## Description

The routines compute all the eigenvalues and eigenvectors for standard eigenvalue problems,  $Ax = \lambda x$ , within a given search interval.

## Input Parameters

|                   |                                                                                                                                                                                                                                                                                                         |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>uplo</i>       | Must be 'U' or 'L' or 'F' .<br>If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular parts of <i>A</i> .<br>If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular parts of <i>A</i> .<br>If <i>uplo</i> = 'F' , <i>a</i> stores the full matrix <i>A</i> .                                    |
| <i>n</i>          | Sets the size of the problem. $n > 0$ .                                                                                                                                                                                                                                                                 |
| <i>kla</i>        | The number of super- or sub-diagonals within the band in <i>A</i> ( $kla \geq 0$ ).                                                                                                                                                                                                                     |
| <i>a</i>          | Array of dimension <i>lda</i> by <i>n</i> , contains either full matrix <i>A</i> or upper or lower triangular part of the matrix <i>A</i> , as specified by <i>uplo</i>                                                                                                                                 |
| <i>lda</i>        | The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$ .                                                                                                                                                                                                                           |
| <i>fpm</i>        | Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See <a href="#">Extended Eigensolver Input Parameters</a> for a complete description of the parameters and their default values.                                                               |
| <i>emin, emax</i> | The lower and upper bounds of the interval to be searched for eigenvalues; $emin \leq emax$ .                                                                                                                                                                                                           |
| <i>m0</i>         | On entry, specifies the initial guess for subspace dimension to be used, $0 < m0 \leq n$ . Set $m0 \geq m$ where <i>m</i> is the total number of eigenvalues located in the interval [ <i>emin</i> , <i>emax</i> ]. If the initial guess is wrong, Extended Eigensolver routines return <i>info</i> =3. |
| <i>x</i>          | On entry, if <i>fpm</i> [4]=1, the array <i>x</i> of size <i>n</i> by <i>m</i> contains a basis of guess subspace where <i>n</i> is the order of the input matrix.                                                                                                                                      |

## Output Parameters

|               |                                                                                                                      |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| <i>epsout</i> | On output, contains the relative error on the trace: $ trace_j - trace_{j-1}  / \max( emin ,  emax )$                |
| <i>loop</i>   | On output, contains the number of refinement loop executed. Ignored on input.                                        |
| <i>e</i>      | Array of length <i>m0</i> . On output, the first <i>m</i> entries of <i>e</i> are eigenvalues found in the interval. |

|             |                                                                                                                                                                                                                                                                                                              |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>x</i>    | On output, the first <i>m</i> columns of <i>x</i> contain the orthonormal eigenvectors corresponding to the computed eigenvalues <i>e</i> , with the <i>i</i> -th column of <i>x</i> holding the eigenvector associated with <i>e</i> [ <i>i</i> ].                                                          |
| <i>m</i>    | The total number of eigenvalues found in the interval [ <i>emin</i> , <i>emax</i> ]: $0 \leq m \leq m0$ .                                                                                                                                                                                                    |
| <i>res</i>  | Array of length <i>m0</i> . On exit, the first <i>m</i> components contain the relative residual vector: $\frac{\ Ax_i - \lambda_i x_i\ _1}{\max( E_{\min} ,  E_{\max} ) \ x_i\ _1}$ for <i>i</i> =1, 2, ..., <i>m</i> , and where <i>m</i> is the total number of eigenvalues found in the search interval. |
| <i>info</i> | If <i>info</i> =0, the execution is successful. If <i>info</i> ≠ 0, see <a href="#">Output Eigensolver info Details</a> .                                                                                                                                                                                    |

#### Description

The routines compute all the eigenvalues and eigenvectors for generalized eigenvalue problems,  $Ax = \lambda Bx$ , within a given search interval.

**NOTE**

Both matrices *A* and *B* must use the same family of storage format. The bandwidth, however, can be different (*klb* can be different from *kla*).

**Input Parameters**

|                   |                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>uplo</i>       | Must be 'U' or 'L' or 'F' .<br><br>If <i>UPLO</i> = 'U', <i>a</i> and <i>b</i> store the upper triangular parts of <i>A</i> and <i>B</i> respectively.<br><br>If <i>UPLO</i> = 'L', <i>a</i> and <i>b</i> store the lower triangular parts of <i>A</i> and <i>B</i> respectively.<br><br>If <i>UPLO</i> = 'F', <i>a</i> and <i>b</i> store the full matrices <i>A</i> and <i>B</i> respectively. |
| <i>n</i>          | Sets the size of the problem. $n > 0$ .                                                                                                                                                                                                                                                                                                                                                          |
| <i>kla</i>        | The number of super- or sub-diagonals within the band in <i>A</i> ( $kla \geq 0$ ).                                                                                                                                                                                                                                                                                                              |
| <i>a</i>          | Array of dimension <i>lda</i> by <i>n</i> , contains either full matrix <i>A</i> or upper or lower triangular part of the matrix <i>A</i> , as specified by <i>uplo</i>                                                                                                                                                                                                                          |
| <i>lda</i>        | The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$ .                                                                                                                                                                                                                                                                                                                    |
| <i>klb</i>        | The number of super- or sub-diagonals within the band in <i>B</i> ( $klb \geq 0$ ).                                                                                                                                                                                                                                                                                                              |
| <i>b</i>          | Array of dimension <i>ldb</i> by <i>n</i> , contains either full matrix <i>B</i> or upper or lower triangular part of the matrix <i>B</i> , as specified by <i>uplo</i>                                                                                                                                                                                                                          |
| <i>ldb</i>        | The leading dimension of the array <i>B</i> . Must be at least $\max(1, n)$ .                                                                                                                                                                                                                                                                                                                    |
| <i>fpm</i>        | Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See <a href="#">Extended Eigensolver Input Parameters</a> for a complete description of the parameters and their default values.                                                                                                                                                        |
| <i>emin, emax</i> | The lower and upper bounds of the interval to be searched for eigenvalues; $emin \leq emax$ .                                                                                                                                                                                                                                                                                                    |
| <i>m0</i>         | On entry, specifies the initial guess for subspace dimension to be used, $0 < m0 \leq n$ . Set $m0 \geq m$ where <i>m</i> is the total number of eigenvalues located in the interval [ <i>emin</i> , <i>emax</i> ]. If the initial guess is wrong, Extended Eigensolver routines return <i>info</i> =3.                                                                                          |
| <i>x</i>          | On entry, if <i>fpm</i> [4]=1, the array <i>x</i> of size <i>n</i> by <i>m</i> contains a basis of guess subspace where <i>n</i> is the order of the input matrix.                                                                                                                                                                                                                               |

**Output Parameters**

|               |                                                                                                       |
|---------------|-------------------------------------------------------------------------------------------------------|
| <i>epsout</i> | On output, contains the relative error on the trace: $ trace_i - trace_{i-1}  / \max( emin ,  emax )$ |
| <i>loop</i>   | On output, contains the number of refinement loop executed. Ignored on input.                         |

|             |                                                                                                                                                                                                                                                                                                                |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>e</i>    | Array of length <i>m0</i> . On output, the first <i>m</i> entries of <i>e</i> are eigenvalues found in the interval.                                                                                                                                                                                           |
| <i>x</i>    | On output, the first <i>m</i> columns of <i>x</i> contain the orthonormal eigenvectors corresponding to the computed eigenvalues <i>e</i> , with the <i>i</i> -th column of <i>x</i> holding the eigenvector associated with <i>e</i> [ <i>i</i> ].                                                            |
| <i>m</i>    | The total number of eigenvalues found in the interval [ <i>emin</i> , <i>emax</i> ]: $0 \leq m \leq m0$ .                                                                                                                                                                                                      |
| <i>res</i>  | Array of length <i>m0</i> . On exit, the first <i>m</i> components contain the relative residual vector: $\frac{\ Ax_i - \lambda_i Bx_i\ _1}{\max( E_{\min} ,  E_{\max} ) \ Bx_i\ _1}$ for <i>i</i> =1, 2, ..., <i>m</i> , and where <i>m</i> is the total number of eigenvalues found in the search interval. |
| <i>info</i> | If <i>info</i> =0, the execution is successful. If <i>info</i> ≠ 0, see <a href="#">Output Eigensolver info Details</a> .                                                                                                                                                                                      |

#### Description

The routines compute all the eigenvalues and eigenvectors for standard eigenvalue problems,  $Ax = \lambda x$ , within a given search interval.

## Input Parameters

|                   |                                                                                                                                                                                                                                                                                                               |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>uplo</i>       | Must be 'U' or 'L' or 'F' .<br>If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular parts of <i>A</i> .<br>If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular parts of <i>A</i> .<br>If <i>uplo</i> = 'F' , <i>a</i> stores the full matrix <i>A</i> .                                          |
| <i>n</i>          | Sets the size of the problem. $n > 0$ .                                                                                                                                                                                                                                                                       |
| <i>a</i>          | Array containing the nonzero elements of either the full matrix <i>A</i> or the upper or lower triangular part of the matrix <i>A</i> , as specified by <i>uplo</i> .                                                                                                                                         |
| <i>ia</i>         | Array of length $n + 1$ , containing indices of elements in the array <i>a</i> , such that <i>ia</i> [ <i>i</i> ] is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i> . The value of the last element <i>ia</i> [ <i>n</i> ] is equal to the number of non-zeros plus one. |
| <i>ja</i>         | Array containing the column indices for each non-zero element of the matrix <i>A</i> being represented in the array <i>a</i> . Its length is equal to the length of the array <i>a</i> .                                                                                                                      |
| <i>fpm</i>        | Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See <a href="#">Extended Eigensolver Input Parameters</a> for a complete description of the parameters and their default values.                                                                     |
| <i>emin, emax</i> | The lower and upper bounds of the interval to be searched for eigenvalues; $emin \leq emax$ .                                                                                                                                                                                                                 |
| <i>m0</i>         | On entry, specifies the initial guess for subspace dimension to be used, $0 < m0 \leq n$ . Set $m0 \geq m$ where <i>m</i> is the total number of eigenvalues located in the interval [ <i>emin</i> , <i>emax</i> ]. If the initial guess is wrong, Extended Eigensolver routines return <i>info</i> =3.       |
| <i>x</i>          | On entry, if <i>fpm</i> [4]=1, the array <i>x</i> of size <i>n</i> by <i>m</i> contains a basis of guess subspace where <i>n</i> is the order of the input matrix.                                                                                                                                            |

## Output Parameters

|               |                                                                                                                                                                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>fpm</i>    | On output, the last 64 values correspond to Intel MKL PARDISO <i>iparm</i> [0] to <i>iparm</i> [63] (regardless of the value of <i>fpm</i> [63] on input).                                                                                          |
| <i>epsout</i> | On output, contains the relative error on the trace: $ trace_i - trace_{i-1}  / \max( emin ,  emax )$                                                                                                                                               |
| <i>loop</i>   | On output, contains the number of refinement loop executed. Ignored on input.                                                                                                                                                                       |
| <i>e</i>      | Array of length <i>m0</i> . On output, the first <i>m</i> entries of <i>e</i> are eigenvalues found in the interval.                                                                                                                                |
| <i>x</i>      | On output, the first <i>m</i> columns of <i>x</i> contain the orthonormal eigenvectors corresponding to the computed eigenvalues <i>e</i> , with the <i>i</i> -th column of <i>x</i> holding the eigenvector associated with <i>e</i> [ <i>i</i> ]. |

|             |                                                                                                                                                                                                                                                                                                   |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>m</i>    | The total number of eigenvalues found in the interval [ <i>emin</i> , <i>emax</i> ]: $0 \leq m \leq m0$ .                                                                                                                                                                                         |
| <i>res</i>  | Array of length <i>m0</i> . On exit, the first <i>m</i> components contain the relative residual vector: $\frac{\ Ax_i - \lambda_i x_i\ _1}{\max( E_{\min} ,  E_{\max} ) \ x_i\ _1}$ for $i=1, 2, \dots, m$ , and where <i>m</i> is the total number of eigenvalues found in the search interval. |
| <i>info</i> | If <i>info</i> =0, the execution is successful. If <i>info</i> ≠ 0, see <a href="#">Output Eigensolver info Details</a> .                                                                                                                                                                         |

#### Description

The routines compute all the eigenvalues and eigenvectors for generalized eigenvalue problems,  $Ax = \lambda Bx$ , within a given search interval.

**NOTE**

Both matrices  $A$  and  $B$  must use the same family of storage format. The position of the non-zero elements can be different (CSR coordinates  $ib$  and  $jb$  can be different from  $ia$  and  $ja$ ).

**Input Parameters**

|                   |                                                                                                                                                                                                                                                                                                                          |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>uplo</i>       | Must be 'U' or 'L' or 'F' .<br><br>If $UPLO = 'U'$ , $a$ and $b$ store the upper triangular parts of $A$ and $B$ respectively.<br><br>If $UPLO = 'L'$ , $a$ and $b$ store the lower triangular parts of $A$ and $B$ respectively.<br><br>If $UPLO = 'F'$ , $a$ and $b$ store the full matrices $A$ and $B$ respectively. |
| <i>n</i>          | Sets the size of the problem. $n > 0$ .                                                                                                                                                                                                                                                                                  |
| <i>a</i>          | Array containing the nonzero elements of either the full matrix $A$ or the upper or lower triangular part of the matrix $A$ , as specified by <i>uplo</i> .                                                                                                                                                              |
| <i>ia</i>         | Array of length $n + 1$ , containing indices of elements in the array $a$ , such that $ia[i - 1]$ is the index in the array $a$ of the first non-zero element from the row $i$ . The value of the last element $ia[n]$ is equal to the number of non-zeros plus one.                                                     |
| <i>ja</i>         | Array containing the column indices for each non-zero element of the matrix $A$ being represented in the array $a$ . Its length is equal to the length of the array $a$ .                                                                                                                                                |
| <i>b</i>          | Array of dimension $ldb$ by $*$ , contains the nonzero elements of either the full matrix $B$ or the upper or lower triangular part of the matrix $B$ , as specified by <i>uplo</i> .                                                                                                                                    |
| <i>ib</i>         | Array of length $n + 1$ , containing indices of elements in the array $b$ , such that $ib[i - 1]$ is the index in the array $b$ of the first non-zero element from the row $i$ . The value of the last element $ib[n]$ is equal to the number of non-zeros plus one.                                                     |
| <i>jb</i>         | Array containing the column indices for each non-zero element of the matrix $B$ being represented in the array $b$ . Its length is equal to the length of the array $b$ .                                                                                                                                                |
| <i>fpm</i>        | Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See <a href="#">Extended Eigensolver Input Parameters</a> for a complete description of the parameters and their default values.                                                                                |
| <i>emin, emax</i> | The lower and upper bounds of the interval to be searched for eigenvalues; $emin \leq emax$ .                                                                                                                                                                                                                            |
| <i>m0</i>         | On entry, specifies the initial guess for subspace dimension to be used, $0 < m0 \leq n$ . Set $m0 \geq m$ where $m$ is the total number of eigenvalues located in the interval $[emin, emax]$ . If the initial guess is wrong, Extended Eigensolver routines return $info=3$ .                                          |

$x$  On entry, if  $fpm[4]=1$ , the array  $x$  of size  $n$  by  $m$  contains a basis of guess subspace where  $n$  is the order of the input matrix.

## Output Parameters

$fpm$  On output, the last 64 values correspond to Intel MKL PARDISO  $iparm[0]$  to  $iparm[63]$  (regardless of the value of  $fpm[63]$  on input).

$epsout$  On output, contains the relative error on the trace:  $|trace_i - trace_{i-1}| / \max(|emin|, |emax|)$

$loop$  On output, contains the number of refinement loop executed. Ignored on input.

$e$  Array of length  $m0$ . On output, the first  $m$  entries of  $e$  are eigenvalues found in the interval.

$x$  On output, the first  $m$  columns of  $x$  contain the orthonormal eigenvectors corresponding to the computed eigenvalues  $e$ , with the  $i$ -th column of  $x$  holding the eigenvector associated with  $e[i]$ .

$m$  The total number of eigenvalues found in the interval  $[emin, emax]$ :  $0 \leq m \leq m0$ .

$res$  Array of length  $m0$ . On exit, the first  $m$  components contain the relative residual vector:

$$\frac{\|Ax_i - \lambda_i Bx_i\|_1}{\max(|E_{\min}|, |E_{\max}|) \|Bx_i\|_1}$$

for  $i=1, 2, \dots, m$ , and where  $m$  is the total number of eigenvalues found in the search interval.

$info$  If  $info=0$ , the execution is successful. If  $info \neq 0$ , see [Output Eigensolver info Details](#).

# Vector Mathematical Functions

This chapter describes Intel® MKL Vector Mathematics functions (VM), which compute a mathematical function of each of the vector elements. VM includes a set of highly optimized functions (arithmetic, power, trigonometric, exponential, hyperbolic, special, and rounding) that operate on vectors of real and complex numbers.

Application programs that improve performance with VM include nonlinear programming software, computation of integrals, financial calculations, computer graphics, and many others.

VM functions fall into the following groups according to the operations they perform:

- [VM Mathematical Functions](#) compute values of mathematical functions, such as sine, cosine, exponential, or logarithm, on vectors stored contiguously in memory.
- [VM Pack/Unpack Functions](#) convert to and from vectors with positive increment indexing, vector indexing, and mask indexing (see [Appendix B](#) for details on vector indexing methods).
- [VM Service Functions](#) set/get the accuracy modes and the error codes, and free memory.

The VM mathematical functions take an input vector as an argument, compute values of the respective function element-wise, and return the results in an output vector. All the VM mathematical functions can perform in-place operations, where the input and output arrays are at the same memory locations.

The Intel MKL interfaces are given in `mkl_vml_functions.h`.

Examples that demonstrate how to use the VM functions are located in:

```
$(MKL)/examples/vmlc/source
```

See VM performance and accuracy data in the online VM Performance and Accuracy Data document available at <http://software.intel.com/en-us/articles/intel-math-kernel-library-documentation/>

## Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## VM Data Types, Accuracy Modes, and Performance Tips

VM includes mathematical and pack/unpack vector functions for single and double precision vector arguments of real and complex types. Intel MKL provides Fortran and C interfaces for all VM functions, including the associated service functions. The Function Naming Conventions section below shows how to call these functions.

Performance depends on a number of factors, including vectorization and threading overhead. The recommended usage is as follows:

- Use VM for vector lengths larger than 40 elements.
- Use the Intel® Compiler for vector lengths less than 40 elements.

All VM vector functions support the following accuracy modes:

- High Accuracy (HA), the default mode
- Low Accuracy (LA), which improves performance by reducing accuracy of the two least significant bits
- Enhanced Performance (EP), which provides better performance at the cost of significantly reduced accuracy. Approximately half of the bits in the mantissa are correct.

Note that using the EP mode does not guarantee accurate processing of corner cases and special values. Although the default accuracy is HA, LA is sufficient in most cases. For applications that require less accuracy (for example, media applications, some Monte Carlo simulations, etc.), the EP mode may be sufficient.

VM handles special values in accordance with the C99 standard [C99].

Intel MKL offers both functions and environment variables to switch between modes for VM. See the *Intel MKL Developer Guide* for details about the environment variables. Use the `vmlSetMode(mode)` function (see [Table "Values of the mode Parameter"](#)) to switch between the HA, LA, and EP modes. The `vmlGetMode()` function returns the current mode.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

[VM Naming Conventions](#)

## VM Naming Conventions

The VM function names are of mixed (lower and upper) case.

The VM mathematical and pack/unpack function names have the following structure:

`v[m]<?><name><mod>`

where

- `v` is a prefix indicating vector operations.
- `[m]` is an optional prefix for mathematical functions that indicates additional argument to specify a VM mode for a given function call (see [vmlSetMode](#) for possible values and their description).
- `<?>` is a precision prefix that indicates one of the following the data types:

|                |                |
|----------------|----------------|
| <code>s</code> | float.         |
| <code>d</code> | double.        |
| <code>c</code> | MKL_Complex8.  |
| <code>z</code> | MKL_Complex16. |

- `<name>` indicates the function short name, with some of its letters in uppercase. See examples in [Table "VM Mathematical Functions"](#).
- `<mod>` field (written in uppercase) is present only in the pack/unpack functions and indicates the indexing method used:

|                |                                    |
|----------------|------------------------------------|
| <code>i</code> | indexing with a positive increment |
| <code>v</code> | indexing with an index vector      |

*m* indexing with a mask vector.

The VM service function names have the following structure:

*vm*<name>

where

<name> indicates the function short name, with some of its letters in uppercase. See examples in [Table "VM Service Functions"](#).

To call VM functions from an application program, use conventional function calls. For example, call the vector single precision real exponential function as

```
vsExp (n, a, y);
```

## VM Function Interfaces

VM interfaces include the function names and argument lists. The following sections describe the interfaces for the VM functions. Note that some of the functions have multiple input and output arguments

Some VM functions may also take scalar arguments as input. See the function description for the naming conventions of such arguments.

### VM Mathematical Function Interfaces

```
v<?><name>(n, a, [scalar input arguments],y);
v<?><name>(n, a, b, [scalar input arguments],y);
v<?><name>(n, a, y, z);
vm<?><name>(n, a, [scalar input arguments],y, mode);
vm<?><name>(n, a, b, [scalar input arguments],y, mode);
vm<?><name>(n, a, y, z, mode);
```

### VM Pack Function Interfaces

```
v<?>PackI(n, a, inca, y);
v<?>PackV(n, a, ia, y);
v<?>PackM(n, a, ma, y);
```

### VM Unpack Function Interfaces

```
v<?>UnpackI(n, a, y, incy);
v<?>UnpackV(n, a, y, iy);
v<?>UnpackM(n, a, y, my);
```

### VM Service Function Interfaces

```
oldmode = vmlSetMode(mode);
mode = vmlGetMode(void);
olderr = vmlSetErrStatus (err);
err = vmlGetErrStatus(void);
olderr = vmlClearErrStatus(void);
oldcallback = vmlSetErrorCallBack(callback);
callback = vmlGetErrorCallBack(void);
oldcallback = vmlClearErrorCallBack(void);
```

Note that *oldmode*, *oldcerr*, and *oldcallback* refer to settings prior to the call.

## VM Input Function Interfaces

|                 |                                                 |
|-----------------|-------------------------------------------------|
| <i>n</i>        | number of elements to be calculated             |
| <i>a</i>        | first input vector                              |
| <i>b</i>        | second input vector                             |
| <i>inca</i>     | vector increment for the input vector <i>a</i>  |
| <i>ia</i>       | index vector for the input vector <i>a</i>      |
| <i>ma</i>       | mask vector for the input vector <i>a</i>       |
| <i>incy</i>     | vector increment for the output vector <i>y</i> |
| <i>iy</i>       | index vector for the output vector <i>y</i>     |
| <i>my</i>       | mask vector for the output vector <i>y</i>      |
| <i>err</i>      | error code                                      |
| <i>mode</i>     | VM mode                                         |
| <i>callback</i> | address of the callback function                |

## VM Output Function Interfaces

|                    |                                         |
|--------------------|-----------------------------------------|
| <i>y</i>           | first output vector                     |
| <i>z</i>           | second output vector                    |
| <i>err</i>         | error code                              |
| <i>mode</i>        | VM mode                                 |
| <i>olderr</i>      | former error code                       |
| <i>oldmode</i>     | former VM mode                          |
| <i>callback</i>    | address of the callback function        |
| <i>oldcallback</i> | address of the former callback function |

See the data types of the parameters used in each function in the respective function description section. All the Intel MKL VM mathematical functions can perform in-place operations.

## Vector Indexing Methods

---

VM mathematical functions work only with unit stride. To accommodate arrays with other increments, or more complicated indexing, you can gather the elements into a contiguous vector and then scatter them after the computation is complete.

VM uses the three following indexing methods to do this task:

- positive increment
- index vector
- mask vector

The indexing method used in a particular function is indicated by the indexing modifier (see the description of the `<mod>` field in [Function Naming Conventions](#)). For more information on the indexing methods, see [Vector Arguments in VM](#) in Appendix B.

## VM Error Diagnostics

The VM mathematical functions incorporate the error handling mechanism, which is controlled by the following service functions:

|                                                                                                        |                                                                                                                                                                                                                         |
|--------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>vmlGetErrStatus,</code><br><code>vmlSetErrStatus,</code><br><code>vmlClearErrStatus</code>       | These functions operate with a global variable called VM Error Status. The VM Error Status flags an error, a warning, or a successful execution of a VM function.                                                       |
| <code>vmlGetErrCallback,</code><br><code>vmlSetErrCallback,</code><br><code>vmlClearErrCallback</code> | These functions enable you to customize the error handling. For example, you can identify a particular argument in a vector where an error occurred or that caused a warning.                                           |
| <code>vmlSetMode, vmlGetMode</code>                                                                    | These functions get and set a VM mode. If you set a new VM mode using the <code>vmlSetMode</code> function, you can store the previous VM mode returned by the routine and restore it at any point of your application. |

If both an error and a warning situation occur during the function call, the VM Error Status variable keeps only the value of the error code. See [Table "Values of the VM Error Status"](#) for possible values. If a VM function does not encounter errors or warnings, it sets the VM Error Status to `VML_STATUS_OK`.

If you use incorrect input arguments to a VM function (`VML_STATUS_BADSIZE` and `VML_STATUS_BADMEM`), the function calls `xerbla` to report errors. See [Table "Values of the VM Error Status"](#) for details

You can use the `vmlSetMode` and `vmlGetMode` functions to modify error handling behavior. Depending on the VM mode, the error handling behavior includes the following operations:

- setting the VM Error Status to a value corresponding to the observed error or warning
- setting the `errno` variable to one of the values described in [Table "Set Values of the `errno` Variable"](#)
- writing error text information to the `stderr` stream
- raising the appropriate exception on an error, if necessary
- calling the additional error handler callback function that is set by `vmlSetErrorCallback`.

### Set Values of the `errno` Variable

| Value of <code>errno</code> | Description                                                               |
|-----------------------------|---------------------------------------------------------------------------|
| <code>0</code>              | No errors are detected.                                                   |
| <code>EINVAL</code>         | The array dimension is not positive.                                      |
| <code>EACCES</code>         | NULL pointer is passed.                                                   |
| <code>EDOM</code>           | At least one of array values is out of a range of definition.             |
| <code>ERANGE</code>         | At least one of array values caused a singularity, overflow or underflow. |

### See Also

[vmlGetErrStatus](#) Gets the VM Error Status.

[vmlSetErrStatus](#) Sets the new VM Error Status according to `err` and stores the previous VM Error Status to `olderr`.

[vmlClearErrStatus](#) Sets the VM Error Status to `VML_STATUS_OK` and stores the previous VM Error Status to `olderr`.

[vmlSetErrorCallback](#) Sets the additional error handler callback function and gets the old callback function.

[vmlGetErrorCallback](#) Gets the additional error handler callback function.

**vmClearErrorCallback** Deletes the additional error handler callback function and retrieves the former callback function.

**vmGetMode** Gets the VM mode.

**vmSetMode** Sets a new mode for VM functions according to the *mode* parameter and stores the previous VM mode to *oldmode*.

## VM Mathematical Functions

This section describes VM functions that compute values of mathematical functions on real and complex vector arguments with unit increment.

Each function is introduced by its short name, a brief description of its purpose, and the calling sequence for each type of data, as well as a description of the input/output arguments.

The input range of parameters is equal to the mathematical range of the input data type, unless the function description specifies input threshold values, which mark off the precision overflow, as follows:

- *FLT\_MAX* denotes the maximum number representable in single precision real data type
- *DBL\_MAX* denotes the maximum number representable in double precision real data type

Table "VM Mathematical Functions" lists available mathematical functions and associated data types.

### VM Mathematical Functions

| <code>v?NearbyInt</code>    | $s, d$       | Rounding according to current mode                                                                   |
| <code>v?Rint</code>         | $s, d$       | Rounding according to current mode and raising inexact result exception                              |
| <code>v?Modf</code>         | $s, d$       | Computation of the integer and fractional parts                                                      |
| <code>v?Frac</code>         | $s, d$       | Computation of the fractional part                                                                   |

## Special Value Notations

This section defines notations of special values for complex functions. The definitions are provided in text, tables, or formulas.

- $z, z1, z2$ , etc. denote complex numbers.
- $i, i^2=-1$  is the imaginary unit.
- $x, X, x1, x2$ , etc. denote real imaginary parts.
- $y, Y, y1, y2$ , etc. denote imaginary parts.
- $X$  and  $Y$  represent any finite positive IEEE-754 floating point values, if not stated otherwise.
- Quiet NaN and signaling NaN are denoted with `QNaN` and `SNAN`, respectively.

- The IEEE-754 positive infinities or floating-point numbers are denoted with a + sign before  $x$ ,  $y$ , etc.
- The IEEE-754 negative infinities or floating-point numbers are denoted with a – sign before  $x$ ,  $y$ , etc.

CONJ( $z$ ) and CIS( $z$ ) are defined as follows:

$$\text{CONJ}(x+i \cdot y)=x-i \cdot y$$

$$\text{CIS}(y)=\cos (y)+i \cdot \sin (y) .$$

The special value tables show the result of the function for the  $z$  argument at the intersection of the  $\text{RE}(z)$  column and the  $i \cdot \text{IM}(z)$  row. If the function raises an exception on the argument  $z$ , the lower part of this cell shows the raised exception and the VM Error Status. An empty cell indicates that this argument is normal and the result is defined mathematically.

## Arithmetic Functions

Arithmetic functions perform the basic mathematical operations like addition, subtraction, multiplication or computation of the absolute value of the vector elements.

### v?Add

*Performs element by element addition of vector  $a$  and vector  $b$ .*

#### Syntax

```
vsAdd(n, a, b, y);
vmsAdd(n, a, b, y, mode);
vdAdd(n, a, b, y);
vmdAdd(n, a, b, y, mode);
vcAdd(n, a, b, y);
vmcAdd(n, a, b, y, mode);
vzAdd(n, a, b, y);
vmzAdd(n, a, b, y, mode);
```

#### Include Files

- `mkl.h`

#### Input Parameters

| Name   | Type                                                                                                                                                                                                                                                                                                                       | Description                                                     |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------|
| $n$    | <code>const MKL_INT</code>                                                                                                                                                                                                                                                                                                 | Specifies the number of elements to be calculated.              |
| $a, b$ | <code>const float*</code> for <code>vsAdd</code> , <code>vmsAdd</code><br><code>const double*</code> for <code>vdAdd</code> , <code>vmdAdd</code><br><code>const MKL_Complex8*</code> for <code>vcAdd</code> ,<br><code>vmcAdd</code><br><code>const MKL_Complex16*</code> for <code>vzAdd</code> ,<br><code>vmzAdd</code> | Pointers to arrays that contain the input vectors $a$ and $b$ . |

| Name        | Type            | Description                                                                                                                        |
|-------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------|
| <i>mode</i> | const MKL_INT64 | Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description. |

## Output Parameters

| Name     | Type                                                                                                                         | Description                                                    |
|----------|------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| <i>y</i> | float* for vsAdd, vmsAdd<br>double* for vdAdd, vmdAdd<br>MKL_Complex8* for vcAdd, vmcAdd<br>MKL_Complex16* for vzAdd, vmzAdd | Pointer to an array that contains the output vector <i>y</i> . |

## Description

The *v?Add* function performs element by element addition of vector *a* and vector *b*.

### Special values for Real Function *v?Add(x)*

| Argument 1 | Argument 2 | Result | Exception |
|------------|------------|--------|-----------|
| +0         | +0         | +0     |           |
| +0         | -0         | +0     |           |
| -0         | +0         | +0     |           |
| -0         | -0         | -0     |           |

| non-SNAN   | QNAN       | QNAN   |           |

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Add}(x1+i*y1, x2+i*y2) = (x1+x2) + i*(y1+y2)$$

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when *x1*, *x2*, *y1*, *y2* are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the OVERFLOW exception, and sets the VM Error Status to VML\_STATUS\_OVERFLOW (overriding any possible VML\_STATUS\_ACCURACYWARNING status).

## *v?Sub*

*Performs element by element subtraction of vector b from vector a.*

### Syntax

```
vsSub(n, a, b, y);
```

```
vmsSub(n, a, b, y, mode);
```

```
vdSub(n, a, b, y);
```

```
vmdSub(n, a, b, y, mode);
```

```
vcSub(n, a, b, y);
vmcSub(n, a, b, y, mode);
vzSub(n, a, b, y);
vmzSub(n, a, b, y, mode);
```

## Include Files

- mkl.h

## Input Parameters

## Description

The `v?MulByConj` function performs element by element multiplication of vector *a* element and conjugated vector *b* element.

Specifications for special values of the functions are found according to the formula

$$\text{MulByConj}(x1+i*y1, x2+i*y2) = \text{Mul}(x1+i*y1, x2-i*y2).$$

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when *x1*, *x2*, *y1*, *y2* are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns  $\infty$  in that part of the result, raises the `OVERFLOW` exception, and sets the VM Error Status to `VML_STATUS_OVERFLOW` (overriding any possible `VML_STATUS_ACCURACYWARNING` status).

## v?Conj

*Performs element by element conjugation of the vector.*

| <i>a</i>    | const MKL_Complex8* for vcConj, vmcConj<br>const MKL_Complex16* for vzConj, vmzConj | Pointer to an array that contains the input vector <i>a</i> .                                                                      |
| <i>mode</i> | const MKL_INT64                                                                     | Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description. |

## Output Parameters

| Name     | Type                                                                    | Description                                                    |
|----------|-------------------------------------------------------------------------|----------------------------------------------------------------|
| <i>y</i> | MKL_Complex8* for vcConj, vmcConj<br>MKL_Complex16* for vzConj, vmzConj | Pointer to an array that contains the output vector <i>y</i> . |

## Description

The `v?Conj` function performs element by element conjugation of the vector.

No special values are specified. The function does not raise floating-point exceptions.

## v?Abs

*Computes absolute value of vector elements.*

### Syntax

```
vsAbs(n, a, y);
```

```
vmsAbs(n, a, y, mode);
```

```
vdAbs(n, a, y);
```

```
vmdAbs(n, a, y, mode);
```

```
vcAbs(n, a, y);
```

```
vmcAbs(n, a, y, mode);
```

```
vzAbs(n, a, y);
```

```
vmzAbs(n, a, y, mode);
```

## Include Files

| <i>n</i>    | const MKL_INT                                                                                                                                        | Specifies the number of elements to be calculated.                                                                                 |
| <i>a</i>    | const float* for vsAbs, vmsAbs<br>const double* for vdAbs, vmdAbs<br>const MKL_Complex8* for vcAbs, vmcAbs<br>const MKL_Complex16* for vzAbs, vmzAbs | Pointer to an array that contains the input vector <i>a</i> .                                                                      |
| <i>mode</i> | const MKL_INT64                                                                                                                                      | Overrides global VM mode setting for this function call. See <a href="#">vm1SetMode</a> for possible values and their description. |

## Output Parameters

| Name     | Type                                                                                | Description                                                    |
|----------|-------------------------------------------------------------------------------------|----------------------------------------------------------------|
| <i>y</i> | float* for vsAbs, vmsAbs, vcAbs, vmcAbs<br>double* for vdAbs, vmdAbs, vzAbs, vmzAbs | Pointer to an array that contains the output vector <i>y</i> . |

## Description

The *v?Abs* function computes an absolute value of vector elements.

### Special Values for Real Function *v?Abs(x)*

| Argument | Result | Exception |
|----------|--------|-----------|
| +0       | +0     |           |
| -0       | +0     |           |
| +∞       | +∞     |           |
| -∞       | +∞     |           |
| QNAN     | QNAN   |           |
| SNAN     | QNAN   | INVALID   |

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Abs}(z) = \text{Hypot}(\text{RE}(z), \text{IM}(z)).$$

### *v?Arg*

*Computes argument of vector elements.*

### Syntax

```
vcArg(n, a, y);
```

```
vmcArg(n, a, y, mode);
```

```
vzArg(n, a, y);
```

```
vmzArg(n, a, y, mode);
```

## Description

The `v?Arg` function computes argument of vector elements.

See the [Special Value Notations](#) section for the conventions used in the table below.

### Special Values for Complex Function `v?Arg(z)`

| <b>RE(z)</b><br><b>i·IM(z)</b><br><b>)</b> | <b>-∞</b>           | <b>-X</b>         | <b>-0</b>         | <b>+0</b>         | <b>+X</b>         | <b>+∞</b>         | <b>NAN</b> |
|--------------------------------------------|---------------------|-------------------|-------------------|-------------------|-------------------|-------------------|------------|
| <code>+i·∞</code>                          | <code>+3·π/4</code> | <code>+π/2</code> | <code>+π/2</code> | <code>+π/2</code> | <code>+π/2</code> | <code>+π/4</code> | NAN        |
| <code>+i·Y</code>                          | <code>+π</code>     |                   | <code>+π/2</code> | <code>+π/2</code> |                   | <code>+0</code>   | NAN        |
| <code>+i·0</code>                          | <code>+π</code>     | <code>+π</code>   | <code>+π</code>   | <code>+0</code>   | <code>+0</code>   | <code>+0</code>   | NAN        |
| <code>-i·0</code>                          | <code>-π</code>     | <code>-π</code>   | <code>-π</code>   | <code>-0</code>   | <code>-0</code>   | <code>-0</code>   | NAN        |
| <code>-i·Y</code>                          | <code>-π</code>     |                   | <code>-π/2</code> | <code>-π/2</code> |                   | <code>-0</code>   | NAN        |
| <code>-i·∞</code>                          | <code>-3·π/4</code> | <code>-π/2</code> | <code>-π/2</code> | <code>-π/2</code> | <code>-π/2</code> | <code>-π/4</code> | NAN        |
| <code>+i·NAN</code>                        | NAN                 | NAN               | NAN               | NAN               | NAN               | NAN               | NAN        |

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- $\text{Arg}(z) = \text{Atan2}(\text{IM}(z), \text{RE}(z))$ .

## `v?LinearFrac`

Performs linear fraction transformation of vectors `a` and `b` with scalar parameters.

## Syntax

```
vsLinearFrac(n, a, b, scalea, shifta, scaleb, shiftb, y);
vmsLinearFrac(n, a, b, scalea, shifta, scaleb, shiftb, y, mode);
vdLinearFrac(n, a, b, scalea, shifta, scaleb, shiftb, y)
vmdLinearFrac(n, a, b, scalea, shifta, scaleb, shiftb, y, mode);
```

## Include Files

| <i>mode</i>           | const MKL_INT64                                                                                   | Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description. |

## Output Parameters

| Name     | Type                                                                                  | Description                                                    |
|----------|---------------------------------------------------------------------------------------|----------------------------------------------------------------|
| <i>y</i> | float* for vsLinearFrac, vmsLinearFrac<br><br>double* for vdLinearFrac, vmdLinearFrac | Pointer to an array that contains the output vector <i>y</i> . |

## Description

The `v?LinearFrac` function performs a linear fraction transformation of vector *a* by vector *b* with scalar parameters: scaling multipliers *scalea*, *scaleb* and shifting addends *shifta*, *shiftb*:

$$y[i] = (scalea \cdot a[i] + shifta) / (scaleb \cdot b[i] + shiftb), i=1,2 \dots n$$

The `v?LinearFrac` function is implemented in the EP accuracy mode only, therefore no special values are defined for this function. If used in HA or LA mode, `v?LinearFrac` sets the VM Error Status to `VML_STATUS_ACCURACYWARNING` (see the [Values of the VM Status](#) table). Correctness is guaranteed within the threshold limitations defined for each input parameter (see the table below); otherwise, the behavior is unspecified.

---

#### Threshold Limitations on Input Parameters

---

$$2^{E_{\text{MIN}}/2} \leq |scalea| \leq 2^{(E_{\text{MAX}}-2)/2}$$

$$2^{E_{\text{MIN}}/2} \leq |scaleb| \leq 2^{(E_{\text{MAX}}-2)/2}$$

$$|shiffta| \leq 2^{E_{\text{MAX}}-2}$$

$$|shifftb| \leq 2^{E_{\text{MAX}}-2}$$

$$2^{E_{\text{MIN}}/2} \leq a[i] \leq 2^{(E_{\text{MAX}}-2)/2}$$

$$2^{E_{\text{MIN}}/2} \leq b[i] \leq 2^{(E_{\text{MAX}}-2)/2}$$

$$a[i] \neq - (shiffta/scalea) * (1-\delta_1), \quad |\delta_1| \leq 2^{1-(p-1)/2}$$

$$b[i] \neq - (shifftb/scaleb) * (1-\delta_2), \quad |\delta_2| \leq 2^{1-(p-1)/2}$$

---

$E_{\text{MIN}}$  and  $E_{\text{MAX}}$  are the minimum and maximum exponents and  $p$  is the number of significant bits (precision) for the corresponding data type according to the ANSI/IEEE Standard 754-2008 ([IEEE754]):

- for single precision  $E_{\text{MIN}} = -126$ ,  $E_{\text{MAX}} = 127$ ,  $p = 24$
- for double precision  $E_{\text{MIN}} = -1022$ ,  $E_{\text{MAX}} = 1023$ ,  $p = 53$

The thresholds become less strict for common cases with  $scalea=0$  and/or  $scaleb=0$ :

- if  $scalea=0$ , there are no limitations for the values of  $a[i]$  and  $shiffta$ .
- if  $scaleb=0$ , there are no limitations for the values of  $b[i]$  and  $shifftb$ .

### Example

To use the `v?LinearFrac` to shift vector  $a$  by a scalar value, set  $scaleb$  to 0. Note that even if  $scaleb$  is 0,  $b$  must be declared.

```
#include <stdio.h>
#include "mkl_vml.h"

int main()
{
 double a[10], *b;
 double r[10];
 double scalea = 1.0, scaleb = 0.0;
 double shiffta = -1.0, shifftb = 1.0;

 MKL_INT i=0,n=10;

 a[0]=-10000.0000;
 a[1]=-7777.7777;
 a[2]=-5555.5555;
 a[3]=-3333.3333;
 a[4]=-1111.1111;
 a[5]=1111.1111;
 a[6]=3333.3333;
 a[7]=5555.5555;
 a[8]=7777.7777;
 a[9]=10000.0000;
```

```

vdLinearFrac(n, a, b, scalea, shifta, scaleb, shiftb, r);

for(i=0;i<10;i++) {
 printf("%25.14f %25.14f\n",a[i],r[i]);
}

return 0;
}

```

To use the `v?LinearFrac` to compute  $shifta/(scaleb \cdot b[i] + shiftb)$ , set `scalea` to 0. Note that even if `scalea` is 0, `a` must be declared.

## Power and Root Functions

### v?Inv

*Performs element by element inversion of the vector.*

#### Syntax

```

vsInv(n, a, y);
vmsInv(n, a, y, mode);
vdInv(n, a, y);
vmdInv(n, a, y, mode);

```

#### Include Files

- `mkl.h`

See <a href="#">vmlSetMode</a> for possible values and their description. |

#### Output Parameters

| Name           | Type                                                                                                                                      | Description                                                          |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| <code>y</code> | <code>float*</code> for <code>vsInv</code> , <code>vmsInv</code><br><br><code>double*</code> for <code>vdInv</code> , <code>vmdInv</code> | Pointer to an array that contains the output vector <code>y</code> . |

#### Description

The `v?Inv` function performs element by element inversion of the vector.

**Special Values for Real Function v?Inv(x)**

| Argument  | Result    | VM Error Status | Exception  |
|-----------|-----------|-----------------|------------|
| +0        | $+\infty$ | VML_STATUS_SING | ZERODIVIDE |
| -0        | $-\infty$ | VML_STATUS_SING | ZERODIVIDE |
| $+\infty$ | +0        |                 |            |
| $-\infty$ | -0        |                 |            |
| QNAN      | QNAN      |                 |            |
| SNAN      | QNAN      |                 | INVALID    |

**v?Div**

Performs element by element division of vector *a* by vector *b*

**Syntax**

```
vsDiv(n, a, b, y);
vmsDiv(n, a, b, y, mode);
vdDiv(n, a, b, y);
vmdDiv(n, a, b, y, mode);
vcDiv(n, a, b, y);
vmcDiv(n, a, b, y, mode);
vzDiv(n, a, b, y);
vmzDiv(n, a, b, y, mode);
```

| <i>a, b</i> | const float* for vsDiv, vmsDiv<br>const double* for vdDiv, vmdDiv<br>const MKL_Complex8* for vcDiv, vmcDiv<br>const MKL_Complex16* for vzDiv, vmzDiv | Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .                                                          |
| <i>mode</i> | const MKL_INT64                                                                                                                                      | Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description. |

**Precision Overflow Thresholds for Real v?Div Function**

| Data Type        | Threshold Limitations on Input Parameters               |
|------------------|---------------------------------------------------------|
| single precision | $\text{abs}(a[i]) < \text{abs}(b[i]) * \text{FLT\_MAX}$ |
| double precision | $\text{abs}(a[i]) < \text{abs}(b[i]) * \text{DBL\_MAX}$ |

Precision overflow thresholds for the complex `v?Div` function are beyond the scope of this document.

## Output Parameters

| Name           | Type                                                                                                                                                                                                                                                                                         | Description                                                          |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| <code>y</code> | <code>float*</code> for <code>vsDiv</code> , <code>vmsDiv</code><br><code>double*</code> for <code>vdDiv</code> , <code>vmdDiv</code><br><code>MKL_Complex8*</code> for <code>vcDiv</code> , <code>vmcDiv</code><br><code>MKL_Complex16*</code> for <code>vzDiv</code> , <code>vmzDiv</code> | Pointer to an array that contains the output vector <code>y</code> . |

## Description

The `v?Div` function performs element by element division of vector `a` by vector `b`.

### Special values for Real Function `v?Div(x)`

| Argument 1             | Argument 2        | Result            | VM Error Status              | Exception               |
|------------------------|-------------------|-------------------|------------------------------|-------------------------|
| <code>X &gt; +0</code> | <code>+0</code>   | <code>+∞</code>   | <code>VML_STATUS_SING</code> | <code>ZERODIVIDE</code> |
| <code>X &gt; +0</code> | <code>-0</code>   | <code>-∞</code>   | <code>VML_STATUS_SING</code> | <code>ZERODIVIDE</code> |
| <code>X &lt; +0</code> | <code>+0</code>   | <code>-∞</code>   | <code>VML_STATUS_SING</code> | <code>ZERODIVIDE</code> |
| <code>X &lt; +0</code> | <code>-0</code>   | <code>+∞</code>   | <code>VML_STATUS_SING</code> | <code>ZERODIVIDE</code> |
| <code>+0</code>        | <code>+0</code>   | <code>QNAN</code> | <code>VML_STATUS_SING</code> |                         |
| <code>-0</code>        | <code>-0</code>   | <code>QNAN</code> | <code>VML_STATUS_SING</code> |                         |
| <code>X &gt; +0</code> | <code>+∞</code>   | <code>+0</code>   |                              |                         |
| <code>X &gt; +0</code> | <code>-∞</code>   | <code>-0</code>   |                              |                         |
| <code>+∞</code>        | <code>+∞</code>   | <code>QNAN</code> |                              |                         |
| <code>-∞</code>        | <code>-∞</code>   | <code>QNAN</code> |                              |                         |
| <code>QNAN</code>      | <code>QNAN</code> | <code>QNAN</code> |                              |                         |
| <code>SNAN</code>      | <code>SNAN</code> | <code>QNAN</code> |                              | <code>INVALID</code>    |

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Div}(x_1+i*y_1, x_2+i*y_2) = (x_1+i*y_1) * (x_2-i*y_2) / (x_2*x_2+y_2*y_2).$$

Overflow in a complex function occurs when `x2+i*y2` is not zero, `x1`, `x2`, `y1`, `y2` are finite numbers, but the real or imaginary part of the exact result is so large that it does not fit the target precision. In that case, the function returns `∞` in that part of the result, raises the `OVERFLOW` exception, and sets the VM Error Status to `VML_STATUS_OVERFLOW`.

## `v?Sqrt`

*Computes a square root of vector elements.*

### Syntax

```
vsSqrt(n, a, y);
vmsSqrt(n, a, y, mode);
vdSqrt(n, a, y);
vmdSqrt(n, a, y, mode);
vcSqrt(n, a, y);
vmcSqrt(n, a, y, mode);
vzSqrt(n, a, y);
vmzSqrt(n, a, y, mode);
```

## Include Files

See <a href="#">vm1SetMode</a> for possible values and their description. |

### Output Parameters

| <b>Name</b>    | <b>Type</b>                                                                                                                                           | <b>Description</b>                                                   |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| <code>y</code> | <code>float*</code> for <code>vsInvSqrt</code> , <code>vmsInvSqrt</code><br><code>double*</code> for <code>vdInvSqrt</code> , <code>vmdInvSqrt</code> | Pointer to an array that contains the output vector <code>y</code> . |

## Description

The `v?InvSqrt` function computes an inverse square root of vector elements.

### Special Values for Real Function `v?InvSqrt(x)`

| Argument  | Result    | VM Error Status   | Exception  |
|-----------|-----------|-------------------|------------|
| $X < +0$  | QNAN      | VML_STATUS_ERRDOM | INVALID    |
| $+0$      | $+\infty$ | VML_STATUS_SING   | ZERODIVIDE |
| $-0$      | $-\infty$ | VML_STATUS_SING   | ZERODIVIDE |
| $-\infty$ | QNAN      | VML_STATUS_ERRDOM | INVALID    |
| $+\infty$ | $+0$      |                   |            |
| QNAN      | QNAN      |                   |            |
| SNAN      | QNAN      |                   | INVALID    |

## `v?Cbrt`

*Computes a cube root of vector elements.*

### Syntax

```
vsCbrt(n, a, y);
```

```
vmsCbrt(n, a, y, mode);
```

```
vdCbrt(n, a, y);
```

```
vmdCbrt(n, a, y, mode);
```

### Include Files

| <i>mode</i> | const MKL_INT64                                                                         | Overrides global VM mode setting for this function call. See <a href="#">vm1SetMode</a> for possible values and their description. |

### Precision Overflow Thresholds for Pow3o2 Function

| Data Type        | Threshold Limitations on Input Parameters    |
|------------------|----------------------------------------------|
| single precision | $\text{abs}(a[i]) < (\text{FLT\_MAX})^{2/3}$ |
| double precision | $\text{abs}(a[i]) < (\text{DBL\_MAX})^{2/3}$ |

### Output Parameters

| Name     | Type                                                                  | Description                                                    |
|----------|-----------------------------------------------------------------------|----------------------------------------------------------------|
| <i>y</i> | float* for vsPow3o2, vmsPow3o2<br><br>double* for vdPow3o2, vmdPow3o2 | Pointer to an array that contains the output vector <i>y</i> . |

### Description

The v?Pow3o2 function raises each element of a vector to the constant power  $3/2$ .

**Special Values for Real Function v?Pow3o2(x)**

| Argument  | Result    | VM Error Status   | Exception |
|-----------|-----------|-------------------|-----------|
| $X < +0$  | QNAN      | VML_STATUS_ERRDOM | INVALID   |
| +0        | +0        |                   |           |
| -0        | -0        |                   |           |
| $-\infty$ | QNAN      | VML_STATUS_ERRDOM | INVALID   |
| $+\infty$ | $+\infty$ |                   |           |
| QNAN      | QNAN      |                   |           |
| SNAN      | QNAN      |                   | INVALID   |

**v?Pow**

Computes  $a$  to the power  $b$  for elements of two vectors.

**Syntax**

```
vsPow(n, a, b, y);
vmsPow(n, a, b, y, mode);
vdPow(n, a, b, y);
vmdPow(n, a, b, y, mode);
vcPow(n, a, b, y);
vmcPow(n, a, b, y, mode);
vzPow(n, a, b, y);
vmzPow(n, a, b, y, mode);
```

**Include Files**

## Description

The `v?Pow` function computes  $a$  to the power  $b$  for elements of two vectors.

The real function `v(s/d)Pow` has certain limitations on the input range of  $a$  and  $b$  parameters. Specifically, if  $a[i]$  is positive, then  $b[i]$  may be arbitrary. For negative  $a[i]$ , the value of  $b[i]$  must be an integer (either positive or negative).

The complex function `v(c/z)Pow` has no input range limitations.

### Special values for Real Function `v?Pow(x)`

| Argument 1 | Argument 2        | Result    | VM Error Status   | Exception  |
|------------|-------------------|-----------|-------------------|------------|
| +0         | neg. odd integer  | $+\infty$ | VML_STATUS_ERRDOM | ZERODIVIDE |
| -0         | neg. odd integer  | $-\infty$ | VML_STATUS_ERRDOM | ZERODIVIDE |
| +0         | neg. even integer | $+\infty$ | VML_STATUS_ERRDOM | ZERODIVIDE |
| -0         | neg. even integer | $+\infty$ | VML_STATUS_ERRDOM | ZERODIVIDE |
| +0         | neg. non-integer  | $+\infty$ | VML_STATUS_ERRDOM | ZERODIVIDE |
| -0         | neg. non-integer  | $+\infty$ | VML_STATUS_ERRDOM | ZERODIVIDE |
| -0         | pos. odd integer  | +0        |                   |            |
| -0         | pos. odd integer  | -0        |                   |            |
| +0         | pos. even integer | +0        |                   |            |
| -0         | pos. even integer | +0        |                   |            |
| +0         | pos. non-integer  | +0        |                   |            |
| -0         | pos. non-integer  | +0        |                   |            |
| -1         | $+\infty$         | +1        |                   |            |
| -1         | $-\infty$         | +1        |                   |            |
| +1         | any value         | +1        |                   |            |
| +1         | +0                | +1        |                   |            |
| +1         | -0                | +1        |                   |            |
| +1         | $+\infty$         | +1        |                   |            |

| SNAN       | SNAN              | QNAN      |                   | INVALID    |

The complex double precision versions of this function, `vzPow` and `vmzPow`, are implemented in the EP accuracy mode only. If used in HA or LA mode, `vzPow` and `vmzPow` set the VM Error Status to `VML_STATUS_ACCURACYWARNING` (see the [Values of the VM Status](#) table).

