_sph_np(DFTI_DESCRIPTOR* handle, int* ipar, int* stat);
```

Input Parameters

<i>handle_s, handle_c,</i> <i>handle</i>	DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”). The structures <i>handle_s</i> and <i>handle_c</i> are used only in <i>free_sph_p</i> , and <i>handle</i> is used only in <i>free_sph_np</i> .
<i>ipar</i>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).

Output Parameters

<i>handle_s, handle_c,</i> <i>handle</i>	Data structures used by the Intel MKL FFT interface. Memory allocated for the structures is released on output.
<i>ipar</i>	Contains integer data to be used by Fast Helmholtz Solver on a sphere. Status of the routine call is written to <i>ipar[0]</i> .
<i>stat</i>	int*. Routine completion status, which is also written to <i>ipar[0]</i> .

Description

The routine is declared in the `mkl_poisson.h` header file for the C interface and `mkl_poisson.f90` header file for the Fortran interface. The routine cleans the memory used by the *handle_s*, *handle_c* or *handle* structures, needed for calling the Intel MKL FFT functions. To release memory allocated for other parameters, include cleaning of the memory in your code.

Return Values

<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -1000</code>	The routine stopped because of the Intel MKL FFT or TT interface error.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

Common Parameters

This section provides description of array parameters *ipar*, *dpar* and *spar*, which hold PL routine options in both Cartesian and spherical cases.

NOTE. Initial values are assigned to the array parameters by the appropriate `?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np` and `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np` routines.

<i>ipar</i>	int array of size 128, holds integer data needed for Fast Helmholtz Solver (both for Cartesian and spherical coordinate systems). Its elements are described in Table 13-6 :
-------------	--

Table 13-6 Elements of the ipar Array

Index	Description
0	Contains status value of the last called PL routine. In general, it should be 0 to proceed with Fast Helmholtz Solver. The element has no predefined values. This element can also be used to inform the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np</code> routines of how the Commit step of the computation should be carried out (see Figure 13-3). A non-zero value of <i>ipar</i> [0] with decimal representation

$$\overline{abc} = 100a + 10b + c$$

where each of *a*, *b*, and *c* is equal to 0 or 9, indicates that some parts of the Commit step should be omitted.

Index	Description
	<ul style="list-style-type: none">• If $c=9$, the routine omits checking of parameters and initialization of the data structures.• If $b=9$, then in the Cartesian case, the routine omits the adjustment of the right-hand side vector f to the Neumann boundary condition (multiplication of boundary values by 0.5 as well as incorporation of the boundary function g) and/or the Dirichlet boundary condition (setting boundary values to 0 as well as incorporation of the boundary function G). In this case, the routine also omits the adjustment of the right-hand side vector f to the particular boundary functions. For the Helmholtz solver on a sphere, the routine omits computation of the spherical weights for the $dpar/spar$ array.• If $a=9$, then the routine omits the normalization of the right-hand side vector f. In the 2D Cartesian case, it is the multiplication by h_y^2, where h_y is the mesh size in the y direction (for details, see Poisson Library Implemented). In the 3D (Cartesian) case, it is the multiplication by h_z^2, where h_z is the mesh size in the z direction. For the Helmholtz solver on a sphere, it is the multiplication by h_θ^2, where h_θ is the mesh size in the θ direction (for details, see Poisson Library Implemented).

Using `ipar[0]` you can adjust the routine to your needs and gain efficiency in solving multiple Helmholtz problems that differ only in the right-hand side. You must be cautious using this opportunity, because misunderstanding of the commit process may cause wrong results or program failure (see also [Caveat on Parameter Modifications](#)).

- 1
- Contains error messaging options:
- `ipar[1]=-1` indicates that all error messages will be printed to the file `MKL_Poisson_Library_log.txt` in the folder from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device.
 - `ipar[1]=0` indicates that no error messages will be printed.
 - `ipar[1]=1` is the default value. It indicates that all error messages will be printed to the preconnected default output device (usually, screen).
- In case of errors, the `stat` parameter will acquire a non-zero value regardless of the `ipar[1]` setting.
- 2
- Contains warning messaging options:

Index	Description
	<ul style="list-style-type: none"> <code>ipar[2]=-1</code> indicates that all warning messages will be printed to the file <code>MKL_Poisson_Library_log.txt</code> in the directory from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. <code>ipar[2]=0</code> indicates that no warning messages will be printed. <code>ipar[2]=1</code> is the default value. It indicates that all warning messages will be printed to the preconnected default output device (usually, screen). <p>In case of warnings, the <code>stat</code> parameter will acquire a non-zero value regardless of the <code>ipar[2]</code> setting.</p>
3	<p>Contains the number of the combination of boundary conditions. In the Cartesian case, it corresponds to the value that the <code>BCtype</code> parameter holds:</p> <ul style="list-style-type: none"> In the 2D case, <ul style="list-style-type: none"> 0 corresponds to 'DDDD' 1 corresponds to 'DDDN' ... 15 corresponds to 'NNNN' In the 3D case, <ul style="list-style-type: none"> 0 corresponds to 'DDDDDD' 1 corresponds to 'DDDDDN' ... 63 corresponds to 'NNNNNNN'. <p>The Helmholtz solver on a sphere uses this parameter only in a periodic case. The <code>bp</code> and <code>bt</code> parameters of the <code>?_init_sph_p/?_init_sph_np</code> routine, which initializes <code>ipar[3]</code>, determine its value:</p> <ul style="list-style-type: none"> 0 corresponds to the problem without poles. 1 corresponds to the problem on the entire sphere. <p>Parameters 4 through 9 are used only in Cartesian case.</p>
4	Takes the value of 1 if <code>BCtype[0]='N'</code> , 0 if <code>BCtype[0]='D'</code> , and -1 otherwise.

Index	Description
5	Takes the value of 1 if $B\text{Ctype}[1]='N'$, 0 if $B\text{Ctype}[1]='D'$, and -1 otherwise.
6	Takes the value of 1 if $B\text{Ctype}[2]='N'$, 0 if $B\text{Ctype}[2]='D'$, and -1 otherwise.
7	Takes the value of 1 if $B\text{Ctype}[3]='N'$, 0 if $B\text{Ctype}[3]='D'$, and -1 otherwise.
8	Takes the value of 1 if $B\text{Ctype}[4]='N'$, 0 if $B\text{Ctype}[4]='D'$, and -1 otherwise. This parameter is used only in the 3D case.
9	Takes the value of 1 if $B\text{Ctype}[5]='N'$, 0 if $B\text{Ctype}[5]='D'$, and -1 otherwise. This parameter is used only in the 3D case.
10	Takes the value of <ul style="list-style-type: none"> nx, that is, the number of intervals along x-axis, in the Cartesian case. np, that is, the number of intervals along ϕ-axis, in the spherical case.
11	Takes the value of <ul style="list-style-type: none"> ny, that is, the number of intervals along y-axis, in the Cartesian case nt, that is, the number of intervals along θ-axis, in the spherical case.
12	Takes the value of nz , the number of intervals along z -axis. This parameter is used only in the 3D case (Cartesian).
13	Takes the value of 6, which specifies the internal partitioning of the $dpar/spar$ array.
14	Takes the value of $ipar[13]+ipar[10]+1$, which specifies the internal partitioning of the $dpar/spar$ array.

Subsequent values of $ipar$ depend upon the dimension of the problem or upon whether the solver on a sphere is periodic.

	2D case	3D case	Periodic case	Non-periodic case
15	Unused		Takes the value of $ipar[14]+1$, which specifies the internal partitioning of the $dpar/spar$ array.	

Index	Description			
16	Unused	Takes the value of $ipar[14] + ipar[11] + 1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.		
17	Takes the value of $ipar[14] + 1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[16] + 1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.		
18	Takes the value of $ipar[14] + 3 * ipar[10] / 2 + 1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[16] + 3 * ipar[10] / 2 + 1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[16] + 3 * ipar[10] / 4 + 1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[16] + 3 * ipar[10] / 2 + 1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.
19	Unused	Takes the value of $ipar[18] + 1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.		Unused
20	Unused	Takes the value of $ipar[18] + 3 * ipar[11] / 2 + 1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[18] + 3 * ipar[10] / 4 + 1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Unused

Subsequent values of *ipar* are assigned regardless.

- 21 Contains message style options:
- $ipar[21] = 0$ indicates that PL routines print all error and warning messages in Fortran-style notations.
 - $ipar[21] = 1$ (default) indicates that PL routines print the messages in C-style notations.

Index	Description
22	Contains the number of threads to be used for computations in a multithreaded environment. The default value is 1.
23 through 39	Unused in the current implementation of the Poisson Library.
40 through 59	Contain the first twenty elements of the <i>ipar</i> array of the first Trigonometric Transform that the Solver uses. (For details, see Common Parameters in the “Trigonometric Transform Routines” chapter.)
60 through 79	Contain the first twenty elements of the <i>ipar</i> array of the second Trigonometric Transform that the 3D and periodic solvers use. (For details, see Common Parameters in the “Trigonometric Transform Routines” chapter.)

NOTE. You may declare the *ipar* array in your code as `int ipar[80]`. However, for compatibility with later versions of Intel MKL Poisson Library, which may require more *ipar* values, it is highly recommended to declare *ipar* as `int ipar[128]`.

Arrays *dpar* and *spar* are the same except in the data precision:

<i>dpar</i>	<p>Holds data needed for double-precision Fast Helmholtz Solver computations.</p> <ul style="list-style-type: none">• For the Cartesian solver, <code>double</code> array of size $5 \cdot nx/2 + 7$ in the 2D case or $5 \cdot (nx + ny)/2 + 9$ in the 3D case; initialized in the <code>d_init_Helmholtz_2D/d_init_Helmholtz_3D</code> and <code>d_commit_Helmholtz_2D/d_commit_Helmholtz_3D</code> routines.• For the spherical solver, <code>double</code> array of size $5 \cdot np/2 + nt + 10$; initialized in the <code>d_init_sph_p/d_init_sph_np</code> and <code>d_commit_sph_p/d_commit_sph_np</code> routines.
<i>spar</i>	<p>Holds data needed for single-precision Fast Helmholtz Solver computations.</p> <ul style="list-style-type: none">• For the Cartesian solver, <code>float</code> array of size $5 \cdot nx/2 + 7$ in the 2D case or $5 \cdot (nx + ny)/2 + 9$ in the 3D case; initialized in the <code>s_init_Helmholtz_2D/s_init_Helmholtz_3D</code> and <code>s_commit_Helmholtz_2D/s_commit_Helmholtz_3D</code> routines.

- For the spherical solver, `float` array of size $5 \cdot n_p/2 + n_t + 10$; initialized in the `s_init_sph_p/s_init_sph_np` and `s_commit_sph_p/s_commit_sph_np` routines.

As *dpar* and *spar* have similar elements in respective positions, the elements are described together in Table 13-7:

Table 13-7 Elements of the dpar and spar Arrays

Index	Description
0	<p>In the Cartesian case, contains the length of the interval along x-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size h_x in the x direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine.</p> <p>In the spherical case, contains the length of the interval along ϕ-axis right after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine or the mesh size h_ϕ in the ϕ direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.</p>
1	<p>In the Cartesian case, contains the length of the interval along y-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size h_y in the y direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine.</p> <p>In the spherical case, contains the length of the interval along θ-axis right after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine or the mesh size h_θ in the θ direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.</p>
2	<p>In the Cartesian case, contains the length of the interval along z-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size h_z in the z direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. In the Cartesian solver, this parameter is used only in the 3D case.</p> <p>In the spherical solver, contains the coordinate of the leftmost boundary along θ-axis after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine.</p>

Index	Description
3	Contains the value of the coefficient q after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np</code> routine.
4	<p>Contains the tolerance parameter after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np</code> routine.</p> <ul style="list-style-type: none"> In the Cartesian case, this value is used only for the pure Neumann boundary conditions (<code>BCTYPE="NNNN"</code> in the 2D case; <code>BCTYPE="NNNNNN"</code> in the 3D case). This is a special case, because the right-hand side of the problem cannot be arbitrary if the coefficient q is zero. Poisson Library verifies that the classical solution exists (up to rounding errors) using this tolerance. In any case, Poisson Library computes the normal solution, that is, the solution that has the minimal Euclidean norm of residual. Nevertheless, the <code>?_Helmholtz_2D/?_Helmholtz_3D</code> routine informs the user that the solution may not exist in a classical sense (up to rounding errors). In the spherical case, the value is used for the special case of a periodic problem on the entire sphere. This special case is similar to the above described Cartesian case with pure Neumann boundary conditions. So, here Poisson Library computes the normal solution as well. The parameter is also used to detect whether the problem is periodic up to rounding errors. <p>The default value for this parameter is 1.0E-10 in case of double-precision computations or 1.0E-4 in case of single-precision computations. You can increase the value of the tolerance, for instance, to avoid the warnings that may appear.</p>
<code>ipar[13]-1</code> through <code>ipar[14]-1</code>	<p>In the Cartesian case, contain the spectrum of the 1D problem along x-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine.</p> <p>In the spherical case, contains the spectrum of the 1D problem along ϕ-axis after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.</p>
<code>ipar[15]-1</code> through <code>ipar[16]-1</code>	In the Cartesian case, contain the spectrum of the 1D problem along y -axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. These elements are used only in the 3D case.

Index	Description
	In the spherical case, contains the spherical weights after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.
<i>ipar</i> [17]-1 through <i>ipar</i> [18]-1	Take the values of the (staggered) sine/cosine in the mesh points: <ul style="list-style-type: none">• along <i>x</i>-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine for a Cartesian solver• along ϕ-axis after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine for a spherical solver.
<i>ipar</i> [19]-1 through <i>ipar</i> [20]-1	Take the values of the (staggered) sine/cosine in the mesh points: <ul style="list-style-type: none">• along <i>y</i>-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine for a Cartesian 3D solver• along ϕ-axis after a call to the <code>?_commit_sph_p</code> routine for a spherical periodic solver. <p>These elements are not used in the 2D Cartesian case and in the non-periodic spherical case.</p>

NOTE. You may define the array size depending upon the type of the problem to solve.

Caveat on Parameter Modifications

Flexibility of the PL interface enables you to skip calling the `?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np` routine and to initialize the basic data structures explicitly in your code. You may also need to modify contents of *ipar*, *dpar* and *spar* arrays after initialization. When doing so, provide correct and consistent data in the arrays. Mistakenly altered arrays cause errors or wrong computation. You can perform a basic check for correctness and consistency of parameters by calling the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine; however, this does not ensure the correct solution but only reduces the chance of errors or wrong results.

NOTE. To supply correct and consistent parameters to PL routines, you should have considerable experience in using the PL interface and good understanding of the solution process as well as elements that the *ipar*, *spar* and *dpar* arrays contain and dependencies between values of these elements.

However, in rare occurrences, even advanced users might fail in tuning parameters for the Fast Helmholtz Solver. In cases like these, refer for technical support at <http://www.intel.com/software/products/support/>.

WARNING. The only way that ensures a proper solution of a Helmholtz problem is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of *ipar*, *dpar* and *spar* arrays unless a strong need arises.

Implementation Details

Several aspects of the Intel MKL PL interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, users are provided with the PL language-specific header files to include in their code. Currently, the following header files are available:

- `mkl_poisson.h`, to be used together with `mkl_dfti.h`, for C programs.
- `mkl_poisson.f90`, to be used together with `mkl_dfti.f90`, for Fortran 90 programs.

NOTE. Use of the Intel MKL PL software without including one of the above header files is not supported.

The include files define function prototypes for appropriate languages.

C-specific Header File

The C-specific header file defines the following function prototypes for the Cartesian solver:

```
void d_init_Helmholtz_2D(double*, double*, double*, double*, int*, int*, char*, double*,
int*, double*, int*);
```

```
void d_commit_Helmholtz_2D(double*, double*, double*, double*, double*,
DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);
```

```
void d_Helmholtz_2D(double*, double*, double*, double*, double*, DFTI_DESCRIPTOR_HANDLE*,
int*, double*, int*);

void s_init_Helmholtz_2D(float*, float*, float*, float*, int*, int*, char*, float*, int*,
float*, int*);

void s_commit_Helmholtz_2D(float*, float*, float*, float*, float*, DFTI_DESCRIPTOR_HANDLE*,
int*, float*, int*);
```

```

void s_Helmholtz_2D(float*, float*, float*, float*, float*, DFTI_DESCRIPTOR_HANDLE*, int*,
float*, int*);

void free_Helmholtz_2D(DFTI_DESCRIPTOR_HANDLE*, int*, int*);

void d_init_Helmholtz_3D(double*, double*, double*, double*, double*, double*, int*, int*,
int*, char*, double*, int*, double*, int*);

void d_commit_Helmholtz_3D(double*, double*, double*, double*, double*, double*, double*,
DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);

void d_Helmholtz_3D(double*, double*, double*, double*, double*, double*, double*,
DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);

void s_init_Helmholtz_3D(float*, float*, float*, float*, float*, float*, int*, int*, int*,
char*, float*, int*, float*, int*);

void s_commit_Helmholtz_3D(float*, float*, float*, float*, float*, float*, float*,
DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);

void s_Helmholtz_3D(float*, float*, float*, float*, float*, float*, float*,
DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);

void free_Helmholtz_3D(DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, int*);

```

The C-specific header file defines the following function prototypes for the spherical solver:

```

void d_init_sph_p(double*, double*, double*, double*, int*, int*, double*, int*, double*,
int*);

void d_commit_sph_p(double*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*,
int*);

void d_sph_p(double*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*,
int*);

void s_init_sph_p(float*, float*, float*, float*, int*, int*, float*, int*, float*, int*);

void s_commit_sph_p(float*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, float*,
int*);

void s_sph_p(float*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);

void free_sph_p(DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, int*);

void d_init_sph_np(double*, double*, double*, double*, int*, int*, double*, int*, double*,
int*);

void d_commit_sph_np(double*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);

void d_sph_np(double*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);

void s_init_sph_np(float*, float*, float*, float*, int*, int*, float*, int*, float*, int*);

void s_commit_sph_np(float*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);

```

```
void s_sph_np(float*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);
void free_sph_np(DFTI_DESCRIPTOR_HANDLE*, int*, int*);
```

Fortran-Specific Header File

The Fortran90-specific header file defines the following function prototypes for the Cartesian solver:

```
SUBROUTINE D_INIT_HELMHOLTZ_2D (AX, BX, AY, BY, NX, NY, BCTYPE, Q, IPAR, DPAR, STAT)

Fortran 90 specifics of the PL routines usage are similar for all Intel MKL PDE support tools and described in the [Calling PDE Support Routines from Fortran 90](#) section.

Calling PDE Support Routines from Fortran 90

The calling interface for all the Intel MKL TT and PL routines is designed to be easily used in C. However, you can invoke each TT or PL routine directly from Fortran 90 if you are familiar with the inter-language calling conventions of your platform.

The TT or PL interface cannot be invoked from Fortran 77 due to restrictions imposed by the use of the Intel MKL FFT interface.

The inter-language calling conventions include, but are not limited to, the argument passing mechanisms for the language, the data type mappings from C to Fortran 90 and how C external names are decorated on the platform.

To promote portability and relieve a user of dealing with the calling conventions specifics, Fortran 90 header file `mkl_trig_transforms.f90` for TT routines and `mkl_poisson.f90` for PL routines, used together with `mkl_dfti.f90`, declare a set of macros and introduce type definitions intended to hide the inter-language calling conventions and provide an interface to the routines that looks natural in Fortran 90.

For example, consider a hypothetical library routine, `foo`, which takes a double-precision vector of length `n`. C users access such a function as follows:

```

int n;

double *x;

...

foo(x, &n);

```

As noted above, to invoke `foo`, Fortran 90 users would need to know what Fortran 90 data types correspond to C types `int` and `double` (or `float` in case of single-precision), what argument-passing mechanism the C compiler uses and what, if any, name decoration is performed by the C compiler when generating the external symbol `foo`. However, with the Fortran 90 header files `mkl_trig_transforms.f90` / `mkl_poisson.f90` and `mkl_dfti.f90` included, the invocation of `foo` within a Fortran 90 program will look as follows:

- For TT interface,

```
use mkl_dfti
use mkl_trig_transforms
INTEGER n
DOUBLE PRECISION, ALLOCATABLE :: x
...
CALL FOO(x,n)
```

- For PL interface,

```
use mkl_dfti
use mkl_poisson
INTEGER n
DOUBLE PRECISION, ALLOCATABLE :: x
...
CALL FOO(x,n)
```

Note that in the above example, the header files `mkl_trig_transforms.f90` / `mkl_poisson.f90` and `mkl_dfti.f90` provide a definition for the subroutine `FOO`. To ease the use of PL or TT routines in Fortran 90, the general approach of providing Fortran 90 definitions of names is used throughout the libraries. Specifically, if a name from a PL or TT interface is documented as having the C-specific name `foo`, then the Fortran 90 header files provide an appropriate Fortran 90 language type definition `FOO`.

One of the key differences between Fortran 90 and C is the language argument-passing mechanism: C programs use pass-by-value semantics and Fortran 90 programs use pass-by-reference semantics. The Fortran 90 headers ensure proper treatment of this difference. In particular, in the above example, the header files `mkl_trig_transforms.f90` / `mkl_poisson.f90` and `mkl_dfti.f90` hide the difference by defining a macro `FOO` that takes the address of the appropriate arguments.

Nonlinear Optimization Problem Solvers

14

Intel® Math Kernel Library provides tools for solving nonlinear least squares problems using the Trust-Region (TR) algorithms. Subroutines are available to solve nonlinear least squares problems with and without boundary constraints and also to compute the Jacobi matrix based on a central difference scheme.

For more information on the key concepts required to understand the use of the Intel MKL nonlinear least squares problem solver routines, see [[Conn00](#)]

Nonlinear optimization problem solver routines of Intel MKL are subdivided according to their purpose as follows:

[Nonlinear Least Squares Problem without Constraints](#)

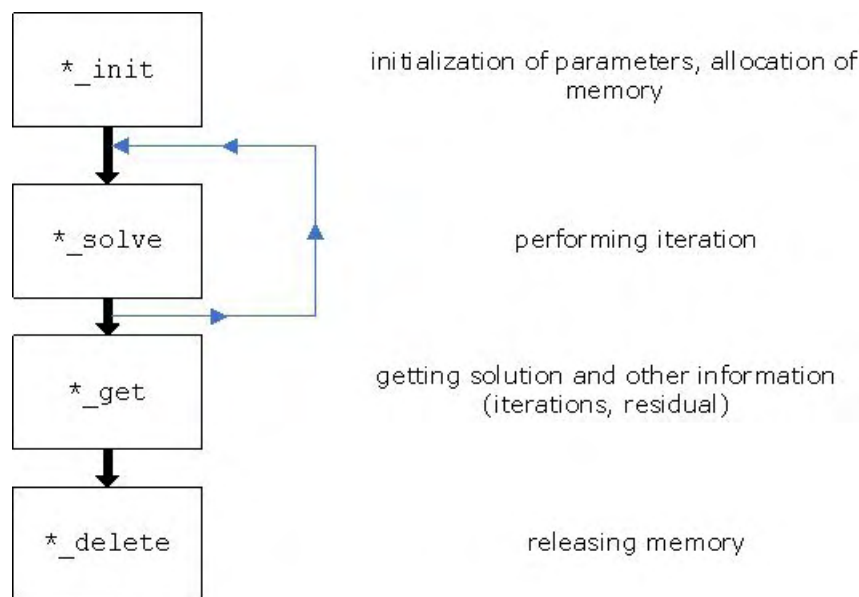

[Nonlinear Least Squares Problem with Linear \(Boundary\) Constraints](#)

[Jacobi Matrix Calculation Routines.](#)

Organization and Implementation

The TR solvers provided have reverse communication interfaces (RCI). RCI means that you need to provide certain information (or perform operations) to the solver, for example, the values of the objective function or a corresponding Jacobi matrix. This makes the solver independent of specific implementation of the operations. However, this approach requires some additional work from you.

Figure 14-1 Typical order for invoking RCI solver routines

The Trust-Region solvers are implemented with OpenMP* support. To use the multiprocessing mode, set the number of threads in the environment variable `MKL_NUM_THREADS`.

Memory Allocation and Handles

To make the routines easy to use, you are not required to allocate temporary working storage. The solver allocates any required memory. To allow multiple users to access the solver simultaneously, the solver keeps track of the storage allocated for a particular application by using a data object called a *handle*. Each RCI TR solver routine creates, uses, or deletes a handle.

C and C++ programmers should declare a handle as:

```
#include "mkl_rci.h"

_TRNSP_HANDLE_t handle;

or

_TRNSPBC_HANDLE_t handle;
```

Fortran programmers using compilers that support eight byte integers should declare a handle as:

```
INCLUDE "mkl_rci.fi"

INTEGER*8 handle
```

In addition to the necessary definition, for the correct declaration of a handle, the include file also defines the following:

- function prototypes for languages that support prototypes
- symbolic constants that are used for the error returns
- user options for the solver routines
- message severity.

Nonlinear Least Squares Problem without Constraints

The nonlinear least squares problem without constraints can be described as follows:

$$\min_{x \in \mathbb{R}^n} \|F(x)\|_2^2 = \min_{x \in \mathbb{R}^n} \|y - f(x)\|_2^2, \quad y \in \mathbb{R}^m, \quad x \in \mathbb{R}^n, \quad f: \mathbb{R}^n \rightarrow \mathbb{R}^m, \quad m \geq n,$$

where $F(x) : \mathbb{R}^n \rightarrow \mathbb{R}^m$ is a twice differentiable function in \mathbb{R}^n . Solving a nonlinear least squares problem means searching for the best approximation to the vector y with the model function $f_i(x)$ and nonlinear variables x . The best approximation means that the sum of squares of residuals $y_i - f_i(x)$ is the minimum.

See [Example C-43](#) and [Example C-44](#) for usage examples in FORTRAN and C, respectively, in Appendix C.

Table 14-1 RCI TR Routines

Routine Name	Operation
<code>dtrnlsp_init</code>	Initializes the solver.
<code>dtrnlsp_solve</code>	Solves a nonlinear least squares problem using RCI and Trust-Region algorithms.
<code>dtrnlsp_get</code>	Retrieves the number of iterations, stop criterion, initial residual, and final residual.
<code>dtrnlsp_delete</code>	Releases allocated data.

dtrnlsp_init

Initializes the solver of nonlinear least squares problem.

Syntax

Fortran:

```
res = dtrnlsp_init(handle, n, m, x, eps, iter1, iter2, rs)
```

C:

```
res = dtrnlsp_init(&handle, &n, &m, x, eps, &iter1, &iter2, &rs);
```

Description

This routine is declared in `mk1_rci.fi` for Fortran interface and in `mk1_rci.h` for C interface.

The routine initializes the solver. After initialization, all subsequent invocations of the `dtrnlsp_solve` routine should use the values of the handle returned by `dtrnlsp_init`.

The `eps` array contains the stopping criteria:

`eps(1)`: $\Delta < \text{eps}(1)$

`eps(2)`: $\|F(x)\|_2 < \text{eps}(2)$

`eps(3)`: the Jacobi matrix is singular. $\|J(x)_{(1:m,j)}\|_2 < \text{eps}(3)$, $j = 1, \dots, n$

`eps(4)`: $\|s\|_2 < \text{eps}(4)$

`eps(5)`: $\|F(x)\|_2 - \|F(x) - J(x)s\|_2 < \text{eps}(5)$

$eps(6)$: the trial step precision. If $eps(6) = 0$, then $eps(6) = 1.d-10$,

where $J(x)$ is the Jacobi matrix, Δ is the trust-region area, $F(x)$ is the value of the functional, s is the trial step.

Input Parameters

n	INTEGER. Length of x .
m	INTEGER. Length of $F(x)$.
x	DOUBLE PRECISION. Array of size n . Initial guess.
eps	DOUBLE PRECISION. Array of size 6; contains stopping criteria. See the values in Description.
$iter1$	INTEGER. Specifies the maximum number of iterations.
$iter2$	INTEGER. Specifies the maximum number of iterations of trial step calculation.
rs	DOUBLE PRECISION. Positive input variable used in determining the initial step bound. In most cases the factor should lie within the interval (0.1, 100.0). The generally recommended value is 100.

Output Parameters

$handle$	Type <code>_TRNSP_HANDLE_t</code> in C/C++ and <code>INTEGER*8</code> in FORTRAN.
res	INTEGER. Informs about the task completion. $res = TR_SUCCESS$ means the routine completed the task normally. $res = TR_INVALID_OPTION$ means an error in the input parameters. $res = TR_OUT_OF_MEMORY$ means a memory error.

dtrnlsp_solve

Solves a nonlinear least squares problem using the Trust-Region algorithm.

Syntax

Fortran:

```
res = dtrnlsp_solve(handle, fvec, fjac, RCI_Request)
```

C:

```
res = dtrnlsp_solve(&handle, fvec, fjac, &RCI_Request);
```

Description

This routine is declared in `mk1_rci.fi` for Fortran interface and in `mk1_rci.h` for C interface.

The `dtrnlsp_solve` routine uses the Trust-Region algorithm to solve nonlinear least squares problems.

The problem is stated as follows:

$$\min_{x \in R^n} \|F(x)\|_2^2 = \min_{x \in R^n} \|y - f(x)\|_2^2, y \in R^m, x \in R^n, f: R^n \rightarrow R^m, m \geq n,$$

where $F(x): R^n \rightarrow R^m$ and $m \geq n$. From a current point $x_{current}$, the algorithm uses the trust-region approach:

$$\min_{x \in R^n} \|F(x_{current}) + J(x_{current})(x_{new} - x_{current})\|_2^2 \quad \text{subject to} \quad \|x_{new} - x_{current}\| \leq \Delta_{current}$$

to get $x_{new} = x_{current} + s$ that satisfies

$$\min_{x \in R^n} \|J^T(x)J(x)s + J^T F(x)\|_2^2,$$

where $J(x)$ is the Jacobi matrix, s is the trial step, and $\|s\|_2 \leq \Delta_{current}$.

The `RCI_Request` parameter provides additional information:

`RCI_Request= 2` indicates the requirement to calculate the Jacobian matrix and put the result into `fjac`.

`RCI_Request= 1` indicates the requirement to recalculate the function at vector x and put the result into `fvec`.

`RCI_Request= 0` indicates a successful iteration on a current trust-region radius but does not mean that the value of x has changed.

`RCI_Request= -1` indicates that the algorithm has exceeded the maximum number of iterations.

`RCI_Request= -2` indicates that $\Delta < \text{eps}(1)$

$RCI_Request = -3$ indicates that $\|F(x)\|_2 < \epsilon(2)$

$RCI_Request = -4$ indicates that the Jacobi matrix is singular. $\|J(x)_{(1:m,j)}\|_2 < \epsilon(3)$,
 $j = 1, \dots, n$

$RCI_Request = -5$ indicates that $\|s\|_2 < \epsilon(4)$

$RCI_Request = -6$ indicates that $\|F(x) - J(x)s\|_2 < \epsilon(5)$,

where $J(x)$ is the Jacobi matrix, Δ is the trust-region area, $F(x)$ is the value of the functional, and s is the trial step.

Input Parameters

<i>handle</i>	Type <code>_TRNSP_HANDLE_t</code> in C/C++ and <code>INTEGER*8</code> in FORTRAN.
<i>fvec</i>	DOUBLE PRECISION. Array of size m . Contains the function values at X , where $fvec(i) = (y_i - f_i(x))$.
<i>fjac</i>	DOUBLE PRECISION. Array of size (m,n) . Contains the Jacobi matrix of the function.

Output Parameters

<i>fvec</i>	DOUBLE PRECISION. Array of size m . Contains the updated function values at X .
<i>RCI_Request</i>	INTEGER. Informs about the task stage. See Description for the other values of the parameter and their meaning.
<i>res</i>	INTEGER. Informs about the task completion. $res = TR_SUCCESS$ means the routine completed the task normally.

dtrnlsp_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

Syntax

Fortran:

```
res = dtrnlsp_get(handle, iter, st_cr, r1, r2)
```

C:

```
res = dtrnlsp_get(&handle, &iter, &st_cr, &r1, &r2);
```

Description

This routine is declared in `mk1_rci.fi` for Fortran interface and in `mk1_rci.h` for C interface.

The routine retrieves the current number of iterations, the stop criterion, the initial residual, and final residual.

The `st_cr` parameter contains the stop criterion:

`st_cr = 1` indicates that the algorithm has exceeded the maximum number of iterations.

`st_cr = 2` indicates that $\Delta < \text{eps}(1)$

`st_cr = 3` indicates that $\|F(x)\|_2 < \text{eps}(2)$

`st_cr = 4` indicates that the Jacobi matrix is singular. $\|J(x)_{(1:m,j)}\|_2 < \text{eps}(3)$, $j = 1, \dots, n$

`st_cr = 5` indicates that $\|s\|_2 < \text{eps}(4)$

`st_cr = 6` indicates that $\|F(x)\|_2 - \|F(x) - J(x)s\|_2 < \text{eps}(5)$,

where $J(x)$ is the Jacobi matrix, Δ is the trust region area, $F(x)$ is the value of the functional, and s is the trial step.

Input Parameters

`handle` Type `_TRNSP_HANDLE_t` in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

`iter` INTEGER. Contains the current number of iterations.

`st_cr` INTEGER. Contains the stop criterion.
See Description for the parameter values and their meanings.

`r1` DOUBLE PRECISION. Contains the residual, $(\|y - f(x)\|)$ given the initial x .

`r2` DOUBLE PRECISION. Contains the final residual, that is, the value of the functional $(\|y - f(x)\|)$ of the final x resulting from the algorithm operation.

`res` INTEGER. Informs about the task completion.
`res = TR_SUCCESS` means the routine completed the task normally.

dtrnlsp_delete

Releases allocated data.

Syntax

Fortran:

```
res = dtrnlsp_delete(handle)
```

C:

```
res = dtrnlsp_delete(&handle);
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface. The routine releases allocated data.

Input Parameters

handle Type `_TRNSP_HANDLE_t` in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

res `INTEGER`. Informs about the task completion.
res = `TR_SUCCESS` means the routine completed the task normally.

Nonlinear Least Squares Problem with Linear (Bound) Constraints

The nonlinear least squares problem with linear bound constraints can be described and solved in the same way as the [nonlinear least squares problem without constraints](#) but it has the following constraints:

$$l_i \leq x_i \leq u_i, i = 1, \dots, n, \quad l, u \in R^n.$$

See [Example C-45](#) and [Example C-46](#) for usage examples in FORTRAN and C, respectively, in Appendix C.

Table 14-2 RCI TR Routines for Problem with Bound Constraints

Routine Name	Operation
<code>dtrnlspbc_init</code>	Initializes the solver.
<code>dtrnlspbc_solve</code>	Solves a nonlinear least squares problem using RCI and the Trust-Region algorithm.
<code>dtrnlspbc_get</code>	Retrieves the number of iterations, stop criterion, initial residual, and final residual.
<code>dtrnlspbc_delete</code>	Releases allocated data.

`dtrnlspbc_init`

Initializes the solver of nonlinear least squares problem with linear (boundary) constraints.

Syntax

Fortran:

```
res = dtrnlspbc_init(handle, n, m, x, LW, UP, eps, iter1, iter2, rs)
```

C:

```
res = dtrnlspbc_init(&handle, &n, &m, x, LW, UP, eps, &iter1, &iter2, &rs);
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine initializes the solver. After initialization all subsequent invocations of the `dtrnlspbc_solve` routine should use the values of the handle returned by `dtrnlspbc_init`.

The `eps` array contains the stopping criteria:

`eps(1)`: $\Delta < \text{eps}(1)$

`eps(2)`: $\|F(x)\|_2 < \text{eps}(2)$

`eps(3)`: the Jacobi matrix is singular. $\|J(x)_{(1:m,j)}\|_2 < \text{eps}(3)$, $j = 1, \dots, n$

`eps(4)`: $\|s\| < \text{eps}(4)$

`eps(5)`: $\|F(x)\|_2 - \|F(x) - J(x)s\|_2 < \text{eps}(5)$

$eps(6)$: the trial step precision. If $eps(6) = 0$, then $eps(6) = 1.d-10$,

where $J(x)$ is the Jacobi matrix, Δ is the trust-region area, $F(x)$ is the value of the functional, and s is the trial step.

Input Parameters

n	INTEGER. Length of x .
m	INTEGER. Length of $F(x)$.
x	DOUBLE PRECISION. Array of size n . Initial guess.
LW	DOUBLE PRECISION. Array of size n . Contains low bounds for x ($lw_i \leq x_i$).
UP	DOUBLE PRECISION. Array of size n . Contains upper bounds for x ($up_i \leq x_i$).
eps	DOUBLE PRECISION. Array of size 6; contains stopping criteria. See the values in Description.
$iter1$	INTEGER. Specifies the maximum number of iterations.
$iter2$	INTEGER. Specifies the maximum number of iterations of trial step calculation.
rs	DOUBLE PRECISION. Positive input variable used in determining the initial step bound. In most cases the factor should lie within the interval (0.1, 100.0). The generally recommended value is 100.

Output Parameters

$handle$	Type <code>_TRNSPBC_HANDLE_t</code> in C/C++ and <code>INTEGER*8</code> in FORTRAN.
res	INTEGER. Informs about the task completion. $res = TR_SUCCESS$ means the routine completed the task normally. $res = TR_INVALID_OPTION$ means an error in the input parameters. $res = TR_OUT_OF_MEMORY$ means a memory error.

dtrnlspbc_solve

Solves a nonlinear least squares problem with linear (bound) constraints using the Trust-Region algorithm.

Syntax

Fortran:

```
res = dtrnlspbc_solve(handle, fvec, fjac, RCI_Request)
```

C:

```
res = dtrnlspbc_solve(&handle, fvec, fjac, &RCI_Request);
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The `dtrnlspbc_solve` routine, based on RCI, uses the Trust-Region algorithm to solve nonlinear least squares problems with linear (bound) constraints. The problem is stated as follows:

$$\min_{x \in R^n} \|F(x)\|_2^2 = \min_{x \in R^n} \|y - f(x)\|_2^2, y \in R^m, x \in R^n, f: R^n \rightarrow R^m, m \geq n, \text{ where } l_i \leq x_i \leq u_i, i = 1, \dots, n.$$

The `RCI_Request` parameter provides additional information:

`RCI_Request= 2` indicates the requirement to calculate the Jacobian matrix and put the result into `fjac`.

`RCI_Request= 1` indicates the requirement to recalculate the function at vector `x` and put the result into `fvec`.

`RCI_Request= 0` indicates a successful iteration on a current trust-region radius but does not mean that the value of `x` has changed.

`RCI_Request= -1` indicates that the algorithm has exceeded the maximum number of iterations.

`RCI_Request= -2` indicates that $\Delta < \text{eps}(1)$

`RCI_Request= -3` indicates that $\|F(x)\|_2 < \text{eps}(2)$

`RCI_Request= -4` indicates that the Jacobi matrix is singular. $\|J(x)_{(1:m,j)}\|_2 < \text{eps}(3)$, $j = 1, \dots, N$

$RCI_Request = -5$ indicates that $\|s\|_2 < \epsilon(4)$

$RCI_Request = -6$ indicates that $\|F(x)\|_2 - \|F(x) - J(x)s\|_2 < \epsilon(5)$,

where $J(x)$ is the Jacobi matrix, Δ is the trust-region area, $F(x)$ is the value of the functional, and s is the trial step.

Input Parameters

<i>handle</i>	Type <code>_TRNSPBC_HANDLE_t</code> in C/C++ and <code>INTEGER*8</code> in FORTRAN.
<i>fvec</i>	DOUBLE PRECISION. Array of size m . Contains the function values at X , where $fvec(i) = (y_i - f_i(x))$.
<i>fjac</i>	DOUBLE PRECISION. Array of size m by n . Contains the Jacobi matrix of the function.

Output Parameters

<i>fvec</i>	DOUBLE PRECISION. Array of size m . Contains the updated function values at X .
<i>RCI_Request</i>	INTEGER. Informs about the task stage. See Description for the other values of the parameter and their meaning.
<i>res</i>	INTEGER. Informs about the task completion. $res = TR_SUCCESS$ means the routine completed the task normally.

dtrnlspsc_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

Syntax

Fortran:

```
res = dtrnlspsc_get(handle, iter, st_cr, r1, r2)
```

C:

```
res = dtrnlspsc_get(&handle, &iter, &st_cr, &r1, &r2);
```

Description

This routine is declared in `mk1_rci.fi` for Fortran interface and in `mk1_rci.h` for C interface.

The routine retrieves the current number of iterations, the stop criterion, the initial residual, and final residual.

The *st_cr* parameter contains the stop criterion:

st_cr = 1 indicates that the algorithm has exceeded the maximum number of iterations.

st_cr = 2 indicates that $\Delta < \text{eps}(1)$

st_cr = 3 indicates that $\|F(x)\|_2 < \text{eps}(2)$

st_cr = 4 indicates that the Jacobi matrix is singular. $\|J(x)_{(1:m,j)}\|_2 < \text{eps}(3)$, $j = 1, \dots, n$

st_cr = 5 indicates that $\|s\|_2 < \text{eps}(4)$

st_cr = 6 indicates that $\|F(x)\|_2 - \|F(x) - J(x)s\|_2 < \text{eps}(5)$,

where $J(x)$ is the Jacobi matrix, Δ is the trust region area, $F(x)$ is the value of the functional, and s is the trial step.

Input Parameters

handle Type `_TRNSPBC_HANDLE_t` in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

<i>iter</i>	INTEGER. Contains the current number of iterations.
<i>st_cr</i>	INTEGER. Contains the stop criterion. See Description for the parameter values and their meanings.
<i>r1</i>	DOUBLE PRECISION. Contains the residual, $(\ y - f(x)\)$ given the initial x .
<i>r2</i>	DOUBLE PRECISION. Contains the final residual, that is, the value of the function $(\ y - f(x)\)$ of the final x resulting from the algorithm operation.
<i>res</i>	INTEGER. Informs about the task completion. <i>res</i> = <code>TR_SUCCESS</code> means the routine completed the task normally.

dtrnlspbc_delete

Releases allocated data.

Syntax

Fortran:

```
res = dtrnlspbc_delete(handle)
```

C:

```
res = dtrnlspbc_delete(&handle);
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface. The routine releases allocated data.

Input Parameters

handle Type `_TRNSPBC_HANDLE_t` in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

res `INTEGER`. Informs about the task completion.
res = `TR_SUCCESS` means the routine completed the task normally.

Jacobi Matrix Calculation Routines

This section describes routines that compute the Jacobi matrix using central differences. Jacobi matrix calculation is required to solve nonlinear least squares problem and systems of nonlinear equations (with or without linear bound constraints). Routines for calculation of the Jacobi matrix have "Black-Box" interfaces, where users pass the objective function via parameters. Note that in this case the user's objective function must have fixed interface.

Table 14-3 Jacobi Matrix Calculation Routines

Routine Name	Operation
<code>djacobi_init</code>	Initializes the solver.
<code>djacobi_solve</code>	Computes the Jacobi matrix of the function on the basis of RCI using the central difference.

Routine Name	Operation
<code>djacobi_delete</code>	Removes data.
<code>djacobi</code>	Computes the Jacobi matrix of the <code>fcn</code> function using the central difference.
<code>djacobix</code>	Presents an alternative interface for the <code>djacobi</code> function enabling the user to pass additional data into the user's function.

djacobi_init

Initializes the solver for Jacobian calculations.

Syntax

Fortran:

```
res = djacobi_init(handle, n, m, x, fjac, esp)
```

C:

```
res = djacobi_init(&handle, &n, &m, x, fjac, &eps);
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine initializes the solver.

Input Parameters

<i>n</i>	INTEGER. Length of <i>x</i> .
<i>m</i>	INTEGER. Length of <i>F</i> .
<i>x</i>	DOUBLE PRECISION. Array of size <i>n</i> . Vector, at which the function is evaluated.
<i>eps</i>	DOUBLE PRECISION. Precision of the Jacobi matrix calculation.
<i>fjac</i>	DOUBLE PRECISION. Array of size (m,n) . Contains the Jacobi matrix of the function.

Output Parameters

<i>handle</i>	Data object of the <code>_JACOBIMATRIX_HANDLE_t</code> type in C/C++ and <code>INTEGER*8</code> in FORTRAN.
<i>res</i>	<p>INTEGER. Informs about the task completion.</p> <p><i>res</i> = <code>TR_SUCCESS</code> indicates that the routine completed the task normally.</p> <p><i>res</i> = <code>TR_INVALID_OPTION</code> indicates an error in the input parameters.</p> <p><i>res</i> = <code>TR_OUT_OF_MEMORY</code> indicates a memory error.</p>

djacobi_solve

Computes the Jacobi matrix of the function using RCI and the central difference.

Syntax

Fortran:

```
res = djacobi_solve(handle, f1, f2, RCI_Request)
```

C:

```
res = djacobi_solve(&handle, f1, f2, &RCI_Request);
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The `djacobi_solve` routine computes the Jacobi matrix of the function using RCI and the central difference.

See [Example C-47](#) and [Example C-48](#) for the usage examples in FORTRAN and C, respectively, in Appendix C.

Input Parameters

<i>handle</i>	Type <code>_JACOBIMATRIX_HANDLE_t</code> in C/C++ and <code>INTEGER*8</code> in FORTRAN.
---------------	--

Output Parameters

<i>f1</i>	DOUBLE PRECISION. Array of size <i>m</i> . Contains the updated function values at $x + \text{eps}$.
-----------	---

<i>f2</i>	DOUBLE PRECISION. Array of size <i>m</i> . Contains the updated function values at $X - \epsilon$.
<i>RCI_Request</i>	INTEGER. Informs about the task completion. When equal to 0, the task is completed successfully. <i>RCI_Request</i> = 1 indicates the user should calculate the Jacobian matrix and put the result into <i>f1</i> . <i>RCI_Request</i> = 2 indicates the user should calculate the Jacobian matrix and put the result into <i>f2</i> .
<i>res</i>	INTEGER. Informs about the task completion. <i>res</i> = TR_SUCCESS indicates that the routine has completed the task normally. <i>res</i> = TR_INVALID_OPTION indicates an error in the input parameters.

djacobi_delete

Releases allocated data.

Syntax

Fortran:

```
res = djacobi_delete(handle)
```

C:

```
res = djacobi_delete(&handle);
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface. The routine releases allocated data.

Input Parameters

handle Type `_JACOBI_MATRIX_HANDLE_t` in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

res INTEGER. Informs about the task completion.
res = TR_SUCCESS means the routine completed the task normally.

djacobi

Computes the Jacobi matrix of the user's objective function using the central difference.

Syntax

Fortran:

```
res = djacobi(fcn, n, m, fjac, x, jac_eps)
```

C:

```
res = djacobi(fcn, &n, &m, fjac, x, &jac_eps);
```

Description

This routine is declared in `mkl_rci.fi` for Fortran interface and in `mkl_rci.h` for C interface.

The routine computes the Jacobi matrix for function `fcn` using the central difference. This routine has a "Black-Box" interface, where the user inputs the objective function via parameters. Note that in this case the user's objective function must have a fixed interface.

See [Example C-49](#) and [Example C-50](#) for examples of the function usage in FORTRAN and C, respectively, in Appendix C.

Input Parameters

<code>fcn</code>	User-supplied subroutine to evaluate the function that defines the least squares problem. Call <code>fcn (m, n, x, f)</code> with the following parameters: <code>m</code> - INTEGER. Input parameter. Length of <code>f</code> <code>n</code> - INTEGER. Input parameter. Length of <code>x</code> . <code>x</code> - DOUBLE PRECISION. Input parameter. Array of size <code>n</code> . Vector, at which the function is evaluated. The <code>fcn</code> function should not change this parameter. <code>f</code> - DOUBLE PRECISION. Output parameter. Array of size <code>m</code> ; contains the function values at <code>x</code> . Declare <code>fcn</code> as EXTERNAL in the calling program.
<code>n</code>	INTEGER. Length of <code>x</code> .
<code>m</code>	INTEGER. Length of <code>F</code> .
<code>x</code>	DOUBLE PRECISION. Array of size <code>n</code> . Vector at which the function is evaluated.

eps DOUBLE PRECISION. Precision of the Jacobi matrix calculation.

Output Parameters

fjac DOUBLE PRECISION. Array of size (m,n) . Contains the Jacobi matrix of the function.

res INTEGER. Informs about the task completion.
res = TR_SUCCESS indicates that the routine has completed the task normally.
res = TR_INVALID_OPTION indicates an error in the input parameters.
res = TR_OUT_OF_MEMORY indicates a memory error.

djacobix

Alternative interface for djacobi function enabling user to pass additional data into user's objective function.

Syntax

Fortran:

```
res = djacobix(fcn, n, m, fjac, x, jac_eps, user_data)
```

C:

```
res = djacobix(fcn, &n, &m, fjac, x, &jac_eps, user_data);
```

Description

This routine is declared in `mk1_rci.fi` for Fortran interface and in `mk1_rci.h` for C interface.

This routine presents an alternative interface for the `djacobi` function that enables the user to pass additional data into the user's objective function *fcn*.

See [Example C-51](#) for an example of the function usage in C in Appndix C.

Input Parameters

fcn User-supplied subroutine to evaluate the function that defines the least squares problem. Call *fcn* (*m*, *n*, *x*, *f*, *user_data*) with the following parameters:
m - INTEGER. Input parameter. Length of *f*
n - INTEGER. Input parameter. Length of *x*.

x - DOUBLE PRECISION. Input parameter. Array of size n . Vector, at which the function is evaluated. The `fcn` function should not change this parameter.

f - DOUBLE PRECISION. Output parameter. Array of size m ; contains the function values at x .

`user_data` - Pointer to void (for FORTRAN, `integer user_data(*)`). Input parameter. Contains additional user's data, if any. Otherwise, a dummy argument.

Declare `fcn` as EXTERNAL in the calling program.

n INTEGER. Length of x .

m INTEGER. Length of F .

x DOUBLE PRECISION. Array of size n . Vector at which the function is evaluated.

eps DOUBLE PRECISION. Precision of the Jacobi matrix calculation.

`user_data` Pointer to void (for FORTRAN, `integer user_data(*)`). Input parameter. Contains additional user's data, if any. Otherwise, a dummy argument.

Output Parameters

$fjac$ DOUBLE PRECISION. Array of size (m,n) . Contains the Jacobi matrix of the function.

res INTEGER. Informs about the task completion.

$res = \text{TR_SUCCESS}$ indicates that the routine has completed the task normally.

$res = \text{TR_INVALID_OPTION}$ indicates an error in the input parameters.

$res = \text{TR_OUT_OF_MEMORY}$ indicates a memory error.

Support Functions

Intel® MKL support functions are used to:

- retrieve information about the current Intel MKL version
- additionally control the number of threads
- handle errors
- test characters and character strings for equality
- measure user time for a process and elapsed CPU time
- set and measure CPU frequency
- free memory allocated by Intel MKL memory management software

Functions described below are subdivided according to their purpose into the following groups:

[Version Information Functions](#)

[Threading Control Functions](#)

[Error Handling Functions](#)

[Equality Test Functions](#)

[Timing Functions](#)

[Memory Functions](#)

[Miscellaneous Utility Functions](#)

Table 15-1 contains the list of support functions common for Intel MKL.

Table 15-1 Intel MKL Support Functions

Function Name	Operation
Version Information Functions	
<code>mkl_get_version</code>	Returns information about the active library version.
<code>mkl_get_version_string</code>	Returns information about the library version string.
Threading Control Functions	
<code>mkl_set_num_threads</code>	Suggests the number of threads to use.

Function Name	Operation
<code>mkl_domain_set_num_threads</code>	Suggests the number of threads for a particular function domain.
<code>mkl_set_dynamic</code>	Enables Intel MKL to dynamically change the number of threads.
<code>mkl_get_max_threads</code>	Inquires about the number of threads targeted for parallelism.
<code>mkl_domain_get_max_threads</code>	Inquires about the number of threads targeted for parallelism in different domains.
<code>mkl_get_dynamic</code>	Returns the current value of the <code>MKL_DYNAMIC</code> variable.
Error Handling Functions	
<code>xerbla</code>	Handles error conditions for the BLAS, LAPACK, VSL, VML routines.
<code>pxerbla</code>	Handles error conditions for the ScaLAPACK routines.
Equality Test Functions	
<code>lsame</code>	Tests two characters for equality regardless of the case.
<code>lsamen</code>	Tests two character strings for equality regardless of the case.
Timing Functions	
<code>second/dsecnd</code>	Returns user time for a process.
<code>mkl_get_cpu_clocks</code>	Returns full precision elapsed CPU clocks.
<code>mkl_get_cpu_frequency</code>	Returns CPU frequency value in GHz.
<code>mkl_set_cpu_frequency</code>	Sets CPU frequency value in GHz.
Memory Functions	

Function Name	Operation
<code>mkl_free_buffers</code>	Frees memory buffers.
<code>mkl_thread_free_buffers</code>	Frees memory buffers allocated only in the current thread.
<code>mkl_mem_stat</code>	Reports an amount of memory utilized by MKL Memory Manager.
<code>mkl_malloc</code>	Allocates the aligned memory buffer.
<code>mkl_free</code>	Frees the aligned memory buffer allocated by <code>MKL_malloc</code> .
Miscellaneous Utility Functions	
<code>mkl_progress</code>	Tracks computational progress of selective MKL routines.
<code>mkl_enable_instructions</code>	Allows Intel MKL to dispatch Intel® Advanced Vector Extensions (Intel® AVX) if run on the respective hardware (or simulation).

Version Information Functions

Intel® MKL provides two methods for extracting information about the library version number:

- extracting a version string using the `mkl_get_version_string` function
- using the `mkl_get_version` function to obtain an `MKLVersion` structure that contains the version information

A makefile is also provided to automatically build the examples and output summary files containing the version information for the current library.

mkl_get_version

Returns information about the active library C version.

Syntax

```
void mkl_get_version( MKLVersion* pVersion );
```

Output Parameters

pVersion Pointer to the MKLVersion structure.

Description

The C interface for this function is declared in `mkl_service.h` header file.

The `mkl_get_version` function collects information about the active C version of the Intel MKL software and returns this information in a structure of `MKLVersion` type by the *pVersion* address. The `MKLVersion` structure type is defined in the `mkl_types.h` file. The following fields of the `MKLVersion` structure are available:

MajorVersion	is the major number of the current library version.
MinorVersion	is the minor number of the current library version.
UpdateVersion	is the update number of the current library version.
ProductStatus	is the status of the current library version. Possible variants could be "Beta", "Product".
Build	is the string that contains the build date and the internal build number.
Processor	is the processor optimization that is targeted for the specific processor. It is not the definition of the processor installed in the system, rather the MKL library detection that is optimal for the processor installed in the system.

NOTE. `MKLGetVersion` is an obsolete name for the `mkl_get_version` function that is referenced in the library for back compatibility purposes but is deprecated and subject to removal in subsequent releases.

mkl_get_version Usage

```
#include <stdio.h>
#include <stdlib.h>
#include "mkl_service.h"

int main(void)
{
    MKLVersion Version;

    mkl_get_version(&Version);

    // MKL_Get_Version(&Version);

    printf("Major version:          %d\n",Version.MajorVersion);
    printf("Minor version:            %d\n",Version.MinorVersion);
    printf("Update version:             %d\n",Version.UpdateVersion);
    printf("Product status:             %s\n",Version.ProductStatus);
    printf("Build:                       %s\n",Version.Build);
    printf("Processor optimization:      %s\n",Version.Processor);
    printf("=====\n");
    printf("\n");

    return 0;
}
```

Output:

Major Version	9
Minor Version	0

Update Version	0
Product status	Product
Build	061909.09
Processor optimization	Intel® Xeon® Processor with Intel® 64 architecture

mkl_get_version_string

Gets the library version string.

Syntax

Fortran:

```
call mkl_get_version_string( buf )
```

C:

```
mkl_get_version_string( buf, len );
```

Output Parameters

Name	Type	Description
<i>buf</i>	FORTTRAN: CHARACTER*198 C: char*	Source string
<i>len</i>	FORTTRAN: INTEGER C: int	Length of the source string

Description

The FORTRAN 77 interface for this function is declared in `mkl_service.fi` and the C interface in `mkl_service.h`.

The function returns a string that contains the library version information.

NOTE. `MKLGetVersionString` is an obsolete name for the `mkl_get_version_string` function that is referenced in the library for back compatibility purposes but is deprecated and subject to removal in subsequent releases.

See example below:

Examples

Fortran:

```
program mkl_get_version_string
character*198 buf
call mkl_get_version_string(buf)
write(*,'(a)') buf
end
```

C:

```
#include <stdio.h>
#include "mkl_blas.h"
int main(void)
{
    int len=198;
    char buf[198];
    mkl_get_version_string(buf, len);
    printf("%s\n",buf);
    printf("\n");
    return 0;
}
```

Threading Control Functions

Intel® MKL provides optional threading control functions that take precedence over OpenMP* environment variable settings with the same purpose (see *Intel® MKL User's Guide* for details).

These functions enable you to specify the number of threads for Intel MKL independently of the OpenMP* settings and takes precedence over them. Although Intel MKL may actually use a different number of threads from the number suggested, the controls also enable you to instruct the library to try using the suggested number when the number used in the calling application is unavailable.

See the following examples of Fortran and C usage:

Fortran Usage

```
call mkl_set_num_threads( foo )
ierr = mkl_domain_set_num_threads( num, MKL_BLAS )
call mkl_set_dynamic ( 1 )
num = mkl_get_max_threads()
num = mkl_domain_get_max_threads( MKL_BLAS );
ret = mkl_get_dynamic()
```

C Usage

```
#include "mkl.h" // Mandatory to make these definitions work!
mkl_set_num_threads(num);
return_code = mkl_domain_set_num_threads( num, MKL_FFT );
mkl_set_dynamic( 1 );
num = mkl_get_max_threads();
num = mkl_domain_get_max_threads( MKL_FFT );
return_code = mkl_get_dynamic();
```

NOTE. Always remember to add `#include "mkl.h"` to use the C usage syntax.

mkl_set_num_threads

Suggests the number of threads to use.

Syntax

Fortran:

```
call mkl_set_num_threads( number )
```

C:

```
void mkl_set_num_threads( number );
```

Input Parameters

Name	Type	Description
<i>number</i>	FORTRAN: INTEGER C: int	Number of threads suggested by user

Description

The FORTRAN 77 interface for this function is declared in `mkl_service.fi` and the C interface in `mkl_service.h`.

This function allows you to request independently of OpenMP* how many threads MKL should use. This is just a hint, and it is not guaranteed that this number of threads will be used. Enter a positive integer. This routine takes precedence over the `MKL_NUM_THREADS` environment variable.

NOTE. Always remember to add `#include "mkl.h"` to use the C usage syntax.

See *Intel MKL User's Guide* for implementation details.

mkl_domain_set_num_threads

Suggests the number of threads for a particular function domain.

Syntax

Fortran:

```
ierr = mkl_domain_set_num_threads( num, mask )
```

C:

```
ierr = mkl_domain_set_num_threads( num, mask );
```

Input Parameters

Name	Type	Description
<i>num</i>	FORTRAN: INTEGER C: int	Number of threads suggested by user
<i>mask</i>	FORTRAN: INTEGER C: int	Name of the targeted domain

Description

The FORTRAN 77 interface for this function is declared in `mkl_service.fi` and the C interface in `mkl_service.h`.

This function allows you to request different domains of Intel MKL to use different numbers of threads. The currently supported domains are:

- `MKL_BLAS` - BLAS domain
- `MKL_FFT` - FFT domain (excluding cluster FFT)
- `MKL_VML` - vector math library
- `MKL_ALL` - another way to do what `mkl_set_num_threads` does

This is only a hint, and use of this number of threads is not guaranteed. Enter a valid domain and a positive integer for the number of threads. This routine has precedence over the `MKL_DOMAIN_NUM_THREADS` environment variable.

See *Intel MKL User's Guide* for implementation details.

Return Values

<code>1 (true)</code>	Indicates no error, execution is successful.
<code>0 (false)</code>	Indicates failure, possibly because the inputs were invalid.

mkl_set_dynamic

Enables Intel MKL to dynamically change the number of threads.

Syntax

Fortran:

```
call mkl_set_dynamic( boolean_var )
```

C:

```
void mkl_set_dynamic( boolean_var );
```

Input Parameters

Name	Type	Description
<i>boolean_var</i>	FORTTRAN: INTEGER C: int	The parameter that determines whether dynamic adjustment of the number of threads is enabled or disabled.

Description

The FORTRAN 77 interface for this function is declared in `mkl_service.fi` and the C interface in `mkl_service.h`.

This function indicates whether or not Intel MKL can dynamically change the number of threads. The default for this is `true`, regardless of how the `OMP_DYNAMIC` variable is set. This will also hold precedent over the `OMP_DYNAMIC` variable.

A value of `false` does not guarantee that the user's requested number of threads will be used. But it means that MKL will attempt to use that value. This routine takes precedence over the environment variable `MKL_DYNAMIC`.

Note that if MKL is called from within a parallel region, MKL may not thread unless `MKL_DYNAMIC` is set to `false`, either with the environment variable or by this routine call.

See *Intel MKL User's Guide* for implementation details.

mkl_get_max_threads

Inquires about the number of threads targeted for parallelism.

Syntax

Fortran:

```
num = mkl_get_max_threads()
```

C:

```
num = mkl_get_max_threads();
```

Description

The FORTRAN 77 interface for this function is declared in `mkl_service.fi` and the C interface in `mkl_service.h`.

This function allows you to inquire independently of OpenMP* how many threads Intel MKL is targeting for parallelism. This is just a hint, and it is not guaranteed that this number of threads will be used.

See *Intel MKL User's Guide* for implementation details.

Return Values

The output is `INTEGER` equal to the number of threads.

mkl_domain_get_max_threads

Inquires about the number of threads targeted for parallelism in different domains.

Syntax

Fortran:

```
ierr = mkl_domain_get_max_threads( mask )
```

C:

```
ierr = mkl_domain_get_max_threads( mask );
```

Input Parameters

Name	Type	Description
<i>mask</i>	FORTRAN: INTEGER C: int	The name of the targeted domain

Description

The FORTRAN 77 interface for this function is declared in `mkl_service.fi` and the C interface in `mkl_service.h`.

This function allows the user of different domains of Intel MKL to inquire what number of threads is being used as a hint. The inquiry does not imply that this is the actual number of threads used. The number may vary depending on the value of the `MKL_DYNAMIC` variable and/or problem size, system resources, etc. But the function returns the value that MKL is targeting for a given domain.

The currently supported domains are:

- `MKL_BLAS` - BLAS domain
- `MKL_FFT` - FFT domain (excluding cluster FFT)
- `MKL_VML` - vector math library
- `MKL_ALL` - another way to do what `mkl_get_max_threads` does.

You are supposed to enter a valid domain.

See *Intel MKL User's Guide* for implementation details.

Return Values

Returns the hint about the number of threads for a given domain.

`mkl_get_dynamic`

Returns current value of `MKL_DYNAMIC` variable.

Syntax

Fortran:

```
ret = mkl_get_dynamic()
```

C:

```
ret = mkl_get_dynamic();
```

Description

The FORTRAN 77 interface for this function is declared in `mkl_service.fi` and the C interface in `mkl_service.h`.

This function returns the current value of the `MKL_DYNAMIC` variable. This variable can be changed by manipulating the `MKL_DYNAMIC` environment variable before the MKL run is launched or by calling `mkl_set_dynamic()`. Doing the latter has precedence over the former.

The function returns a value of 0 or 1: 1 indicates that `MKL_DYNAMIC` is true, 0 indicates that `MKL_DYNAMIC` is false. This variable indicates whether or not Intel MKL can dynamically change the number of threads. A value of `false` does not guarantee that the user's requested number of threads will be used. But it means that Intel MKL will attempt to use that value.

Note that if MKL is called from within a parallel region, MKL may not thread unless `MKL_DYNAMIC` is set to `false`, either with the environment variable or by this routine call.

See *Intel MKL User's Guide* for implementation details.

Return Values

1	Indicates <code>MKL_DYNAMIC</code> is true.
0	Indicates <code>MKL_DYNAMIC</code> is false.

Error Handling Functions

xerbla

Error handling routine called by BLAS, LAPACK, VML, VSL routines.

Syntax

Fortran:

```
call xerbla( sname, info )
```

C:

```
xerbla( sname, info, len );
```

Input Parameters

Name	Type	Description
sname	FORTTRAN: CHARACTER*(*) C: char*	The name of the routine that called xerbla
info	FORTTRAN: INTEGER C: int*	The position of the invalid parameter in the parameter list of the calling routine
len	C: int	Length of the source string

Description

The FORTRAN 77 interface for this routine is declared in `mkl_blas.fi` and the C interface in `mkl_blas.h`.

The routine `xerbla` is an error handler for the BLAS, LAPACK, VSL, and VML routines. It is called by a BLAS, LAPACK, VSL or VML routine if an input parameter has an invalid value. If an issue is found with an input parameter, `xerbla` prints a message similar to the following:

```
MKL ERROR: Parameter 6 was incorrect on entry to DGEMM
```

and then returns to the user application.

Note that `xerbla` is an internal function. You can change or disable printing of an error message by providing your own `xerbla` function. FORTRAN and C examples are provided below.

Examples

Fortran:

```
subroutine xerbla (sname, info)
character*(*) sname  !Name of subprogram that called xerbla
integer*4      info  !Position of the invalid parameter in the
parameter list
return          !Return to the calling subprogram
end
```

C:

```
void xerbla(char* sname, int* info, int len){
// sname - name of the function that called xerbla
// info - position of the invalid parameter in the parameter list
// len - length of the name in bytes
printf("\nXERBLA is called :%s: %d\n",sname,*info);
}
```

pxerbla

Error handling routine called by ScaLAPACK routines.

Syntax

call pxerbla(*ictxt*, *sname*, *info*)

Input Parameters

<i>ictxt</i>	(global) INTEGER The BLACS context handle, indicating the global context of the operation. The context itself is global.
<i>sname</i>	(global) CHARACTER*6 The name of the routine which called pxerbla.
<i>info</i>	(global) INTEGER. The position of the invalid parameter in the parameter list of the calling routine.

Description

The C interface for this routine is declared in `mk1_scalapack.h` file.

This routine is an error handler for the *ScaLAPACK* routines. It is called if an input parameter has an invalid value. A message is printed and program execution continues. For *ScaLAPACK* driver and computational routines, a `RETURN` statement is issued following the call to `pxerbla`.

Control returns to the higher-level calling routine, and you can determine how the program should proceed. However, in the specialized low-level ScaLAPACK routines (auxiliary routines that are Level 2 equivalents of computational routines), the call to `pxerbla()` is immediately followed by a call to `BLACS_ABORT()` to terminate program execution since recovery from an error at this level in the computation is not possible.

It is always good practice to check for a nonzero value of *info* on return from a ScaLAPACK routine. Installers may consider modifying this routine in order to call system-specific exception-handling facilities.

Equality Test Functions

lsame

Tests two characters for equality regardless of the case.

Syntax

Fortran:

```
val = lsame( ca, cb )
```

C:

```
val = lsame( ca, cb );
```

Input Parameters

Name	Type	Description
<i>ca, cb</i>	FORTTRAN: CHARACTER*1	FORTTRAN: The single characters to be compared
	C: const char*	C: Pointers to the single characters to be compared

Output Parameters

Name	Type	Description
<i>val</i>	FORTTRAN: LOGICAL	Result of the comparison
	C: int	

Description

The FORTRAN 77 interface for this function is declared in `mkl_blas.fi` and the C interface in `mkl_blas.h`.

This logical function returns `.TRUE.` if `ca` is the same letter as `cb` regardless of the case, and `.FALSE.` otherwise.

lsamen

Tests two character strings for equality regardless of the case.

Syntax

Fortran:

```
val = lsamen( n, ca, cb )
```

C:

```
val = lsamen( n, ca, cb );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER C: <code>const int*</code>	FORTTRAN: The number of characters in <i>ca</i> and <i>cb</i> to be compared. C: Pointer to the number of characters in <i>ca</i> and <i>cb</i> to be compared.
<i>ca, cb</i>	FORTTRAN: CHARACTER*(*) C: <code>const char*</code>	Specify two character strings of length at least <i>n</i> to be compared. Only the first <i>n</i> characters of each string will be accessed.

Output Parameters

Name	Type	Description
<code>val</code>	FORTTRAN: LOGICAL C: int	FORTTRAN: Result of the comparison. <code>.TRUE.</code> if <code>ca</code> and <code>cb</code> are equivalent except for the case, and <code>.FALSE.</code> otherwise. The function also returns <code>.FALSE.</code> if <code>len(ca)</code> or <code>len(cb)</code> is less than <code>n</code> . C: Result of the comparison. Non-zero if <code>ca</code> and <code>cb</code> are equivalent except for the case, and zero otherwise.

Description

The FORTRAN 77 interface for this function is declared in `mkl_lapack.fi` and the C interface in `mkl_lapack.h`.

This logical function tests if the first `n` letters of one string are the same as the first `n` letters of another string, regardless of the case.

Timing Functions

second/dsecnd

Returns elapsed CPU time in seconds.

Syntax

Fortran:

```
val = second()  
val = dsecnd()
```

C:

```
val = second();  
val = dsecnd();
```

Output Parameters

Name	Type	Description
<code>val</code>	FORTTRAN: REAL for <code>second</code> DOUBLE PRECISION for <code>dsecnd</code> C: float for <code>second</code> double for <code>dsecnd</code>	Elapsed CPU time in seconds

Description

The FORTRAN 77 interface for this function is declared in `mkl_lapack.fi` and the C interface in `mkl_lapack.h`.

The `second`/`dsecnd` functions return the elapsed CPU time in seconds. These versions get the time from the elapsed CPU clocks divided by CPU frequency. The difference is that `dsecnd` returns the result with double precision.

The functions should be applied in pairs: the first time, before a routine to be measured, and the second time - after the measurement. The difference between the returned values is the time spent in the routine. The usage of `second` is discouraged for measuring short time intervals because the single precision format is not capable of holding sufficient timer precision.

`mkl_get_cpu_clocks`

Returns full precision elapsed CPU clocks.

Syntax

Fortran:

```
call mkl_get_cpu_clocks( clocks )
```

C:

```
mkl_get_cpu_clocks( &clocks );
```

Output Parameters

Name	Type	Description
<code>clocks</code>	FORTRAN: INTEGER*8 C: unsigned MKL_INT64	Elapsed CPU clocks

Description

The FORTRAN 77 interface for this function is declared in `mkl_service.fi` and the C interface in `mkl_service.h`.

The `mkl_get_cpu_clocks` function returns the elapsed CPU clocks.

This may be useful when timing short intervals with high resolution. The `mkl_get_cpu_clocks` function is also applied in pairs like `second/dsecnd`. Note that out-of-order code execution on IA-32 or Intel® 64 architecture processors may disturb the exact elapsed CPU clocks value a little bit, which may be important while measuring extremely short time intervals.

NOTE. `getcpuclocks` is an obsolete name for the `mkl_get_cpu_clocks` function that is referenced in the library for back compatibility purposes but is deprecated and subject to removal in subsequent releases.

`mkl_get_cpu_frequency`

Returns CPU frequency value in GHz.

Syntax

Fortran:

```
freq = mkl_get_cpu_frequency()
```

C:

```
freq = mkl_get_cpu_frequency();
```

Output Parameters

Name	Type	Description
<i>freq</i>	FORTRAN: DOUBLE PRECISION C: double	CPU frequency value in GHz

Description

The FORTRAN 77 interface for this function is declared in `mkl_service.fi` and the C interface in `mkl_service.h`.