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when  $x_1$ ,  $x_2$ ,  $y_1$ ,  $y_2$  are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns  $\infty$  in that part of the result, raises the `OVERFLOW` exception, and sets the VM Error Status to `VML_STATUS_OVERFLOW` (overriding any possible `VML_STATUS_ACCURACYWARNING` status).

### **v?Powx**

*Raises each element of a vector to the constant power.*

### **Syntax**

```
vsPowx(n, a, b, y);
```

```
vmsPowx(n, a, b, y, mode);
```

```
vdPowx(n, a, b, y);
vmdPowx(n, a, b, y, mode);
vcPowx(n, a, b, y);
vmcPowx(n, a, b, y, mode);
vzPowx(n, a, b, y);
vmzPowx(n, a, b, y, mode);
```

## Description

The `v?Powx` function raises each element of a vector to the constant power.

The real function `v(s/d)Powx` has certain limitations on the input range of  $a$  and  $b$  parameters. Specifically, if  $a[i]$  is positive, then  $b$  may be arbitrary. For negative  $a[i]$ , the value of  $b$  must be an integer (either positive or negative).

The complex function `v(c/z)Powx` has no input range limitations.

Special values and VM Error Status treatment are the same as for the `v?Pow` function.

## v?Hypot

Computes a square root of sum of two squared elements.

## Syntax

```
vsHypot(n, a, b, y);
vmsHypot(n, a, b, y, mode);
vdHypot(n, a, b, y);
vmdHypot(n, a, b, y, mode);
```

## Input Parameters

| Name   | Type                                                                                                                                                                | Description                                                                                                                        |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| $n$    | <code>const MKL_INT</code>                                                                                                                                          | Number of elements to be calculated.                                                                                               |
| $a, b$ | <code>const float*</code> for <code>vsHypot</code> ,<br><code>vmsHypot</code><br><br><code>const double*</code> for <code>vdHypot</code> ,<br><code>vmdHypot</code> | Pointers to arrays that contain the input vectors $a$ and $b$ .                                                                    |
| $mode$ | <code>const MKL_INT64</code>                                                                                                                                        | Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description. |

## Precision Overflow Thresholds for Hypot Function

| Data Type        | Threshold Limitations on Input Parameters                                                              |
|------------------|--------------------------------------------------------------------------------------------------------|
| single precision | $\text{abs}(a[i]) < \text{sqrt}(\text{FLT\_MAX})$<br>$\text{abs}(b[i]) < \text{sqrt}(\text{FLT\_MAX})$ |
| double precision | $\text{abs}(a[i]) < \text{sqrt}(\text{DBL\_MAX})$<br>$\text{abs}(b[i]) < \text{sqrt}(\text{DBL\_MAX})$ |

## Output Parameters

| Name | Type                                                          | Description                                               |
|------|---------------------------------------------------------------|-----------------------------------------------------------|
| $y$  | float* for vsHypot, vmsHypot<br>double* for vdHypot, vmdHypot | Pointer to an array that contains the output vector $y$ . |

## Description

The function  $v?Hypot$  computes a square root of sum of two squared elements.

### Special values for Real Function $v?Hypot(x)$

| Argument 1 | Argument 2 | Result    | Exception |
|------------|------------|-----------|-----------|
| +0         | +0         | +0        |           |
| -0         | -0         | +0        |           |
| $+\infty$  | any value  | $+\infty$ |           |
| any value  | $+\infty$  | $+\infty$ |           |
| SNAN       | any value  | QNAN      | INVALID   |
| any value  | SNAN       | QNAN      | INVALID   |
| QNAN       | any value  | QNAN      |           |
| any value  | QNAN       | QNAN      |           |

## Exponential and Logarithmic Functions

### $v?Exp$

*Computes an exponential of vector elements.*

### Syntax

```
vsExp(n, a, y);
vmsExp(n, a, y, mode);
vdExp(n, a, y);
vmdExp(n, a, y, mode);
vcExp(n, a, y);
vmcExp(n, a, y, mode);
vzExp(n, a, y);
vmzExp(n, a, y, mode);
```

### Include Files

- mkl.h

### Input Parameters

| Name | Type          | Description                                        |
|------|---------------|----------------------------------------------------|
| $n$  | const MKL_INT | Specifies the number of elements to be calculated. |

| Name        | Type                                                                                                                                                 | Description                                                                                                                        |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <i>a</i>    | const float* for vsExp, vmsExp<br>const double* for vdExp, vmdExp<br>const MKL_Complex8* for vcExp, vmcExp<br>const MKL_Complex16* for vzExp, vmzExp | Pointer to an array that contains the input vector <i>a</i> .                                                                      |
| <i>mode</i> | const MKL_INT64                                                                                                                                      | Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description. |

### Precision Overflow Thresholds for Real v?Exp Function

| Data Type        | Threshold Limitations on Input Parameters |
|------------------|-------------------------------------------|
| single precision | $a[i] < \text{Ln}(\text{FLT\_MAX})$       |
| double precision | $a[i] < \text{Ln}(\text{DBL\_MAX})$       |

Precision overflow thresholds for the complex v?Exp function are beyond the scope of this document.

### Output Parameters

| Name     | Type                                                                                                                         | Description                                                    |
|----------|------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| <i>y</i> | float* for vsExp, vmsExp<br>double* for vdExp, vmdExp<br>MKL_Complex8* for vcExp, vmcExp<br>MKL_Complex16* for vzExp, vmzExp | Pointer to an array that contains the output vector <i>y</i> . |

### Description

The v?Exp function computes an exponential of vector elements.

### Special Values for Real Function v?Exp(x)

| Argument      | Result | VM Error Status      | Exception |
|---------------|--------|----------------------|-----------|
| +0            | +1     |                      |           |
| -0            | +1     |                      |           |
| X > overflow  | +∞     | VML_STATUS_OVERFLOW  | OVERFLOW  |
| X < underflow | +0     | VML_STATUS_UNDERFLOW | UNDERFLOW |
| +∞            | +∞     |                      |           |
| -∞            | +0     |                      |           |
| QNAN          | QNAN   |                      |           |
| SNAN          | QNAN   |                      | INVALID   |

See the [Special Value Notations](#) section for the conventions used in the table below.

### Special Values for Complex Function v?Exp(z)

| RE(z)<br>i·IM(z) | -∞     | -X                     | -0                     | +0                     | +X                     | +∞                   | NAN                    |
|------------------|--------|------------------------|------------------------|------------------------|------------------------|----------------------|------------------------|
| +i∞              | +0+i·0 | QNAN+i·QNAN<br>INVALID | QNAN+i·QNAN<br>INVALID | QNAN+i·QNAN<br>INVALID | QNAN+i·QNAN<br>INVALID | +∞+i·QNAN<br>INVALID | QNAN+i·QNAN<br>INVALID |

| <b>RE(z)</b><br><b>i·IM(z)</b> | <b>-∞</b> | <b>-X</b>              | <b>-0</b>              | <b>+0</b>              | <b>+X</b>              | <b>+∞</b>            | <b>NAN</b>  |
|--------------------------------|-----------|------------------------|------------------------|------------------------|------------------------|----------------------|-------------|
| <b>+i·Y</b>                    | +0·CIS(Y) |                        |                        |                        |                        | +∞·CIS(Y)            | QNAN+i·QNAN |
| <b>+i·0</b>                    | +0·CIS(0) |                        | +1+i·0                 | +1+i·0                 |                        | +∞+i·0               | QNAN+i·0    |
| <b>-i·0</b>                    | +0·CIS(0) |                        | +1-i·0                 | +1-i·0                 |                        | +∞-i·0               | QNAN-i·0    |
| <b>-i·Y</b>                    | +0·CIS(Y) |                        |                        |                        |                        | +∞·CIS(Y)            | QNAN+i·QNAN |
| <b>-i·∞</b>                    | +0-i·0    | QNAN+i·QNAN<br>INVALID | QNAN+i·QNAN<br>INVALID | QNAN+i·QNAN<br>INVALID | QNAN+i·QNAN<br>INVALID | +∞+i·QNAN<br>INVALID | QNAN+i·QNAN |
| <b>+i·NAN</b>                  | +0+i·0    | QNAN+i·QNAN<br>INVALID | QNAN+i·QNAN<br>INVALID | QNAN+i·QNAN<br>INVALID | QNAN+i·QNAN<br>INVALID | +∞+i·QNAN            | QNAN+i·QNAN |

## Notes:

- raises the `INVALID` exception when real or imaginary part of the argument is `SNAN`
- raises the `INVALID` exception on argument  $z = -\infty + i \cdot \text{QNAN}$
- raises the `OVERFLOW` exception and sets the VM Error Status to `VML_STATUS_OVERFLOW` in the case of overflow, that is, when  $\text{RE}(z)$ ,  $\text{IM}(z)$  are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.

## v?Expml

Computes an exponential of vector elements decreased by 1.

### Syntax

```
vsExpml(n, a, y);
vmsExpml(n, a, y, mode);
vdExpml(n, a, y);
vmdExpml(n, a, y, mode);
```

### Include Files

- `mkl.h`

### Input Parameters

| <b>Name</b>       | <b>Type</b>                                                                                                                                                     | <b>Description</b>                                                                                                                 |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <code>n</code>    | <code>const MKL_INT</code>                                                                                                                                      | Specifies the number of elements to be calculated.                                                                                 |
| <code>a</code>    | <code>const float*</code> for <code>vsExpml</code> ,<br><code>vmsExpml</code><br><code>const double*</code> for <code>vdExpml</code> ,<br><code>vmdExpml</code> | Pointer to an array that contains the input vector <code>a</code> .                                                                |
| <code>mode</code> | <code>const MKL_INT64</code>                                                                                                                                    | Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description. |

**Precision Overflow Thresholds for Exp<sub>m</sub>1 Function**

| Data Type        | Threshold Limitations on Input Parameters |
|------------------|-------------------------------------------|
| single precision | $a[i] < \text{Ln}(\text{FLT\_MAX})$       |
| double precision | $a[i] < \text{Ln}(\text{DBL\_MAX})$       |

**Output Parameters**

| Name | Type                                                                                                              | Description                                               |

| <i>mode</i> | const MKL_INT64                                                                     | Overrides global VM mode setting for this function call. See <a href="#">vm1SetMode</a> for possible values and their description. |

## Output Parameters

| Name | Type                                                          | Description                                               |
|------|---------------------------------------------------------------|-----------------------------------------------------------|
| $y$  | float* for vsLog1p, vmsLog1p<br>double* for vdLog1p, vmdLog1p | Pointer to an array that contains the output vector $y$ . |

## Description

The `v?Log1p` function computes a natural logarithm of vector elements that are increased by 1.

### Special Values for Real Function `v?Log1p(x)`

| Argument  | Result    | VM Error Status   | Exception  |
|-----------|-----------|-------------------|------------|
| -1        | $-\infty$ | VML_STATUS_SING   | ZERODIVIDE |
| $X < -1$  | QNAN      | VML_STATUS_ERRDOM | INVALID    |
| +0        | +0        |                   |            |
| -0        | -0        |                   |            |
| $-\infty$ | QNAN      | VML_STATUS_ERRDOM | INVALID    |
| $+\infty$ | $+\infty$ |                   |            |
| QNAN      | QNAN      |                   |            |
| SNAN      | QNAN      |                   | INVALID    |

## Trigonometric Functions

### `v?Cos`

*Computes cosine of vector elements.*

### Syntax

```
vsCos(n, a, y);
vmsCos(n, a, y, mode);
vdCos(n, a, y);
vmdCos(n, a, y, mode);
vcCos(n, a, y);
vmcCos(n, a, y, mode);
vzCos(n, a, y);
vmzCos(n, a, y, mode);
```

### Include Files

- `mk1.h`

### Input Parameters

| Name | Type          | Description                                        |

| <i>mode</i> | const MKL_INT64                                                                                                                                      | Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description. |

## Output Parameters

| Name     | Type                                                                                                                         | Description                                                    |
|----------|------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| <i>y</i> | float* for vsCos, vmsCos<br>double* for vdCos, vmdCos<br>MKL_Complex8* for vcCos, vmcCos<br>MKL_Complex16* for vzCos, vmzCos | Pointer to an array that contains the output vector <i>y</i> . |

## Description

The *v?Cos* function computes cosine of vector elements.

Note that arguments  $\text{abs}(a[i]) \leq 2^{13}$  and  $\text{abs}(a[i]) \leq 2^{16}$  for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VM provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VM High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VM Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

### Special Values for Real Function *v?Cos(x)*

| Argument  | Result | VM Error Status   | Exception |
|-----------|--------|-------------------|-----------|
| +0        | +1     |                   |           |
| -0        | +1     |                   |           |
| $+\infty$ | QNAN   | VML_STATUS_ERRDOM | INVALID   |
| $-\infty$ | QNAN   | VML_STATUS_ERRDOM | INVALID   |
| QNAN      | QNAN   |                   |           |
| SNAN      | QNAN   |                   | INVALID   |

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Cos}(z) = \text{Cosh}(i*z).$$

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain

## Optimization Notice

optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

**v?CIS**

Computes complex exponent of real vector elements (cosine and sine of real vector elements combined to complex value).

**Syntax**

```
vcCIS(n, a, y);
vmcCIS(n, a, y, mode);
vzCIS(n, a, y);
vmzCIS(n, a, y, mode);
```

**Include Files**

- mkl.h

**Input Parameters**

| Name        | Type                                                              | Description                                                                                                                        |
|-------------|-------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>    | const MKL_INT                                                     | Specifies the number of elements to be calculated.                                                                                 |
| <i>a</i>    | const float* for vcCIS, vmcCIS<br>const double* for vzCIS, vmzCIS | Pointer to an array that contains the input vector <i>a</i> .                                                                      |
| <i>mode</i> | const MKL_INT64                                                   | Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description. |

**Output Parameters**

| Name     | Type                                                                | Description                                                    |
|----------|---------------------------------------------------------------------|----------------------------------------------------------------|
| <i>y</i> | MKL_Complex8* for vcCIS, vmcCIS<br>MKL_Complex16* for vzCIS, vmzCIS | Pointer to an array that contains the output vector <i>y</i> . |

**Description**

The v?CIS function computes complex exponent of real vector elements (cosine and sine of real vector elements combined to complex value).

See the [Special Value Notations](#) section for the conventions used in the table below.

**Special Values for Complex Function v?CIS(x)**

| <b>x</b> | <b>CIS(x)</b>          |
|----------|------------------------|
| + ∞      | QNAN+i·QNAN<br>INVALID |
| + 0      | +1+i·0                 |

| <b>x</b> | <b>CIS(x)</b>          |
|----------|------------------------|
| - 0      | +1-i·0                 |
| - ∞      | QNAN+i·QNAN<br>INVALID |
| NAN      | QNAN+i·QNAN            |

Notes:

- raises `INVALID` exception when the argument is `SNAN`
- raises `INVALID` exception and sets the VM Error Status to `VML_STATUS_ERRDOM` for  $x=+\infty$ ,  $x=-\infty$

## v?Tan

*Computes tangent of vector elements.*

### Syntax

```
vsTan(n, a, y);
vmsTan(n, a, y, mode);
vdTan(n, a, y);
vmdTan(n, a, y, mode);
vcTan(n, a, y);
vmcTan(n, a, y, mode);
vzTan(n, a, y);
vmzTan(n, a, y, mode);
```

| <code>mode</code> | <code>const MKL_INT64</code>                                                                                                                                                                                                                                                                                               | Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description. |

## Output Parameters

| Name | Type                                                                                                                         | Description                                               |
|------|------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------|
| $y$  | float* for vsTan, vmsTan<br>double* for vdTan, vmdTan<br>MKL_Complex8* for vcTan, vmcTan<br>MKL_Complex16* for vzTan, vmzTan | Pointer to an array that contains the output vector $y$ . |

## Description

The  $v?Tan$  function computes tangent of vector elements.

Note that arguments  $abs(a[i]) \leq 2^{13}$  and  $abs(a[i]) \leq 2^{16}$  for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VM provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VM High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VM Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

### Special Values for Real Function $v?Tan(x)$

| Argument  | Result | VM Error Status   | Exception |
|-----------|--------|-------------------|-----------|
| +0        | +0     |                   |           |
| -0        | -0     |                   |           |
| $+\infty$ | QNAN   | VML_STATUS_ERRDOM | INVALID   |
| $-\infty$ | QNAN   | VML_STATUS_ERRDOM | INVALID   |
| QNAN      | QNAN   |                   |           |
| SNAN      | QNAN   |                   | INVALID   |

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Tan}(z) = -i * \text{Tanh}(i * z).$$

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## $v?Acos$

*Computes inverse cosine of vector elements.*

### Syntax

```
vsAcos(n, a, y);
```

```
vmsAcos(n, a, y, mode);
```

```
vdAcos(n, a, y);
```

```
vmdAcos(n, a, y, mode);
```

```
vcAcos(n, a, y);
```

```
vmcAcos(n, a, y, mode);
vzAcos(n, a, y);
vmzAcos(n, a, y, mode);
```

## Include Files

- mkl.h

## Input Parameters

| Name        | Type                                                                                                                                                         | Description                                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|

| <b>+i·NAN</b>            | QNAN+i·∞                           | QNAN+i·QNAN                       | $+\frac{\pi}{2} + i \cdot \text{QNAN}$ | $+\frac{\pi}{2} + i \cdot \text{QNAN}$ | QNAN+i·QNAN                       | QNAN+i·∞                          | QNAN+i·QNAN |

Notes:

- raises INVALID exception when real or imaginary part of the argument is SNAN
- $\text{Acos}(\text{CONJ}(z)) = \text{CONJ}(\text{Acos}(z))$ .

**v?Asin**

*Computes inverse sine of vector elements.*

**Syntax**

```
vsAsin(n, a, y);
vmsAsin(n, a, y, mode);
vdAsin(n, a, y);
vmdAsin(n, a, y, mode);
vcAsin(n, a, y);
vmcAsin(n, a, y, mode);
vzAsin(n, a, y);
vmzAsin(n, a, y, mode);
```

**Include Files**

- mkl.h

**Input Parameters**

| <b>Name</b> | <b>Type</b>                                                           | <b>Description</b>                                            |
|-------------|-----------------------------------------------------------------------|---------------------------------------------------------------|
| <i>n</i>    | const MKL_INT                                                         | Specifies the number of elements to be calculated.            |
| <i>a</i>    | const float* for vsAsin, vmsAsin<br>const double* for vdAsin, vmdAsin | Pointer to an array that contains the input vector <i>a</i> . |

| Name | Type                                     | Description                                                                                                                        |
|------|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
|      | const MKL_Complex8* for vcAsin, vmcAsin  |                                                                                                                                    |
|      | const MKL_Complex16* for vzAsin, vmzAsin |                                                                                                                                    |
| mode | const MKL_INT64                          | Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description. |

## Output Parameters

| Name | Type                                                                                                                                 | Description                                                    |
|------|--------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| y    | float* for vsAsin, vmsAsin<br>double* for vdAsin, vmdAsin<br>MKL_Complex8* for vcAsin, vmcAsin<br>MKL_Complex16* for vzAsin, vmzAsin | Pointer to an array that contains the output vector <i>y</i> . |

## Description

The `v?Asin` function computes inverse sine of vector elements.

### Special Values for Real Function `v?Asin(x)`

| Argument  | Result   | VM Error Status   | Exception |
|-----------|----------|-------------------|-----------|
| +0        | +0       |                   |           |
| -0        | -0       |                   |           |
| +1        | $+\pi/2$ |                   |           |
| -1        | $-\pi/2$ |                   |           |
| $ X  > 1$ | QNAN     | VML_STATUS_ERRDOM | INVALID   |
| $+\infty$ | QNAN     | VML_STATUS_ERRDOM | INVALID   |
| $-\infty$ | QNAN     | VML_STATUS_ERRDOM | INVALID   |
| QNAN      | QNAN     |                   |           |
| SNAN      | QNAN     |                   | INVALID   |

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Asin}(z) = -i \cdot \text{Asinh}(i \cdot z).$$

## `v?Atan`

*Computes inverse tangent of vector elements.*

### Syntax

```
vsAtan(n, a, y);
```

```
vmsAtan(n, a, y, mode);
```

```
vdAtan(n, a, y);
```

```
vmdAtan(n, a, y, mode);
```

```
vcAtan(n, a, y);
```

```
vmcAtan(n, a, y, mode);
```

```

vzAtan(n, a, y);
vmzAtan(n, a, y, mode);

```

## Description

The `v?Atan` function computes inverse tangent of vector elements.

### Special Values for Real Function `v?Atan(x)`

| Argument  | Result   | VM Error Status | Exception |
|-----------|----------|-----------------|-----------|
| +0        | +0       |                 |           |
| -0        | -0       |                 |           |
| $+\infty$ | $+\pi/2$ |                 |           |
| $-\infty$ | $-\pi/2$ |                 |           |
| QNAN      | QNAN     |                 |           |
| SNAN      | QNAN     |                 | INVALID   |

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Atan}(z) = -i \cdot \text{Atanh}(i \cdot z).$$

## v?Atan2

Computes four-quadrant inverse tangent of elements of two vectors.

### Syntax

```
vsAtan2(n, a, b, y);
vmsAtan2(n, a, b, y, mode);
vdAtan2(n, a, b, y);
vmdAtan2(n, a, b, y, mode);
```

### Include Files

- mkl.h

### Input Parameters

| Name        | Type                                                                                | Description                                                                                                                        |

| <i>n</i>    | const MKL_INT                                                                       | Specifies the number of elements to be calculated.                                                                                 |
| <i>a, b</i> | const float* for vsAtan2,<br>vmsAtan2<br><br>const double* for vdAtan2,<br>vmdAtan2 | Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .                                                          |
| <i>mode</i> | const MKL_INT64                                                                     | Overrides global VM mode setting for this function call. See <a href="#">vm1SetMode</a> for possible values and their description. |

### Output Parameters

| Name     | Type                                                          | Description                                                    |
|----------|---------------------------------------------------------------|----------------------------------------------------------------|
| <i>y</i> | float* for vsAtan2, vmsAtan2<br>double* for vdAtan2, vmdAtan2 | Pointer to an array that contains the output vector <i>y</i> . |

### Description

The `v?Atan2` function computes four-quadrant inverse tangent of elements of two vectors.

The elements of the output vector *y* are computed as the four-quadrant arctangent of  $a[i] / b[i]$ .

### Special values for Real Function v?Atan2(x)

| Argument 1 | Argument 2 | Result     | Exception |
|------------|------------|------------|-----------|
| $-\infty$  | $-\infty$  | $-3*\pi/4$ |           |
| $-\infty$  | $X < +0$   | $-\pi/2$   |           |
| $-\infty$  | $-0$       | $-\pi/2$   |           |
| $-\infty$  | $+0$       | $-\pi/2$   |           |
| $-\infty$  | $X > +0$   | $-\pi/2$   |           |
| $-\infty$  | $+\infty$  | $-\pi/4$   |           |
| $X < +0$   | $-\infty$  | $-\pi$     |           |
| $X < +0$   | $-0$       | $-\pi/2$   |           |

| Argument 1 | Argument 2 | Result     | Exception |
|------------|------------|------------|-----------|
| X < +0     | +0         | $-\pi/2$   |           |
| X < +0     | $+\infty$  | -0         |           |
| -0         | $-\infty$  | $-\pi$     |           |
| -0         | X < +0     | $-\pi$     |           |
| -0         | -0         | $-\pi$     |           |

## Hyperbolic Functions

### v?Cosh

Computes hyperbolic cosine of vector elements.

#### Syntax

```
vsCosh(n, a, y);
```

```
vmsCosh(n, a, y, mode);
```

```
vdCosh(n, a, y);
```

```
vmdCosh(n, a, y, mode);
```

```
vcCosh(n, a, y);
```

```
vmcCosh(n, a, y, mode);
```

```
vzCosh(n, a, y);
```

```
vmzCosh(n, a, y, mode);
```

## Include Files

- mkl.h

## Input Parameters

| Name        | Type                                                                                                                                                         | Description                                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|

Notes:

- raises the INVALID exception when the real or imaginary part of the argument is SNAN
- raises the OVERFLOW exception and sets the VM Error Status to VML\_STATUS\_OVERFLOW in the case of overflow, that is, when RE(z), IM(z) are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.
- $\text{Cosh}(\text{CONJ}(z)) = \text{CONJ}(\text{Cosh}(z))$
- $\text{Cosh}(-z) = \text{Cosh}(z)$ .

### $v?Sinh$

*Computes hyperbolic sine of vector elements.*

#### Syntax

```
vsSinh(n, a, y);
vmsSinh(n, a, y, mode);
vdSinh(n, a, y);
vmdSinh(n, a, y, mode);
vcSinh(n, a, y);
vmcSinh(n, a, y, mode);
vzSinh(n, a, y);
vmzSinh(n, a, y, mode);
```

## Precision Overflow Thresholds for Real $v?Sinh$ Function

| Data Type        | Threshold Limitations on Input Parameters                             |
|------------------|-----------------------------------------------------------------------|
| single precision | $-\ln(\text{FLT\_MAX}) - \ln 2 < a[i] < \ln(\text{FLT\_MAX}) + \ln 2$ |
| double precision | $-\ln(\text{DBL\_MAX}) - \ln 2 < a[i] < \ln(\text{DBL\_MAX}) + \ln 2$ |

Precision overflow thresholds for the complex  $v?Sinh$  function are beyond the scope of this document.

## Output Parameters

| Name     | Type                                                                                                                                                                                                                                                                                                 | Description                                                    |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| <i>y</i> | <code>float*</code> for <code>vsSinh</code> , <code>vmsSinh</code><br><code>double*</code> for <code>vdSinh</code> , <code>vmdSinh</code><br><code>MKL_Complex8*</code> for <code>vcSinh</code> , <code>vmcSinh</code><br><code>MKL_Complex16*</code> for <code>vzSinh</code> , <code>vmzSinh</code> | Pointer to an array that contains the output vector <i>y</i> . |

## Description

The  $v?Sinh$  function computes hyperbolic sine of vector elements.

## Special Values for Real Function $v?Sinh(x)$

| Argument               | Result    | VM Error Status     | Exception |
|------------------------|-----------|---------------------|-----------|
| +0                     | +0        |                     |           |
| -0                     | -0        |                     |           |
| $X > \text{overflow}$  | $+\infty$ | VML_STATUS_OVERFLOW | OVERFLOW  |
| $X < \text{-overflow}$ | $-\infty$ | VML_STATUS_OVERFLOW | OVERFLOW  |
| $+\infty$              | $+\infty$ |                     |           |
| $-\infty$              | $-\infty$ |                     |           |
| QNAN                   | QNAN      |                     |           |
| SNAN                   | QNAN      |                     | INVALID   |

See the [Special Value Notations](#) section for the conventions used in the table below.

### Special Values for Complex Function $v?Sinh(z)$

| <b>+i·Y</b>                    | -∞·Cos(Y)+<br>i·∞·Sin(Y) |                        |                      |                      |                        | +∞·CIS(Y)            | QNAN+i·QNAN |
| <b>+i·0</b>                    | -∞+i·0                   |                        | -0+i·0               | +0+i·0               |                        | +∞+i·0               | QNAN+i·0    |
| <b>-i·0</b>                    | -∞-i·0                   |                        | -0-i·0               | +0-i·0               |                        | +∞-i·0               | QNAN-i·0    |
| <b>-i·Y</b>                    | -∞·Cos(Y)+<br>i·∞·Sin(Y) |                        |                      |                      |                        | +∞·CIS(Y)            | QNAN+i·QNAN |
| <b>-i·∞</b>                    | -∞+i·QNAN<br>INVALID     | QNAN+i·QNAN<br>INVALID | -0+i·QNAN<br>INVALID | +0+i·QNAN<br>INVALID | QNAN+i·QNAN<br>INVALID | +∞+i·QNAN<br>INVALID | QNAN+i·QNAN |
| <b>+i·NAN</b>                  | -∞+i·QNAN                | QNAN+i·QNAN            | -0+i·QNAN            | +0+i·QNAN            | QNAN+i·QNAN            | +∞+i·QNAN            | QNAN+i·QNAN |

**Notes:**

- raises the `INVALID` exception when the real or imaginary part of the argument is `SNAN`
- raises the `OVERFLOW` exception and sets the VM Error Status to `VML_STATUS_OVERFLOW` in the case of overflow, that is, when `RE(z)`, `IM(z)` are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.
- $Sinh(CONJ(z)) = CONJ(Sinh(z))$
- $Sinh(-z) = -Sinh(z)$ .

### $v?Tanh$

*Computes hyperbolic tangent of vector elements.*

#### Syntax

```
vsTanh(n, a, y);
vmsTanh(n, a, y, mode);
vdTanh(n, a, y);
vmdTanh(n, a, y, mode);
vcTanh(n, a, y);
vmcTanh(n, a, y, mode);
vzTanh(n, a, y);
vmzTanh(n, a, y, mode);
```

#### Include Files

- `mk1.h`

## Input Parameters

| Name        | Type                                                                                                                                                         | Description                                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>    | const MKL_INT                                                                                                                                                | Specifies the number of elements to be calculated.                                                                                 |
| <i>a</i>    | const float* for vsTanh, vmsTanh<br>const double* for vdTanh, vmdTanh<br>const MKL_Complex8* for vcTanh, vmcTanh<br>const MKL_Complex16* for vzTanh, vmzTanh | Pointer to an array that contains the input vector <i>a</i> .                                                                      |
| <i>mode</i> | const MKL_INT64                                                                                                                                              | Overrides global VM mode setting for this function call. See <a href="#">vm1SetMode</a> for possible values and their description. |

## Output Parameters

| Name     | Type                                                                                                                                 | Description                                                    |
|----------|--------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- $\text{Tanh}(\text{CONJ}(z)) = \text{CONJ}(\text{Tanh}(z))$
- $\text{Tanh}(-z) = -\text{Tanh}(z)$ .

### v?Acosh

Computes inverse hyperbolic cosine (nonnegative) of vector elements.

#### Syntax

```
vsAcosh(n, a, y);
vmsAcosh(n, a, y, mode);
vdAcosh(n, a, y);
vmdAcosh(n, a, y, mode);
vcAcosh(n, a, y);
vmcAcosh(n, a, y, mode);
vzAcosh(n, a, y);
vmzAcosh(n, a, y, mode);
```

#### Include Files

- `mkl.h`

#### Input Parameters

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- `Acosh (CONJ (z)) =CONJ (Acosh (z))`.

## v?Asinh

Computes inverse hyperbolic sine of vector elements.

### Syntax

```

vsAsinh(n, a, y);
vmsAsinh(n, a, y, mode);
vdAsinh(n, a, y);
vmdAsinh(n, a, y, mode);
vcAsinh(n, a, y);
vmcAsinh(n, a, y, mode);
vzAsinh(n, a, y);
vmzAsinh(n, a, y, mode);

```

### Include Files

- mkl.h

### Input Parameters

| $y$  | float* for vsErf, vmsErf<br>double* for vdErf, vmdErf | Pointer to an array that contains the output vector $y$ . |

## Description

The `erf` function computes the error function values for elements of the input vector  $a$  and writes them to the output vector  $y$ .

The error function is defined as given by:

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt .$$

Useful relations:

$$1. \quad \text{erfc}(x) = 1 - \text{erf}(x) ,$$

where `erfc` is the complementary error function.

$$2. \quad \Phi(x) = \frac{1}{2} \text{erf} (x/\sqrt{2}) ,$$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp ( - t^2/2) dt$$

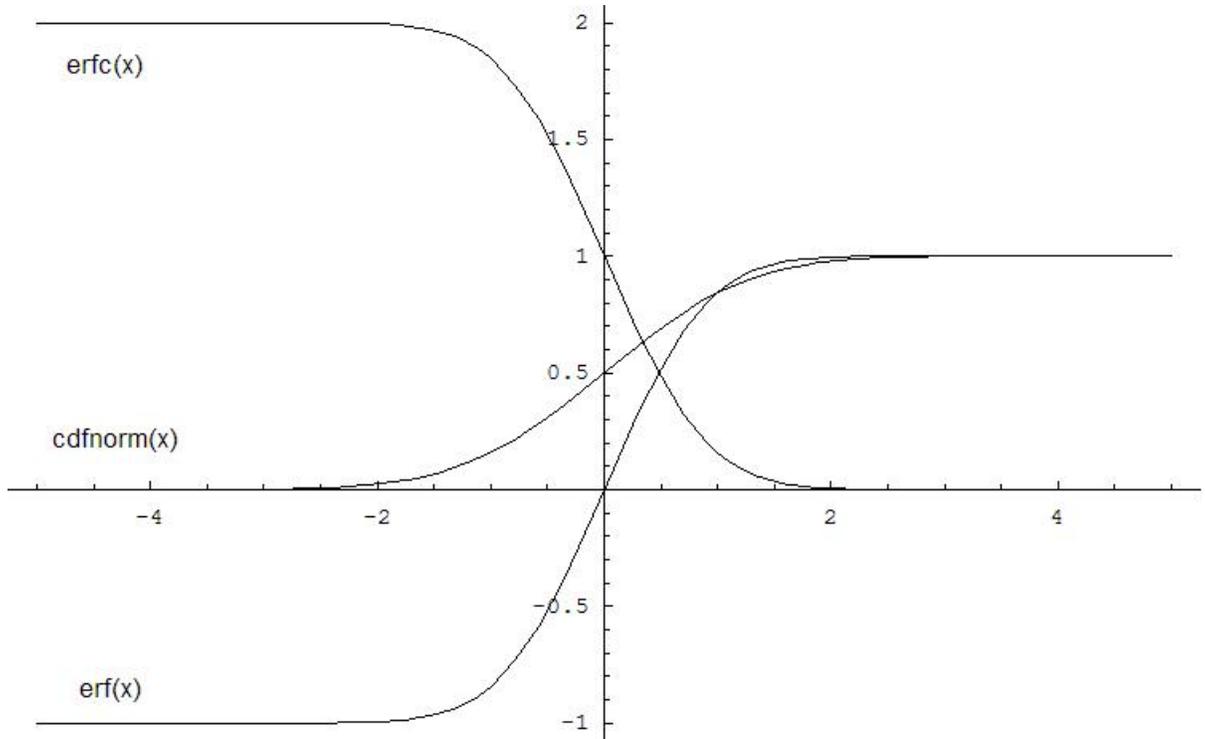

is the cumulative normal distribution function.

$$3. \quad \Phi^{-1}(x) = \sqrt{2} \text{erf}^{-1}(2x - 1) ,$$

where  $\Phi^{-1}(x)$  and  $\text{erf}^{-1}(x)$  are the inverses to  $\Phi(x)$  and  $\text{erf}(x)$  respectively.

The following figure illustrates the relationships among `Erf` family functions (`Erf`, `Erfc`, `CdfNorm`).

## Erf Family Functions Relationship

Useful relations for these functions:

$$\text{erf}(x) + \text{erfc}(x) = 1$$

$$\text{cdfnorm}(x) = \frac{1}{2} \left( 1 + \text{erf} \left( \frac{x}{\sqrt{2}} \right) \right) = 1 - \frac{1}{2} \text{erfc} \left( \frac{x}{\sqrt{2}} \right)$$

### Special Values for Real Function v?Erf(x)

| Argument  | Result | Exception |
|-----------|--------|-----------|

## Description

The `Erfc` function computes the complementary error function values for elements of the input vector  $a$  and writes them to the output vector  $y$ .

The complementary error function is defined as follows:

$$\operatorname{erfc}(x) = \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt .$$

Useful relations:

1.  $\operatorname{erfc}(x) = 1 - \operatorname{erf}(x)$ .

2.  $\Phi(x) = \frac{1}{2} \operatorname{erf}(x/\sqrt{2})$ ,

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

is the cumulative normal distribution function.

3.  $\Phi^{-1}(x) = \sqrt{2} \operatorname{erf}^{-1}(2x - 1)$ ,

where  $\Phi^{-1}(x)$  and  $\operatorname{erf}^{-1}(x)$  are the inverses to  $\Phi(x)$  and  $\operatorname{erf}(x)$  respectively.

See also [Figure "Erf Family Functions Relationship"](#) in `Erf` function description for `Erfc` function relationship with the other functions of `Erf` family.

See <a href="#">vmlSetMode</a> for possible values and their description. |

## Output Parameters

| Name     | Type                                                                                                                                                  | Description                                                    |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| <i>y</i> | <code>float*</code> for <code>vsCdfNorm</code> , <code>vmsCdfNorm</code><br><code>double*</code> for <code>vdCdfNorm</code> , <code>vmdCdfNorm</code> | Pointer to an array that contains the output vector <i>y</i> . |

## Description

The `CdfNorm` function computes the cumulative normal distribution function values for elements of the input vector  $a$  and writes them to the output vector  $y$ .

The cumulative normal distribution function is defined as given by:

$$\text{CdfNorm}(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{t^2}{2}} dt .$$

Useful relations:

$$\text{cdfnorm}(x) = \frac{1}{2} \left( 1 + \text{erf} \left( \frac{x}{\sqrt{2}} \right) \right) = 1 - \frac{1}{2} \text{erfc} \left( \frac{x}{\sqrt{2}} \right)$$

where `Erf` and `Erfc` are the error and complementary error functions.

See also [Figure "Erf Family Functions Relationship"](#) in `Erf` function description for `CdfNorm` function relationship with the other functions of `Erf` family.

| <i>y</i> | float* for vsErfInv, vmsErfInv<br>double* for vdErfInv, vmdErfInv | Pointer to an array that contains the output vector <i>y</i> . |

## Description

The `ErfInv` function computes the inverse error function values for elements of the input vector *a* and writes them to the output vector *y*

$$y = \text{erf}^{-1}(a),$$

where `erf(x)` is the error function defined as given by:

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt .$$

Useful relations:

- $\text{erf}^{-1}(x) = \text{erfc}^{-1}(1 - x),$

where `erfc` is the complementary error function.

- $\Phi(x) = \frac{1}{2} \text{erf}(x/\sqrt{2}),$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

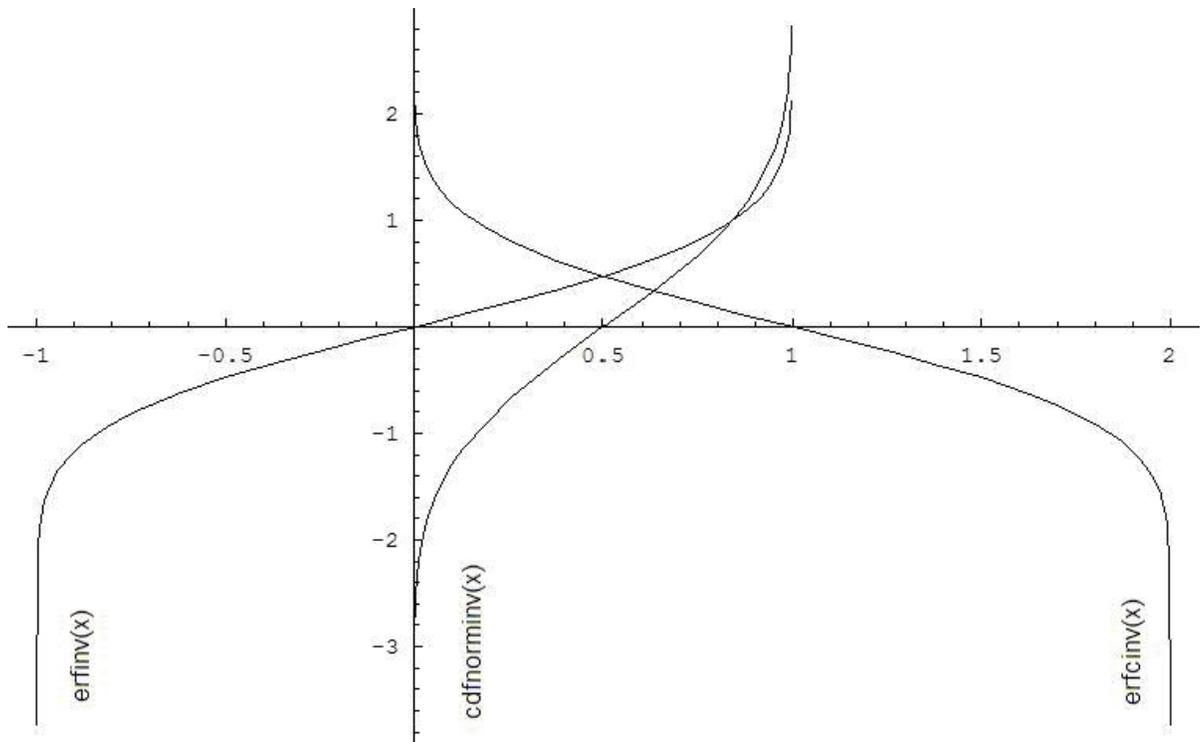

is the cumulative normal distribution function.

$$3. \Phi^{-1}(x) = \sqrt{2} \operatorname{erf}^{-1}(2x - 1),$$

where  $\Phi^{-1}(x)$  and  $\operatorname{erf}^{-1}(x)$  are the inverses to  $\Phi(x)$  and  $\operatorname{erf}(x)$  respectively.

Figure "ErfInv Family Functions Relationship" illustrates the relationships among ErfInv family functions (ErfInv, ErfcInv, CdfNormInv).

**ErfInv Family Functions Relationship**

Useful relations for these functions:

$$\operatorname{erfcinv}(x) = \operatorname{erfinv}(1 - x)$$

$$\operatorname{cdfnorminv}(x) = \sqrt{2}\operatorname{erfinv}(2x - 1) = \sqrt{2}\operatorname{erfcinv}(2 - 2x)$$

## Description

The `ErfcInv` function computes the inverse complimentary error function values for elements of the input vector *a* and writes them to the output vector *y*.

The inverse complementary error function is defined as given by:

$$\text{erfcinv}(x) = \text{erfinv}(1 - x)$$

$$\operatorname{erfinv}(x) = \operatorname{erf}^{-1}(x)$$

$$\operatorname{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

where  $\operatorname{erf}(x)$  denotes the error function and  $\operatorname{erfinv}(x)$  denotes the inverse error function.

See also [Figure "ErfInv Family Functions Relationship"](#) in `ErfInv` function description for `ErfcInv` function relationship with the other functions of `ErfInv` family.

### Special Values for Real Function `v?ErfcInv(x)`

## Output Parameters

| Name     | Type                                                                                        | Description                                                    |
|----------|---------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| <i>y</i> | float* for vsCdfNormInv,<br>vmsCdfNormInv<br><br>double* for vdCdfNormInv,<br>vmdCdfNormInv | Pointer to an array that contains the output vector <i>y</i> . |

## Description

The `CdfNormInv` function computes the inverse cumulative normal distribution function values for elements of the input vector *a* and writes them to the output vector *y*.

The inverse cumulative normal distribution function is defined as given by:

$$\text{CdfNormInv}(x) = \text{CdfNorm}^{-1}(x) ,$$

where `CdfNorm(x)` denotes the cumulative normal distribution function.

Useful relations:

$$\text{cdfnorminv}(x) = \sqrt{2}\text{erfinv}(2x - 1) = \sqrt{2}\text{erfcinv}(2 - 2x)$$

where `erfinv(x)` denotes the inverse error function and `erfcinv(x)` denotes the inverse complementary error functions.

See also [Figure "ErfInv Family Functions Relationship"](#) in `ErfInv` function description for `CdfNormInv` function relationship with the other functions of `ErfInv` family.

## Special Values for Real Function v?CdfNormInv(x)

| Argument  | Result    | VM Error Status   | Exception  |
|-----------|-----------|-------------------|------------|
| +0.5      | +0        |                   |            |
| +1        | $+\infty$ | VML_STATUS_SING   | ZERODIVIDE |
| -0        | $-\infty$ | VML_STATUS_SING   | ZERODIVIDE |
| +0        | $-\infty$ | VML_STATUS_SING   | ZERODIVIDE |
| $X < -0$  | QNAN      | VML_STATUS_ERRDOM | INVALID    |
| $X > +1$  | QNAN      | VML_STATUS_ERRDOM | INVALID    |
| $+\infty$ | QNAN      | VML_STATUS_ERRDOM | INVALID    |
| $-\infty$ | QNAN      | VML_STATUS_ERRDOM | INVALID    |

| Argument | Result | VM Error Status | Exception |
|----------|--------|-----------------|-----------|
| QNaN     | QNaN   |                 |           |
| SNAN     | QNaN   |                 | INVALID   |

## Output Parameters

| Name     | Type                                                                                                                                                  | Description                                                    |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| <i>y</i> | <code>float*</code> for <code>vsLGamma</code> , <code>vmsLGamma</code><br><br><code>double*</code> for <code>vdLGamma</code> , <code>vmdLGamma</code> | Pointer to an array that contains the output vector <i>y</i> . |

## Description

The `v?LGamma` function computes the natural logarithm of the absolute value of gamma function for elements of the input vector *a* and writes them to the output vector *y*. Precision overflow thresholds for the `v?LGamma` function are beyond the scope of this document. If the result does not meet the target precision, the function raises the `OVERFLOW` exception and sets the VM Error Status to `VML_STATUS_OVERFLOW`.

## Special Values for Real Function v?LGamma(x)

| Argument         | Result | VM Error Status     | Exception  |
|------------------|--------|---------------------|------------|
| +1               | +0     |                     |            |
| +2               | +0     |                     |            |
| +0               | +?     | VML_STATUS_SING     | ZERODIVIDE |
| -0               | +?     | VML_STATUS_SING     | ZERODIVIDE |

See <a href="#">vmlSetMode</a> for possible values and their description. |

### Output Parameters

| Name | Type                                                                     | Description                                               |
|------|--------------------------------------------------------------------------|-----------------------------------------------------------|
| $y$  | <code>float*</code> for <code>vsExpInt1</code> , <code>vmsExpInt1</code> | Pointer to an array that contains the output vector $y$ . |

| Name | Type | Description |
|------|------|-------------|
|------|------|-------------|

double\* for vdExpInt1, vmdExpInt1

## Description

The v?ExpInt1 function computes the exponential integral  $E_1$  of vector elements.

For positive real values  $x$ , this can be written as:

$$E_1(x) = \int_x^\infty \frac{e^{-t}}{t} dt = \int_1^\infty \frac{e^{-xt}}{t} dt.$$

For negative real values  $x$ , the result is defined as NAN.

### Special Values for Real Function v?ExpInt1(x)

| Argument  | Result    | VM Error Status   | Exception  |
|-----------|-----------|-------------------|------------|
| $x < +0$  | QNAN      | VML_STATUS_ERRDOM | INVALID    |
| +0        | $+\infty$ | VML_STATUS_SING   | ZERODIVIDE |
| -0        | $+\infty$ | VML_STATUS_SING   | ZERODIVIDE |
| $+\infty$ | +0        |                   |            |
| $-\infty$ | QNAN      | VML_STATUS_ERRDOM | INVALID    |
| QNAN      | QNAN      |                   |            |
| SNAN      | QNAN      |                   | INVALID    |

## Rounding Functions

### v?Floor

Computes an integer value rounded towards minus infinity for each vector element.

### Syntax

```
vsFloor(n, a, y);
vmsFloor(n, a, y, mode);
vdFloor(n, a, y);
vmdFloor(n, a, y, mode);
```

### Include Files

- mkl.h

### Input Parameters

| Name | Type                                                                                | Description                                              |

| <i>a</i>    | const float* for vsCeil, vmsCeil<br>const double* for vdCeil, vmdCeil | Pointer to an array that contains the input vector <i>a</i> .                                                                      |
| <i>mode</i> | const MKL_INT64                                                       | Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description. |

## Output Parameters

| Name     | Type                                                      | Description                                                    |
|----------|-----------------------------------------------------------|----------------------------------------------------------------|
| <i>y</i> | float* for vsCeil, vmsCeil<br>double* for vdCeil, vmdCeil | Pointer to an array that contains the output vector <i>y</i> . |

## Description

The function computes an integer value rounded towards plus infinity for each vector element.

$$y_i = \lceil a_i \rceil$$

## Special Values for Real Function v?Ceil(x)

| Argument  | Result    | Exception |
|-----------|-----------|-----------|
| +0        | +0        |           |
| -0        | -0        |           |
| $+\infty$ | $+\infty$ |           |
| $-\infty$ | $-\infty$ |           |
| SNAN      | QNAN      | INVALID   |
| QNAN      | QNAN      |           |

## v?Trunc

Computes an integer value rounded towards zero for each vector element.

## Syntax

```
vsTrunc(n, a, y);
```

```
vmsTrunc(n, a, y, mode);
```

```
vdTrunc(n, a, y);
```

```
vmdTrunc(n, a, y, mode);
```

## Include Files

See <a href="#">vm1SetMode</a> for possible values and their description. |

## Output Parameters

| Name           | Type                                                                                                                                              | Description                                                          |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| <code>y</code> | <code>float*</code> for <code>vsRound</code> , <code>vmsRound</code><br><br><code>double*</code> for <code>vdRound</code> , <code>vmdRound</code> | Pointer to an array that contains the output vector <code>y</code> . |

## Description

The function computes a value rounded to the nearest integer for each vector element. Input elements that are halfway between two consecutive integers are always rounded away from zero regardless of the rounding mode.

### Special Values for Real Function `v?Round(x)`

| Argument | Result | Exception |
|----------|--------|-----------|
| +0       | +0     |           |

See <a href="#">vmlSetMode</a> for possible values and their description. |

## Output Parameters

| Name     | Type                                                                                                                                      | Description                                                    |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| <i>y</i> | <code>float*</code> for <code>vsRint</code> , <code>vmsRint</code><br><code>double*</code> for <code>vdRint</code> , <code>vmdRint</code> | Pointer to an array that contains the output vector <i>y</i> . |

## Description

The `v?Rint` function computes a rounded floating-point integer value using the current rounding mode for each vector element.

The rounding mode affects the results computed for inputs that fall between consecutive integers. For example:

- $f(0.5) = 0$ , for rounding modes set to round to nearest round toward zero or to minus infinity.
- $f(0.5) = 1$ , for rounding modes set to plus infinity.
- $f(-1.5) = -2$ , for rounding modes set to round to nearest or to minus infinity.
- $f(-1.5) = -1$ , for rounding modes set to round toward zero or to plus infinity.

## Special Values for Real Function `v?Rint(x)`

| Argument  | Result    | Exception |
|-----------|-----------|-----------|
| +0        | +0        |           |
| -0        | -0        |           |
| $+\infty$ | $+\infty$ |           |
| $-\infty$ | $-\infty$ |           |
| SNAN      | QNAN      | INVALID   |
| QNAN      | QNAN      |           |

## `v?Modf`

*Computes a truncated integer value and the remaining fraction part for each vector element.*

## Syntax

```
vsModf(n, a, y, z);
```

```
vmsModf(n, a, y, z, mode);
```

```
vdModf(n, a, y, z);
```

```
vmdModf(n, a, y, z, mode);
```

## Include Files

- mkl.h

## Input Parameters

| Name        | Type                                                                  | Description                                                                                                                        |
|-------------|-----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>    | const MKL_INT                                                         | Specifies the number of elements to be calculated.                                                                                 |
| <i>a</i>    | const float* for vsModf, vmsModf<br>const double* for vdModf, vmdModf | Pointer to an array that contains the input vector <i>a</i> .                                                                      |
| <i>mode</i> | const MKL_INT64                                                       | Overrides global VM mode setting for this function call. See <a href="#">vm1SetMode</a> for possible values and their description. |

## Output Parameters

| Name        | Type                                                      | Description                                                                 |
|-------------|-----------------------------------------------------------|-----------------------------------------------------------------------------|
| <i>y, z</i> | float* for vsModf, vmsModf<br>double* for vdModf, vmdModf | Pointer to an array that contains the output vector <i>y</i> and <i>z</i> . |

## Description

The function computes a truncated integer value and the remaining fraction part for each vector element.

$$a_i \geq 0, \begin{cases} y_i = \lfloor a_i \rfloor \\ z_i = a_i - \lfloor a_i \rfloor \end{cases}$$

$$a_i < 0, \begin{cases} y_i = \lceil a_i \rceil \\ z_i = a_i - \lceil a_i \rceil \end{cases}$$

## Special Values for Real Function v?Modf(x)

| Argument  | Result: <i>y</i> ( <i>i</i> ) | Result: <i>z</i> ( <i>i</i> ) | Exception |

## v?Frac

Computes a signed fractional part for each vector element.