The function `mkl_get_cpu_frequency` returns the CPU frequency in GHz. This value is used by `second` / `dsecnd` functions while converting CPU clocks into seconds.

Obtaining a frequency may take some time when `second` / `dsecnd` / `mkl_get_cpu_frequency` is called for the first time. To avoid it, call `mkl_set_cpu_frequency` before setting the exact CPU frequency if it is known in advance.

NOTE. `getcpufrequency` is an obsolete name for the `mkl_get_cpu_frequency` function that is referenced in the library for back compatibility purposes but is deprecated and subject to removal in subsequent releases.

mkl_set_cpu_frequency

Sets CPU frequency value in GHz.

Syntax

Fortran:

```
call mkl_set_cpu_frequency( freq )
```

C:

```
mkl_set_cpu_frequency( &freq );
```

Input Parameters

Name	Type	Description
<i>freq</i>	FORTRAN: DOUBLE PRECISION C: double	CPU frequency value in GHz

Description

The FORTRAN 77 interface for this function is declared in `mkl_service.fi` and the C interface in `mkl_service.h`.

The `mkl_set_cpu_frequency` function sets the CPU frequency in GHz, used then by `second` /`dsecnd` functions while converting CPU clocks into seconds. Setting the exact CPU frequency is useful to bypass obtaining a frequency by `mkl_get_cpu_frequency`.

Initially, CPU frequency value is unset. The CPU frequency value can be set only by `mkl_set_cpu_frequency` call, or during the first call of `mkl_get_cpu_frequency`, if `mkl_set_cpu_frequency` has not been called before. Calling `mkl_set_cpu_frequency` with a special parameter `freq = -1.0` forces the CPU frequency value be unset.

Note that the CPU frequency of your machine is not actually changed when the `mkl_set_cpu_frequency` subroutine is called.

NOTE. `setcpufrequency` is an obsolete name for the `mkl_set_cpu_frequency` function that is referenced in the library for back compatibility purposes but is deprecated and subject to removal in subsequent releases.

Memory Functions

This section describes the Intel MKL memory support functions. See the *Intel® MKL User's Guide* for details of the Intel MKL memory management.

mkl_free_buffers

Frees memory buffers.

Syntax

Fortran:

```
call mkl_free_buffers
```

C:

```
mkl_free_buffers();
```

Description

The FORTRAN 77 interface for this function is declared in `mkl_service.fi` and the C interface in `mkl_service.h`.

The `mkl_free_buffers` function frees the memory allocated by the Intel MKL Memory Manager. The Memory Manager allocates new buffers if no free buffers are currently available. Call `mkl_free_buffers()` to free all memory buffers and to avoid memory leaking on completion of work with the Intel MKL functions, that is, after the last call of an Intel MKL function from your application.

See *Intel® MKL User's Guide* for details.

NOTE. `MKL_FreeBuffers` is an obsolete name for the `mkl_free_buffers` function that is referenced in the library for back compatibility purposes but is deprecated and subject to removal in subsequent releases.

mkl_free_buffers Usage with FFT Functions

```
-----
DFTI_DESCRIPTOR_HANDLE hand1;
DFTI_DESCRIPTOR_HANDLE hand2;
void mkl_free_buffers(void);
. . . . .
/* Using MKL FFT */
Status = DftiCreateDescriptor(&hand1, DFTI_SINGLE, DFTI_COMPLEX, dim, m1);
Status = DftiCommitDescriptor(hand1);
Status = DftiComputeForward(hand1, s_array1);
. . . . .
Status = DftiCreateDescriptor(&hand2, DFTI_SINGLE, DFTI_COMPLEX, dim, m2);
Status = DftiCommitDescriptor(hand2);
. . . . .
Status = DftiFreeDescriptor(&hand1);
/* Do not call mkl_free_buffers() here as the hand2 descriptor will be corrupted! */
. . . . .
Status = DftiComputeBackward(hand2, s_array2));
Status = DftiFreeDescriptor(&hand2);
/* Here user finishes the MKL FFT usage */
/* Memory leak will be triggered by any memory control tool */
/* Use mkl_free_buffers() to avoid memory leaking */
mkl_free_buffers();
-----
```

If the memory space is sufficient, use `mkl_free_buffers` after the last call of the MKL functions. Otherwise, a drop in performance can occur due to reallocation of buffers for the subsequent MKL functions.

WARNING. For FFT calls, do not use `mkl_free_buffers` between `DftiCreateDescriptor(hand)` and `DftiFreeDescriptor(&hand)`.

mkl_thread_free_buffers

Frees memory buffers allocated in the current thread.

Syntax

Fortran:

```
call mkl_thread_free_buffers
```

C:

```
mkl_thread_free_buffers();
```

Description

The FORTRAN 77 interface for this function is declared in `mkl_service.fi` and the C interface in `mkl_service.h`.

The `mkl_thread_free_buffers` function frees the memory allocated by the Intel MKL Memory Manager in the current thread only. Memory buffers allocated in other threads are not affected. Call `mkl_thread_free_buffers()` to avoid memory leaking if you are unable to call the `mkl_free_buffers` function in the multi-threaded application when you are not sure if all the other running Intel MKL functions completed operation.

mkl_mem_stat

Reports amount of memory utilized by MKL Memory Manager.

Syntax

Fortran:

```
AllocatedBytes = mkl_mem_stat( AllocatedBuffers )
```

C:

```
AllocatedBytes = mkl_mem_stat( &AllocatedBuffers );
```

Output Parameters

Name	Type	Description
<i>AllocatedBytes</i>	FORTRAN: INTEGER*8 C: MKL_INT64	Amount of allocated bytes
<i>AllocatedBuffers</i>	FORTRAN: INTEGER*4, C: int	Number of allocated buffers

Description

The FORTRAN 77 interface for this function is declared in `mkl_service.fi` and the C interface in `mkl_service.h`.

The function returns the amount of the allocated memory in the *AllocatedBuffers* buffers. If there are no allocated buffers at the moment, the function returns 0. Call the `mkl_mem_stat()` function to check the Intel MKL memory status.

Note that after calling `mkl_free_buffers` there should not be any allocated buffers.

See [Example “mkl_malloc\(\), mkl_free\(\), mkl_mem_stat\(\) Usage”](#).

NOTE. `MKL_MemStat` is an obsolete name for the `MKL_Mem_Stat` function that is referenced in the library for back compatibility purposes but is deprecated and subject to removal in subsequent releases.

mkl_malloc

Allocates the aligned memory buffer.

Syntax

Fortran:

```
a_ptr = mkl_malloc( alloc_size, alignment )
```

C:

```
a_ptr = mkl_malloc( alloc_size, alignment );
```

Input Parameters

Name	Type	Description
<i>alloc_size</i>	FORTTRAN: INTEGER*4 C: size_t	Size of the buffer to be allocated Note that Fortran type INTEGER*4 is given for the 32-bit systems. Otherwise, it is INTEGER*8.
<i>alignment</i>	FORTTRAN: INTEGER*4 C: int	Alignment of the allocated buffer

Output Parameters

Name	Type	Description
<i>a_ptr</i>	FORTTRAN: POINTER C: void*	Pointer to the allocated buffer

Description

The FORTRAN 77 interface for this function is declared in `mkl_service.fi` and the C interface in `mkl_service.h`.

The function allocates a *size*-bytes buffer, aligned on the *alignment* boundary, and returns a pointer to this buffer.

The function returns `NULL` if *size* < 1. If alignment is not power of 2, the alignment 32 is used.

See [Example “mkl_malloc\(\), mkl_free\(\), mkl_mem_stat\(\) Usage”](#).

mkl_free

Frees the aligned memory buffer allocated by mkl_malloc.

Syntax

Fortran:

```
call mkl_free( a_ptr )
```

C:

```
mkl_free( a_ptr );
```

Input Parameters

Name	Type	Description
a_ptr	FORTRAN: POINTER C: void*	Pointer to the buffer to be freed

Description

The FORTRAN 77 interface for this function is declared in `mkl_service.fi` and the C interface in `mkl_service.h`.

The function frees the buffer pointed by `ptr` and allocated by `mkl_malloc()`.

See [Example “mkl_malloc\(\), mkl_free\(\), mkl_mem_stat\(\) Usage”](#).

Examples of mkl_malloc(), mkl_free(), mkl_mem_stat() Usage

Usage Example in Fortran

```
PROGRAM FOO

REAL*8      A,B,C
POINTER      (A_PTR,A(1)), (B_PTR,B(1)), (C_PTR,C(1))
INTEGER      N,I
REAL*8      ALPHA, BETA
INTEGER*8    ALLOCATED_BYTES
INTEGER*4    ALLOCATED_BUFFERS

#ifdef  SYSTEM_BITS32
  INTEGER*4  MKL_MALLOC
  INTEGER*4  ALLOC_SIZE
#else
  INTEGER*8  MKL_MALLOC
  INTEGER*8  ALLOC_SIZE
#endif

INTEGER      MKL_MEM_STAT
EXTERNAL     MKL_MALLOC, MKL_FREE, MKL_MEM_STAT

ALPHA = 1.1; BETA = -1.2
N = 1000
```

```

ALLOC_SIZE = 8*N*N
A_PTR = MKL_MALLOC(ALLOC_SIZE,128)
B_PTR = MKL_MALLOC(ALLOC_SIZE,128)
C_PTR = MKL_MALLOC(ALLOC_SIZE,128)
DO I=1,N*N
    A(1) = I
    B(1) = -I
    C(1) = 0.0
END DO

CALL DGEMM('N','N',N,N,N,ALPHA,A,N,B,N,BETA,C,N);

ALLOCATED_BYTES = MKL_MEM_STAT(ALLOCATED_BUFFERS)
PRINT *, 'DGEMM uses ', ALLOCATED_BYTES, ' bytes in ',
$  ALLOCATED_BUFFERS, ' buffers '

CALL MKL_FREE_BUFFERS

ALLOCATED_BYTES = MKL_MEM_STAT(ALLOCATED_BUFFERS)
IF (ALLOCATED_BYTES > 0) THEN
    PRINT *, 'MKL MEMORY LEAK!'
    PRINT *, 'AFTER MKL_FREE_BUFFERS there are ',
$  ALLOCATED_BYTES, ' bytes in ',
$  ALLOCATED_BUFFERS, ' buffers'
END IF

CALL MKL_FREE(A_PTR)
CALL MKL_FREE(B_PTR)
CALL MKL_FREE(C_PTR)

STOP
END

```

Usage Example in C

```

#include <stdio.h>
#include <mkl.h>
int main(void) {
    double *a, *b, *c;
    int n, i;
    double alpha, beta;
    MKL_INT64 AllocatedBytes;
    int N_AllocatedBuffers;

    alpha = 1.1; beta = -1.2;
    n = 1000;
    a = (double*)mkl_malloc(n*n*sizeof(double),128);
    b = (double*)mkl_malloc(n*n*sizeof(double),128);
    c = (double*)mkl_malloc(n*n*sizeof(double),128);
    for (i=0;i<(n*n);i++) {
        a[i] = (double)(i+1);
    }
}

```

```

        b[i] = (double) (-i-1);
        c[i] = 0.0;
    }

    dgemm("N", "N", &n, &n, &n, &alpha, a, &n, b, &n, &beta, c, &n);

    AllocatedBytes = mkl_mem_stat(&N_AllocatedBuffers);
    printf("\nDGEMM uses %ld bytes in %d buffers', (long)AllocatedBytes, N_AllocatedBuffers);

    mkl_free_buffers();

    AllocatedBytes = mkl_mem_stat(&N_AllocatedBuffers);
    if (AllocatedBytes > 0) {
        printf("\nMKL memory leak!");
        printf("\nAfter mkl_free_buffers there are %ld bytes in %d buffers",
            (long)AllocatedBytes, N_AllocatedBuffers);
    }

    mkl_free(a);
    mkl_free(b);
    mkl_free(c);

    return 0;
}

```

Miscellaneous Utility Functions

mkl_progress

Provides progress information.

Syntax

Fortran:

```
stopflag = mkl_progress( thread, step, stage )
```

C:

```
stopflag = mkl_progress( thread, step, stage, lstage );
```

Input Parameters

Name	Type	Description
<i>thread</i>	FORTRAN: INTEGER*4 C: const int*	FORTRAN: The number of the thread the progress routine is called from. 0 is passed for sequential code. C: Pointer to the number of the thread the progress routine is called from. 0 is passed for sequential code.
<i>step</i>	FORTRAN: INTEGER*4 C: const int*	FORTRAN: The linear progress indicator that shows the amount of work done. Increases from 0 to the linear size of the problem during the computation. C: Pointer to the linear progress indicator that shows the amount of work done. Increases from 0 to the linear size of the problem during the computation.
<i>stage</i>	FORTRAN: CHARACTER* (*) C: const char*	Message indicating the name of the routine or the name of the computation stage the progress routine is called from.
<i>lstage</i>	C: int	The length of a stage string excluding the trailing NULL character.

Output Parameters

Name	Type	Description
<i>stopflag</i>	FORTRAN: INTEGER C: int	The stopping flag. A non-zero flag forces the routine to be interrupted. The zero flag is the default return value.

Description

The FORTRAN 77 interface for this function is declared in `mkl_service.fi`, and the C interface in `mkl_lapack.h` and `mkl_service.h`.

This function is intended to track progress of a lengthy computation and/or interrupt the computation. By default this routine does nothing but the user application can redefine it to obtain the computation progress information. You can set it to perform certain operations during the routine computation, for instance, to print a progress indicator. A non-zero return value may be supplied by the redefined function to break the computation.

The progress function `mkl_progress` is regularly called from some LAPACK and DSS/PARDISO functions during the computation. Refer to a specific LAPACK or DSS/PARDISO function description to see whether the function supports this feature or not.

Application Notes

Note that `mkl_progress` is a Fortran routine, that is, to redefine the progress routine from C, the name should be spelt differently, parameters should be passed by reference, and an extra parameter meaning the length of the stage string should be considered. The stage string is not terminated with the `NULL` character. The C interface of the progress routine is as follows:

```
int mkl_progress ( int* thread, int* step, char* stage, int lstage ); // Linux, Mac
int MKL_PROGRESS( int* thread, int* step, char* stage, int lstage ); // Windows
```

See further the examples of printing a progress information on the standard output in Fortran and C languages:

Examples

Fortran:

```
integer function mkl_progress( thread, step, stage )
integer*4 thread, step
character*(*) stage
print*, 'Thread:', thread, ', stage:', stage, ', step:', step
mkl_progress = 0
return
end
```

C:

```
#include <string.h>

#define BUFLen 16

int mkl_progress_( int* ithr, int* step, char* stage, int lstage
){
    char buf[BUFLen];
    if( lstage >= BUFLen ) lstage = BUFLen-1;
    strncpy( buf, stage, lstage );
    buf[lstage] = '\\0';
    printf( 'In thread %i, at stage %s, steps passed %i\\n', *ithr,
buf, *step );
    return 0;
}
```

mkl_enable_instructions

Allows dispatching Intel® Advanced Vector Extensions.

Syntax

Fortran:

```
irc = mkl_enable_instructions(MKL_AVX_ENABLE)
```

C:

```
irc = mkl_enable_instructions(MKL_AVX_ENABLE);
```

Input Parameters

<i>MKL_AVX_ENABLE</i>	Parameter indicating which new instructions the user needs to enable.
-----------------------	---

Output Parameters

Name	Type	Description
<i>irc</i>	FORTTRAN: INTEGER*4	Value reflecting AVX usage status:
	C: int	=1 MKL uses the AVX code, if the hardware supports Intel® AVX.
		=0 The request is rejected. Most likely, <code>mkl_enable_instructions</code> has been called after another Intel MKL function.

Description

The FORTRAN 77 interface for this function is declared in `mkl_service.fi` and the C interface in `mkl_service.h`.

This function allows Intel MKL to dispatch Intel® Advanced Vector Extensions (Intel® AVX) if run on Intel® AVX-enabled hardware (or simulation). Note that `mkl_enable_instructions` must be executed before any other Intel MKL call.

NOTE. Always remember to add `#include "mkl.h"` to use the C usage syntax.

See *Intel MKL User’s Guide* for implementation details.

BLACS Routines

This chapter describes the Intel® Math Kernel Library implementation of FORTRAN 77 routines from the BLACS (Basic Linear Algebra Communication Subprograms) package. These routines are used to support a linear algebra oriented message passing interface that may be implemented efficiently and uniformly across a large range of distributed memory platforms.

The BLACS routines make linear algebra applications both easier to program and more portable. For this purpose, they are used in Intel MKL intended for the Linux* and Windows* OSs as the communication layer of ScaLAPACK and Cluster FFT.

On computers, a linear algebra matrix is represented by a two dimensional array (2D array), and therefore the BLACS operate on 2D arrays. See description of the basic [matrix shapes](#) in a special section.

The BLACS routines implemented in Intel MKL are of four categories:

- Combines
- Point to Point Communication
- Broadcast
- Support.

The [Combines](#) take data distributed over processes and combine the data to produce a result. The [Point to Point](#) routines are intended for point-to-point communication and [Broadcast](#) routines send data possessed by one process to all processes within a scope.

The [Support routines](#) perform distinct tasks that can be used for initialization, destruction, information, and miscellaneous tasks.

Matrix Shapes

The BLACS routines recognize the two most common classes of matrices for dense linear algebra. The first of these classes consists of general rectangular matrices, which in machine storage are 2D arrays consisting of m rows and n columns, with a leading dimension, lda , that determines the distance between successive columns in memory.

The *general rectangular* matrices take the following parameters as input when determining what array to operate on:

m	(input) INTEGER. The number of matrix rows to be operated on.
n	(input) INTEGER. The number of matrix columns to be operated on.
a	(input/output) TYPE (depends on routine), array of dimension (lda, n) . A pointer to the beginning of the (sub)array to be sent.

lda (input) INTEGER. The distance between two elements in matrix row.

The second class of matrices recognized by the BLACS are *trapezoidal* matrices (triangular matrices are a sub-class of trapezoidal). Trapezoidal arrays are defined by m , n , and lda , as above, but they have two additional parameters as well. These parameters are:

uplo (input) CHARACTER*1 . Indicates whether the matrix is upper or lower trapezoidal, as discussed below.

diag (input) CHARACTER*1 . Indicates whether the diagonal of the matrix is unit diagonal (will not be operated on) or otherwise (will be operated on).

The shape of the trapezoidal arrays is determined by these parameters as follows:

Figure 16-1 Trapezoidal Arrays Shapes

The packing of arrays, if required, so that they may be sent efficiently is hidden, allowing the user to concentrate on the logical matrix, rather than on how the data is organized in the system memory.

BLACS Combine Operations

This section describes BLACS routines that combine the data to produce a result.

In a combine operation, each participating process contributes data that is combined with other processes' data to produce a result. This result can be given to a particular process (called the *destination* process), or to all participating processes. If the result is given to only one process, the operation is referred to as a *leave-on-one* combine, and if the result is given to all participating processes the operation is referenced as a *leave-on-all* combine.

At present, three kinds of combines are supported. They are:

- element-wise summation
- element-wise absolute value maximization
- element-wise absolute value minimization

of general rectangular arrays.

Note that a combine operation combines data between processes. By definition, a combine performed across a scope of only one process does not change the input data. This is why the operations (*max/min/sum*) are specified as *element-wise*. Element-wise indicates that each element of the input array will be combined with the corresponding element from all other processes' arrays to produce the result. Thus, a 4 x 2 array of inputs produces a 4 x 2 answer array.

When the *max/min* comparison is being performed, absolute value is used. For example, -5 and 5 are equivalent. However, the returned value is unchanged; that is, it is not the absolute value, but is a signed value instead. Therefore, if you performed a BLACS absolute value maximum combine on the numbers -5, 3, 1, 8 the result would be -8.

The initial symbol ? in the routine names below masks the data type:

i	integer
s	single precision real
d	double precision real
c	single precision complex
z	double precision complex.

Table 16-1 BLACS Combines

Routine name	Results of operation
?gamx2d	Entries of result matrix will have the value of the greatest absolute value found in that position.
?gamn2d	Entries of result matrix will have the value of the smallest absolute value found in that position.
?gsum2d	Entries of result matrix will have the summation of that position.

?gamx2d

Performs element-wise absolute value maximization.

Syntax

```
call igamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call sgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call dgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call cgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call zgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
<i>top</i>	CHARACTER*1. Communication pattern to use during the combine operation.
<i>m</i>	INTEGER. The number of matrix rows to be combined.
<i>n</i>	INTEGER. The number of matrix columns to be combined.
<i>a</i>	TYPE array (<i>lda</i> , <i>n</i>). Matrix to be compared with to produce the maximum.
<i>lda</i>	INTEGER. The leading dimension of the matrix <i>A</i> , that is, the distance between two successive elements in a matrix row.
<i>rcflag</i>	INTEGER. If <i>rcflag</i> = -1, the arrays <i>ra</i> and <i>ca</i> are not referenced and need not exist. Otherwise, <i>rcflag</i> indicates the leading dimension of these arrays, and so must be $\geq m$.

<i>rdest</i>	<p>INTEGER.</p> <p>The process row coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.</p>
<i>cdest</i>	<p>INTEGER.</p> <p>The process column coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.</p>

Output Parameters

<i>a</i>	<p>TYPE array (<i>lda</i>, <i>n</i>). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.</p>
<i>ra</i>	<p>INTEGER array (<i>rcflag</i>, <i>n</i>).</p> <p>If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> × <i>n</i>) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.</p>
<i>ca</i>	<p>INTEGER array (<i>rcflag</i>, <i>n</i>).</p> <p>If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> × <i>n</i>) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.</p>

Description

This routine performs element-wise absolute value maximization, that is, each element of matrix *A* is compared with the corresponding element of the other process's matrices. Note that the value of *A* is returned, but the absolute value is used to determine the maximum (the 1-norm is used for complex numbers). Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

?gamn2d

Performs element-wise absolute value minimization.

Syntax

```
call igamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call sgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call dgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call cgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call zgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
<i>top</i>	CHARACTER*1. Communication pattern to use during the combine operation.
<i>m</i>	INTEGER. The number of matrix rows to be combined.
<i>n</i>	INTEGER. The number of matrix columns to be combined.
<i>a</i>	TYPE array (lda, n). Matrix to be compared with to produce the minimum.
<i>lda</i>	INTEGER. The leading dimension of the matrix A, that is, the distance between two successive elements in a matrix row.
<i>rcflag</i>	INTEGER.

If *rcflag* = -1, the arrays *ra* and *ca* are not referenced and need not exist. Otherwise, *rcflag* indicates the leading dimension of these arrays, and so must be $\geq m$.

rdest

INTEGER.

The process row coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.

cdest

INTEGER.

The process column coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.

Output Parameters

a

TYPE array (*lda*, *n*). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.

ra

INTEGER array (*rcflag*, *n*).

If *rcflag* = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least *rcflag* \times *n*) indicating the row index of the process that provided the minimum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

ca

INTEGER array (*rcflag*, *n*).

If *rcflag* = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least *rcflag* \times *n*) indicating the row index of the process that provided the minimum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

Description

This routine performs element-wise absolute value minimization, that is, each element of matrix *A* is compared with the corresponding element of the other process's matrices. Note that the value of *A* is returned, but the absolute value is used to determine the minimum (the 1-norm is used for complex numbers). Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

?gsum2d

Performs element-wise summation.

Syntax

```
call igsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call sgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call dgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call cgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call zgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
<i>top</i>	CHARACTER*1. Communication pattern to use during the combine operation.
<i>m</i>	INTEGER. The number of matrix rows to be combined.
<i>n</i>	INTEGER. The number of matrix columns to be combined.
<i>a</i>	TYPE array (lda, n). Matrix to be added to produce the sum.
<i>lda</i>	INTEGER. The leading dimension of the matrix <i>A</i> , that is, the distance between two successive elements in a matrix row.
<i>rdest</i>	INTEGER. The process row coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.
<i>cdest</i>	INTEGER.

The process column coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.

Output Parameters

a TYPE array (*lda*, *n*). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.

Description

This routine performs element-wise summation, that is, each element of matrix *A* is summed with the corresponding element of the other process's matrices. Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

BLACS Point To Point Communication

This section describes BLACS routines for point to point communication.

Point to point communication requires two complementary operations. The *send* operation produces a message that is then consumed by the *receive* operation. These operations have various resources associated with them. The main such resource is the buffer that holds the data to be sent or serves as the area where the incoming data is to be received. The level of *blocking* indicates what correlation the return from a send/receive operation has with the availability of these resources and with the status of message.

Non-blocking

The return from the *send* or *receive* operations does not imply that the resources may be reused, that the message has been sent/received or that the complementary operation has been called. Return means only that the send/receive has been started, and will be completed at some later date. Polling is required to determine when the operation has finished.

In non-blocking message passing, the concept of *communication/computation overlap* (abbreviated C/C overlap) is important. If a system possesses C/C overlap, independent computation can occur at the same time as communication. That means a nonblocking operation can be posted, and unrelated work can be done while the message is sent/received in parallel. If C/C overlap is not present, after returning from the routine call, computation will be interrupted at some later date when the message is actually sent or received.

Locally-blocking

Return from the *send* or *receive* operations indicates that the resources may be reused. However, since this only depends on local information, it is unknown whether the complementary operation has been called. There are no locally-blocking receives: the send must be completed before the receive buffer is available for re-use.

If a receive has not been posted at the time a locally-blocking send is issued, buffering will be required to avoid losing the message. Buffering can be done on the sending process, the receiving process, or not done at all, losing the message.

Globally-blocking

Return from a globally-blocking procedure indicates that the operation resources may be reused, and that complement of the operation has at least been posted. Since the receive has been posted, there is no buffering required for globally-blocking sends: the message is always sent directly into the user's receive buffer.

Almost all processors support non-blocking communication, as well as some other level of blocking sends. What level of blocking the send possesses varies between platforms. For instance, the Intel® processors support locally-blocking sends, with buffering done on the

receiving process. This is a very important distinction, because codes written assuming locally-blocking sends will hang on platforms with globally-blocking sends. Below is a simple example of how this can occur:

```
IAM = MY_PROCESS_ID()
IF (IAM .EQ. 0) THEN
    SEND TO PROCESS 1
    RECV FROM PROCESS 1
ELSE IF (IAM .EQ. 1) THEN
    SEND TO PROCESS 0
    RECV FROM PROCESS 0
END IF
```

If the send is globally-blocking, process 0 enters the send, and waits for process 1 to start its receive before continuing. In the meantime, process 1 starts to send to 0, and waits for 0 to receive before continuing. Both processes are now waiting on each other, and the program will never continue.

The solution for this case is obvious. One of the processes simply reverses the order of its communication calls and the hang is avoided. However, when the communication is not just between two processes, but rather involves a hierarchy of processes, determining how to avoid this kind of difficulty can become problematic.

For this reason, it was decided the BLACS would support locally-blocking sends. On systems natively supporting globally-blocking sends, non-blocking sends coupled with buffering is used to simulate locally-blocking sends. The BLACS support globally-blocking receives.

In addition, the BLACS specify that point to point messages between two given processes will be strictly ordered. If process 0 sends three messages (label them *A*, *B*, and *C*) to process 1, process 1 must receive *A* before it can receive *B*, and message *C* can be received only after both *A* and *B*. The main reason for this restriction is that it allows for the computation of message identifiers.

Note, however, that messages from different processes are not ordered. If processes 0, . . . , 3 send messages *A*, . . . , *D* to process 4, process 4 may receive these messages in any order that is convenient.

Convention

The convention used in the communication routine names follows the template `?xxyy2d`, where the letter in the `?` position indicates the data type being sent, `xx` is replaced to indicate the shape of the matrix, and the `yy` positions are used to indicate the type of communication to perform:

i	integer
s	single precision real
d	double precision real
c	single precision complex
z	double precision complex
ge	The data to be communicated is stored in a general rectangular matrix.
tr	The data to be communicated is stored in a trapezoidal matrix.
sd	Send. One process sends to another.
rv	Receive. One process receives from another.

Table 16-2 BLACS Point To Point Communication

Routine name	Operation performed
<code>?gesd2d</code>	Take the indicated matrix and send it to the destination process.
<code>?trsd2d</code>	
<code>?gerv2d</code>	Receive a message from the process into the matrix.
<code>?trrv2d</code>	

As a simple example, the pseudo code given above is rewritten below in terms of the BLACS. It is further specified that the data being exchanged is the double precision vector x , which is 5 elements long.

```
CALL GRIDINFO(NPROW, NPCOL, MYPROW, MYPCOL)

IF (MYPROW.EQ.0 .AND. MYPCOL.EQ.0) THEN
    CALL DGESD2D(5, 1, X, 5, 1, 0)
    CALL DGERV2D(5, 1, X, 5, 1, 0)
ELSE IF (MYPROW.EQ.1 .AND. MYPCOL.EQ.0) THEN
    CALL DGESD2D(5, 1, X, 5, 0, 0)
    CALL DGERV2D(5, 1, X, 5, 0, 0)
END IF
```

?gesd2d

Takes a general rectangular matrix and sends it to the destination process.

Syntax

```
call igesd2d( icontxt, m, n, a, lda, rdest, cdest )
call sgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call dgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call cgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call zgesd2d( icontxt, m, n, a, lda, rdest, cdest )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>m, n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rdest</i>	INTEGER. The process row coordinate of the process to send the message to.
<i>cdest</i>	INTEGER.

The process column coordinate of the process to send the message to.

Description

This routine takes the indicated general rectangular matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix *A*) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

See Also

- [BLACS Point To Point Communication](#)
- [BLACS Routines Usage Example](#)

?trsd2d

Takes a trapezoidal matrix and sends it to the destination process.

Syntax

```
call itrtd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call strtd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call dtrtd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call ctrtd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call ztrtd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>uplo, diag, m, n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rdest</i>	INTEGER. The process row coordinate of the process to send the message to.
<i>cdest</i>	INTEGER. The process column coordinate of the process to send the message to.

Description

This routine takes the indicated trapezoidal matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix *A*) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

?gerv2d

Receives a message from the process into the general rectangular matrix.

Syntax

```
call igerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call sgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call dgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call cgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call zgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER. The process row coordinate of the source of the message.
<i>csrc</i>	INTEGER. The process column coordinate of the source of the message.

Output Parameters

<i>a</i>	An array of dimension (lda, n) to receive the incoming message into.
----------	--

Description

This routine receives a message from process {RSRC, CSRC} into the general rectangular matrix *A*. This routine is globally-blocking, that is, return from the routine indicates that the message has been received into *A*.

See Also

- [BLACS Point To Point Communication](#)
- [BLACS Routines Usage Example](#)

?trrv2d

Receives a message from the process into the trapezoidal matrix.

Syntax

```
call itrsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call strsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call dtrsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call ctrsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call ztrsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>uplo, diag, m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER. The process row coordinate of the source of the message.
<i>csrc</i>	INTEGER. The process column coordinate of the source of the message.

Output Parameters

<i>a</i>	An array of dimension (lda, n) to receive the incoming message into.
----------	--

Description

This routine receives a message from process {RSRC, CSRC} into the trapezoidal matrix *A*. This routine is globally-blocking, that is, return from the routine indicates that the message has been received into *A*.

BLACS Broadcast Routines

This section describes BLACS broadcast routines.

A broadcast sends data possessed by one process to all processes within a scope. Broadcast, much like point to point communication, has two complementary operations. The process that owns the data to be broadcast issues a *broadcast/send*. All processes within the same scope must then issue the complementary *broadcast/receive*.

The BLACS define that both broadcast/send and broadcast/receive are *globally-blocking*. Broadcasts/receives cannot be locally-blocking since they must post a receive. Note that receives cannot be locally-blocking. When a given process can leave, a broadcast/receive operation is topology dependent, so, to avoid a hang as topology is varied, the broadcast/receive must be treated as if no process can leave until all processes have called the operation.

Broadcast/sends could be defined to be *locally-blocking*. Since no information is being received, as long as locally-blocking point to point sends are used, the broadcast/send will be locally blocking. However, defining one process within a scope to be locally-blocking while all other processes are globally-blocking adds little to the programmability of the code. On the other hand, leaving the option open to have globally-blocking broadcast/sends may allow for optimization on some platforms.

The fact that broadcasts are defined as globally-blocking has several important implications. The first is that scoped operations (broadcasts or combines) must be strictly ordered, that is, all processes within a scope must agree on the order of calls to separate scoped operations. This constraint falls in line with that already in place for the computation of message IDs, and is present in point to point communication as well.

A less obvious result is that scoped operations with `SCOPE = 'ALL'` must be ordered with respect to any other scoped operation. This means that if there are two broadcasts to be done, one along a column, and one involving the entire process grid, all processes within the process column issuing the column broadcast must agree on which broadcast will be performed first.

The convention used in the communication routine names follows the template `?xxyy2d`, where the letter in the `?` position indicates the data type being sent, `xx` is replaced to indicate the shape of the matrix, and the `yy` positions are used to indicate the type of communication to perform:

`i` integer

s	single precision real
d	double precision real
c	single precision complex
z	double precision complex
ge	The data to be communicated is stored in a general rectangular matrix.
tr	The data to be communicated is stored in a trapezoidal matrix.
bs	Broadcast/send. A process begins the broadcast of data within a scope.
br	Broadcast/receive A process receives and participates in the broadcast of data within a scope.

Table 16-3 BLACS Broadcast Routines

Routine name	Operation performed
<code>?gebs2d</code>	Start a broadcast along a scope.
<code>?trbs2d</code>	
<code>?gebr2d</code>	Receive and participate in a broadcast along a scope.
<code>?trbr2d</code>	

?gebs2d

Starts a broadcast along a scope for a general rectangular matrix.

Syntax

```
call igebs2d( icontxt, scope, top, m, n, a, lda )
call sgebs2d( icontxt, scope, top, m, n, a, lda )
call dgebs2d( icontxt, scope, top, m, n, a, lda )
call cgebs2d( icontxt, scope, top, m, n, a, lda )
call zgebs2d( icontxt, scope, top, m, n, a, lda )
```

Input Parameters

icontxt INTEGER. Integer handle that indicates the context.

<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>m, n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.

Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix *A*.

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

See Also

- [BLACS Broadcast Routines](#)
- [BLACS Routines Usage Example](#)

?trbs2d

Starts a broadcast along a scope for a trapezoidal matrix.

Syntax

```
call itrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call strbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call dtrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call ctrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call ztrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.

<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>uplo, diag, m, n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.

Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix *A*.

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

?gebr2d

Receives and participates in a broadcast along a scope for a general rectangular matrix.