## Syntax

```
vsFrac(n, a, y);
vmsFrac(n, a, y, mode);
vdFrac(n, a, y);
vmdFrac(n, a, y, mode);
```

## Include Files

- mkl.h

## Input Parameters

| Name        | Type                                                                  | Description                                                                                                                        |
|-------------|-----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>    | const MKL_INT                                                         | Specifies the number of elements to be calculated.                                                                                 |
| <i>a</i>    | const float* for vsFrac, vmsFrac<br>const double* for vdFrac, vmdFrac | Pointer to an array that contains the input vector <i>a</i> .                                                                      |
| <i>mode</i> | const MKL_INT64                                                       | Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description. |

## Output Parameters

| Name     | Type                                                      | Description                                                    |
|----------|-----------------------------------------------------------|----------------------------------------------------------------|
| <i>y</i> | float* for vsFrac, vmsFrac<br>double* for vdFrac, vmdFrac | Pointer to an array that contains the output vector <i>y</i> . |

## Description

The function computes a signed fractional part for each vector element.

$$y_i = \begin{cases} a_i - \lfloor a_i \rfloor, & a_i \geq 0 \\ a_i - \lceil a_i \rceil, & a_i < 0 \end{cases}$$

## Special Values for Real Function v?Frac(x)

| Argument  | Result | Exception |
|-----------|--------|-----------|
| +0        | +0     |           |
| -0        | -0     |           |
| $+\infty$ | +0     |           |
| $-\infty$ | -0     |           |
| SNAN      | QNAN   | INVALID   |
| QNAN      | QNAN   |           |

## VM Pack/Unpack Functions

This section describes VM functions that convert vectors with unit increment to and from vectors with positive increment indexing, vector indexing, and mask indexing (see Appendix B for details on vector indexing methods).

The table below lists available VM Pack/Unpack functions, together with data types and indexing methods associated with them.

### VM Pack/Unpack Functions

| Function Short Name   | Data Types                  | Indexing Methods | Description                                                 |
|-----------------------|-----------------------------|------------------|-------------------------------------------------------------|
| <code>v?Pack</code>   | <i>s, d, c,</i><br><i>z</i> | <i>I, V, M</i>   | Gathers elements of arrays, indexed by different methods.   |
| <code>v?Unpack</code> | <i>s, d, c,</i><br><i>z</i> | <i>I, V, M</i>   | Scatters vector elements to arrays with different indexing. |

Vector Arguments in VM

### v?Pack

*Copies elements of an array with specified indexing to a vector with unit increment.*

### Syntax

```
vsPackI(n, a, inca, y);
vsPackV(n, a, ia, y);
vsPackM(n, a, ma, y);
vdPackI(n, a, inca, y);
vdPackV(n, a, ia, y);
vdPackM(n, a, ma, y);
vcPackI(n, a, inca, y);
vcPackV(n, a, ia, y);
vcPackM(n, a, ma, y);
vzPackI(n, a, inca, y);
vzPackV(n, a, ia, y);
vzPackM(n, a, ma, y);
```

| <i>inca</i> | const MKL_INT for vsPackI,<br>vdPackI, vcPackI, vzPackI                                                                                                                 | Specifies the increment for the elements of <i>a</i> .                                                                                        |
| <i>ia</i>   | const int* for vsPackV, vdPackV,<br>vcPackV, vzPackV                                                                                                                    | Specifies the pointer to an array of size at least <i>n</i> that contains the index vector for the elements of <i>a</i> .                     |
| <i>ma</i>   | const int* for vsPackM, vdPackM,<br>vcPackM, vzPackM                                                                                                                    | Specifies the pointer to an array of size at least <i>n</i> that contains the mask vector for the elements of <i>a</i> .                      |

## Output Parameters

| Name     | Type                                                                                                                                                                                                             | Description                                                                              |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| <i>y</i> | float* for vsPackI, vsPackV,<br>vsPackM<br><br>double* for vdPackI, vdPackV,<br>vdPackM<br><br>const MKL_Complex8* for vcPackI,<br>vcPackV, vcPackM<br><br>const MKL_Complex16* for vzPackI,<br>vzPackV, vzPackM | Pointer to an array of size at least <i>n</i> that contains the output vector <i>y</i> . |

## v?Unpack

*Copies elements of a vector with unit increment to an array with specified indexing.*

### Syntax

```

vsUnpackI(n, a, y, incy);
vsUnpackV(n, a, y, iy);
vsUnpackM(n, a, y, my);
vdUnpackI(n, a, y, incy);
vdUnpackV(n, a, y, iy);
vdUnpackM(n, a, y, my);
vcUnpackI(n, a, y, incy);
vcUnpackV(n, a, y, iy);
vcUnpackM(n, a, y, my);
vzUnpackI(n, a, y, incy);

```

```
vzUnpackV(n, a, y, iy);
```

```
vzUnpackM(n, a, y, my);
```

## VM Service Functions

The VM Service functions enable you to set/get the accuracy mode and error code. These functions are available both in the Fortran and C interfaces. The table below lists available VM Service functions and their short description.

## VM Service Functions

| Function Short Name                | Description                                                                                      |
|------------------------------------|--------------------------------------------------------------------------------------------------|
| <code>vmlSetMode</code>            | Sets the VM mode                                                                                 |
| <code>vmlGetMode</code>            | Gets the VM mode                                                                                 |
| <code>MKLFreeTls</code>            | Frees allocated VM/VS thread local storage memory from within DllMain routine (Windows* OS only) |
| <code>vmlSetErrStatus</code>       | Sets the VM Error Status                                                                         |
| <code>vmlGetErrStatus</code>       | Gets the VM Error Status                                                                         |
| <code>vmlClearErrStatus</code>     | Clears the VM Error Status                                                                       |
| <code>vmlSetErrorCallBack</code>   | Sets the additional error handler callback function                                              |
| <code>vmlGetErrorCallBack</code>   | Gets the additional error handler callback function                                              |
| <code>vmlClearErrorCallBack</code> | Deletes the additional error handler callback function                                           |

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## vmlSetMode

Sets a new mode for VM functions according to the *mode* parameter and stores the previous VM mode to *oldmode*.

### Syntax

```
oldmode = vmlSetMode(mode);
```

### Include Files

- `mkl.h`

### Input Parameters

| Name        | Type                        | Description                      |
|-------------|-----------------------------|----------------------------------|
| <i>mode</i> | <code>const MKL_UINT</code> | Specifies the VM mode to be set. |

### Output Parameters

| Name           | Type                      | Description                   |
|----------------|---------------------------|-------------------------------|
| <i>oldmode</i> | <code>unsigned int</code> | Specifies the former VM mode. |

### Description

The `vmlSetMode` function sets a new mode for VM functions according to the *mode* parameter and stores the previous VM mode to *oldmode*. The mode change has a global effect on all the VM functions within a thread.

**NOTE**

You can override the global mode setting and change the mode for a given VM function call by using a respective `vm[s, d]<Func>` variant of the function.

The *mode* parameter is designed to control accuracy, handling of denormalized numbers, and error handling. Table "Values of the *mode* Parameter" lists values of the *mode* parameter. You can obtain all other possible values of the *mode* parameter from the *mode* parameter values by using bitwise OR ( | ) operation to combine one value for accuracy, one value for handling of denormalized numbers, and one value for error control options. The default value of the *mode* parameter is `VML_HA | VML_FTZDAZ_OFF | VML_ERRMODE_DEFAULT`.

The `VML_FTZDAZ_ON` mode is specifically designed to improve the performance of computations that involve denormalized numbers at the cost of reasonable accuracy loss. This mode changes the numeric behavior of the functions: denormalized input values are treated as zeros (`DAZ = denormals-are-zero`) and denormalized results are flushed to zero (`FTZ = flush-to-zero`). Accuracy loss may occur if input and/or output values are close to denormal range.

**Values of the *mode* Parameter**

| Value of <i>mode</i>                         | Description                                                                                                             |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>Accuracy Control</b>                      |                                                                                                                         |
| <code>VML_HA</code>                          | high accuracy versions of VM functions                                                                                  |
| <code>VML_LA</code>                          | low accuracy versions of VM functions                                                                                   |
| <code>VML_EP</code>                          | enhanced performance accuracy versions of VM functions                                                                  |
| <b>Denormalized Numbers Handling Control</b> |                                                                                                                         |
| <code>VML_FTZDAZ_ON</code>                   | Faster processing of denormalized inputs is enabled.                                                                    |
| <code>VML_FTZDAZ_OFF</code>                  | Faster processing of denormalized inputs is disabled.                                                                   |
| <b>Error Mode Control</b>                    |                                                                                                                         |
| <code>VML_ERRMODE_IGNORE</code>              | No action is set for computation errors.                                                                                |
| <code>VML_ERRMODE_ERRNO</code>               | On error, the <i>errno</i> variable is set.                                                                             |
| <code>VML_ERRMODE_STDERR</code>              | On error, the error text information is written to <i>stderr</i> .                                                      |
| <code>VML_ERRMODE_EXCEPT</code>              | On error, an exception is raised.                                                                                       |
| <code>VML_ERRMODE_CALLBACK</code>            | On error, an additional error handler function is called.                                                               |
| <code>VML_ERRMODE_DEFAULT</code>             | On error, the <i>errno</i> variable is set, an exception is raised, and an additional error handler function is called. |

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

**Examples**

The following example shows how to set low accuracy, fast processing for denormalized numbers and `stderr` error mode:

```
vmlSetMode(VML_LA);
vmlSetMode(VML_LA | VML_FTZDAZ_ON | VML_ERRMODE_STDERR);
```

## vmlGetMode

*Gets the VM mode.*

### Syntax

```
mod = vmlGetMode(void);
```

### Include Files

- mkl.h

### Output Parameters

| Name       | Type         | Description                                 |
|------------|--------------|---------------------------------------------|
| <i>mod</i> | unsigned int | Specifies the packed <i>mode</i> parameter. |

### Description

The function `vmlGetMode` returns the VM *mode* parameter that controls accuracy, handling of denormalized numbers, and error handling options. The *mod* variable value is a combination of the values listed in the table "Values of the *mode* Parameter". You can obtain these values using the respective mask from the table "Values of Mask for the *mode* Parameter".

#### Values of Mask for the *mode* Parameter

| Value of mask     | Description                                        |
|-------------------|----------------------------------------------------|
| VML_ACCURACY_MASK | Specifies mask for accuracy <i>mode</i> selection. |
| VML_FTZDAZ_MASK   | Specifies mask for FTZDAZ <i>mode</i> selection.   |
| VML_ERRMODE_MASK  | Specifies mask for error <i>mode</i> selection.    |

See example below:

### Examples

```
accm = vmlGetMode(void) & VML_ACCURACY_MASK;
denm = vmlGetMode(void) & VML_FTZDAZ_MASK;
errm = vmlGetMode(void) & VML_ERRMODE_MASK;
```

## MKLFreeTls

*Frees allocated VM/VS thread local storage memory from within DllMain routine. Use on Windows\* OS only.*

### Syntax

```
void MKLFreeTls(const MKL_UINT fdwReason);
```

### Include Files

- mkl\_vml\_functions\_win.h

## Description

The `MKLFreeTls` routine frees thread local storage (TLS) memory which has been allocated when using MKL static libraries to link into a DLL on the Windows\* OS. The routine should only be used within `DllMain`.

### NOTE

It is only necessary to use `MKLFreeTls` for TLS data in the VM and VS domains.

## Input Parameters

| Name                   | Type                        | Description                                     |
|------------------------|-----------------------------|-------------------------------------------------|
| <code>fdwReason</code> | <code>const MKL_UINT</code> | Reason code from the <code>DllMain</code> call. |

## Example

```
BOOL WINAPI DllMain(HINSTANCE hInst, DWORD fdwReason, LPVOID lpvReserved)
{
 /*customer code*/
 MKLFreeTls(fdwReason);
 /*customer code*/
}
```

## vmlSetErrStatus

Sets the new VM Error Status according to `err` and stores the previous VM Error Status to `olderr`.

## Syntax

```
olderr = vmlSetErrStatus(status);
```

## Include Files

- `mk1.h`

## Input Parameters

| Name                | Type                       | Description                              |
|---------------------|----------------------------|------------------------------------------|
| <code>status</code> | <code>const MKL_INT</code> | Specifies the VM error status to be set. |

## Output Parameters

| Name                | Type             | Description                           |
|---------------------|------------------|---------------------------------------|
| <code>olderr</code> | <code>int</code> | Specifies the former VM error status. |

## Description

Table "Values of the VM Status" lists possible values of the `err` parameter.

## Values of the VM Status

| Status                      | Description                               |
|-----------------------------|-------------------------------------------|
| <b>Successful Execution</b> |                                           |
| <code>VML_STATUS_OK</code>  | The execution was completed successfully. |

| Status                     | Description                                                                                                    |
|----------------------------|----------------------------------------------------------------------------------------------------------------|
| <b>Warnings</b>            |                                                                                                                |
| VML_STATUS_ACCURACYWARNING | The execution was completed successfully in a different accuracy mode.                                         |
| <b>Errors</b>              |                                                                                                                |
| VML_STATUS_BADSIZE         | The function does not support the preset accuracy mode. The Low Accuracy mode is used instead.                 |
| VML_STATUS_BADMEM          | NULL pointer is passed.                                                                                        |
| VML_STATUS_ERRDOM          | At least one of array values is out of a range of definition.                                                  |
| VML_STATUS_SING            | At least one of the input array values causes a divide-by-zero exception or produces an invalid (QNaN) result. |
| VML_STATUS_OVERFLOW        | An overflow has happened during the calculation process.                                                       |
| VML_STATUS_UNDERFLOW       | An underflow has happened during the calculation process.                                                      |

## Examples

```
olderr = vmlSetErrStatus(VML_STATUS_OK);
```

```
olderr = vmlSetErrStatus(VML_STATUS_ERRDOM);
```

```
olderr = vmlSetErrStatus(VML_STATUS_UNDERFLOW);
```

## vmlGetErrStatus

*Gets the VM Error Status.*

### Syntax

```
err = vmlGetErrStatus(void);
```

### Include Files

- mkl.h

### Output Parameters

| Name | Type | Description                    |
|------|------|--------------------------------|
| err  | int  | Specifies the VM error status. |

## vmlClearErrStatus

*Sets the VM Error Status to VML\_STATUS\_OK and stores the previous VM Error Status to olderr.*

### Syntax

```
olderr = vmlClearErrStatus(void);
```

### Include Files

- mkl.h

## Output Parameters

| Name                | Type             | Description                           |
|---------------------|------------------|---------------------------------------|
| <code>olderr</code> | <code>int</code> | Specifies the former VM error status. |

## `vmlSetErrorCallback`

*Sets the additional error handler callback function and gets the old callback function.*

---

### Syntax

```
oldcallback = vmlSetErrorCallBack(callback);
```

### Include Files

- `mk1.h`

## Input Parameters

| Name                  | Description                       |
|-----------------------|-----------------------------------|
| <code>callback</code> | Pointer to the callback function. |

The callback function has the following format:

```
static int __stdcall
MyHandler(DefVmlErrorContext*
pContext)
{
 /* Handler body */
};
```

**Name****Description**

The passed error structure is defined as follows:

```
typedef struct _DefVmlErrorContext
{
 int iCode; /* Error status value */
 int iIndex; /* Index for bad array
 element, or bad array
 dimension, or bad
 array pointer */
 double dbA1; /* Error argument 1 */
 double dbA2; /* Error argument 2 */
 double dbR1; /* Error result 1 */
 double dbR2; /* Error result 2 */
 char cFuncName[64]; /* Function name */
 int iFuncNameLen; /* Length of
 functionname*/
 double dbA1Im; /* Error argument 1, imag
 part*/
 double dbA2Im; /* Error argument 2, imag
 part*/
 double dbR1Im; /* Error result 1, imag
 part*/
 double dbR2Im; /* Error result 2, imag
 part*/
} DefVmlErrorContext;
```

**Output Parameters****Name****Type****Description**

`oldcallback`    `int`

Pointer to the former callback function.

**Description**

The callback function is called on each VM mathematical function error if `VML_ERRMODE_CALLBACK` error mode is set (see "Values of the *mode* Parameter").

Use the `vmlSetErrorCallBack()` function if you need to define your own callback function instead of default empty callback function.

The input structure for a callback function contains the following information about the error encountered:

- the input value that caused an error
- location (array index) of this value
- the computed result value
- error code

- name of the function in which the error occurred.

You can insert your own error processing into the callback function. This may include correcting the passed result values in order to pass them back and resume computation. The standard error handler is called after the callback function only if it returns 0.

## **vmlGetErrorCallBack**

*Gets the additional error handler callback function.*

---

### **Syntax**

```
callback = vmlGetErrorCallBack(void);
```

### **Include Files**

- mkl.h

### **Output Parameters**

| <b>Name</b>     | <b>Description</b>               |
|-----------------|----------------------------------|
| <i>callback</i> | Pointer to the callback function |

## **vmlClearErrorCallBack**

*Deletes the additional error handler callback function and retrieves the former callback function.*

---

### **Syntax**

```
oldcallback = vmlClearErrorCallBack(void);
```

### **Include Files**

- mkl.h

### **Output Parameters**

| <b>Name</b>        | <b>Type</b> | <b>Description</b>                      |
|--------------------|-------------|-----------------------------------------|
| <i>oldcallback</i> | int         | Pointer to the former callback function |

# Statistical Functions

Statistical functions in Intel® MKL are known as the Vector Statistics (VS). They are designed for the purpose of

- generating vectors of pseudorandom, quasi-random, and non-deterministic random numbers
- performing mathematical operations of convolution and correlation
- computing basic statistical estimates for single and double precision multi-dimensional datasets

The corresponding functionality is described in the respective [Random Number Generators](#), [Convolution and Correlation](#), and [Summary Statistics](#) sections.

See VS performance data in the online VS Performance Data document available at <http://software.intel.com/en-us/articles/intel-math-kernel-library-documentation/>

The basic notion in VS is a task. The task object is a data structure or descriptor that holds the parameters related to a specific statistical operation: random number generation, convolution and correlation, or summary statistics estimation. Such parameters can be an identifier of a random number generator, its internal state and parameters, data arrays, their shape and dimensions, an identifier of the operation and so forth. You can modify the VS task parameters using the VS service functions.

## Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## Random Number Generators

Intel MKL VS provides a set of routines implementing commonly used pseudorandom, quasi-random, or non-deterministic random number generators with continuous and discrete distribution. To improve performance, all these routines were developed using the calls to the highly optimized *Basic Random Number Generators* (BRNGs) and vector mathematical functions (VM, see [Chapter 9, "Vector Mathematical Functions"](#)).

VS provides interfaces both for Fortran and C languages. For users of the C and C++ languages the `mk1_vs1.h` header file is provided. All header files are found in the following directory:

```
{MKL}/include
```

All VS routines can be classified into three major categories:

- Transformation routines for different types of statistical distributions, for example, uniform, normal (Gaussian), binomial, etc. These routines indirectly call basic random number generators, which are pseudorandom, quasi-random, or non-deterministic random number generators. Detailed description of the generators can be found in [Distribution Generators](#) section.
- Service routines to handle random number streams: create, initialize, delete, copy, save to a binary file, load from a binary file, get the index of a basic generator. The description of these routines can be found in [Service Routines](#) section.
- Registration routines for basic pseudorandom generators and routines that obtain properties of the registered generators (see [Advanced Service Routines](#) section).

The last two categories are referred to as service routines.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

**Random Number Generators Conventions**

This document makes no specific differentiation between random, pseudorandom, and quasi-random numbers, nor between random, pseudorandom, and quasi-random number generators unless the context requires otherwise. For details, refer to the 'Random Numbers' section in [VS Notes](#) document provided at the Intel® MKL web page.

All generators of nonuniform distributions, both discrete and continuous, are built on the basis of the uniform distribution generators, called Basic Random Number Generators (BRNGs). The pseudorandom numbers with nonuniform distribution are obtained through an appropriate transformation of the uniformly distributed pseudorandom numbers. Such transformations are referred to as *generation methods*. For a given distribution, several generation methods can be used. See [VS Notes](#) for the description of methods available for each generator.

An RNG task determines environment in which random number generation is performed, in particular parameters of the BRNG and its internal state. Output of VS generators is a stream of random numbers that are used in Monte Carlo simulations. A *random stream descriptor* and a *random stream* are used as synonyms of an *RNG task* in the document unless the context requires otherwise.

The *random stream descriptor* specifies which BRNG should be used in a given transformation method. See the *Random Streams and RNGs in Parallel Computation* section of [VS Notes](#).

The term *computational node* means a logical or physical unit that can process data in parallel.

**Random Number Generators Mathematical Notation**

The following notation is used throughout the text:

- $N$  The set of natural numbers  $N = \{1, 2, 3 \dots\}$ .
- $Z$  The set of integers  $Z = \{\dots -3, -2, -1, 0, 1, 2, 3 \dots\}$ .
- $R$  The set of real numbers.
- $\lfloor a \rfloor$  The floor of  $a$  (the largest integer less than or equal to  $a$ ).
- $\oplus$  or **xor** Bitwise exclusive OR.
- $C_{\alpha}^k$  or  $\binom{\alpha}{k}$  Binomial coefficient or combination ( $\alpha \in R, \alpha \geq 0; k \in \mathbb{N} \cup \{0\}$ ).
- $C_{\alpha}^0 = 1$
- For  $\alpha \geq k$  binomial coefficient is defined as

$$C_{\alpha}^{\kappa} = \frac{\alpha(\alpha - 1) \dots (\alpha - \kappa + 1)}{\kappa!}$$

If  $\alpha < \kappa$ , then

$$C_{\alpha}^{\kappa} = 0$$

$\Phi(x)$

Cumulative Gaussian distribution function

$$\Phi(x) = \int_{-\infty}^x \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{y^2}{2}\right) dy$$

defined over  $-\infty < x < +\infty$ .

$\Phi(-\infty) = 0$ ,  $\Phi(+\infty) = 1$ .

$\Gamma(\alpha)$

The complete gamma function

$$\Gamma(\alpha) = \int_0^{\infty} t^{\alpha-1} e^{-t} dt$$

where  $\alpha > 0$ .

$B(p, q)$

The complete beta function

$$B(p, q) = \int_0^1 t^{p-1} (1-t)^{q-1} dt$$

where  $p > 0$  and  $q > 0$ .

LCG( $a, c, m$ )

Linear Congruential Generator  $x_{n+1} = (ax_n + c) \bmod m$ , where  $a$  is called the *multiplier*,  $c$  is called the *increment*, and  $m$  is called the *modulus* of the generator.

MCG( $a, m$ )

Multiplicative Congruential Generator  $x_{n+1} = (ax_n) \bmod m$  is a special case of Linear Congruential Generator, where the increment  $c$  is taken to be 0.

GFSR( $p, q$ )

Generalized Feedback Shift Register Generator

$$x_n = x_{n-p} \oplus x_{n-q}$$

### Random Number Generators Naming Conventions

The names of the routines, types, and constants in VS random number generators are case-sensitive and can contain lowercase and uppercase characters (`viRngUniform`).

The names of generator routines have the following structure:

```
v<type of result>Rng<distribution>
```

where

- *v* is the prefix of a VS vector function.
- *<type of result>* is either *s*, *d*, or *i* and specifies one of the following types:

|          |        |
|----------|--------|
| <i>s</i> | float  |
| <i>d</i> | double |
| <i>i</i> | int    |

Prefixes *s* and *d* apply to continuous distributions only, prefix *i* applies only to discrete case.

- *rng* indicates that the routine is a random generator.
- *<distribution>* specifies the type of statistical distribution.

Names of service routines follow the template below:

```
vsl<name>
```

where

- *vsl* is the prefix of a VS service function.
- *<name>* contains a short function name.

For a more detailed description of service routines, refer to [Service Routines](#) and [Advanced Service Routines](#) sections.

The prototype of each generator routine corresponding to a given probability distribution fits the following structure:

```
status = <function name>(method, stream, n, r, [<distribution parameters>])
```

where

- *method* defines the method of generation. A detailed description of this parameter can be found in table "[Values of <method> in method parameter](#)". See the next page, where the structure of the *method* parameter name is explained.
- *stream* defines the descriptor of the random stream and must have a non-zero value. Random streams, descriptors, and their usage are discussed further in [Random Streams](#) and [Service Routines](#).
- *n* defines the number of random values to be generated. If *n* is less than or equal to zero, no values are generated. Furthermore, if *n* is negative, an error condition is set.
- *r* defines the destination array for the generated numbers. The dimension of the array must be large enough to store at least *n* random numbers.
- *status* defines the error status of a VS routine. See [Error Reporting](#) section for a detailed description of error status values.

Additional parameters included into *<distribution parameters>* field are individual for each generator routine and are described in detail in [Distribution Generators](#) section.

To invoke a distribution generator, use a call to the respective VS routine. For example, to obtain a vector *r*, composed of *n* independent and identically distributed random numbers with normal (Gaussian) distribution, that have the mean value *a* and standard deviation *sigma*, write the following:

```
status = vsRngGaussian(method, stream, n, r, a, sigma)
```

The name of a *method* parameter has the following structure:

```
VSL_RNG_METHOD_method<distribution>_<method>
```

```
VSL_RNG_METHOD_<distribution>_<method>_ACCURATE
```

where

- `<distribution>` is the probability distribution.
- `<method>` is the method name.

Type of the name structure for the `method` parameter corresponds to fast and accurate modes of random number generation (see "Distribution Generators" section and VS Notes for details).

Method names `VSL_RNG_METHOD_<distribution>_<method>`

and

`VSL_RNG_METHOD_<distribution>_<method>_ACCURATE`

should be used with

`v<precision>Rng<distribution>`

function only, where

- `<precision>` is
  - `s` for single precision continuous distribution
  - `d` for double precision continuous distribution
  - `i` for discrete distribution
- `<distribution>` is the probability distribution.

is the probability distribution. Table "Values of `<method>` in `method` parameter" provides specific predefined values of the `method` name. The third column contains names of the functions that use the given method.

**Values of `<method>` in `method` parameter**

| Method     | Short Description                                                                                                                                                                                                                                         | Functions                                                                           |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| STD        | Standard method. Currently there is only one method for these functions.                                                                                                                                                                                  | Uniform (continuous), Uniform (discrete), UniformBits, UniformBits32, UniformBits64 |
| BOXMULLER  | BOXMULLER generates normally distributed random number $x$ thru the pair of uniformly distributed numbers $u_1$ and $u_2$ according to the formula:<br><br>$x = \sqrt{-2 \ln u_1} \sin 2\pi u_2$                                                          | Gaussian, GaussianMV                                                                |
| BOXMULLER2 | BOXMULLER2 generates normally distributed random numbers $x_1$ and $x_2$ thru the pair of uniformly distributed numbers $u_1$ and $u_2$ according to the formulas:<br><br>$x_1 = \sqrt{-2 \ln u_1} \sin 2\pi u_2$ $x_2 = \sqrt{-2 \ln u_1} \cos 2\pi u_2$ | Gaussian, GaussianMV, Lognormal                                                     |
| ICDF       | Inverse cumulative distribution function method.                                                                                                                                                                                                          | Exponential, Laplace, Weibull, Cauchy, Rayleigh,                                    |

| Method   | Short Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Functions                                                                    |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------|
|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Gumbel,<br>Bernoulli,<br>Geometric,<br>Gaussian,<br>GaussianMV,<br>Lognormal |
| GNORM    | For $\alpha > 1$ , a gamma distributed random number is generated as a cube of properly scaled normal random number; for $0.6 \leq \alpha < 1$ , a gamma distributed random number is generated using rejection from Weibull distribution; for $\alpha < 0.6$ , a gamma distributed random number is obtained using transformation of exponential power distribution; for $\alpha = 1$ , gamma distribution is reduced to exponential distribution.                                                                                                                                | Gamma                                                                        |
| CJA      | For $\min(p, q) > 1$ , Cheng method is used; for $\min(p, q) < 1$ , Johnk method is used, if $q + K \cdot p^2 + C \leq 0$ ( $K = 0.852\dots$ , $C = -0.956\dots$ ) otherwise, Atkinson switching algorithm is used; for $\max(p, q) < 1$ , method of Johnk is used; for $\min(p, q) < 1$ , $\max(p, q) > 1$ , Atkinson switching algorithm is used (CJA stands for the first letters of Cheng, Johnk, Atkinson); for $p = 1$ or $q = 1$ , inverse cumulative distribution function method is used; for $p = 1$ and $q = 1$ , beta distribution is reduced to uniform distribution. | Beta                                                                         |
| BTPE     | Acceptance/rejection method for $n \cdot \min(p, 1 - p) \geq 30$ with decomposition into 4 regions: <ul style="list-style-type: none"> <li>- 2 parallelograms</li> <li>- triangle</li> <li>- left exponential tail</li> <li>- right exponential tail</li> </ul>                                                                                                                                                                                                                                                                                                                    | Binomial                                                                     |

**NOTE**

In this document, routines are often referred to by their base name (`Gaussian`) when this does not lead to ambiguity. In the routine reference, the full name (`vsrnggaussian`, `vsRngGaussian`) is always used in prototypes and code examples.

## Basic Generators

VS provides pseudorandom, quasi-random, and non-deterministic random number generators. This includes the following BRNGs, which differ in speed and other properties:

- the 31-bit multiplicative congruential pseudorandom number generator `MCG(1132489760, 231 - 1)` [[L'Ecuyer99](#)]
- the 32-bit generalized feedback shift register pseudorandom number generator `GFSR(250, 103)` [[Kirkpatrick81](#)]
- the combined multiple recursive pseudorandom number generator `MRG32k3a` [[L'Ecuyer99a](#)]
- the 59-bit multiplicative congruential pseudorandom number generator `MCG(1313, 259)` from NAG Numerical Libraries [[NAG](#)]
- Wichmann-Hill pseudorandom number generator (a set of 273 basic generators) from NAG Numerical Libraries [[NAG](#)]
- Mersenne Twister pseudorandom number generator `MT19937` [[Matsumoto98](#)] with period length 2<sup>19937</sup>-1 of the produced sequence
- Set of 6024 Mersenne Twister pseudorandom number generators `MT2203` [[Matsumoto98](#)], [[Matsumoto00](#)]. Each of them generates a sequence of period length equal to 2<sup>2203</sup>-1. Parameters of the generators provide mutual independence of the corresponding sequences.
- SIMD-oriented Fast Mersenne Twister pseudorandom number generator `SFMT19937` [[Saito08](#)] with a period length equal to 2<sup>19937</sup>-1 of the produced sequence.
- Sobol quasi-random number generator [[Sobol76](#)], [[Bratley88](#)], which works in arbitrary dimension. For dimensions greater than 40 the user should supply initialization parameters (initial direction numbers and primitive polynomials or direction numbers) by using `vs1NewStreamEx` function. See additional details on interface for registration of the parameters in the library in [VS Notes](#).
- Niederreiter quasi-random number generator [[Bratley92](#)], which works in arbitrary dimension. For dimensions greater than 318 the user should supply initialization parameters (irreducible polynomials or direction numbers) by using `vs1NewStreamEx` function. See additional details on interface for registration of the parameters in the library in [VS Notes](#).
- Non-deterministic random number generator (RDRAND-based generators only) [[AVX](#)], [[IntelSWMan](#)].

**NOTE**

You can use a non-deterministic random number generator only if the underlying hardware supports it. For instructions on how to detect if an Intel CPU supports a non-deterministic random number generator see, for example, *Chapter 8: Post-32nm Processor Instructions* in [AVX] or *Chapter 4: RdRand Instruction Usage* in [BMT].

**NOTE**

The time required by some non-deterministic sources to generate a random number is not constant, so you might have to make multiple requests before the next random number is available. VS limits the number of retries for requests to the non-deterministic source to 10. You can redefine the maximum number of retries during the initialization of the non-deterministic random number generator with the `vslNewStreamEx` function.

For more details on the non-deterministic source implementation for Intel CPUs please refer to Section 7.3.17, Volume 1, *Random Number Generator Instruction* in [IntelSWMAn] and Section 4.2.2, *RdRand Retry Loop* in [BMT].

- Philox4x32-10 counter-based pseudorandom number generator with a period of  $2^{128}$  `PHILOX4X32X10` [Salmon11].
- ARS-5 counter-based pseudorandom number generator with a period of  $2^{128}$ , which uses instructions from the AES-NI set `ARS5` [Salmon11].

See some testing results for the generators in [VS Notes](#) and comparative performance data at <https://software.intel.com/en-us/articles/intel-math-kernel-library-documentation>.

VS provides means of registration of such user-designed generators through the steps described in [Advanced Service Routines](#) section.

For some basic generators, VS provides two methods of creating independent random streams in multiprocessor computations, which are the leapfrog method and the block-splitting method. These sequence splitting methods are also useful in sequential Monte Carlo.

In addition, MT2203 pseudorandom number generator is a set of 6024 generators designed to create up to 6024 independent random sequences, which might be used in parallel Monte Carlo simulations. Another generator that has the same feature is Wichmann-Hill. It allows creating up to 273 independent random streams. The properties of the generators designed for parallel computations are discussed in detail in [Coddington94].

You may want to design and use your own basic generators. VS provides means of registration of such user-designed generators through the steps described in [Advanced Service Routines](#) section.

There is also an option to utilize externally generated random numbers in VS distribution generator routines. For this purpose VS provides three additional basic random number generators:

- for external random data packed in 32-bit integer array
- for external random data stored in double precision floating-point array; data is supposed to be uniformly distributed over  $(a,b)$  interval
- for external random data stored in single precision floating-point array; data is supposed to be uniformly distributed over  $(a,b)$  interval.

Such basic generators are called the abstract basic random number generators.

See [VS Notes](#) for a more detailed description of the generator properties.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain

**Optimization Notice**

optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

**BRNG Parameter Definition**

Predefined values for the *brng* input parameter are as follows:

**Values of *brng* parameter**

| Value                  | Short Description                                                                                                                                       |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| VSL_BRNG_MCG31         | A 31-bit multiplicative congruential generator.                                                                                                         |
| VSL_BRNG_R250          | A generalized feedback shift register generator.                                                                                                        |
| VSL_BRNG_MRG32K3A      | A combined multiple recursive generator with two components of order 3.                                                                                 |
| VSL_BRNG_MCG59         | A 59-bit multiplicative congruential generator.                                                                                                         |
| VSL_BRNG_WH            | A set of 273 Wichmann-Hill combined multiplicative congruential generators.                                                                             |
| VSL_BRNG_MT19937       | A Mersenne Twister pseudorandom number generator.                                                                                                       |
| VSL_BRNG_MT2203        | A set of 6024 Mersenne Twister pseudorandom number generators.                                                                                          |
| VSL_BRNG_SFMT19937     | A SIMD-oriented Fast Mersenne Twister pseudorandom number generator.                                                                                    |
| VSL_BRNG_SOBOL         | A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \leq s \leq 40$ ; user-defined dimensions are also available.  |
| VSL_BRNG_NIEDERR       | A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \leq s \leq 318$ ; user-defined dimensions are also available. |
| VSL_BRNG_IABSTRACT     | An abstract random number generator for integer arrays.                                                                                                 |
| VSL_BRNG_DABSTRACT     | An abstract random number generator for double precision floating-point arrays.                                                                         |
| VSL_BRNG_SABSTRACT     | An abstract random number generator for single precision floating-point arrays.                                                                         |
| VSL_BRNG_NONDETERM     | A non-deterministic random number generator.                                                                                                            |
| VSL_BRNG_PHILOX4X32X10 | A Philox4x32-10 counter-based pseudorandom number generator.                                                                                            |
| VSL_BRNG_ARS5          | An ARS-5 counter-based pseudorandom number generator that uses instructions from the AES-NI set.                                                        |

See [VS Notes](#) for detailed description.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

**Random Streams**

*Random stream* (or *stream*) is an abstract source of pseudo- and quasi-random sequences of uniform distribution. You can operate with stream state descriptors only. A stream state descriptor, which holds state descriptive information for a particular BRNG, is a necessary parameter in each routine of a distribution generator. Only the distribution generator routines operate with random streams directly. See [VS Notes](#) for details.

**NOTE**

Random streams associated with abstract basic random number generator are called the abstract random streams. See [VS Notes](#) for detailed description of abstract streams and their use.

You can create unlimited number of random streams by [VS Service Routines](#) like [NewStream](#) and utilize them in any distribution generator to get the sequence of numbers of given probability distribution. When they are no longer needed, the streams should be deleted calling service routine [DeleteStream](#).

VS provides service functions [SaveStreamF](#) and [LoadStreamF](#) to save random stream descriptive data to a binary file and to read this data from a binary file respectively. See [VS Notes](#) for detailed description.

**BRNG Data Types**

```
typedef(void*) VSLStreamStatePtr;
```

See [Advanced Service Routines](#) for the format of the stream state structure for user-designed generators.

**Error Reporting**

VS RNG routines return status codes of the performed operation to report errors to the calling program. The application should perform error-related actions and/or recover from the error. The status codes are of integer type and have the following format:

VSL\_ERROR\_<ERROR\_NAME> - indicates VS errors common for all VS domains.

VSL\_RNG\_ERROR\_<ERROR\_NAME> - indicates VS RNG errors.

VS RNG errors are of negative values while warnings are of positive values. The status code of zero value indicates successful completion of the operation: VSL\_ERROR\_OK (or synonymic VSL\_STATUS\_OK).

**Status Codes**

| Status Code                 | Description                        |
|-----------------------------|------------------------------------|
| <b>Common VSL</b>           |                                    |
| VSL_ERROR_OK, VSL_STATUS_OK | No error, execution is successful. |
| VSL_ERROR_BADARGS           | Input argument value is not valid. |

| <b>Status Code</b>                    | <b>Description</b>                                                                                                               |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| VSL_ERROR_CPU_NOT_SUPPORTED           | CPU version is not supported.                                                                                                    |
| VSL_ERROR_FEATURE_NOT_IMPLEMENTED     | Feature invoked is not implemented.                                                                                              |
| VSL_ERROR_MEM_FAILURE                 | System cannot allocate memory.                                                                                                   |
| VSL_ERROR_NULL_PTR                    | Input pointer argument is NULL.                                                                                                  |
| VSL_ERROR_UNKNOWN                     | Unknown error.                                                                                                                   |
| <b>VS RNG Specific</b>                |                                                                                                                                  |
| VSL_RNG_ERROR_BAD_FILE_FORMAT         | File format is unknown.                                                                                                          |
| VSL_RNG_ERROR_BAD_MEM_FORMAT          | Descriptive random stream format is unknown.                                                                                     |
| VSL_RNG_ERROR_BAD_NBITS               | The value in <code>NBits</code> field is bad.                                                                                    |
| VSL_RNG_ERROR_BAD_NSEEDS              | The value in <code>NSeeds</code> field is bad.                                                                                   |
| VSL_RNG_ERROR_BAD_STREAM              | The random stream is invalid.                                                                                                    |
| VSL_RNG_ERROR_BAD_STREAM_STATE_SIZE   | The value in <code>StreamStateSize</code> field is bad.                                                                          |
| VSL_RNG_ERROR_BAD_UPDATE              | Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, $< 0$ or $> n_{max}$ . |
| VSL_RNG_ERROR_BAD_WORD_SIZE           | The value in <code>WordSize</code> field is bad.                                                                                 |
| VSL_RNG_ERROR_BRNG_NOT_SUPPORTED      | BRNG is not supported by the function.                                                                                           |
| VSL_RNG_ERROR_BRNG_TABLE_FULL         | Registration cannot be completed due to lack of free entries in the table of registered BRNGs.                                   |
| VSL_RNG_ERROR_BRNGS_INCOMPATIBLE      | Two BRNGs are not compatible for the operation.                                                                                  |
| VSL_RNG_ERROR_FILE_CLOSE              | Error in closing the file.                                                                                                       |
| VSL_RNG_ERROR_FILE_OPEN               | Error in opening the file.                                                                                                       |
| VSL_RNG_ERROR_FILE_READ               | Error in reading the file.                                                                                                       |
| VSL_RNG_ERROR_FILE_WRITE              | Error in writing the file.                                                                                                       |
| VSL_RNG_ERROR_INVALID_ABSTRACT_STREAM | The abstract random stream is invalid.                                                                                           |
| VSL_RNG_ERROR_INVALID_BRNG_INDEX      | BRNG index is not valid.                                                                                                         |
| VSL_RNG_ERROR_LEAPFROG_UNSUPPORTED    | BRNG does not support Leapfrog method.                                                                                           |
| VSL_RNG_ERROR_NO_NUMBERS              | Callback function for an abstract BRNG returns zero as the number of updated entries in a buffer.                                |
| VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED     | Period of the generator is exceeded.                                                                                             |
| VSL_RNG_ERROR_SKIPAHEAD_UNSUPPORTED   | BRNG does not support Skip-Ahead method.                                                                                         |

| Status Code                               | Description                                                                                                                                                                                    |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VSL_RNG_ERROR_UNSUPPORTED_FILE_VER        | File format version is not supported.                                                                                                                                                          |
| VSL_RNG_ERROR_NONDETERM_NOT_SUPPORTED     | Non-deterministic random number generator is not supported on the CPU running the application.                                                                                                 |
| VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED | Number of retries to generate a random number using non-deterministic random number generator exceeds threshold (see Section 7.2.1.12 <i>Non-deterministic</i> in [VS Notes] for more details) |
| VSL_RNG_ERROR_ARS5_NOT_SUPPORTED          | ARS-5 random number generator is not supported on the CPU running the application.                                                                                                             |

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## VS RNG Usage Model

A typical algorithm for VS random number generators is as follows:

1. Create and initialize stream/streams. Functions `vslNewStream`, `vslNewStreamEx`, `vslCopyStream`, `vslCopyStreamState`, `vslLeapfrogStream`, `vslSkipAheadStream`.
2. Call one or more RNGs.
3. Process the output.
4. Delete the stream/streams. Function `vslDeleteStream`.

### NOTE

You may reiterate steps 2-3. Random number streams may be generated for different threads.

The following example demonstrates generation of a random stream that is output of basic generator MT19937. The seed is equal to 777. The stream is used to generate 10,000 normally distributed random numbers in blocks of 1,000 random numbers with parameters  $a = 5$  and  $\sigma = 2$ . Delete the streams after completing the generation. The purpose of the example is to calculate the sample mean for normal distribution with the given parameters.

### Example of VS RNG Usage

```
#include <stdio.h>
#include "mkl_vsl.h"

int main()
{
 double r[1000]; /* buffer for random numbers */
 double s; /* average */
 VSLStreamStatePtr stream;
 int i, j;
```

```

/* Initializing */
s = 0.0;
vslNewStream(&stream, VSL_BRNG_MT19937, 777);

/* Generating */
for (i=0; i<10; i++) {
 vdRngGaussian(VSL_RNG_METHOD_GAUSSIAN_ICDF, stream, 1000, r, 5.0, 2.0);
 for (j=0; j<1000; j++) {
 s += r[j];
 }
}
s /= 10000.0;

/* Deleting the stream */
vslDeleteStream(&stream);

/* Printing results */
printf("Sample mean of normal distribution = %f\n", s);

return 0;
}

```

Additionally, examples that demonstrate usage of VS random number generators are available in:

`$(MKL)/examples/vslc/source`

## Service Routines

Stream handling comprises routines for creating, deleting, or copying the streams and getting the index of a basic generator. A random stream can also be saved to and then read from a binary file. [Table "Service Routines"](#) lists all available service routines

### Service Routines

| Routine                            | Short Description                                                                             |
|------------------------------------|-----------------------------------------------------------------------------------------------|
| <code>vslNewStream</code>          | Creates and initializes a random stream.                                                      |
| <code>vslNewStreamEx</code>        | Creates and initializes a random stream for the generators with multiple initial conditions.  |
| <code>vслиNewAbstractStream</code> | Creates and initializes an abstract random stream for integer arrays.                         |
| <code>vslдNewAbstractStream</code> | Creates and initializes an abstract random stream for double precision floating-point arrays. |
| <code>vslsNewAbstractStream</code> | Creates and initializes an abstract random stream for single precision floating-point arrays. |
| <code>vslDeleteStream</code>       | Deletes previously created stream.                                                            |
| <code>vslCopyStream</code>         | Copies a stream to another stream.                                                            |
| <code>vslCopyStreamState</code>    | Creates a copy of a random stream state.                                                      |
| <code>vslSaveStreamF</code>        | Writes a stream to a binary file.                                                             |
| <code>vslLoadStreamF</code>        | Reads a stream from a binary file.                                                            |
| <code>vslSaveStreamM</code>        | Writes a random stream descriptive data, including state, to a memory buffer.                 |

| Routine                               | Short Description                                                                                 |
|---------------------------------------|---------------------------------------------------------------------------------------------------|
| <a href="#">vslLoadStreamM</a>        | Creates a new stream and reads stream descriptive data, including state, from the memory buffer.  |
| <a href="#">vslGetStreamSize</a>      | Computes size of memory necessary to hold the random stream.                                      |
| <a href="#">vslLeapfrogStream</a>     | Initializes the stream by the leapfrog method to generate a subsequence of the original sequence. |
| <a href="#">vslSkipAheadStream</a>    | Initializes the stream by the skip-ahead method.                                                  |
| <a href="#">vslGetStreamStateBrng</a> | Obtains the index of the basic generator responsible for the generation of a given random stream. |
| <a href="#">vslGetNumRegBrngs</a>     | Obtains the number of currently registered basic generators.                                      |

Most of the generator-based work comprises three basic steps:

1. Creating and initializing a stream ([vslNewStream](#), [vslNewStreamEx](#), [vslCopyStream](#), [vslCopyStreamState](#), [vslLeapfrogStream](#), [vslSkipAheadStream](#)).
2. Generating random numbers with given distribution, see [Distribution Generators](#).
3. Deleting the stream ([vslDeleteStream](#)).

Note that you can concurrently create multiple streams and obtain random data from one or several generators by using the stream state. You must use the [vslDeleteStream](#) function to delete all the streams afterwards.

## vslNewStream

*Creates and initializes a random stream.*

### Syntax

```
status = vslNewStream(&stream, brng, seed);
```

### Include Files

- `mk1.h`

### Input Parameters

| Name              | Type                        | Description                                                                                                                                                                                                                                                                       |
|-------------------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>brng</code> | <code>const MKL_INT</code>  | Index of the basic generator to initialize the stream. See <a href="#">Table Values of <code>brng</code> parameter</a> for specific value.                                                                                                                                        |
| <code>seed</code> | <code>const MKL_UINT</code> | Initial condition of the stream. In the case of a quasi-random number generator seed parameter is used to set the dimension. If the dimension is greater than the dimension that <code>brng</code> can support or is less than 1, then the dimension is assumed to be equal to 1. |

### Output Parameters

| Name                | Type                            | Description             |
|---------------------|---------------------------------|-------------------------|
| <code>stream</code> | <code>VSLStreamStatePtr*</code> | Stream state descriptor |

## Description

For a basic generator with number *brng*, this function creates a new stream and initializes it with a 32-bit seed. The seed is an initial value used to select a particular sequence generated by the basic generator *brng*. The function is also applicable for generators with multiple initial conditions. Use this function to create and initialize a new stream with a 32-bit seed only. If you need to provide multiple initial conditions such as several 32-bit or wider seeds, use the function [vslNewStreamEx](#). See [VS Notes](#) for a more detailed description of stream initialization for different basic generators.

### NOTE

This function is not applicable for abstract basic random number generators. Please use [vslNewAbstractStream](#), [vslsNewAbstractStream](#) or [vsldNewAbstractStream](#) to utilize integer, single-precision or double-precision external random data respectively.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## Return Values

|                                              |                                                                                    |
|----------------------------------------------|------------------------------------------------------------------------------------|
| VSL_ERROR_OK, VSL_STATUS_OK                  | Indicates no error, execution is successful.                                       |
| VSL_RNG_ERROR_INVALID_BRNG_INDEX             | BRNG index is invalid.                                                             |
| VSL_ERROR_MEM_FAILURE                        | System cannot allocate memory for <i>stream</i> .                                  |
| VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED | Non-deterministic random number generator is not supported.                        |
| VSL_RNG_ERROR_ARS5_NOT_SUPPORTED             | ARS-5 random number generator is not supported on the CPU running the application. |

## vslNewStreamEx

*Creates and initializes a random stream for generators with multiple initial conditions.*

### Syntax

```
status = vslNewStreamEx(&stream, brng, n, params);
```

### Include Files

- `mkl.h`

## Input Parameters

| Name          | Type               | Description                                                                                                                                                                                                                                                                                                                                                                       |
|---------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>brng</i>   | const MKL_INT      | Index of the basic generator to initialize the stream. See <a href="#">Table "Values of <i>brng</i> parameter"</a> for specific value.                                                                                                                                                                                                                                            |
| <i>n</i>      | const MKL_INT      | Number of initial conditions contained in <i>params</i>                                                                                                                                                                                                                                                                                                                           |
| <i>params</i> | const unsigned int | Array of initial conditions necessary for the basic generator <i>brng</i> to initialize the stream. In the case of a quasi-random number generator only the first element in <i>params</i> parameter is used to set the dimension. If the dimension is greater than the dimension that <i>brng</i> can support or is less than 1, then the dimension is assumed to be equal to 1. |

## Output Parameters

| Name          | Type               | Description             |
|---------------|--------------------|-------------------------|
| <i>stream</i> | VSLStreamStatePtr* | Stream state descriptor |

## Description

The `vslNewStreamEx` function provides an advanced tool to set the initial conditions for a basic generator if its input arguments imply several initialization parameters. Initial values are used to select a particular sequence generated by the basic generator *brng*. Whenever possible, use `vslNewStream`, which is analogous to `vslNewStreamEx` except that it takes only one 32-bit initial condition. In particular, `vslNewStreamEx` may be used to initialize the state table in Generalized Feedback Shift Register Generators (GFSRs). A more detailed description of this issue can be found in [VS Notes](#).

This function is also used to pass user-defined initialization parameters of quasi-random number generators into the library. See [VS Notes](#) for the format for their passing and registration in VS.

### NOTE

This function is not applicable for abstract basic random number generators. Please use `vslNewAbstractStream`, `vslsNewAbstractStream` or `vslldNewAbstractStream` to utilize integer, single-precision or double-precision external random data respectively.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## Return Values

`VSL_ERROR_OK`, `VSL_STATUS_OK` Indicates no error, execution is successful.

|                                              |                                                                                    |
|----------------------------------------------|------------------------------------------------------------------------------------|
| VSL_RNG_ERROR_INVALID_BRNG_INDEX             | BRNG index is invalid.                                                             |
| VSL_ERROR_MEM_FAILURE                        | System cannot allocate memory for <i>stream</i> .                                  |
| VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED | Non-deterministic random number generator is not supported.                        |
| VSL_RNG_ERROR_ARS5_NOT_SUPPORTED             | ARS-5 random number generator is not supported on the CPU running the application. |

### vsliNewAbstractStream

Creates and initializes an abstract random stream for integer arrays.

#### Syntax

```
status = vsliNewAbstractStream(&stream, n, ibuf, icallback);
```

#### Include Files

- mkl.h

#### Input Parameters

| Name             | Type               | Description                                                  |
|------------------|--------------------|--------------------------------------------------------------|
| <i>n</i>         | const MKL_INT      | Size of the array <i>ibuf</i>                                |
| <i>ibuf</i>      | const unsigned int | Array of <i>n</i> 32-bit integers                            |
| <i>icallback</i> |                    | Pointer to the callback function used for <i>ibuf</i> update |

#### NOTE

Format of the callback function:

```
int iUpdateFunc(VSLStreamStatePtrstream, int* n, unsigned int ibuf[], int* nmin, int* nmax, int* idx);
```

The callback function returns the number of elements in the array actually updated by the function. [Table \*icallback\* Callback Function Parameters](#) gives the description of the callback function parameters.

#### *icallback* Callback Function Parameters

| Parameters    | Short Description                                                        |
|---------------|--------------------------------------------------------------------------|
| <i>stream</i> | Abstract random stream descriptor                                        |
| <i>n</i>      | Size of <i>ibuf</i>                                                      |
| <i>ibuf</i>   | Array of random numbers associated with the stream <i>stream</i>         |
| <i>nmin</i>   | Minimal quantity of numbers to update                                    |
| <i>nmax</i>   | Maximal quantity of numbers that can be updated                          |
| <i>idx</i>    | Position in cyclic buffer <i>ibuf</i> to start update $0 \leq idx < n$ . |

## Output Parameters

| Name          | Type               | Description                              |
|---------------|--------------------|------------------------------------------|
| <i>stream</i> | VSLStreamStatePtr* | Descriptor of the stream state structure |

## Description

The `vslNewAbstractStream` function creates a new abstract stream and associates it with an integer array *ibuf* and your callback function *icallback* that is intended for updating of *ibuf* content.

## Return Values

|                             |                                                                 |
|-----------------------------|-----------------------------------------------------------------|
| VSL_ERROR_OK, VSL_STATUS_OK | Indicates no error, execution is successful.                    |
| VSL_ERROR_BADARGS           | Parameter <i>n</i> is not positive.                             |
| VSL_ERROR_MEM_FAILURE       | System cannot allocate memory for <i>stream</i> .               |
| VSL_ERROR_NULL_PTR          | Either buffer or callback function parameter is a NULL pointer. |

## vslNewAbstractStream

*Creates and initializes an abstract random stream for double precision floating-point arrays.*

## Syntax

```
status = vslNewAbstractStream(&stream, n, dbuf, a, b, dcallback);
```

## Include Files

- mkl.h

## Input Parameters

| Name             | Type                  | Description                                                                                                    |
|------------------|-----------------------|----------------------------------------------------------------------------------------------------------------|
| <i>n</i>         | const MKL_INT         | Size of the array <i>dbuf</i>                                                                                  |
| <i>dbuf</i>      | const double          | Array of <i>n</i> double precision floating-point random numbers with uniform distribution over interval (a,b) |
| <i>a</i>         | const double          | Left boundary a                                                                                                |
| <i>b</i>         | const double          | Right boundary b                                                                                               |
| <i>dcallback</i> | See <i>Note</i> below | Pointer to the callback function used for update of the array <i>dbuf</i>                                      |

## Output Parameters

| Name          | Type               | Description                              |
|---------------|--------------------|------------------------------------------|
| <i>stream</i> | VSLStreamStatePtr* | Descriptor of the stream state structure |

**NOTE**

Format of the callback function:

```
int dUpdateFunc(VSLStreamStatePtr stream, int* n, double dbuf[], int* nmin, int* nmax, int*
idx);
```

The callback function returns the number of elements in the array actually updated by the function. [Table dcallback Callback Function Parameters](#) gives the description of the callback function parameters.

**dcallback Callback Function Parameters**

| Parameters    | Short Description                                                        |
|---------------|--------------------------------------------------------------------------|
| <i>stream</i> | Abstract random stream descriptor                                        |
| <i>n</i>      | Size of <i>dbuf</i>                                                      |
| <i>dbuf</i>   | Array of random numbers associated with the stream <i>stream</i>         |
| <i>nmin</i>   | Minimal quantity of numbers to update                                    |
| <i>nmax</i>   | Maximal quantity of numbers that can be updated                          |
| <i>idx</i>    | Position in cyclic buffer <i>dbuf</i> to start update $0 \leq idx < n$ . |

**Description**

The `vslNewAbstractStream` function creates a new abstract stream for double precision floating-point arrays with random numbers of the uniform distribution over interval  $(a,b)$ . The function associates the stream with a double precision array *dbuf* and your callback function *dcallback* that is intended for updating of *dbuf* content.

**Return Values**

|                             |                                                                 |
|-----------------------------|-----------------------------------------------------------------|
| VSL_ERROR_OK, VSL_STATUS_OK | Indicates no error, execution is successful.                    |
| VSL_ERROR_BADARGS           | Parameter <i>n</i> is not positive.                             |
| VSL_ERROR_MEM_FAILURE       | System cannot allocate memory for <i>stream</i> .               |
| VSL_ERROR_NULL_PTR          | Either buffer or callback function parameter is a NULL pointer. |

**vslsNewAbstractStream**

*Creates and initializes an abstract random stream for single precision floating-point arrays.*

**Syntax**

```
status = vslsNewAbstractStream(&stream, n, sbuf, a, b, scallback);
```

**Include Files**

- `mkl.h`

## Input Parameters

| Name             | Type                  | Description                                                                                                    |
|------------------|-----------------------|----------------------------------------------------------------------------------------------------------------|
| <i>n</i>         | const MKL_INT         | Size of the array <i>sbuf</i>                                                                                  |
| <i>sbuf</i>      | const float           | Array of <i>n</i> single precision floating-point random numbers with uniform distribution over interval (a,b) |
| <i>a</i>         | const float           | Left boundary a                                                                                                |
| <i>b</i>         | const float           | Right boundary b                                                                                               |
| <i>scallback</i> | See <i>Note</i> below | Pointer to the callback function used for update of the array <i>sbuf</i>                                      |

## Output Parameters

| Name          | Type               | Description                              |
|---------------|--------------------|------------------------------------------|
| <i>stream</i> | VSLStreamStatePtr* | Descriptor of the stream state structure |

### NOTE

Format of the callback function in C:

```
int sUpdateFunc(VSLStreamStatePtr stream, int* n, float sbuf[], int* nmin, int* nmax, int* idx);
```

The callback function returns the number of elements in the array actually updated by the function. [Table \*scallback\* Callback Function Parameters](#) gives the description of the callback function parameters.

## scallback Callback Function Parameters

| Parameters    | Short Description                                                        |
|---------------|--------------------------------------------------------------------------|
| <i>stream</i> | Abstract random stream descriptor                                        |
| <i>n</i>      | Size of <i>sbuf</i>                                                      |
| <i>sbuf</i>   | Array of random numbers associated with the stream <i>stream</i>         |
| <i>nmin</i>   | Minimal quantity of numbers to update                                    |
| <i>nmax</i>   | Maximal quantity of numbers that can be updated                          |
| <i>idx</i>    | Position in cyclic buffer <i>sbuf</i> to start update $0 \leq idx < n$ . |

## Description

The `vslsNewAbstractStream` function creates a new abstract stream for single precision floating-point arrays with random numbers of the uniform distribution over interval (a,b). The function associates the stream with a single precision array *sbuf* and your callback function *scallback* that is intended for updating of *sbuf* content.

## Return Values

|                             |                                              |
|-----------------------------|----------------------------------------------|
| VSL_ERROR_OK, VSL_STATUS_OK | Indicates no error, execution is successful. |
| VSL_ERROR_BADARGS           | Parameter <i>n</i> is not positive.          |

|                       |                                                                 |
|-----------------------|-----------------------------------------------------------------|
| VSL_ERROR_MEM_FAILURE | System cannot allocate memory for <i>stream</i> .               |
| VSL_ERROR_NULL_PTR    | Either buffer or callback function parameter is a NULL pointer. |

## vslDeleteStream

*Deletes a random stream.*

---

### Syntax

```
status = vslDeleteStream(&stream);
```

### Include Files

- mkl.h

### Input/Output Parameters

| Name          | Type               | Description                                                                                                              |
|---------------|--------------------|--------------------------------------------------------------------------------------------------------------------------|
| <i>stream</i> | VSLStreamStatePtr* | Stream state descriptor. Must have non-zero value. After the stream is successfully deleted, the pointer is set to NULL. |

### Description

The function deletes the random stream created by one of the initialization functions.

### Return Values

|                             |                                              |
|-----------------------------|----------------------------------------------|
| VSL_ERROR_OK, VSL_STATUS_OK | Indicates no error, execution is successful. |
| VSL_ERROR_NULL_PTR          | <i>stream</i> parameter is a NULL pointer.   |
| VSL_RNG_ERROR_BAD_STREAM    | <i>stream</i> is not a valid random stream.  |

## vslCopyStream

*Creates a copy of a random stream.*

---

### Syntax

```
status = vslCopyStream(&newstream, srcstream);
```

### Include Files

- mkl.h

### Input Parameters

| Name             | Type                    | Description                                        |
|------------------|-------------------------|----------------------------------------------------|
| <i>srcstream</i> | const VSLStreamStatePtr | Pointer to the stream state structure to be copied |

## Output Parameters

| Name             | Type               | Description                     |
|------------------|--------------------|---------------------------------|
| <i>newstream</i> | VSLStreamStatePtr* | Copied random stream descriptor |

## Description

The function creates an exact copy of *srcstream* and stores its descriptor to *newstream*.

## Return Values

|                             |                                                      |
|-----------------------------|------------------------------------------------------|
| VSL_ERROR_OK, VSL_STATUS_OK | Indicates no error, execution is successful.         |
| VSL_ERROR_NULL_PTR          | <i>srcstream</i> parameter is a NULL pointer.        |
| VSL_RNG_ERROR_BAD_STREAM    | <i>srcstream</i> is not a valid random stream.       |
| VSL_ERROR_MEM_FAILURE       | System cannot allocate memory for <i>newstream</i> . |

## vslCopyStreamState

*Creates a copy of a random stream state.*

## Syntax

```
status = vslCopyStreamState(deststream, srcstream);
```

## Include Files

- mkl.h

## Input Parameters

| Name             | Type                    | Description                                                                     |
|------------------|-------------------------|---------------------------------------------------------------------------------|
| <i>srcstream</i> | const VSLStreamStatePtr | Pointer to the stream state structure, from which the state structure is copied |

## Output Parameters

| Name              | Type              | Description                                                            |
|-------------------|-------------------|------------------------------------------------------------------------|
| <i>deststream</i> | VSLStreamStatePtr | Pointer to the stream state structure where the stream state is copied |

## Description

The `vslCopyStreamState` function copies a stream state from *srcstream* to the existing *deststream* stream. Both the streams should be generated by the same basic generator. An error message is generated when the index of the BRNG that produced *deststream* stream differs from the index of the BRNG that generated *srcstream* stream.

Unlike `vslCopyStream` function, which creates a new stream and copies both the stream state and other data from *srcstream*, the function `vslCopyStreamState` copies only *srcstream* stream state data to the generated *deststream* stream.

## Return Values

|                                  |                                                                                                       |
|----------------------------------|-------------------------------------------------------------------------------------------------------|
| VSL_ERROR_OK, VSL_STATUS_OK      | Indicates no error, execution is successful.                                                          |
| VSL_ERROR_NULL_PTR               | Either <i>srcstream</i> or <i>deststream</i> is a NULL pointer.                                       |
| VSL_RNG_ERROR_BAD_STREAM         | Either <i>srcstream</i> or <i>deststream</i> is not a valid random stream.                            |
| VSL_RNG_ERROR_BRNGS_INCOMPATIBLE | BRNG associated with <i>srcstream</i> is not compatible with BRNG associated with <i>deststream</i> . |

## vslSaveStreamF

Writes random stream descriptive data, including stream state, to binary file.

### Syntax

```
errstatus = vslSaveStreamF(stream, fname);
```

### Include Files

- mkl.h

### Input Parameters

| Name          | Type                    | Description                                     |
|---------------|-------------------------|-------------------------------------------------|
| <i>stream</i> | const VSLStreamStatePtr | Random stream to be written to the file         |
| <i>fname</i>  | const char*             | File name specified as a null-terminated string |

### Output Parameters

| Name             | Type | Description                   |
|------------------|------|-------------------------------|
| <i>errstatus</i> | int  | Error status of the operation |

### Description

The `vslSaveStreamF` function writes the random stream descriptive data, including the stream state, to the binary file. Random stream descriptive data is saved to the binary file with the name *fname*. The random stream *stream* must be a valid stream created by `vslNewStream`-like or `vslCopyStream`-like service routines. If the stream cannot be saved to the file, *errstatus* has a non-zero value. The random stream can be read from the binary file using the `vslLoadStreamF` function.

## Return Values

|                             |                                                         |
|-----------------------------|---------------------------------------------------------|
| VSL_ERROR_OK, VSL_STATUS_OK | Indicates no error, execution is successful.            |
| VSL_ERROR_NULL_PTR          | Either <i>fname</i> or <i>stream</i> is a NULL pointer. |
| VSL_RNG_ERROR_BAD_STREAM    | <i>stream</i> is not a valid random stream.             |
| VSL_RNG_ERROR_FILE_OPEN     | Indicates an error in opening the file.                 |
| VSL_RNG_ERROR_FILE_WRITE    | Indicates an error in writing the file.                 |

|                          |                                                   |
|--------------------------|---------------------------------------------------|
| VSL_RNG_ERROR_FILE_CLOSE | Indicates an error in closing the file.           |
| VSL_ERROR_MEM_FAILURE    | System cannot allocate memory for internal needs. |

## vslLoadStreamF

Creates new stream and reads stream descriptive data, including stream state, from binary file.

### Syntax

```
errstatus = vslLoadStreamF(&stream, fname);
```

### Include Files

- mkl.h

### Input Parameters

| Name         | Type        | Description                                     |
|--------------|-------------|-------------------------------------------------|
| <i>fname</i> | const char* | File name specified as a null-terminated string |

### Output Parameters

| Name             | Type               | Description                    |
|------------------|--------------------|--------------------------------|
| <i>stream</i>    | VSLStreamStatePtr* | Pointer to a new random stream |
| <i>errstatus</i> | int                | Error status of the operation  |

### Description

The `vslLoadStreamF` function creates a new stream and reads stream descriptive data, including the stream state, from the binary file. A new random stream is created using the stream descriptive data from the binary file with the name *fname*. If the stream cannot be read (for example, an I/O error occurs or the file format is invalid), *errstatus* has a non-zero value. To save random stream to the file, use `vslSaveStreamF` function.

#### CAUTION

Calling `vslLoadStreamF` with a previously initialized *stream* pointer can have unintended consequences such as a memory leak. To initialize a stream which has been in use until calling `vslLoadStreamF`, you should call the `vslDeleteStream` function first to deallocate the resources.

#### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## Return Values

|                                              |                                                                                    |
|----------------------------------------------|------------------------------------------------------------------------------------|
| VSL_ERROR_OK, VSL_STATUS_OK                  | Indicates no error, execution is successful.                                       |
| VSL_ERROR_NULL_PTR                           | <i>fname</i> is a NULL pointer.                                                    |
| VSL_RNG_ERROR_FILE_OPEN                      | Indicates an error in opening the file.                                            |
| VSL_RNG_ERROR_FILE_WRITE                     | Indicates an error in writing the file.                                            |
| VSL_RNG_ERROR_FILE_CLOSE                     | Indicates an error in closing the file.                                            |
| VSL_ERROR_MEM_FAILURE                        | System cannot allocate memory for internal needs.                                  |
| VSL_RNG_ERROR_BAD_FILE_FORMAT                | Unknown file format.                                                               |
| VSL_RNG_ERROR_UNSUPPORTED_FILE_VER           | File format version is unsupported.                                                |
| VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED | Non-deterministic random number generator is not supported.                        |
| VSL_RNG_ERROR_ARS5_NOT_SUPPORTED             | ARS-5 random number generator is not supported on the CPU running the application. |

## vslSaveStreamM

Writes random stream descriptive data, including stream state, to a memory buffer.

### Syntax

```
errstatus = vslSaveStreamM(stream, memptr);
```

### Include Files

- mkl.h

### Input Parameters

| Name          | Type                    | Description                                             |
|---------------|-------------------------|---------------------------------------------------------|
| <i>stream</i> | const VSLStreamStatePtr | Random stream to be written to the memory               |
| <i>memptr</i> | char*                   | Memory buffer to save random stream descriptive data to |

### Output Parameters

| Name             | Type | Description                   |
|------------------|------|-------------------------------|
| <i>errstatus</i> | int  | Error status of the operation |

### Description

The `vslSaveStreamM` function writes the random stream descriptive data, including the stream state, to the memory at `memptr`. Random stream `stream` must be a valid stream created by `vslNewStream`-like or `vslCopyStream`-like service routines. The `memptr` parameter must be a valid pointer to the memory of size sufficient to hold the random stream `stream`. Use the service routine `vslGetStreamSize` to determine this amount of memory.

If the stream cannot be saved to the memory, *errstatus* has a non-zero value. The random stream can be read from the memory pointed by *memptr* using the [vslLoadStreamM](#) function.

## Return Values

|                             |                                                          |
|-----------------------------|----------------------------------------------------------|
| VSL_ERROR_OK, VSL_STATUS_OK | Indicates no error, execution is successful.             |
| VSL_ERROR_NULL_PTR          | Either <i>memptr</i> or <i>stream</i> is a NULL pointer. |
| VSL_RNG_ERROR_BAD_STREAM    | <i>stream</i> is a NULL pointer.                         |

## vslLoadStreamM

*Creates a new stream and reads stream descriptive data, including stream state, from the memory buffer.*

## Syntax

```
errstatus = vslLoadStreamM(&stream, memptr);
```

## Include Files

- mkl.h

## Input Parameters

| Name          | Type        | Description                                               |
|---------------|-------------|-----------------------------------------------------------|
| <i>memptr</i> | const char* | Memory buffer to load random stream descriptive data from |

## Output Parameters

| Name             | Type               | Description                    |
|------------------|--------------------|--------------------------------|
| <i>stream</i>    | VSLStreamStatePtr* | Pointer to a new random stream |
| <i>errstatus</i> | int                | Error status of the operation  |

## Description

The [vslLoadStreamM](#) function creates a new stream and reads stream descriptive data, including the stream state, from the memory buffer. A new random stream is created using the stream descriptive data from the memory pointer by *memptr*. If the stream cannot be read (for example, *memptr* is invalid), *errstatus* has a non-zero value. To save random stream to the memory, use [vslSaveStreamM](#) function. Use the service routine [vslGetStreamSize](#) to determine the amount of memory sufficient to hold the random stream.

### CAUTION

Calling [LoadStreamM](#) with a previously initialized *stream* pointer can have unintended consequences such as a memory leak. To initialize a stream which has been in use until calling [vslLoadStreamM](#), you should call the [vslDeleteStream](#) function first to deallocate the resources.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or

**Optimization Notice**

effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

**Return Values**

|                                              |                                                                                    |
|----------------------------------------------|------------------------------------------------------------------------------------|
| VSL_ERROR_OK, VSL_STATUS_OK                  | Indicates no error, execution is successful.                                       |
| VSL_ERROR_NULL_PTR                           | <i>memptr</i> is a NULL pointer.                                                   |
| VSL_ERROR_MEM_FAILURE                        | System cannot allocate memory for internal needs.                                  |
| VSL_RNG_ERROR_BAD_MEM_FORMAT                 | Descriptive random stream format is unknown.                                       |
| VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED | Non-deterministic random number generator is not supported.                        |
| VSL_RNG_ERROR_ARS5_NOT_SUPPORTED             | ARS-5 random number generator is not supported on the CPU running the application. |

**vslGetStreamSize**

Computes size of memory necessary to hold the random stream.

**Syntax**

```
memsize = vslGetStreamSize(stream);
```

**Include Files**

- mkl.h

**Input Parameters**

| Name          | Type                    | Description   |
|---------------|-------------------------|---------------|
| <i>stream</i> | const VSLStreamStatePtr | Random stream |

**Output Parameters**

| Name           | Type | Description                                                                                 |
|----------------|------|---------------------------------------------------------------------------------------------|
| <i>memsize</i> | int  | Amount of memory in bytes necessary to hold descriptive data of random stream <i>stream</i> |

**Description**

The `vslGetStreamSize` function returns the size of memory in bytes which is necessary to hold the given random stream. Use the output of the function to allocate the buffer to which you will save the random stream by means of the `vslSaveStreamM` function.

## Return Values

VSL\_ERROR\_OK, VSL\_STATUS\_OK Indicates no error, execution is successful.

VSL\_RNG\_ERROR\_BAD\_STREAM *stream* is a NULL pointer.

## vslLeapfrogStream

Initializes a stream using the leapfrog method.

### Syntax

```
status = vslLeapfrogStream(stream, k, nstreams);
```

### Include Files

- mkl.h

### Input Parameters

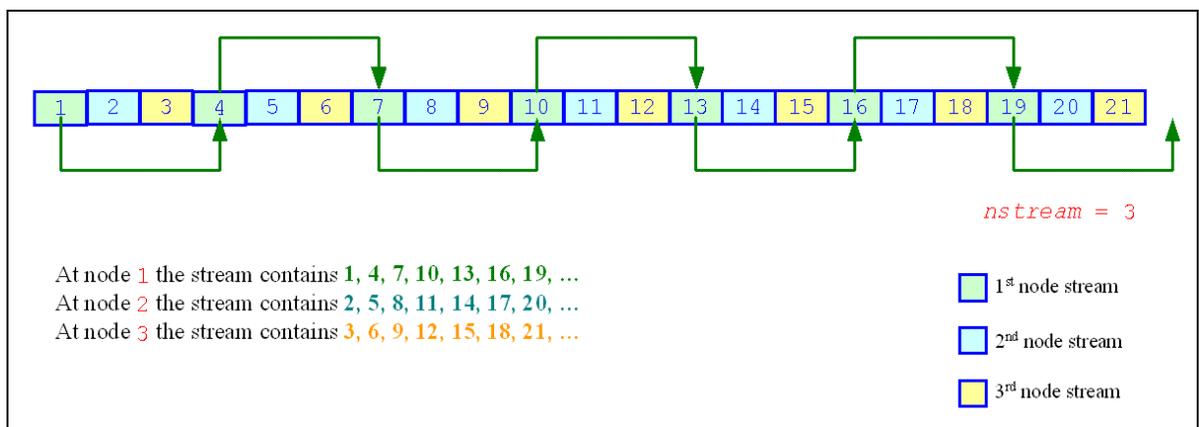

| Name            | Type              | Description                                                               |
|-----------------|-------------------|---------------------------------------------------------------------------|
| <i>stream</i>   | VSLStreamStatePtr | Pointer to the stream state structure to which leapfrog method is applied |
| <i>k</i>        | const MKL_INT     | Index of the computational node, or stream number                         |
| <i>nstreams</i> | const MKL_INT     | Largest number of computational nodes, or stride                          |

### Description

The `vslLeapfrogStream` function generates random numbers in a random stream with non-unit stride. This feature is particularly useful in distributing random numbers from the original stream across the `nstreams` buffers without generating the original random sequence with subsequent manual distribution.

One of the important applications of the leapfrog method is splitting the original sequence into non-overlapping subsequences across `nstreams` computational nodes. The function initializes the original random stream (see [Figure "Leapfrog Method"](#)) to generate random numbers for the computational node  $k$ ,  $0 \leq k < nstreams$ , where `nstreams` is the largest number of computational nodes used.

### Leapfrog Method

The leapfrog method is supported only for those basic generators that allow splitting elements by the leapfrog method, which is more efficient than simply generating them by a generator with subsequent manual distribution across computational nodes. See [VS Notes](#) for details.

For quasi-random basic generators, the leapfrog method allows generating individual components of quasi-random vectors instead of whole quasi-random vectors. In this case *nstreams* parameter should be equal to the dimension of the quasi-random vector while *k* parameter should be the index of a component to be generated ( $0 \leq k < nstreams$ ). Other parameters values are not allowed.

The following code illustrates the initialization of three independent streams using the leapfrog method:

### Code for Leapfrog Method

```
...
VSLStreamStatePtr stream1;
VSLStreamStatePtr stream2;
VSLStreamStatePtr stream3;

/* Creating 3 identical streams */
status = vslNewStream(&stream1, VSL_BRNG_MCG31, 174);
status = vslCopyStream(&stream2, stream1);
status = vslCopyStream(&stream3, stream1);

/* Leapfrogging the streams
*/
status = vslLeapfrogStream(stream1, 0, 3);
status = vslLeapfrogStream(stream2, 1, 3);
status = vslLeapfrogStream(stream3, 2, 3);

/* Generating random numbers
*/
...
/* Deleting the streams
*/
status = vslDeleteStream(&stream1);
status = vslDeleteStream(&stream2);
status = vslDeleteStream(&stream3);
...
```

### Return Values

|                                    |                                              |
|------------------------------------|----------------------------------------------|
| VSL_ERROR_OK, VSL_STATUS_OK        | Indicates no error, execution is successful. |
| VSL_ERROR_NULL_PTR                 | <i>stream</i> is a NULL pointer.             |
| VSL_RNG_ERROR_BAD_STREAM           | <i>stream</i> is not a valid random stream.  |
| VSL_RNG_ERROR_LEAPFROG_UNSUPPORTED | BRNG does not support Leapfrog method.       |

### vslSkipAheadStream

*Initializes a stream using the block-splitting method.*

#### Syntax

```
status = vslSkipAheadStream(stream, nskip);
```

## Include Files

- `mkl.h`

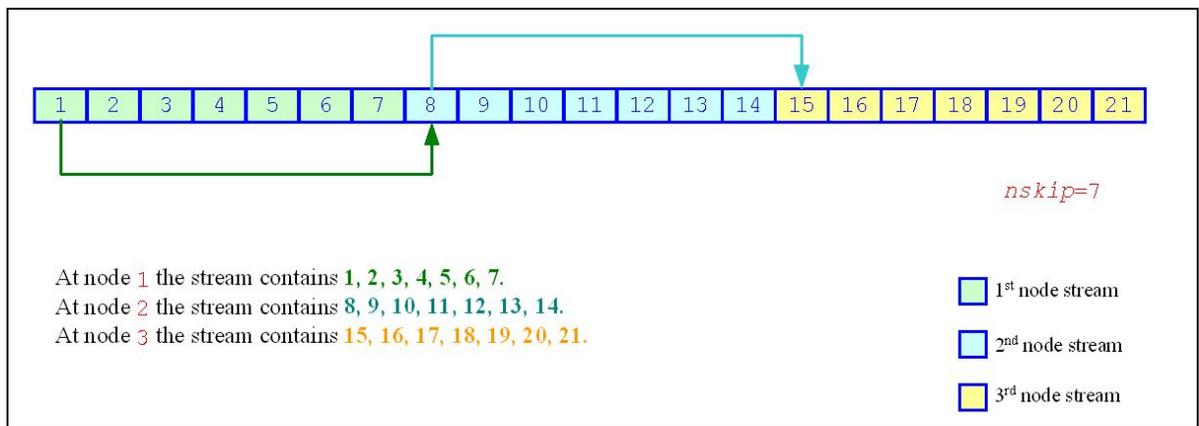

## Input Parameters

| Name                | Type                             | Description                                                                      |
|---------------------|----------------------------------|----------------------------------------------------------------------------------|
| <code>stream</code> | <code>VSLStreamStatePtr</code>   | Pointer to the stream state structure to which block-splitting method is applied |
| <code>nskip</code>  | <code>const long long int</code> | Number of skipped elements                                                       |

## Description

The `vslSkipAheadStream` function skips a given number of elements in a random stream. This feature is particularly useful in distributing random numbers from original random stream across different computational nodes. If the largest number of random numbers used by a computational node is `nskip`, then the original random sequence may be split by `vslSkipAheadStream` into non-overlapping blocks of `nskip` size so that each block corresponds to the respective computational node. The number of computational nodes is unlimited. This method is known as the block-splitting method or as the skip-ahead method. (see Figure "Block-Splitting Method").

## Block-Splitting Method

The skip-ahead method is supported only for those basic generators that allow skipping elements by the skip-ahead method, which is more efficient than simply generating them by generator with subsequent manual skipping. See [VS Notes](#) for details.

Please note that for quasi-random basic generators the skip-ahead method works with components of quasi-random vectors rather than with whole quasi-random vectors. Therefore, to skip `NS` quasi-random vectors, set the `nskip` parameter equal to the `NS*DIMEN`, where `DIMEN` is the dimension of the quasi-random vector. If this operation results in exceeding the period of the quasi-random number generator, which is  $2^{32}-1$ , the library returns the `VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED` error code.

The following code illustrates how to initialize three independent streams using the `vslSkipAheadStream` function:

## Code for Block-Splitting Method

```
VSLStreamStatePtr stream1;
VSLStreamStatePtr stream2;
VSLStreamStatePtr stream3;
```

```

/* Creating the 1st stream
*/
status = vslNewStream(&stream1, VSL_BRNG_MCG31, 174);

/* Skipping ahead by 7 elements the 2nd stream */
status = vslCopyStream(&stream2, stream1);
status = vslSkipAheadStream(stream2, 7);

/* Skipping ahead by 7 elements the 3rd stream */
status = vslCopyStream(&stream3, stream2);
status = vslSkipAheadStream(stream3, 7);

/* Generating random numbers
*/
...
/* Deleting the streams
*/
status = vslDeleteStream(&stream1);
status = vslDeleteStream(&stream2);
status = vslDeleteStream(&stream3);
...

```

## Return Values

|                                     |                                                          |
|-------------------------------------|----------------------------------------------------------|
| VSL_ERROR_OK, VSL_STATUS_OK         | Indicates no error, execution is successful.             |
| VSL_ERROR_NULL_PTR                  | <i>stream</i> is a NULL pointer.                         |
| VSL_RNG_ERROR_BAD_STREAM            | <i>stream</i> is not a valid random stream.              |
| VSL_RNG_ERROR_SKIPAHEAD_UNSUPPORTED | BRNG does not support the Skip-Ahead method.             |
| VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED   | Period of the quasi-random number generator is exceeded. |

## vslGetStreamStateBrng

Returns index of a basic generator used for generation of a given random stream.

## Syntax

```
brng = vslGetStreamStateBrng(stream);
```

## Include Files

- mkl.h

## Input Parameters

| Name          | Type                    | Description                           |
|---------------|-------------------------|---------------------------------------|
| <i>stream</i> | const VSLStreamStatePtr | Pointer to the stream state structure |

## Output Parameters

| Name        | Type | Description                                                                                              |
|-------------|------|----------------------------------------------------------------------------------------------------------|
| <i>brng</i> | int  | Index of the basic generator assigned for the generation of <i>stream</i> ; negative in case of an error |

### Description

The `vslGetStreamStateBrng` function retrieves the index of a basic generator used for generation of a given random stream.

### Return Values

|                          |                                             |
|--------------------------|---------------------------------------------|
| VSL_ERROR_NULL_PTR       | <i>stream</i> is a NULL pointer.            |
| VSL_RNG_ERROR_BAD_STREAM | <i>stream</i> is not a valid random stream. |

## vslGetNumRegBrngs

Obtains the number of currently registered basic generators.

### Syntax

```
nregbrngs = vslGetNumRegBrngs(void);
```

### Include Files

- `mkl.h`

## Output Parameters

| Name             | Type | Description                                                              |
|------------------|------|--------------------------------------------------------------------------|
| <i>nregbrngs</i> | int  | Number of basic generators registered at the moment of the function call |

### Description

The `vslGetNumRegBrngs` function obtains the number of currently registered basic generators. Whenever user registers a user-designed basic generator, the number of registered basic generators is incremented. The maximum number of basic generators that can be registered is determined by the `VSL_MAX_REG_BRNGS` parameter.

## Distribution Generators

Intel MKL VS routines are used to generate random numbers with different types of distribution. Each function group is introduced below by the type of underlying distribution and contains a short description of its functionality, as well as specifications of the call sequence and the explanation of input and output parameters. [Table "Continuous Distribution Generators"](#) and [Table "Discrete Distribution Generators"](#) list the random number generator routines with data types and output distributions, and sets correspondence between data types of the generator routines and the basic random number generators.

### Continuous Distribution Generators

| Type of Distribution     | Data Types  | BRNG Data Type | Description                                             |
|--------------------------|-------------|----------------|---------------------------------------------------------|
| <code>vRngUniform</code> | <i>s, d</i> | <i>s, d</i>    | Uniform continuous distribution on the interval $[a,b)$ |

| Type of Distribution         | Data Types | BRNG Data Type | Description                                            |
|------------------------------|------------|----------------|--------------------------------------------------------|
| <code>vRngGaussian</code>    | s, d       | s, d           | Normal (Gaussian) distribution                         |
| <code>vRngGaussianMV</code>  | s, d       | s, d           | Multivariate normal (Gaussian) distribution            |
| <code>vRngExponential</code> | s, d       | s, d           | Exponential distribution                               |
| <code>vRngLaplace</code>     | s, d       | s, d           | Laplace distribution (double exponential distribution) |
| <code>vRngWeibull</code>     | s, d       | s, d           | Weibull distribution                                   |
| <code>vRngCauchy</code>      | s, d       | s, d           | Cauchy distribution                                    |
| <code>vRngRayleigh</code>    | s, d       | s, d           | Rayleigh distribution                                  |
| <code>vRngLognormal</code>   | s, d       | s, d           | Lognormal distribution                                 |
| <code>vRngGumbel</code>      | s, d       | s, d           | Gumbel (extreme value) distribution                    |
| <code>vRngGamma</code>       | s, d       | s, d           | Gamma distribution                                     |
| <code>vRngBeta</code>        | s, d       | s, d           | Beta distribution                                      |

### Discrete Distribution Generators

| Type of Distribution            | Data Types | BRNG Data Type                                                                                                                                                                         | Description                                            |
|---------------------------------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|
| <code>vRngUniform</code>        | i          | d                                                                                                                                                                                      | Uniform discrete distribution on the interval $[a,b]$  |
| <code>vRngUniformBits</code>    | i          | i                                                                                                                                                                                      | Underlying BRNG integer recurrence                     |
| <code>vRngUniformBits 32</code> | i          | i                                                                                                                                                                                      | Uniformly distributed bits in 32-bit chunks            |
| <code>vRngUniformBits 64</code> | i          | i                                                                                                                                                                                      | Uniformly distributed bits in 64-bit chunks            |
| <code>vRngBernoulli</code>      | i          | s                                                                                                                                                                                      | Bernoulli distribution                                 |
| <code>vRngGeometric</code>      | i          | s                                                                                                                                                                                      | Geometric distribution                                 |
| <code>vRngBinomial</code>       | i          | d                                                                                                                                                                                      | Binomial distribution                                  |

## Modes of random number generation

The library provides two modes of random number generation, accurate and fast. Accurate generation mode is intended for the applications that are highly demanding to accuracy of calculations. When used in this mode, the generators produce random numbers lying completely within definitional domain for all values of the distribution parameters. For example, random numbers obtained from the generator of continuous distribution that is uniform on interval  $[a,b]$  belong to this interval irrespective of what  $a$  and  $b$  values may be. Fast mode provides high performance of generation and also guarantees that generated random numbers belong to the definitional domain except for some specific values of distribution parameters. The generation mode is set by specifying relevant value of the method parameter in generator routines. List of distributions that support accurate mode of generation is given in the table below.

### Distribution Generators Supporting Accurate Mode

| Type of Distribution         | Data Types        |
|------------------------------|-------------------|
| <code>vRngUniform</code>     | <code>s, d</code> |
| <code>vRngExponential</code> | <code>s, d</code> |
| <code>vRngWeibull</code>     | <code>s, d</code> |
| <code>vRngRayleigh</code>    | <code>s, d</code> |
| <code>vRngLognormal</code>   | <code>s, d</code> |
| <code>vRngGamma</code>       | <code>s, d</code> |
| <code>vRngBeta</code>        | <code>s, d</code> |

See additional details about accurate and fast mode of random number generation in [VS Notes](#).

## New method names

The current version of Intel MKL has a modified structure of VS RNG method names. (See [RNG Naming Conventions](#) for details.) The old names are kept for backward compatibility. The set correspondence between the new and legacy method names for VS random number generators.

### Method Names for Continuous Distribution Generators

## Continuous Distributions

This section describes routines for generating random numbers with continuous distribution.

### vRngUniform Continuous Distribution Generators

Generates random numbers with uniform distribution.

#### Syntax

```
status = vsRngUniform(method, stream, n, r, a, b);
```

```
status = vdRngUniform(method, stream, n, r, a, b);
```

#### Include Files

- `mkl.h`

#### Input Parameters

|----------|-----------------------------------------------------|------------------------------------------------------------------------------------|
| <i>r</i> | float* for vsRngUniform<br>double* for vdRngUniform | Vector of <i>n</i> random numbers uniformly distributed over the interval $[a, b)$ |

### Description

The `vdRngUniform` function generates random numbers uniformly distributed over the interval  $[a, b)$ , where  $a, b$  are the left and right bounds of the interval, respectively, and  $a, b \in \mathbb{R}; a < b$ .

The probability density function is given by:

$$f_{a,b}(x) = \begin{cases} \frac{1}{b-a}, & x \in [a, b) \\ 0, & x \notin [a, b) \end{cases}, \quad -\infty < x < +\infty$$

The cumulative distribution function is as follows:

$$F_{a,b}(x) = \begin{cases} 0, & x < a \\ \frac{x-a}{b-a}, & a \leq x < b \\ 1, & x \geq b \end{cases}, \quad -\infty < x < +\infty.$$

#### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

|----------|-------------------------------------------------------|--------------------------------------------------------|
| <i>r</i> | float* for vsRngGaussian<br>double* for vdRngGaussian | Vector of <i>n</i> normally distributed random numbers |

### Description

The `vdRngGaussian` function generates random numbers with normal (Gaussian) distribution with mean value *a* and standard deviation  $\sigma$ , where

$$a, \sigma \in \mathbb{R} ; \sigma > 0.$$

The probability density function is given by:

$$f_{a, \sigma}(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x - a)^2}{2\sigma^2}\right), \quad -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a, \sigma}(x) = \int_{-\infty}^x \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(y - a)^2}{2\sigma^2}\right) dy, \quad -\infty < x < +\infty.$$

The cumulative distribution function  $F_{a, \sigma}(x)$  can be expressed in terms of standard normal distribution  $\Phi(x)$  as

$$F_{a, \sigma}(x) = \Phi((x - a)/\sigma)$$

#### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

### Return Values

VSL\_ERROR\_OK, VSL\_STATUS\_OK Indicates no error, execution is successful.

### Description

The `vsRngGaussianMV` function generates random numbers with  $d$ -variate normal (Gaussian) distribution with mean value  $a$  and variance-covariance matrix  $C$ , where  $a \in R^d$ ;  $C$  is a  $d \times d$  symmetric positive-definite matrix.

The probability density function is given by:

$$f_{a,C}(x) = \frac{1}{\sqrt{\det(2\pi C)}} \exp(-1/2(x - a)^T C^{-1}(x - a)),$$

where  $x \in R^d$ .

Matrix  $C$  can be represented as  $C = TT^T$ , where  $T$  is a lower triangular matrix - Cholesky factor of  $C$ .

Instead of variance-covariance matrix  $C$  the generation routines require Cholesky factor of  $C$  in input. To compute Cholesky factor of matrix  $C$ , the user may call Intel MKL LAPACK routines for matrix factorization: `?potrf` or `?pptrf` for `v?RngGaussianMV/v?rnggaussianmv` routines (? means either `s` or `d` for single and double precision respectively). See [Application Notes](#) for more details.

#### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-

**Optimization Notice**

dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

**Application Notes**

Since matrices are stored in Fortran by columns, while in C they are stored by rows, the usage of Intel MKL factorization routines (assuming Fortran matrices storage) in combination with multivariate normal RNG (assuming C matrix storage) is slightly different in C and Fortran. The following tables help in using these routines in C and Fortran. For further information please refer to the appropriate VS example file.

| <i>r</i> | float* for vsRngExponential<br>double* for vdRngExponential | Vector of <i>n</i> exponentially distributed random numbers |

#### Description

The `vsRngExponential` function generates random numbers with exponential distribution that has displacement *a* and scalefactor  $\beta$ , where  $a, \beta \in \mathbb{R}$ ;  $\beta > 0$ .

The probability density function is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{1}{\beta} \exp(-(x-a)/\beta), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp(-(x-a)/\beta), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

| <i>r</i> | <code>float*</code> for <code>vsRngLaplace</code><br><code>double*</code> for <code>vdRngLaplace</code> | Vector of <i>n</i> Laplace distributed random numbers |

## Description

The `vsRngLaplace` function generates random numbers with Laplace distribution with mean value (or average) *a* and scalefactor  $\beta$ , where  $a, \beta \in \mathbb{R}$ ;  $\beta > 0$ . The scalefactor value determines the standard deviation as

$$\sigma = \beta\sqrt{2}$$

The probability density function is given by:

$$f_{a,\beta}(x) = \frac{1}{\sqrt{2}\beta} \exp\left(-\frac{|x-a|}{\beta}\right), -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$f_{\alpha,\beta}(x) = \begin{cases} \frac{1}{2} \exp\left(-\frac{|x-a|}{\beta}\right), & x \geq a \\ 1 - \frac{1}{2} \exp\left(-\frac{|x-a|}{\beta}\right), & x < a \end{cases}, -\infty < x < +\infty.$$

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

## Description

The `vdRngWeibull` function generates Weibull distributed random numbers with displacement  $a$ , scalefactor  $\beta$ , and shape  $\alpha$ , where  $\alpha, \beta, a \in \mathbb{R}; \alpha > 0, \beta > 0$ .

The probability density function is given by:

$$f_{a,\alpha,\beta}(x) = \begin{cases} \frac{\alpha}{\beta^\alpha} (x - a)^{\alpha-1} \exp\left(-\left(\frac{x - a}{\beta}\right)^\alpha\right), & x \geq a \\ 0, & x < a \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\alpha,\beta}(x) = \begin{cases} 1 - \exp\left(-\left(\frac{x-a}{\beta}\right)^\alpha\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

### Description

The `vsRngRayleigh` function generates Rayleigh distributed random numbers with displacement  $a$  and scalefactor  $\beta$ , where  $a, \beta \in \mathbb{R}$ ;  $\beta > 0$ .

The Rayleigh distribution is a special case of the `Weibull` distribution, where the shape parameter  $\alpha = 2$ .

The probability density function is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{2(x-a)}{\beta^2} \exp\left(-\frac{(x-a)^2}{\beta^2}\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp\left(-\frac{(x-a)^2}{\beta^2}\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

#### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain

**Optimization Notice**

optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

|----------|-------------------------------------------------------------|-----------------------------------------------------------|
| <i>r</i> | float* for vsRngLognormal<br><br>double* for vdRngLognormal | Vector of <i>n</i> lognormally distributed random numbers |

### Description

The `vsRngLognormal` function generates lognormally distributed random numbers with average of distribution *a* and standard deviation  $\sigma$  of subject normal distribution, displacement *b*, and scalefactor  $\beta$ , where  $a, \sigma, b, \beta \in \mathbb{R}$ ;  $\sigma > 0, \beta > 0$ .

The probability density function is given by:

$$f_{a,\sigma,b,\beta}(x) = \begin{cases} \frac{1}{\sigma(x-b)\sqrt{2\pi}} \exp\left(-\frac{[\ln((x-b)/\beta) - a]^2}{2\sigma^2}\right), & x > b \\ 0, & x \leq b \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\sigma,b,\beta}(x) = \begin{cases} \Phi((\ln((x-b)/\beta) - a)/\sigma), & x > b \\ 0, & x \leq b \end{cases}$$

| <i>r</i> | float* for vsRngGamma<br>double* for vdRngGamma | Vector of $n$ random numbers with gamma distribution |

### Description

The `vrngGamma` function generates random numbers with gamma distribution that has shape parameter  $\alpha$ , displacement  $a$ , and scale parameter  $\beta$ , where  $\alpha, \beta$ , and  $a \in \mathbb{R}$ ;  $\alpha > 0, \beta > 0$ .

The probability density function is given by:

$$f_{\alpha,a,\beta}(x) = \begin{cases} \frac{1}{\Gamma(\alpha)\beta^\alpha} (x - a)^{\alpha-1} e^{-(x-a)/\beta}, & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty$$

where  $\Gamma(\alpha)$  is the complete gamma function.

The cumulative distribution function is as follows:

$$F_{\alpha,a,\beta}(x) = \begin{cases} \int_a^x \frac{1}{\Gamma(\alpha)\beta^\alpha} (y - a)^{\alpha-1} e^{-(y-a)/\beta} dy, & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty$$

#### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

|----------|-----------------------------------------------|-----------------------------------------------------|
| <i>r</i> | float* for vsRngBeta<br>double* for vdRngBeta | Vector of $n$ random numbers with beta distribution |

### Description

The `vdRngBeta` function generates random numbers with beta distribution that has shape parameters  $p$  and  $q$ , displacement  $a$ , and scale parameter  $\beta$ , where  $p, q, a$ , and  $\beta \in \mathbb{R}$ ;  $p > 0$ ,  $q > 0$ ,  $\beta > 0$ .

The probability density function is given by:

$$f_{p,q,a,\beta}(x) = \begin{cases} \frac{1}{B(p,q)\beta^{p+q-1}} (x-a)^{p-1} (\beta+a-x)^{q-1}, & a \leq x < a + \beta \\ 0, & x < a, x \geq a + \beta \end{cases}, -\infty < x < \infty,$$

where  $B(p, q)$  is the complete beta function.

The cumulative distribution function is as follows:

$$F_{p,q,a,\beta}(x) = \begin{cases} 0, & x < a \\ \int_a^x \frac{1}{B(p,q)\beta^{p+q-1}} (y-a)^{p-1} (\beta+a-y)^{q-1} dy, & a \leq x < a + \beta \\ 1, & x \geq a + \beta \end{cases}, -\infty < x < \infty.$$

#### Optimization Notice

| <i>method</i> | const MKL_INT     | Generation method; the specific value is as follows:<br><br>VSL_RNG_METHOD_UNIFORM_STD<br><br>Standard method. Currently there is only one method for this distribution generator. |
| <i>stream</i> | VSLStreamStatePtr | Pointer to the stream state structure                                                                                                                                              |
| <i>n</i>      | const MKL_INT     | Number of random values to be generated                                                                                                                                            |
| <i>a</i>      | const int         | Left interval bound a                                                                                                                                                              |
| <i>b</i>      | const int         | Right interval bound b                                                                                                                                                             |

## Output Parameters

| Name | Type              | Description                                                                   |
|------|-------------------|-------------------------------------------------------------------------------|
| $r$  | <code>int*</code> | Vector of $n$ random numbers uniformly distributed over the interval $[a, b)$ |

## Description

The `vRngUniform` function generates random numbers uniformly distributed over the interval  $[a, b)$ , where  $a, b$  are the left and right bounds of the interval respectively, and  $a, b \in \mathbb{Z}; a < b$ .

The probability distribution is given by:

$$P(X = k) = \frac{1}{b - a}, k \in \{a, a + 1, \dots, b - 1\}.$$

The cumulative distribution function is as follows:

$$F_{a,b}(x) = \begin{cases} 0, & x < a \\ \frac{\lfloor x - a + 1 \rfloor}{b - a}, & a \leq x < b, x \in \mathbb{R}. \\ 1, & x \geq b \end{cases}$$

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. ## Return Values

|                                          |                                                                                                                               |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>VSL_ERROR_OK, VSL_STATUS_OK</code> | Indicates no error, execution is successful.                                                                                  |
| <code>VSL_ERROR_NULL_PTR</code>          | <i>stream</i> is a NULL pointer.                                                                                              |
| <code>VSL_RNG_ERROR_BAD_STREAM</code>    | <i>stream</i> is not a valid random stream.                                                                                   |
| <code>VSL_RNG_ERROR_BAD_UPDATE</code>    | Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, $< 0$ or $> nmax$ . |

|                                           |                                                                                                                     |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| VSL_RNG_ERROR_NO_NUMBERS                  | Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.                      |
| VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED         | Period of the generator has been exceeded.                                                                          |
| VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED | Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold. |
| VSL_RNG_ERROR_ARS5_NOT_SUPPORTED          | ARS-5 random number generator is not supported on the CPU running the application.                                  |

## vRngUniformBits

Generates bits of underlying BRNG integer recurrence.

### Syntax

```
status = viRngUniformBits(method, stream, n, r);
```

### Include Files

- mkl.h

### Input Parameters

| Name          | Type              | Description                                                                          |
|---------------|-------------------|--------------------------------------------------------------------------------------|
| <i>method</i> | const MKL_INT     | Generation method; the specific value is <code>VSL_RNG_METHOD_UNIFORMBITS_STD</code> |
| <i>stream</i> | VSLStreamStatePtr | Pointer to the stream state structure                                                |
| <i>n</i>      | const MKL_INT     | Number of random values to be generated                                              |

### Output Parameters

| Name     | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>r</i> | unsigned int* | Vector of <i>n</i> random integer numbers. If the <i>stream</i> was generated by a 64 or a 128-bit generator, each integer value is represented by two or four elements of <i>r</i> respectively. The number of bytes occupied by each integer is contained in the field <i>WordSize</i> of the structure <code>VSLBRngProperties</code> . The total number of bits that are actually used to store the value are contained in the field <i>NBits</i> of the same structure. See <a href="#">Advanced Service Routines</a> for a more detailed discussion of <code>VSLBRngProperties</code> . |

### Description

The `viRngUniformBits` function generates integer random values with uniform bit distribution. The generators of uniformly distributed numbers can be represented as recurrence relations over integer values in modular arithmetic. Apparently, each integer can be treated as a vector of several bits. In a truly random generator, these bits are random, while in pseudorandom generators this randomness can be violated. For example, a well known drawback of linear congruential generators is that lower bits are less random than

higher bits (for example, see [Knuth81]). For this reason, care should be taken when using this function. Typically, in a 32-bit LCG only 24 higher bits of an integer value can be considered random. See [VS Notes](#) for details.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

### Return Values

|                                           |                                                                                                                          |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| VSL_ERROR_OK, VSL_STATUS_OK               | Indicates no error, execution is successful.                                                                             |
| VSL_ERROR_NULL_PTR                        | <i>stream</i> is a NULL pointer.                                                                                         |
| VSL_RNG_ERROR_BAD_STREAM                  | <i>stream</i> is not a valid random stream.                                                                              |
| VSL_RNG_ERROR_BAD_UPDATE                  | Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax. |
| VSL_RNG_ERROR_NO_NUMBERS                  | Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.                           |
| VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED         | Period of the generator has been exceeded.                                                                               |
| VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED | Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.      |
| VSL_RNG_ERROR_ARS5_NOT_SUPPORTED          | ARS-5 random number generator is not supported on the CPU running the application.                                       |

### vRngUniformBits32

*Generates uniformly distributed bits in 32-bit chunks.*

### Syntax

```
status = viRngUniformBits32(method, stream, n, r);
```

### Include Files

- mkl.h

## Input Parameters

| Name          | Type              | Description                                                                  |
|---------------|-------------------|------------------------------------------------------------------------------|
| <i>method</i> | const MKL_INT     | Generation method; the specific value is<br>VSL_RNG_METHOD_UNIFORMBITS32_STD |
| <i>stream</i> | VSLStreamStatePtr | Pointer to the stream state structure                                        |
| <i>n</i>      | const MKL_INT     | Number of random values to be generated                                      |

## Output Parameters

| Name     | Type          | Description                                                                     |
|----------|---------------|---------------------------------------------------------------------------------|
| <i>r</i> | unsigned int* | Vector of <i>n</i> 32-bit random integer numbers with uniform bit distribution. |

## Description

The `vRngUniformBits32` function generates uniformly distributed bits in 32-bit chunks. Unlike `vRngUniformBits`, which provides the output of underlying integer recurrence and does not guarantee uniform distribution across bits, `vRngUniformBits32` is designed to ensure each bit in the 32-bit chunk is uniformly distributed. See [VS Notes](#) for details.

| VSL_RNG_ERROR_ARS5_NOT_SUPPORTED              | ARS-5 random number generator is not supported on the CPU running the application.                                  |

**vRngUniformBits64**

*Generates uniformly distributed bits in 64-bit chunks.*

**Syntax**

```
status = viRngUniformBits64(method, stream, n, r);
```

**Include Files**

- mkl.h

**Input Parameters**

| Name          | Type              | Description                                                                               |
|---------------|-------------------|-------------------------------------------------------------------------------------------|
| <i>method</i> | const MKL_INT     | Generation method; the specific value is<br><code>VSL_RNG_METHOD_UNIFORMBITS64_STD</code> |
| <i>stream</i> | VSLStreamStatePtr | Pointer to the stream state structure                                                     |
| <i>n</i>      | const MKL_INT     | Number of random values to be generated                                                   |

**Output Parameters**

| Name     | Type                | Description                                                                     |
|----------|---------------------|---------------------------------------------------------------------------------|
| <i>r</i> | unsigned MKL_INT64* | Vector of <i>n</i> 64-bit random integer numbers with uniform bit distribution. |

**Description**

The `vRngUniformBits64` function generates uniformly distributed bits in 64-bit chunks. Unlike `vRngUniformBits`, which provides the output of underlying integer recurrence and does not guarantee uniform distribution across bits, `vRngUniformBits64` is designed to ensure each bit in the 64-bit chunk is uniformly distributed. See [VS Notes](#) for details.

|----------|------|---------------------------------------------------|
| <i>r</i> | int* | Vector of $n$ Bernoulli distributed random values |

### Description

The `vRngBernoulli` function generates Bernoulli distributed random numbers with probability  $p$  of a single trial success, where

$$p \in \mathbb{R}; 0 \leq p \leq 1.$$

A variate is called Bernoulli distributed, if after a trial it is equal to 1 with probability of success  $p$ , and to 0 with probability  $1 - p$ .

The probability distribution is given by:

$$P(X = 1) = p$$

$$P(X = 0) = 1 - p$$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - p, & 0 \leq x < 1, x \in R. \\ 1, & x \geq 1 \end{cases}$$

### Optimization Notice

## Description

The `vRngGeometric` function generates geometrically distributed random numbers with probability  $p$  of a single trial success, where  $p \in \mathbb{R}$ ;  $0 < p < 1$ .

A geometrically distributed variate represents the number of independent Bernoulli trials preceding the first success. The probability of a single Bernoulli trial success is  $p$ .

The probability distribution is given by:

$$P(X = k) = p \cdot (1 - p)^k, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - (1 - p)^{\lfloor x+1 \rfloor}, & 0 \geq x \end{cases} \quad x \in \mathbb{R}.$$

### Optimization Notice

|----------|------|----------------------------------------------------|
| <i>r</i> | int* | Vector of $n$ binomially distributed random values |

#### Description

The `vRngBinomial` function generates binomially distributed random numbers with number of independent Bernoulli trials  $m$ , and with probability  $p$  of a single trial success, where  $p \in \mathbb{R}$ ;  $0 \leq p \leq 1$ ,  $m \in \mathbb{N}$ .

A binomially distributed variate represents the number of successes in  $m$  independent Bernoulli trials with probability of a single trial success  $p$ .