Syntax

```
call igebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call sgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call dgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call cgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call zgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER.

csrc The process row coordinate of the process that called broadcast/send.
 INTEGER.
 The process column coordinate of the process that called broadcast/send.

Output Parameters

a An array of dimension (lda, n) to receive the incoming message into.

Description

This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix *A*. Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

See Also

- [BLACS Broadcast Routines](#)

?trbr2d

Receives and participates in a broadcast along a scope for a trapezoidal matrix.

Syntax

```
call itrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call strbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call dtrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call ctrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call ztrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
```

Input Parameters

icontxt INTEGER. Integer handle that indicates the context.

<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>uplo, diag, m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER. The process row coordinate of the process that called broadcast/send.
<i>csrc</i>	INTEGER. The process column coordinate of the process that called broadcast/send.

Output Parameters

<i>a</i>	An array of dimension (lda, n) to receive the incoming message into.
----------	--

Description

This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix *A*. Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

BLACS Support Routines

The support routines perform distinct tasks that can be used for:

[Initialization](#)

[Destruction](#)

[Information Purposes](#)

[Miscellaneous Tasks.](#)

Initialization Routines

This section describes BLACS routines that deal with grid/context creation, and processing before the grid/context has been defined.

Table 16-4 BLACS Initialization Routines

Routine name	Operation performed
<code>blacs_pinfo</code>	Returns the number of processes available for use.
<code>blacs_setup</code>	Allocates virtual machine and spawns processes.
<code>blacs_get</code>	Gets values that BLACS use for internal defaults.
<code>blacs_set</code>	Sets values that BLACS use for internal defaults.
<code>blacs_gridinit</code>	Assigns available processes into BLACS process grid.
<code>blacs_gridmap</code>	Maps available processes into BLACS process grid.

blacs_pinfo

Returns the number of processes available for use.

Syntax

```
call blacs_pinfo( mypnum, nprocs )
```

Output Parameters

<i>mypnum</i>	INTEGER. An integer between 0 and (<i>nprocs</i> - 1) that uniquely identifies each process.
<i>nprocs</i>	INTEGER. The number of processes available for BLACS use.

Description

This routine is used when some initial system information is required before the BLACS are set up. On all platforms except PVM, *nprocs* is the actual number of processes available for use, that is, $nrows * ncols \leq nprocs$. In PVM, the virtual machine may not have been set up before this call, and therefore no parallel machine exists. In this case, *nprocs* is returned as less than one. If a process has been spawned via the keyboard, it receives *mypnum* of 0, and all other processes get *mypnum* of -1. As a result, the user can distinguish between processes. Only after the virtual machine has been set up via a call to `BLACS_SETUP`, this routine returns the correct values for *mypnum* and *nprocs*.

See Also

- [Initialization Routines](#)
- [BLACS Routines Usage Example](#)

blacs_setup

Allocates virtual machine and spawns processes.

Syntax

```
call blacs_setup( mypnum, nprocs )
```

Input Parameters

<i>nprocs</i>	INTEGER. On the process spawned from the keyboard rather than from <code>pvmspawn</code> , this parameter indicates the number of processes to create when building the virtual machine.
---------------	--

Output Parameters

<i>mypnum</i>	INTEGER. An integer between 0 and (<i>nprocs</i> - 1) that uniquely identifies each process.
<i>nprocs</i>	INTEGER. For all processes other than spawned from the keyboard, this parameter means the number of processes available for BLACS use.

Description

This routine only accomplishes meaningful work in the PVM BLACS. On all other platforms, it is functionally equivalent to `blacs_pinfo`. The BLACS assume a static system, that is, the given number of processes does not change. PVM supplies a dynamic system, allowing processes to be added to the system on the fly.

`blacs_setup` is used to allocate the virtual machine and spawn off processes. It reads in a file called `blacs_setup.dat`, in which the first line must be the name of your executable. The second line is optional, but if it exists, it should be a PVM spawn flag. Legal values at this time are 0 (`PvmTaskDefault`), 4 (`PvmTaskDebug`), 8 (`PvmTaskTrace`), and 12 (`PvmTaskDebug + PvmTaskTrace`). The primary reason for this line is to allow the user to easily turn on and off PVM debugging. Additional lines, if any, specify what machines should be added to the current configuration before spawning *nprocs*-1 processes to the machines in a round robin fashion.

nprocs is input on the process which has no PVM parent (that is, *mypnum*=0), and both parameters are output for all processes. So, on PVM systems, the call to `blacs_pinfo` informs you that the virtual machine has not been set up, and a call to `blacs_setup` then sets up the machine and returns the real values for *mypnum* and *nprocs*.

Note that if the file `blacs_setup.dat` does not exist, the BLACS prompt the user for the executable name, and processes are spawned to the current PVM configuration.

See Also

- [Initialization Routines](#)
- [BLACS Routines Usage Example](#)

blacs_get

Gets values that BLACS use for internal defaults.

Syntax

```
call blacs_get( icontxt, what, val )
```

Input Parameters

<i>icontxt</i>	INTEGER. On values of <i>what</i> that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.
<i>what</i>	<p>INTEGER. Indicates what BLACS internal(s) should be returned in <i>val</i>. Present options are:</p> <ul style="list-style-type: none"> • <i>what</i> = 0 : Handle indicating default system context • <i>what</i> = 1 : The BLACS message ID range • <i>what</i> = 2 : The BLACS debug level the library was compiled with • <i>what</i> = 10 : Handle indicating the system context used to define the BLACS context whose handle is <i>icontxt</i> • <i>what</i> = 11 : Number of rings multiring topology is presently using • <i>what</i> = 12 : Number of branches general tree topology is presently using.

Output Parameters

val INTEGER. The value of the BLACS internal.

Description

This routine gets the values that the BLACS are using for internal defaults. Some values are tied to a BLACS context, and some are more general. The most common use is in retrieving a default system context for input into `blacs_gridinit` or `blacs_gridmap`.

Some systems, such as MPI*, supply their own version of context. For those users who mix system code with BLACS code, a BLACS context should be formed in reference to a system context. Thus, the grid creation routines take a system context as input. If you wish to have strictly portable code, you may use `blacs_get` to retrieve a default system context that will include all available processes. This value is not tied to a BLACS context, so the parameter *icontxt* is unused.

`blacs_get` returns information on three quantities that are tied to an individual BLACS context, which is passed in as `icontxt`. The information that may be retrieved is:

- The handle of the system context upon which this BLACS context was defined
- The number of rings for `TOP = 'M'` (multiring broadcast)
- The number of branches for `TOP = 'T'` (general tree broadcast/general tree gather).

See Also

- Initialization Routines
- BLACS Routines Usage Example

blacs_set

Sets values that BLACS use for internal defaults.

Syntax

```
call blacs_set( icontxt, what, val )
```

Input Parameters

icontxt INTEGER. For values of *what* that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.

<i>what</i>	<p>INTEGER. Indicates what BLACS internal(s) should be set. Present values are:</p> <ul style="list-style-type: none"> • 1 = The BLACS message ID range • 11 = Number of rings for multiring topology to use • 12 = Number of branches for general tree topology to use.
<i>val</i>	<p>INTEGER. Array of dimension (*). Indicates the value(s) the internals should be set to. The specific meanings depend on <i>what</i> values, as discussed in Description below.</p>

Description

This routine sets the BLACS internal defaults depending on *what* values:

<i>what</i> = 1	<p>Setting the BLACS message ID range.</p> <p>If you wish to mix the BLACS with other message-passing packages, restrict the BLACS to a certain message ID range not to be used by the non-BLACS routines. The message ID range must be set before the first call to <code>blacs_gridinit</code> or <code>blacs_gridmap</code>. Subsequent calls will have no effect. Because the message ID range is not tied to a particular context, the parameter <i>icontxt</i> is ignored, and <i>val</i> is defined as:</p> <p>VAL (input) INTEGER array of dimension (2)</p> <p>VAL(1) : The smallest message ID (also called message type or message tag) the BLACS should use.</p> <p>VAL(2) : The largest message ID (also called message type or message tag) the BLACS should use.</p>
<i>what</i> = 11	<p>Set number of rings for TOP = 'M' (multiring broadcast). This quantity is tied to a context, so <i>icontxt</i> is used, and <i>val</i> is defined as:</p> <p>VAL (input) INTEGER array of dimension (1)</p> <p>VAL(1) : The number of rings for multiring topology to use.</p>
<i>what</i> = 12	<p>Set number of rings for TOP = 'T' (general tree broadcast/general tree gather). This quantity is tied to a context, so <i>icontxt</i> is used, and <i>val</i> is defined as:</p> <p>VAL (input) INTEGER array of dimension (1)</p> <p>VAL(1) : The number of branches for general tree topology to use.</p>

blacs_gridinit

Assigns available processes into BLACS process grid.

Syntax

```
call blacs_gridinit( icontxt, order, nprow, npcol )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle indicating the system context to be used in creating the BLACS context. Call <code>blacs_get</code> to obtain a default system context.
<i>order</i>	CHARACTER*1. Indicates how to map processes to BLACS grid. Options are: <ul style="list-style-type: none"> • 'R' : Use row-major natural ordering • 'C' : Use column-major natural ordering • ELSE : Use row-major natural ordering
<i>nprow</i>	INTEGER. Indicates how many process rows the process grid should contain.
<i>npcol</i>	INTEGER. Indicates how many process columns the process grid should contain.

Output Parameters

<i>icontxt</i>	INTEGER. Integer handle to the created BLACS context.
----------------	---

Description

All BLACS codes must call this routine, or its sister routine `blacs_gridmap`. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are actual processors (hardware), and they are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine `blacs_setup` should be used to create the virtual machine.

This routine creates a simple `nprow × npcol` process grid. This process grid uses the first `nprow * npcol` processes, and assigns them to the grid in a row- or column-major natural ordering. If these process-to-grid mappings are unacceptable, call `blacs_gridmap`.

blacs_gridmap

Maps available processes into BLACS process grid.

Syntax

```
call blacs_gridmap( icontxt, usermap, ldumap, nprow, npcol )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle indicating the system context to be used in creating the BLACS context. Call <code>blacs_get</code> to obtain a default system context.
<i>usermap</i>	INTEGER. Array, dimension (<i>ldumap</i> , <i>npcol</i>), indicating the process-to-grid mapping.
<i>ldumap</i>	INTEGER. Leading dimension of the 2D array <i>usermap</i> . <i>ldumap</i> ≥ <i>nprow</i> .
<i>nprow</i>	INTEGER. Indicates how many process rows the process grid should contain.

npcol INTEGER. Indicates how many process columns the process grid should contain.

Output Parameters

icontxt INTEGER. Integer handle to the created BLACS context.

Description

All BLACS codes must call this routine, or its sister routine `blacs_gridinit`. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are actual processors (hardware), and they are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine `blacs_setup` should be used to create the virtual machine.

This routine allows the user to map processes to the process grid in an arbitrary manner. `usermap(i,j)` holds the process number of the process to be placed in `{i, j}` of the process grid. On most distributed systems, this process number is a machine defined number between 0 ... `nprow-1`. For PVM, these node numbers are the PVM TIDS (Task IDs). The `blacs_gridmap` routine is intended for an experienced user. The `blacs_gridinit` routine is much simpler. `blacs_gridinit` simply performs a `gridmap` where the first `nprow * npcol` processes are mapped into the current grid in a row-major natural ordering. If you are an experienced user, `blacs_gridmap` allows you to take advantage of your system's actual layout. That is, you can map nodes that are physically connected to be neighbors in the BLACS grid, etc. The `blacs_gridmap` routine also opens the way for *multigridding*: you can separate your nodes into arbitrary grids, join them together at some later date, and then re-split them into new grids. `blacs_gridmap` also provides the ability to make arbitrary grids or subgrids (for example, a "nearest neighbor" grid), which can greatly facilitate operations among processes that do not fall on a row or column of the main process grid.

Destruction Routines

This section describes BLACS routines that destroy grids, abort processes, and free resources.

Table 16-5 BLACS Destruction Routines

Routine name	Operation performed
<code>blacs_freebuff</code>	Frees BLACS buffer.
<code>blacs_gridexit</code>	Frees a BLACS context.
<code>blacs_abort</code>	Aborts all processes.
<code>blacs_exit</code>	Frees all BLACS contexts and releases all allocated memory.

`blacs_freebuff`

Frees BLACS buffer.

Syntax

```
call blacs_freebuff( icontxt, wait )
```

Input Parameters

<code>icontxt</code>	INTEGER. Integer handle that indicates the BLACS context.
<code>wait</code>	INTEGER. Parameter indicating whether to wait for non-blocking operations or not. If equals 0, the operations should not be waited for; free only unused buffers. Otherwise, wait in order to free all buffers.

Description

This routine releases the BLACS buffer.

The BLACS have at least one internal buffer that is used for packing messages. The number of internal buffers depends on what platform you are running the BLACS on. On systems where memory is tight, keeping this buffer or buffers may become expensive. Call `freebuff` to release the buffer. However, the next call of a communication routine that requires packing reallocates the buffer.

The `wait` parameter determines whether the BLACS should wait for any non-blocking operations to be completed or not. If `wait = 0`, the BLACS free any buffers that can be freed without waiting. If `wait` is not 0, the BLACS free all internal buffers, even if non-blocking operations must be completed first.

blacs_gridexit

Frees a BLACS context.

Syntax

```
call blacs_gridexit( ictxt )
```

Input Parameters

<code>ictxt</code>	INTEGER. Integer handle that indicates the BLACS context to be freed.
--------------------	---

Description

This routine frees a BLACS context.

Release the resources when contexts are no longer needed. After freeing a context, the context no longer exists, and its handle may be re-used if new contexts are defined.

blacs_abort

Aborts all processes.

Syntax

```
call blacs_abort( ictxt, errornum )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the BLACS context to be aborted.
<i>errornum</i>	INTEGER. User-defined integer error number.

Description

This routine aborts all the BLACS processes, not only those confined to a particular context.

Use `blacs_abort` to abort all the processes in case of a serious error. Note that both parameters are input, but the routine uses them only in printing out the error message. The context handle passed in is not required to be a valid context handle.

blacs_exit

Frees all BLACS contexts and releases all allocated memory.

Syntax

```
call blacs_exit( continue )
```

Input Parameters

<i>continue</i>	INTEGER. Flag indicating whether message passing continues after the BLACS are done. If <i>continue</i> is non-zero, the user is assumed to continue using the machine after completing the BLACS. Otherwise, no message passing is assumed after calling this routine.
-----------------	---

Description

This routine frees all BLACS contexts and releases all allocated memory.

This routine should be called when a process has finished all use of the BLACS. The *continue* parameter indicates whether the user will be using the underlying communication platform after the BLACS are finished. This information is most important for the PVM BLACS. If *continue* is set to 0, then `pvm_exit` is called; otherwise, it is not called. Setting *continue* not equal to 0 indicates that explicit PVM `send/recvs` will be called after the BLACS routines are used. Make sure your code calls `pvm_exit`. PVM users should either call `blacs_exit` or explicitly call `pvm_exit` to avoid PVM problems.

Informational Routines

This section describes BLACS routines that return information involving the process grid.

Table 16-6 BLACS Informational Routines

Routine name	Operation performed
<code>blacs_gridinfo</code>	Returns information on the current grid.
<code>blacs_pnum</code>	Returns the system process number of the process in the process grid.
<code>blacs_pcoord</code>	Returns the row and column coordinates in the process grid.

blacs_gridinfo

Returns information on the current grid.

Syntax

```
call blacs_gridinfo( icontxt, nprow, npcol, myprow, mypcol )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
----------------	---

Output Parameters

<i>nprow</i>	INTEGER. Number of process rows in the current process grid.
<i>npcol</i>	INTEGER. Number of process columns in the current process grid.
<i>mypro</i>	INTEGER. Row coordinate of the calling process in the process grid.
<i>mypcol</i>	INTEGER. Column coordinate of the calling process in the process grid.

Description

This routine returns information on the current grid. If the context handle does not point at a valid context, all quantities are returned as -1.

See Also

- [Informational Routines](#)
- [BLACS Routines Usage Example](#)

blacs_pnum

Returns the system process number of the process in the process grid.

Syntax

```
call blacs_pnum( ictxt, prow, pcol )
```

Input Parameters

<i>ictxt</i>	INTEGER. Integer handle that indicates the context.
<i>prow</i>	INTEGER. Row coordinate of the process the system process number of which is to be determined.
<i>pcol</i>	INTEGER. Column coordinate of the process the system process number of which is to be determined.

Description

This function returns the system process number of the process at {*PROW*, *PCOL*} in the process grid.

See Also

- [Informational Routines](#)
- [BLACS Routines Usage Example](#)

blacs_pcoord

Returns the row and column coordinates in the process grid.

Syntax

```
call blacs_pcoord( ictxt, pnum, prow, pcol )
```

Input Parameters

<i>ictxt</i>	INTEGER. Integer handle that indicates the context.
<i>pnum</i>	INTEGER. Process number the coordinates of which are to be determined. This parameter stand for the process number of the underlying machine, that is, it is a <code>tid</code> for PVM.

Output Parameters

<i>prow</i>	INTEGER. Row coordinates of the <i>pnum</i> process in the BLACS grid.
<i>pcol</i>	INTEGER. Column coordinates of the <i>pnum</i> process in the BLACS grid.

Description

Given the system process number, this function returns the row and column coordinates in the BLACS process grid.

Miscellaneous Routines

This section describes `blacs_barrier` routine.

Table 16-7 BLACS Informational Routines

Routine name	Operation performed
<code>blacs_barrier</code>	Holds up execution of all processes within the indicated scope until they have all called the routine.

blacs_barrier

Holds up execution of all processes within the indicated scope.

Syntax

```
call blacs_barrier( icontxt, scope )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Parameter that indicates whether a process row (<i>scope</i> ='R'), column ('C'), or entire grid ('A') will participate in the barrier.

Description

This routine holds up execution of all processes within the indicated scope until they have all called the routine.

Examples of BLACS Routines Usage

Example 16-1. BLACS Usage. Hello World

The following routine takes the available processes, forms them into a process grid, and then has each process check in with the process at {0,0} in the process grid.

```
PROGRAM HELLO

Example 16-2. BLACS Usage. PROCMAP

This routine maps processes to a grid using `blacs_gridmap`.

```

SUBROUTINE PROCMAP(CONTEXT, MAPPING, BEGPROC, NPROW, NPCOL, IMAP)

*
*   -- BLACS example code --
*   Written by Clint Whaley 7/26/94
*   ..
*   .. Scalar Arguments ..
      INTEGER CONTEXT, MAPPING, BEGPROC, NPROW, NPCOL
*   ..
*   .. Array Arguments ..
      INTEGER IMAP(NPROW, *)
*   ..
*
* Purpose
* =====
*
* PROCMAP maps NPROW*NPCOL processes starting from process BEGPROC to
* the grid in a variety of ways depending on the parameter MAPPING.
*
* Arguments
* =====
*
* CONTEXT      (output) INTEGER
*
*              This integer is used by the BLACS to indicate a context.
*
*              A context is a universe where messages exist and do not
*
*              interact with other context's messages.  The context
*
*              includes the definition of a grid, and each process's

```

* coordinates in it.

*

* MAPPING (input) INTEGER

* Way to map processes to grid. Choices are:

* 1 : row-major natural ordering

* 2 : column-major natural ordering

*

* BEGPROC (input) INTEGER

* The process number (between 0 and NPROCS-1) to use as

* {0,0}. From this process, processes will be assigned

* to the grid as indicated by MAPPING.

*

* NPROW (input) INTEGER

* The number of process rows the created grid

* should have.

*

* NPCOL (input) INTEGER

* The number of process columns the created grid

* should have.

*

* IMAP (workspace) INTEGER array of dimension (NPROW, NPCOL)

* Workspace, where the array which maps the

* processes to the grid will be stored for the

* call to GRIDMAP.

Linear Solvers Basics

Many applications in science and engineering require the solution of a system of linear equations. This problem is usually expressed mathematically by the matrix-vector equation, $Ax = b$, where A is an m -by- n matrix, x is the n element column vector and b is the m element column vector. The matrix A is usually referred to as the coefficient matrix, and the vectors x and b are referred to as the solution vector and the right-hand side, respectively.

Basic concepts related to solving linear systems with sparse matrices are described in section [Sparse Linear Systems](#) that follows.

Sparse Linear Systems

In many real-life applications, most of the elements in A are zero. Such a matrix is referred to as sparse. Conversely, matrices with very few zero elements are called dense. For sparse matrices, computing the solution to the equation $Ax = b$ can be made much more efficient with respect to both storage and computation time, if the sparsity of the matrix can be exploited. The more an algorithm can exploit the sparsity without sacrificing the correctness, the better the algorithm.

Generally speaking, computer software that finds solutions to systems of linear equations is called a solver. A solver designed to work specifically on sparse systems of equations is called a sparse solver. Solvers are usually classified into two groups - direct and iterative.

Iterative Solvers start with an initial approximation to a solution and attempt to estimate the difference between the approximation and the true result. Based on the difference, an iterative solver calculates a new approximation that is closer to the true result than the initial approximation. This process is repeated until the difference between the approximation and the true result is sufficiently small. The main drawback to iterative solvers is that the rate of convergence depends greatly on the values in the matrix A . Consequently, it is not possible to predict how long it will take for an iterative solver to produce a solution. In fact, for ill-conditioned matrices, the iterative process will not converge to a solution at all. However, for well-conditioned matrices it is possible for iterative solvers to converge to a solution very quickly. Consequently for the right applications, iterative solvers can be very efficient.

Direct Solvers, on the other hand, often factor the matrix A into the product of two triangular matrices and then perform a forward and backward triangular solve.

This approach makes the time required to solve a systems of linear equations relatively predictable, based on the size of the matrix. In fact, for sparse matrices, the solution time can be predicted based on the number of non-zero elements in the array A .

Matrix Fundamentals

A matrix is a rectangular array of either real or complex numbers. A matrix is denoted by a capital letter; its elements are denoted by the same lower case letter with row/column subscripts. Thus, the value of the element in row i and column j in matrix A is denoted by $a(i, j)$. For example, a 3 by 4 matrix A , is written as follows:

$$A = \begin{bmatrix} a(1, 1) & a(1, 2) & a(1, 3) & a(1, 4) \\ a(2, 1) & a(2, 2) & a(2, 3) & a(2, 4) \\ a(3, 1) & a(3, 2) & a(3, 3) & a(3, 4) \end{bmatrix}$$

Note that with the above notation, we assume the standard Fortran programming language convention of starting array indices at 1 rather than the C programming language convention of starting them at 0.

A matrix in which all of the elements are real numbers is called a real matrix. A matrix that contains at least one complex number is called a complex matrix. A real or complex matrix A with the property that $a(i, j) = a(j, i)$, is called a symmetric matrix. A complex matrix A with the property that $a(i, j) = \text{conj}(a(j, i))$, is called a Hermitian matrix. Note that programs that manipulate symmetric and Hermitian matrices need only store half of the matrix values, since the values of the non-stored elements can be quickly reconstructed from the stored values.

A matrix that has the same number of rows as it has columns is referred to as a square matrix. The elements in a square matrix that have same row index and column index are called the diagonal elements of the matrix, or simply the diagonal of the matrix.

The transpose of a matrix A is the matrix obtained by “flipping” the elements of the array about its diagonal. That is, we exchange the elements $a(i, j)$ and $a(j, i)$. For a complex matrix, if we both flip the elements about the diagonal and then take the complex conjugate of the element, the resulting matrix is called the Hermitian transpose or conjugate transpose of the original matrix. The transpose and Hermitian transpose of a matrix A are denoted by A^T and A^H respectively.

A column vector, or simply a vector, is a $n \times 1$ matrix, and a row vector is a $1 \times n$ matrix. A real or complex matrix A is said to be positive definite if the vector-matrix product $x^T A x$ is greater than zero for all non-zero vectors x . A matrix that is not positive definite is referred to as indefinite.

An upper (or lower) triangular matrix, is a square matrix in which all elements below (or above) the diagonal are zero. A unit triangular matrix is an upper or lower triangular matrix with all 1's along the diagonal.

A matrix P is called a permutation matrix if, for any matrix A , the result of the matrix product PA is identical to A except for interchanging the rows of A . For a square matrix, it can be shown that if PA is a permutation of the rows of A , then AP^T is the same permutation of the columns of A . Additionally, it can be shown that the inverse of P is P^T .

In order to save space, a permutation matrix is usually stored as a linear array, called a permutation vector, rather than as an array. Specifically, if the permutation matrix maps the i -th row of a matrix to the j -th row, then the i -th element of the permutation vector is j .

A matrix with non-zero elements only on the diagonal is called a diagonal matrix. As is the case with a permutation matrix, it is usually stored as a vector of values, rather than as a matrix.

Direct Method

For solvers that use the direct method, the basic technique employed in finding the solution of the system $Ax = b$ is to first factor A into triangular matrices. That is, find a lower triangular matrix L and an upper triangular matrix U , such that $A = LU$. Having obtained such a factorization (usually referred to as an LU decomposition or LU factorization), the solution to the original problem can be rewritten as follows.

$$\begin{aligned} Ax &= b \\ \Rightarrow LUx &= b \\ \Rightarrow (Ux) &= b \end{aligned}$$

This leads to the following two-step process for finding the solution to the original system of equations:

1. Solve the systems of equations $Ly = b$.
2. Solve the system $Ux = y$.

Solving the systems $Ly = b$ and $Ux = y$ is referred to as a forward solve and a backward solve, respectively.

If a symmetric matrix A is also positive definite, it can be shown that A can be factored as LL^T where L is a lower triangular matrix. Similarly, a Hermitian matrix, A , that is positive definite can be factored as $A = LL^H$. For both symmetric and Hermitian matrices, a factorization of this form is called a Cholesky factorization.

In a Cholesky factorization, the matrix U in an LU decomposition is either L^T or L^H . Consequently, a solver can increase its efficiency by only storing L , and one-half of A , and not computing U . Therefore, users who can express their application as the solution of a system of positive definite equations will gain a significant performance improvement over using a general representation.

For matrices that are symmetric (or Hermitian) but not positive definite, there are still some significant efficiencies to be had. It can be shown that if A is symmetric but not positive definite, then A can be factored as $A = LDL^T$, where D is a diagonal matrix and L is a lower unit triangular matrix. Similarly, if A is Hermitian, it can be factored as $A = LDL^H$. In either case, we again only need to store L , D , and half of A and we need not compute U . However, the backward solve phases must be amended to solving $L^T x = D^{-1} y$ rather than $L^T x = y$.

Fill-In and Reordering of Sparse Matrices

Two important concepts associated with the solution of sparse systems of equations are fill-in and reordering. The following example illustrates these concepts.

Consider the system of linear equation $Ax = b$, where A is the symmetric positive definite sparse matrix defined by the following:

$$A = \begin{bmatrix} 9 & \frac{3}{2} & 6 & \frac{3}{4} & 3 \\ \frac{3}{2} & 1 & * & * & * \\ 6 & * & 12 & * & * \\ \frac{3}{4} & * & \frac{5}{8} & * & * \\ 3 & * & * & * & 16 \end{bmatrix} b = \begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{bmatrix}$$

A star (*) is used to represent zeros and to emphasize the sparsity of A . The Cholesky factorization of A is: $A = LL^T$, where L is the following:

$$L = \begin{bmatrix} 3 & * & * & * & * \\ \frac{1}{2} & \frac{1}{2} & * & * & * \\ 2 & -2 & 2 & * & * \\ \frac{1}{4} & \frac{1}{-4} & \frac{1}{-2} & \frac{1}{2} & * \\ 1 & -1 & -2 & -3 & 1 \end{bmatrix}$$

Notice that even though the matrix A is relatively sparse, the lower triangular matrix L has no zeros below the diagonal. If we computed L and then used it for the forward and backward solve phase, we would do as much computation as if A had been dense.

The situation of L having non-zeros in places where A has zeros is referred to as fill-in. Computationally, it would be more efficient if a solver could exploit the non-zero structure of A in such a way as to reduce the fill-in when computing L . By doing this, the solver would only need to compute the non-zero entries in L . Toward this end, consider permuting the rows and columns of A . As described in [Matrix Fundamentals](#) section, the permutations of the rows of A can be represented as a permutation matrix, P . The result of permuting the rows is the product of P and A . Suppose, in the above example, we swap the first and fifth row of A , then swap the first and fifth columns of A , and call the resulting matrix B . Mathematically, we can express the process of permuting the rows and columns of A to get B as $B = PAP^T$. After permuting the rows and columns of A , we see that B is given by the following:

$$B = \begin{bmatrix} 16 & * & * & * & 3 \\ * & \frac{1}{2} & * & * & \frac{3}{2} \\ * & * & 12 & * & 6 \\ * & * & * & \frac{5}{8} & \frac{3}{4} \\ 3 & \frac{3}{2} & 6 & \frac{3}{4} & 9 \end{bmatrix}$$

Since B is obtained from A by simply switching rows and columns, the numbers of non-zero entries in A and B are the same. However, when we find the Cholesky factorization, $B = LL^T$, we see the following:

$$L = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix}$$

The fill-in associated with B is much smaller than the fill-in associated with A . Consequently, the storage and computation time needed to factor B is much smaller than to factor A . Based on this, we see that an efficient sparse solver needs to find permutation P of the matrix A , which minimizes the fill-in for factoring $B = PAP^T$, and then use the factorization of B to solve the original system of equations.

Although the above example is based on a symmetric positive definite matrix and a Cholesky decomposition, the same approach works for a general LU decomposition. Specifically, let P be a permutation matrix, $B = PAP^T$ and suppose that B can be factored as $B = LU$. Then

$$Ax = b$$

$$\Rightarrow PA(P^{-1}P)x = Pb$$

$$\Rightarrow PA(P^TP)x = Pb$$

$$\Rightarrow (PA P^T)(Px) = Pb$$

$$\Rightarrow B(Px) = Pb$$

$$\Rightarrow LU(Px) = Pb$$

It follows that if we obtain an LU factorization for B , we can solve the original system of equations by a three step process:

- 1.** Solve $Ly = Pb$.
- 2.** Solve $Uz = y$.
- 3.** Set $x = P^Tz$.

If we apply this three-step process to the current example, we first need to perform the forward solve of the systems of equation $Ly = Pb$:

$$L = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix} * \begin{bmatrix} y1 \\ y2 \\ y3 \\ y4 \\ y5 \end{bmatrix} = \begin{bmatrix} 5 \\ 2 \\ 3 \\ 4 \\ 1 \end{bmatrix}$$

This gives: $y^T = \frac{5}{4}, 2\sqrt{2}, \frac{\sqrt{3}}{2}, \frac{16}{\sqrt{10}}, \frac{-979\sqrt{3}}{12}$.

The second step is to perform the backward solve, $Uz = y$. Or, in this case, since we are using a Cholesky factorization, $L^T z = y$.

$$\begin{bmatrix} 4 & * & * & * & \frac{3}{4} \\ * & \frac{1}{\sqrt{2}} & * & * & \frac{3}{\sqrt{2}} \\ * & * & 2(\sqrt{3}) & * & \sqrt{3} \\ * & * & * & \frac{\sqrt{10}}{4} & \frac{3}{\sqrt{10}} \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix} * \begin{bmatrix} z1 \\ z2 \\ z3 \\ z4 \\ z5 \end{bmatrix} = \begin{bmatrix} \frac{5}{4} \\ 2(\sqrt{2}) \\ \frac{\sqrt{3}}{2} \\ \frac{16}{\sqrt{10}} \\ \frac{-979\sqrt{3}}{12} \end{bmatrix}$$

This gives $z = \frac{123}{2}, 983, \frac{1961}{12}, 398, \frac{-979}{3}$.

The third and final step is to set $x = P^T z$. This gives $X^T = \frac{-979}{3}, 983, \frac{1961}{12}, 398, \frac{123}{2}$.

Sparse Matrix Storage Formats

As discussed above, it is more efficient to store only the non-zero elements of a sparse matrix. There are a number of common storage formats used for sparse matrices, but most of them employ the same basic technique. That is, store all non-zero elements of the matrix into a linear array and provide auxiliary arrays to describe the locations of the non-zero elements in the original matrix.

Storage Formats for the Direct Sparse Solvers

The storing the non-zero elements of a sparse matrix into a linear array is done by walking down each column (column-major format) or across each row (row-major format) in order, and writing the non-zero elements to a linear array in the order they appear in the walk.

For symmetric matrices, it is necessary to store only the upper triangular half of the matrix (upper triangular format) or the lower triangular half of the matrix (lower triangular format).

The Intel MKL direct sparse solvers use a row-major upper triangular storage format: the matrix is compressed row-by-row and for symmetric matrices only non-zero elements in the upper triangular half of the matrix are stored.

The Intel MKL sparse matrix storage format for direct sparse solvers is specified by three arrays: *values*, *columns*, and *rowIndex*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix.

<i>values</i>	A real or complex array that contains the non-zero elements of a sparse matrix. The non-zero elements are mapped into the <i>values</i> array using the row-major upper triangular storage mapping described above.
<i>columns</i>	Element <i>i</i> of the integer array <i>columns</i> is the number of the column that contains the <i>i</i> -th element in the <i>values</i> array.
<i>rowIndex</i>	Element <i>j</i> of the integer array <i>rowIndex</i> gives the index of the element in the <i>values</i> array that is first non-zero element in a row <i>j</i> .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in the matrix.

As the `rowIndex` array gives the location of the first non-zero element within a row, and the non-zero elements are stored consecutively, the number of non-zero elements in the I -th row is equal to the difference of `rowIndex(I)` and `rowIndex(I+1)`.

To have this relationship hold for the last row of the matrix, an additional entry (dummy entry) is added to the end of `rowIndex`. Its value is equal to the number of non-zero elements plus one. This makes the total length of the `rowIndex` array one larger than the number of rows in the matrix.

NOTE. The Intel MKL sparse storage scheme for the direct sparse solvers uses the Fortran programming language convention of starting array indices at 1.

Consider the symmetric matrix A :

$$A = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -1 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -3 & * & 6 & 7 & * \\ * & * & 4 & * & -5 \end{bmatrix}$$

Only elements from the upper triangle are stored. The actual arrays for the matrix A are as follows:

Table A-1 Storage Arrays for a Symmetric Matrix

<code>values</code>	=	(1	-1	-3	5	4	6	4	7	-5)
<code>columns</code>	=	(1	2	4	2	3	4	5	4	5)
<code>rowIndex</code>	=	(1	4	5	8	9	10)			

For a non-symmetric or non-Hermitian matrix, all non-zero elements need to be stored. Consider the non-symmetric matrix B :

$$B = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{bmatrix}$$

The matrix *B* has 13 non-zero elements, and all of them are stored as follows:

Table A-2 Storage Arrays for a Non-Symmetric Matrix

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>columns</i>	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
<i>rowIndex</i>	=	(1	4	6	9	12	14)							

Direct sparse solvers can also solve symmetrically structured systems of equations. A symmetrically structured system of equations is one where the pattern of non-zero elements is symmetric. That is, a matrix has a symmetric structure if $a(j, i)$ is not zero if and only if $a(i, j)$ is not zero. From the point of view of the solver software, a "non-zero" element of a matrix is any element stored in the *values* array, even if its value is equal to 0. In that sense, any non-symmetric matrix can be turned into a symmetrically structured matrix by carefully adding zeros to the *values* array. For example, the above matrix *B* can be turned into a symmetrically structured matrix by adding two non-zero entries:

$$B = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & 0 \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & 0 & * & -5 \end{bmatrix}$$

The matrix *B* can be considered to be symmetrically structured with 15 non-zero elements and represented as:

Table A-3 Storage Arrays for a Symmetrically Structured Matrix

<i>values</i>	=	(1	-1	-3	-2	5	0	4	6	4	-4	2	7	8	0	-5)
---------------	---	----	----	----	----	---	---	---	---	---	----	---	---	---	---	-----

<i>columns</i>	=	(1 2 4 1 2 5 3 4 5 1 3 4 2 3 5)
<i>rowIndex</i>	=	(1 4 7 10 13 16)

Storage Format Restrictions

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
- no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

Sparse Matrix Storage Formats for Sparse BLAS Levels 2 and Level 3

This section describes in detail the sparse matrix storage formats supported in the current version of the Intel MKL Sparse BLAS Level 2 and Level 3.

CSR Format

The Intel MKL compressed sparse row (CSR) format is specified by four arrays: the *values*, *columns*, *pointerB*, and *pointerE*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

<i>values</i>	A real or complex array that contains the non-zero elements of <i>A</i> . Values of the non-zero elements of <i>A</i> are mapped into the <i>values</i> array using the row-major storage mapping described above.
<i>columns</i>	Element <i>I</i> of the integer array <i>columns</i> is the number of the column in <i>A</i> that contains the <i>I</i> -th value in the <i>values</i> array.
<i>pointerB</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>values</i> array that is first non-zero element in a row <i>j</i> of <i>A</i> . Note that this index is equal to <i>pointerB(j) - pointerB(1)+1</i> .
<i>pointerE</i>	An integer array that contains row indices, such that <i>pointerE(j)-pointerB(1)</i> is the index of the element in the <i>values</i> array that is last non-zero element in a row <i>j</i> of <i>A</i> .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in *A*.The length of the *pointerB* and *pointerE* arrays is equal to the number of rows in *A*.

NOTE. Note that the Intel MKL Sparse BLAS routines support the CSR format both with one-based indexing and zero-based indexing.

The matrix B

$$B = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{bmatrix}$$

can be represented in the CSR format as:

Table A-4 Storage Arrays for a Matrix in CSR Format

one-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
pointerB	=	(1	4	6	9	12)								
pointerE	=	(4	6	9	12	14)								
zero-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
pointerB	=	(0	3	5	8	11)								
pointerE	=	(3	5	8	11	13)								

This storage format is used in the NIST Sparse BLAS library [[Rem05](#)].

Note that the storage format accepted for the direct sparse solvers and described above (see [Storage Formats for the Direct Sparse Solvers](#)) is a variation of the CSR format. It also is used in the Intel MKL Sparse BLAS Level 2 both with one-based indexing and zero-based indexing. The above matrix B can be represented in this format (referred to as the 3-array variation of the CSR format) as:

Table A-5 Storage Arrays for a Matrix in CSR Format (3-Array Variation)

one-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
rowIndex	=	(1	4	6	9	12	14)							
zero-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
rowIndex	=	(0	3	5	8	11	13)							

The 3-array variation of the CSR format has a restriction: all non-zero elements are stored continuously, that is the set of non-zero elements in the row J goes just after the set of non-zero elements in the row $J-1$.

There are no such restrictions in the general (NIST) CSR format. This may be useful, for example, if there is a need to operate with different submatrices of the matrix at the same time. In this case, it is enough to define the arrays *pointerB* and *pointerE* for each needed submatrix so that all these arrays are pointers to the same array *values*.

Comparing the array *rowIndex* from the [Table A-2](#) with the arrays *pointerB* and *pointerE* from the [Table A-4](#) it is easy to see that

pointerB(*I*) = *rowIndex*(*I*) for *I*=1, ..5;

pointerE(*I*) = *rowIndex*(*I*+1) for *I*=1, ..5.

This enables calling a routine that has *values*, *columns*, *pointerB* and *pointerE* as input parameters for a sparse matrix stored in the format accepted for the direct sparse solvers. For example, a routine with the interface:

Subroutine name_routine(.... , values, columns, pointerB, pointerE, ...)

can be called with parameters *values*, *columns*, *rowIndex* as follows:

call name_routine(.... , values, columns, rowIndex, rowindex(2), ...).

CSC Format

The compressed sparse column format (CSC) is similar to the CSR format, but the columns are used instead the rows. In other words, the CSC format is identical to the CSR format for the transposed matrix. The CSR format is specified by four arrays: *values*, *columns*, *pointerB*, and *pointerE*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

<i>values</i>	A real or complex array that contains the non-zero elements of <i>A</i> . Values of the non-zero elements of <i>A</i> are mapped into the <i>values</i> array using the column-major storage mapping.
<i>rows</i>	Element <i>I</i> of the integer array <i>rows</i> is the number of the row in <i>A</i> that contains the <i>I</i> -th value in the <i>values</i> array.
<i>pointerB</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>values</i> array that is first non-zero element in a column <i>j</i> of <i>A</i> . Note that this index is equal to <i>pointerB(j) - pointerB(1)+1</i> .
<i>pointerE</i>	An integer array that contains column indices, such that <i>pointerE(j)-pointerB(1)</i> is the index of the element in the <i>values</i> array that is last non-zero element in a column <i>j</i> of <i>A</i> .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in *A*. The length of the *pointerB* and *pointerE* arrays is equal to the number of columns in *A*.

NOTE. Note that the Intel MKL Sparse BLAS routines support the CSC format both with one-based indexing and zero-based indexing.

The above matrix *B* can be represented in the CSC format as:

Table A-6 Storage Arrays for a Matrix in CSC Format

one-based indexing														
<i>values</i>	=	(1	-2	-4	-1	5	8	4	2	-3	6	7	4	-5)
<i>rows</i>	=	(1	2	4	1	2	5	3	4	1	3	4	2	5)
<i>pointerB</i>	=	(1	4	7	9	12)								
<i>pointerE</i>	=	(4	7	9	12	14)								
zero-based indexing														
<i>values</i>	=	(1	-2	-4	-1	5	8	4	2	-3	6	7	4	-5)

<i>rows</i>	=	(0	1	3	0	1	4	2	3	0	2	3	1	4)
<i>pointerB</i>	=	(0	3	6	8	11)								
<i>pointerE</i>	=	(3	6	8	11	13)								

Coordinate Format

The coordinate format is the most flexible and simplest format for the sparse matrix representation. Only non-zero elements are stored, and the coordinates of each non-zero element are given explicitly. Many commercial libraries support the matrix-vector multiplication for the sparse matrices in the coordinate format.

The Intel MKL coordinate format is specified by three arrays: *values*, *rows*, and *column*, and a parameter *nnz* which is number of non-zero elements in *A*. All three arrays have dimension *nnz*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

<i>values</i>	A real or complex array that contains the non-zero elements of <i>A</i> in any order.
<i>rows</i>	Element <i>I</i> of the integer array <i>rows</i> is the number of the row in <i>A</i> that contains the <i>I</i> -th value in the <i>values</i> array.
<i>columns</i>	Element <i>I</i> of the integer array <i>columns</i> is the number of the column in <i>A</i> that contains the <i>I</i> -th value in the <i>values</i> array .

NOTE. Note that the Intel MKL Sparse BLAS routines support the coordinate format both with one-based indexing and zero-based indexing.

For example, the sparse matrix *C*

$$C = \begin{bmatrix} 1 & -1 & -3 & 0 & 0 \\ -2 & 5 & 0 & 0 & 0 \\ 0 & 0 & 4 & 6 & 4 \\ -4 & 0 & 2 & 7 & 0 \\ 0 & 8 & 0 & 0 & -5 \end{bmatrix}$$

can be represented in the coordinate format as follows:

Table A-7 Storage Arrays for an Example Matrix in case of the coordinate format

one-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
rows	=	(1	1	1	2	2	3	3	3	4	4	4	5	5)
columns	=	(1	2	3	1	2	3	4	5	1	3	4	2	5)
zero-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
rows	=	(0	0	0	1	1	2	2	2	3	3	3	4	4)
columns	=	(0	1	2	0	1	2	3	4	0	2	3	1	4)

Diagonal Storage Format

If the sparse matrix has diagonals containing only zero elements, then the diagonal storage format can be used to reduce the amount of information needed to locate the non-zero elements. This storage format is particularly useful in many applications where the matrix arises from a finite element or finite difference discretization. The Intel MKL diagonal storage format is specified by two arrays: *values* and *distance*, and two parameters: *ndiag*, which is the number of non-empty diagonals, and *lval*, which is the declared leading dimension in the calling (sub)programs. The following table describes the arrays *values* and *distance*:

<i>values</i>	A real or complex two-dimensional array is dimensioned as <i>lval</i> by <i>ndiag</i> . Each column of it contains the non-zero elements of certain diagonal of <i>A</i> . The key point of the storage is that each element in <i>values</i> retains the row number of the original matrix. To achieve this diagonals in the lower triangular part of the matrix are padded from the top, and those in the upper triangular part are padded from the bottom. Note that the value of <i>distance(I)</i> is the number of elements to be padded for diagonal <i>I</i> .
<i>distance</i>	An integer array with dimension <i>ndiag</i> . Element <i>I</i> of the array <i>distance</i> is the distance between <i>I</i> -diagonal and the main diagonal. The distance is positive if the diagonal is above the main diagonal, and negative if the diagonal is below the main diagonal. The main diagonal has a distance equal to zero.

The above matrix *C* can be represented in the diagonal storage format as follows:

$$\begin{aligned}
 \text{distance} &= (-3 \quad -1 \quad 0 \quad 1 \quad 2) \\
 \text{values} &= \begin{bmatrix} * & * & 1 & -1 & -3 \\ * & -2 & 5 & 0 & 0 \\ * & 0 & 4 & 6 & 4 \\ -4 & 2 & 7 & 0 & * \\ 8 & 0 & -5 & * & * \end{bmatrix}
 \end{aligned}$$

where the asterisks denote padded elements.

When storing symmetric, Hermitian, or skew-symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For the Intel MKL triangular solver routines elements of the array *distance* must be sorted in increasing order. In all other cases the diagonals and distances can be stored in arbitrary order.

Skyline Storage Format

The skyline storage format is important for the direct sparse solvers, and it is well suited for Cholesky or LU decomposition when no pivoting is required.

The skyline storage format accepted in Intel MKL can store only triangular matrix or triangular part of a matrix. This format is specified by two arrays: *values* and *pointers*. The following table describes these arrays:

<i>values</i>	A scalar array. For a lower triangular matrix it contains the set of elements from each row of the matrix starting from the first non-zero element to and including the diagonal element. For an upper triangular matrix it contains the set of elements from each column of the matrix starting with the first non-zero element down to and including the diagonal element. Encountered zero elements are included in the sets.
<i>pointers</i>	An integer array with dimension $(m+1)$, where m is the number of rows for lower triangle (columns for the upper triangle). $\text{pointers}(I) - \text{pointers}(1) + 1$ gives the index of element in <i>values</i> that is first non-zero element in row (column) I . The value of $\text{pointers}(m+1)$ is set to $\text{nnz} + \text{pointers}(1)$, where nnz is the number of elements in the array <i>values</i> .

For example, the low triangle of the matrix *c* given above can be stored as follows:

```
values = ( 1  -2  5  4  -4  0  2  7  8  0  0  -5 )
```

```
pointers = ( 1  2  4  5  9  13 )
```

and the upper triangle of this matrix *c* can be stored as follows:

```
values = ( 1  -1  5  -3  0  4  6  7  4  0  -5 )
```

```
pointers = ( 1  2  4  7  9  12 )
```

This storage format is supported by the NIST Sparse BLAS library [[Rem05](#)].

Note that the Intel MKL Sparse BLAS routines operating with the skyline storage format does not support general matrices.

BSR Format

The Intel MKL block compressed sparse row (BSR) format for sparse matrices is specified by four arrays: *values*, *columns*, *pointerB*, and *pointerE*. The following table describes these arrays.

<i>values</i>	A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block-by-block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of them is equal to zero. Within each non-zero block elements are stored in column-major order in the case of one-based indexing, and in row-major order in the case of the zero-based indexing.
<i>columns</i>	Element <i>i</i> of the integer array <i>columns</i> is the number of the column in the block matrix that contains the <i>i</i> -th non-zero block.
<i>pointerB</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>columns</i> array that is first non-zero block in a row <i>j</i> of the block matrix.
<i>pointerE</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>columns</i> array that contains the last non-zero block in a row <i>j</i> of the block matrix plus 1.

The length of the *values* array is equal to the number of all elements in the non-zero blocks, the length of the *columns* array is equal to the number of non-zero blocks. The length of the *pointerB* and *pointerE* arrays is equal to the number of block rows in the block matrix.

NOTE. Note that the Intel MKL Sparse BLAS routines support BSR format both with one-based indexing and zero-based indexing.

For example, consider the sparse matrix D

$$D = \begin{bmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ * & * & 1 & 4 & * & * \\ * & * & 5 & 2 & * & * \\ * & * & 4 & 3 & 7 & 2 \\ * & * & 0 & 0 & 0 & 0 \end{bmatrix}$$

If the size of the block equals 2, then the sparse matrix D can be represented as a 3x3 block matrix E with the following structure:

$$E = \begin{bmatrix} L & M & * \\ * & N & * \\ * & P & Q \end{bmatrix}$$

where

$$L = \begin{bmatrix} 1 & 0 \\ 2 & 1 \end{bmatrix}, M = \begin{bmatrix} 6 & 7 \\ 8 & 2 \end{bmatrix}, N = \begin{bmatrix} 1 & 4 \\ 5 & 1 \end{bmatrix}, P = \begin{bmatrix} 4 & 3 \\ 0 & 0 \end{bmatrix}, Q = \begin{bmatrix} 7 & 2 \\ 0 & 0 \end{bmatrix}$$

The matrix D can be represented in the BSR format as follows:

one-based indexing

`values = (1 2 0 1 6 8 7 2 1 5 4 1 4 0 3 0 7 0 2 0)`

`columns = (1 2 2 2 3)`

`pointerB = (1 3 4)`

`pointerE = (3 4 6)`

zero-based indexing

```
values = (1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0)
columns = (0  1  1  1  2)
pointerB = (0  2  3)
pointerE = (2  3  5)
```

This storage format is supported by the NIST Sparse BLAS library [[Rem05](#)].

Intel MKL supports the variation of the BSR format that is specified by three arrays: *values*, *columns*, and *rowIndex*. The following table describes these arrays.

<i>values</i>	A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block by block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of them is equal to zero. Within each non-zero block the elements are stored in column major order in the case of the one-based indexing, and in row major order in the case of the zero-based indexing.
<i>columns</i>	Element <i>I</i> of the integer array <i>columns</i> is the number of the column in the block matrix that contains the <i>I</i> -th non-zero block.
<i>rowIndex</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>columns</i> array that is first non-zero block in a row <i>j</i> of the block matrix.

The length of the *values* array is equal to the number of all elements in the non-zero blocks, the length of the *columns* array is equal to the number of non-zero blocks.

As the *rowIndex* array gives the location of the first non-zero block within a row, and the non-zero blocks are stored consecutively, the number of non-zero blocks in the *I*-th row is equal to the difference of *rowIndex*(*I*) and *rowIndex*(*I*+1).

To retain this relationship for the last row of the block matrix, an additional entry (dummy entry) is added to the end of *rowIndex* with value equal to the number of non-zeros blocks plus one. This makes the total length of the *rowIndex* array one larger than the number of rows of the block matrix.

The above matrix *D* can be represented in this 3-array variation of the BSR format as follows:

one-based indexing

```
values = (1 2 0 1 6 8 7 2 1 5 4 2 4 0 3 0 7 0 2 0)
columns = (1  2  2  2  3)
rowIndex = (1  3  4  6)
```

zero-based indexing

```
values = (1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0)
```

```
columns = (0 1 1 1 2)
```

```
rowIndex = (0 2 3 5)
```

When storing symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For example, consider the symmetric sparse matrix F :

$$F = \begin{bmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ 6 & 8 & 1 & 4 & * & * \\ 7 & 2 & 5 & 2 & * & * \\ * & * & * & * & 7 & 2 \\ * & * & * & * & 0 & 0 \end{bmatrix}$$

If the size of the block equals 2, then the sparse matrix F can be represented as a 3x3 block matrix G with the following structure:

$$G = \begin{bmatrix} L & M & * \\ M' & N & * \\ * & * & Q \end{bmatrix}$$

where

$$L = \begin{bmatrix} 1 & 0 \\ 2 & 1 \end{bmatrix}, M = \begin{bmatrix} 6 & 7 \\ 8 & 2 \end{bmatrix}, M' = \begin{bmatrix} 6 & 8 \\ 7 & 2 \end{bmatrix}, N = \begin{bmatrix} 1 & 4 \\ 5 & 2 \end{bmatrix}, Q = \begin{bmatrix} 7 & 2 \\ 0 & 0 \end{bmatrix}$$

The symmetric matrix F can be represented in this 3-array variation of the BSR format (storing only upper triangular) as follows:

one-based indexing

`values = (1 2 0 1 6 8 7 2 1 5 4 2 7 0 2 0)`

`columns = (1 2 2 3)`

`rowIndex = (1 3 4 5)`

zero-based indexing

`values = (1 0 2 1 6 7 8 2 1 4 5 2 7 2 0 0)`

`columns = (0 1 1 2)`

`rowIndex = (0 2 3 4)`

Routine and Function Arguments

B

The major arguments in the BLAS routines are vector and matrix, whereas VML functions work on vector arguments only. The sections that follow discuss each of these arguments and provide examples.

Vector Arguments in BLAS

Vector arguments are passed in one-dimensional arrays. The array dimension (length) and vector increment are passed as integer variables. The length determines the number of elements in the vector. The increment (also called stride) determines the spacing between vector elements and the order of the elements in the array in which the vector is passed.

A vector of length n and increment $incx$ is passed in a one-dimensional array x whose values are defined as

$x(1), x(1+|incx|), \dots, x(1+(n-1)*|incx|)$

If $incx$ is positive, then the elements in array x are stored in increasing order. If $incx$ is negative, the elements in array x are stored in decreasing order with the first element defined as $x(1+(n-1)*|incx|)$. If $incx$ is zero, then all elements of the vector have the same value, $x(1)$. The dimension of the one-dimensional array that stores the vector must always be at least

$idimx = 1 + (n-1)*|incx|$

Example B-1 One-dimensional Real Array

Let $x(1:7)$ be the one-dimensional real array

$x = (1.0, 3.0, 5.0, 7.0, 9.0, 11.0, 13.0)$.

If $incx = 2$ and $n = 3$, then the vector argument with elements in order from first to last is $(1.0, 5.0, 9.0)$.

If $incx = -2$ and $n = 4$, then the vector elements in order from first to last is $(13.0, 9.0, 5.0, 1.0)$.

If $incx = 0$ and $n = 4$, then the vector elements in order from first to last is $(1.0, 1.0, 1.0, 1.0)$.

One-dimensional substructures of a matrix, such as the rows, columns, and diagonals, can be passed as vector arguments with the starting address and increment specified. In Fortran, storing the m -by- n matrix is based on column-major ordering where the increment between elements in the same column is 1, the increment between elements in the same row is m , and the increment between elements on the same diagonal is $m + 1$.

Example B-2 Two-dimensional Real Matrix

Let a be the real 5 x 4 matrix declared as `REAL A (5,4)`.

To scale the third column of a by 2.0, use the BLAS routine `sscal` with the following calling sequence:

```
callsscal (5, 2.0, a(1,3), 1)
```

To scale the second row, use the statement:

```
callsscal (4, 2.0, a(2,1), 5)
```

To scale the main diagonal of A by 2.0, use the statement:

```
callsscal (5, 2.0, a(1,1), 6)
```

NOTE. The default vector argument is assumed to be 1.

Vector Arguments in VML

Vector arguments of VML mathematical functions are passed in one-dimensional arrays with unit vector increment. It means that a vector of length n is passed contiguously in an array a whose values are defined as $a[0]$, $a[1]$, ..., $a[n-1]$ (for C- interface).

To accommodate for arrays with other increments, or more complicated indexing, VML contains auxiliary pack/unpack functions that gather the array elements into a contiguous vector and then scatter them after the computation is complete.

Generally, if the vector elements are stored in a one-dimensional array a as

```
a[m0], a[m1], ..., a[mn-1]
```

and need to be regrouped into an array y as

```
y[k0], y[k1], ..., y[kn-1],
```

VML pack/unpack functions can use one of the following indexing methods:

Positive Increment Indexing

```
kj = incy * j, mj = inca * j, j = 0, ..., n-1
```

Constraint: $incy > 0$ and $inca > 0$.

For example, setting $incy = 1$ specifies gathering array elements into a contiguous vector.

This method is similar to that used in BLAS, with the exception that negative and zero increments are not permitted.

Index Vector Indexing

$kj = iy[j], mj = ia[j], j = 0, \dots, n-1,$

where ia and iy are arrays of length n that contain index vectors for the input and output arrays a and y , respectively.

Mask Vector Indexing

Indices kj, mj are such that:

$my[kj] \neq 0, ma[mj] \neq 0, j = 0, \dots, n-1,$

where ma and my are arrays that contain mask vectors for the input and output arrays a and y , respectively.

Matrix Arguments

Matrix arguments of the Intel® Math Kernel Library routines can be stored in either one- or two-dimensional arrays, using the following storage schemes:

- **conventional full storage** (in a two-dimensional array)
- **packed storage** for Hermitian, symmetric, or triangular matrices (in a one-dimensional array)
- **band storage** for band matrices (in a two-dimensional array)
- **rectangular full packed storage** for symmetric, Hermitian, or triangular matrices as compact as the Packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels.

Full storage is the following obvious scheme: a matrix A is stored in a two-dimensional array a , with the matrix element a_{ij} stored in the array element $a(i, j)$.

If a matrix is triangular (upper or lower, as specified by the argument *uplo*), only the elements of the relevant triangle are stored; the remaining elements of the array need not be set.

Routines that handle symmetric or Hermitian matrices allow for either the upper or lower triangle of the matrix to be stored in the corresponding elements of the array:

if *uplo* = 'U', a_{ij} is stored in $a(i, j)$ for $i \leq j$, other elements of a need not be set.

if *uplo* = 'L', a_{ij} is stored in $a(i, j)$ for $j \leq i$, other elements of a need not be set.

Packed storage allows you to store symmetric, Hermitian, or triangular matrices more compactly: the relevant triangle (again, as specified by the argument *uplo*) is packed by columns in a one-dimensional array *ap*:

if $uplo = 'U'$, a_{ij} is stored in $ap(i+j(j-1)/2)$ for $i \leq j$

if $uplo = 'L'$, a_{ij} is stored in $ap(i+(2*n-j)*(j-1)/2)$ for $j \leq i$.

In descriptions of LAPACK routines, arrays with packed matrices have names ending in p .

Band storage is as follows: an m -by- n band matrix with kl non-zero sub-diagonals and ku non-zero super-diagonals is stored compactly in a two-dimensional array ab with $kl+ku+1$ rows and n columns. Columns of the matrix are stored in the corresponding columns of the array, and diagonals of the matrix are stored in rows of the array. Thus,

a_{ij} is stored in $ab(ku+1+i-j, j)$ for $\max(1, j-ku) \leq i \leq \min(n, j+kl)$.

Use the band storage scheme only when kl and ku are much less than the matrix size n . Although the routines work correctly for all values of kl and ku , using the band storage is inefficient if your matrices are not really banded.

The band storage scheme is illustrated by the following example, when

$m = n = 6$, $kl = 2$, $ku = 1$

Array elements marked * are not used by the routines:

Banded matrix A						Band storage of A					
a_{11}	a_{12}	0	0	0	0	*	a_{12}	a_{23}	a_{34}	a_{45}	a_{56}
a_{21}	a_{22}	a_{23}	0	0	0	a_{11}	a_{22}	a_{33}	a_{44}	a_{55}	a_{66}
a_{31}	a_{42}	a_{43}	a_{34}	0	0	a_{21}	a_{32}	a_{43}	a_{54}	a_{65}	*
0	a_{42}	a_{43}	a_{44}	a_{45}	0	a_{31}	a_{42}	a_{53}	a_{64}	*	*
0	0	a_{53}	a_{54}	a_{55}	a_{56}						
0	0	0	a_{64}	a_{65}	a_{66}						

When a general band matrix is supplied for *LU factorization*, space must be allowed to store kl additional super-diagonals generated by fill-in as a result of row interchanges. This means that the matrix is stored according to the above scheme, but with $kl + ku$ super-diagonals. Thus,

a_{ij} is stored in $ab(kl+ku+1+i-j, j)$ for $\max(1, j-ku) \leq i \leq \min(n, j+kl)$.

The band storage scheme for LU factorization is illustrated by the following example, when $m = n = 6$, $kl = 2$, $ku = 1$:

Banded matrix A						Band storage of A					
a_{11}	a_{12}	0	0	0	0	*	*	*	+	+	+
a_{21}	a_{22}	a_{23}	0	0	0	*	*	+	+	+	+
a_{31}	a_{42}	a_{43}	a_{34}	0	0	*	a_{12}	a_{23}	a_{34}	a_{45}	a_{56}
0	a_{42}	a_{43}	a_{44}	a_{45}	0	a_{11}	a_{22}	a_{33}	a_{44}	a_{55}	a_{66}
0	0	a_{53}	a_{54}	a_{55}	a_{56}	a_{21}	a_{32}	a_{43}	a_{54}	a_{65}	*
0	0	0	a_{64}	a_{65}	a_{66}	a_{31}	a_{42}	a_{53}	a_{64}	*	*

Array elements marked * are not used by the routines; elements marked + need not be set on entry, but are required by the LU factorization routines to store the results. The input array will be overwritten on exit by the details of the LU factorization as follows:

*	*	*	u_{14}	u_{25}	u_{36}
*	*	u_{13}	u_{24}	u_{35}	u_{46}
*	u_{12}	u_{23}	u_{34}	u_{45}	u_{56}
u_{11}	u_{22}	u_{33}	u_{44}	u_{55}	u_{66}
m_{21}	m_{32}	m_{43}	m_{54}	m_{65}	*
m_{31}	m_{42}	m_{53}	m_{64}	*	*

where u_{ij} are the elements of the upper triangular matrix U, and m_{ij} are the multipliers used during factorization.

Triangular band matrices are stored in the same format, with either $kl=0$ if upper triangular, or $ku=0$ if lower triangular. For symmetric or Hermitian band matrices with k sub-diagonals or super-diagonals, you need to store only the upper or lower triangle, as specified by the argument *uplo*:

if *uplo* = 'U', a_{ij} is stored in $ab(k+1+i-j, j)$ for $\max(1, j-k) \leq i \leq j$

if *uplo* = 'L', a_{ij} is stored in $ab(1+i-j, j)$ for $j \leq i \leq \min(n, j+k)$.

In descriptions of LAPACK routines, arrays that hold matrices in band storage have names ending in *b*.

In Fortran, column-major ordering of storage is assumed. This means that elements of the same column occupy successive storage locations.

Three quantities are usually associated with a two-dimensional array argument: its leading dimension, which specifies the number of storage locations between elements in the same row, its number of rows, and its number of columns. For a matrix in full storage, the leading dimension of the array must be at least as large as the number of rows in the matrix.

A character transposition parameter is often passed to indicate whether the matrix argument is to be used in normal or transposed form or, for a complex matrix, if the conjugate transpose of the matrix is to be used.

The values of the transposition parameter for these three cases are the following:

'N' or 'n'	normal (no conjugation, no transposition)
'T' or 't'	transpose
'C' or 'c'	conjugate transpose.

Example B-3 Two-Dimensional Complex Array

Suppose $A(1:5, 1:4)$ is the complex two-dimensional array presented by matrix

$$\begin{bmatrix} (1.1, 0.11) & (1.2, 0.12) & (1.3, 0.13) & (1.4, 0.14) \\ (2.1, 0.21) & (2.2, 0.22) & (2.3, 0.23) & (1.4, 0.24) \\ (3.1, 0.31) & (3.2, 0.32) & (3.3, 0.33) & (1.4, 0.34) \\ (4.1, 0.41) & (4.2, 0.42) & (4.3, 0.43) & (1.4, 0.44) \\ (5.1, 0.51) & (5.2, 0.52) & (5.3, 0.53) & (1.4, 0.54) \end{bmatrix}$$

Let *transa* be the transposition parameter, *m* be the number of rows, *n* be the number of columns, and *lda* be the leading dimension. Then if

transa = 'N', *m* = 4, *n* = 2, and *lda* = 5, the matrix argument would be

$$\begin{bmatrix} (1.1, 0.11) & (1.2, 0.12) \\ (2.1, 0.21) & (2.2, 0.22) \\ (3.1, 0.31) & (3.2, 0.32) \\ (4.1, 0.41) & (4.2, 0.42) \end{bmatrix}$$

If `transa = 'T'`, `m = 4`, `n = 2`, and `lda = 5`, the matrix argument would be

$$\begin{bmatrix} (1.1, 0.11) & (2.1, 0.21) & (3.1, 0.31) & (4.1, 0.41) \\ (1.2, 0.12) & (2.2, 0.22) & (3.2, 0.32) & (4.2, 0.42) \end{bmatrix}$$

If `transa = 'C'`, `m = 4`, `n = 2`, and `lda = 5`, the matrix argument would be

$$\begin{bmatrix} (1.1, -0.11) & (2.1, -0.21) & (3.1, -0.31) & (4.1, -0.41) \\ (1.2, -0.12) & (2.2, -0.22) & (3.2, -0.32) & (4.2, -0.42) \end{bmatrix}$$

Note that care should be taken when using a leading dimension value which is different from the number of rows specified in the declaration of the two-dimensional array. For example, suppose the array `A` above is declared as `COMPLEX A (5,4)`.

Then if `transa = 'N'`, `m = 3`, `n = 4`, and `lda = 4`, the matrix argument will be

$$\begin{bmatrix} (1.1, 0.11) & (5.1, 0.51) & (4.2, 0.42) & (3.3, 0.33) \\ (2.1, 0.21) & (1.2, 0.12) & (5.2, 0.52) & (4.3, 0.43) \\ (3.1, 0.31) & (2.2, 0.22) & (1.3, 0.13) & (5.3, 0.53) \end{bmatrix}$$

Rectangular Full Packed storage allows you to store symmetric, Hermitian, or triangular matrices as compact as the Packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels. To store an n -by- n triangle (and suppose for simplicity that n is even), you partition the triangle into three parts: two $n/2$ -by- $n/2$ triangles and an $n/2$ -by- $n/2$ square, then pack this as an n -by- $n/2$ rectangle (or $n/2$ -by- n rectangle), by transposing (or transpose-conjugating) one of the triangles and packing it next to the other triangle. Since the two triangles are stored in full storage, you can use existing efficient routines on them.

There are eight cases of RFP storage representation: when n is even or odd, the packed matrix is transposed or not, the triangular matrix is lower or upper. See below for all the eight storage schemes illustrated:

n is odd, A is lower triangular

Intel MKL provides a number of routines such as [?hfrk](#), [?sfrk](#) performing BLAS operations working directly on RFP matrices, as well as some conversion routines, for instance, [?tpttf](#) goes from the standard packed format to RFP and [?trttf](#) goes from the full format to RFP.

Please refer to the Netlib site for more information.

Note that in the descriptions of LAPACK routines, arrays with RFP matrices have names ending in `fp`.

Code Examples

This appendix presents code examples of using some Intel MKL routines and functions. You can find here example code written in both Fortran and C.

Please refer to respective chapters in the manual for detailed descriptions of function parameters and operation.

BLAS Code Examples

Example C-1. Using BLAS Level 1 Function

The following example illustrates a call to the BLAS Level 1 function `sdot`. This function performs a vector-vector operation of computing a scalar product of two single-precision real vectors x and y .

Parameters

<i>n</i>	Specifies the number of elements in vectors x and y .
<i>incx</i>	Specifies the increment for the elements of x .
<i>incy</i>	Specifies the increment for the elements of y .

```
program dot_main
real x(10), y(10), sdot, res
integer n, incx, incy, i
external sdot
n = 5
incx = 2
incy = 1
do i = 1, 10
    x(i) = 2.0e0
    y(i) = 1.0e0
end do
res = sdot (n, x, incx, y, incy)
print*, `SDOT = `, res
end
```

As a result of this program execution, the following line is printed:

SDOT = 10.000

Example C-2. Using BLAS Level 1 Routine

The following example illustrates a call to the BLAS Level 1 routine `scopy`. This routine performs a vector-vector operation of copying a single-precision real vector x to a vector y .

Parameters

<i>n</i>	Specifies the number of elements in vectors <i>x</i> and <i>y</i> .
<i>incx</i>	Specifies the increment for the elements of <i>x</i> .
<i>incy</i>	Specifies the increment for the elements of <i>y</i> .

```

program copy_main
real x(10), y(10)
integer n, incx, incy, i
n = 3
incx = 3
incy = 1
do i = 1, 10
    x(i) = i
end do
call scopy (n, x, incx, y, incy)
print*, 'Y = ', (y(i), i = 1, n)
end

```

As a result of this program execution, the following line is printed:

Y = 1.00000 4.00000 7.00000

Example C-3. Using BLAS Level 2 Routine

The following example illustrates a call to the BLAS Level 2 routine `sger`. This routine performs a matrix-vector operation

$a := \alpha x y' + a.$

Parameters

<i>alpha</i>	Specifies a scalar <i>alpha</i> .
<i>x</i>	<i>m</i> -element vector.
<i>y</i>	<i>n</i> -element vector.
<i>a</i>	<i>m</i> -by- <i>n</i> matrix.

```

program ger_main
real a(5,3), x(10), y(10), alpha
integer m, n, incx, incy, i, j, lda
m = 2
n = 3
lda = 5
incx = 2
incy = 1
alpha = 0.5
do i = 1, 10

```

```

    x(i) = 1.0
    y(i) = 1.0
end do
do i = 1, m
    do j = 1, n
        a(i,j) = j
    end do
end do
call sger (m, n, alpha, x, incx, y, incy, a, lda)
print*, `Matrix A: `
do i = 1, m
    print*, (a(i,j), j = 1, n)
end do
end

```

As a result of this program execution, matrix *a* is printed as follows:

Matrix A:

```

1.50000 2.50000 3.50000
1.50000 2.50000 3.50000

```

Example C-4. Using BLAS Level 3 Routine

The following example illustrates a call to the BLAS Level 3 routine `ssymm`. This routine performs a matrix-matrix operation

c := *alpha***a***b*' + *beta***c*.

Parameters

<i>alpha</i>	Specifies a scalar <i>alpha</i> .
<i>beta</i>	Specifies a scalar <i>beta</i> .
<i>a</i>	Symmetric matrix
<i>b</i>	<i>m</i> -by- <i>n</i> matrix
<i>c</i>	<i>m</i> -by- <i>n</i> matrix

```

program symm_main
real a(3,3), b(3,2), c(3,3), alpha, beta
integer m, n, lda, ldb, ldc, i, j
character uplo, side
uplo = 'u'
side = 'l'
m = 3
n = 2
lda = 3
ldb = 3
ldc = 3

```

```
alpha = 0.5
beta = 2.0
do i = 1, m
    do j = 1, m
        a(i,j) = 1.0
    end do
end do
do i = 1, m
    do j = 1, n
        c(i,j) = 1.0
        b(i,j) = 2.0
    end do
end do
call ssymm (side, uplo, m, n, alpha,
a, lda, b, ldb, beta, c, ldc)
print*, 'Matrix C: \'
do i = 1, m
    print*, (c(i,j), j = 1, n)
end do
end
```

As a result of this program execution, matrix *c* is printed as follows:

Matrix C:

5.00000 5.00000

5.00000 5.00000

5.00000 5.00000

The following example illustrates a call from a C program to the complex BLAS Level 1 function `zdotc()`. This function computes the dot product of two double-precision complex vectors.

Example C-5. Calling a Complex BLAS Level 1 Function from C

In this example, the complex dot product is returned in the structure *c*.