The probability distribution is given by:

$$P(X = k) = C_m^k p^k (1 - p)^{m-k}, k \in \{0, 1, \dots, m\}.$$

The cumulative distribution function is as follows:

$$F_{m,p}(x) = \begin{cases} 0, & x < 0 \\ \sum_{k=0}^{\lfloor x \rfloor} C_m^k p^k (1 - p)^{m-k}, & 0 \leq x < m, x \in R \\ 1, & x \geq m \end{cases}$$

#### Output Parameters

| Name     | Type | Description                                                     |
|----------|------|-----------------------------------------------------------------|
| <i>r</i> | int* | Vector of <i>n</i> hypergeometrically distributed random values |

#### Description

The `viRngHypergeometric` function generates hypergeometrically distributed random values with lot size *l*, size of sampling *s*, and number of marked elements in the lot *m*, where  $l, m, s \in \mathbb{N} \cup \{0\}$ ;  $l \geq \max(s, m)$ .

Consider a lot of *l* elements comprising *m* "marked" and *l*-*m* "unmarked" elements. A trial sampling without replacement of exactly *s* elements from this lot helps to define the hypergeometric distribution, which is the probability that the group of *s* elements contains exactly *k* marked elements.

The probability distribution is given by:)

$$P(X = k) = \frac{C_m^k C_{l-m}^{s-k}}{C_l^s}$$

,  $k \in \{\max(0, s + m - l), \dots, \min(s, m)\}$

The cumulative distribution function is as follows:

$$F_{1,s,m}(x) = \begin{cases} 0, & x < \max(0, s + m - 1) \\ \sum_{k=\max(0, s+m-1)}^{\lfloor x \rfloor} \frac{C_m^k C_{1-m}^{s-k}}{C_1^s}, & \max(0, s + m - 1) \leq x \leq \min(s, m) \\ 1, & x > \min(s, m) \end{cases}$$

## Description

The `vRng"Poisson` function generates Poisson distributed random numbers with distribution parameter  $\lambda$ , where  $\lambda \in R$ ;  $\lambda > 0$ .

The probability distribution is given by:

$$P(X = k) = \frac{\lambda^k e^{-\lambda}}{k!},$$

$k \in \{0, 1, 2, \dots\}$ .

The cumulative distribution function is as follows:

$$F_{\lambda}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda^k e^{-\lambda}}{k!}, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in R$$

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

| $r$  | <code>int*</code> | Vector of $n$ Poisson distributed random values |

## Description

The `vRngPoissonV` function generates  $n$  Poisson distributed random numbers  $x_i (i = 1, \dots, n)$  with distribution parameter  $\lambda_i$ , where  $\lambda_i \in \mathbb{R}; \lambda_i > 0$ .

The probability distribution is given by:

$$P(X_i = k) = \frac{\lambda_i^k \exp(-\lambda_i)}{k!}, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_{\lambda_i}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda_i^k e^{-\lambda_i}}{k!}, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in \mathbb{R}$$

|----------|------|-----------------------------------------------------------------------|
| <i>r</i> | int* | Vector of <i>n</i> random values with negative binomial distribution. |

#### Description

The `vRngNegBinomial` function generates random numbers with negative binomial distribution and distribution parameters *a* and *p*, where  $p, a \in \mathbb{R}; 0 < p < 1; a > 0$ .

If the first distribution parameter  $a \in \mathbb{N}$ , this distribution is the same as Pascal distribution. If  $a \in \mathbb{N}$ , the distribution can be interpreted as the expected time of *a*-th success in a sequence of Bernoulli trials, when the probability of success is *p*.

The probability distribution is given by:

$$P(X = k) = C_{a+k-1}^k p^a (1 - p)^k, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_{a,p}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} C_{a+k-1}^k p^a (1-p)^k, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in \mathbb{R}$$

### Advanced Service Routines

This section describes service routines for registering a user-designed basic generator ([vslRegisterBrng](#)) and for obtaining properties of the previously registered basic generators ([vslGetBrngProperties](#)). See [VS Notes](#) ("Basic Generators" section of VS Structure chapter) for substantiation of the need for several basic generators including user-defined BRNGs.

### Advanced Service Routine Data Types

The Advanced Service routines refer to a structure defining the properties of the basic generator.

This structure is described as follows:

```
typedef struct _VSLBRngProperties {
 int StreamStateSize;
 int NSeeds;
 int IncludesZero;
 int WordSize;
 int NBits;
 InitStreamPtr InitStream;
 sBRngPtr sBRng;
 dBRngPtr dBRng;
 iBRngPtr iBRng;
} VSLBRngProperties;
```

The following table provides brief descriptions of the fields engaged in the above structure:

### Field Descriptions

| Field           | Short Description                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| StreamStateSize | The size, in bytes, of the stream state structure for a given basic generator.                                                                                                                                                                                                                                                                                                                           |
| NSeeds          | The number of 32-bit initial conditions (seeds) necessary to initialize the stream state structure for a given basic generator.                                                                                                                                                                                                                                                                          |
| IncludesZero    | Flag value indicating whether the generator can produce a random 0.                                                                                                                                                                                                                                                                                                                                      |
| WordSize        | Machine word size, in bytes, used in integer-value computations. Possible values: 4, 8, and 16 for 32, 64, and 128-bit generators, respectively.                                                                                                                                                                                                                                                         |
| NBits           | The number of bits required to represent a random value in integer arithmetic. Note that, for instance, 48-bit random values are stored to 64-bit (8 byte) memory locations. In this case, <code>wordsize/WordSize</code> is equal to 8 (number of bytes used to store the random value), while <code>nbits/NBits</code> contains the actual number of bits occupied by the value (in this example, 48). |
| InitStream      | Contains the pointer to the initialization routine of a given basic generator.                                                                                                                                                                                                                                                                                                                           |
| sBRng           | Contains the pointer to the basic generator of single precision real numbers uniformly distributed over the interval $(a,b)$ ( <code>float</code> ).                                                                                                                                                                                                                                                     |
| dBRng           | Contains the pointer to the basic generator of double precision real numbers uniformly distributed over the interval $(a,b)$ ( <code>double</code> ).                                                                                                                                                                                                                                                    |
| iBRng           | Contains the pointer to the basic generator of integer numbers with uniform bit distribution ( <code>unsigned int</code> ).                                                                                                                                                                                                                                                                              |

### vslRegisterBrng

*Registers user-defined basic generator.*

#### Syntax

```
brng = vslRegisterBrng(&properties);
```

<sup>1</sup> A specific generator that permits operations over single bits and bit groups of random numbers.

## Include Files

- `mkl.h`

## Input Parameters

| Name                    | Type                                  | Description                                                                            |
|-------------------------|---------------------------------------|----------------------------------------------------------------------------------------|
| <code>properties</code> | <code>const VSLBRngProperties*</code> | Pointer to the structure containing properties of the basic generator to be registered |

## Output Parameters

| Name              | Type             | Description                                                                                                                 |
|-------------------|------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>brng</code> | <code>int</code> | Number (index) of the registered basic generator; used for identification. Negative values indicate the registration error. |

## Description

An example of a registration procedure can be found in the respective directory of the VS examples.

## Return Values

|                                                  |                                                                                                                                       |
|--------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>VSL_ERROR_OK, VSL_STATUS_OK</code>         | Indicates no error, execution is successful.                                                                                          |
| <code>VSL_RNG_ERROR_BRNG_TABLE_FULL</code>       | Registration cannot be completed due to lack of free entries in the table of registered BRNGs.                                        |
| <code>VSL_RNG_ERROR_BAD_STREAM_STATE_SIZE</code> | Bad value in <code>StreamStateSize</code> field.                                                                                      |
| <code>VSL_RNG_ERROR_BAD_WORD_SIZE</code>         | Bad value in <code>WordSize</code> field.                                                                                             |
| <code>VSL_RNG_ERROR_BAD_NSEEDS</code>            | Bad value in <code>NSeeds</code> field.                                                                                               |
| <code>VSL_RNG_ERROR_BAD_NBITS</code>             | Bad value in <code>NBits</code> field.                                                                                                |
| <code>VSL_ERROR_NULL_PTR</code>                  | At least one of the fields <code>iBrng</code> , <code>dBrng</code> , <code>sBrng</code> or <code>InitStream</code> is a NULL pointer. |

## **vslGetBrngProperties**

Returns structure with properties of a given basic generator.

### Syntax

```
status = vslGetBrngProperties(brng, &properties);
```

## Include Files

- `mkl.h`

## Input Parameters

| Name        | Type      | Description                                                                                                                                                                                                  |
|-------------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>brng</i> | const int | Number (index) of the registered basic generator; used for identification. See specific values in <a href="#">Table "Values of <i>brng</i> parameter"</a> . Negative values indicate the registration error. |

## Output Parameters

| Name              | Type               | Description                                                                             |
|-------------------|--------------------|-----------------------------------------------------------------------------------------|
| <i>properties</i> | VSLBRngProperties* | Pointer to the structure containing properties of the generator with number <i>brng</i> |

## Description

The `vslGetBrngProperties` function returns a structure with properties of a given basic generator.

## Return Values

|                                  |                                              |
|----------------------------------|----------------------------------------------|
| VSL_ERROR_OK, VSL_STATUS_OK      | Indicates no error, execution is successful. |
| VSL_RNG_ERROR_INVALID_BRNG_INDEX | BRNG index is invalid.                       |

## Formats for User-Designed Generators

To register a user-designed basic generator using `vslRegisterBrng` function, you need to pass the pointer `iBrng` to the integer-value implementation of the generator; the pointers `sBrng` and `dBrng` to the generator implementations for single and double precision values, respectively; and pass the pointer `InitStream` to the stream initialization routine. See recommendations below on defining such functions with input and output arguments. An example of the registration procedure for a user-designed generator can be found in the respective directory of VS examples.

The respective pointers are defined as follows:

```
typedef int(*InitStreamPtr)(int method, VSLStreamStatePtr stream, int n, const unsigned int
params[]);
```

```
typedef int(*sBrngPtr)(VSLStreamStatePtr stream, int n, float r[], float a, float b);
```

```
typedef int(*dBrngPtr)(VSLStreamStatePtr stream, int n, double r[], double a, double b);
```

```
typedef int(*iBrngPtr)(VSLStreamStatePtr stream, int n, unsigned int r[]);
```

## InitStream

```
int MyBrngInitStream(int method, VSLStreamStatePtr stream, int n, const unsigned int params[])
{
 /* Initialize the stream */
 ...
} /* MyBrngInitStream */
```

## Description

The initialization routine of a user-designed generator must initialize `stream` according to the specified initialization `method`, initial conditions `params` and the argument `n`. The value of `method` determines the initialization method to be used.

- If `method` is equal to 1, the initialization is by the standard generation method, which must be supported by all basic generators. In this case the function assumes that the `stream` structure was not previously initialized. The value of `n` is used as the actual number of 32-bit values passed as initial conditions

through *params*. Note, that the situation when the actual number of initial conditions passed to the function is not sufficient to initialize the generator is not an error. Whenever it occurs, the basic generator must initialize the missing conditions using default settings.

- If *method* is equal to 2, the generation is by the leapfrog method, where *n* specifies the number of computational nodes (independent streams). Here the function assumes that the *stream* was previously initialized by the standard generation method. In this case *params* contains only one element, which identifies the computational node. If the generator does not support the leapfrog method, the function must return the error code `VSL_RNG_ERROR_LEAPFROG_UNSUPPORTED`.
- If *method* is equal to 3, the generation is by the block-splitting method. Same as above, the *stream* is assumed to be previously initialized by the standard generation method; *params* is not used, *n* identifies the number of skipped elements. If the generator does not support the block-splitting method, the function must return the error code `VSL_RNG_ERROR_SKIPAHEAD_UNSUPPORTED`.

For a more detailed description of the leapfrog and the block-splitting methods, refer to the description of [vslLeapfrogStream](#) and [vslSkipAheadStream](#), respectively.

Stream state structure is individual for every generator. However, each structure has a number of fields that are the same for all the generators:

```
typedef struct
{
 unsigned int Reserved1[2];
 unsigned int Reserved2[2];
 [fields specific for the given generator]
} MyStreamState;
```

The fields *Reserved1* and *Reserved2* are reserved for private needs only, and must not be modified by the user. When including specific fields into the structure, follow the rules below:

- The fields must fully describe the current state of the generator. For example, the state of a linear congruential generator can be identified by only one initial condition;
- If the generator can use both the leapfrog and the block-splitting methods, additional fields should be introduced to identify the independent streams. For example, in  $LCG(a, c, m)$ , apart from the initial conditions, two more fields should be specified: the value of the multiplier  $a^k$  and the value of the increment  $(a^k - 1)c / (a - 1)$ .

For a more detailed discussion, refer to [Knuth81], and [Gentle98]. An example of the registration procedure can be found in the respective directory of VS examples.

## iBRng

```
int iMyBrng(VSLStreamStatePtr stream, int n, unsigned int r[])
{
 int i; /* Loop variable */
 /* Generating integer random numbers */
 /* Pay attention to word size needed to
 store only random number */
 for(i = 0; i < n; i++)
 {
 r[i] = ...;
 }
 /* Update stream state */
 ...
 return errcode;
} /* iMyBrng */
```

**NOTE**

When using 64 and 128-bit generators, consider digit capacity to store the numbers to the random vector  $r$  correctly. For example, storing one 64-bit value requires two elements of  $r$ , the first to store the lower 32 bits and the second to store the higher 32 bits. Similarly, use 4 elements of  $r$  to store a 128-bit value.

**sBRng**

```
int sMyBrng(VSLStreamStatePtr stream, int n, float r[], float a, float b)
{
 int i; /* Loop variable */
 /* Generating float (a,b) random numbers */
 for (i = 0; i < n; i++)
 {
 r[i] = ...;
 }
 /* Update stream state */
 ...
 return errcode;
} /* sMyBrng */
```

**dBRng**

```
int dMyBrng(VSLStreamStatePtr stream, int n, double r[], double a, double b)
{
 int i; /* Loop variable */
 /* Generating double (a,b) random numbers */
 for (i = 0; i < n; i++)
 {
 r[i] = ...;
 }
 /* Update stream state */
 ...
 return errcode;
} /* dMyBrng */
```

## Convolution and Correlation

Intel MKL VS provides a set of routines intended to perform linear convolution and correlation transformations for single and double precision real and complex data.

For correct definition of implemented operations, see the [Mathematical Notation and Definitions](#) section.

The current implementation provides:

- Fourier algorithms for one-dimensional single and double precision real and complex data
- Fourier algorithms for multi-dimensional single and double precision real and complex data
- Direct algorithms for one-dimensional single and double precision real and complex data
- Direct algorithms for multi-dimensional single and double precision real and complex data

One-dimensional algorithms cover the following functions from the IBM\* ESSL library:

SCONF, SCORE

SCOND, SCORD

SDCON, SDCOR

DDCON, DDCOR

SDDCON, SDDCOR.

Special wrappers are designed to simulate these ESSL functions. The wrappers are provided as sample sources:

```
{MKL}/examples/vslc/essl/vsl_wrappers
```

Additionally, you can browse the examples demonstrating the calculation of the ESSL functions through the wrappers:

```
{MKL}/examples/vslc/essl
```

The convolution and correlation API provides interfaces for Fortran 90 and C/89 languages. You can use the C89 interface with later versions of the C/C++.

Intel MKL provides the `mkl_vsl.h` header file. All header files are in the directory

```
{MKL}/include
```

The convolution and correlation API is implemented through task objects, or tasks. Task object is a data structure, or descriptor, which holds parameters that determine the specific convolution or correlation operation. Such parameters may be precision, type, and number of dimensions of user data, an identifier of the computation algorithm to be used, shapes of data arrays, and so on.

All the Intel MKL VS convolution and correlation routines process task objects in one way or another: either create a new task descriptor, change the parameter settings, compute mathematical results of the convolution or correlation using the stored parameters, or perform other operations. Accordingly, all routines are split into the following groups:

**Task Constructors** - routines that create a new task object descriptor and set up most common parameters.

**Task Editors** - routines that can set or modify some parameter settings in the existing task descriptor.

**Task Execution Routines** - compute results of the convolution or correlation operation over the actual input data, using the operation parameters held in the task descriptor.

**Task Copy** - routines used to make several copies of the task descriptor.

**Task Destructors** - routines that delete task objects and free the memory.

When the task is executed or copied for the first time, a special process runs which is called task commitment. During this process, consistency of task parameters is checked and the required work data are prepared. If the parameters are consistent, the task is tagged as committed successfully. The task remains committed until you edit its parameters. Hence, the task can be executed multiple times after a single commitment process. Since the task commitment process may include costly intermediate calculations such as preparation of Fourier transform of input data, launching the process only once can help speed up overall performance.

## Convolution and Correlation Naming Conventions

The names of routines, types, and constants in the convolution and correlation API are case-sensitive and can contain both lowercase and uppercase characters (`vslsConvExec`).

The names of routines have the following structure:

```
vsl[datatype]{Conv|Corr}<base name>
```

where

- `vsl` is a prefix indicating that the routine belongs to Intel® MKL Vector Statistics.

- [*datatype*] is optional. If present, the symbol specifies the type of the input and output data and can be *s* (for single precision real type), *d* (for double precision real type), *c* (for single precision complex type), or *z* (for double precision complex type).
- `Conv` or `Corr` specifies whether the routine refers to convolution or correlation task, respectively.
- `<base name>` field specifies a particular functionality that the routine is designed for, for example, `NewTask`, `DeleteTask`.

## Convolution and Correlation Data Types

All convolution or correlation routines use the following types for specifying data objects:

| Type           | Data Object                                        |
|----------------|----------------------------------------------------|
| VSLConvTaskPtr | Pointer to a task descriptor for convolution       |
| VSLCorrTaskPtr | Pointer to a task descriptor for correlation       |
| float          | Input/output user real data in single precision    |
| double         | Input/output user real data in double precision    |
| MKL_Complex8   | Input/output user complex data in single precision |
| MKL_Complex16  | Input/output user complex data in double precision |
| int            | All other data                                     |

Generic integer type (without specifying the byte size) is used for all integer data.

---

### NOTE

The actual size of the generic integer type is platform-dependent. Before you compile your application, set an appropriate byte size for integers. See details in the 'Using the ILP64 Interface vs. LP64 Interface' section of the *Intel® MKL Developer Guide*.

---

## Convolution and Correlation Parameters

Basic parameters held by the task descriptor are assigned values when the task object is created, copied, or modified by task editors. Parameters of the correlation or convolution task are initially set up by task constructors when the task object is created. Parameter changes or additional settings are made by task editors. More parameters which define location of the data being convolved need to be specified when the task execution routine is invoked.

According to how the parameters are passed or assigned values, all of them can be categorized as either explicit (directly passed as routine parameters when a task object is created or executed) or optional (assigned some default or implicit values during task construction).

The following table lists all applicable parameters used in the Intel MKL convolution and correlation API.

### Convolution and Correlation Task Parameters

| Name        | Category | Type    | Default Value Label             | Description                                                                                        |
|-------------|----------|---------|---------------------------------|----------------------------------------------------------------------------------------------------|
| <i>job</i>  | explicit | integer | Implied by the constructor name | Specifies whether the task relates to convolution or correlation                                   |
| <i>type</i> | explicit | integer | Implied by the constructor name | Specifies the type (real or complex) of the input/output data. Set to real in the current version. |

| Name                             | Category | Type           | Default Value Label                        | Description                                                                                                                                                                                                                                           |
|----------------------------------|----------|----------------|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>precision</i>                 | explicit | integer        | Implied by the constructor name            | Specifies precision (single or double) of the input/output data to be provided in arrays <i>x,y,z</i> .                                                                                                                                               |
| <i>mode</i>                      | explicit | integer        | None                                       | Specifies whether the convolution/correlation computation should be done via Fourier transforms, or by a direct method, or by automatically choosing between the two. See <a href="#">SetMode</a> for the list of named constants for this parameter. |
| <i>method</i>                    | optional | integer        | "auto"                                     | Hints at a particular computation method if several methods are available for the given <i>mode</i> . Setting this parameter to "auto" means that software will choose the best available method.                                                     |
| <i>internal_precision</i>        | optional | integer        | Set equal to the value of <i>precision</i> | Specifies precision of internal calculations. Can enforce double precision calculations even when input/output data are single precision. See <a href="#">SetInternalPrecision</a> for the list of named constants for this parameter.                |
| <i>dims</i>                      | explicit | integer        | None                                       | Specifies the rank (number of dimensions) of the user data provided in arrays <i>x,y,z</i> . Can be in the range from 1 to 7.                                                                                                                         |
| <i>x,y</i>                       | explicit | real arrays    | None                                       | Specify input data arrays. See <a href="#">Data Allocation</a> for more information.                                                                                                                                                                  |
| <i>z</i>                         | explicit | real array     | None                                       | Specifies output data array. See <a href="#">Data Allocation</a> for more information.                                                                                                                                                                |
| <i>xshape, yshape, zshape</i>    | explicit | integer arrays | None                                       | Define shapes of the arrays <i>x, y, z</i> . See <a href="#">Data Allocation</a> for more information.                                                                                                                                                |
| <i>xstride, ystride, zstride</i> | explicit | integer arrays | None                                       | Define strides within arrays <i>x, y, z</i> , that is specify the physical location of the input and output data in these arrays. See <a href="#">Data Allocation</a> for more information.                                                           |
| <i>start</i>                     | optional | integer array  | Undefined                                  | Defines the first element of the mathematical result that will be stored to output array <i>z</i> . See <a href="#">SetStart</a> and <a href="#">Data Allocation</a> for more information.                                                            |
| <i>decimation</i>                | optional | integer array  | Undefined                                  | Defines how to thin out the mathematical result that will be stored to output array <i>z</i> . See <a href="#">SetDecimation</a> and <a href="#">Data Allocation</a> for more information.                                                            |

Users may pass the NULL pointer instead of either or all of the parameters *xstride, ystride, or zstride* for multi-dimensional calculations. In this case, the software assumes the dense data allocation for the arrays *x, y, or z* due to the Fortran-style "by columns" representation of multi-dimensional arrays.

## Convolution and Correlation Task Status and Error Reporting

The task status is an integer value, which is zero if no error has been detected while processing the task, or a specific non-zero error code otherwise. Negative status values indicate errors, and positive values indicate warnings.

An error can be caused by invalid parameter values, a system fault like a memory allocation failure, or can be an internal error self-detected by the software.

Each task descriptor contains the current status of the task. When creating a task object, the constructor assigns the `VSL_STATUS_OK` status to the task. When processing the task afterwards, other routines such as editors or executors can change the task status if an error occurs and write a corresponding error code into the task status field.

Note that at the stage of creating a task or editing its parameters, the set of parameters may be inconsistent. The parameter consistency check is only performed during the task commitment operation, which is implicitly invoked before task execution or task copying. If an error is detected at this stage, task execution or task copying is terminated and the task descriptor saves the corresponding error code. Once an error occurs, any further attempts to process that task descriptor is terminated and the task keeps the same error code.

Normally, every convolution or correlation function (except `DeleteTask`) returns the status assigned to the task while performing the function operation.

The header files define symbolic names for the status codes. These names are defined as macros via the `#define` statements.

If there is no error, the `VSL_STATUS_OK` status is returned, which is defined as zero:

```
#define VSL_STATUS_OK 0
```

In case of an error, a non-zero error code is returned, which indicates the origin of the failure. The following status codes for the convolution/correlation error codes are pre-defined in the header files.

### Convolution/Correlation Status Codes

| Status Code                                  | Description                                 |
|----------------------------------------------|---------------------------------------------|
| <code>VSL_CC_ERROR_NOT_IMPLEMENTED</code>    | Requested functionality is not implemented. |
| <code>VSL_CC_ERROR_ALLOCATION_FAILURE</code> | Memory allocation failure.                  |
| <code>VSL_CC_ERROR_BAD_DESCRIPTOR</code>     | Task descriptor is corrupted.               |
| <code>VSL_CC_ERROR_SERVICE_FAILURE</code>    | A service function has failed.              |
| <code>VSL_CC_ERROR_EDIT_FAILURE</code>       | Failure while editing the task.             |
| <code>VSL_CC_ERROR_EDIT_PROHIBITED</code>    | You cannot edit this parameter.             |
| <code>VSL_CC_ERROR_COMMIT_FAILURE</code>     | Task commitment has failed.                 |
| <code>VSL_CC_ERROR_COPY_FAILURE</code>       | Failure while copying the task.             |
| <code>VSL_CC_ERROR_DELETE_FAILURE</code>     | Failure while deleting the task.            |
| <code>VSL_CC_ERROR_BAD_ARGUMENT</code>       | Bad argument or task parameter.             |
| <code>VSL_CC_ERROR_JOB</code>                | Bad parameter: <i>job</i> .                 |
| <code>SL_CC_ERROR_KIND</code>                | Bad parameter: <i>kind</i> .                |
| <code>VSL_CC_ERROR_MODE</code>               | Bad parameter: <i>mode</i> .                |
| <code>VSL_CC_ERROR_METHOD</code>             | Bad parameter: <i>method</i> .              |
| <code>VSL_CC_ERROR_TYPE</code>               | Bad parameter: <i>type</i> .                |

| Status Code                     | Description                                                                                                             |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| VSL_CC_ERROR_EXTERNAL_PRECISION | Bad parameter: <i>external_precision</i> .                                                                              |
| VSL_CC_ERROR_INTERNAL_PRECISION | Bad parameter: <i>internal_precision</i> .                                                                              |
| VSL_CC_ERROR_PRECISION          | Incompatible external/internal precisions.                                                                              |
| VSL_CC_ERROR_DIMS               | Bad parameter: <i>dims</i> .                                                                                            |
| VSL_CC_ERROR_XSHAPE             | Bad parameter: <i>xshape</i> .                                                                                          |
| VSL_CC_ERROR_YSHAPE             | Bad parameter: <i>yshape</i> .                                                                                          |
|                                 | Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or >nmax. |
| VSL_CC_ERROR_ZSHAPE             | Bad parameter: <i>zshape</i> .                                                                                          |
| VSL_CC_ERROR_XSTRIDE            | Bad parameter: <i>xstride</i> .                                                                                         |
| VSL_CC_ERROR_YSTRIDE            | Bad parameter: <i>ystride</i> .                                                                                         |
| VSL_CC_ERROR_ZSTRIDE            | Bad parameter: <i>zstride</i> .                                                                                         |
| VSL_CC_ERROR_X                  | Bad parameter: <i>x</i> .                                                                                               |
| VSL_CC_ERROR_Y                  | Bad parameter: <i>y</i> .                                                                                               |
| VSL_CC_ERROR_Z                  | Bad parameter: <i>z</i> .                                                                                               |
| VSL_CC_ERROR_START              | Bad parameter: <i>start</i> .                                                                                           |
| VSL_CC_ERROR_DECIMATION         | Bad parameter: <i>decimation</i> .                                                                                      |
| VSL_CC_ERROR_OTHER              | Another error.                                                                                                          |

## Convolution and Correlation Task Constructors

Task constructors are routines intended for creating a new task descriptor and setting up basic parameters. No additional parameter adjustment is typically required and other routines can use the task object.

Intel® MKL implementation of the convolution and correlation API provides two different forms of constructors: a general form and an X-form. X-form constructors work in the same way as the general form constructors but also assign particular data to the first operand vector used in the convolution or correlation operation (stored in array *x*).

Using X-form constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector held in array *x* against different vectors held in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

Each constructor routine has an associated one-dimensional version that provides algorithmic and computational benefits.

---

### NOTE

If the constructor fails to create a task descriptor, it returns the `NULL` task pointer.

---

The [Table "Task Constructors"](#) lists available task constructors:

**Task Constructors**

| <b>Routine</b>                                        | <b>Description</b>                                                                                 |
|-------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| <code>vslConvNewTask/vslCorrNewTask</code>            | Creates a new convolution or correlation task descriptor for a multidimensional case.              |
| <code>vslConvNewTask1D/<br/>vslCorrNewTask1D</code>   | Creates a new convolution or correlation task descriptor for a one-dimensional case.               |
| <code>vslConvNewTaskX/vslCorrNewTaskX</code>          | Creates a new convolution or correlation task descriptor as an X-form for a multidimensional case. |
| <code>vslConvNewTaskX1D/<br/>vslCorrNewTaskX1D</code> | Creates a new convolution or correlation task descriptor as an X-form for a one-dimensional case.  |

**vslConvNewTask/vslCorrNewTask**

*Creates a new convolution or correlation task descriptor for multidimensional case.*

**Syntax**

```
status = vslsConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vsldConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslcConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslzConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslsCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vsldCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslcCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslzCorrNewTask(task, mode, dims, xshape, yshape, zshape);
```

**Input Parameters**

| <b>Name</b>         | <b>Type</b>                | <b>Description</b>                                                                                                                                                                                                                           |
|---------------------|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mode</code>   | <code>const MKL_INT</code> | Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See <a href="#">Table "Values of mode parameter"</a> for a list of possible values.      |
| <code>dims</code>   | <code>const MKL_INT</code> | Rank of user data. Specifies number of dimensions for the input and output arrays <i>x</i> , <i>y</i> , and <i>z</i> used during the execution stage. Must be in the range from 1 to 7. The value is explicitly assigned by the constructor. |
| <code>xshape</code> | <code>const int[]</code>   | Defines the shape of the input data for the source array <i>x</i> . See <a href="#">Data Allocation</a> for more information.                                                                                                                |
| <code>yshape</code> | <code>const int[]</code>   | Defines the shape of the input data for the source array <i>y</i> . See <a href="#">Data Allocation</a> for more information.                                                                                                                |

| Name                | Type                     | Description                                                                                                                           |
|---------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------|

## Description

Each `vslConvNewTask/vslCorrNewTask` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)).

The parameters `xshape`, `yshape`, and `zshape` define the shapes of the input and output data provided by the arrays `x`, `y`, and `z`, respectively. Each shape parameter is an array of integers with its length equal to the value of `dims`. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter `dims` is 1, then `xshape`, `yshape`, `zshape` are equal to the number of elements read from the arrays `x` and `y` or stored to the array `z`. Note that values of shape parameters may differ from physical shapes of arrays `x`, `y`, and `z` if non-trivial strides are assigned.

If the constructor fails to create a task descriptor, it returns a NULL task pointer.

## vslConvNewTask1D/vslCorrNewTask1D

*Creates a new convolution or correlation task descriptor for one-dimensional case.*

### Syntax

```
status = vslsConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vsldConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vslcConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vslzConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vslsCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vsldCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vslcCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vslzCorrNewTask1D(task, mode, xshape, yshape, zshape);
```

## Description

Each `vslConvNewTask1D/vslCorrNewTask1D` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)). Unlike `vslConvNewTask/vslCorrNewTask`, these routines represent a special one-dimensional version of the constructor which assumes that the value of the parameter `dims` is 1. The parameters `xshape`, `yshape`, and `zshape` are equal to the number of elements read from the arrays `x` and `y` or stored to the array `z`. You explicitly assign the shape parameters when calling the constructor.

### **`vslConvNewTaskX/vslCorrNewTaskX`**

*Creates a new convolution or correlation task descriptor for multidimensional case and assigns source data to the first operand vector.*

### Syntax

```
status = vslsConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
```

```

status = vsldConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslcConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslzConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslsCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vsldCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslcCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslzCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);

```

## Description

Each `vslConvNewTaskX/vslCorrNewTaskX` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)).

Unlike `vslConvNewTask/vslCorrNewTask`, these routines represent the so called X-form version of the constructor, which means that in addition to creating the task descriptor they assign particular data to the first operand vector in array *x* used in convolution or correlation operation. The task descriptor created by the `vslConvNewTaskX/vslCorrNewTaskX` constructor keeps the pointer to the array *x* all the time, that is, until the task object is deleted by one of the destructor routines (see `vslConvDeleteTask/vslCorrDeleteTask`).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array *x* against different vectors in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters *xshape*, *yshape*, and *zshape* define the shapes of the input and output data provided by the arrays *x*, *y*, and *z*, respectively. Each shape parameter is an array of integers with its length equal to the value of *dims*. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter *dims* is 1, then *xshape*, *yshape*, and *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. Note that values of shape parameters may differ from physical shapes of arrays *x*, *y*, and *z* if non-trivial strides are assigned.

The stride parameter *xstride* specifies the physical location of the input data in the array *x*. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter *xstride* is *s*, then only every *s*<sup>th</sup> element of the array *x* will be used to form the input sequence. The stride value must be positive or negative but not zero.

### **vslConvNewTaskX1D/vslCorrNewTaskX1D**

*Creates a new convolution or correlation task descriptor for one-dimensional case and assigns source data to the first operand vector.*

### Syntax

```
status = vslsConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vsldConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslcConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
```

```

status = vslzConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslsCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vsldCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslcCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslzCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);

```

| <i>status</i> | int                                                                                                            | Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise. |

## Description

Each `vslConvNewTaskX1D/vslCorrNewTaskX1D` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)).

These routines represent a special one-dimensional version of the so called X-form of the constructor. This assumes that the value of the parameter `dims` is 1 and that in addition to creating the task descriptor, constructor routines assign particular data to the first operand vector in array `x` used in convolution or correlation operation. The task descriptor created by the `vslConvNewTaskX1D/vslCorrNewTaskX1D` constructor keeps the pointer to the array `x` all the time, that is, until the task object is deleted by one of the destructor routines (see [vslConvDeleteTask/vslCorrDeleteTask](#)).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters `xshape`, `yshape`, and `zshape` are equal to the number of elements read from the arrays `x` and `y` or stored to the array `z`. You explicitly assign the shape parameters when calling the constructor.

The [stride parameters](#) `xstride` specifies the physical location of the input data in the array `x` and is an interval between locations of consecutive elements of the array. For example, if the value of the parameter `xstride` is `s`, then only every `s`<sup>th</sup> element of the array `x` will be used to form the input sequence. The stride value must be positive or negative but not zero.

## Convolution and Correlation Task Editors

Task editors in convolution and correlation API of Intel MKL are routines intended for setting up or changing the following task parameters (see [Table "Convolution and Correlation Task Parameters"](#)):

- `mode`
- `internal_precision`
- `start`
- `decimation`

For setting up or changing each of the above parameters, a separate routine exists.

---

### NOTE

Fields of the task descriptor structure are accessible only through the set of task editor routines provided with the software.

---

The work data computed during the last commitment process may become invalid with respect to new parameter settings. That is why after applying any of the editor routines to change the task descriptor settings, the task loses its commitment status and goes through the full commitment process again during the next execution or copy operation. For more information on task commitment, see the [Introduction to Convolution and Correlation](#).

Table "Task Editors" lists available task editors.

### Task Editors

| Routine                                                                   | Description                                                                                                   |
|---------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------|
| <code>vslConvSetMode/vslCorrSetMode</code>                                | Changes the value of the parameter <i>mode</i> for the operation of convolution or correlation.               |
| <code>vslConvSetInternalPrecision/<br/>vslCorrSetInternalPrecision</code> | Changes the value of the parameter <i>internal_precision</i> for the operation of convolution or correlation. |
| <code>vslConvSetStart/vslCorrSetStart</code>                              | Sets the value of the parameter <i>start</i> for the operation of convolution or correlation.                 |
| <code>vslConvSetDecimation/<br/>vslCorrSetDecimation</code>               | Sets the value of the parameter <i>decimation</i> for the operation of convolution or correlation.            |

#### NOTE

You can use the `NULL` task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

### `vslConvSetMode/vslCorrSetMode`

Changes the value of the parameter *mode* in the convolution or correlation task descriptor.

#### Syntax

```
status = vslConvSetMode(task, newmode);
```

```
status = vslCorrSetMode(task, newmode);
```

#### Include Files

- `mkl.h`

#### Input Parameters

| Name           | Type                                                                                                                           | Description                              |
|----------------|--------------------------------------------------------------------------------------------------------------------------------|------------------------------------------|
| <i>task</i>    | <code>VSLConvTaskPtr</code> for <code>vslConvSetMode</code><br><br><code>VSLCorrTaskPtr</code> for <code>vslCorrSetMode</code> | Pointer to the task descriptor.          |
| <i>newmode</i> | <code>const MKL_INT</code>                                                                                                     | New value of the parameter <i>mode</i> . |

#### Output Parameters

| Name          | Type             | Description                 |
|---------------|------------------|-----------------------------|
| <i>status</i> | <code>int</code> | Current status of the task. |

#### Description

This function is declared in `mkl_vsl_functions.h`.

The function routine changes the value of the parameter `mode` for the operation of convolution or correlation. This parameter defines whether the computation should be done via Fourier transforms of the input/output data or using a direct algorithm. Initial value for `mode` is assigned by a task constructor.

Predefined values for the `mode` parameter are as follows:

### Values of `mode` parameter

| Value                             | Purpose                                                      |
|-----------------------------------|--------------------------------------------------------------|
| <code>VSL_CONV_MODE_FFT</code>    | Compute convolution by using fast Fourier transform.         |
| <code>VSL_CORR_MODE_FFT</code>    | Compute correlation by using fast Fourier transform.         |
| <code>VSL_CONV_MODE_DIRECT</code> | Compute convolution directly.                                |
| <code>VSL_CORR_MODE_DIRECT</code> | Compute correlation directly.                                |
| <code>VSL_CONV_MODE_AUTO</code>   | Automatically choose direct or Fourier mode for convolution. |
| <code>VSL_CORR_MODE_AUTO</code>   | Automatically choose direct or Fourier mode for correlation. |

### `vslConvSetInternalPrecision/vslCorrSetInternalPrecision`

Changes the value of the parameter `internal_precision` in the convolution or correlation task descriptor.

#### Syntax

```
status = vslConvSetInternalPrecision(task, precision);
```

```
status = vslCorrSetInternalPrecision(task, precision);
```

#### Include Files

- `mkl.h`

#### Input Parameters

| Name                   | Type                                                                                                                                                             | Description                                                  |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|
| <code>task</code>      | <code>VSLConvTaskPtr</code> for<br><code>vslConvSetInternalPrecision</code><br>or<br><code>VSLCorrTaskPtr</code> for<br><code>vslCorrSetInternalPrecision</code> | Pointer to the task descriptor.                              |
| <code>precision</code> | <code>const MKL_INT</code>                                                                                                                                       | New value of the parameter <code>internal_precision</code> . |

#### Output Parameters

| Name                | Type             | Description                 |
|---------------------|------------------|-----------------------------|
| <code>status</code> | <code>int</code> | Current status of the task. |

## Description

The `vslConvSetInternalPrecision/vslCorrSetInternalPrecision` routine changes the value of the parameter `internal_precision` for the operation of convolution or correlation. This parameter defines whether the internal computations of the convolution or correlation result should be done in single or double precision. Initial value for `internal_precision` is assigned by a task constructor and set to either "single" or "double" according to the particular flavor of the constructor used.

Changing the `internal_precision` can be useful if the default setting of this parameter was "single" but you want to calculate the result with double precision even if input and output data are represented in single precision.

Predefined values for the `internal_precision` input parameter are as follows:

### Values of `internal_precision` Parameter

| Value                                  | Purpose                                    |
|----------------------------------------|--------------------------------------------|
| <code>VSL_CONV_PRECISION_SINGLE</code> | Compute convolution with single precision. |
| <code>VSL_CORR_PRECISION_SINGLE</code> | Compute correlation with single precision. |
| <code>VSL_CONV_PRECISION_DOUBLE</code> | Compute convolution with double precision. |
| <code>VSL_CORR_PRECISION_DOUBLE</code> | Compute correlation with double precision. |

### `vslConvSetStart/vslCorrSetStart`

*Changes the value of the parameter `start` in the convolution or correlation task descriptor.*

### Syntax

```
status = vslConvSetStart(task, start);
status = vslCorrSetStart(task, start);
```

### Include Files

- `mkl.h`

### Input Parameters

| Name               | Type                                                                                                                             | Description                                     |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------|
| <code>task</code>  | <code>VSLConvTaskPtr</code> for <code>vslConvSetStart</code><br><br><code>VSLCorrTaskPtr</code> for <code>vslCorrSetStart</code> | Pointer to the task descriptor.                 |
| <code>start</code> | <code>const int[]</code>                                                                                                         | New value of the parameter <code>start</code> . |

### Output Parameters

| Name                | Type             | Description                 |
|---------------------|------------------|-----------------------------|
| <code>status</code> | <code>int</code> | Current status of the task. |

## Description

The `vslConvSetStart/vslCorrSetStart` routine sets the value of the parameter `start` for the operation of convolution or correlation. In a one-dimensional case, this parameter points to the first element in the mathematical result that should be stored in the output array. In a multidimensional case, `start` is an array of indices and its length is equal to the number of dimensions specified by the parameter `dims`. For more information about the definition and effect of this parameter, see [Data Allocation](#).

During the initial task descriptor construction, the default value for `start` is undefined and this parameter is not used. Therefore the only way to set and use the `start` parameter is via assigning it some value by one of the `vslConvSetStart/vslCorrSetStart` routines.

## vslConvSetDecimation/vslCorrSetDecimation

*Changes the value of the parameter `decimation` in the convolution or correlation task descriptor.*

## Syntax

```
status = vslConvSetDecimation(task, decimation);
```

```
status = vslCorrSetDecimation(task, decimation);
```

## Include Files

- `mkl.h`

## Input Parameters

| Name                                      | Type                                                                                                                   | Description                                          |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|
| <code>task</code>                         | VSLConvTaskPtr for<br><code>vslConvSetDecimation</code><br><br>VSLCorrTaskPtr for<br><code>vslCorrSetDecimation</code> | Pointer to the task descriptor.                      |
| <code>decimation</code><br><code>n</code> | <code>const int[]</code>                                                                                               | New value of the parameter <code>decimation</code> . |

## Output Parameters

| Name                | Type             | Description                 |
|---------------------|------------------|-----------------------------|
| <code>status</code> | <code>int</code> | Current status of the task. |

## Description

The routine sets the value of the parameter `decimation` for the operation of convolution or correlation. This parameter determines how to thin out the mathematical result of convolution or correlation before writing it into the output data array. For example, in a one-dimensional case, if `decimation = d > 1`, only every `d`-th element of the mathematical result is written to the output array `z`. In a multidimensional case, `decimation` is an array of indices and its length is equal to the number of dimensions specified by the parameter `dims`. For more information about the definition and effect of this parameter, see [Data Allocation](#).

During the initial task descriptor construction, the default value for `decimation` is undefined and this parameter is not used. Therefore the only way to set and use the `decimation` parameter is via assigning it some value by one of the `vslSetDecimation` routines.

## Task Execution Routines

Task execution routines compute convolution or correlation results based on parameters held by the task descriptor and on the user data supplied for input vectors.

After you create and adjust a task, you can execute it multiple times by applying to different input/output data of the same type, precision, and shape.

Intel MKL provides the following forms of convolution/correlation execution routines:

- **General form** executors that use the task descriptor created by the general form constructor and expect to get two source data arrays *x* and *y* on input
- **X-form** executors that use the task descriptor created by the X-form constructor and expect to get only one source data array *y* on input because the first array *x* has been already specified on the construction stage

When the task is executed for the first time, the execution routine includes a task commitment operation, which involves two basic steps: parameters consistency check and preparation of auxiliary data (for example, this might be the calculation of Fourier transform for input data).

Each execution routine has an associated one-dimensional version that provides algorithmic and computational benefits.

---

### NOTE

You can use the `NULL` task pointer in calls to execution routines. In this case, the routine is terminated and no system crash occurs.

---

If the task is executed successfully, the execution routine returns the zero status code. If an error is detected, the execution routine returns an error code which signals that a specific error has occurred. In particular, an error status code is returned in the following cases:

- if the task pointer is `NULL`
- if the task descriptor is corrupted
- if calculation has failed for some other reason.

---

### NOTE

Intel® MKL does not control floating-point errors, like overflow or gradual underflow, or operations with NaNs, etc.

---

If an error occurs, the task descriptor stores the error code.

The table below lists all task execution routines.

### Task Execution Routines

| Routine                                    | Description                                                                |
|--------------------------------------------|----------------------------------------------------------------------------|
| <code>vslConvExec/vslCorrExec</code>       | Computes convolution or correlation for a multidimensional case.           |
| <code>vslConvExec1D/vslCorrExec1D</code>   | Computes convolution or correlation for a one-dimensional case.            |
| <code>vslConvExecX/vslCorrExecX</code>     | Computes convolution or correlation as X-form for a multidimensional case. |
| <code>vslConvExecX1D/vslCorrExecX1D</code> | Computes convolution or correlation as X-form for a one-dimensional case.  |

### `vslConvExec/vslCorrExec`

*Computes convolution or correlation for multidimensional case.*

---

## Syntax

```

status = vslsConvExec(task, x, xstride, y, ystride, z, zstride);
status = vsldConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslcConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslzConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslsCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vsldCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vslcCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vslzCorrExec(task, x, xstride, y, ystride, z, zstride);

## Description

Each of the `vslConvExec/vslCorrExec` routines computes convolution or correlation of the data provided by the arrays *x* and *y* and then stores the results in the array *z*. Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTask/vslCorrNewTask` constructor and pointed to by *task*. If *task* is NULL, no operation is done.

The stride parameters *xstride*, *ystride*, and *zstride* specify the physical location of the input and output data in the arrays *x*, *y*, and *z*, respectively. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter *zstride* is *s*, then only every *s*<sup>th</sup> element of the array *z* will be used to store the output data. The stride value must be positive or negative but not zero.

## vslConvExec1D/vslCorrExec1D

*Computes convolution or correlation for one-dimensional case.*

### Syntax

```

status = vslsConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vsldConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslcConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslzConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslsCorrExec1D(task, x, xstride, y, ystride, z, zstride);
status = vsldCorrExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslcCorrExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslzCorrExec1D(task, x, xstride, y, ystride, z, zstride);

```

## Description

Each of the `vslConvExec1D/vslCorrExec1D` routines computes convolution or correlation of the data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special one-dimensional version of the operation, assuming that the value of the parameter `dims` is 1. Using this version of execution routines can help speed up performance in case of one-dimensional data.

Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTask1D/vslCorrNewTask1D` constructor and pointed to by `task`. If `task` is `NULL`, no operation is done.

## vslConvExecX/vslCorrExecX

*Computes convolution or correlation for multidimensional case with the fixed first operand vector.*

---

## Syntax

```
status = vslsConvExecX(task, y, ystride, z, zstride);
status = vsldConvExecX(task, y, ystride, z, zstride);
status = vslcConvExecX(task, y, ystride, z, zstride);
status = vslzConvExecX(task, y, ystride, z, zstride);
status = vslsCorrExecX(task, y, ystride, z, zstride);
status = vslcCorrExecX(task, y, ystride, z, zstride);
status = vslzCorrExecX(task, y, ystride, z, zstride);
status = vsldCorrExecX(task, y, ystride, z, zstride);
```

## Description

Each of the `vs1ConvExecX/vs1CorrExecX` routines computes convolution or correlation of the data provided by the arrays *x* and *y* and then stores the results in the array *z*. These routines represent a special version of the operation, which assumes that the first operand vector was set on the task construction stage and the task object keeps the pointer to the array *x*.

Parameters of the operation are read from the task descriptor created previously by a corresponding `vs1ConvNewTaskX/vs1CorrNewTaskX` constructor and pointed to by *task*. If *task* is NULL, no operation is done.

Using this form of execution routines is recommended when you need to compute multiple convolutions or correlations with the same data vector in array *x* against different vectors in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

### `vs1ConvExecX1D/vs1CorrExecX1D`

*Computes convolution or correlation for one-dimensional case with the fixed first operand vector.*

### Syntax

```
status = vs1sConvExecX1D(task, y, ystride, z, zstride);
```

```

status = vsldConvExecX1D(task, y, ystride, z, zstride);
status = vslcConvExecX1D(task, y, ystride, z, zstride);
status = vslzConvExecX1D(task, y, ystride, z, zstride);
status = vslsCorrExecX1D(task, y, ystride, z, zstride);
status = vslcCorrExecX1D(task, y, ystride, z, zstride);
status = vslzCorrExecX1D(task, y, ystride, z, zstride);
status = vsldCorrExecX1D(task, y, ystride, z, zstride);

```

| <i>status</i> | int                                                                                                                                                                                                                 | Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise. |

## Description

Each of the `vslConvExecX1D/vslCorrExecX1D` routines computes convolution or correlation of one-dimensional (assuming that `dims = 1`) data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special version of the operation, which expects that the first operand vector was set on the task construction stage.

Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTaskX1D/vslCorrNewTaskX1D` constructor and pointed to by `task`. If `task` is NULL, no operation is done.

Using this form of execution routines is recommended when you need to compute multiple one-dimensional convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

## Convolution and Correlation Task Destructors

Task destructors are routines designed for deleting task objects and deallocating memory.

### `vslConvDeleteTask/vslCorrDeleteTask`

*Destroys the task object and frees the memory.*

#### Syntax

```
errcode = vslConvDeleteTask(task);
```

```
errcode = vslCorrDeleteTask(task);
```

#### Include Files

- `mkl.h`

#### Input Parameters

| Name        | Type                                                  | Description                     |
|-------------|-------------------------------------------------------|---------------------------------|
| <i>task</i> | VSLConvTaskPtr* for<br><code>vslConvDeleteTask</code> | Pointer to the task descriptor. |

| Name | Type                                     | Description |
|------|------------------------------------------|-------------|
|      | VSLCorrTaskPtr* for<br>vslCorrDeleteTask |             |

### Output Parameters

| Name           | Type | Description                                                                                            |
|----------------|------|--------------------------------------------------------------------------------------------------------|
| <i>errcode</i> | int  | Contains 0 if the task object is deleted successfully.<br>Contains an error code if an error occurred. |

### Description

The `vslConvDeleteTask/vslCorrvDeleteTask` routine deletes the task descriptor object and frees any working memory and the memory allocated for the data structure. The task pointer is set to `NULL`.

Note that if the `vslConvDeleteTask/vslCorrvDeleteTask` routine does not delete the task successfully, the routine returns an error code. This error code has no relation to the task status code and does not change it.

---

#### NOTE

You can use the `NULL` task pointer in calls to destructor routines. In this case, the routine terminates with no system crash.

---

## Convolution and Correlation Task Copiers

The routines are designed for copying convolution and correlation task descriptors.

### `vslConvCopyTask/vslCorrCopyTask`

*Copies a descriptor for convolution or correlation task.*

#### Syntax

```
status = vslConvCopyTask(newtask, srctask);
```

```
status = vslCorrCopyTask(newtask, srctask);
```

#### Include Files

- `mkl.h`

### Input Parameters

| Name           | Type                                                                                                                     | Description                            |
|----------------|--------------------------------------------------------------------------------------------------------------------------|----------------------------------------|
| <i>srctask</i> | const VSLConvTaskPtr for<br><code>vslConvCopyTask</code><br><br>const VSLCorrTaskPtr for<br><code>vslCorrCopyTask</code> | Pointer to the source task descriptor. |

## Output Parameters

| Name           | Type                                                                                 | Description                         |
|----------------|--------------------------------------------------------------------------------------|-------------------------------------|
| <i>newtask</i> | VSLConvTaskPtr* for<br>vslConvCopyTask<br><br>VSLCorrTaskPtr* for<br>vslCorrCopyTask | Pointer to the new task descriptor. |
| <i>status</i>  | int                                                                                  | Current status of the source task.  |

## Description

If a task object *srctask* already exists, you can use an appropriate `vslConvCopyTask/vslCorrCopyTask` routine to make its copy in *newtask*. After the copy operation, both source and new task objects will become committed (see [Introduction to Convolution and Correlation](#) for information about task commitment). If the source task was not previously committed, the commitment operation for this task is implicitly invoked before copying starts. If an error occurs during source task commitment, the task stores the error code in the status field. If an error occurs during copy operation, the routine returns a `NULL` pointer instead of a reference to a new task object.

## Convolution and Correlation Usage Examples

This section demonstrates how you can use the Intel MKL routines to perform some common convolution and correlation operations both for single-threaded and multithreaded calculations. The following two sample functions `scond1` and `sconf1` simulate the convolution and correlation functions `SCOND` and `SCONF` found in IBM ESSL\* library. The functions assume single-threaded calculations and can be used with C or C++ compilers.

### Function `scond1` for Single-Threaded Calculations

```
#include "mkl_vsl.h"

int acond1(
 float h[], int inch,
 float x[], int incx,
 float y[], int incy,
 int nh, int nx, int iy0, int ny)
{
 int status;
 VSLConvTaskPtr task;
 vslsConvNewTask1D(&task, VSL_CONV_MODE_DIRECT, nh, nx, ny);
 vslConvSetStart(task, &iy0);
 status = vslsConvExec1D(task, h, inch, x, incx, y, incy);
 vslConvDeleteTask(&task);
 return status;
}
```

## Function `sconf1` for Single-Threaded Calculations

```
#include "mkl_vsl.h"

int sconf1(
 int init,
 float h[], int inclh,
 float x[], int inclx, int inc2x,
 float y[], int incly, int inc2y,
 int nh, int nx, int m, int iy0, int ny,
 void* aux1, int nau1, void* aux2, int nau2)
{
 int status;

 /* assume that aux1!=0 and nau1 is big enough */
 VSLConvTaskPtr* task = (VSLConvTaskPtr*)aux1;

 if (init != 0)
 /* initialization: */
 status = vslsConvNewTaskX1D(task, VSL_CONV_MODE_FFT,
 nh, nx, ny, h, inclh);

 if (init == 0) {
 /* calculations: */
 int i;
 vslConvSetStart(*task, &iy0);
 for (i=0; i<m; i++) {
 float* xi = &x[inc2x * i];
 float* yi = &y[inc2y * i];

 /* task is implicitly committed at i==0 */
 status = vslsConvExecX1D(*task, xi, inclx, yi, incly);
 };
 };

 vslConvDeleteTask(task);

 return status;
}
```

## Using Multiple Threads

For functions such as `sconf1` described in the previous example, parallel calculations may be more preferable instead of cycling. If  $m > 1$ , you can use multiple threads for invoking the task execution against different data sequences. For such cases, use task copy routines to create  $m$  copies of the task object before the calculations stage and then run these copies with different threads. Ensure that you make all necessary parameter adjustments for the task (using [Task Editors](#)) before copying it.

The sample code in this case may look as follows:

```
if (init == 0) {
 int i, status, ss[M];
 VSLConvTaskPtr tasks[M];
 /* assume that M is big enough */
 . . .
 vslConvSetStart(*task, &iy0);
 . . .
 for (i=0; i<m; i++)
 /* implicit commitment at i==0 */
 vslConvCopyTask(&tasks[i],*task);
 . . .
}
```

Then,  $m$  threads may be started to execute different copies of the task:

```
. . .
 float* xi = &x[inc2x * i];
 float* yi = &y[inc2y * i];
 ss[i]=vslsConvExecX1D(tasks[i], xi,inc1x, yi,inc1y);
 . . .
}
```

And finally, after all threads have finished the calculations, overall status should be collected from all task objects. The following code signals the first error found, if any:

```
. . .
for (i=0; i<m; i++) {
 status = ss[i];
 if (status != 0) /* 0 means "OK" */
 break;
};
return status;
}; /* end if init==0 */
```

Execution routines modify the task internal state (fields of the task structure). Such modifications may conflict with each other if different threads work with the same task object simultaneously. That is why different threads must use different copies of the task.

#### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

### Convolution and Correlation Mathematical Notation and Definitions

The following notation is necessary to explain the underlying mathematical definitions used in the text:

|                                                            |                                                                                |
|------------------------------------------------------------|--------------------------------------------------------------------------------|
| $\mathbf{R} = (-\infty, +\infty)$                          | The set of real numbers.                                                       |
| $\mathbf{Z} = \{0, \pm 1, \pm 2, \dots\}$                  | The set of integer numbers.                                                    |
| $\mathbf{Z}^N = \mathbf{Z} \times \dots \times \mathbf{Z}$ | The set of N-dimensional series of integer numbers.                            |
| $p = (p_1, \dots, p_N) \in \mathbf{Z}^N$                   | N-dimensional series of integers.                                              |
| $u: \mathbf{Z}^N \rightarrow \mathbf{R}$                   | Function $u$ with arguments from $\mathbf{Z}^N$ and values from $\mathbf{R}$ . |
| $u(p) = u(p_1, \dots, p_N)$                                | The value of the function $u$ for the argument $(p_1, \dots, p_N)$ .           |
| $w = u * v$                                                | Function $w$ is the convolution of the functions $u, v$ .                      |
| $w = u \bullet v$                                          | Function $w$ is the correlation of the functions $u, v$ .                      |

Given series  $p, q \in \mathbf{Z}^N$ :

- series  $r = p + q$  is defined as  $r^n = p^n + q^n$  for every  $n=1, \dots, N$
- series  $r = p - q$  is defined as  $r^n = p^n - q^n$  for every  $n=1, \dots, N$
- series  $r = \sup\{p, q\}$  is defines as  $r^n = \max\{p^n, q^n\}$  for every  $n=1, \dots, N$
- series  $r = \inf\{p, q\}$  is defined as  $r^n = \min\{p^n, q^n\}$  for every  $n=1, \dots, N$
- inequality  $p \leq q$  means that  $p^n \leq q^n$  for every  $n=1, \dots, N$ .

A function  $u(p)$  is called a finite function if there exist series  $p^{\min}, p^{\max} \in \mathbf{Z}^N$  such that:

$$u(p) \neq 0$$

implies

$$p^{\min} \leq p \leq p^{\max}.$$

Operations of convolution and correlation are only defined for finite functions.

Consider functions  $u, v$  and series  $p^{\min}, p^{\max}, q^{\min}, q^{\max} \in \mathbf{Z}^N$  such that:

$$u(p) \neq 0 \text{ implies } p^{\min} \leq p \leq p^{\max}.$$

$$v(q) \neq 0 \text{ implies } q^{\min} \leq q \leq q^{\max}.$$

Definitions of linear correlation and linear convolution for functions  $u$  and  $v$  are given below.

#### Linear Convolution

If function  $w = u * v$  is the convolution of  $u$  and  $v$ , then:

$$w(r) \neq 0 \text{ implies } \mathbf{R}^{\min} \leq r \leq \mathbf{R}^{\max},$$

$$\text{where } \mathbf{R}^{\min} = p^{\min} + q^{\min} \text{ and } \mathbf{R}^{\max} = p^{\max} + q^{\max}.$$

If  $\mathbf{R}^{\min} \leq r \leq \mathbf{R}^{\max}$ , then:

$$w(r) = \sum u(t) \cdot v(r-t) \text{ is the sum for all } t \in \mathbf{Z}^N \text{ such that } \mathbf{T}^{\min} \leq t \leq \mathbf{T}^{\max},$$

$$\text{where } \mathbf{T}^{\min} = \sup\{p^{\min}, r - q^{\max}\} \text{ and } \mathbf{T}^{\max} = \inf\{p^{\max}, r - q^{\min}\}.$$

#### Linear Correlation

If function  $w = u \bullet v$  is the correlation of  $u$  and  $v$ , then:

$$w(r) \neq 0 \text{ implies } \mathbf{R}^{\min} \leq r \leq \mathbf{R}^{\max},$$

$$\text{where } \mathbf{R}^{\min} = q^{\min} - p^{\max} \text{ and } \mathbf{R}^{\max} = q^{\max} - p^{\min}.$$

If  $\mathbf{R}^{\min} \leq r \leq \mathbf{R}^{\max}$ , then:

$w(r) = \sum u(t) \cdot v(r+t)$  is the sum for all  $t \in \mathbf{Z}^N$  such that  $\mathbf{T}^{\min} \leq t \leq \mathbf{T}^{\max}$ , where  $\mathbf{T}^{\min} = \sup\{\mathbf{P}^{\min}, \mathbf{Q}^{\min}-r\}$  and  $\mathbf{T}^{\max} = \inf\{\mathbf{P}^{\max}, \mathbf{Q}^{\max}-r\}$ .

Representation of the functions  $u$ ,  $v$ ,  $w$  as the input/output data for the Intel MKL convolution and correlation functions is described in the [Data Allocation](#) section below.

## Convolution and Correlation Data Allocation

This section explains the relation between:

- mathematical finite functions  $u$ ,  $v$ ,  $w$  introduced in the section [Mathematical Notation and Definitions](#);
- multi-dimensional input and output data vectors representing the functions  $u$ ,  $v$ ,  $w$ ;
- arrays  $u$ ,  $v$ ,  $w$  used to store the input and output data vectors in computer memory

The convolution and correlation routine parameters that determine the allocation of input and output data are the following:

- Data arrays  $x$ ,  $y$ ,  $z$
- Shape arrays  $xshape$ ,  $yshape$ ,  $zshape$
- Strides within arrays  $xstride$ ,  $ystride$ ,  $zstride$
- Parameters  $start$ ,  $decimation$

### Finite Functions and Data Vectors

The finite functions  $u(p)$ ,  $v(q)$ , and  $w(r)$  introduced above are represented as multi-dimensional vectors of input and output data:

`inputu(i1, ..., idims)` for  $u(p_1, \dots, p_N)$

`inputv(j1, ..., jdims)` for  $v(q_1, \dots, q_N)$

`output(k1, ..., kdims)` for  $w(r_1, \dots, r_N)$ .

Parameter *dims* represents the number of dimensions and is equal to  $N$ .

The parameters *xshape*, *yshape*, and *zshape* define the shapes of input/output vectors:

`inputu(i1, ..., idims)` is defined if  $1 \leq i_n \leq xshape(n)$  for every  $n=1, \dots, dims$

`inputv(j1, ..., jdims)` is defined if  $1 \leq j_n \leq yshape(n)$  for every  $n=1, \dots, dims$

`output(k1, ..., kdims)` is defined if  $1 \leq k_n \leq zshape(n)$  for every  $n=1, \dots, dims$ .

Relation between the input vectors and the functions  $u$  and  $v$  is defined by the following formulas:

`inputu(i1, ..., idims)` =  $u(p_1, \dots, p_N)$ , where  $p_n = P_n^{\min} + (i_n - 1)$  for every  $n$

`inputv(j1, ..., jdims)` =  $v(q_1, \dots, q_N)$ , where  $q_n = Q_n^{\min} + (j_n - 1)$  for every  $n$ .

The relation between the output vector and the function  $w(r)$  is similar (but only in the case when parameters *start* and *decimation* are not defined):

`output(k1, ..., kdims)` =  $w(r_1, \dots, r_N)$ , where  $r_n = R_n^{\min} + (k_n - 1)$  for every  $n$ .

If the parameter *start* is defined, it must belong to the interval  $R_n^{\min} \leq start(n) \leq R_n^{\max}$ . If defined, the *start* parameter replaces  $R_n^{\min}$  in the formula:

`output(k1, ..., kdims)` =  $w(r_1, \dots, r_N)$ , where  $r_n = start(n) + (k_n - 1)$

If the parameter *decimation* is defined, it changes the relation according to the following formula:

`output(k1, ..., kdims)` =  $w(r_1, \dots, r_N)$ , where  $r_n = R_n^{\min} + (k_n - 1) * decimation(n)$

If both parameters *start* and *decimation* are defined, the formula is as follows:

$\text{output}(k_1, \dots, k_{\text{dims}}) = w(r_1, \dots, r_N)$ , where  $r_n = \text{start}(n) + (k_n - 1) \cdot \text{decimation}(n)$

The convolution and correlation software checks the values of *zshape*, *start*, and *decimation* during task commitment. If  $r_n$  exceeds  $R_n^{\text{max}}$  for some  $k_n, n=1, \dots, \text{dims}$ , an error is raised.

### Allocation of Data Vectors

Both parameter arrays *x* and *y* contain input data vectors in memory, while array *z* is intended for storing output data vector. To access the memory, the convolution and correlation software uses only pointers to these arrays and ignores the array shapes.

For parameters *x*, *y*, and *z*, you can provide one-dimensional arrays with the requirement that actual length of these arrays be sufficient to store the data vectors.

The allocation of the input and output data inside the arrays *x*, *y*, and *z* is described below assuming that the arrays are one-dimensional. Given multi-dimensional indices  $i, j, k \in \mathbf{Z}^N$ , one-dimensional indices  $e, f, g \in \mathbf{Z}$  are defined such that:

$\text{inputu}(i_1, \dots, i_{\text{dims}})$  is allocated at  $x(e)$   
 $\text{inputv}(j_1, \dots, j_{\text{dims}})$  is allocated at  $y(f)$   
 $\text{output}(k_1, \dots, k_{\text{dims}})$  is allocated at  $z(g)$ .

The indices *e*, *f*, and *g* are defined as follows:

$e = 1 + \sum x\text{stride}(n) \cdot dx(n)$  (the sum is for all  $n=1, \dots, \text{dims}$ )  
 $f = 1 + \sum y\text{stride}(n) \cdot dy(n)$  (the sum is for all  $n=1, \dots, \text{dims}$ )  
 $g = 1 + \sum z\text{stride}(n) \cdot dz(n)$  (the sum is for all  $n=1, \dots, \text{dims}$ )

The distances  $dx(n)$ ,  $dy(n)$ , and  $dz(n)$  depend on the signum of the stride:

$dx(n) = i_n - 1$  if  $x\text{stride}(n) > 0$ , or  $dx(n) = i_n - x\text{shape}(n)$  if  $x\text{stride}(n) < 0$   
 $dy(n) = j_n - 1$  if  $y\text{stride}(n) > 0$ , or  $dy(n) = j_n - y\text{shape}(n)$  if  $y\text{stride}(n) < 0$   
 $dz(n) = k_n - 1$  if  $z\text{stride}(n) > 0$ , or  $dz(n) = k_n - z\text{shape}(n)$  if  $z\text{stride}(n) < 0$

The definitions of indices *e*, *f*, and *g* assume that indexes for arrays *x*, *y*, and *z* are started from unity:

$x(e)$  is defined for  $e=1, \dots, \text{length}(x)$   
 $y(f)$  is defined for  $f=1, \dots, \text{length}(y)$   
 $z(g)$  is defined for  $g=1, \dots, \text{length}(z)$

Below is a detailed explanation about how elements of the multi-dimensional output vector are stored in the array *z* for one-dimensional and two-dimensional cases.

**One-dimensional case.** If  $\text{dims}=1$ , then *zshape* is the number of the output values to be stored in the array *z*. The actual length of array *z* may be greater than *zshape* elements.

If  $z\text{stride} > 1$ , output values are stored with the stride:  $\text{output}(1)$  is stored to  $z(1)$ ,  $\text{output}(2)$  is stored to  $z(1+z\text{stride})$ , and so on. Hence, the actual length of *z* must be at least  $1+z\text{stride} \cdot (z\text{shape}-1)$  elements or more.

If  $z\text{stride} < 0$ , it still defines the stride between elements of array *z*. However, the order of the used elements is the opposite. For the *k*-th output value,  $\text{output}(k)$  is stored in  $z(1+|z\text{stride}| \cdot (z\text{shape}-k))$ , where  $|z\text{stride}|$  is the absolute value of *zstride*. The actual length of the array *z* must be at least  $1+|z\text{stride}| \cdot (z\text{shape} - 1)$  elements.

**Two-dimensional case.** If  $\text{dims}=2$ , the output data is a two-dimensional matrix. The value  $z\text{stride}(1)$  defines the stride inside matrix columns, that is, the stride between the  $\text{output}(k_1, k_2)$  and  $\text{output}(k_1+1, k_2)$  for every pair of indices  $k_1, k_2$ . On the other hand,  $z\text{stride}(2)$  defines the stride between columns, that is, the stride between  $\text{output}(k_1, k_2)$  and  $\text{output}(k_1, k_2+1)$ .

If `zstride(2)` is greater than `zshape(1)`, this causes sparse allocation of columns. If the value of `zstride(2)` is smaller than `zshape(1)`, this may result in the transposition of the output matrix. For example, if `zshape = (2,3)`, you can define `zstride = (3,1)` to allocate output values like transposed matrix of the shape `3x2`.

Whether `zstride` assumes this kind of transformations or not, you need to ensure that different elements output ( $k_1, \dots, k_{\text{dims}}$ ) will be stored in different locations  $z(g)$ .

## Summary Statistics

The Summary Statistics domain provides routines that compute basic statistical estimates for single and double precision multi-dimensional datasets.

The Summary Statistics routines calculate:

- raw and central moments up to the fourth order
- skewness and excess kurtosis (further referred to as *kurtosis* for brevity)
- variation coefficient
- quantiles and order statistics
- minimum and maximum
- variance-covariance/correlation matrix
- pooled/group variance-covariance matrix and mean
- partial variance-covariance/correlation matrix
- robust estimators for variance-covariance matrix and mean in presence of outliers
- raw/central partial sums up to the fourth order (for brevity referred to as *raw/central sums*)
- matrix of cross-products and sums of squares (for brevity referred to as *cross-product matrix*)
- median absolute deviation, mean absolute deviation

The library also contains functions to perform the following tasks:

- Detect outliers in datasets
- Support missing values in datasets
- Parameterize correlation matrices
- Compute quantiles for streaming data

The [Mathematical Notation and Definitions](#) section defines the supported operations in the Summary Statistics routines.

You can access the Summary Statistics routines through the Fortran 90 and C89 language interfaces. You can use the C89 interface with later versions of the C/C++.

The `mk1_vs1.h` header file is in the `/${MKL}/include` directory.

You can find examples that demonstrate calculation of the Summary Statistics estimates in the `/${MKL}/examples/vslc` example directory.

The Summary Statistics API is implemented through task objects, or tasks. A task object is a data structure, or a descriptor, holding parameters that determine a specific Summary Statistics operation. For example, such parameters may be precision, dimensions of user data, the matrix of the observations, or shapes of data arrays.

All the Summary Statistics routines process a task object as follows:

1. Create a task.
2. Modify settings of the task parameters.
3. Compute statistical estimates.
4. Destroy the task.

The Summary Statistics functions fall into the following categories:

**Task Constructors** - routines that create a new task object descriptor and set up most common parameters (dimension, number of observations, and matrix of the observations).

**Task Editors** - routines that can set or modify some parameter settings in the existing task descriptor.

**Task Computation Routine** - a routine that computes specified statistical estimates.

**Task Destructor** - a routine that deletes the task object and frees the memory.

A Summary Statistics task object contains a series of pointers to the input and output data arrays. You can read and modify the datasets and estimates at any time but you should allocate and release memory for such data.

See detailed information on the algorithms, API, and their usage in the *Intel® MKL Summary Statistics Application Notes [SS Notes]*.

## Summary Statistics Naming Conventions

The names of Summary Statistics routines, types, and constants are case-sensitive and can contain lowercase and uppercase characters (`vslsSSEditQuantiles`).

The names of routines have the following structure:

```
vsl[datatype]SS<base name>
```

where

- `vsl` is a prefix indicating that the routine belongs to Intel MKL Vector Statistics.
- `[datatype]` specifies the type of the input and/or output data and can be `s` (single precision real type), `d` (double precision real type), or `i` (integer type).
- `SS/ss` indicates that the routine is intended for calculations of the Summary Statistics estimates.
- `<base name>` specifies a particular functionality that the routine is designed for, for example, `NewTask`, `Compute`, `DeleteTask`.

---

### NOTE

The Summary Statistics routine `vslDeleteTask` for deletion of the task is independent of the data type and its name omits the `[datatype]` field.

---

## Summary Statistics Data Types

The Summary Statistics routines use the following data types for calculations:

| Type                                           | Data Object                                |
|------------------------------------------------|--------------------------------------------|
| <code>VSLSSSTaskPtr</code>                     | Pointer to a Summary Statistics task       |
| <code>float</code>                             | Input/output user data in single precision |
| <code>double</code>                            | Input/output user data in double precision |
| <code>MKL_INT</code> or <code>long long</code> | Other data                                 |

---

### NOTE

The actual size of the generic integer type is platform-specific and can be 32 or 64 bits in length. Before you compile your application, set an appropriate size for integers. See details in the 'Using the ILP64 Interface vs. LP64 Interface' section of the *Intel® MKL Developer Guide*.

---

## Summary Statistics Parameters

The basic parameters in the task descriptor (addresses of dimensions, number of observations, and datasets) are assigned values when the task editors create or modify the task object. Other parameters are determined by the specific task and changed by the task editors.

## Summary Statistics Task Status and Error Reporting

The task status is an integer value, which is zero if no error is detected, or a specific non-zero error code otherwise. Negative status values indicate errors, and positive values indicate warnings. An error can be caused by invalid parameter values or a memory allocation failure.

The header files define symbolic names for the status codes. These names are defined as macros via `#define` statements.

The header files define the following status codes for the Summary Statistics error codes:

### Summary Statistics Status Codes

| Status Code                        | Description                                                     |
|------------------------------------|-----------------------------------------------------------------|
| VSL_STATUS_OK                      | Operation is successfully completed.                            |
| VSL_SS_ERROR_ALLOCATION_FAILURE    | Memory allocation has failed.                                   |
| VSL_SS_ERROR_BAD_DIMEN             | Dimension value is invalid.                                     |
| VSL_SS_ERROR_BAD_OBSERV_N          | Invalid number (zero or negative) of observations was obtained. |
| VSL_SS_ERROR_STORAGE_NOT_SUPPORTED | Storage format is not supported.                                |
| VSL_SS_ERROR_BAD_INDC_ADDR         | Array of indices is not defined.                                |
| VSL_SS_ERROR_BAD_WEIGHTS           | Array of weights contains negative values.                      |
| VSL_SS_ERROR_BAD_MEAN_ADDR         | Array of means is not defined.                                  |
| VSL_SS_ERROR_BAD_2R_MOM_ADDR       | Array of the second order raw moments is not defined.           |
| VSL_SS_ERROR_BAD_3R_MOM_ADDR       | Array of the third order raw moments is not defined.            |
| VSL_SS_ERROR_BAD_4R_MOM_ADDR       | Array of the fourth order raw moments is not defined.           |
| VSL_SS_ERROR_BAD_2C_MOM_ADDR       | Array of the second order central moments is not defined.       |
| VSL_SS_ERROR_BAD_3C_MOM_ADDR       | Array of the third order central moments is not defined.        |
| VSL_SS_ERROR_BAD_4C_MOM_ADDR       | Array of the fourth order central moments is not defined.       |
| VSL_SS_ERROR_BAD_KURTOSIS_ADDR     | Array of kurtosis values is not defined.                        |
| VSL_SS_ERROR_BAD_SKEWNESS_ADDR     | Array of skewness values is not defined.                        |
| VSL_SS_ERROR_BAD_MIN_ADDR          | Array of minimum values is not defined.                         |
| VSL_SS_ERROR_BAD_MAX_ADDR          | Array of maximum values is not defined.                         |

| Status Code                               | Description                                                                                |
|-------------------------------------------|--------------------------------------------------------------------------------------------|
| VSL_SS_ERROR_BAD_VARIATION_ADDR           | Array of variation coefficients is not defined.                                            |
| VSL_SS_ERROR_BAD_COV_ADDR                 | Covariance matrix is not defined.                                                          |
| VSL_SS_ERROR_BAD_COR_ADDR                 | Correlation matrix is not defined.                                                         |
| VSL_SS_ERROR_BAD_QUANT_ORDER_ADDR         | Array of quantile orders is not defined.                                                   |
| VSL_SS_ERROR_BAD_QUANT_ORDER              | Quantile order value is invalid.                                                           |
| VSL_SS_ERROR_BAD_QUANT_ADDR               | Array of quantiles is not defined.                                                         |
| VSL_SS_ERROR_BAD_ORDER_STATS_ADDR         | Array of order statistics is not defined.                                                  |
| VSL_SS_ERROR_MOMORDER_NOT_SUPPORTED       | Moment of requested order is not supported.                                                |
| VSL_SS_NOT_FULL_RANK_MATRIX               | Correlation matrix is not of full rank.                                                    |
| VSL_SS_ERROR_ALL_OBSERVS_OUTLIERS         | All observations are outliers. (At least one observation must not be an outlier.)          |
| VSL_SS_ERROR_BAD_ROBUST_COV_ADDR          | Robust covariance matrix is not defined.                                                   |
| VSL_SS_ERROR_BAD_ROBUST_MEAN_ADDR         | Array of robust means is not defined.                                                      |
| VSL_SS_ERROR_METHOD_NOT_SUPPORTED         | Requested method is not supported.                                                         |
| VSL_SS_ERROR_NULL_TASK_DESCRIPTOR         | Task descriptor is null.                                                                   |
| VSL_SS_ERROR_BAD_OBSERV_ADDR              | Dataset matrix is not defined.                                                             |
| VSL_SS_ERROR_BAD_ACCUM_WEIGHT_ADDR        | Pointer to the variable that holds the value of accumulated weight is not defined.         |
| VSL_SS_ERROR_SINGULAR_COV                 | Covariance matrix is singular.                                                             |
| VSL_SS_ERROR_BAD_POOLED_COV_ADDR          | Pooled covariance matrix is not defined.                                                   |
| VSL_SS_ERROR_BAD_POOLED_MEAN_ADDR         | Array of pooled means is not defined.                                                      |
| VSL_SS_ERROR_BAD_GROUP_COV_ADDR           | Group covariance matrix is not defined.                                                    |
| VSL_SS_ERROR_BAD_GROUP_MEAN_ADDR          | Array of group means is not defined.                                                       |
| VSL_SS_ERROR_BAD_GROUP_INDC_ADDR          | Array of group indices is not defined.                                                     |
| VSL_SS_ERROR_BAD_GROUP_INDC               | Group indices have improper values.                                                        |
| VSL_SS_ERROR_BAD_OUTLIERS_PARAMS_ADDR     | Array of parameters for the outlier detection algorithm is not defined.                    |
| VSL_SS_ERROR_BAD_OUTLIERS_PARAMS_N_ADDR   | Pointer to size of the parameter array for the outlier detection algorithm is not defined. |
| VSL_SS_ERROR_BAD_OUTLIERS_WEIGHTS_ADDR    | Output of the outlier detection algorithm is not defined.                                  |
| VSL_SS_ERROR_BAD_ROBUST_COV_PARAMS_ADDR   | Array of parameters of the robust covariance estimation algorithm is not defined.          |
| VSL_SS_ERROR_BAD_ROBUST_COV_PARAMS_N_ADDR | Pointer to the number of parameters of the algorithm for robust covariance is not defined. |

| Status Code                               | Description                                                                                                    |

| VSL_SS_ERROR_BAD_2R_SUM_ADDR                | Array of raw sums of 2nd order is not defined.                                                                |
| VSL_SS_ERROR_BAD_3R_SUM_ADDR                | Array of raw sums of 3rd order is not defined.                                                                |
| VSL_SS_ERROR_BAD_4R_SUM_ADDR                | Array of raw sums of 4th order is not defined.                                                                |
| VSL_SS_ERROR_BAD_2C_SUM_ADDR                | Array of central sums of 2nd order is not defined.                                                            |
| VSL_SS_ERROR_BAD_3C_SUM_ADDR                | Array of central sums of 3rd order is not defined.                                                            |
| VSL_SS_ERROR_BAD_4C_SUM_ADDR                | Array of central sums of 4th order is not defined.                                                            |
| VSL_SS_ERROR_BAD_CP_SUM_ADDR                | Cross-product matrix is not defined.                                                                          |
| VSL_SS_ERROR_BAD_MDAD_ADDR                  | Array of median absolute deviations is not defined.                                                           |
| VSL_SS_ERROR_BAD_MNAD_ADDR                  | Array of mean absolute deviations is not defined.                                                             |
| VSL_SS_ERROR_BAD_SORTED_OBSERV_ADDR         | Array for storing observation sorting results is not defined.                                                 |
| VSL_SS_ERROR_ERROR_INDICES_NOT_SUPPORTED    | Array of indices is not supported.                                                                            |

Routines for robust covariance estimation, outlier detection, partial covariance estimation, multiple imputation, and parameterization of a correlation matrix can return internal error codes that are related to a specific implementation. Such error codes indicate invalid input data or other bugs in the Intel MKL routines other than the Summary Statistics routines.

## Summary Statistics Task Constructors

Task constructors are routines intended for creating a new task descriptor and setting up basic parameters.

---

### NOTE

If the constructor fails to create a task descriptor, it returns the `NULL` task pointer.

---

### vs1sSSNewTask

*Creates and initializes a new summary statistics task descriptor.*

---

#### Syntax

```
status = vs1sSSNewTask(&task, p, n, xstorage, x, w, indices);
```

```
status = vs1dSSNewTask(&task, p, n, xstorage, x, w, indices);
```

#### Include Files

- `mkl.h`

#### Input Parameters

| Name                  | Type                                                                                                                  | Description                                                                                                                                                                          |

| <code>x</code>        | <code>const float*</code> for <code>vs1sSSNewTask</code><br><code>const double*</code> for <code>vs1dSSNewTask</code> | Matrix of observations                                                                                                                                                               |
| <code>w</code>        | <code>const float*</code> for <code>vs1sSSNewTask</code><br><code>const double*</code> for <code>vs1dSSNewTask</code> | Array of weights of size <code>n</code> . Elements of the arrays are non-negative numbers. If a <code>NULL</code> pointer is passed, each observation is assigned weight equal to 1. |
| <code>indices</code>  | <code>const MKL_INT*</code>                                                                                           | Array of vector components that will be processed. Size of array is <code>p</code> . If a <code>NULL</code> pointer is passed, all components of random vector are processed.        |

#### Output Parameters

| Name              | Type                       | Description            |
|-------------------|----------------------------|------------------------|
| <code>task</code> | <code>VSLSSTaskPtr*</code> | Descriptor of the task |

| Name                | Type             | Description                                                                                                         |
|---------------------|------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>status</code> | <code>int</code> | Set to <code>VSL_STATUS_OK</code> if the task is created successfully, otherwise a non-zero error code is returned. |

## Description

Each `vslSSNewTask` constructor routine creates a new summary statistics task descriptor with the user-specified value for a required parameter, dimension of the task. The optional parameters (matrix of observations, its storage format, number of observations, weights of observations, and indices of the random vector components) are set to their default values.

The observations of random  $p$ -dimensional vector  $\xi = (\xi_1, \dots, \xi_j, \dots, \xi_p)$ , which are  $n$  vectors of dimension  $p$ , are passed as a one-dimensional array  $x$ . The parameter `xstorage` defines the storage format of the observations and takes one of the possible values listed in [Table "Storage format of matrix of observations and order statistics"](#).

### Storage format of matrix of observations, order statistics, and matrix of sorted observations

| Parameter                               | Description                                                                                                                                                                                                              |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>VSL_SS_MATRIX_STORAGE_ROWS</code> | The observations of random vector $\xi$ are packed by rows: $n$ data points for the vector component $\xi_1$ come first, $n$ data points for the vector component $\xi_2$ come second, and so forth.                     |
| <code>VSL_SS_MATRIX_STORAGE_COLS</code> | The observations of random vector $\xi$ are packed by columns: the first $p$ -dimensional observation of the vector $\xi$ comes first, the second $p$ -dimensional observation of the vector comes second, and so forth. |

A one-dimensional array  $w$  of size  $n$  contains non-negative weights assigned to the observations. You can pass a `NULL` array into the constructor. In this case, each observation is assigned the default value of the weight.

You can choose vector components for which you wish to compute statistical estimates. If an element of the vector indices of size  $p$  contains 0, the observations that correspond to this component are excluded from the calculations. If you pass the `NULL` value of the parameter into the constructor, statistical estimates for all random variables are computed.

If the constructor fails to create a task descriptor, it returns the `NULL` task pointer.

## Summary Statistics Task Editors

Task editors are intended to set up or change the task parameters listed in [Table "Parameters of Summary Statistics Task to Be Initialized or Modified"](#). As an example, to compute the sample mean for a one-dimensional dataset, initialize a variable for the mean value, and pass its address into the task as shown in the example below:

```
#define DIM 1
#define N 1000

int main()
{
 VSLSSTaskPtr task;
 double x[N];
 double mean;
 MKL_INT p, n, xstorage;
 int status;
```

```

/* initialize variables used in the computations of sample mean */
p = DIM;
n = N;
xstorage = VSL_SS_MATRIX_STORAGE_ROWS;
mean = 0.0;

/* create task */
status = vsldSSNewTask(&task, &p, &n, &xstorage, x, 0, 0);

/* initialize task parameters */
status = vsldSSEditTask(task, VSL_SS_ED_MEAN, &mean);

/* compute mean using SS fast method */
status = vsldSSCompute(task, VSL_SS_MEAN, VSL_SS_METHOD_FAST);

/* deallocate task resources */
status = vsldSSDeleteTask(&task);

return 0;
}

```

Use the single (`vsldssedittask`) or double (`vsldssedittask`) version of an editor, to initialize single or double precision version task parameters, respectively. Use an integer version of an editor (`vsldssedittask`) to initialize parameters of the integer type.

Table "Summary Statistics Task Editors" lists the task editors for Summary Statistics. Each of them initializes and/or modifies a respective group of related parameters.

### Summary Statistics Task Editors

| Editor                                   | Description                                                                                      |
|------------------------------------------|--------------------------------------------------------------------------------------------------|
| <code>vsldSSEditTask</code>              | Changes a pointer in the task descriptor.                                                        |
| <code>vsldSSEditMoments</code>           | Changes pointers to arrays associated with raw and central moments.                              |
| <code>vsldSSEditSums</code>              | Modifies the pointers to arrays that hold sum estimates.                                         |
| <code>vsldSSEditCovCor</code>            | Changes pointers to arrays associated with covariance and/or correlation matrices.               |
| <code>vsldSSEditCP</code>                | Modifies the pointers to cross-product matrix parameters.                                        |
| <code>vsldSSEditPartialCovCor</code>     | Changes pointers to arrays associated with partial covariance and/or correlation matrices.       |
| <code>vsldSSEditQuantiles</code>         | Changes pointers to arrays associated with quantile/order statistics calculations.               |
| <code>vsldSSEditStreamQuantiles</code>   | Changes pointers to arrays for quantile related calculations for streaming data.                 |
| <code>vsldSSEditPooledCovariance</code>  | Changes pointers to arrays associated with algorithms related to a pooled covariance matrix.     |
| <code>vsldSSEditRobustCovariance</code>  | Changes pointers to arrays for robust estimation of a covariance matrix and mean.                |
| <code>vsldSSEditOutliersDetection</code> | Changes pointers to arrays for detection of outliers.                                            |
| <code>vsldSSEditMissingValues</code>     | Changes pointers to arrays associated with the method of supporting missing values in a dataset. |

| Editor                                       | Description                                                                                            |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------|
| <a href="#">vslSSEditCorParameterization</a> | Changes pointers to arrays associated with the algorithm for parameterization of a correlation matrix. |

**NOTE**

You can use the `NULL` task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

**vslSSEditTask**

Modifies address of an input/output parameter in the task descriptor.

**Syntax**

```
status = vslsSSEditTask(task, parameter, par_addr);
```

```
status = vsldSSEditTask(task, parameter, par_addr);
```

```
status = vsliSSEditTask(task, parameter, par_addr);
```

**Include Files**

- `mkl.h`

**Input Parameters**

| Name                   | Type                                                                                                                                                                                   | Description                  |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|
| <code>task</code>      | <code>VSLSSTaskPtr</code>                                                                                                                                                              | Descriptor of the task       |
| <code>parameter</code> | <code>const MKL_INT</code>                                                                                                                                                             | Parameter to change          |
| <code>par_addr</code>  | <code>const float*</code> for <code>vslsSSEditTask</code><br><code>const double*</code> for <code>vsldSSEditTask</code><br><code>const MKL_INT*</code> for <code>vsliSSEditTask</code> | Address of the new parameter |

**Output Parameters**

| Name                | Type             | Description                |
|---------------------|------------------|----------------------------|
| <code>status</code> | <code>int</code> | Current status of the task |

**Description**

The `vslSSEditTask` routine replaces the pointer to the parameter stored in the Summary Statistics task descriptor with the `par_addr` pointer. If you pass the `NULL` pointer to the editor, no changes take place in the task and a corresponding error code is returned. See [Table "Parameters of Summary Statistics Task to Be Initialized or Modified"](#) for the predefined values of the parameter.

Use the single (`vslsssedittask`) or double (`vsldsssedittask`) version of the editor, to initialize single or double precision version task parameters, respectively. Use an integer version of the editor (`vsliSSEditTask`) to initialize parameters of the integer type.

**Parameters of Summary Statistics Task to Be Initialized or Modified**

| <b>Parameter Value</b>   | <b>Type</b> | <b>Purpose</b>                                                                 | <b>Initialization</b>                                                                                                                                                                                                                                                                          |
|--------------------------|-------------|--------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VSL_SS_ED_DIMEN          | i           | Address of a variable that holds the task dimension                            | Required. Positive integer value.                                                                                                                                                                                                                                                              |
| VSL_SS_ED_OBSERV_N       | i           | Address of a variable that holds the number of observations                    | Required. Positive integer value.                                                                                                                                                                                                                                                              |
| VSL_SS_ED_OBSERV         | d, s        | Address of the observation matrix                                              | Required. Provide the matrix containing your observations.                                                                                                                                                                                                                                     |
| VSL_SS_ED_OBSERV_STORAGE | i           | Address of a variable that holds the storage format for the observation matrix | Required. Provide a storage format supported by the library whenever you pass a matrix of observations. <sup>1</sup>                                                                                                                                                                           |
| VSL_SS_ED_INDC           | i           | Address of the array of indices                                                | Optional. Provide this array if you need to process individual components of the random vector. Set entry <i>i</i> of the array to one to include the <i>i</i> th coordinate in the analysis. Set entry <i>i</i> of the array to zero to exclude the <i>i</i> th coordinate from the analysis. |
| VSL_SS_ED_WEIGHTS        | d, s        | Address of the array of observation weights                                    | Optional. If the observations have weights different from the default weight (one), set entries of the array to non-negative floating point values.                                                                                                                                            |
| VSL_SS_ED_MEAN           | d, s        | Address of the array of means                                                  | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.                                                                                                                              |
| VSL_SS_ED_2R_MOM         | d, s        | Address of an array of raw moments of the second order                         | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.                                                                                                                              |
| VSL_SS_ED_3R_MOM         | d, s        | Address of an array of raw moments of the third order                          | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.                                                                                                                              |
| VSL_SS_ED_4R_MOM         | d, s        | Address of an array of raw moments of the fourth order                         | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.                                                                                                                              |

| <b>Parameter Value</b> | <b>Type</b> | <b>Purpose</b>                                             | <b>Initialization</b>                                                                                                                                                                                                                                              |
|------------------------|-------------|------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VSL_SS_ED_2C_MOM       | d, s        | Address of an array of central moments of the second order | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first and second order.                 |
| VSL_SS_ED_3C_MOM       | d, s        | Address of an array of central moments of the third order  | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, and third order.         |
| VSL_SS_ED_4C_MOM       | d, s        | Address of an array of central moments of the fourth order | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, third, and fourth order. |
| VSL_SS_ED_KURTOSIS     | d, s        | Address of the array of kurtosis estimates                 | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, third, and fourth order. |
| VSL_SS_ED_SKEWNESS     | d, s        | Address of the array of skewness estimates                 | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, and third order.         |
| VSL_SS_ED_MIN          | d, s        | Address of the array of minimum estimates                  | Optional. Set entries of array to meaningful values, such as the values of the first observation.                                                                                                                                                                  |
| VSL_SS_ED_MAX          | d, s        | Address of the array of maximum estimates                  | Optional. Set entries of array to meaningful values, such as the values of the first observation.                                                                                                                                                                  |

| Parameter Value         | Type | Purpose                                                                                                                                                       | Initialization                                                                                                                                                                                                                                                             |
|-------------------------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VSL_SS_ED_VARIATION     | d, s | Address of the array of variation coefficients                                                                                                                | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first and second order.                         |
| VSL_SS_ED_COV           | d, s | Address of a covariance matrix                                                                                                                                | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Make sure you also provide an array for the mean.                                                                                                |
| VSL_SS_ED_COV_STORAGE   | i    | Address of the variable that holds the storage format for a covariance matrix                                                                                 | Required. Provide a storage format supported by the library whenever you intend to compute the covariance matrix. <sup>2</sup>                                                                                                                                             |
| VSL_SS_ED_COR           | d, s | Address of a correlation matrix                                                                                                                               | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. If you initialize the matrix in non-trivial way, make sure that the main diagonal contains variance values. Also, provide an array for the mean. |
| VSL_SS_ED_COR_STORAGE   | i    | Address of the variable that holds the correlation storage format for a correlation matrix                                                                    | Required. Provide a storage format supported by the library whenever you intend to compute the correlation matrix. <sup>2</sup>                                                                                                                                            |
| VSL_SS_ED_ACCUM_WEIGHT  | d, s | Address of the array of size 2 that holds the accumulated weight (sum of weights) in the first position and the sum of weights squared in the second position | Optional. Set the entries of the matrix to meaningful values (typically zero) if you intend to do progressive processing of the dataset or need the sum of weights and sum of squared weights assigned to observations.                                                    |
| VSL_SS_ED_QUANT_ORDER_N | i    | Address of the variable that holds the number of quantile orders                                                                                              | Required. Positive integer value. Provide the number of quantile orders whenever you compute quantiles.                                                                                                                                                                    |
| VSL_SS_ED_QUANT_ORDER   | d, s | Address of the array of quantile orders                                                                                                                       | Required. Set entries of array to values from the interval (0,1). Provide this parameter whenever you compute quantiles.                                                                                                                                                   |

| Parameter Value                   | Type | Purpose                                                                                                              | Initialization                                                                                                                                                                |
|-----------------------------------|------|----------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VSL_SS_ED_QUANT_QUANTILE<br>S     | d, s | Address of the array of quantiles                                                                                    | None.                                                                                                                                                                         |
| VSL_SS_ED_ORDER_STATS             | d, s | Address of the array of order statistics                                                                             | None.                                                                                                                                                                         |
| VSL_SS_ED_GROUP_INDC              | i    | Address of the array of group indices used in computation of a pooled covariance matrix                              | Required. Set entry $i$ to integer value $k$ if the observation belongs to group $k$ . Values of $k$ take values in the range $[0, g-1]$ , where $g$ is the number of groups. |
| VSL_SS_ED_POOLED_COV_STO<br>RAGE  | i    | Address of a variable that holds the storage format for a pooled covariance matrix                                   | Required. Provide a storage format supported by the library whenever you intend to compute pooled covariance. <sup>2</sup>                                                    |
| VSL_SS_ED_POOLED_MEAN             | d, s | Address of an array of pooled means                                                                                  | None.                                                                                                                                                                         |
| VSL_SS_ED_POOLED_COV              | d, s | Address of pooled covariance matrices                                                                                | None.                                                                                                                                                                         |
| VSL_SS_ED_GROUP_COV_INDC          | i    | Address of an array of indices for which covariance/means should be computed                                         | Optional. Set the $k$ th entry of the array to 1 if you need group covariance and mean for group $k$ ; otherwise set it to zero.                                              |
| VSL_SS_ED_REQ_GROUP_INDC          | i    | Address of an array of indices for which group estimates such as covariance or means are requested                   | Optional. Set the $k$ th entry of the array to 1 if you need an estimate for group $k$ ; otherwise set it to zero.                                                            |
| VSL_SS_ED_GROUP_MEANS             | i    | Address of an array of group means                                                                                   | None.                                                                                                                                                                         |
| VSL_SS_ED_GROUP_COV_STOR<br>AGE   | d, s | Address of a variable that holds the storage format for a group covariance matrix                                    | Required. Provide a storage format supported by the library whenever you intend to get group covariance. <sup>2</sup>                                                         |
| VSL_SS_ED_GROUP_COV               | d, s | Address of group covariance matrices                                                                                 | None.                                                                                                                                                                         |
| VSL_SS_ED_ROBUST_COV_STO<br>RAGE  | d, s | Address of a variable that holds the storage format for a robust covariance matrix                                   | Required. Provide a storage format supported by the library whenever you compute robust covariance <sup>2</sup> .                                                             |
| VSL_SS_ED_ROBUST_COV_PAR<br>AMS_N | i    | Address of a variable that holds the number of algorithmic parameters of the method for robust covariance estimation | Required. Set to the number of TBS parameters,<br><i>VSL_SS_TBS_PARAMS_N</i> .                                                                                                |

| Parameter Value               | Type | Purpose                                                                                                  | Initialization                                                                                                              |
|-------------------------------|------|----------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| VSL_SS_ED_ROBUST_COV_PARAMS   | d, s | Address of an array of parameters of the method for robust estimation of a covariance                    | Required. Set the entries of the array according to the description in <a href="#">vslSSEditRobustCovariance</a> .          |
| VSL_SS_ED_ROBUST_MEAN         | i    | Address of an array of robust means                                                                      | None.                                                                                                                       |
| VSL_SS_ED_ROBUST_COV          | d, s | Address of a robust covariance matrix                                                                    | None.                                                                                                                       |
| VSL_SS_ED_OUTLIERS_PARAMS_N   | d, s | Address of a variable that holds the number of parameters of the outlier detection method                | Required. Set to the number of outlier detection parameters, <i>VSL_SS_BACON_PARAMS_N</i> .                                 |
| VSL_SS_ED_OUTLIERS_PARAMS     | i    | Address of an array of algorithmic parameters for the outlier detection method                           | Required. Set the entries of the array according to the description in <a href="#">vslSSEditOutliersDetection</a> .         |
| VSL_SS_ED_OUTLIERS_WEIGHT     | d, s | Address of an array of weights assigned to observations by the outlier detection method                  | None.                                                                                                                       |
| VSL_SS_ED_ORDER_STATS_STORAGE | d, s | Address of a variable that holds the storage format of an order statistics matrix                        | Required. Provide a storage format supported by the library whenever you compute a matrix of order statistics. <sup>1</sup> |
| VSL_SS_ED_PARTIAL_COV_ID_X    | i    | Address of an array that encodes subcomponents of a random vector                                        | Required. Set the entries of the array according to the description in <a href="#">vslSSEditPartialCovCor</a> .             |
| VSL_SS_ED_PARTIAL_COV         | d, s | Address of a partial covariance matrix                                                                   | None.                                                                                                                       |
| VSL_SS_ED_PARTIAL_COV_STORAGE | i    | Address of a variable that holds the storage format of a partial covariance matrix                       | Required. Provide a storage format supported by the library whenever you compute the partial covariance. <sup>2</sup>       |
| VSL_SS_ED_PARTIAL_COR         | d, s | Address of a partial correlation matrix                                                                  | None.                                                                                                                       |
| VSL_SS_ED_PARTIAL_COR_STORAGE | i    | Address of a variable that holds the storage format for a partial correlation matrix                     | Required. Provide a storage format supported by the library whenever you compute the partial correlation. <sup>2</sup>      |
| VSL_SS_ED_MI_PARAMS_N         | i    | Address of a variable that holds the number of algorithmic parameters for the Multiple Imputation method | Required. Set to the number of MI parameters, <i>VSL_SS_MI_PARAMS_SIZE</i> .                                                |

| Parameter Value               | Type | Purpose                                                                                                         | Initialization                                                                                                                                                                                                                                              |
|-------------------------------|------|-----------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VSL_SS_ED_MI_PARAMS           | d, s | Address of an array of algorithmic parameters for the Multiple Imputation method                                | Required. Set entries of the array according to the description in <a href="#">vslSSEditMissingValues</a> .                                                                                                                                                 |
| VSL_SS_ED_MI_INIT_ESTIMATES_N | i    | Address of a variable that holds the number of initial estimates for the Multiple Imputation method             | Optional. Set to $p+p*(p+1)/2$ , where $p$ is the task dimension.                                                                                                                                                                                           |
| VSL_SS_ED_MI_INIT_ESTIMATES   | d, s | Address of an array of initial estimates for the Multiple Imputation method                                     | Optional. Set the values of the array according to the description in "Basic Components of the Multiple Imputation Function in Summary Statistics" in the <i>Intel® MKL Summary Statistics Application Notes</i> document [ <a href="#">SS Notes</a> ].     |
| VSL_SS_ED_MI_SIMUL_VALS_N     | i    | Address of a variable that holds the number of simulated values in the Multiple Imputation method               | Optional. Positive integer indicating the number of missing points in the observation matrix.                                                                                                                                                               |
| VSL_SS_ED_MI_SIMUL_VALS       | d, s | Address of an array of simulated values in the Multiple Imputation method                                       | None.                                                                                                                                                                                                                                                       |
| VSL_SS_ED_MI_ESTIMATES_N      | i    | Address of a variable that holds the number of estimates obtained as a result of the Multiple Imputation method | Optional. Positive integer number defined according to the description in "Basic Components of the Multiple Imputation Function in Summary Statistics" in the <i>Intel® MKL Summary Statistics Application Notes</i> document [ <a href="#">SS Notes</a> ]. |
| VSL_SS_ED_MI_ESTIMATES        | d, s | Address of an array of estimates obtained as a result of the Multiple Imputation method                         | None.                                                                                                                                                                                                                                                       |
| VSL_SS_ED_MI_PRIOR_N          | i    | Address of a variable that holds the number of prior parameters for the Multiple Imputation method              | Optional. If you pass a user-defined array of prior parameters, set this parameter to $(p^2+3*p+4)/2$ , where $p$ is the task dimension.                                                                                                                    |
| VSL_SS_ED_MI_PRIOR            | d, s | Address of an array of prior parameters for the Multiple Imputation method                                      | Optional. Set entries of the array of prior parameters according to the description in "Basic Components of the Multiple Imputation Function in Summary                                                                                                     |

| Parameter Value                  | Type | Purpose                                                                                                       | Initialization                                                                                                                                                                                                       |
|----------------------------------|------|---------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                  |      |                                                                                                               | Statistics" in the <i>Intel® MKL Summary Statistics Application Notes</i> document [ <a href="#">SS Notes</a> ].                                                                                                     |
| VSL_SS_ED_PARAMTR_COR            | d, s | Address of a parameterized correlation matrix                                                                 | None.                                                                                                                                                                                                                |
| VSL_SS_ED_PARAMTR_COR_STORAGE    | i    | Address of a variable that holds the storage format of a parameterized correlation matrix                     | Required. Provide a storage format supported by the library whenever you compute the parameterized correlation matrix. <sup>2</sup>                                                                                  |
| VSL_SS_ED_STREAM_QUANT_PARAMS_N  | i    | Address of a variable that holds the number of parameters of a quantile computation method for streaming data | Required. Set to the number of quantile computation parameters, <i>VSL_SS_SQUANTS_ZW_PARAMS_N</i> .                                                                                                                  |
| VSL_SS_ED_STREAM_QUANT_PARAMS    | d, s | Address of an array of parameters of a quantile computation method for streaming data                         | Required. Set the entries of the array according to the description in "Computing Quantiles for Streaming Data" in the <i>Intel® MKL Summary Statistics Application Notes</i> document [ <a href="#">SS Notes</a> ]. |
| VSL_SS_ED_STREAM_QUANT_ORDER_N   | i    | Address of a variable that holds the number of quantile orders for streaming data                             | Required. Positive integer value.                                                                                                                                                                                    |
| VSL_SS_ED_STREAM_QUANT_ORDER     | d, s | Address of an array of quantile orders for streaming data                                                     | Required. Set entries of the array to values from the interval (0,1). Provide this parameter whenever you compute quantiles.                                                                                         |
| VSL_SS_ED_STREAM_QUANT_QUANTILES | d, s | Address of an array of quantiles for streaming data                                                           | None.                                                                                                                                                                                                                |
| VSL_SS_ED_SUM                    | d, s | Address of array of sums                                                                                      | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.                                                    |
| VSL_SS_ED_2R_SUM                 | d, s | Address of array of raw sums of 2nd order                                                                     | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.                                                    |
| VSL_SS_ED_3R_SUM                 | d, s | Address of array of raw sums of 3rd order                                                                     | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.                                                    |

| Parameter Value                 | Type | Purpose                                                                 | Initialization                                                                                                                                                    |
|---------------------------------|------|-------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VSL_SS_ED_4R_SUM                | d, s | Address of array of raw sums of 4th order                               | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. |
| VSL_SS_ED_2C_SUM                | d, s | Address of array of central sums of 2nd order                           | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. |
| VSL_SS_ED_3C_SUM                | d, s | Address of array of central sums of 3rd order                           | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. |
| VSL_SS_ED_4C_SUM                | d, s | Address of array of central sums of 4th order                           | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. |
| VSL_SS_ED_CP                    | d, s | Address of cross-product matrix                                         | Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. |
| VSL_SS_ED_MDAD                  | d, s | Address of array of median absolute deviations                          | None.                                                                                                                                                             |
| VSL_SS_ED_MNAD                  | d, s | Address of array of mean absolute deviations                            | None.                                                                                                                                                             |
| VSL_SS_ED_SORTED_OBSERV         | d, s | Address of the array that stores sorted results                         | None.                                                                                                                                                             |
| VSL_SS_ED_SORTED_OBSERV_STORAGE | i    | Address of a variable that holds the storage format of an output matrix | Required. Provide a supported storage format whenever you specify sorting of the observation matrix.                                                              |

1. See [Table: "Storage format of matrix of observations and order statistics"](#) for storage formats.
2. See [Table: "Storage formats of a variance-covariance/correlation matrix"](#) for storage formats.

### vsLSSEditMoments

*Modifies the pointers to arrays that hold moment estimates.*

#### Syntax

```
status = vsLSSEditMoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m);
status = vsLdSSEditMoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m);
```

## Include Files

- `mkl.h`

## Input Parameters

| Name              | Type                                                                                                              | Description                                                          |
|-------------------|-------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| <code>task</code> | <code>VSLSTaskPtr</code>                                                                                          | Descriptor of the task                                               |
| <code>mean</code> | <code>float*</code> for <code>vslsSSEditMoments</code><br><code>double*</code> for <code>vsldSSEditMoments</code> | Pointer to the array of means                                        |
| <code>r2m</code>  | <code>float*</code> for <code>vslsSSEditMoments</code><br><code>double*</code> for <code>vsldSSEditMoments</code> | Pointer to the array of raw moments of the 2 <sup>nd</sup> order     |
| <code>r3m</code>  | <code>float*</code> for <code>vslsSSEditMoments</code><br><code>double*</code> for <code>vsldSSEditMoments</code> | Pointer to the array of raw moments of the 3 <sup>rd</sup> order     |
| <code>r4m</code>  | <code>float*</code> for <code>vslsSSEditMoments</code><br><code>double*</code> for <code>vsldSSEditMoments</code> | Pointer to the array of raw moments of the 4 <sup>th</sup> order     |
| <code>c2m</code>  | <code>float*</code> for <code>vslsSSEditMoments</code><br><code>double*</code> for <code>vsldSSEditMoments</code> | Pointer to the array of central moments of the 2 <sup>nd</sup> order |
| <code>c3m</code>  | <code>float*</code> for <code>vslsSSEditMoments</code><br><code>double*</code> for <code>vsldSSEditMoments</code> | Pointer to the array of central moments of the 3 <sup>rd</sup> order |
| <code>c4m</code>  | <code>float*</code> for <code>vslsSSEditMoments</code><br><code>double*</code> for <code>vsldSSEditMoments</code> | Pointer to the array of central moments of the 4 <sup>th</sup> order |

## Output Parameters

| Name                | Type             | Description                |
|---------------------|------------------|----------------------------|
| <code>status</code> | <code>int</code> | Current status of the task |

## Description

The `vslsSSEditMoments` routine replaces pointers to the arrays that hold estimates of raw and central moments with values passed as corresponding parameters of the routine. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

## vslSSEditSums

*Modifies the pointers to arrays that hold sum estimates.*

---

### Syntax