```
#define N 5
void main()
{
    int n, inca = 1, incb = 1, i;
    typedef struct{ double re; double im; } complex16;
    complex16 a[N], b[N], c;
    void zdotc();
    n = N;
    for( i = 0; i < n; i++ ){
        a[i].re = (double)i; a[i].im = (double)i * 2.0;
        b[i].re = (double)(n - i); b[i].im = (double)i * 2.0;
    }
}
```

```

zdotc( &c, &n, a, &inca, b, &incb );
printf( "The complex dot product is: ( %.2f, %.2f )\n", c.re, c.im );
}

```

NOTE. Instead of calling BLAS directly from C programs, you might wish to use the CBLAS interface; this is the supported way of calling BLAS from C. For more information about CBLAS, see [Appendix D](#), which presents CBLAS, the C interface to the Basic Linear Algebra Subprograms (BLAS) implemented in Intel® MKL.

PARDISO Code Examples

This section presents code examples of using the PARDISO direct solver for computing solutions of linear systems with sparse matrices. For description of this solver, refer to Chapter 8 of the manual.

Examples for Sparse Symmetric Linear Systems

In this section two examples (Fortran, C) are provided to solve symmetric linear systems with PARDISO. To solve the systems of equations $Ax = b$, where

$$A = \begin{bmatrix} 7.0 & 0.0 & 1.0 & 0.0 & 0.0 & 2.0 & 7.0 & 0.0 \\ 0.0 & -4.0 & 8.0 & 0.0 & 2.0 & 0.0 & 0.0 & 0.0 \\ 1.0 & 8.0 & 1.0 & 0.0 & 0.0 & 0.0 & 0.0 & 5.0 \\ 0.0 & 0.0 & 0.0 & 7.0 & 0.0 & 0.0 & 9.0 & 0.0 \\ 0.0 & 2.0 & 0.0 & 0.0 & 5.0 & 1.0 & 5.0 & 0.0 \\ 2.0 & 0.0 & 0.0 & 0.0 & 1.0 & -1.0 & .0 & 5.0 \\ 7.0 & 0.0 & 0.0 & 9.0 & 5.0 & 0.0 & 11.0 & 0.0 \\ 0.0 & 0.0 & 5.0 & 0.0 & 0.0 & 5.0 & 0.0 & 5.0 \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \end{bmatrix}$$

Example Results for Symmetric Systems

Upon successful execution of the solver, the result of the solution x is as follows

```
Reordering completed ...
Number of nonzeros in factors = 30
Number of factorization MFLOPS = 0
Factorization completed ...
Solve completed ...
The solution of the system is
x(1) = -0.0418602013
x(2) = -0.00341312416
x(3) = 0.117250377
x(4) = -0.11263958
x(5) = 0.0241722445
x(6) = -0.10763334
x(7) = 0.198719673
x(8) = 0.190382964
```

Examples for Sparse Unsymmetric Linear Systems

In this section two examples (Fortran, C) are provided to solve unsymmetric linear systems with PARDISO. To solve the systems of equations $Ax = b$, where

$$A = \begin{bmatrix} 1.0 & -1.0 & 0.0 & -3.0 & 0.0 \\ -2.0 & 5.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 4.0 & 6.0 & 4.0 \\ -4.0 & 0.0 & 2.0 & 7.0 & 0.0 \\ 0.0 & 8.0 & 0.0 & 0.0 & -5.0 \end{bmatrix} \text{ and } B = \begin{bmatrix} 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \end{bmatrix}$$

Example Results for Unsymmetric Systems

Upon successful execution of the solver, the result of the solution x is as follows

```
Reordering completed ...
Number of nonzeros in factors = 21
Number of factorization MFLOPS = 0
Factorization completed ...
Solve completed ...
The solution of the system is
x( 1) = -0.522321429
x( 2) = -0.00892857143
x( 3) = 1.22098214
x( 4) = -0.504464286
x( 5) = -0.214285714
```

Direct Sparse Solver Code Examples

This section contains example code in FORTRAN 77, Fortran 90 and C. For description of the sparse solver routines used in this code, refer to "Direct Sparse Solver (DSS) Interface Routines" in Chapter 8 of the manual. The example code solves the equations presented in Direct Method section of Appendix A - a symmetric positive definite system of equations $Ax=b$ with a sparse matrix, where

$$A = \begin{bmatrix} 9 & 1.5 & 6 & 0.75 & 3 \\ 1.5 & 0.5 & 0 & 0 & 0 \\ 6 & 0 & 12 & 0 & 0 \\ 0.75 & 0 & 0 & 0.625 & 0 \\ 3 & 0 & 0 & 0 & 16 \end{bmatrix} \text{ and } B = \begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{bmatrix}$$

Example results for symmetric systems

Upon successful execution of the solver, the determinant and the result of the solution array are as follows

```

pow of determinant is      0.000
base of determinant is      2.250
Determinant is      2.250
Solution Array:  -326.333   983.000  163.417   398.000   61.500

```

Example C-10. FORTRAN 77 example to Solve Symmetric Positive Definite System

Iterative Sparse Solver Code Examples

This section contains example code in FORTRAN 77 and C. For description of the iterative sparse solver routines based on the reverse communication interface (RCI ISS) used in this code, refer to “Iterative Sparse Solvers based on Reverse Communication Interface (RCI ISS)” in Chapter 8 of the manual . More examples can be found in the `examples/solver` subdirectory of the Intel MKL installation directory.

Example of Use RCI (Preconditioned) Conjugate Gradient Solver for Systems with Single Right Hand Size

Example results for symmetric positive definite systems. Upon successful execution of the solver, the result of the solution array is as follows:

```
The system has been solved
The following solution obtained
  1.000  0.000  1.000  0.000
  1.000  0.000  1.000  0.000
Expected solution
  1.000  0.000  1.000  0.000
  1.000  0.000  1.000  0.000
Number of iterations: 8
This example has successfully PASSED through all steps of computation!
```

```

Fortran Example of Using RCI (Preconditioned) Flexible Generalized Minimal Residual Solver.

Fortran example results for a non-symmetric indefinite system. Upon successful execution of the solver, the following result is printed (up to rounding errors that depend on the computer system used):

```
-----
The SIMPLEST example of usage of RCI FGMRES solver
to solve a non-symmetric indefinite non-degenerate
algebraic system of linear equations
-----

Some info about the current run of RCI FGMRES method:

As IPAR(8)=1, the automatic test for the maximal number of iterations will be
performed
+++
As IPAR(9)=1, the automatic residual test will be performed
+++
As IPAR(10)=0, the user-defined stopping test will not be requested, thus,
RCI_REQUEST will not take the value 2
+++
As IPAR(11)=0, the Preconditioned FGMRES iterations will not be performed,
thus, RCI_REQUEST will not take the value 3
+++
As IPAR(12)=1, the automatic test for the norm of the next generated vector is
not equal to zero up to rounding and computational errors will be performed,
thus, RCI_REQUEST will not take the value 4
+++

The system has been solved

The following solution has been obtained:
COMPUTED_SOLUTION(1)=-0.100E+01
COMPUTED_SOLUTION(2)= 0.100E+01
COMPUTED_SOLUTION(3)=-0.805E-15
COMPUTED_SOLUTION(4)= 0.100E+01
COMPUTED_SOLUTION(5)=-0.100E+01

The expected solution is:
EXPECTED_SOLUTION(1)=-0.100E+01
EXPECTED_SOLUTION(2)= 0.100E+01
EXPECTED_SOLUTION(3)= 0.000E+00
EXPECTED_SOLUTION(4)= 0.100E+01
EXPECTED_SOLUTION(5)=-0.100E+01

Number of iterations:          5
This example has successfully PASSED through all steps of computation!
```

C Example of Using RCI (Preconditioned) Flexible Generalized Minimal Residual Solver.

C example results for the same non-symmetric indefinite system as in the previous example. The results are the same up to the notational convention between C and Fortran. Please pay special attention to how it is recommended to handle the differences between the Fortran and C arrays. Specifically, in this example the addresses for input/result are adjusted for user-defined

operations from IPAR(22) to *ipar*[21]-1, and from IPAR(23) to *ipar*[22]-1, respectively. Upon successful execution of the solver, the following result is printed (up to rounding errors that depend on the computer system used):

```
-----
The SIMPLEST example of usage of RCI FGMRES solver
to solve a non-symmetric indefinite non-degenerate
algebraic system of linear equations
-----

Some info about the current run of RCI FGMRES method:

As ipar[7]=1, the automatic test for the maximal number of iterations will be
performed
+++
As ipar[8]=1, the automatic residual test will be performed
+++
As ipar[9]=0, the user-defined stopping test will not be requested, thus,
RCI_request will not take the value 2
+++
As ipar[10]=0, the Preconditioned FGMRES iterations will not be performed,
thus, RCI_request will not take the value 3
+++
As ipar[11]=1, the automatic test for the norm of the next generated vector is
not equal to zero up to rounding and computational errors will be performed,
thus, RCI_request will not take the value 4
+++

The system has been solved

The following solution has been obtained:
computed_solution[0]=-1.000000e+00
computed_solution[1]=1.000000e-00
computed_solution[2]=-8.049117e-16
computed_solution[3]=1.000000e-00
computed_solution[4]=-1.000000e+00

The expected solution is:
expected_solution[0]=-1.000000e+00
expected_solution[1]=1.000000e+00
expected_solution[2]=0.000000e+00
expected_solution[3]=1.000000e+00
expected_solution[4]=-1.000000e+00

Number of iterations: 5

This example has successfully PASSED through all steps of computation!
```

Fourier Transform Functions Code Examples

This section presents code examples of functions described in the “[FFT Functions](#)” and “[Cluster FFT Functions](#)” sections in the “Fourier Transform Functions” chapter. The examples are grouped in subsections

- [Examples for FFT Functions](#), including [Examples of Using Multi-Threading for FFT Computation](#)
- [Examples for Cluster FFT Functions](#)
- [Auxiliary data transformations](#).

FFT Code Examples

This section presents code examples of using the FFT interface functions described in “[Fourier Transform Functions](#)” chapter. Here are the examples of two one-dimensional computations. These examples use the default settings for all of the configuration parameters, which are specified in “[Configuration Settings](#)”.

Example C-16 One-dimensional In-place FFT (Fortran Interface)

```

! Fortran example.
! 1D complex to complex, and real to conjugate-even
Use MKL_DFTI
Complex :: X(32)
Real :: Y(34)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle
Integer :: Status
!...put input data into X(1),...,X(32); Y(1),...,Y(32)

! Perform a complex to complex transform
Status = DftiCreateDescriptor( My_Desc1_Handle, DFTI_SINGLE,&
    DFTI_COMPLEX, 1, 32 )
Status = DftiCommitDescriptor( My_Desc1_Handle )
Status = DftiComputeForward( My_Desc1_Handle, X )
Status = DftiFreeDescriptor(My_Desc1_Handle)
! result is given by {X(1),X(2),...,X(32)}

! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor(My_Desc2_Handle, DFTI_SINGLE,&
    DFTI_REAL, 1, 32)

```

```

Status = DftiCommitDescriptor(My_Desc2_Handle)
Status = DftiComputeForward(My_Desc2_Handle, Y)
Status = DftiFreeDescriptor(My_Desc2_Handle)
! result is given in CCS format.

```

Example C-16a One-dimensional Out-of-place FFT (Fortran Interface)

```

! Fortran example.
! 1D complex to complex, and real to conjugate-even
Use MKL_DFTI
Complex :: X_in(32)
Complex :: X_out(32)
Real :: Y_in(32)
Real :: Y_out(32)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle
Integer :: Status
...put input data into X_in(1),...,X_in(32); Y_in(1),...,Y_in(32)
! Perform a complex to complex transform
Status = DftiCreateDescriptor( My_Desc1_Handle, DFTI_SINGLE,
DFTI_COMPLEX, 1, 32 )
Status = DftiSetValue( My_Desc1_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor( My_Desc1_Handle )
Status = DftiComputeForward( My_Desc1_Handle, X_in, X_out )
Status = DftiFreeDescriptor(My_Desc1_Handle)
! result is given by {X_out(1),X_out(2),...,X_out(32)}
! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor(My_Desc2_Handle, DFTI_SINGLE,
DFTI_REAL, 1, 32)
Status = DftiSetValue( My_Desc2_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor(My_Desc2_Handle)
Status = DftiComputeForward(My_Desc2_Handle, Y_in, Y_out)
Status = DftiFreeDescriptor(My_Desc2_Handle)
! result is given by Y_out in CCS format.

```

Example C-17 One-dimensional In-place FFT (C Interface)

```

/* C example, float_Complex is defined in C9X */
#include "mkl_dfti.h"
float_Complex x[32];
float y[32];
DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle;
MKL_LONG status;
//...put input data into x[0],...,x[31]; y[0],...,y[31]
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,

```

```

        DFTI_COMPLEX, 1, 32);
status = DftiCommitDescriptor( my_desc1_handle );
status = DftiComputeForward( my_desc1_handle, x);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is x[0], ..., x[31]* */
status = DftiCreateDescriptor( &my_desc2_handle, DFTI_SINGLE,
        DFTI_REAL, 1, 32);
status = DftiCommitDescriptor( my_desc2_handle);
status = DftiComputeForward( my_desc2_handle, y);
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is given in CCS format*/

```

Example C-17a One-dimensional Out-of-place FFT (C Interface)

```

/* C example, float_Complex is defined in C9X */
#include "mkl_dfti.h"
float_Complex x_in[32];
float_Complex x_out[32];
float y_in[32];
float y_out[34];

DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle;
MKL_LONG status;
//...put input data into x_in[0],...,x_in[31]; y_in[0],...,y_in[31]
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,
        DFTI_COMPLEX, 1, 32);
status = DftiSetValue( my_desc1_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor( my_desc1_handle );
status = DftiComputeForward( my_desc1_handle, x_in, x_out);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is x_out[0], ..., x_out[31]* */
status = DftiCreateDescriptor( &my_desc2_handle, DFTI_SINGLE,
        DFTI_REAL, 1, 32);
Status = DftiSetValue( My_Desc2_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor( my_desc2_handle);
status = DftiComputeForward( my_desc2_handle, y_in, y_out);
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is given by y_out in CCS format*

```

Example C-18 Two-dimensional FFT (Fortran Interface)

The following is an example of two simple two-dimensional transforms. Notice that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

```
! Fortran example.
! 2D complex to complex, and real to conjugate-even
Use MKL_DFTI
Complex :: X_2D(32,100)
Real :: Y_2D(34, 102)
Complex :: X(3200)
Real :: Y(3468)
Equivalence (X_2D, X)
Equivalence (Y_2D, Y)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle
Integer :: Status, L(2)
!...put input data into X_2D(j,k), Y_2D(j,k), 1<=j<=32, 1<=k<=100
!...set L(1) = 32, L(2) = 100
!...the transform is a 32-by-100

! Perform a complex to complex transform
Status = DftiCreateDescriptor( My_Desc1_Handle, DFTI_SINGLE,&
    DFTI_COMPLEX, 2, L)
Status = DftiCommitDescriptor( My_Desc1_Handle)
Status = DftiComputeForward( My_Desc1_Handle, X)
Status = DftiFreeDescriptor(My_Desc1_Handle)
! result is given by X_2D(j,k), 1<=j<=32, 1<=k<=100

! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc2_Handle, DFTI_SINGLE,&
    DFTI_REAL, 2, L)
Status = DftiCommitDescriptor( My_Desc2_Handle)
Status = DftiComputeForward( My_Desc2_Handle, Y)
Status = DftiFreeDescriptor(My_Desc2_Handle)
! result is given by the complex value z(j,k) 1<=j<=32; 1<=k<=100
! and is stored in CCS format
```

Example C-19 Two-dimensional FFT (C Interface)

```
/* C99 example */
#include "mkl_dfti.h"
float _Complex x[32][100];
float y[34][102];
DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle;
```

```

MKL_LONG status, l[2];
//...put input data into x[j][k] 0<=j<=31, 0<=k<=99
//...put input data into y[j][k] 0<=j<=31, 0<=k<=99
l[0] = 32; l[1] = 100;
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,
    DFTI_COMPLEX, 2, 1);
status = DftiCommitDescriptor( my_desc1_handle);
status = DftiComputeForward( my_desc1_handle, x);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is the complex value x[j][k], 0<=j<=31, 0<=k<=99 */
status = DftiCreateDescriptor( &my_desc2_handle, DFTI_SINGLE,
    DFTI_REAL, 2, 1);
status = DftiCommitDescriptor( my_desc2_handle);
status = DftiComputeForward( my_desc2_handle, y);
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is the complex value z(j,k) 0<=j<=31; 0<=k<=99
/* and is stored in CCS format*/

```

The following examples demonstrate how you can change the default configuration settings by using the `DftiSetValue` function.

For instance, to preserve the input data after the FFT computation, the configuration of the `DFTI_PLACEMENT` should be changed to "not in place" from the default choice of "in place."

Example C-20 Changing Default Settings (Fortran)

The code below illustrates how this can be done:

```

! Fortran example
! 1D complex to complex, not in place
Use MKL_DFTI
Complex :: X_in(32), X_out(32)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status
!...put input data into X_in(j), 1<=j<=32
Status = DftiCreateDescriptor( My_Desc_Handle,& DFTI_SINGLE, DFTI_COMPLEX, 1, 32)
Status = DftiSetValue( My_Desc_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor( My_Desc_Handle)
Status = DftiComputeForward( My_Desc_Handle, X_in, X_out)
Status = DftiFreeDescriptor( My_Desc_Handle)
! result is X_out(1),X_out(2),...,X_out(32)

```

Example C-21 Changing Default Settings (C)

```
/* C99 example */
#include "mkl_dfti.h"
float _Complex x_in[32], x_out[32];
DFTI_DESCRIPTOR_HANDLE my_desc_handle;
MKL_LONG status;
//...put input data into x_in[j], 0 <= j < 32
status = DftiCreateDescriptor( &my_desc_handle, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 32);
status = DftiSetValue( my_desc_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor( my_desc_handle);
status = DftiComputeForward( my_desc_handle, x_in, x_out);
status = DftiFreeDescriptor(&my_desc_handle);
/* result is x_out[0], x_out[1], ..., x_out[31] */
```

Example C-22 Using Status Checking Functions

The example illustrates the use of status checking functions described in [Chapter 11](#).

```
/* C */
DFTI_DESCRIPTOR_HANDLE desc;
MKL_LONG status;
// . . . descriptor creation and other code
status = DftiCommitDescriptor(desc);
if (status && !DftiErrorClass(status,DFTI_NO_ERROR))
{
    printf ('Error: %s\n', DftiErrorMessage(status));
}

! Fortran
type(DFTI_DESCRIPTOR), POINTER :: desc
integer status
! ...descriptor creation and other code
status = DftiCommitDescriptor(desc)
if (status .ne. 0) then
    if (.not. DftiErrorClass(status,DFTI_NO_ERROR) then
        print *, 'Error: ', DftiErrorMessage(status)
    endif
endif
endif
```

Example C-23. Computing 2D FFT by One-Dimensional Transforms

Below is an example where a 20-by-40 two-dimensional FFT is computed explicitly using one-dimensional transforms. Notice that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

```
! Fortran
use mkl_dfti
Complex :: X_2D(20,40)
Complex :: X(800)
Equivalence (X_2D, X)
INTEGER :: STRIDE(2)
type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle_Dim1
type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle_Dim2
! ...
Status = DftiCreateDescriptor(Desc_Handle_Dim1, DFTI_SINGLE,&
                             DFTI_COMPLEX, 1, 20)
Status = DftiCreateDescriptor(Desc_Handle_Dim2, DFTI_SINGLE,&
                             DFTI_COMPLEX, 1, 40)
! perform 40 one-dimensional transforms along 1st dimension
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_NUMBER_OF_TRANSFORMS, 40 )
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_INPUT_DISTANCE, 20 )
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_OUTPUT_DISTANCE, 20 )
Status = DftiCommitDescriptor( Desc_Handle_Dim1 )
Status = DftiComputeForward( Desc_Handle_Dim1, X )
! perform 20 one-dimensional transforms along 2nd dimension
Stride(1) = 0; Stride(2) = 20
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_NUMBER_OF_TRANSFORMS, 20 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_INPUT_DISTANCE, 1 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_OUTPUT_DISTANCE, 1 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_INPUT_STRIDES, Stride )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_OUTPUT_STRIDES, Stride )
Status = DftiCommitDescriptor( Desc_Handle_Dim2 )
Status = DftiComputeForward( Desc_Handle_Dim2, X )
Status = DftiFreeDescriptor( Desc_Handle_Dim1 )
Status = DftiFreeDescriptor( Desc_Handle_Dim2 )

/* C */
#include "mkl_dfti.h"
float_Complex x[20][40];
MKL_LONG stride[2];
MKL_LONG status;
DFTI_DESCRIPTOR_HANDLE desc_handle_dim1;
DFTI_DESCRIPTOR_HANDLE desc_handle_dim2;
//...
status = DftiCreateDescriptor( &desc_handle_dim1, DFTI_SINGLE,
                             DFTI_COMPLEX, 1, 20 );
status = DftiCreateDescriptor( &desc_handle_dim2, DFTI_SINGLE,
```

```

DFTI_COMPLEX, 1, 40 );

/* perform 40 one-dimensional transforms along 1st dimension */
/* note that the 1st dimension data are not unit-stride */
stride[0] = 0; stride[1] = 40;
status = DftiSetValue( desc_handle_dim1, DFTI_NUMBER_OF_TRANSFORMS, 40 );
status = DftiSetValue( desc_handle_dim1, DFTI_INPUT_DISTANCE, 1 );
status = DftiSetValue( desc_handle_dim1, DFTI_OUTPUT_DISTANCE, 1 );
status = DftiSetValue( desc_handle_dim1, DFTI_INPUT_STRIDES, stride );
status = DftiSetValue( desc_handle_dim1, DFTI_OUTPUT_STRIDES, stride );
status = DftiCommitDescriptor( desc_handle_dim1 );
status = DftiComputeForward( desc_handle_dim1, x );
/* perform 20 one-dimensional transforms along 2nd dimension */
/* note that the 2nd dimension is unit stride */
status = DftiSetValue( desc_handle_dim2, DFTI_NUMBER_OF_TRANSFORMS, 20 );
status = DftiSetValue( desc_handle_dim2,
DFTI_INPUT_DISTANCE, 40 );
status = DftiSetValue( desc_handle_dim2,
DFTI_OUTPUT_DISTANCE, 40 );
status = DftiCommitDescriptor( desc_handle_dim2 );
status = DftiComputeForward( desc_handle_dim2, x );
status = DftiFreeDescriptor( &Desc_Handle_dim1 );
status = DftiFreeDescriptor( &Desc_Handle_dim2 );

```

The following are examples of real multi-dimensional transforms with CCE format storage of conjugate-even complex matrix. [Example C-24](#) is two-dimensional in-place transform and [Example C-24a](#) is two-dimensional out-of-place transform in Fortran interface. [Example C-25](#) is three-dimensional out-of-place transform in C interface. Note that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

Example C-24. Two-Dimensional REAL In-place FFT (Fortran Interface)

```

! Fortran example.
! 2D and real to conjugate-even
Use MKL_DFTI
Real :: X 2D(34,100) ! 34 = (32/2 + 1)*2
Real :: X(3400)
Equivalence (X 2D, X)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status, L(2)
Integer :: strides_in(3)
Integer :: strides_out(3)
! ...put input data into X 2D(j,k), 1<=j=32,1<=k=100
! ...set L(1) = 32, L(2) = 100

```

```
! ...set strides_in(1) = 0, strides_in(2) = 1, strides_in(3) = 34
! ...set strides_out(1) = 0, strides_out(2) = 1, strides_out(3) = 17
! ...the transform is a 32-by-100
! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc_Handle, DFTI_SINGLE,&
DFTI_REAL, 2, L )
Status = DftiSetValue(My_Desc_Handle, DFTI_CONJUGATE_EVEN_STORAGE,&
DFTI_COMPLEX_COMPLEX)
Status = DftiSetValue(My_Desc_Handle, DFTI_INPUT_STRIDES, strides_in)
Status = DftiSetValue(My_Desc_Handle, DFTI_OUTPUT_STRIDES, strides_out)
Status = DftiCommitDescriptor( My_Desc_Handle)
Status = DftiComputeForward( My_Desc_Handle, X )
Status = DftiFreeDescriptor(My_Desc_Handle)
! result is given by the complex value z(j,k) 1<=j<=17; 1<=k<=100 and
! is stored in real matrix X_2D in CCE format.
```

Example C-24a. Two-Dimensional REAL Out-of-place FFT (Fortran Interface)

```
! Fortran example.
! 2D and real to conjugate-even
Use MKL_DFTI
Real :: X_2D(32,100)
Complex :: Y_2D(17, 100) ! 17 = 32/2 + 1
Real :: X(3200)
Complex :: Y(1700)
Equivalence (X_2D, X)
Equivalence (Y_2D, Y)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status, L(2)
Integer :: strides_out(3)

! ...put input data into X_2D(j,k), 1<=j<=32,1<=k<=100
! ...set L(1) = 32, L(2) = 100
! ...set strides_out(1) = 0, strides_out(2) = 1, strides_out(3) = 17

! ...the transform is a 32-by-100
! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc_Handle, DFTI_SINGLE,&
DFTI_REAL, 2, L )
Status = DftiSetValue(My_Desc_Handle,&
DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX)
Status = DftiSetValue( My_Desc_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE )
Status = DftiSetValue(My_Desc_Handle,&
DFTI_OUTPUT_STRIDES, strides_out)

Status = DftiCommitDescriptor(My_Desc_Handle)
Status = DftiComputeForward(My_Desc_Handle, X, Y)
Status = DftiFreeDescriptor(My_Desc_Handle)
! result is given by the complex value z(j,k) 1<=j<=17; 1<=k<=100 and
! is stored in complex matrix Y_2D in CCE format.
```

Example C-25 Three-Dimensional REAL FFT (C Interface)

```

/* C99 example */
#include "mkl_dfti.h"
float x[32][100][19];
float_Complex y[32][100][10]; /* 10 = 19/2 + 1 */
DFTI_DESCRIPTOR_HANDLE my_desc_handle;
MKL_LONG status, l[3];
MKL_LONG strides_out[4];

//...put input data into x[j][k][s] 0<=j<=31, 0<=k<=99, 0<=s<=18
l[0] = 32; l[1] = 100; l[2] = 19;

strides_out[0] = 0; strides_out[1] = 1000;
strides_out[2] = 10; strides_out[3] = 1;

status = DftiCreateDescriptor( &my_desc_handle, DFTI_SINGLE,
DFTI_REAL, 3, l );
status = DftiSetValue(my_desc_handle,
DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX);
status = DftiSetValue( my_desc_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE );
status = DftiSetValue(my_desc_handle,
DFTI_OUTPUT_STRIDES, strides_out);

status = DftiCommitDescriptor(my_desc_handle);
status = DftiComputeForward(my_desc_handle, x, y);
status = DftiFreeDescriptor(&my_desc_handle);
/* result is the complex value  $\bar{z}(j,k,s)$  0<=j<=31; 0<=k<=99, 0<=s<=9
and is stored in complex matrix y in CCE format. */

```

Examples of Using Multi-Threading for FFT Computation

The following sample program shows how to employ internal threading in Intel MKL for FFT computation (see case "a" in ["Number of user threads"](#)).

To specify the number of threads inside Intel MKL, use the following settings:

set `MKL_NUM_THREADS = 1` for one-threaded mode;

set `MKL_NUM_THREADS = 4` for multi-threaded mode.

Note that the configuration parameter `DFTI_NUMBER_OF_USER_THREADS` must be equal to its default value 1.

Example C-26 Using Intel MKL Internal Threading Mode

```
#include "mkl_dfti.h"

void main () {

float x[200][100];
DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
MKL_LONG status, len[2];
//...put input data into x[j][k] 0<=j<=199, 0<=k<=99

len[0] = 200; len[1] = 100;
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,DFTI_REAL, 2,
    len);
status = DftiCommitDescriptor(
my_desc1_handle);
status = DftiComputeForward(
my_desc1_handle, x);
status = DftiFreeDescriptor(&my_desc1_handle);
}
```

The following [Example C-27](#) and [Example C-27a](#) illustrate a parallel customer program with each descriptor instance used only in a single thread (see cases "b" and "c" in [Number of user threads](#)).

Specify the number of threads for [Example C-27](#) like this:

set `MKL_SERIAL = yes` (or `YES`) for Intel MKL to work in the single-threaded mode (recommended);

set `OMP_NUM_THREADS = 4` for the customer program to work in the multi-threaded mode.

The configuration parameter `DFTI_NUMBER_OF_USER_THREADS` must have its default value of 1.

Example C-27 Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region

Note that in this example, the program can be transformed to become single-threaded at the customer level but using parallel mode within Intel MKL (case "a"). To achieve this, you need to set the parameter `DFTI_NUMBER_OF_TRANSFORMS = 4` and to set the corresponding parameter `DFTI_INPUT_DISTANCE = 5000`.

```
#include "mkl_dfti.h"
#include "omp.h"
void main ()
{
    float _Complex x[200][100];
```

```

MKL_LONG len[2];
//...put input data into x[j][k] 0<=j<=199, 0<=k<=99
len[0] = 50; len[1] = 100;

// each thread calculates real FFT for matrix (50*100)
#pragma omp parallel
{
    DFTI_DESCRIPTOR_HANDLE my_desc_handle;
    MKL_LONG myStatus;
    int myID = omp_get_thread_num ();

myStatus    =  DftiCreateDescriptor (&my_desc_handle, DFTI_SINGLE,
DFTI_COMPLEX, 2, len);
    myStatus = DftiCommitDescriptor (my_desc_handle);
    myStatus = DftiComputeForward (my_desc_handle, &x[myID * len[0] * len[1]]);
    myStatus = DftiFreeDescriptor (&my_desc_handle);
} /* End OpenMP parallel region */
}

```

Specify the number of threads for [Example C-27a](#) like this:

set `MKL_NUM_THREADS = 1` for Intel MKL to work in the single-threaded mode (obligatory);

set `OMP_NUM_THREADS = 4` for the customer program to work in the multi-threaded mode.

The configuration parameter `DFTI_NUMBER_OF_USER_THREADS` must have the default value of 1.

Example C-27a Using Parallel Mode with Multiple Descriptors Initialized in One Thread

```

#include "mkl_dfti.h"
#include "omp.h"
void main ()
{
    float _Complex x[200][100];
    MKL_LONG len[2];
    MKL_LONG i;
    //...put input data into x[j][k] 0<=j<=199, 0<=k<=99
    len[0] = 50; len[1] = 100;
    DFTI_DESCRIPTOR_HANDLE my_desc_handle[4];
    MKL_LONG myStatus;
    for (i=0; i<3; i++) myStatus = DftiCreateDescriptor (&my_desc_handle[i], DFTI_SINGLE, DFTI_COMPLEX,
    2, len);
    // each thread calculates real FFT for matrix (50*100)
    #pragma omp parallel
    {
        int myID = omp_get_thread_num ();
        myStatus = DftiCommitDescriptor (my_desc_handle[myID]);
        myStatus = DftiComputeForward (my_desc_handle[myID], &x[myID * len[0] * len[1]]);
    }
}

```

```

} /* End OpenMP parallel region */
for (i=0;i<3;i++) myStatus = DftiFreeDescriptor (&my_desc_handle[i]);
}

```

The following [Example C-28](#) illustrates a parallel customer program with a common descriptor used in several threads (see case "d" in ["Number of user threads"](#)).

In this case, the number of threads, as well as any other configuration parameter, must not be changed after FFT initialization by the `DftiCommitDescriptor()` function is done.

Example C-28 Using Parallel Mode with a Common Descriptor

```

// set number of threads inside Intel MKL:
//rem set MKL_SERIAL = YES - is not required
// since one-threaded mode for Intel MKL is forced automatically
// set OMP_NUM_THREADS = 4 - multi-threaded mode for customer

#include "mkl_dfti.h"
#include "omp.h"
void main ()
{
    float_Complex x[200][100];
    MKL_LONG status;
    DFTI_DESCRIPTOR_HANDLE desc_handle;
    int nThread = omp_get_max_threads ();
    MKL_LONG len[2];
    //...put input data into x[j][k] 0<=j<=199, 0<=k<=99
    len[0] = 50; len[1] = 100;

    status =
DftiCreateDescriptor (&desc_handle, DFTI_SINGLE, DFTI_COMPLEX, 2, len);
    status = DftiSetValue (desc_handle,
DFTI_NUMBER_OF_USER_THREADS, nThread);
    status = DftiCommitDescriptor (desc_handle);

    // each thread calculates real FFT for matrix (50*100)
    #pragma omp parallel num_threads(nThread)
    {
        MKL_LONG myStatus;
        int myID = omp_get_thread_num ();

        myStatus = DftiComputeForward (desc_handle, &x[myID * len[0] * len[1]]);
    } /* End OpenMP parallel region */

    status = DftiFreeDescriptor (&desc_handle);
}

```

Examples for Cluster FFT Functions

The following C example computes a 2-dimensional out-of-place FFT using the cluster FFT interface:

Example 29. 2D Out-of-place Cluster FFT Computation

```
DFTI_DESCRIPTOR_DM_HANDLE desc;
MKL_LONG len[2],v,i,j,n,s;
Complex *in,*out;

MPI_Init(...);

// Create descriptor for 2D FFT
len[0]=nx;
len[1]=ny;
DftiCreateDescriptorDM(MPI_COMM_WORLD,&desc,DFTI_DOUBLE,DFTI_COMPLEX,2,len);
// Ask necessary length of in and out arrays and allocate memory
DftiGetValueDM(desc,CDFT_LOCAL_SIZE,&v);
in=(Complex*)malloc(v*sizeof(Complex));
out=(Complex*)malloc(v*sizeof(Complex));
// Fill local array with initial data. Current process performs n rows,
// 0 row of in corresponds to s row of virtual global array
DftiGetValueDM(desc,CDFT_LOCAL_NX,&n);
DftiGetValueDM(desc,CDFT_LOCAL_X_START,&s);
// Virtual global array globalIN is defined by function f as
// globalIN[i*ny+j]=f(i,j)
for(i=0;i<n;i++)
    for(j=0;j<ny;j++) in[i*ny+j]=f(i+s,j);
// Set that we want out-of-place transform (default is DFTI_INPLACE)
DftiSetValueDM(desc,DFTI_PLACEMENT,DFTI_NOT_INPLACE);
// Commit descriptor, calculate FFT, free descriptor
DftiCommitDescriptorDM(desc);
DftiComputeForwardDM(desc,in,out);
// Virtual global array globalOUT is defined by function g as
// globalOUT[i*ny+j]=g(i,j)
// Now out contains result of FFT. out[i*ny+j]=g(i+s,j)
DftiFreeDescriptorDM(&desc);
free(in);
free(out);
MPI_Finalize();
```

Example 30. 1D In-place Cluster FFT Computations

The C example below illustrates one-dimensional in-place cluster FFT computations effected with a user-defined workspace:

```
DFTI_DESCRIPTOR_DM_HANDLE desc;
MKL_LONG len, v, i, n_out, s_out;
Complex *in, *work;

MPI_Init(...);
// Create descriptor for 1D FFT
DftiCreateDescriptorDM(MPI_COMM_WORLD, &desc, DFTI_DOUBLE, DFTI_COMPLEX, 1, 1, len);
// Ask necessary length of array and workspace and allocate memory
DftiGetValueDM(desc, CDFT_LOCAL_SIZE, &v);
in = (Complex*)malloc(v * sizeof(Complex));
work = (Complex*)malloc(v * sizeof(Complex));
// Fill local array with initial data. Local array has n elements,
// 0 element of in corresponds to s element of virtual global array
DftiGetValueDM(desc, CDFT_LOCAL_NX, &n);
DftiGetValueDM(desc, CDFT_LOCAL_X_START, &s);
// Set work array as a workspace
DftiSetValueDM(desc, CDFT_WORKSPACE, work);
// Virtual global array globalIN is defined by function f as globalIN[i]=f(i)
for(i=0; i<n; i++) in[i]=f(i+s);
// Commit descriptor, calculate FFT, free descriptor
DftiCommitDescriptorDM(desc);
DftiComputeForwardDM(desc, in);
DftiGetValueDM(desc, CDFT_LOCAL_OUT_NX, &n_out);
DftiGetValueDM(desc, CDFT_LOCAL_OUT_X_START, &s_out);
// Virtual global array globalOUT is defined by function g as globalOUT[i]=g(i)
// Now in contains result of FFT. Local array has n_out elements,
// 0 element of in corresponds to s_out element of virtual global array.
// in[i]==g(i+s_out)
DftiFreeDescriptorDM(&desc);
free(in);
free(work);
MPI_Finalize();
```

Auxiliary Data Transformations

This section presents code examples for conversion from the Cartesian to polar representation of complex data and vice versa.