```
status = vslsSSEditSums(task, sum, r2s, r3s, r4s, c2s, c3s, c4s);
```

```
status = vsldSSEditSums(task, sum, r2s, r3s, r4s, c2s, c3s, c4s);
```

## Include Files

- `mkl.h`

## Input Parameters

| Name              | Type                                                                                                        | Description                                              |
|-------------------|-------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| <code>task</code> | <code>VSLSTaskPtr</code>                                                                                    | Descriptor of the task                                   |
| <code>sum</code>  | <code>float*</code> for <code>vslsSSEditSums</code><br><code>double*</code> for <code>vsldSSEditSums</code> | Pointer to the array of sums                             |
| <code>r2s</code>  | <code>float*</code> for <code>vslsSSEditSums</code><br><code>double*</code> for <code>vsldSSEditSums</code> | Pointer to the array of raw sums of the second order     |
| <code>r3s</code>  | <code>float*</code> for <code>vslsSSEditSums</code><br><code>double*</code> for <code>vsldSSEditSums</code> | Pointer to the array of raw sums of the third order      |
| <code>r4s</code>  | <code>float*</code> for <code>vslsSSEditSums</code><br><code>double*</code> for <code>vsldSSEditSums</code> | Pointer to the array of raw sums of the fourth order     |
| <code>c2s</code>  | <code>float*</code> for <code>vslsSSEditSums</code><br><code>double*</code> for <code>vsldSSEditSums</code> | Pointer to the array of central sums of the second order |
| <code>c3s</code>  | <code>float*</code> for <code>vslsSSEditSums</code><br><code>double*</code> for <code>vsldSSEditSums</code> | Pointer to the array of central sums of the third order  |
| <code>c4s</code>  | <code>float*</code> for <code>vslsSSEditSums</code><br><code>double*</code> for <code>vsldSSEditSums</code> | Pointer to the array of central sums of the fourth order |

## Output Parameters

| Name                | Type             | Description                |
|---------------------|------------------|----------------------------|
| <code>status</code> | <code>int</code> | Current status of the task |

## Description

The `vslsSSEditSums` routine replaces pointers to the arrays that hold estimates of raw and central sums with values passed as corresponding parameters of the routine. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

## `vslsSSEditCovCor`

*Modifies the pointers to covariance/correlation/cross-product parameters.*

## Syntax

```
status = vslsSSEditCovCor(task, mean, cov, cov_storage, cor, cor_storage);
status = vsldSSEditCovCor(task, mean, cov, cov_storage, cor, cor_storage);
```

## Include Files

- `mkl.h`

## Input Parameters

| Name               | Type                                                        | Description                                             |

| <i>task</i>        | VSLSTaskPtr                                                 | Descriptor of the task                                  |
| <i>mean</i>        | float* for vslsSSEditCovCor<br>double* for vsldSSEditCovCor | Pointer to the array of means                           |
| <i>cov</i>         | float* for vslsSSEditCovCor<br>double* for vsldSSEditCovCor | Pointer to a covariance matrix                          |
| <i>cov_storage</i> | const MKL_INT*                                              | Pointer to the storage format of the covariance matrix  |
| <i>cor</i>         | float* for vslsSSEditCovCor<br>double* for vsldSSEditCovCor | Pointer to a correlation matrix                         |
| <i>cor_storage</i> | const MKL_INT*                                              | Pointer to the storage format of the correlation matrix |

## Output Parameters

| Name          | Type | Description                |
|---------------|------|----------------------------|
| <i>status</i> | int  | Current status of the task |

## Description

The `vslsSSEditCovCor` routine replaces pointers to the array of means, covariance/correlation arrays, and their storage format with values passed as corresponding parameters of the routine. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

The storage parameters, `cov_storage` and `cor_storage`, describe the storage format used for the  $p$ -by- $p$  symmetric variance-covariance/correlation/cross-product matrix  $C$ . The matrix  $C$  can be described as

$$C = \begin{pmatrix} c_{1,1} & c_{1,2} & \cdots & \cdots & \cdots & c_{1,p} \\ c_{2,1} & c_{2,2} & \cdots & \cdots & \cdots & c_{2,p} \\ \vdots & \vdots & \ddots & & & \vdots \\ \vdots & \vdots & & c_{i,j} & & \vdots \\ \vdots & \vdots & & & \ddots & \vdots \\ c_{p,1} & c_{p,2} & \cdots & \cdots & \cdots & c_{p,p} \end{pmatrix}$$

Table "Storage formats of a variance-covariance/correlation/cross-product matrix" shows how the matrix is stored in a one-dimensional array  $cp$  for different values of the storage parameters.

## Storage formats of variance-covariance/correlation/cross-product matrices

| Parameter                  | Description                                                                                                                                                                           |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## vslSSEditCP

Modifies the pointers to cross-product matrix parameters.

### Syntax

```
status = vslsSSEditCP(task, mean, sum, cp, cp_storage);
status = vsldSSEditCP(task, mean, sum, cp, cp_storage);
```

### Include Files

- mkl.h

### Input Parameters

| Name        | Type                                                | Description                       |
|-------------|-----------------------------------------------------|-----------------------------------|
| <i>task</i> | VSLSSTaskPtr                                        | Descriptor of the task            |
| <i>mean</i> | float* for vslsSSEditCP<br>double* for vsldSSEditCP | Pointer to array of means         |
| <i>sum</i>  | float* for vslsSSEditCP<br>double* for vsldSSEditCP | Pointer to array of sums          |
| <i>cp</i>   | float* for vslsSSEditCP<br>double* for vsldSSEditCP | Pointer to a cross-product matrix |

| Name              | Type           | Description                                               |
|-------------------|----------------|-----------------------------------------------------------|
| <i>cp_storage</i> | const MKL_INT* | Pointer to the storage format of the cross-product matrix |

### Output Parameters

| Name          | Type | Description                |
|---------------|------|----------------------------|
| <i>status</i> | int  | Current status of the task |

### Description

The `vslSSEditCP` routine replaces pointers to the array of means, array of sums, cross-product matrix, and its storage format with values passed as corresponding parameters of the routine. See [Table: "Storage formats of a variance-covariance/correlation/cross-product matrix"](#) for possible values of the *cp\_storage* parameter. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

|                      | double* for vsldSSEditPartialCovCor |                                                                 |
| <i>p_cor_storage</i> | const MKL_INT*                      | Pointer to the storage format of the partial correlation matrix |

### Output Parameters

| Name          | Type | Description                |
|---------------|------|----------------------------|
| <i>status</i> | int  | Current status of the task |

### Description

The `vs1sSEditPartialCovCor` routine replaces pointers to covariance/correlation arrays, partial covariance/correlation arrays, and their storage format with values passed as corresponding parameters of the routine. See [Table "Storage formats of a variance-covariance/correlation matrix"](#) for possible values of the `cov_storage`, `cor_storage`, `p_cov_storage`, and `p_cor_storage` parameters. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

### vs1sSEditQuantiles

*Modifies the pointers to parameters related to quantile computations.*

### Syntax

```
status = vs1sSEditQuantiles(task, quant_order_n, quant_order, quants, order_stats, order_stats_storage);
```

```

| <i>order_stats</i>   | float* for vs1sSEditQuantiles<br>double* for vsldSSEditQuantiles             | Pointer to the array of order statistics |

| Name                             | Type                        | Description                                                 |
|----------------------------------|-----------------------------|-------------------------------------------------------------|
| <code>order_stats_storage</code> | <code>const MKL_INT*</code> | Pointer to the storage format of the order statistics array |

## Output Parameters

| Name                | Type             | Description                |
|---------------------|------------------|----------------------------|
| <code>status</code> | <code>int</code> | Current status of the task |

## Description

The `vslsSSEditQuantiles` routine replaces pointers to the number of quantile orders, the array of quantile orders, the array of quantiles, the array that holds order statistics, and the storage format for the order statistics with values passed into the routine. See [Table "Storage format of matrix of observations and order statistics"](#) for possible values of the `order_statistics_storage` parameter. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

## vslsSSEditStreamQuantiles

*Modifies the pointers to parameters related to quantile computations for streaming data.*

## Syntax

```
status = vslsSSEditStreamQuantiles(task, quant_order_n, quant_order, quants, nparams,
params);
```

```
status = vsldSSEditStreamQuantiles(task, quant_order_n, quant_order, quants, nparams,
params);
```

## Output Parameters

| Name                | Type             | Description                |
|---------------------|------------------|----------------------------|
| <code>status</code> | <code>int</code> | Current status of the task |

## Description

The `vslsSSEditPooledCovariance` routine replaces pointers to the array of group indices, the array of pooled means, the array for a pooled covariance matrix, and pointers to the array of indices of group matrices, the array of group means, and the array for group covariance matrices with values passed in the editors. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.. Use the `vslsSSEditTask` routine to replace the storage format for pooled and group covariance matrices.

## vslsSSEditRobustCovariance

*Modifies pointers to arrays related to a robust covariance matrix.*

## Syntax

```
status = vslsSSEditRobustCovariance(task, rcov_storage, nparams, params, rmean, rcov);
status = vsldSSEditRobustCovariance(task, rcov_storage, nparams, params, rmean, rcov);
```

### Output Parameters

| Name          | Type | Description                |
|---------------|------|----------------------------|
| <i>status</i> | int  | Current status of the task |

### Description

The `vs1sSSEditRobustCovariance` routine uses values passed as parameters of the routine to replace:

- pointers to covariance matrix storage
- pointers to the number of method parameters and to the array of the method parameters of size *nparams*
- pointers to the arrays that hold robust means and covariance

See [Table "Storage formats of a variance-covariance/correlation matrix"](#) for possible values of the *rcov\_storage* parameter. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

Intel MKL provides a Translated Biweight S-estimator (TBS) for robust estimation of a variance-covariance matrix and mean [Rocke96]. Use one iteration of the Maronna algorithm with the reweighting step [Maronna02] to compute the initial point of the algorithm. Pack the parameters of the TBS algorithm into the *params* array and pass them into the editor. [Table "Structure of the Array of TBS Parameters"](#) describes the *params* structure.

### Structure of the Array of TBS Parameters

| Array Position | Algorithm Parameter | Description                                                                                                                 |
|----------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------|
| 0              | $\epsilon$          | Breakdown point, the number of outliers the algorithm can hold. By default, the value is $(n-p) / (2n)$ .                   |
| 1              | $\alpha$            | Asymptotic rejection probability, see details in [Rocke96]. By default, the value is 0.001.                                 |
| 2              | $\delta$            | Stopping criterion: the algorithm is terminated if weights are changed less than $\delta$ . By default, the value is 0.001. |
| 3              | <i>max_iter</i>     | Maximum number of iterations. The algorithm terminates after <i>max_iter</i> iterations. By default, the value is 10.       |

| Array Position | Algorithm Parameter | Description                                                                                                                                                     |
|----------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                |                     | If you set this parameter to zero, the function returns a robust estimate of the variance-covariance matrix computed using the Maronna method [Maronna02] only. |

The robust estimator of variance-covariance implementation in Intel MKL requires that the number of observations  $n$  be greater than twice the number of variables:  $n > 2p$ .

See additional details of the algorithm usage model in the *Intel® MKL Summary Statistics Application Notes* document [SS Notes].

### vsLSSEditOutliersDetection

| <i>w</i>       | float* for<br>vsLSSEditOutliersDetection<br><br>double* for<br>vsLDSEditOutliersDetection             | Pointer to an array of size $n$ . The array holds the weights of observations to be marked as outliers. |

#### Output Parameters

| Name          | Type | Description                |
|---------------|------|----------------------------|
| <i>status</i> | int  | Current status of the task |

#### Description

The `vsLSSEditOutliersDetection` routine uses the parameters passed to replace

- the pointers to the number of method parameters and to the array of the method parameters of size *nparams*

- the pointer to the array that holds the calculated weights of the observations

If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

Intel MKL provides the BACON algorithm ([Billor00]) for the detection of multivariate outliers. Pack the parameters of the BACON algorithm into the `params` array and pass them into the editor. Table "Structure of the Array of BACON Parameters" describes the `params` structure.

### Structure of the Array of BACON Parameters

| Array Position | Algorithm Parameter           | Description                                                                                                                                                                                                                                                                                                                                |
|----------------|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | Method to start the algorithm | The parameter takes one of the following possible values:<br><br><code>VSL_SS_METHOD_BACON_MEDIAN_INIT</code> , if the algorithm is started using the median estimate. This is the default value of the parameter.<br><br><code>VSL_SS_METHOD_BACON_MAHALANOBIS_INIT</code> , if the algorithm is started using the Mahalanobis distances. |
| 1              | $\alpha$                      | One-tailed probability that defines the $(1 - \alpha)$ quantile of $\chi^2$ distribution with $p$ degrees of freedom. The recommended value is $\alpha/n$ , where $n$ is the number of observations. By default, the value is 0.05.                                                                                                        |
| 2              | $\delta$                      | Stopping criterion; the algorithm is terminated if the size of the basic subset is changed less than $\delta$ . By default, the value is 0.005.                                                                                                                                                                                            |

Output of the algorithm is the vector of weights, `BaconWeights`, such that `BaconWeights(i) = 0` if  $i$ -th observation is detected as an outlier. Otherwise `BaconWeights(i) = w(i)`, where  $w$  is the vector of input weights. If you do not provide the vector of input weights, `BaconWeights(i)` is set to 1 if the  $i$ -th observation is not detected as an outlier.

See additional details about usage model of the algorithm in the *Intel(R) MKL Summary Statistics Application Notes* document [SS Notes].

### vslsSSEditMissingValues

*Modifies pointers to arrays associated with the method of supporting missing values in a dataset.*

#### Syntax

```
status = vslsSSEditMissingValues(task, nparams, params, init_estimates_n,
init_estimates, prior_n, prior, simul_missing_vals_n, simul_missing_vals, estimates_n,
estimates);
```

```
status = vsldSSEditMissingValues(task, nparams, params, init_estimates_n,
init_estimates, prior_n, prior, simul_missing_vals_n, simul_missing_vals, estimates_n,
estimates);
```

## Description

The `vslSSEditMissingValues` routine uses values passed as parameters of the routine to replace pointers to the number and the array of the method parameters, pointers to the number and the array of initial mean/variance-covariance estimates, the pointer to the number and the array of prior parameters, pointers to the number and the array of simulated missing values, and pointers to the number and the array of the intermediate mean/covariance estimates. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

Before you call the Summary Statistics routines to process missing values, preprocess the dataset and denote missing observations with one of the following predefined constants:

- `VSL_SS_SNAN`, if the dataset is stored in single precision floating-point arithmetic
- `VSL_SS_DNAN`, if the dataset is stored in double precision floating-point arithmetic

Intel MKL provides the `VSL_SS_METHOD_MI` method to support missing values in the dataset based on the Multiple Imputation (MI) approach described in [Schafer97]. The following components support Multiple Imputation:

- Expectation Maximization (EM) algorithm to compute the start point for the Data Augmentation (DA) procedure
- DA function

---

### NOTE

The DA component of the MI procedure is simulation-based and uses the `VSL_BRNG_MCG59` basic random number generator with predefined  $seed = 2^{50}$  and the Gaussian distribution generator (`ICDF` method) available in Intel MKL [Gaussian].

---

Pack the parameters of the MI algorithm into the `params` array. Table "Structure of the Array of MI Parameters" describes the `params` structure.

### Structure of the Array of MI Parameters

| Array Position | Algorithm Parameter                | Description                                                                                                                                                                                                                         |
|----------------|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0              | <code>em_iter_num</code>           | Maximal number of iterations for the EM algorithm. By default, this value is 50.                                                                                                                                                    |
| 1              | <code>da_iter_num</code>           | Maximal number of iterations for the DA algorithm. By default, this value is 30.                                                                                                                                                    |
| 2              | <code><math>\epsilon</math></code> | Stopping criterion for the EM algorithm. The algorithm terminates if the maximal module of the element-wise difference between the previous and current parameter values is less than $\epsilon$ . By default, this value is 0.001. |
| 3              | <code>m</code>                     | Number of sets to impute                                                                                                                                                                                                            |
| 4              | <code>missing_vals_num</code>      | Total number of missing values in the datasets                                                                                                                                                                                      |

You can also pass initial estimates into the EM algorithm by packing both the vector of means and the variance-covariance matrix as a one-dimensional array `init_estimates`. The size of the array should be at least  $p + p(p + 1)/2$ . For  $i=0, \dots, p-1$ , the `init_estimates[i]` array contains the initial estimate of means. The remaining positions of the array are occupied by the upper triangular part of the variance-covariance matrix.

If you provide no initial estimates for the EM algorithm, the editor uses the default values, that is, the vector of zero means and the unitary matrix as a variance-covariance matrix. You can also pass *prior* parameters for  $\mu$  and  $\Sigma$  into the library:  $\mu_0$ ,  $\tau$ ,  $m$ , and  $\Lambda^{-1}$ . Pack these parameters as a one-dimensional array *prior* with a size of at least

$$(p^2 + 3p + 4)/2.$$

The storage format is as follows:

- *prior*[0], ..., *prior*[*p*-1] contain the elements of the vector  $\mu_0$ .
- *prior*[*p*] contains the parameter  $\tau$ .
- *prior*[*p*+1] contains the parameter  $m$ .
- The remaining positions are occupied by the upper-triangular part of the inverted matrix  $\Lambda^{-1}$ .

If you provide no *prior* parameters, the editor uses their default values:

- The array of  $p$  zeros is used as  $\mu_0$ .
- $\tau$  is set to 0.
- $m$  is set to  $p$ .
- The zero matrix is used as an initial approximate of  $\Lambda^{-1}$ .

The `EditMissingValues` editor returns  $m$  sets of imputed values and/or a sequence of parameter estimates drawn during the DA procedure.

The editor returns the imputed values as the *simul\_missing\_vals* array. The size of the array should be sufficient to hold  $m$  sets each of the *missing\_vals\_num* size, that is, at least  $m \cdot \text{missing\_vals\_num}$  in total. The editor packs the imputed values one by one in the order of their appearance in the matrix of observations.

For example, consider a task of dimension 4. The total number of observations  $n$  is 10. The second observation vector misses variables 1 and 2, and the seventh observation vector lacks variable 1. The number of sets to impute is  $m=2$ . Then, *simul\_missing\_vals*[0] and *simul\_missing\_vals*[1] contains the first and the second points for the second observation vector, and *simul\_missing\_vals*[2] holds the first point for the seventh observation. Positions 3, 4, and 5 are formed similarly.

To estimate convergence of the DA algorithm and choose a proper value of the number of DA iterations, request the sequence of parameter estimates that are produced during the DA procedure. The editor returns the sequence of parameters as a single array. The size of the array is

$$m \cdot \text{da\_iter\_num} \cdot (p + (p^2 + p) / 2)$$

where

- $m$  is the number of sets of values to impute.
- *da\_iter\_num* is the number of DA iterations.
- The value  $p + (p^2 + p) / 2$  determines the size of the memory to hold one set of the parameter estimates.

In each set of the parameters, the vector of means occupies the first  $p$  positions and the remaining  $(p^2 + p) / 2$  positions are intended for the upper triangular part of the variance-covariance matrix.

Upon successful generation of  $m$  sets of imputed values, you can place them in cells of the data matrix with missing values and use the Summary Statistics routines to analyze and get estimates for each of the  $m$  complete datasets.

---

**NOTE**

Intel MKL implementation of the MI algorithm rewrites cells of the dataset that contain the `VSL_SS_SNaN/VSL_SS_DNaN` values. If you want to use the Summary Statistics routines to process the data with missing values again, mask the positions of the empty cells.

---

See additional details of the algorithm usage model in the *Intel® MKL Summary Statistics Application Notes* document [[SS Notes](#)].

## vsSSEditCorParameterization

Modifies pointers to arrays related to the algorithm of correlation matrix parameterization.

### Syntax

```
status = vsSSEditCorParameterization(task, cor, cor_storage, pcor, pcor_storage);
```

```
status = vsdSSEditCorParameterization(task, cor, cor_storage, pcor, pcor_storage);
```

### Description

The `vsSSEditCorParameterization` routine uses values passed as parameters of the routine to replace pointers to the correlation matrix, pointers to the correlation matrix storage format, a pointer to the parameterized correlation matrix, and a pointer to the parameterized correlation matrix storage format. See [Table "Storage formats of a variance-covariance/correlation matrix"](#) for possible values of the `cor_storage` and `pcor_storage` parameters. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

## Summary Statistics Task Computation Routines

Task computation routines calculate statistical estimates on the data provided and parameters held in the task descriptor. After you create the task and initialize its parameters, you can call the computation routines as many times as necessary. [Table "Summary Statistics Estimates Obtained with vsSCompute Routine"](#) lists the statistical estimates that you can obtain using the `vsSCompute` routine.

**NOTE**

The Summary Statistics computation routines do not signal floating-point errors, such as overflow or gradual underflow, or operations with NaNs (except for the missing values in the observations).

| VSL_SS_SUM       | Yes                                                | Computes the array of sums.                                                                                                 |
| VSL_SS_2R_MOM    | Yes                                                | Computes the array of the 2 <sup>nd</sup> order raw moments.                                                                |
| VSL_SS_2R_SUM    | Yes                                                | Computes the array of raw sums of the 2 <sup>nd</sup> order.                                                                |
| VSL_SS_3R_MOM    | Yes                                                | Computes the array of the 3 <sup>rd</sup> order raw moments.                                                                |
| VSL_SS_3R_SUM    | Yes                                                | Computes the array of raw sums of the 3 <sup>rd</sup> order.                                                                |
| VSL_SS_4R_MOM    | Yes                                                | Computes the array of the 4 <sup>th</sup> order raw moments.                                                                |
| VSL_SS_4R_SUM    | Yes                                                | Computes the array of raw sums of the 4 <sup>th</sup> order.                                                                |
| VSL_SS_2C_MOM    | Yes                                                | Computes the array of the 2 <sup>nd</sup> order central moments.                                                            |
| VSL_SS_2C_SUM    | Yes                                                | Computes the array of central sums of the 2 <sup>nd</sup> order.                                                            |
| VSL_SS_3C_MOM    | Yes                                                | Computes the array of the 3 <sup>rd</sup> order central moments.                                                            |
| VSL_SS_3C_SUM    | Yes                                                | Computes the array of central sums of the 3 <sup>rd</sup> order.                                                            |
| VSL_SS_4C_MOM    | Yes                                                | Computes the array of the 4 <sup>th</sup> order central moments.                                                            |
| VSL_SS_4C_SUM    | Yes                                                | Computes the array of central sums of the 4 <sup>th</sup> order.                                                            |
| VSL_SS_KURTOSIS  | Yes                                                | Computes the array of kurtosis values.                                                                                      |
| VSL_SS_SKEWNESS  | Yes                                                | Computes the array of skewness values.                                                                                      |
| VSL_SS_MIN       | Yes                                                | Computes the array of minimum values.                                                                                       |
| VSL_SS_MAX       | Yes                                                | Computes the array of maximum values.                                                                                       |
| VSL_SS_VARIATION | Yes                                                | Computes the array of variation coefficients.                                                                               |
| VSL_SS_COV       | Yes                                                | Computes a covariance matrix.                                                                                               |
| VSL_SS_COR       | Yes                                                | Computes a correlation matrix. The main diagonal of the correlation matrix holds variances of the random vector components. |

| Estimate             | Support of Observations Available in Blocks | Description                                                      |
|----------------------|---------------------------------------------|------------------------------------------------------------------|
| VSL_SS_CP            | Yes                                         | Computes a cross-product matrix.                                 |
| VSL_SS_POOLED_COV    | No                                          | Computes a pooled covariance matrix.                             |
| VSL_SS_POOLED_MEAN   | No                                          | Computes an array of pooled means.                               |
| VSL_SS_GROUP_COV     | No                                          | Computes group covariance matrices.                              |
| VSL_SS_GROUP_MEAN    | No                                          | Computes group means.                                            |
| VSL_SS_QUANTS        | No                                          | Computes quantiles.                                              |
| VSL_SS_ORDER_STATS   | No                                          | Computes order statistics.                                       |
| VSL_SS_ROBUST_COV    | No                                          | Computes a robust covariance matrix.                             |
| VSL_SS_OUTLIERS      | No                                          | Detects outliers in the dataset.                                 |
| VSL_SS_PARTIAL_COV   | No                                          | Computes a partial covariance matrix.                            |
| VSL_SS_PARTIAL_COR   | No                                          | Computes a partial correlation matrix.                           |
| VSL_SS_MISSING_VALS  | No                                          | Supports missing values in datasets.                             |
| VSL_SS_PARAMTR_COR   | No                                          | Computes a parameterized correlation matrix.                     |
| VSL_SS_STREAM_QUANTS | Yes                                         | Computes quantiles for streaming data.                           |
| VSL_SS_MDAD          | No                                          | Computes median absolute deviation.                              |
| VSL_SS_MNAD          | No                                          | Computes mean absolute deviation.                                |
| VSL_SS_SORTED_OBSERV | No                                          | Sorts the dataset by the components of the random vector $\xi$ . |

Table "Summary Statistics Computation Method" lists estimate calculation methods supported by Intel MKL. See the *Intel(R) MKL Summary Statistics Application Notes* document [SS Notes] for a detailed description of the methods.

### Summary Statistics Computation Method

| Method                       | Description                                                                                                                                                                                                                                                                                                                           |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VSL_SS_METHOD_FAST           | Fast method for calculation of the estimates: <ul style="list-style-type: none"> <li>raw/central moments/sums, skewness, kurtosis, variation, variance-covariance/correlation/cross-product matrix</li> <li>min/max/quantile/order statistics</li> <li>partial variance-covariance</li> <li>median/mean absolute deviation</li> </ul> |
| VSL_SS_METHOD_FAST_USER_MEAN | Fast method for calculation of the estimates given user-defined mean: <ul style="list-style-type: none"> <li>central moments/sums of 2-4 order, skewness, kurtosis, variation, variance-covariance/correlation/cross-product matrix, mean absolute deviation</li> </ul>                                                               |
| VSL_SS_METHOD_1PASS          | One-pass method for calculation of estimates:                                                                                                                                                                                                                                                                                         |

| Method                        | Description                                                                                                                                                                                             |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               | <ul style="list-style-type: none"> <li>raw/central moments/sums, skewness, kurtosis, variation, variance-covariance/correlation/cross-product matrix</li> <li>pooled/group covariance matrix</li> </ul> |
| VSL_SS_METHOD_TBS             | TBS method for robust estimation of covariance and mean                                                                                                                                                 |
| VSL_SS_METHOD_BACON           | BACON method for detection of multivariate outliers                                                                                                                                                     |
| VSL_SS_METHOD_MI              | Multiple imputation method for support of missing values                                                                                                                                                |
| VSL_SS_METHOD_SD              | Spectral decomposition method for parameterization of a correlation matrix                                                                                                                              |
| VSL_SS_METHOD_SQUANTS_ZW      | Zhang-Wang (ZW) method for quantile estimation for streaming data                                                                                                                                       |
| VSL_SS_METHOD_SQUANTS_ZW_FAST | Fast ZW method for quantile estimation for streaming data                                                                                                                                               |
| VSL_SS_METHOD_RADIX           | Radix method for dataset sorting                                                                                                                                                                        |

You can calculate all requested estimates in one call of the routine. For example, to compute a kurtosis and covariance matrix using a fast method, pass a combination of the pre-defined parameters into the `Compute` routine as shown in the example below:

```
...
method = VSL_SS_METHOD_FAST;
task_params = VSL_SS_KURTOSIS|VSL_SS_COV;
...
status = vsldSSCompute(task, task_params, method);
```

To compute statistical estimates for the next block of observations, you can do one of the following:

- copy the observations to memory, starting with the address available to the task
- use one of the appropriate [Editors](#) to modify the pointer to the new dataset in the task.

The library does not detect your changes of the dataset and computed statistical estimates. To obtain statistical estimates for a new matrix, change the observations and initialize relevant arrays. You can follow this procedure to compute statistical estimates for observations that come in portions. See [Table "Summary Statistics Estimates Obtained with vsldSSCompute Routine"](#) for information on such observations supported by the Intel MKL Summary Statistics estimators.

To modify parameters of the task using the Task Editors, set the address of the targeted matrix of the observations or change the respective vector component indices. After you complete editing the task parameters, you can compute statistical estimates in the modified environment.

If the task completes successfully, the computation routine returns the zero status code. If an error is detected, the computation routine returns an error code. In particular, an error status code is returned in the following cases:

- the task pointer is `NULL`
- memory allocation has failed
- the calculation has failed for some other reason

#### NOTE

You can use the `NULL` task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

## vslSSCompute

Computes Summary Statistics estimates.

---

### Syntax

```
status = vslsSSCompute(task, estimates, method);
```

```
status = vsldSSCompute(task, estimates, method);
```

### Include Files

- mkl.h

### Input Parameters

| Name             | Type            | Description                              |
|------------------|-----------------|------------------------------------------|
| <i>task</i>      | VSLSSTaskPtr    | Descriptor of the task                   |
| <i>estimates</i> | const MKL_INT64 | List of statistical estimates to compute |
| <i>method</i>    | const MKL_INT   | Method to be used in calculations        |

### Output Parameters

| Name          | Type | Description                |
|---------------|------|----------------------------|
| <i>status</i> | int  | Current status of the task |

### Description

The `vslSSCompute` routine calculates statistical estimates passed as the *estimates* parameter using the algorithms passed as the *method* parameter of the routine. The computations are done in the context of the task descriptor that contains pointers to all required and optional, if necessary, properly initialized arrays. In one call of the function, you can compute several estimates using proper methods for their calculation. See [Table "Summary Statistics Estimates Obtained with Compute Routine"](#) for the list of the estimates that you can calculate with the `vslSSCompute` routine. See [Table "Summary Statistics Computation Methods"](#) for the list of possible values of the *method* parameter.

To initialize single or double precision version task parameters, use the single (`vslssscompute`) or double (`vsldsscompute`) version of the editor, respectively. To initialize parameters of the integer type, use an integer version of the editor (`vslisscompute`).

---

**NOTE**

Requesting a combination of the `VSL_SS_MISSING_VALS` value and any other estimate parameter in the `Compute` function results in processing only the missing values.

---

### Application Notes

Be aware that when computing a correlation matrix, the `vslSSCompute` routine allocates an additional array for each thread which is running the task. If you are running on a large number of threads `vslSSCompute` might consume large amounts of memory.

When calculating covariance, correlation, or cross product, the number of bytes of memory required is at least  $(P*P*T + P*T)*b$ , where  $P$  is the dimension of the task or number of variables,  $T$  is the number of threads, and  $b$  is the number of bytes required for each unit of data. If observation is weighted and the method is `VSL_SS_METHOD_FAST`, then the memory required is at least  $(P*P*T + P*T + N*P)*b$ , where  $N$  is the number of observations.

## Summary Statistics Task Destructor

Task destructor is the `vslSSDeleteTask` routine intended to delete task objects and release memory.

### `vslSSDeleteTask`

*Destroys the task object and releases the memory.*

### Syntax

```
status = vslSSDeleteTask(&task);
```

### Include Files

- `mkl.h`

### Input Parameters

| Name              | Type                       | Description                       |
|-------------------|----------------------------|-----------------------------------|
| <code>task</code> | <code>VSLSSTaskPtr*</code> | Descriptor of the task to destroy |

### Output Parameters

| Name                | Type             | Description                                                                                       |
|---------------------|------------------|---------------------------------------------------------------------------------------------------|
| <code>status</code> | <code>int</code> | Sets to <code>VSL_STATUS_OK</code> if the task is deleted; otherwise a non-zero code is returned. |

### Description

The `vslSSDeleteTask` routine deletes the task descriptor object, releases the memory allocated for the structure, and sets the task pointer to `NULL`. If `vslSSDeleteTask` fails to delete the task successfully, it returns an error code.

#### NOTE

Call of the destructor with the `NULL` pointer as the parameter results in termination of the function with no system crash.

## Summary Statistics Usage Examples

The following examples show various standard operations with Summary Statistics routines.

### Calculating Fixed Estimates for Fixed Data

The example shows recurrent calculation of the same estimates with a given set of variables for the complete life cycle of the task in the case of a variance-covariance matrix. The set of vector components to process remains unchanged, and the data comes in blocks. Before you call the `vslSSCompute` routine, initialize pointers to arrays for mean and covariance and set buffers.

```
...
double w[2];
double indices[DIM] = {1, 0, 1};

/* calculating mean for 1st and 3d random vector components */
```

```

/* Initialize parameters of the task */
p = DIM;
n = N;

xstorage = VSL_SS_MATRIX_STORAGE_ROWS;
covstorage = VSL_SS_MATRIX_STORAGE_FULL;

w[0] = 0.0; w[1] = 0.0;

for (i = 0; i < p; i++) mean[i] = 0.0;
for (i = 0; i < p*p; i++) cov[i] = 0.0;

status = vsldSSNewTask(&task, &p, &n, &xstorage, x, 0, indices);

status = vsldSSEditTask (task, VSL_SS_ED_ACCUM_WEIGHT, w);
status = vsldSSEditCovCor(task, mean, cov, &covstorage, 0, 0);

```

You can process data arrays that come in blocks as follows:

```

for (i = 0; i < num_of_blocks; i++)
{
 status = vsldSSCompute(task, VSL_SS_COV, VSL_SS_METHOD_FAST);
 /* Read new data block into array x */
}
...

```

### Calculating Different Estimates for Variable Data

The context of your calculation may change in the process of data analysis. The example below shows the data that comes in two blocks. You need to estimate a covariance matrix for the complete data, and the third central moment for the second block of the data using the weights that were accumulated for the previous datasets. The second block of the data is stored in another array. You can proceed as follows:

```

/* Set parameters for the task */
p = DIM;
n = N;
xstorage = VSL_SS_MATRIX_STORAGE_ROWS;
covstorage = VSL_SS_MATRIX_STORAGE_FULL;

w[0] = 0.0; w[1] = 0.0;

for (i = 0; i < p; i++) mean[i] = 0.0;
for (i = 0; i < p*p; i++) cov[i] = 0.0;

/* Create task */
status = vsldSSNewTask(&task, &p, &n, &xstorage, x1, 0, indices);

/* Initialize the task parameters */
status = vsldSSEditTask(task, VSL_SS_ED_ACCUM_WEIGHT, w);
status = vsldSSEditCovCor(task, mean, cov, &covstorage, 0, 0);

/* Calculate covariance for the x1 data */
status = vsldSSCompute(task, VSL_SS_COV, VSL_SS_METHOD_FAST);

/* Initialize array of the 3d central moments and pass the pointer to the task */
for (i = 0; i < p; i++) c3_m[i] = 0.0;

/* Modify task context */
status = vsldSSEditTask(task, VSL_SS_ED_3C_MOM, c3_m);

```

```

status = vsldSSEditTask(task, VSL_SS_ED_OBSERV, x2);

/* Calculate covariance for the x1 & x2 data block */
/* Calculate the 3d central moment for the 2nd data block using earlier accumulated weight */
status = vsldSSCompute(task, VSL_SS_COV|VSL_SS_3C_MOM, VSL_SS_METHOD_FAST);
...
status = vsldSSDeleteTask(&task);

```

Similarly, you can modify indices of the variables to be processed for the next data block.

## Summary Statistics Mathematical Notation and Definitions

The following notations are used in the mathematical definitions and the description of the Intel MKL Summary Statistics functions.

### Matrix and Weights of Observations

For a random  $p$ -dimensional vector  $\xi = (\xi_1, \dots, \xi_j, \dots, \xi_p)$ , this manual denotes the following:

- $(X)_i = (x_{ij})_{j=1..n}$  is the result of  $n$  independent observations for the  $i$ -th component  $\xi_i$  of the vector  $\xi$ .
- The two-dimensional array  $X = (x_{ij})_{n \times p}$  is the matrix of observations.
- The column  $[X]_j = (x_{ij})_{i=1..n}$  of the matrix  $X$  is the  $j$ -th observation of the random vector  $\xi$ .

Each observation  $[X]_j$  is assigned a non-negative weight  $w_j$ , where

- The vector  $(w_j)_{j=1..n}$  is a vector of weights corresponding to  $n$  observations of the random vector  $\xi$ .

- $$W = \sum_{i=1}^n w_i$$

is the accumulated weight corresponding to observations  $X$ .

### Vector of sample means

$$M(X) = (M_1(X), \dots, M_p(X)) \text{ with } M_i(X) = \frac{1}{w} \sum_{j=1}^n w_j x_{ij}$$

for all  $i = 1, \dots, p$ .

### Vector of sample partial sums

$$S(X) = (S_1(X), \dots, S_p(X)) \text{ with } S_i(X) = \sum_{j=1}^n w_j x_{ij}$$

for all  $i = 1, \dots, p$ .

### Vector of sample variances

$$V(X) = (V_1(X), \dots, V_p(X)) \text{ with } V_i(X) = \frac{1}{B} \sum_{j=1}^n w_j (x_{ij} - M_i(X))^2, B = W - \sum_{j=1}^n w_j^2 / W$$

for all  $i = 1, \dots, p$ .

### Vector of sample raw/algebraic moments of $k$ -th order, $k \geq 1$

$$R^{(k)}(X) = (R_1^{(k)}(X), \dots, R_p^{(k)}(X)) \text{ with } R_i^{(k)}(X) = \frac{1}{W} \sum_{j=1}^n w_j x_{ij}^k$$

for all  $i = 1, \dots, p$ .

**Vector of sample raw/algebraic partial sums of  $k$ -th order,  $k= 2, 3, 4$  (raw/algebraic partial sums of squares/cubes/fourth powers)**

$$S^k(X) = (S_1^k(X), \dots, S_p^k(X)) \text{ with } S_i^k(X) = \sum_{j=1}^n w_j x_{ij}^k$$

for all  $i = 1, \dots, p$ .

**Vector of sample central moments of the third and the fourth order**

$$C^{(k)}(X) = (C_1^{(k)}(X), \dots, C_p^{(k)}(X)) \text{ with } C_i^{(k)}(X) = \frac{1}{B} \sum_{j=1}^n w_j (x_{ij} - M_i(X))^k, B = \sum_{j=1}^n w_j$$

for all  $i = 1, \dots, p$  and  $k = 3, 4$ .

**Vector of sample central partial sums of  $k$ -th order,  $k= 2, 3, 4$  (central partial sums of squares/cubes/fourth powers)**

$$S^k(X) = (S_1^k(X), \dots, S_p^k(X)) \text{ with } S_i^k(X) = \sum_{j=1}^n w_j (x_{ij} - S_i(X))^k$$

for all  $i = 1, \dots, p$ .

**Vector of sample excess kurtosis values**

$$B(X) = (B_1(X), \dots, B_p(X)) \text{ with } B_i(X) = \frac{C_i^{(4)}(X)}{V_i^2(X)} - 3$$

for all  $i = 1, \dots, p$ .

**Vector of sample skewness values**

$$\Gamma(X) = (\Gamma_1(X), \dots, \Gamma_p(X)) \text{ with } \Gamma_i(X) = \frac{C_i^{(3)}(X)}{V_i^{1.5}(X)}$$

for all  $i = 1, \dots, p$ .

**Vector of sample variation coefficients**

$$VC(X) = (VC_1(X), \dots, VC_p(X)) \text{ with } VC_i(X) = \frac{V_i^{0.5}(X)}{M_i(X)}$$

for all  $i = 1, \dots, p$ .

**Matrix of order statistics**

Matrix  $Y = (Y_{ij})_{p \times n}$ , in which the  $i$ -th row  $(Y)_i = (Y_{ij})_{j=1..n}$  is obtained as a result of sorting in the ascending order of row  $(X)_i = (X_{ij})_{j=1..n}$  in the original matrix of observations.

**Vector of sample minimum values**

$$Min(X) = (Min_1(X), \dots, Min_p(X)), \text{ where } Min_i(X) = y_{i1}$$

for all  $i = 1, \dots, p$ .

**Vector of sample maximum values**

$$Max(X) = (Max_1(X), \dots, Max_p(X)), \text{ where } Max_i(X) = y_{in}$$

for all  $i = 1, \dots, p$ .

### Vector of sample median values

$$Med(X) = (Med_1(X), \dots, Med_p(X)), \text{ where } Med_i(X) = \begin{cases} y_{i, (n+1)/2}, & \text{if } n \text{ is odd} \\ (y_{i, n/2} + y_{i, n/2+1})/2, & \text{if } n \text{ is even} \end{cases}$$

for all  $i = 1, \dots, p$ .

### Vector of sample median absolute deviations

$$MDAD(X) = (MDAD_1(X), \dots, MDAD_p(X)), \text{ where } MDAD_i(X) = Med_i(Z) \text{ with } Z = (z_{ij})_{i=1\dots p, j=1\dots n'}$$

$$z_{ij} = |x_{ij} - Med_i(X)|$$

for all  $i = 1, \dots, p$ .

### Vector of sample mean absolute deviations

$$MNAD(X) = (MNAD_1(X), \dots, MNAD_p(X)), \text{ where } MNAD_i(X) = M_i(Z) \text{ with } Z = (z_{ij})_{i=1\dots p, j=1\dots n'}$$

$$z_{ij} = |x_{ij} - M_i(X)|$$

for all  $i = 1, \dots, p$ .

### Vector of sample quantile values

For a positive integer number  $q$  and  $k$  belonging to the interval  $[0, q-1]$ , point  $z_i$  is the  $k$ -th  $q$  quantile of the random variable  $\xi_i$  if  $P\{\xi_i \leq z_i\} \geq \beta$  and  $P\{\xi_i \leq z_i\} \geq 1 - \beta$ , where

- $P$  is the probability measure.
- $\beta = k/n$  is the quantile order.

The calculation of quantiles is as follows:

$j = [(n-1)\beta]$  and  $f = \{(n-1)\beta\}$  as integer and fractional parts of the number  $(n-1)\beta$ , respectively, and the vector of sample quantile values is

$$Q(X, \beta) = (Q_1(X, \beta), \dots, Q_p(X, \beta))$$

where

$$(Q_i(X, \beta) = Y_{i, j+1} + f(Y_{i, j+2} - Y_{i, j+1}))$$

for all  $i = 1, \dots, p$ .

### Variance-covariance matrix

$$C(X) = (c_{ij}(X))_{p \times p}$$

where

$$c_{ij}(X) = \frac{1}{B} \sum_{k=1}^n w_k (x_{ik} - M_i(X))(x_{jk} - M_j(X)), \quad B = W - \sum_{j=1}^n w_j^2 / W$$

### Cross-product matrix (matrix of cross-products and sums of squares)

$$CP(X) = (cp_{ij}(X))_{p \times p}$$

where

$$cp_{ij}(X) = \sum_{k=1}^n w_k (x_{ik} - M_i(X))(x_{jk} - M_j(X))$$

## Pooled and group variance-covariance matrices

The set  $N = \{1, \dots, n\}$  is partitioned into non-intersecting subsets

$$G_i, i = 1..g, N = \bigcup_{i=1}^g G_i$$

The observation  $[X]_j = (x_{ij})_{i=1..p}$  belongs to the group  $r$  if  $j \in G_r$ . One observation belongs to one group only. The group mean and variance-covariance matrices are calculated similarly to the formulas above:

$$M^{(r)}(X) = (M_1^{(r)}(X), \dots, M_p^{(r)}(X)) \text{ with } M_i^{(r)}(X) = \frac{1}{W^{(r)}} \sum_{j \in G_r} w_j x_{ij}, W^{(r)} = \sum_{j \in G_r} w_j$$

for all  $i = 1, \dots, p$ ,

$$C^{(r)}(X) = (c_{ij}^{(r)}(X))_{p \times p}$$

where

$$c_{ij}^{(r)}(X) = \frac{1}{B^{(r)}} \sum_{k \in G_r} w_k (x_{ik} - M_i^{(r)}(X))(x_{jk} - M_j^{(r)}(X)), B^{(r)} = W^{(r)} - \sum_{j \in G_r} w_j^2 / W^{(r)}$$

for all  $i = 1, \dots, p$  and  $j = 1, \dots, p$ .

A pooled variance-covariance matrix and a pooled mean are computed as weighted mean over group covariance matrices and group means, correspondingly:

$$M^{pooled}(X) = (M_1^{pooled}(X), \dots, M_p^{pooled}(X)) \text{ with } M_i^{pooled}(X) = \frac{1}{W^{(1)} + \dots + W^{(g)}} \sum_{r=1}^g W^{(r)} M_i^{(r)}(X)$$

for all  $i = 1, \dots, p$ ,

$$C^{pooled}(X) = (c_{ij}^{pooled}(X))_{p \times p}, c_{ij}^{pooled}(X) = \frac{1}{B^{(1)} + \dots + B^{(g)}} \sum_{r=1}^g B^{(r)} c_{ij}^{(r)}(X)$$

for all  $i = 1, \dots, p$  and  $j = 1, \dots, p$ .

## Correlation matrix

$$R(X) = (r_{ij}(X))_{p \times p}, \text{ where } r_{ij}(X) = \frac{c_{ij}}{\sqrt{c_{ii}c_{jj}}}$$

for all  $i = 1, \dots, p$  and  $j = 1, \dots, p$ .

## Partial variance-covariance matrix

For a random vector  $\xi$  partitioned into two components  $Z$  and  $Y$ , a variance-covariance matrix  $C$  describes the structure of dependencies in the vector  $\xi$ :

$$C(X) = \begin{pmatrix} C_Z(X) & C_{ZY}(X) \\ C_{YZ}(X) & C_Y(X) \end{pmatrix}.$$

The partial covariance matrix  $P(X) = (p_{ij}(X))_{k \times k}$  is defined as

$$P(X) = C_Y(X) - C_{YZ}(X)C_Z^{-1}C_{ZY}(X).$$

where  $k$  is the dimension of  $Y$ .

## Partial correlation matrix

The following is a partial correlation matrix for all  $i = 1, \dots, k$  and  $j = 1, \dots, k$ :

$$RP(X) = (rp_{ij}(X))_{k \times k}, \text{ where } rp_{ij}(X) = \frac{p_{ij}(X)}{\sqrt{p_{ii}(X)p_{jj}(X)}}$$

where

- $k$  is the dimension of  $Y$ .
- $\rho_{ij}(X)$  are elements of the partial variance-covariance matrix.

### Sorted dataset

Matrix  $Y = (y_{ij})_{p \times n}$ , in which the  $i$ -th row  $(Y)_i$  is obtained as a result of sorting in ascending order the row  $(X)_i = (x_{ij})_{j=1..n}$  in the original matrix of observations.

# Fourier Transform Functions

The general form of the discrete Fourier transform is

$$z_{k_1, k_2, \dots, k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \dots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1, j_2, \dots, j_d} \exp\left(\delta i 2\pi \sum_{l=1}^d j_l k_l / n_l\right)$$

for  $k_l = 0, \dots, n_l-1$  ( $l = 1, \dots, d$ ), where  $\sigma$  is a scale factor,  $\delta = -1$  for the forward transform, and  $\delta = +1$  for the inverse (backward) transform. In the forward transform, the input (periodic) sequence  $\{w_{j_1, j_2, \dots, j_d}\}$  belongs to the set of complex-valued sequences and real-valued sequences. Respective domains for the backward transform are represented by complex-valued sequences and complex-valued conjugate-even sequences.

The Intel® Math Kernel Library (Intel® MKL) provides an interface for computing a discrete Fourier transform through the fast Fourier transform algorithm. Prefixes `Dfti` in function names and `DFTI` in the names of configuration parameters stand for Discrete Fourier Transform Interface.

This chapter describes the following implementations of the fast Fourier transform functions available in Intel MKL:

- Fast Fourier transform (FFT) functions for single-processor or shared-memory systems (see [FFT Functions](#))
- [Cluster FFT functions](#) for distributed-memory architectures (available only for Intel® 64 and Intel® Many Integrated Core architectures)

---

## NOTE

Intel MKL also supports the FFTW3\* interfaces to the fast Fourier transform functionality for shared memory paradigm (SMP) systems.

---

Both FFT and Cluster FFT functions compute an FFT in five steps:

1. Allocate a fresh descriptor for the problem with a call to the `DftiCreateDescriptor` or `DftiCreateDescriptorDM` function. The descriptor captures the configuration of the transform, such as the dimensionality (or rank), sizes, number of transforms, memory layout of the input/output data (defined by strides), and scaling factors. Many of the configuration settings are assigned default values in this call which you might need to modify in your application.
2. Optionally adjust the descriptor configuration with a call to the `DftiSetValue` or `DftiSetValueDM` function as needed. Typically, you must carefully define the data storage layout for an FFT or the data distribution among processes for a Cluster FFT. The configuration settings of the descriptor, such as the default values, can be obtained with the `DftiGetValue` or `DftiGetValueDM` function.
3. Commit the descriptor with a call to the `DftiCommitDescriptor` or `DftiCommitDescriptorDM` function, that is, make the descriptor ready for the transform computation. Once the descriptor is committed, the parameters of the transform, such as the type and number of transforms, strides and distances, the type and storage layout of the data, and so on, are "frozen" in the descriptor.
4. Compute the transform with a call to the `DftiComputeForward/DftiComputeBackward` or `DftiComputeForwardDM/DftiComputeBackwardDM` functions as many times as needed. Because the descriptor is defined and committed separately, all that the compute functions do is take the input and output data and compute the transform as defined. To modify any configuration parameters for another call to a compute function, use `DftiSetValue` followed by `DftiCommitDescriptor` (`DftiSetValueDM` followed by `DftiCommitDescriptorDM`) or create and commit another descriptor.
5. Deallocate the descriptor with a call to the `DftiFreeDescriptor` or `DftiFreeDescriptorDM` function. This returns the memory internally consumed by the descriptor to the operating system.

All the above functions return an integer status value, which is zero upon successful completion of the operation. You can interpret a non-zero status with the help of the [DftiErrorClass](#) or [DftiErrorMessage](#) function.

The FFT functions support lengths with arbitrary factors. You can improve performance of the Intel MKL FFT if the length of your data vector permits factorization into powers of optimized radices. See the *Intel MKL Developer Guide* for specific radices supported efficiently.

**NOTE**

The FFT functions assume the Cartesian representation of complex data (that is, the real and imaginary parts define a complex number). The Intel MKL Vector Mathematical Functions provide efficient tools for conversion to and from polar representation (see [Example "Conversion from Cartesian to polar representation of complex data"](#) and [Example "Conversion from polar to Cartesian representation of complex data"](#)).

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## FFT Functions

The fast Fourier transform function library of Intel MKL provides one-dimensional, two-dimensional, and multi-dimensional transforms (of up to seven dimensions) and offers both Fortran and C interfaces for all transform functions.

Table "FFT Functions in Intel MKL" lists FFT functions implemented in Intel MKL:

### FFT Functions in Intel MKL

| Function Name                        | Operation                                                                                     |
|--------------------------------------|-----------------------------------------------------------------------------------------------|
| Descriptor Manipulation Functions    |                                                                                               |
| <a href="#">DftiCreateDescriptor</a> | Allocates the descriptor data structure and initializes it with default configuration values. |
| <a href="#">DftiCommitDescriptor</a> | Performs all initialization for the actual FFT computation.                                   |
| <a href="#">DftiFreeDescriptor</a>   | Frees memory allocated for a descriptor.                                                      |
| <a href="#">DftiCopyDescriptor</a>   | Makes a copy of an existing descriptor.                                                       |
| FFT Computation Functions            |                                                                                               |
| <a href="#">DftiComputeForward</a>   | Computes the forward FFT.                                                                     |
| <a href="#">DftiComputeBackward</a>  | Computes the backward FFT.                                                                    |
| Descriptor Configuration Functions   |                                                                                               |
| <a href="#">DftiSetValue</a>         | Sets one particular configuration parameter with the specified configuration value.           |
| <a href="#">DftiGetValue</a>         | Gets the value of one particular configuration parameter.                                     |

| Function Name                 | Operation                                                       |
|-------------------------------|-----------------------------------------------------------------|
| Status Checking Functions     |                                                                 |
| <code>DftiErrorClass</code>   | Checks if the status reflects an error of a predefined class.   |
| <code>DftiErrorMessage</code> | Translates the numeric value of an error status into a message. |

## FFT Interface

The Intel MKL FFT functions are provided with the Fortran and C interfaces.