Example C-30a Conversion from Cartesian to polar representation of complex data

```
// Cartesian->polar conversion of complex data
// Cartesian representation:  $z = re + I \cdot im$ 
// Polar representation:  $z = r \cdot \exp(I \cdot \phi)$ 
#include <mkl_vml.h>

void
variant1_Cartesian2Polar(int n, const double *re, const double *im,
                        double *r, double *phi)
{
    vdHypot(n, re, im, r);          // compute radii r[]
    vdAtan2(n, re, im, phi);        // compute phases phi[]
}

void
variant2_Cartesian2Polar(int n, const MKL_Complex16 *z, double *r, double *phi,
                        double *temp_re, double *temp_im)
{
    vzAbs(n, z, r);                // compute radii r[]
    vdPackI(n, (double*)z + 0, 2, temp_re);
    vdPackI(n, (double*)z + 1, 2, temp_im);
    vdAtan2(n, temp_re, temp_im, phi); // compute phases phi[]
}
```

Example C-30b Conversion from polar to Cartesian representation of complex data

```
// Polar->Cartesian conversion of complex data.
// Polar representation:  $z = r \cdot \exp(I \cdot \phi)$ 
// Cartesian representation:  $z = re + I \cdot im$ 
#include <mkl_vml.h>

void
variant1_Polar2Cartesian(int n, const double *r, const double *phi,
                        double *re, double *im)
{
    vdSinCos(n, phi, im, re);       // compute direction, i.e.  $z[]/abs(z[])$ 
    vdMul(n, r, re, re);           // scale real part
    vdMul(n, r, im, im);           // scale imaginary part
}

void
variant2_Polar2Cartesian(int n, const double *r, const double *phi,
                        MKL_Complex16 *z,
                        double *temp_re, double *temp_im)
{
    vdSinCos(n, phi, temp_im, temp_re); // compute direction, i.e.  $z[]/abs(z[])$ 
}
```

```
vdMul(n,r,temp_im,temp_im); // scale imaginary part
vdMul(n,r,temp_re,temp_re); // scale real part
vdUnpackI(n,temp_re,(double*)z + 0, 2); // fill in result.re
vdUnpackI(n,temp_im,(double*)z + 1, 2); // fill in result.im
}
```

PDE Support Code Examples

This section presents code examples for routines described in the in the [“Partial Differential Equations Support” chapter](#). The examples are grouped in subsections

- [Trigonometric Transform Code Examples](#)
- [Poisson Library Code Examples](#).

Trigonometric Transforms Interface Code Examples

Code presented in this section computes solutions of three simple 1D Helmholtz problems with different boundary conditions: DD, NN and ND cases, where “D” denotes a Dirichlet boundary condition and “N” stands for a Neumann boundary condition. [Example C-31](#) implements the computations in C and [Example C-32](#) provides Fortran 90 code. You can find more examples in `examples/pdettc` and `examples/pdettf` subdirectories in the Intel MKL directory.

The algorithm of computing the solution uses [Trigonometric Transform routines](#), described in chapter 13. In the DD case, the sine transform is computed, the NN case uses the cosine transform and the ND case corresponds to the staggered cosine transform.

Other details of the Helmholtz problems being solved are printed out along with the computed solutions.

Upon successful execution of [Example C-31](#) the following text is printed out ([Example C-32](#) generates similar output):

```
Example of use of MKL Trigonometric Transforms
*****

This example gives the the solutions of the 1D differential problems
with the equation -u''+u=f(x), 0<x<1,
and with 3 types of boundary conditions:
DD case: u(0)=u(1)=0,
NN case: u'(0)=u'(1)=0,
ND case: u'(0)=u(1)=0.
-----
In general, the error should be of order O(1.0/n**2)
For this example, the value of n is 8
The approximation error should be of order 5.0e-002 if everything is OK
-----
```

```
=====
DOUBLE PRECISION COMPUTATIONS
=====
The computed solution of DD problem is

u[0]= 0.000
u[1]= 0.153
u[2]= 0.524
u[3]= 0.895
u[4]= 1.049
u[5]= 0.895
u[6]= 0.524
u[7]= 0.153
u[8]= 0.000

Error=4.873e-02

The computed solution of NN problem is

u[0]=-0.026
u[1]= 0.128
u[2]= 0.500
u[3]= 0.872
u[4]= 1.026
u[5]= 0.872
u[6]= 0.500
u[7]= 0.128
u[8]=-0.026

Error=2.583e-02

The computed solution of ND problem is

u[0]=-0.009
u[1]= 0.145
u[2]= 0.517
u[3]= 0.890
u[4]= 1.045
u[5]= 0.892
u[6]= 0.522
u[7]= 0.152
u[8]= 0.000

Error=4.470e-02

This example has successfully PASSED through all steps of computation!

Example C-31 shows C code of the computations.

Poisson Library Code Examples

Cartesian case

The code below computes an approximate solution of a 2D Poisson problem

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} = 8\pi^2 \sin 2\pi x \cdot \sin 2\pi y$$

in the rectangle $0 < x < 1, 0 < y < 1$.

The following boundary conditions are imposed for the problem:

- Dirichlet boundary condition

$$u(0, y) = u(1, y) = 1$$

for $0 \leq y \leq 1$.

- Neumann boundary condition

$$\frac{\partial u}{\partial n}(x, 0) = -2\pi \sin 2\pi x, \frac{\partial u}{\partial n}(x, 1) = 2\pi \sin 2\pi x$$

for $0 < x < 1$.

The exact solution is known to be

$$u(x, y) = \sin 2\pi x \cdot \sin 2\pi y + 1$$

Example [C-33](#) implements the computations in C and Example [C-34](#) provides Fortran 90 code. Mind that PL interface cannot be invoked from Fortran 77 due to restrictions imposed by the use of Intel MKL FFT interface. You can find more examples in `examples/pdepoissonc` and `examples/pdepoissonf` subdirectories in the Intel MKL directory.

The algorithm of computing the approximate solution of a Poisson Problem uses [Poisson Library routines](#), described in chapter 13. Details of the Poisson problem being solved and the errors are printed out between the computed solution and the exact one.

Upon successful execution of Example [C-33](#) the following text is printed out (Example [C-34](#) produces similar output):

```
Example of use of MKL Poisson Library
*****
This example gives the solution of 2D Helmholtz problem
```

```

with the equation -u_xx-u_yy+u=f(x,y), 0<x<1, 0<y<1,
f(x,y)=(8*pi*pi+1)*sin(2*pi*x)*sin(2*pi*y)+1,
and with the following boundary conditions:
u(0,y)=u(1,y)=1 (Dirichlet boundary conditions),
-u_y(x,0)=-2.0*pi*sin(2*pi*x) (Neumann boundary condition),
u_y(x,1)= 2.0*pi*sin(2*pi*x) (Neumann boundary condition).

```

```

-----
In general, the error should be of order  $O(1.0/nx^2+1.0/ny^2)$ 
For this example, the value of nx=ny is 6
The approximation error should be of order 1.0e-01, if everything is OK

Spherical case

The code below computes an approximate solution of a Helmholtz problem on the entire sphere:

$$-\Delta_s u + u = 3 \cos \theta, \quad \Delta_s = \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \varphi^2} + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial}{\partial \theta} \right)$$

with $a_\phi = 0$, $b_\phi = 2\pi$, $a_\theta = 0$, $b_\theta = \pi$, and a boundary condition

$$\left(\sin \theta \frac{\partial u}{\partial \theta} \right)_{\substack{\theta \rightarrow 0 \\ \theta \rightarrow \pi}} = 0$$

at the poles (*periodic* case).

The exact solution is known to be $u(\phi, \theta) = \cos \theta$.

Example [C-35](#) implements the computations in C and Example [C-36](#) provides Fortran 90 code. Mind that PL interface cannot be invoked from Fortran 77 due to restrictions imposed by the use of Intel MKL FFT interface. You can find more examples in `examples/pdepoissonc` and `examples/pdepoissonf` subdirectories in the Intel MKL directory.

The algorithm of computing the approximate solution of a Poisson Problem uses [Poisson Library routines](#), described in chapter 13. Details of the Poisson problem being solved and the errors are printed out between the computed solution and the exact one. Upon successful execution of Example C-35 the following text is printed out (Example C-36 produces similar output):

Example of use of MKL Poisson Library

This example gives the solution of Helmholtz problem on a whole sphere
 $0 < p < 2\pi$, $0 < t < \pi$, with Helmholtz coefficient $q=1$ and right-hand side
 $f(p,t)=3*\cos(t)$

 In general, the error should be of order $O(1.0/np^2+1.0/nt^2)$
 For this example, the value of $np=nt$ is 8
 The approximation error should be of order $1.5e-01$, if everything is OK

 Note that np should be even to solve the PERIODIC problem!

DOUBLE PRECISION COMPUTATIONS

=====

The number of mesh intervals in phi-direction is $np=8$
 The number of mesh intervals in theta-direction is $nt=8$

In the mesh point (0.785,0.000) the error between the computed and the true solution is
 equal to -1.402e-01
 In the mesh point (0.785,0.393) the error between the computed and the true solution is
 equal to -3.097e-02
 In the mesh point (0.785,0.785) the error between the computed and the true solution is
 equal to -6.036e-03
 In the mesh point (0.785,1.178) the error between the computed and the true solution is
 equal to 2.964e-04
 In the mesh point (0.785,1.571) the error between the computed and the true solution is
 equal to 4.979e-17
 In the mesh point (0.785,1.963) the error between the computed and the true solution is
 equal to -2.964e-04
 In the mesh point (0.785,2.356) the error between the computed and the true solution is
 equal to 6.036e-03
 In the mesh point (0.785,2.749) the error between the computed and the true solution is
 equal to 3.097e-02
 In the mesh point (0.785,3.142) the error between the computed and the true solution is
 equal to 1.402e-01

Double precision Helmholtz example on a whole sphere has successfully PASSED
 through all steps of computation!

Note that actual figures in the error may slightly differ from the figures printed above depending on the architecture and operating system used to run the example.

Example C-35 shows C code for the problem.

Example C-35. C Example to Solve Helmholtz Problem on a Sphere

Preconditioner Code Examples

This section contains code examples in FORTRAN 77 and C. For description of the preconditioner routines used in these codes, refer to “Preconditioners based on Incomplete LU Factorization Techniques” in Chapter 8 of the manual.

Fortran Example of Using ILU0 Preconditioner with RCI FGMRES Solver

Example results for non-degenerate system. Upon successful execution of the solver, the output contains the following information:

```

-----
The FULLY ADVANCED example RCI FGMRES with ILU0 preconditioner
to solve the non-degenerate algebraic system of linear equations
-----

```

Some info about the current run of RCI FGMRES method:

```

As IPAR(8)=0, the automatic test for the maximal number of iterations will be skipped
+++
As IPAR(9)=0, the automatic residual test will be skipped
+++

```

```

As IPAR(10)=1, the user-defined stopping test will be requested via RCI_REQUEST=2
+++
As IPAR(11)=1, the Preconditioned FGMRES iterations will be performed, thus,
the preconditioner action will be requested via RCI_REQUEST=3
+++
As IPAR(12)=0, the automatic test for the norm of the next generated vector is
not equal to zero up to rounding and computational errors will be skipped,
thus, the user-defined test will be requested via RCI_REQUEST=4
+++

```

The system has been solved

The following solution has been obtained:

```

COMPUTED_SOLUTION(1)= 0.100E+01
COMPUTED_SOLUTION(2)= 0.100E+01
COMPUTED_SOLUTION(3)= 0.100E+01
COMPUTED_SOLUTION(4)= 0.100E+01

```

The expected solution is:

```

EXPECTED_SOLUTION(1)= 0.100E+01
EXPECTED_SOLUTION(2)= 0.100E+01
EXPECTED_SOLUTION(3)= 0.100E+01
EXPECTED_SOLUTION(4)= 0.100E+01

```

Number of iterations: 2

```

-----
Fortran example of FGMRES with ILU0 preconditioner
has successfully PASSED all stages of computations
-----

```

NOTE. If the ILU0 preconditioner is not used, then the same code requires 7 iterations.

Example C-37. FORTRAN 77 Example to Solve Non-symmetric Non-degenerate Linear System

        CALL DFGMRES_INIT(N, COMPUTED_SOLUTION, RHS, RCI_REQUEST, IPAR,
1 DPAR, TMP)
        IF (RCI_REQUEST.NE.0) GOTO 999

C-----
C Calculate ILU0 preconditioner.
C !ATTENTION!
C DCSRILU0 routine uses some IPAR, DPAR set by DFGMRES_INIT routine.
C Important for DCSRILU0 default entries set by DFGMRES_INIT are
C ipar(2) = 6 - output of error messages to the screen,

```

```

C ipar(6) = 1 - allow output of error messages,
C ipar(31)= 0 - abort DCSRILU0 calculations if routine meets zero diagonal element.
C
C If ILU0 is going to be used out of MKL FGMRES context, than the values
C of ipar(2), ipar(6), ipar(31), dpar(31), and dpar(32) should be user
C provided before the DCSRILU0 routine call.
C
C In this example, specific for DCSRILU0 entries are set in turn:
C ipar(31)= 1 - change small diagonal value to that given by dpar(32),
C dpar(31)= 1.D-20 instead of the default value set by DFGMRES_INIT.
C           It is a small value to compare a diagonal entry with it.
C dpar(32)= 1.D-16 instead of the default value set by DFGMRES_INIT.
C           It is the target value of the diagonal value if it is
C           small as compared to dpar(31) and the routine should change
C           it rather than abort DCSRILU0 calculations.
C-----

      IPAR(31)=1
      DPAR(31)=1.D-20
      DPAR(32)=1.D-16
      CALL DCSRILU0(N, A, IA, JA, BILU0, IPAR, DPAR, IERR)
      NRM2=DNRM2(MATSIZE, BILU0, INCX)

      IF(IERR.ne.0) THEN
        WRITE(*,'(A,A,I1)') ' Error after calculation of the',
1' preconditioner DCSRILU0',IERR
        GOTO 998
      ENDIF

C-----
C Set the desired parameters:
C do the restart after 2 iterations
C LOGICAL parameters:
C do not do the stopping test for the maximal number of iterations
C do the Preconditioned iterations of FGMRES method
C Set parameter IPAR(11) for preconditioner call. For this example,
C it reduces the number of iterations.

C Example of Using ILU0 Preconditioner with RCI FGMRES Solver

C example has the same non-degenerate system as in the previous FORTRAN 77 example. The results are the same up to the notational convention between C and Fortran. Please pay special attention to how it is recommended to handle the differences between the Fortran and C arrays. Specifically, in this example we adjust the addresses for input/result for user-defined operations from `IPAR(22)` to `ipar[21]-1` and from `IPAR(23)` to `ipar[22]-1`, respectively. Specific to ILU0 preconditioner parameter entries are referred to as `ipar[30]`, `dpar[30]`, `dpar[31]`. Upon successful execution of the solver, the following information is printed (up to rounding errors that depend on the computer system):

```
-----
The FULLY ADVANCED example RCI FGMRES with ILU0 preconditioner
to solve the non-degenerate algebraic system of linear equations
-----

Some info about the current run of RCI FGMRES method:

As ipar[7]=0, the automatic test for the maximal number of iterations will be
skipped
+++
As ipar[8]=0, the automatic residual test will be skipped
+++
As ipar[9]=1 the user-defined stopping test will be requested via
RCI_request=2
+++
As ipar[10]=1, the Preconditioned FGMRES iterations will be performed, thus,
the preconditioner action will be requested via RCI_request=3
+++
As ipar[11]=0, the automatic test for the norm of the next generated vector is
not equal to zero up to rounding and computational errors will be skipped,
thus, the user-defined test will be requested via RCI_request=4
+++

The system has been solved

The following solution has been obtained:
computed_solution[0]=1.000000e+00
computed_solution[1]=1.000000e+00
computed_solution[2]=1.000000e+00
```

```
computed_solution[3]=1.000000e+00
```

```
The expected solution is:
```

```
expected_solution[0]=1.000000e+00
```

```
expected_solution[1]=1.000000e+00
```

```
expected_solution[2]=1.000000e+00
```

```
expected_solution[3]=1.000000e+00
```

```
Number of iterations: 2
```

```
-----
C example of FGMRES with ILU0 preconditioner
has successfully PASSED all stages of computations
-----
```

NOTE. If the ILU0 preconditioner is not used, then the same code requires 7 iterations.

Fortran Example of Using ILUT Preconditioner with RCI FGMRES Solver

Example results for non-degenerate system. Upon successful execution of the solver, the output contains the following information:

```

-----
The FULLY ADVANCED example RCI FGMRES with ILUT preconditioner
to solve the non-degenerate algebraic system of linear equations
-----

```

Some info about the current run of RCI FGMRES method:

As IPAR(8)=0, the automatic test for the maximal number of iterations will be skipped

+++

As IPAR(9)=0, the automatic residual test will be skipped

+++

As IPAR(10)=1, the user-defined stopping test will be requested via RCI_REQUEST=2

+++

As IPAR(11)=1, the Preconditioned FGMRES iterations will be performed, thus,
the preconditioner action will be requested via RCI_REQUEST=3

+++

As IPAR(12)=0, the automatic test for the norm of the next generated vector is
not equal to zero up to rounding and computational errors will be skipped,
thus, the user-defined test will be requested via RCI_REQUEST=4

+++

The system has been solved

The following solution has been obtained:

COMPUTED_SOLUTION(1)= 0.1000020E+01

COMPUTED_SOLUTION(2)= 0.1000007E+01

COMPUTED_SOLUTION(3)= 0.1000006E+01

COMPUTED_SOLUTION(4)= 0.9999908E+00

The expected solution is:

EXPECTED_SOLUTION(1)= 0.1000000E+01

EXPECTED_SOLUTION(2)= 0.1000000E+01

EXPECTED_SOLUTION(3)= 0.1000000E+01

EXPECTED_SOLUTION(4)= 0.1000000E+01

Number of iterations: 4

```
-----
Fortran example of FGMRES with ILUT preconditioner
has successfully PASSED all stages of computations
-----
```

NOTE. If the ILUT preconditioner is not used, then the same code requires 10 iterations.

C-----
C Calculate ILUT preconditioner.
C          !ATTENTION!
C DCSRILUT routine uses some IPAR, DPAR set by DFGMRES_INIT routine.
C Important for DCSRILUT default entries set by DFGMRES_INIT are
C ipar(2) = 6 - output of error messages to the screen,
C ipar(6) = 1 - allow output of error messages,
C ipar(31)= 0 - abort DCSRILUT calculations if routine meets zero diagonal element.
C ipar(7) = 1 - output warn messages if any and continue
C
C If ILUT is going to be used out of MKL FGMRES context, than the values
C of ipar(2), ipar(6), ipar(31), and dpar(31), should be user
C provided before the DCSRILUT routine call.
C
C In this example, specific for DCSRILUT entries are set in turn:
C ipar(31)= 1 - change small diagonal value to that given by dpar(31),
C dpar(31)= 1.D-5 instead of the default value set by DFGMRES_INIT.
C          It is the target value of the diagonal value if it is
C          small as compared to given tolerance multiplied
C          by the matrix row norm and the routine should
C          change it rather than abort DCSRILUT calculations.
C-----

C Example of Using ILUT Preconditioner with RCI FGMRES Solver

C example has the same non-degenerate system as in the previous FORTRAN 77 example. The results are the same up to the notational convention between C and Fortran. Please pay special attention to how it is recommended to handle the differences between the Fortran and C arrays. Specifically, in this example we adjust the addresses for input/result for user-defined operations from `IPAR(22)` to `ipar[21]-1` and from `IPAR(23)` to `ipar[22]-1`, respectively. Specific to ILUT preconditioner parameter entries are referred to as `ipar[30]`, `dpar[30]`, `dpar[31]`. Upon successful execution of the solver, the following information is printed (up to rounding errors that depend on the computer system):

```
-----
The FULLY ADVANCED example RCI FGMRES with ILUT
preconditioner to solve
the non-degenerate algebraic system of linear equations
-----

Some info about the current run of RCI FGMRES method:

As ipar[7]=0, the automatic test for the maximal number of iterations will be
skipped
+++
As ipar[8]=0, the automatic residual test will be skipped
+++
As ipar[9]=1, the user-defined stopping test will be requested via
RCI_request=2
+++
As ipar[10]=1, the Preconditioned FGMRES iterations will be performed, thus,
the preconditioner action will be requested via RCI_request=3
+++
As ipar[11]=0, the automatic test for the norm of the next generated vector is
not equal to zero up to rounding and computational errors will be skipped,
thus, the user-defined test will be requested via RCI_request=4
+++

The system has been solved

The following solution has been obtained:
computed_solution[0]=1.000020e+00
computed_solution[1]=1.000007e+00
computed_solution[2]=1.000006e+00
computed_solution[3]=9.999908e-01

The expected solution is:
expected_solution[0]=1.000000e+00
expected_solution[1]=1.000000e+00
expected_solution[2]=1.000000e+00
expected_solution[3]=1.000000e+00
```

Number of iterations: 4

```
-----
C example of FGMRES with ILUT preconditioner
has successfully PASSED all stages of computations
-----
```

NOTE. If the ILUT preconditioner is not used, then the same code requires 10 iterations.

Example C-40. C Example to Solve Non-symmetric Non-degenerate Linear System

Code Examples for Optimization Solvers

This section presents code examples for routines described in the [“Optimization Solver Routines” chapter](#).

Examples of dtrnlsp Usage

Example C-43. dtrnlsp Usage in Fortran

```
C** NONLINEAR LEAST SQUARE PROBLEM WITHOUT BOUNDARY CONSTRAINTS

      PROGRAM EXAMPLE_DTRNLSP_POWELL

      IMPLICIT NONE

C** HEADER-FILE WITH DEFINITIONS (CONSTANTS, EXTERNALS)

      INCLUDE 'mkl_rci.fi'

C** USER'S OBJECTIVE FUNCTION

      EXTERNAL          EXTENDET_POWELL

C** N - NUMBER OF FUNCTION VARIABLES

      INTEGER           N

      PARAMETER         (N = 40)

C** M - DIMENSION OF FUNCTION VALUE

      INTEGER           M

      PARAMETER         (M = 40)

C** SOLUTION VECTOR. CONTAINS VALUES X FOR F(X)

      DOUBLE PRECISION  X (N)

C** PRECISIONS FOR STOP-CRITERIA (SEE MANUAL FOR MORE DETAILS)

      DOUBLE PRECISION  EPS (6)

C** JACOBI CALCULATION PRECISION

      DOUBLE PRECISION  JAC_EPS

C** REVERSE COMMUNICATION INTERFACE PARAMETER

      INTEGER           RCI_REQUEST

C** FUNCTION (F(X)) VALUE VECTOR

      DOUBLE PRECISION  FVEC (M)

C** JACOBI MATRIX

      DOUBLE PRECISION  FJAC (M, N)
```

```
C** NUMBER OF ITERATIONS
      INTEGER          ITER
C** NUMBER OF STOP-CRITERION
      INTEGER          ST_CR
C** CONTROLS OF RCI CYCLE
      INTEGER          SUCCESSFUL
C** MAXIMUM NUMBER OF ITERATIONS
      INTEGER          ITER1
C** MAXIMUM NUMBER OF ITERATIONS OF CALCULATION OF TRIAL-STEP
      INTEGER          ITER2
C** INITIAL STEP BOUND
      DOUBLE PRECISION  RS
C** INITIAL AND FINAL RESIDUALS
      DOUBLE PRECISION  R1, R2
C** TR SOLVER HANDLE
      INTEGER*8         HANDLE
C** CYCLE'S COUNTERS
      INTEGER           I, J

C** SET PRECISIONS FOR STOP-CRITERIA
      DO I = 1, 6
        EPS (I) = 1.D-5
      ENDDO
C** SET MAXIMUM NUMBER OF ITERATIONS
      ITER1 = 1000
C** SET MAXIMUM NUMBER OF ITERATIONS OF CALCULATION OF TRIAL-STEP
      ITER2 = 100
C** SET INITIAL STEP BOUND
```

```

      RS = 100.D0
C** PRECISIONS FOR JACOBI CALCULATION
      JAC_EPS = 1.D-8
C** SET THE INITIAL GUESS
      DO I = 1, N/4

CBLAS Interface to the BLAS

This appendix presents CBLAS, the C interface to the Basic Linear Algebra Subprograms (BLAS) implemented in Intel® MKL.

Similar to BLAS, the CBLAS interface includes the following levels of functions:

- “Level 1 CBLAS” (vector-vector operations)
- “Level 2 CBLAS” (matrix-vector operations)
- “Level 3 CBLAS” (matrix-matrix operations).
- “Sparse CBLAS” (operations on sparse vectors).

To obtain the C interface, the Fortran routine names are prefixed with `cblas_` (for example, `dasum` becomes `cblas_dasum`). Names of all CBLAS functions are in lowercase letters.

Complex functions `?dotc` and `?dotu` become CBLAS subroutines (void functions); they return the complex result via a void pointer, added as the last parameter. CBLAS names of these functions are suffixed with `_sub`. For example, the BLAS function `cdotc` corresponds to `cblas_cdotc_sub`.

WARNING. Users of the CBLAS interface should be aware that the CBLAS are just a C interface to the BLAS, which is based on the FORTRAN standard and subject to the FORTRAN standard restrictions. In particular, the output parameters should not be referenced through more than one argument.

In the descriptions of CBLAS interfaces, links provided for each function group lead to the descriptions of the respective Fortran-interface BLAS functions.

CBLAS Arguments

The arguments of CBLAS functions obey the following rules:

- Input arguments are declared with the `const` modifier.
- Non-complex scalar input arguments are passed by value.
- Complex scalar input arguments are passed as void pointers.
- Array arguments are passed by address.
- BLAS character arguments are replaced by the appropriate enumerated type.

- Level 2 and Level 3 routines acquire an additional parameter of type `CBLAS_ORDER` as their first argument. This parameter specifies whether two-dimensional arrays are row-major (`CblasRowMajor`) or column-major (`CblasColMajor`).

Enumerated Types

The CBLAS interface uses the following enumerated types:

```
enum CBLAS_ORDER {
    CblasRowMajor=101, /* row-major arrays */
    CblasColMajor=102}; /* column-major arrays */
enum CBLAS_TRANSPOSE {
    CblasNoTrans=111, /* trans='N' */
    CblasTrans=112, /* trans='T' */
    CblasConjTrans=113}; /* trans='C' */
enum CBLAS_UPLO {
    CblasUpper=121, /* uplo='U' */
    CblasLower=122}; /* uplo='L' */
enum CBLAS_DIAG {
    CblasNonUnit=131, /* diag='N' */
    CblasUnit=132}; /* diag='U' */
enum CBLAS_SIDE {
    CblasLeft=141, /* side='L' */
    CblasRight=142}; /* side='R' */
```

Level 1 CBLAS

This is an interface to “[BLAS Level 1 Routines and Functions](#)”, which perform basic vector-vector operations.

?asum

```
float cblas_sasum(const int N, const float *X, const int incX);
double cblas_dasum(const int N, const double *X, const int incX);
float cblas_scasum(const int N, const void *X, const int incX);
double cblas_dzasum(const int N, const void *X, const int incX);

```

Sparse CBLAS

This is an interface to “[Sparse BLAS Level 1 Routines and Functions](#)”, which perform a number of common vector operations on sparse vectors stored in compressed form.

Note that all index parameters, *indx*, are in C-type notation and vary in the range [0..N-1].

?axpyi

```
void cblas_saxpyi(const int N, const float alpha, const float *X, const int *indx, float
*Y);
void cblas_daxpyi(const int N, const double alpha, const double *X, const int *indx, double
*Y);
void cblas_caxpyi(const int N, const void *alpha, const void *X, const int *indx, void *Y);
void cblas_zaxpyi(const int N, const void *alpha, const void *X, const int *indx, void *Y);
```

?doti

```
float cblas_sdoti(const int N, const float *X, const int *indx, const float *Y);
double cblas_ddoti(const int N, const double *X, const int *indx, const double *Y);
```

?dotci

```
void cblas_cdotci_sub(const int N, const void *X, const int *indx, const void *Y, void *dotui);
void cblas_zdotci_sub(const int N, const void *X, const int *indx, const void *Y, void *dotui);
```

?dotui

```
void cblas_cdotui_sub(const int N, const void *X, const int *indx, const void *Y, void *dotui);
void cblas_zdotui_sub(const int N, const void *X, const int *indx, const void *Y, void *dotui);
```

?gthr

```
void cblas_sgthr(const int N, const float *Y, float *X, const int *indx);
void cblas_dgthr(const int N, const double *Y, double *X, const int *indx);
void cblas_cgthr(const int N, const void *Y, void *X, const int *indx);
void cblas_zgthr(const int N, const void *Y, void *X, const int *indx);
```

?gthrz

```
void cblas_sgthrz(const int N, float *Y, float *X, const int *indx);
void cblas_dgthrz(const int N, double *Y, double *X, const int *indx);
void cblas_cgthrz(const int N, void *Y, void *X, const int *indx);
void cblas_zgthrz(const int N, void *Y, void *X, const int *indx);
```

?roti

```
void cblas_sroti(const int N, float *X, const int *indx, float *Y, const float c, const float s);
void cblas_droti(const int N, double *X, const int *indx, double *Y, const double c, const double s);
```

?sctr

```
void cblas_ssctr(const int N, const float *X, const int *indx, float *Y);
void cblas_dsctr(const int N, const double *X, const int *indx, double *Y);
void cblas_csctr(const int N, const void *X, const int *indx, void *Y);
void cblas_zsctr(const int N, const void *X, const int *indx, void *Y);
```

Specific Features of Fortran 95 Interfaces for LAPACK Routines

Intel® MKL implements Fortran 95 interface for LAPACK package, further referred to as MKL LAPACK95, to provide full capacity of MKL FORTRAN 77 LAPACK routines. This is the principal difference of Intel MKL from the Netlib Fortran 95 implementation for LAPACK.

A new feature of MKL LAPACK95 by comparison with Intel MKL LAPACK77 implementation is presenting a package of source interfaces along with wrappers that make the implementation compiler-independent. As a result, the MKL LAPACK package can be used in all programming environments intended for Fortran 95.

Depending on the degree and type of difference from Netlib implementation, the MKL LAPACK95 interfaces fall into several groups that require different transformations (see [“MKL Fortran 95 Interfaces for LAPACK Routines vs. Netlib Implementation”](#)). The groups are given in full with the calling sequences of the routines and appropriate differences from Netlib analogs.

The following conventions are used:

```
<interface> ::= <name of interface> '(' <arguments list> ')'  
<arguments list> ::= <first argument> {<argument>}*  
<first argument> ::= <identifier>  
<argument> ::= <required argument> | <optional argument>  
<required argument> ::= '<identifier>  
<optional argument> ::= '[, '<identifier> '  
<name of interface> ::= <identifier>
```

where defined notions are separated from definitions by `::=`, notion names are marked by angle brackets, terminals are given in quotes, and `{...}*` denotes repetition zero, one, or more times.

`<first argument>` and each `<required argument>` should be present in all calls of denoted interface, `<optional argument>` may be omitted. Comments to interface definitions are provided where necessary. Comment lines begin with character `!`.

Two interfaces with one name are presented when two variants of subroutine calls (separated by types of arguments) exist.

FFTW Interface to Intel® Math Kernel Library

Intel® Math Kernel Library (Intel® MKL) offers FFTW2 and FFTW3 interfaces to Intel MKL Fast Fourier Transform and Trigonometric Transform functionality. The purpose of these interfaces is to enable applications using FFTW (www.fftw.org) to gain performance with Intel MKL without changing the program source code.

Both FFTW2 and FFTW3 interfaces are provided in open source as FFTW wrappers to Intel MKL. For ease of use, FFTW3 interface is also integrated in Intel MKL.

Notational Conventions

This appendix typically employs path notations for Windows* OS.

FFTW2 Interface to Intel® Math Kernel Library

This section describes a collection of wrappers for the FFTW 2.x interface. The wrappers are the superstructure of FFTW to be used for calling the Intel MKL Fourier transform interface (FFT interface). The wrappers correspond to FFTW 2.x and the Intel MKL versions 7.0 or higher.

Because of differences between FFTW and Intel MKL FFT functionalities, there are restrictions on using wrappers instead of the FTTW functions. Some FFTW functions have empty wrappers. However, many typical FFTs can be computed using these wrappers.

Refer to [chapter 11 "Fourier Transform Functions"](#), for better understanding the effects from the use of the wrappers.

Additional wrappers may be added in the future to extend FFTW functionality available with Intel MKL.

Wrappers Reference

The section provides a reference for FFTW C interface.

Each FFTW function has its own wrapper. Some of them, which are *not* expressly listed below, are empty and do nothing, but they are still needed to avoid link errors and satisfy the function calls. Intel MKL FFT interface operates on both float and double-precision data types.

Complex Fast Fourier Transforms

One-dimensional FFTs

```
fftw_plan fftw_create_plan(int n, fftw_direction dir, int flags);

fftw_plan fftw_create_plan_specific(int n, fftw_direction dir, int flags,
fftw_complex *in, int istride, fftw_complex *out, int ostride);

void fftw(fftw_plan plan, int howmany, fftw_complex *in, int istride, int
idist, fftw_complex *out, int ostride, int odist);

void fftw_one(fftw_plan plan, fftw_complex *in , fftw_complex *out);

void fftw_destroy_plan(fftw_plan plan);
```

Argument restrictions. The same algorithm corresponds to all values of the *flags* parameter.

Multi-dimensional FFTs

```
fftwnd_plan fftwnd_create_plan(int rank, const int *n, fftw_direction dir,
int flags);

fftwnd_plan fftw2d_create_plan(int nx, int ny, fftw_direction dir, int flags);

fftwnd_plan fftw3d_create_plan(int nx, int ny, int nz, fftw_direction dir,
int flags);

fftwnd_plan fftwnd_create_plan_specific(int rank, const int *n, fftw_direction
dir, int flags, fftw_complex *in, int istride, fftw_complex *out, int
ostride);

fftwnd_plan fftw2d_create_plan_specific(int nx, int ny, fftw_direction dir,
int flags, fftw_complex *in, int istride, fftw_complex *out, int ostride);

fftwnd_plan fftw3d_create_plan_specific(int nx, int ny, int nz, fftw_direction
dir, int flags, fftw_complex *in, int istride, fftw_complex *out, int
ostride);

void fftwnd(fftwnd_plan plan, int howmany, fftw_complex *in, int istride,
int idist, fftw_complex *out, int ostride, int odist);

void fftwnd_one(fftwnd_plan plan, fftw_complex *in, fftw_complex *out);

void fftwnd_destroy_plan(fftwnd_plan plan);
```

Argument restrictions. The same algorithm corresponds to all values of the *flags* parameter.

Real Fast Fourier Transforms

One-dimensional FFTs

All wrappers are empty and do nothing, as the Intel MKL FFT interface does not currently support this functionality (halfcomplex array).

Multi-dimensional FFTs

```

rfftwnd_plan rfftwnd_create_plan(int rank, const int *n, fftw_direction dir,
int flags);

rfftwnd_plan rfftw2d_create_plan(int nx, int ny, fftw_direction dir, int
flags);

rfftwnd_plan rfftw3d_create_plan(int nx, int ny, int nz, fftw_direction dir,
int flags);

void rfftwnd_real_to_complex(rfftwnd_plan plan, int howmany, fftw_real *in,
int istride, int idist, fftw_complex *out, int ostride, int odist);

void rfftwnd_complex_to_real(rfftwnd_plan plan, int howmany, fftw_complex
*in, int istride, int idist, fftw_real *out, int ostride, int odist);

void rfftwnd_one_real_to_complex(rfftwnd_plan plan, fftw_real *in,
fftw_complex *out);

void rfftwnd_one_complex_to_real(rfftwnd_plan plan, fftw_complex *in,
fftw_real *out);

void rfftwnd_destroy_plan(rfftwnd_plan plan);

```

Argument restrictions. The same algorithm corresponds to all values of the *flags* parameter.

Wisdom Wrappers

All wrappers are empty and do nothing, because the Intel MKL FFT interface currently does not support these functionalities.

Memory Allocation

```
void* fftw_malloc(size_t n);
```

```
void fftw_free(void* x);
```

Unlike the `fftw_malloc` function, the `fftw_malloc` wrapper does not align the allocatable array. To do that, it is necessary to allocate extra memory and shift the array address for the FFT data. See also the *"Managing Performance and Memory" chapter in the Intel MKL User's Guide* (file `userguide.pdf`).

Parallel Mode

This section touches upon multi-threaded FFTW wrappers only. MPI FFTW wrappers, available only with Intel MKL for the Linux* and Windows* operating systems, are described in [section "MPI FFTW Wrappers"](#).

Multi-threaded FFTW

FFTW multi-threaded functions use the *number of threads* parameter, which the `fftw_threads_init` function defines. However, the `int fftw_threads_init(void)` wrapper is empty and does nothing, because the Intel MKL FFT interface implements a different mechanism of parallelization. If you want to use Intel MKL FFT routines in a parallel mode or call wrappers from a multi-threaded application, please refer to [the "Number of User Threads" section in chapter 11](#) to learn how to manage the number of threads.

Each of the remaining wrappers in this section is the same as the respective wrapper in [section Complex Fast Fourier Transforms](#) or [Real Fast Fourier Transforms](#) whose name differs from the one of the given wrapper in cutting out 'threads_').

For example,

```
void fftw_threads_one(int threads, fftw_plan plan, fftw_complex *in,
fftw_complex *out);
```

is the same as

```
void fftw_one(fftw_plan plan, fftw_complex *in, fftw_complex *out);
```

Argument restrictions. The *threads* parameter is inessential. Both functions may be single-threaded or parallel depending on Intel MKL variables.

Calling Wrappers from Fortran

Wrappers are available for all Fortran FFTW functions. For example, instead of calling the C wrapper `fftw_one`, in Fortran, you should call the `fftw_f77_one` wrapper.

FFTW Fortran functions are actually the wrappers to FFTW C functions. Fortran wrappers are actually the wrappers to C wrappers. So, their functionality and argument restrictions are the same as of the corresponding C wrappers.

Installation

Wrappers are delivered as source code, which you must compile to build the wrapper library. Then you can substitute the wrapper and Intel MKL libraries for the FFTW library. The source code for the wrappers and makefiles with the wrapper list files are located in the `.\interfaces\fftw2xc` and `.\interfaces\fftw2xf` subdirectory in the Intel MKL directory for C and Fortran wrappers, respectively.

Creating the Wrapper Library

Two header files are used to compile the C wrapper library: `fftw2_mkl.h` and `fftw.h`. The `fftw2_mkl.h` file is located in the `.\interfaces\fftw2xc\wrappers` subdirectory in the Intel MKL directory.

Three header files are used to compile the Fortran wrapper library: `fftw2_mkl.h`, `fftw2_f77_mkl.h`, and `fftw.h`. The `fftw2_mkl.h` and `fftw2_f77_mkl.h` files are located in the `.\interfaces\fftw2xf\wrappers` subdirectory in the Intel MKL directory.

The file `fftw.h`, used to compile libraries for both interfaces and located in the `.\include\fftw` subdirectory in the Intel MKL directory, slightly differs from the original FFTW (www.fftw.org) header file `fftw.h`.

The source code for the wrappers, makefiles, and function list files are located in subdirectories `.\interfaces\fftw2xc` and `.\interfaces\fftw2xf` in the Intel MKL directory for C and Fortran wrappers, respectively.

A wrapper library contains C or Fortran wrappers for complex and real transforms in a serial and multi-threaded mode for one of the two data types (`double` or `float`). A makefile parameter manages the data type.

The makefile parameters specify the platform (required), compiler, and data precision. Specifying the platform is required. The makefile comment heading provides the exact description of these parameters.

Because a C compiler builds the Fortran wrapper library, function names in the wrapper library and Fortran object module may be different. The file `fftw2_f77_mkl.h` in the `.\interfaces\fftw2xf\source` subdirectory in the Intel MKL directory defines function names according to the names in the Fortran module. If a required name is missing in the file, you can modify the file to add the name before building the library.

To build the library, run the `make` command on Linux* OS and Mac OS* X or the `nmake` command on Windows* OS with appropriate parameters.

For example, the command

```
make lib64
```

builds on Linux OS a double-precision wrapper library for IA-64 architecture based applications using the Intel® C++ Compiler or the Intel® Fortran Compiler version 9.1 or higher (compilers and data precision are chosen by default.).

Each makefile creates the library in the directory with the Intel MKL libraries corresponding to the used platform. For example, `./lib/64` (on Linux OS and Mac OS X) or `.\ia32\lib` (on Windows* OS).

In the wrapper library names, the suffix corresponds to the used compiler, the letter "f" precedes the underscore for Fortran, and the letter "c" precedes the underscore for C.

For example,

```
fftw2xf_intel.lib (on Windows OS); libfftw2xf_intel.a (on Linux OS and Mac OS X);
fftw2xc_intel.lib (on Windows OS); libfftw2xc_intel.a (on Linux OS and Mac OS X);
fftw2xc_ms.lib (on Windows OS); libfftw2xc_gnu.a (on Linux OS and Mac OS X).
```

Application Assembling

Use the necessary original FFTW (www.fftw.org) header files without any modifications. Use the created wrapper library and the Intel MKL library instead of the FFTW library.

Running Examples

Intel MKL provides examples to demonstrate how to use the wrapper library. The source code for the examples, makefiles used to run them, and the example list files are located in the `.\examples\fftw2xc` and `.\examples\fftw2xf` subdirectories in the Intel MKL directory for C and Fortran, respectively. To build examples, several additional files are needed: `fftw.h`, `fftw_threads.h`, `rfftw.h`, `rfftw_threads.h`, and `fftw_f77.I`. These files are distributed with permission from FFTW and are available in `.\include\fftw`. The original files can also be found in FFTW 2.1.5 at <http://www.fftw.org/download.html>.

An example makefile uses the `function` parameter in addition to the parameters that the respective wrapper library makefile uses (see [Creating a Wrapper Library](#)). The makefile comment heading provides the exact description of these parameters.

An example makefile normally invokes examples. However, if the appropriate wrapper library is not yet created, the makefile first builds the library the same way as the wrapper library makefile does and then proceeds to examples.

If the parameter `function=<example_name>` is defined, only the specified example runs. Otherwise, all examples from the appropriate subdirectory run. The subdirectory `._results` is created, and the results are stored there in the `<example_name>.res` files.

MPI FFTW

MPI FFTW wrappers are available only with Intel® MKL for the Linux* and Windows* operating systems.

MPI FFTW Wrappers Reference

The section provides a reference for MPI FFTW C interface.

Complex MPI FFTW

Complex One-dimensional MPI FFTW Transforms

```
fftw_mpi_plan fftw_mpi_create_plan(MPI_Comm comm, int n, fftw_direction dir,
int flags);

void fftw_mpi(fftw_mpi_plan p, int n_fields, fftw_complex *local_data,
fftw_complex *work);

void fftw_mpi_local_sizes(fftw_mpi_plan p, int *local_n, int *local_start,
int *local_n_after_transform, int *local_start_after_transform, int
*total_local_size);

void fftw_mpi_destroy_plan(fftw_mpi_plan plan);
```

Argument restrictions:

- Supported values of *flags* are FFTW_ESTIMATE, FFTW_MEASURE, FFTW_SCRAMBLED_INPUT and FFTW_SCRAMBLED_OUTPUT. The same algorithm corresponds to all these values of the flags parameter. If any other *flags* value is supplied, the wrapper library reports an error 'CDFT error in wrapper: unknown flags'.
- The only supported value of *n_fields* is 1.

Complex Multi-dimensional MPI FFTW Transforms

```
fftwnd_mpi_plan fftw2d_mpi_create_plan(MPI_Comm comm, int nx, int ny,
fftw_direction dir, int flags);

fftwnd_mpi_plan fftw3d_mpi_create_plan(MPI_Comm comm, int nx, int ny, int
nz, fftw_direction dir, int flags);

fftwnd_mpi_plan fftwnd_mpi_create_plan(MPI_Comm comm, int dim, int *n,
fftw_direction dir, int flags);
```

```
void fftwnd_mpi(fftwnd_mpi_plan p, int n_fields, fftw_complex *local_data,
fftw_complex *work, fftwnd_mpi_output_order output_order);

void fftwnd_mpi_local_sizes(fftwnd_mpi_plan p, int *local_nx, int
*local_x_start, int *local_ny_after_transpose, int
*local_y_start_after_transpose, int *total_local_size);

void fftwnd_mpi_destroy_plan(fftwnd_mpi_plan plan);
```

Argument restrictions:

- Supported values of *flags* are FFTW_ESTIMATE and FFTW_MEASURE. If any other value of *flags* is supplied, the wrapper library reports an error 'CDFT error in wrapper: unknown flags'.
- The only supported value of *n_fields* is 1.

Real MPI FFTW

Real-to-Complex MPI FFTW Transforms

```
rfftwnd_mpi_plan rfftw2d_mpi_create_plan(MPI_Comm comm, int nx, int ny,
fftw_direction dir, int flags);

rfftwnd_mpi_plan rfftw3d_mpi_create_plan(MPI_Comm comm, int nx, int ny, int
nz, fftw_direction dir, int flags);

rfftwnd_mpi_plan rfftwnd_mpi_create_plan(MPI_Comm comm, int dim, int *n,
fftw_direction dir, int flags);

void rfftwnd_mpi(rfftwnd_mpi_plan p, int n_fields, fftw_real *local_data,
fftw_real *work, fftwnd_mpi_output_order output_order);

void rfftwnd_mpi_local_sizes(rfftwnd_mpi_plan p, int *local_nx, int
*local_x_start, int *local_ny_after_transpose, int
*local_y_start_after_transpose, int *total_local_size);

void rfftwnd_mpi_destroy_plan(rfftwnd_mpi_plan plan);
```

Argument restrictions:

- Supported values of *flags* are FFTW_ESTIMATE and FFTW_MEASURE. If any other value of *flags* is supplied, the wrapper library reports an error 'CDFT error in wrapper: unknown flags'.
- The only supported value of *n_fields* is 1.

- Function `rfftwnd_mpi_create_plan` can be used for both one-dimensional and multi-dimensional transforms.
- Both values of the `output_order` parameter are supported: `FFTW_NORMAL_ORDER` and `FFTW_TRANSPOSED_ORDER`.

Creating MPI FFTW Wrapper Library

The source code for the wrappers, makefile, and wrapper list file are located in the `.\interfaces\fftw2x_cdft` subdirectory in the Intel MKL directory.

A wrapper library contains C wrappers for Complex One-dimensional MPI FFTW Transforms and Complex Multi-dimensional MPI FFTW Transforms. The library also contains empty C wrappers for Real Multi-dimensional MPI FFTW Transforms. For details, see [MPI FFTW Wrappers Reference](#).

The makefile parameters specify the platform (required), compiler, and data precision. Specifying the platform is required. The makefile comment heading provides the exact description of these parameters.

To build the library, run the `make` command on Linux* OS and Mac OS* X or the `nmake` command on Windows* OS with appropriate parameters.

For example, the command

```
make lib64
```

builds on Linux OS a double-precision wrapper library for IA-64 architecture based applications using Intel MPI 2.0 and the Intel® C++ Compiler version 9.1 or higher (compilers and data precision are chosen by default.).

The makefile creates the wrapper library in the directory with the Intel MKL libraries corresponding to the used platform. For example, `./lib/64` (on Linux OS) or `.\ia32\lib` (on Windows* OS).

In the wrapper library names, the suffix corresponds to the used data precision. For example,

`fftw2x_cdft_SINGLE.lib` on Windows OS;

`libfftw2x_cdft_DOUBLE.a` on Linux OS.

Application Assembling with MPI FFTW Wrapper Library

Use the necessary original FFTW (www.fftw.org) header files without any modifications. Use the created MPI FFTW wrapper library and the Intel MKL library instead of the FFTW library.

Running Examples

There are some examples that demonstrate how to use the MPI FFTW wrapper library. The source C code for the examples, makefiles used to run them, and the example list files are located in the `.\examples\fftw2x_cdft` subdirectory in the Intel MKL directory. To build examples, one additional file `fftw_mpi.h` is needed. This file is distributed with permission from FFTW and is available in `.\include\fftw`. The original file can also be found in FFTW 2.1.5 at <http://www.fftw.org/download.html>.

Parameters for the example makefiles are described in the makefile comment headings and are similar to the wrapper library makefile parameters (see [Creating MPI FFTW Wrapper Library](#)).

The table below lists examples available in the `.\examples\fftw2x_cdft\source` subdirectory.

Table G-1 Examples of MPI FFTW Wrappers

Source file for the example	Description
<code>wrappers_c1d.c</code>	One-dimensional Complex MPI FFTW transform, using <code>plan = fftw_mpi_create_plan(...)</code>
<code>wrappers_c2d.c</code>	Two-dimensional Complex MPI FFTW transform, using <code>plan = fftw2d_mpi_create_plan(...)</code>
<code>wrappers_c3d.c</code>	Three-dimensional Complex MPI FFTW transform, using <code>plan = fftw3d_mpi_create_plan(...)</code>
<code>wrappers_c4d.c</code>	Four-dimensional Complex MPI FFTW transform, using <code>plan = fftwnd_mpi_create_plan(...)</code>
<code>wrappers_r1d.c</code>	One-dimensional Real MPI FFTW transform, using <code>plan = rfftw_mpi_create_plan(...)</code>
<code>wrappers_r2d.c</code>	Two-dimensional Real MPI FFTW transform, using <code>plan = rfftw2d_mpi_create_plan(...)</code>
<code>wrappers_r3d.c</code>	Three-dimensional Real MPI FFTW transform, using <code>plan = rfftw3d_mpi_create_plan(...)</code>

Source file for the example	Description
wrappers_r4d.c	Four-dimensional Real MPI FFTW transform, using <code>plan = rfftwnd_mpi_create_plan(...)</code>

FFTW3 Interface to Intel® Math Kernel Library

This section describes a collection of FFTW3 wrappers to Intel MKL. The wrappers translate calls of FFTW3 functions to the calls of the Intel MKL Fourier transform (FFT) or Trigonometric Transform (TT) functions. The purpose of FFTW3 wrappers is to enable developers whose programs currently use the FFTW3 library to gain performance with the Intel MKL Fourier transforms without changing the program source code.

The wrappers correspond to the FFTW release 3.2 and the Intel MKL releases starting with 10.2. For a detailed description of FFTW interface, refer to [www.fftw.org](#). For a detailed description of Intel MKL FFT and TT functionality the wrappers use, refer to [chapter 11](#) and [section](#) in [chapter 13](#), respectively.

The FFTW3 wrappers provide a limited functionality compared to the original FFTW 3.2 library, because of differences between FFTW and Intel MKL FFT and TT functionality. This section describes limitations of the FFTW3 wrappers and hints for their usage. Nevertheless, many typical FFT tasks can be performed using the FFTW3 wrappers to Intel MKL. More functionality may be added to the wrappers and Intel MKL in the future to reduce the constraints of the FFTW3 interface to Intel MKL.

The FFTW3 wrappers are integrated in Intel MKL. The only change required to use Intel MKL through the FFTW3 wrappers is to link your application using FFTW3 against Intel MKL.

A reference implementation of the FFTW3 wrappers is also provided in open source. You can find it in the `interfaces` directory of the Intel MKL distribution. You can use the reference implementation to create your own wrapper library (see [Building Your Own Wrapper Library](#))

Using FFTW3 Wrappers

The FFTW3 wrappers are a set of functions and data structures depending on one another. The wrappers are not designed to provide the interface on a function-per-function basis. Some FFTW3 wrapper functions are empty and do nothing, but they are present to avoid link errors and satisfy function calls.

This manual does not list the declarations of the functions that the FFTW3 wrappers provide (you can find the declarations in the `fftw3.h` header file). Instead, this section comments particular limitations of the wrappers and provides usage hints:

- Long double precision is not supported. The Intel MKL FFT functions operate only on single- and double-precision floating-point data types (`float` and `double`, respectively), therefore the FFTW3 wrappers do not support the `long double` data type. All the FFTW3 wrapper functions with prefix `fftwl_` have an empty body and are provided only for link compatibility.
- The wrappers provide equivalent implementation for double- and single-precision functions (those with prefixes `fftw_` and `fftwf_`, respectively). So, all these comments equally apply to the double- and single-precision functions and will refer to functions with prefix `fftw_`, that is, double-precision functions, for brevity.
- The FFTW3 interface that the wrappers provide is defined in header files `fftw3.h` and `fftw3.f`. These files are borrowed from the FFTW3.2 package and distributed within Intel MKL with permission. Additionally, files `fftw3_mkl.h`, `fftw3_mkl.f`, and `fftw3_mkl_f77.h` define supporting structures, supplementary constants and macros, and expose Fortran interface in C.
- Actual functionality of the plan creation wrappers is implemented in `guru64` set of functions. Basic interface, advanced interface, and `guru` interface plan creation functions call the `guru64` interface functions. Thus, all types of the FFTW3 plan creation interface in the wrappers are functional.
- Plan creation functions may return a `NULL` plan, indicating that the functionality is not supported. So, please carefully check the result returned by plan creation functions in your application. In particular, the following problems return a `NULL` plan:
 - All long double-precision problems.
 - `c2r` and `r2c` problems with a split storage of complex data.
 - `r2r` problems with *kind* values `FFTW_R2HC`, `FFTW_HC2R`, and `FFTW_DHT`. The only supported `r2r` kinds are even/odd DFTs (sine/cosine transforms).
 - Multidimensional `r2r` transforms.
 - Transforms of multidimensional vectors. That is, the only supported values for parameter *howmany_rank* in `guru` and `guru64` plan creation functions are 0 and 1.
 - Multidimensional transforms with *rank* > `MKL_MAXRANK`.
- The `MKL_RODFT00` value of the *kind* parameter is introduced by the FFTW3 wrappers. For better performance, you are strongly encouraged to use this value rather than `FFTW_RODFT00`. To use this *kind* value, provide an extra first element equal to 0.0 for the input/output vectors. Consider the following example:

```
plan1 = fftw_plan_r2r_1d(n, in1, out1, FFTW_RODFT00, FFTW_ESTIMATE);
plan2 = fftw_plan_r2r_1d(n, in2, out2, MKL_RODFT00, FFTW_ESTIMATE);
```

Both plans perform the same transform, except that the *in2/out2* arrays have one extra zero element at location 0. For example, if $n=3$, $in1=\{x,y,z\}$ and $out1=\{u,v,w\}$, then $in2=\{0,x,y,z\}$ and $out2=\{0,u,v,w\}$.

- The *flags* parameter in plan creation functions is always ignored. The same algorithm is used regardless of the value of this parameter. In particular, *flags* values `FFTW_ESTIMATE`, `FFTW_MEASURE`, etc. have no effect.
- For multithreaded plans, use normal sequence of calls to the `fftw_init_threads()` and `fftw_plan_with_nthreads()` functions (refer to FFTW documentation).
- FFTW3 wrappers are not fully thread safe. If the new-array execute functions, such as `fftw_execute_dft()`, share the same plan from parallel user threads, set the number of the sharing threads before creation of the plan. For this purpose, the FFTW3 wrappers provide a header file `fftw3_mkl.h`, which defines a global structure `fftw3_mkl` with a field to be set to the number of sharing threads. Below is an example of setting the number of sharing threads:

```
#include "fftw3.h"
#include "fftw3_mkl.h"
fftw3_mkl.number_of_user_threads = 4;
plan = fftw_plan_dft(...);
```

- Memory allocation function `fftw_malloc` returns memory aligned at a 16-byte boundary. You must free the memory with `fftw_free`.
- The FFTW3 wrappers to Intel MKL use the 32-bit `int` type in both LP64 and ILP64 interfaces of Intel MKL. Use `guru64` FFTW3 interfaces for 64-bit sizes.
- Fortran wrappers (see [Calling Wrappers from Fortran](#)) use the `INTEGER` type, which is 32-bit in LP64 interfaces and 64-bit in ILP64 interfaces.
- The wrappers typically indicate a problem by returning a `NULL` plan. In a few cases, the wrappers may report a descriptive message of the problem detected. By default the reporting is turned off. To turn it on, set variable `fftw3_mkl.verbose` to a non-zero value, for example:

```
#include "fftw3.h"
#include "fftw3_mkl.h"
fftw3_mkl.verbose = 0;
plan = fftw_plan_r2r(...);
```

- The following functions are empty:
 - For saving, loading, and printing plans
 - For saving and loading wisdom
 - For estimating arithmetic cost of the transforms.

- Do not use macro `FFTW_DLL` with the FFTW3 wrappers to Intel MKL.

Calling Wrappers from Fortran

Intel MKL also provides Fortran 77 interfaces of the FFTW3 wrappers. The Fortran wrappers are available for all FFTW3 interface functions and are based on C interface of the FFTW3 wrappers, and so they have the same functionality and restrictions as the corresponding C interface wrappers.

The Fortran wrappers use the default `INTEGER` type for integer arguments. The default `INTEGER` is 32-bit in Intel MKL LP64 interfaces and 64-bit in ILP64 interfaces. Argument `plan` in a Fortran application must have type `INTEGER*8`.

Double-precision wrappers have prefix `dfftw_`, single-precision subroutines have prefix `sfftw_` and provide an equivalent functionality. Long double subroutines (with prefix `lfftw_`) are all empty.

The Fortran FFTW3 wrappers use the default Intel® Fortran compiler convention for name decoration. If your compiler uses a different convention, or if you are using compiler options affecting the name decoration (such as `/Qlowercase`), you may need to compile the wrappers from sources, as described in section [Building Your Own Wrapper Library](#).

For interoperability with C, the declaration of the Fortran FFTW3 interface is provided in header file `include/fftw/fftw3_mkl_f77.h`.

You can call Fortran wrappers from a FORTRAN 77 or Fortran 90 application, although Intel MKL does not provide a Fortran 90 module for the wrappers. For a detailed description of the FFTW Fortran interface, refer to FFTW3 documentation (www.fftw.org).

The following example illustrates calling the FFTW3 wrappers from Fortran:

```
INTEGER*8 plan
INTEGER N
INCLUDE 'fftw3.f'
COMPLEX*16 IN(*), OUT(*)
!...initialize array IN
CALL DFFTW_PLAN_DFT_1D(PLAN, N, IN, OUT, -1, FFTW_ESTIMATE)
IF (PLAN .EQ. 0) STOP
CALL DFFTW_EXECUTE
!...result is in array OUT
```

Building Your Own Wrapper Library

The FFTW3 wrappers to Intel MKL are delivered both integrated in Intel MKL and as source code, which can be compiled to build a standalone wrapper library with exactly the same functionality. Normally you do not need to build the wrappers yourself. However, if your Fortran

application is compiled with a compiler that uses a different name decoration than the Intel® Fortran compiler or if you are using compiler options altering the Fortran name decoration, you may need to build the wrappers that use the appropriate name changing convention.

The source code for the wrappers, makefiles, and function list files are located in subdirectories `.\interfaces\fftw3xc` and `.\interfaces\fftw3xf` in the Intel MKL directory for C and Fortran wrappers, respectively.

To build the wrappers,

1. Change the current directory to the wrapper directory
2. Run the `make` command on Linux* OS and Mac OS* X or the `nmake` command on Windows* OS with a required target and optionally several parameters.

The target, that is, one of `{lib32, lib64, libem64t}`, defines the platform architecture, and the other parameters facilitate selection of the compiler, size of the default `INTEGER` type, and placement of the resulting wrapper library. You can find a detailed and up-to-date description of the parameters in the makefile.

In the following example, the `make` command is used to build the FFTW3 Fortran wrappers to MKL for use from the GNU g77 Fortran compiler on Linux OS based on Intel® 64 architecture:

```
cd interfaces/fftw3xf
make libem64t compiler=gcc fname=a_name__ install_to=/my/path
```

This command builds the wrapper library using the GNU gcc compiler, decorates the name with the second underscore, and places the result, named `libfftw3xf_gcc.a`, into directory `/my/path`. The name of the resulting library is composed of the name of the compiler used and may be changed by an optional parameter.

Building an Application

Normally, the only change needed to build your application with FFTW3 wrappers replacing original FFTW library is to add Intel MKL at the link stage (see section *"Linking Your Application with Intel® Math Kernel Library" in the Intel MKL User's Guide*).

If you recompile your application, add subdirectory `include\fftw` to the search path for header files to avoid FFTW3 version conflicts.

Sometimes, you may have to modify your application according to the following recommendations:

- The application requires

```
#include "fftw3.h",
```

 which it probably already includes.

- The application does not require
`#include "mkl_dfti.h" .`
- The application does not require
`#include "fftw3_mkl.h" .`
 It is required only in case you want to use the `MKL_RODFT00` constant.
- If the application does not check whether a `NULL` plan is returned by plan creation functions, this check must be added, because the FFTW3 to Intel MKL wrappers do not provide 100% of FFTW3 functionality.
- If the application is threaded, take care about shared plans, because the execute functions in the wrappers are not thread safe, unlike the original FFTW3 functions. See a [note about setting `fftw3_mkl.number_of_user_threads` in section "Using FFTW3 wrappers"](#).

Running Examples

There are some examples that demonstrate how to use the wrapper library. The source code for the examples, makefiles used to run them, and the example list files are located in the `.\examples\fftw3xc` and `.\examples\fftw3xf` subdirectories in the Intel MKL directory. To build Fortran examples, one additional file `fftw3.f` is needed. This file is distributed with permission from FFTW and is available in the `.\include\fftw` subdirectory of the Intel MKL directory. The original file can also be found in FFTW 3.2 at <http://www.fftw.org/download.html>.

Example makefile parameters are similar to the wrapper library makefile parameters. Example makefiles normally build and invoke the examples. If the parameter `function=<example_name>` is defined, then only the specified example will run. Otherwise, all examples will be executed. Results of running the examples are saved in subdirectory `._results` in files with extension `.res`.

For detailed information about options for the example makefile, refer to the makefile.

Glossary

A^H	Denotes the conjugate transpose of a general matrix A . <i>See also</i> conjugate matrix.
A^T	Denotes the transpose of a general matrix A . <i>See also</i> transpose.
band matrix	A general m -by- n matrix A such that $a_{ij} = 0$ for $ i - j > 1$, where $1 < 1 < \min(m, n)$. For example, any tridiagonal matrix is a band matrix.
band storage	A special storage scheme for band matrices. A matrix is stored in a two-dimensional array: columns of the matrix are stored in the corresponding columns of the array, and <i>diagonals</i> of the matrix are stored in rows of the array.
BLAS	Abbreviation for Basic Linear Algebra Subprograms. These subprograms implement vector, matrix-vector, and matrix-matrix operations.
BRNG	Abbreviation for Basic Random Number Generator. Basic random number generators are pseudorandom number generators imitating i.i.d. random number sequences of uniform distribution. Distributions other than uniform are generated by applying different transformation techniques to the sequences of random numbers of uniform distribution.
BRNG registration	Standardized mechanism that allows a user to include a user-designed BRNG into the VSL and use it along with the predefined VSL basic generators.
Bunch-Kaufman factorization	Representation of a real symmetric or complex Hermitian matrix A in the form $A = PUDU^H P^T$ (or $A = PLDL^H P^T$) where P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .
c	When found as the first letter of routine names, c indicates the usage of single-precision complex data type.
CBLAS	C interface to the BLAS. <i>See</i> BLAS.
CDF	Cumulative Distribution Function. The function that determines probability distribution for univariate or multivariate random variable x . For univariate distribution the cumulative distribution function is the function of real argument x , which for every x takes a value equal to probability of the event $A: X \leq x$. For multivariate distribution the cumulative distribution function is the function of a real vector $x = (x_1, x_2, \dots, x_n)$, which, for every x , takes a value equal to probability of the event $A = (X_1 \leq x_1 \ \& \ X_2 \leq x_2, \ \& \ \dots, \ \& \ X_n \leq x_n)$.

Cholesky factorization	Representation of a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A in the form $A = U^H U$ or $A = L L^H$, where L is a lower triangular matrix and U is an upper triangular matrix.
condition number	The number $\kappa(A)$ defined for a given square matrix A as follows: $\kappa(A) = \frac{\ A\ }{\ A^{-1}\ }$.
conjugate matrix	The matrix A^H defined for a given general matrix A as follows: $(A^H)_{ij} = (a_{ji})^*$.
conjugate number	The conjugate of a complex number $z = a + bi$ is $z^* = a - bi$.
d	When found as the first letter of routine names, d indicates the usage of double-precision real data type.
dot product	The number denoted $x \cdot y$ and defined for given vectors x and y as follows: $x \cdot y = \sum_i x_i y_i.$ Here x_i and y_i stand for the i -th elements of x and y , respectively.
double precision	A floating-point data type. On Intel® processors, this data type allows you to store real numbers x such that $2.23 \cdot 10^{-308} < x < 1.79 \cdot 10^{308}$. For this data type, the machine precision ε is approximately 10^{-15} , which means that double-precision numbers usually contain no more than 15 significant decimal digits. For more information, refer to <i>Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture</i> .
eigenvalue	See eigenvalue problem.
eigenvalue problem	A problem of finding non-zero vectors x and numbers λ (for a given square matrix A) such that $Ax = \lambda x$. Here the numbers λ are called the eigenvalues of the matrix A and the vectors x are called the eigenvectors of the matrix A .
eigenvector	See eigenvalue problem.
elementary reflector(Householder matrix)	Matrix of a general form $H = I - \tau v v^T$, where v is a column vector and τ is a scalar. In LAPACK elementary reflectors are used, for example, to represent the matrix Q in the QR factorization (the matrix Q is represented as a product of elementary reflectors).
factorization	Representation of a matrix as a product of matrices. See also Bunch-Kaufman factorization, Cholesky factorization, LU factorization, LQ factorization, QR factorization, Schur factorization.
FFTs	Abbreviation for Fast Fourier Transforms. See Chapter 11 of this book.
full storage	A storage scheme allowing you to store matrices of any kind. A matrix A is stored in a two-dimensional array a , with the matrix element a_{ij} stored in the array element $a(i, j)$.

Hermitian matrix	A square matrix A that is equal to its conjugate matrix A^H . The conjugate A^H is defined as follows: $(A^H)_{ij} = (a_{ji})^*$.
I	See identity matrix.
identity matrix	A square matrix I whose diagonal elements are 1, and off-diagonal elements are 0. For any matrix A , $AI = A$ and $IA = A$.
i.i.d.	Independent Identically Distributed.
in-place	Qualifier of an operation. A function that performs its operation in-place takes its input from an array and returns its output to the same array.
Intel MKL	Abbreviation for Intel® Math Kernel Library.
inverse matrix	The matrix denoted as A^{-1} and defined for a given square matrix A as follows: $AA^{-1} = A^{-1}A = I$. A^{-1} does not exist for singular matrices A .
LQ factorization	Representation of an m -by- n matrix A as $A = LQ$ or $A = (L \ 0)Q$. Here Q is an n -by- n orthogonal (unitary) matrix. For $m \leq n$, L is an m -by- m lower triangular matrix with real diagonal elements; for $m > n$,

$$L = \begin{bmatrix} L_1 \\ L_2 \end{bmatrix}$$

	where L_1 is an n -by- n lower triangular matrix, and L_2 is a rectangular matrix.
LU factorization	Representation of a general m -by- n matrix A as $A = PLU$, where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$).
machine precision	The number ε determining the precision of the machine representation of real numbers. For Intel® architecture, the machine precision is approximately 10^{-7} for single-precision data, and approximately 10^{-15} for double-precision data. The precision also determines the number of significant decimal digits in the machine representation of real numbers. <i>See also</i> double precision and single precision.
MPI	Message Passing Interface. This standard defines the user interface and functionality for a wide range of message-passing capabilities in parallel computing.
MPICH	A freely available, portable implementation of MPI standard for message-passing libraries.
orthogonal matrix	A real square matrix A whose transpose and inverse are equal, that is, $A^T = A^{-1}$, and therefore $AA^T = A^TA = I$. All eigenvalues of an orthogonal matrix have the absolute value 1.

packed storage	A storage scheme allowing you to store symmetric, Hermitian, or triangular matrices more compactly. The upper or lower triangle of a matrix is packed by columns in a one-dimensional array.
PDF	Probability Density Function. The function that determines probability distribution for univariate or multivariate continuous random variable x . The probability density function $f(x)$ is closely related with the cumulative distribution function $F(x)$. For univariate distribution the relation is

$$F(x) = \int_{-\infty}^x f(t) dt .$$

For multivariate distribution the relation is

$$F(x_1, x_2, \dots, x_n) = \int_{-\infty}^{x_1} \int_{-\infty}^{x_2} \dots \int_{-\infty}^{x_n} f(t_1, t_2, \dots, t_n) dt_1 dt_2 \dots dt_n .$$

positive-definitematrix	A square matrix A such that $Ax \cdot x > 0$ for any non-zero vector x . Here \cdot denotes the dot product.
pseudorandom number generator	A completely deterministic algorithm that imitates truly random sequences.
QR factorization	Representation of an m -by- n matrix A as $A = QR$, where Q is an m -by- m orthogonal (unitary) matrix, and R is n -by- n upper triangular with real diagonal elements (if $m \geq n$) or trapezoidal (if $m < n$) matrix.
random stream	An abstract source of independent identically distributed random numbers of uniform distribution. In this manual a random stream points to a structure that uniquely defines a random number sequence generated by a basic generator associated with a given random stream.
RNG	Abbreviation for Random Number Generator. In this manual the term "random number generators" stands for pseudorandom number generators, that is, generators based on completely deterministic algorithms imitating truly random sequences.
Rectangular Full Packed (RFP) storage	A storage scheme combining the full and packed storage schemes for the upper or lower triangle of the matrix. This combination enables using half of the full storage as packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels as the full storage.
s	When found as the first letter of routine names, s indicates the usage of single-precision real data type.

ScaLAPACK	Stands for Scalable Linear Algebra PACKage.
Schur factorization	Representation of a square matrix A in the form $A = ZTZ^H$. Here T is an upper quasi-triangular matrix (for complex A , triangular matrix) called the Schur form of A ; the matrix Z is orthogonal (for complex A , unitary). Columns of Z are called Schur vectors.
single precision	A floating-point data type. On Intel® processors, this data type allows you to store real numbers x such that $1.18 \times 10^{-38} < x < 3.40 \times 10^{38}$. For this data type, the machine precision (ϵ) is approximately 10^{-7} , which means that single-precision numbers usually contain no more than 7 significant decimal digits. For more information, refer to <i>Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture</i> .
singular matrix	A matrix whose determinant is zero. If A is a singular matrix, the inverse A^{-1} does not exist, and the system of equations $AX = b$ does not have a unique solution (that is, there exist no solutions or an infinite number of solutions).
singular value	The numbers defined for a given general matrix A as the eigenvalues of the matrix AA^H . <i>See also</i> SVD.
SMP	Abbreviation for Symmetric MultiProcessing. The MKL offers performance gains through parallelism provided by the SMP feature.
sparse BLAS	Routines performing basic vector operations on sparse vectors. Sparse BLAS routines take advantage of vectors' sparsity: they allow you to store only non-zero elements of vectors. <i>See</i> BLAS.
sparse vectors	Vectors in which most of the components are zeros.
storage scheme	The way of storing matrices. <i>See</i> full storage, packed storage, and band storage.
SVD	Abbreviation for Singular Value Decomposition. <i>See also</i> Singular value decomposition section in Chapter 5.
symmetric matrix	A square matrix A such that $a_{ij} = a_{ji}$.
transpose	The transpose of a given matrix A is a matrix A^T such that $(A^T)_{ij} = a_{ji}$ (rows of A become columns of A^T , and columns of A become rows of A^T).
trapezoidal matrix	A matrix A such that $A = (A_1 A_2)$, where A_1 is an upper triangular matrix, A_2 is a rectangular matrix.
triangular matrix	A matrix A is called an upper (lower) triangular matrix if all its subdiagonal elements (superdiagonal elements) are zeros. Thus, for an upper triangular matrix $a_{ij} = 0$ when $i > j$; for a lower triangular matrix $a_{ij} = 0$ when $i < j$.
tridiagonal matrix	A matrix whose non-zero elements are in three diagonals only: the leading diagonal, the first subdiagonal, and the first super-diagonal.

unitary matrix	A complex square matrix A whose conjugate and inverse are equal, that is, that is, $A^H = A^{-1}$, and therefore $AA^H = A^HA = I$. All eigenvalues of a unitary matrix have the absolute value 1.
VML	Abbreviation for Vector Mathematical Library. See Chapter 9 of this book.
VSL	Abbreviation for Vector Statistical Library. See Chapter 10 of this book.
z	When found as the first letter of routine names, z indicates the usage of double-precision complex data type.