The materials presented in this chapter assume the availability of native complex types in C as they are specified in C9X.

To use the FFT functions, you need to include `mkl_dfti.h` in your C code.

The C interface provides the `DFTI_DESCRIPTOR_HANDLE` type, named constants of two enumeration types `DFTI_CONFIG_PARAM` and `DFTI_CONFIG_VALUE`, and functions, some of which accept different numbers of input arguments.

### NOTE

The current version of the library may not support some of the FFT functions or functionality described in the subsequent sections of this chapter. You can find the complete list of the implementation-specific exceptions in the Intel MKL Release Notes.

For the main categories of Intel MKL FFT functions, see [FFT Functions](#).

## Computing an FFT

You can find code examples that compute transforms in the [Fourier Transform Functions Code Examples](#) section in the Code Examples appendix.

Usually you can compute an FFT by five function calls (refer to the [usage model](#) for details). A single data structure, the descriptor, stores configuration parameters that can be changed independently.

The descriptor data structure, when created, contains information about the length and domain of the FFT to be computed, as well as the setting of several configuration parameters. Default settings for some of these parameters are as follows:

- Scale factor: none
- Number of data sets: one
- Data storage: contiguous
- Placement of results: in-place (the computed result overwrites the input data)

The default settings can be changed one at a time through the function `DftiSetValue` as illustrated in [Example "Changing Default Settings \(C\)"](#).

## Configuration Settings

Each of the configuration parameters is identified by a named constant in the `MKL_DFTI` module. These named constants have the enumeration type `DFTI_CONFIG_PARAM`.

All the Intel MKL FFT configuration parameters are readable. Some of them are read-only, while others can be set using the `DftiCreateDescriptor` or `DftiSetValue` function.

Values of the configuration parameters fall into the following groups:

- Values that have native data types. For example, the number of simultaneous transforms requested has an integer value, while the scale factor for a forward transform is a single-precision number.

- Values that are discrete in nature and are provided in the `MKL_DFTI` module as named constants. For example, the domain of the forward transform requires values to be named constants. The named constants for configuration values have the enumeration type `DFTI_CONFIG_VALUE`.

Table "Configuration Parameters" summarises the information on configuration parameters, along with their types and values. For more details of each configuration parameter, see the subsection describing this parameter.

## Configuration Parameters

| Configuration Parameter                                                                                               | Type/Value                                                                      | Comments                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|

Configuring and Computing an FFT in C/C++

## DFTI\_PRECISION

The configuration parameter `DFTI_PRECISION` denotes the floating-point precision in which the transform is to be carried out. A setting of `DFTI_SINGLE` stands for single precision, and a setting of `DFTI_DOUBLE` stands for double precision. The data must be presented in this precision, the computation is carried out in this precision, and the result is delivered in this precision.

`DFTI_PRECISION` does not have a default value. Set it explicitly by calling the `DftiCreateDescriptor` function.

To better understand configuration of the precision of transforms, you can refer to these examples in your Intel MKL directory:

```
./examples/dftc/source/basic_sp_complex_dft_1d.c
./examples/dftc/source/basic_dp_complex_dft_1d.c
```

[DFTI\\_DIMENSION, DFTI\\_LENGTHS](#)  
[DftiCreateDescriptor](#)

## DFTI\_FORWARD\_DOMAIN

The general form of a discrete Fourier transform is

$$z_{k_1, k_2, \dots, k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \dots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1, j_2, \dots, j_d} \exp\left(\delta i 2\pi \sum_{l=1}^d j_l k_l / n_l\right)$$

for  $k_l = 0, \dots, n_l-1$  ( $l = 1, \dots, d$ ), where  $\sigma$  is a scale factor,  $\delta = -1$  for the forward transform, and  $\delta = +1$  for the backward transform.

The Intel MKL implementation of the FFT algorithm, used for fast computation of discrete Fourier transforms, supports forward transforms on input sequences of two domains, as specified by the `DFTI_FORWARD_DOMAIN` configuration parameter: general complex-valued sequences (`DFTI_COMPLEX` domain) and general real-valued sequences (`DFTI_REAL` domain). The forward transform maps the forward domain to the corresponding backward domain, as shown in [Table "Correspondence of Forward and Backward Domain"](#).

The conjugate-even domain covers complex-valued sequences with the symmetry property:

$$x(k_1, k_2, \dots, k_d) = \text{conjugate}(x(n_1 - k_1, n_2 - k_2, \dots, n_d - k_d))$$

where the index arithmetic is performed modulo respective size, that is,

$$x(\dots, \text{expr}_s, \dots) \equiv x(\dots, \text{mod}(\text{expr}_s, n_s), \dots),$$

and therefore

$$x(\dots, n_s, \dots) \equiv x(\dots, 0, \dots).$$

Due to this property of conjugate-even sequences, only a part of such sequence is stored in the computer memory, as described in [DFTI\\_CONJUGATE\\_EVEN\\_STORAGE](#).

### Correspondence of Forward and Backward Domain

| Forward Domain                        | Implied Backward Domain               |
|---------------------------------------|---------------------------------------|
| Complex ( <code>DFTI_COMPLEX</code> ) | Complex ( <code>DFTI_COMPLEX</code> ) |
| Real ( <code>DFTI_REAL</code> )       | Conjugate-even                        |

`DFTI_FORWARD_DOMAIN` does not have a default value. Set it explicitly by calling the `DftiCreateDescriptor` function.

To better understand usage of the `DFTI_FORWARD_DOMAIN` configuration parameter, you can refer to these examples in your Intel MKL directory:

```
./examples/dftc/source/basic_sp_complex_dft_1d.c
./examples/dftc/source/basic_sp_real_dft_1d.c
```

[DftiCreateDescriptor](#)

### DFTI\_DIMENSION, DFTI\_LENGTHS

The dimension of the transform is a positive integer value represented in an integer scalar of `MKL_LONG` data type. For a one-dimensional transform, the transform length is specified by a positive integer value represented in an integer scalar of `MKL_LONG` data type. For multi-dimensional ( $\geq 2$ ) transform, the lengths of each of the dimensions are supplied in an integer array (of `MKL_LONG` data type).

`DFTI_DIMENSION` and `DFTI_LENGTHS` do not have a default value. To set them, use the `DftiCreateDescriptor` function and not the `DftiSetValue` function.

To better understand usage of the `DFTI_DIMENSION` and `DFTI_LENGTHS` configuration parameters, you can refer to basic examples of one-, two-, and three-dimensional transforms in your Intel MKL directory. Naming conventions for the examples are self-explanatory. For example, refer to these examples of single-precision two-dimensional transforms:

```
./examples/dftc/source/basic_sp_real_dft_2d.c
./examples/dftc/source/basic_sp_complex_dft_2d.c
```

### DFTI\_PLACEMENT

By default, the computational functions overwrite the input data with the output result. That is, the default setting of the configuration parameter `DFTI_PLACEMENT` is `DFTI_INPLACE`. You can change that by setting it to `DFTI_NOT_INPLACE`.

---

**NOTE**

The data sets have no common elements.

---

To better understand usage of the `DFTI_PLACEMENT` configuration parameter, refer to the following example in your Intel MKL directory:

```
./examples/dftc/source/config_placement.c
```

### See Also

[DftiSetValue](#)

### DFTI\_FORWARD\_SCALE, DFTI\_BACKWARD\_SCALE

The forward transform and backward transform are each associated with a scale factor  $\sigma$  of its own having the default value of 1. You can specify the scale factors using one or both of the configuration parameters `DFTI_FORWARD_SCALE` and `DFTI_BACKWARD_SCALE`. For example, for a one-dimensional transform of length  $n$ , you can use the default scale of 1 for the forward transform and set the scale factor for the backward transform to be  $1/n$ , thus making the backward transform the inverse of the forward transform.

Set the scale factor configuration parameter using a real floating-point data type of the same precision as the value for `DFTI_PRECISION`.

**NOTE**

For inquiry of the scale factor with the `DftiGetValue` function, the `config_val` parameter must have the same floating-point precision as the descriptor.

[DftiGetValue](#)

**DFTI\_NUMBER\_OF\_USER\_THREADS**

The `DFTI_NUMBER_OF_USER_THREADS` configuration parameter is no longer used and kept for compatibility with previous versions of Intel MKL.

**See Also**

[DftiSetValue](#)

**DFTI\_THREAD\_LIMIT**

In some situations you may need to limit the number of threads that the `DftiComputeForward` and `DftiComputeBackward` functions use. For example, if more than one thread calls Intel MKL, it might be important that the thread calling these functions does not oversubscribe computing resources (CPU cores). Similarly, a known limit of the maximum number of threads to be used in computations might help the `DftiCommitDescriptor` function to select a more optimal computation method.

Set the parameter `DFTI_THREAD_LIMIT` as follows:

- To a positive number, to specify the maximum number of threads to be used by the compute functions.
- To zero (the default value), to use the maximum number of threads permitted in Intel MKL FFT functions. See "Techniques to Set the Number of Threads" in the *Intel MKL Developer Guide* for more information.

On an attempt to set a negative value, the `DftiSetValue` function returns an error and does not update the descriptor.

The value of the `DFTI_THREAD_LIMIT` configuration parameter returned by the `DftiGetValue` function is defined as follows:

- 1 if Intel MKL runs in the sequential mode
- Depends of the commit status of the descriptor if Intel MKL runs in a threaded mode:

| Commit Status | Value                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Not committed | The value of <code>DFTI_THREAD_LIMIT</code> set in a previous call to the <code>DftiSetValue</code> function or the default value   |
| Committed     | The upper limit on the number of threads used by the <code>DftiComputeForward</code> and <code>DftiComputeBackward</code> functions |

To better understand usage of the `DFTI_THREAD_LIMIT` configuration parameter, refer to the following example in your Intel MKL directory:

```
./examples/dftc/source/config_thread_limit.c
```

DFTI\_COMMIT\_STATUS

DFTI\_INPUT\_STRIDES, DFTI\_OUTPUT\_STRIDES

The FFT interface provides configuration parameters that define the layout of multidimensional data in the computer memory. For  $d$ -dimensional data set  $X$  defined by dimensions  $N_1 \times N_2 \times \dots \times N_d$ , the layout describes where a particular element  $X(k_1, k_2, \dots, k_d)$  of the data set is located. The memory address of the element  $X(k_1, k_2, \dots, k_d)$  is expressed by the formula

$$\begin{aligned} \text{address of } X(k_1, k_2, \dots, k_d) &= \text{address of } X(0, 0, \dots, 0) + \text{offset} \\ &= \text{address of } X(0, 0, \dots, 0) + s_0 + k_1*s_1 + k_2*s_2 + \dots + k_d*s_d, \end{aligned}$$

where  $s_0$  is the displacement and  $s_1, \dots, s_d$  are generalized strides. The configuration parameters `DFTI_INPUT_STRIDES` and `DFTI_OUTPUT_STRIDES` enable you to get and set these values. The configuration value is an array of values  $(s_0, s_1, \dots, s_d)$  of `MKL_LONG` data type.

The offset is counted in elements of the data type defined by the descriptor configuration (rather than by the type of the variable passed to the computation functions). Specifically, the `DFTI_FORWARD_DOMAIN`, `DFTI_COMPLEX_STORAGE`, and `DFTI_CONJUGATE_EVEN_STORAGE` configuration parameters define the type of the elements as shown in [Table "Assumed Element Types of the Input/Output Data"](#):

**Assumed Element Types of the Input/Output Data**

| Descriptor Configuration                                                                                    | Element Type in the Forward Domain | Element Type in the Backward Domain |
|-------------------------------------------------------------------------------------------------------------|------------------------------------|-------------------------------------|
| <code>DFTI_FORWARD_DOMAIN=DFTI_COMPLEX</code><br><code>DFTI_COMPLEX_STORAGE=DFTI_COMPLEX_COMPLEX</code>     | Complex                            | Complex                             |
| <code>DFTI_FORWARD_DOMAIN=DFTI_COMPLEX</code><br><code>DFTI_COMPLEX_STORAGE=DFTI_REAL_REAL</code>           | Real                               | Real                                |
| <code>DFTI_FORWARD_DOMAIN=DFTI_REAL</code><br><code>DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_REAL</code>    | Real                               | Real                                |
| <code>DFTI_FORWARD_DOMAIN=DFTI_REAL</code><br><code>DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX</code> | Real                               | Complex                             |

The `DFTI_INPUT_STRIDES` configuration parameter defines the layout of the input data, while the element type is defined by the forward domain for the `DftiComputeForward` function and by the backward domain for the `DftiComputeBackward` function. The `DFTI_OUTPUT_STRIDES` configuration parameter defines the layout of the output data, while the element type is defined by the backward domain for the `DftiComputeForward` function and by the forward domain for `DftiComputeBackward` function.

**NOTE**

The `DFTI_INPUT_STRIDES` and `DFTI_OUTPUT_STRIDES` configuration parameters define the layout of input and output data, and not the forward-domain and backward-domain data. If the data layouts in forward domain and backward domain differ, set `DFTI_INPUT_STRIDES` and `DFTI_OUTPUT_STRIDES` explicitly and then commit the descriptor before calling computation functions.

For in-place transforms (`DFTI_PLACEMENT=DFTI_INPLACE`), the configuration set by `DFTI_OUTPUT_STRIDES` is ignored when the element types in the forward and backward domains are the same. If they are different, set `DFTI_OUTPUT_STRIDES` explicitly (even though the transform is in-place). Ensure a consistent configuration for in-place transforms, that is, the locations of the first elements on input and output must coincide in each dimension.

The FFT interface supports both positive and negative stride values. If you use negative strides, set the displacement of the data as follows:

$$s_0 = \sum_{i=1}^d (N_i - 1) \cdot \max(-s_i, 0).$$

The default setting of strides in a general multi-dimensional case assumes that the array that contains the data has no padding. The order of the strides depends on the programming language. For example:

```
MKL_LONG dims[] = { nd, ..., n2, n1 };
DftiCreateDescriptor(&hand, precision, domain, d, dims);
// The above call assumes data declaration: type X[nd]...[n2][n1]
// Default strides are { 0, nd*...*n2*n1, ..., n2*n1, n1, 1 }
```

Note that in case of a real FFT (`DFTI_FORWARD_DOMAIN=DFTI_REAL`), where different data layouts in the backward domain are available (see `DFTI_PACKED_FORMAT`), the default value of the strides is not intuitive for the recommended CCE format (configuration setting `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX`). In case of an *in-place* real transform with the CCE format, set the strides explicitly, as follows:

```
MKL_LONG dims[] = { nd, ..., n2, n1 };
MKL_LONG rstrides[] = { 0, 2*nd*...*n2*(n1/2+1), ..., 2*n2*(n1/2+1), 2*(n1/2+1), 1 };
MKL_LONG cstrides[] = { 0, nd*...*n2*(n1/2+1), ..., n2*(n1/2+1), (n1/2+1), 1 };
DftiCreateDescriptor(&hand, precision, DFTI_REAL, d, dims);
DftiSetValue(hand, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX);
// Set the strides appropriately for forward/backward transform
```

To better understand configuration of strides, you can also refer to these examples in your Intel MKL directory:

```
./examples/dftc/source/basic_sp_real_dft_2d.c
./examples/dftc/source/basic_sp_real_dft_3d.c
./examples/dftc/source/basic_dp_real_dft_2d.c
./examples/dftc/source/basic_dp_real_dft_3d.c
```

## DFTI\_NUMBER\_OF\_TRANSFORMS

If you need to perform a large number of identical FFTs, you can do this in a single call to a `DftiCompute*` function with the value of the `DFTI_NUMBER_OF_TRANSFORMS` configuration parameter equal to the actual number of the transforms. The default value of this parameter is one. You can set this parameter to a positive integer value using the `MKL_LONG` data type. When setting the number of transforms to a value greater than one, you also need to specify the distance between the input and output data sets using one of the `DFTI_INPUT_DISTANCE` and `DFTI_OUTPUT_DISTANCE` configuration parameters or both.

- 
- The data sets to be transformed must not have common elements.
  - All the sets of data must be located within the same memory block.
- 

To better understand usage of the `DFTI_NUMBER_OF_TRANSFORMS` configuration parameter, refer to the following example in your Intel MKL directory:

```
./examples/dftc/source/config_number_of_transforms.c
```

## See Also

[FFT Computation Functions](#)

[DFTI\\_INPUT\\_DISTANCE](#), [DFTI\\_OUTPUT\\_DISTANCE](#)  
[DftiSetValue](#)

## [DFTI\\_INPUT\\_DISTANCE](#), [DFTI\\_OUTPUT\\_DISTANCE](#)

The FFT interface in Intel MKL enables computation of multiple transforms. To compute multiple transforms, you need to specify the data distribution of the multiple sets of data. The distance between the first data elements of consecutive data sets, [DFTI\\_INPUT\\_DISTANCE](#) for input data or [DFTI\\_OUTPUT\\_DISTANCE](#) for output data, specifies the distribution. The configuration setting is a value of [MKL\\_LONG](#) data type.

The default value for both configuration settings is one. You must set this parameter explicitly if the number of transforms is greater than one (see [DFTI\\_NUMBER\\_OF\\_TRANSFORMS](#)).

The distance is counted in elements of the data type defined by the descriptor configuration (rather than by the type of the variable passed to the computation functions). Specifically, the [DFTI\\_FORWARD\\_DOMAIN](#), [DFTI\\_COMPLEX\\_STORAGE](#), and [DFTI\\_CONJUGATE\\_EVEN\\_STORAGE](#) configuration parameters define the type of the elements as shown in [Table "Assumed Element Types of the Input/Output Data"](#).

---

### NOTE

The configuration parameters [DFTI\\_INPUT\\_DISTANCE](#) and [DFTI\\_OUTPUT\\_DISTANCE](#) define the distance within input and output data, and not within the forward-domain and backward-domain data. If the distances in the forward and backward domains differ, set [DFTI\\_INPUT\\_DISTANCE](#) and [DFTI\\_OUTPUT\\_DISTANCE](#) explicitly and then commit the descriptor before calling computation functions.

---

For in-place transforms ([DFTI\\_PLACEMENT=DFTI\\_INPLACE](#)), the configuration set by [DFTI\\_OUTPUT\\_DISTANCE](#) is ignored when the element types in the forward and backward domains are the same. If they are different, set [DFTI\\_OUTPUT\\_DISTANCE](#) explicitly (even though the transform is in-place). Ensure a consistent configuration for in-place transforms, that is, the locations of the data sets on input and output must coincide.

The following example illustrates setting of the [DFTI\\_INPUT\\_DISTANCE](#) configuration parameter:

```
MKL_LONG dims[] = { nd, ..., n2, n1 };
MKL_LONG distance = nd*...*n2*n1;
DftiCreateDescriptor(&hand, precision, DFTI_COMPLEX, d, dims);
DftiSetValue(hand, DFTI_NUMBER_OF_TRANSFORMS, (MKL_LONG)howmany);
DftiSetValue(hand, DFTI_INPUT_DISTANCE, distance);
```

To better understand configuration of the distances, you can also refer to the following example in your Intel MKL directory:

```
./examples/dftc/source/config_number_of_transforms.c
```

## [DFTI\\_COMPLEX\\_STORAGE](#), [DFTI\\_REAL\\_STORAGE](#), [DFTI\\_CONJUGATE\\_EVEN\\_STORAGE](#)

Depending on the value of the [DFTI\\_FORWARD\\_DOMAIN](#) configuration parameter, the implementation of FFT supports several storage schemes for input and output data (see document [3] for the rationale behind the definition of the storage schemes). The data elements are placed within contiguous memory blocks, defined with generalized strides (see [DFTI\\_INPUT\\_STRIDES](#), [DFTI\\_OUTPUT\\_STRIDES](#)). For multiple transforms, all sets of data should be located within the same memory block, and the data sets should be placed at the same distance from each other (see [DFTI\\_NUMBER\\_OF\\_TRANSFORMS](#) and [DFTI\\_INPUT\\_DISTANCE](#), [DFTI\\_OUTPUT\\_DISTANCE](#)).

**TIP**

Avoid setting up multidimensional arrays with lists of pointers to one-dimensional arrays. Instead use a one-dimensional array with the explicit indexing to access the data elements.

FFT Examples demonstrate the usage of storage formats.

**DFTI\_COMPLEX\_STORAGE: storage schemes for a complex domain**

For the DFTI\_COMPLEX forward domain, both input and output sequences belong to a complex domain. In this case, the configuration parameter DFTI\_COMPLEX\_STORAGE can have one of the two values:

DFTI\_COMPLEX\_COMPLEX (default) or DFTI\_REAL\_REAL.

**NOTE**

In the Intel MKL FFT interface, storage schemes for a forward complex domain and the respective backward complex domain are the same.

With DFTI\_COMPLEX\_COMPLEX storage, complex-valued data sequences are referenced by a single complex parameter (array) AZ so that a complex-valued element  $z_{k_1, k_2, \dots, k_d}$  of the m-th d-dimensional sequence is located at  $AZ[m*distance + stride_0 + k_1*stride_1 + k_2*stride_2 + \dots + k_d*stride_d]$  as a structure consisting of the real and imaginary parts.

The following code illustrates usage of the DFTI\_COMPLEX\_COMPLEX storage:

```
complex *AZ = malloc(N1*N2*N3*M * sizeof(AZ[0]));
MKL_LONG ios[4], iodist; // input/output strides and distance
...
// on input: Z{k1,k2,k3,m}
// = AZ[ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist]
status = DftiComputeForward(desc, AZ);
// on output: Z{k1,k2,k3,m}
// = AZ[ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist]
```

With the DFTI\_REAL\_REAL storage, complex-valued data sequences are referenced by two real parameters AR and AI so that a complex-valued element  $z_{k_1, k_2, \dots, k_d}$  of the m-th sequence is computed as  $AR[m*distance + stride_0 + k_1*stride_1 + k_2*stride_2 + \dots + k_d*stride_d] + \sqrt{-1} * AI[m*distance + stride_0 + k_1*stride_1 + k_2*stride_2 + \dots + k_d*stride_d]$ .

The following code illustrates usage of the DFTI\_REAL\_REAL storage:

```
float *AR = malloc(N1*N2*N3*M * sizeof(AR[0]));
float *AI = malloc(N1*N2*N3*M * sizeof(AI[0]));
MKL_LONG ios[4], iodist; // input/output strides and distance
...
// on input: Z{k1,...,kd,m}
// = AR[ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist]
// + I*AI[ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist]
status = DftiComputeForward(desc, AR, AI);
// on output: Z{k1,...,kd,m}
// = AR[ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist]
// + I*AI[ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist]
```

**DFTI\_REAL\_STORAGE: storage schemes for a real domain**

The Intel MKL FFT interface supports only one configuration value for this storage scheme: DFTI\_REAL\_REAL.

With the DFTI\_REAL\_REAL storage, real-valued data sequences in a real domain are referenced by one real parameter AR so that real-valued element of the m-th sequence is located as  $AR[m*distance + stride_0 + k_1*stride_1 + k_2*stride_2 + \dots + k_d*stride_d]$ .

## DFTI\_CONJUGATE\_EVEN\_STORAGE: storage scheme for a conjugate-even domain

The Intel MKL FFT interface supports two configuration values for this parameter: `DFTI_COMPLEX_REAL` (default) and `DFTI_COMPLEX_COMPLEX`. In both cases, the conjugate-even symmetry of the data enables storing only about a half of the whole mathematical result, so that one part of it can be directly referenced in the memory while the other part can be reconstructed depending on the selected storage configuration.

With the `DFTI_COMPLEX_REAL` storage, the complex-valued data sequences in the conjugate-even domain can be reconstructed as described in section [DFTI\\_PACKED\\_FORMAT](#).

---

### Important

Although `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_REAL` is the default setting for the `DFTI_REAL` forward domain, avoid using this storage scheme because it is supported only for one- and two-dimensional transforms and will be deprecated in future.

---

With the `DFTI_COMPLEX_COMPLEX` storage, the complex-valued data sequences in the conjugate-even domain are referenced by one complex parameter `AZ` so that a complex-valued element  $z_{k_1, k_2, \dots, k_d}$  of the  $m$ -th sequence can be referenced or reconstructed as described below.

---

### Important

Use the `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX` configuration setting, which will become the default in future. This setting is supported for all transform ranks, provides a uniform pattern for reconstructing the entire conjugate-even sequence from the part of it that is actually stored, and is compatible with data layouts supported by other FFT libraries, such as FFTW. This storage scheme disregards the setting of `DFTI_PACKED_FORMAT`.

---

Consider a  $d$ -dimensional real-to-complex transform

$$Z_{k_1, k_2, \dots, k_d} \equiv \sum_{n_1=0}^{N_1-1} \dots \sum_{n_d=0}^{N_d-1} R_{n_1, n_2, \dots, n_d} e^{\frac{-2\pi i}{N_1} k_1 n_1} \dots e^{\frac{-2\pi i}{N_d} k_d n_d}$$

Because the input sequence  $R$  is real-valued, the mathematical result  $Z$  has conjugate-even symmetry:

$$z_{k_1, k_2, \dots, k_d} = \text{conjugate}(z_{N_1-k_1, N_2-k_2, \dots, N_d-k_d}),$$

where index arithmetic is performed modulo the length of the respective dimension. Obviously, the first element of the result is real-valued:

$$z_{0, 0, \dots, 0} = \text{conjugate}(z_{0, 0, \dots, 0}).$$

For dimensions with even lengths, the other elements are real-valued too. For example, if  $N_s$  is even,

$$z_{0, 0, \dots, N_s/2, 0, \dots, 0} = \text{conjugate}(z_{0, 0, \dots, N_s/2, 0, \dots, 0}).$$

With the conjugate-even symmetry, approximately a half of the result suffices to fully reconstruct it. For an arbitrary dimension  $h$ , it suffices to store elements  $z_{k_1, \dots, k_h, \dots, k_d}$  for the following indices:

- $k_h = 0, \dots, [N_h/2]$
- $k_i = 0, \dots, N_i - 1$ , where  $i = 1, \dots, d$  and  $i \neq h$

The symmetry property enables reconstructing the remaining elements: for  $k_h = [N_h/2] + 1, \dots, N_h - 1$ . In the Intel MKL FFT interface, the halved dimension is the last dimension.

The following code illustrates usage of the `DFTI_COMPLEX_COMPLEX` storage for a conjugate-even domain:

```
float *AR = malloc(N1*N2*M * sizeof(AR[0]));
complex *AZ = malloc(N1*(N2/2+1)*M * sizeof(AZ[0]));
MKL_LONG is[3], os[3], idist, odist; // input and output strides and distance
...
// on input: R{k1,k2,m}
// = AR[is[0] + k1*is[1] + k2*is[2] + m*idist]
status = DftiComputeForward(desc, R, C);
// on output:
// for k2=0..N2/2: Z{k1,k2,m} = AZ[os[0]+k1*os[1]+k2*os[2]+m*odist]
// for k2=N2/2+1..N2-1: Z{k1,k2,m} = conj(AZ[os[0]+(N1-k1)%N1*os[1]
// + (N2-k2)%N2*os[2]+m*odist])
```

For the backward transform, the input and output parameters and layouts exchange roles: set the strides describing the layout in the backward/forward domain as input/output strides, respectively. For example:

```
...
status = DftiSetValue(desc, DFTI_INPUT_STRIDES, fwd_domain_strides);
status = DftiSetValue(desc, DFTI_OUTPUT_STRIDES, bwd_domain_strides);
status = DftiCommitDescriptor(desc);
status = DftiComputeForward(desc, ...);
...
status = DftiSetValue(desc, DFTI_INPUT_STRIDES, bwd_domain_strides);
status = DftiSetValue(desc, DFTI_OUTPUT_STRIDES, fwd_domain_strides);
status = DftiCommitDescriptor(desc);
status = DftiComputeBackward(desc, ...);
```

---

### Important

For in-place transforms, ensure the first element of the input data has the same address as the first element of the output data for each dimension.

---

## DFTI\_PACKED\_FORMAT

The result of the forward transform of real data is a conjugate-even sequence. Due to the symmetry property, only a part of the complex-valued sequence is stored in memory. The `DFTI_PACKED_FORMAT` configuration parameter defines how the data is packed. Possible values of `DFTI_PACKED_FORMAT` depend on the values of the `DFTI_CONJUGATE_EVEN_STORAGE` configuration parameter:

- `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX`.

The only value of `DFTI_PACKED_FORMAT` can be `DFTI_CCE_FORMAT`. You can use this value with transforms of any dimension. For a description of the corresponding packed format, see [DFTI\\_CONJUGATE\\_EVEN\\_STORAGE](#).

- `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_REAL`.

`DFTI_PACKED_FORMAT` can be `DFTI_CCS_FORMAT`, `DFTI_PACK_FORMAT`, or `DFTI_PERM_FORMAT`. You can use these values with one- and two-dimensional transforms only. The corresponding packed formats are described below.

---

### NOTE

Although `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_REAL` is the default setting for the `DFTI_REAL` forward domain, avoid using this storage scheme because it is supported only for one- and two-dimensional transforms, is incompatible with storage schemes of other FFT libraries, and will be deprecated in future.

---

### DFTI\_CCS\_FORMAT for One-dimensional Transforms

The following figure illustrates the storage of a one-dimensional (1D) size- $N$  conjugate-even sequence in a real array for the CCS, PACK, and PERM packed formats. The CCS format requires an array of size  $N+2$ , while the other formats require an array of size  $N$ . Zero-based indexing is used.

#### Storage of a 1D Size- $N$ Conjugate-even Sequence in a Real Array

|              | n= | 0              | 1              | 2              | 3              | ... | 2L-2             | 2L-1             | 2L             | 2L+1           | 2L+2     |
|--------------|----|----------------|----------------|----------------|----------------|-----|------------------|------------------|----------------|----------------|----------|
| CCS, N=2L    |    | R <sub>0</sub> | 0              | R <sub>1</sub> | I <sub>1</sub> | ... | R <sub>L-1</sub> | I <sub>L-1</sub> | R <sub>L</sub> | 0              |          |
| PACK, N=2L   |    | R <sub>0</sub> | R <sub>1</sub> | I <sub>1</sub> | R <sub>2</sub> | ... | I <sub>L-1</sub> | R <sub>L</sub>   |                |                |          |
| PERM, N=2L   |    | R <sub>0</sub> | R <sub>L</sub> | R <sub>1</sub> | I <sub>1</sub> | ... | R <sub>L-1</sub> | I <sub>L-1</sub> |                |                |          |
| CCS, N=2L+1  |    | R <sub>0</sub> | 0              | R <sub>1</sub> | I <sub>1</sub> | ... | R <sub>L-1</sub> | I <sub>L-1</sub> | R <sub>L</sub> | I <sub>L</sub> | not used |
| PACK, N=2L+1 |    | R <sub>0</sub> | R <sub>1</sub> | I <sub>1</sub> | R <sub>2</sub> | ... | I <sub>L-1</sub> | R <sub>L</sub>   | I <sub>L</sub> |                |          |
| PERM, N=2L+1 |    | R <sub>0</sub> | R <sub>1</sub> | I <sub>1</sub> | R <sub>2</sub> | ... | I <sub>L-1</sub> | R <sub>L</sub>   | I <sub>L</sub> |                |          |

The real and imaginary parts of the complex-valued conjugate-even sequence  $Z_k$  are located in a real-valued array AC as illustrated by figure "Storage of a 1D Size- $N$  Conjugate-even Sequence in a Real Array" and can be used to reconstruct the whole conjugate-even sequence as follows:

```
float *AR; // malloc(sizeof(float)*N)
float *AC; // malloc(sizeof(float)*(N+2))
...
status = DftiSetValue(desc, DFTI_PACKED_FORMAT, DFTI_CCS_FORMAT);
...
// on input: R{k} = AR[k]
status = DftiComputeForward(desc, AR, AC); // real-to-complex FFT
// on output:
// for k=0...N/2: Z{k} = AC[2*k+0] + I*AC[2*k+1]
// for k=N/2+1...N-1: Z{k} = AC[2*(N-k)%N + 0] - I*AC[2*(N-k)%N + 1]
```

**DFTI\_CCS\_FORMAT for Two-dimensional Transforms**

The following figure illustrates the storage of a two-dimensional (2D)  $M$ -by- $N$  conjugate-even sequence in a real array for the CCS packed format. This format requires an array of size  $(M+2)$ -by- $(N+2)$ . Row-major layout and zero-based indexing are used. Different colors mark logically separate parts of the result. "n/u" means "not used".

**Storage of a 2D  $M$ -by- $N$  Conjugate-even Sequence in a Real Array for the CCS Format**

|      | n=0                | 1   | 2                   | 3                   | ... | 2L-2                  | 2L-1                  | 2L                 | 2L+1 |
|------|--------------------|-----|---------------------|---------------------|-----|-----------------------|-----------------------|--------------------|------|
| m=0  | R <sub>0,0</sub>   | 0   | R <sub>0,1</sub>    | I <sub>0,1</sub>    | ... | R <sub>0,L-1</sub>    | I <sub>0,L-1</sub>    | R <sub>0,L</sub>   | 0    |

## DFTI\_PACK\_FORMAT for One-dimensional Transforms

The real and imaginary parts of the complex-valued conjugate-even sequence  $Z_k$  are located in a real-valued array AC as illustrated by figure "Storage of a 1D Size-N Conjugate-even Sequence in a Real Array" and can be used to reconstruct the whole conjugate-even sequence as follows:

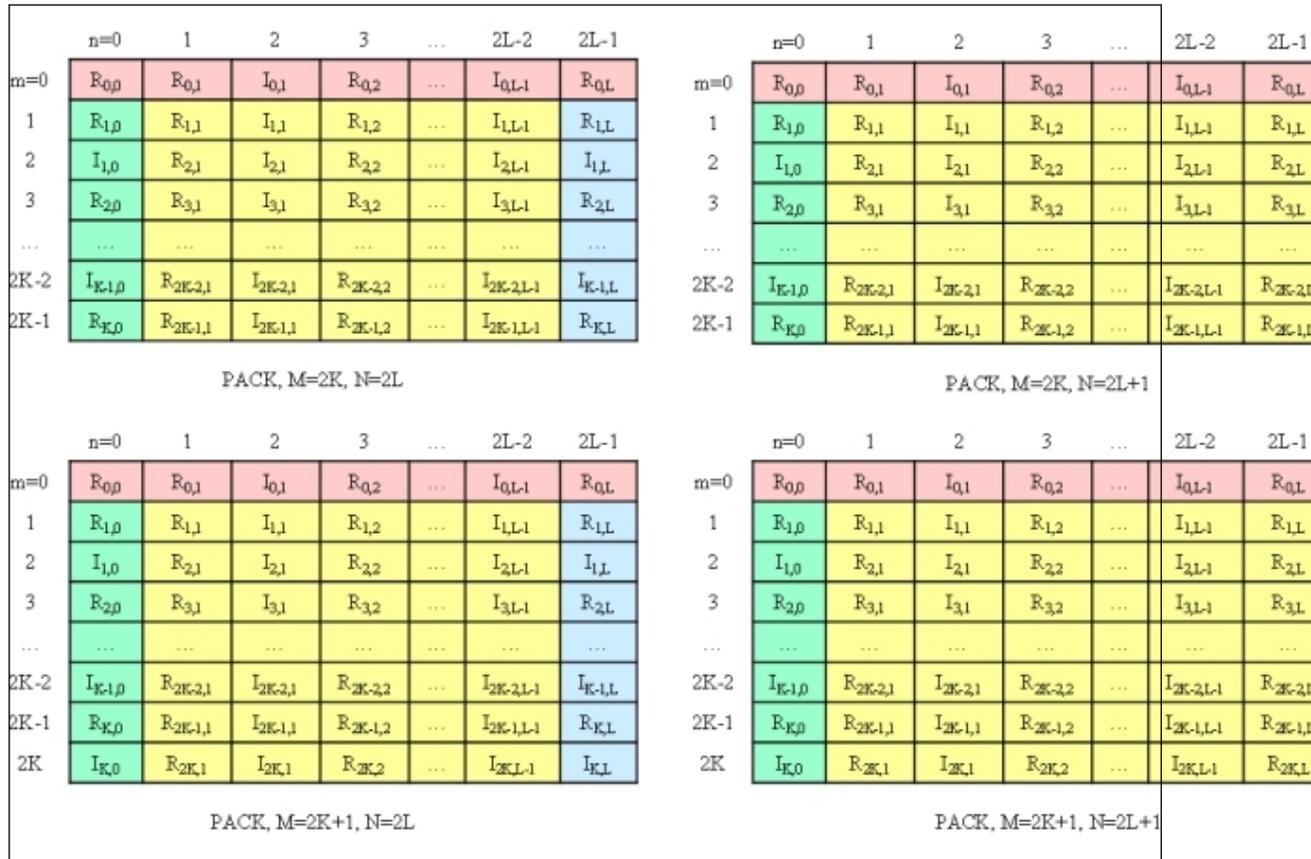

```
float *AR; // malloc(sizeof(float)*N)
float *AC; // malloc(sizeof(float)*N)
...
status = DftiSetValue(desc, DFTI_PACKED_FORMAT, DFTI_PACK_FORMAT);
...
// on input: R{k} = AR[k]
status = DftiComputeForward(desc, AR, AC); // real-to-complex FFT
// on output: Z{k} = re + I*im, where
// if (k == 0) {
// re = AC[0];
// im = 0;
// }
```

```
// } else if (k == N-k) {
// re = AC[2*k-1];
// im = 0;
// } else if (k <= N/2) {
// re = AC[2*k-1];
// im = AC[2*k-0];
// } else {
// re = AC[2*(N-k)-1];
// im = -AC[2*(N-k)-0];
// }
```

**DFTI\_PACK\_FORMAT for Two-dimensional Transforms**

The following figure illustrates the storage of a 2D  $M$ -by- $N$  conjugate-even sequence in a real array for the PACK packed format. This format requires an array of size  $M$ -by- $N$ . Row-major layout and zero-based indexing are used. Different colors mark logically separate parts of the result.

**Storage of a 2D  $M$ -by- $N$  Conjugate-even Sequence in a Real Array for the PACK Format**

The real and imaginary parts of the complex-valued conjugate-even sequence  $Z_{k_1,k_2}$  are located in a real-valued array AC as illustrated by figure "Storage of a 2D  $M$ -by- $N$  Conjugate-even Sequence in a Real Array for the PACK Format" and can be used to reconstruct the whole sequence as follows:

```
float *AR; // malloc(sizeof(float)*N1*N2)
float *AC; // malloc(sizeof(float)*N1*N2)
...
status = DftiSetValue(desc, DFTI_PACKED_FORMAT, DFTI_PACK_FORMAT);
...
// on input: R{k1,k2} = AR[N2*k1 + k2]
status = DftiComputeForward(desc, AR, AC); // real-to-complex FFT
// on output: Z{k1,k2} = re + I*im, where
```

```

// if (k1==0) {
// if (k2 == 0) {
// re = AC[0];
// im = 0;
// } else if (k2 == N2-k2) {
// re = AC[2*k2-1];
// im = 0;
// } else if (k2 <= N2/2) {
// re = AC[2*k2-1];
// im = AC[2*k2-0];
// } else {

// im = -AC[(N1-k1)*N2+2*(N2-k2) - 0];
// }

```

### DFTI\_PERM\_FORMAT for One-dimensional Transforms

The real and imaginary parts of the complex-valued conjugate-even sequence  $Z_k$  are located in real-valued array AC as illustrated by figure "Storage of a 1D Size- $N$  Conjugate-even Sequence in a Real Array" and can be used to reconstruct the whole conjugate-even sequence as follows:

```

float *AR; // malloc(sizeof(float)*N)
float *AC; // malloc(sizeof(float)*N)
...
status = DftiSetValue(desc, DFTI_PACKED_FORMAT, DFTI_PERM_FORMAT);
...
// on input: R{k} = AR[k]
status = DftiComputeForward(desc, AR, AC); // real-to-complex FFT
// on output: Z{k} = re + I*im, where
// if (k == 0) {
// re = AC[0];

```

```

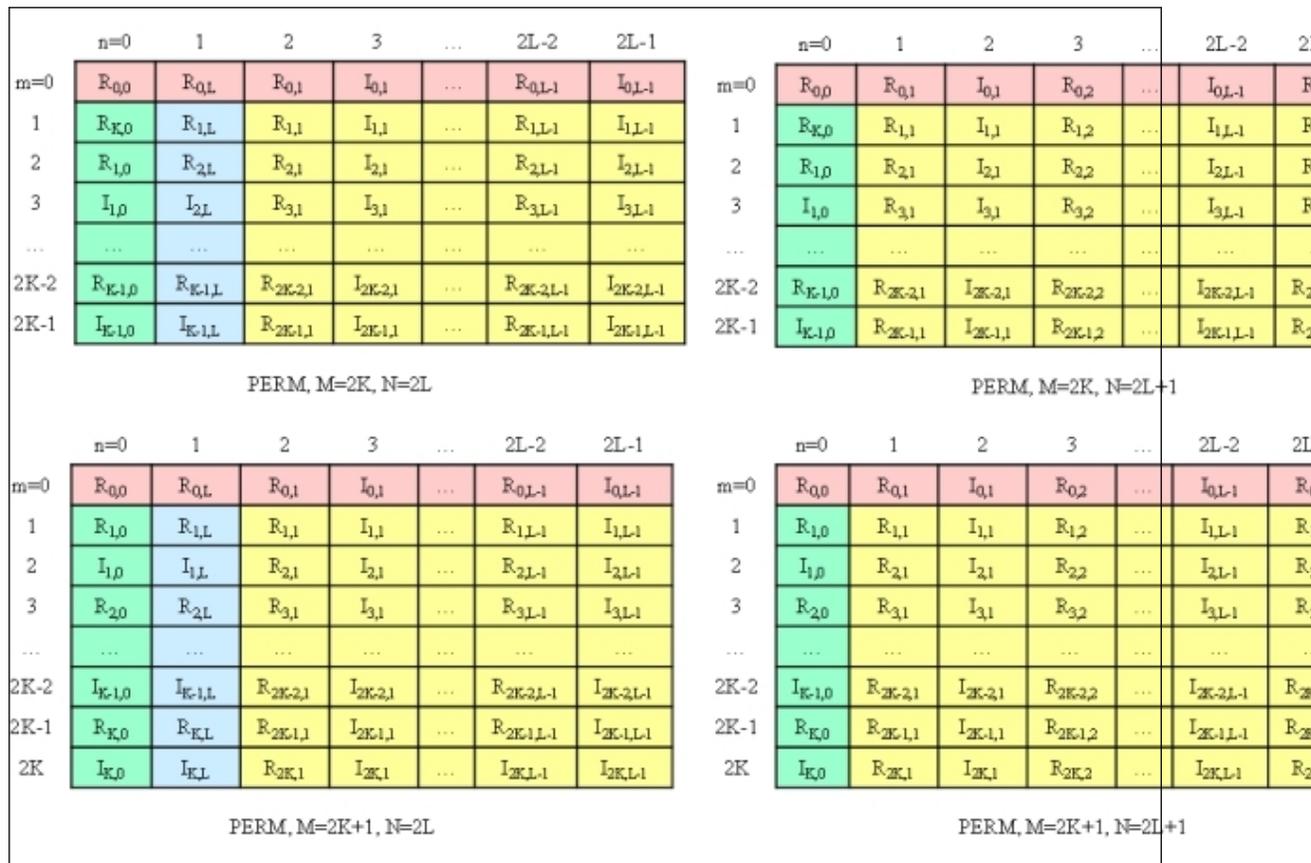

// im = 0;
// } else if (k == N-k) {
// re = AC[1];
// im = 0;
// } else if (k <= N/2) {
// re = AC[2*k+0 - N%2];
// im = AC[2*k+1 - N%2];
// } else {
// re = AC[2*(N-k)+0 - N%2];
// im = -AC[2*(N-k)+1 - N%2];
// }

```

### DFTI\_PERM\_FORMAT for Two-dimensional Transforms

The following figure illustrates the storage of a 2D  $M$ -by- $N$  conjugate-even sequence in a real array for the PERM packed format. This format requires an array of size  $M$ -by- $N$ . Row-major layout and zero-based indexing are used. Different colors mark logically separate parts of the result.

#### Storage of a 2D $M$ -by- $N$ Conjugate-Even Sequence in a Real Array for the PERM Format

The real and imaginary parts of the complex-valued conjugate-even sequence  $Z_{k_1,k_2}$  are located in real-valued array AC as illustrated by figure "Storage of a 2D  $M$ -by- $N$  Conjugate-even Sequence in a Real Array for the PERM Format" and can be used to reconstruct the whole sequence as follows:

```

float *AR; // malloc(sizeof(float)*N1*N2)
float *AC; // malloc(sizeof(float)*N1*N2)
...
status = DftiSetValue(desc, DFTI_PACKED_FORMAT, DFTI_PERM_FORMAT);
...
// on input: R{k1,k2} = AR[N2*k1 + k2]
status = DftiComputeForward(desc, AR, AC); // real-to-complex FFT

```

```
// on output: Z{k1,k2} = re + I*im, where
// if (k1==0) {
// if (k2 == 0) {
// re = AC[0];
// im = 0;
// } else if (k2 == N2-k2) {
// re = AC[1];
// im = 0;
// } else if (k2 <= N2/2) {
// re = AC[2*k2+0 - N2%2];
// im = AC[2*k2+1 - N2%2];
// } else {
// re = AC[2*(N2-k2)+0 - N2%2];
// im = -AC[2*(N2-k2)+1 - N2%2];
// }
// }
// else if (k2==0) {
// if (k1 == N1-k1) {
// re = AC[N2];
// im = 0;
// } else if (k1 <= N1/2) {
// re = AC[(2*k1+0 - N1%2)*N2];
// im = AC[(2*k1+1 - N1%2)*N2];
// } else {
// re = AC[(2*(N1-k1)+0 - N1%2)*N2];
// im = -AC[(2*(N1-k1)+1 - N1%2)*N2];
// }
// }
// else if (k2 == N2-k2) {
// if (k1 == N1-k1) {
// re = AC[N2 + 1];
// im = 0;
// } else if (k1 <= N1/2) {
// re = AC[(2*k1+0 - N1%2)*N2 + 1];
// im = AC[(2*k1+1 - N1%2)*N2 + 1];
// } else {
// re = AC[(2*(N1-k1)+0 - N1%2)*N2 + 1];
// im = -AC[(2*(N1-k1)+1 - N1%2)*N2 + 1];
// }
// }
// else if (k2 <= N2/2) {
// re = AC[k1*N2+2*k2+0 - N2%2];
// im = AC[k1*N2+2*k2+1 - N2%2];
// } else {
// re = AC[(N1-k1)*N2+2*(N2-k2)+0 - N2%2];
// im = -AC[(N1-k1)*N2+2*(N2-k2)+1 - N2%2];
// }
```

To better understand packed formats for two-dimensional transforms, refer to the following example in your Intel MKL directory:

```
./examples/dftc/source/config_conjugate_even_storage.c
```

## DFTI\_WORKSPACE

The computation step for some FFT algorithms requires a scratch space for permutation or other purposes. To manage the use of the auxiliary storage, Intel MKL enables you to set the configuration parameter `DFTI_WORKSPACE` with the following values:

`DFTI_ALLOW` (default) Permits the use of the auxiliary storage.

## FFT Descriptor Manipulation Functions

This category contains the following functions: create a descriptor, commit a descriptor, copy a descriptor, and free a descriptor.

### DftiCreateDescriptor

*Allocates the descriptor data structure and initializes it with default configuration values.*

---

#### Syntax

```
status = DftiCreateDescriptor(&desc_handle, precision, forward_domain, dimension, length);
```

#### Include Files

- mkl.h

#### Input Parameters

| Name                  | Type                                                                   | Description                                                                                                           |

| <i>length</i>         | MKL_LONG if <i>dimension</i> = 1.<br>Array of type MKL_LONG otherwise. | Length of the transform for a one-dimensional transform. Lengths of each dimension for a multi-dimensional transform. |

#### Output Parameters

| Name               | Type                   | Description                 |
|--------------------|------------------------|-----------------------------|
| <i>desc_handle</i> | DFTI_DESCRIPTOR_HANDLE | FFT descriptor.             |
| <i>status</i>      | MKL_LONG               | Function completion status. |

#### Description

This function allocates memory for the descriptor data structure and instantiates it with all the default configuration settings for the precision, forward domain, dimension, and length of the desired transform. Because memory is allocated dynamically, the result is actually a pointer to the created descriptor. This function is slightly different from the "initialization" function that can be found in software packages or libraries that implement more traditional algorithms for computing an FFT. This function does not perform any significant computational work such as computation of twiddle factors. The function [DftiCommitDescriptor](#) does this work after the function [DftiSetValue](#) has set values of all necessary parameters.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

## Prototype

```

/* Note that the preprocessor definition provided below only illustrates
 * that the actual function called may be determined at compile time.
 * You can rely only on the declaration of the function.
 * For precise definition of the preprocessor macro, see the include/mkl_dfti.h
 * file in the Intel MKL directory.
 */
MKL_LONG DftiCreateDescriptor(DFTI_DESCRIPTOR_HANDLE * pHandle,
 enum DFTI_CONFIG_VALUE precision,
 enum DFTI_CONFIG_VALUE domain,
 MKL_LONG dimension, ... /* length/lengths */);

#define DftiCreateDescriptor(desc,prec,domain,dim,sizes) \
 ((prec)==DFTI_SINGLE && (dim)==1) ? \
 some_actual_function_s1d((desc),(domain),(MKL_LONG)(sizes)) : \
 ...

```

Variable *length/lengths* is interpreted as a scalar (MKL\_LONG) or an array (MKL\_LONG\*), depending on the value of parameter *dimension*. If the value of parameter *precision* is known at compile time, an optimizing compiler retains only the call to the respective specific function, thereby reducing the size of the statically linked application. Avoid direct calls to the specific functions used in the preprocessor macro definition, because their interface may change in future releases of the library. If the use of the macro is undesirable, you can safely undefine it after inclusion of the Intel MKL FFT header file, as follows:

```

#include "mkl_dfti.h"
#undef DftiCreateDescriptor

```

## DftiCommitDescriptor

*Performs all initialization for the actual FFT computation.*

## Syntax

```
status = DftiCommitDescriptor(desc_handle);
```

## Include Files

- mkl.h

## Input Parameters

| Name               | Type                   | Description     |
|--------------------|------------------------|-----------------|
| <i>desc_handle</i> | DFTI_DESCRIPTOR_HANDLE | FFT descriptor. |

## Output Parameters

| Name               | Type                   | Description             |
|--------------------|------------------------|-------------------------|
| <i>desc_handle</i> | DFTI_DESCRIPTOR_HANDLE | Updated FFT descriptor. |

| Name          | Type     | Description                 |
|---------------|----------|-----------------------------|
| <i>status</i> | MKL_LONG | Function completion status. |

### Description

This function completes initialization of a previously created descriptor, which is required before the descriptor can be used for FFT computations. Typically, committing the descriptor performs all initialization that is required for the actual FFT computation. The initialization done by the function may involve exploring different factorizations of the input length to find the optimal computation method.

If you call the `DftiSetValue` function to change configuration parameters of a committed descriptor (see [Descriptor Configuration Functions](#)), you must re-commit the descriptor before invoking a computation function. Typically, a committal function call is immediately followed by a computation function call (see [FFT Computation Functions](#)).

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

### Prototype

```
MKL_LONG DftiCommitDescriptor(DFTI_DESCRIPTOR_HANDLE);
```

### DftiFreeDescriptor

*Frees the memory allocated for a descriptor.*

### Syntax

```
status = DftiFreeDescriptor(&desc_handle);
```

### Include Files

- `mkl.h`

### Input Parameters

| Name               | Type                   | Description     |
|--------------------|------------------------|-----------------|
| <i>desc_handle</i> | DFTI_DESCRIPTOR_HANDLE | FFT descriptor. |

### Output Parameters

|--------------------|------------------------|--------------------------------------------|
| <i>desc_handle</i> | DFTI_DESCRIPTOR_HANDLE | Memory for the FFT descriptor is released. |
| <i>status</i>      | MKL_LONG               | Function completion status.                |

### Description

This function frees all memory allocated for a descriptor.

**NOTE**

Memory allocation/deallocation inside Intel MKL is managed by Intel MKL memory management software. So, even after successful completion of `FreeDescriptor`, the memory space may continue being allocated for the application because the memory management software sometimes does not return the memory space to the OS, but considers the space free and can reuse it for future memory allocation. See [Example "mkl\\_free\\_buffers Usage with FFT Functions"](#) in the description of the service function `FreeBuffers` on how to use Intel MKL memory management software and release memory to the OS.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

**Prototype**

```
MKL_LONG DftiFreeDescriptor(DFTI_DESCRIPTOR_HANDLE *);
```

**DftiCopyDescriptor**

*Makes a copy of an existing descriptor.*

**Syntax**

```
status = DftiCopyDescriptor(desc_handle_original, &desc_handle_copy);
```

**Include Files**

- `mkl.h`

**Input Parameters**

| Name                              | Type                                | Description                 |
|-----------------------------------|-------------------------------------|-----------------------------|
| <code>desc_handle_original</code> | <code>DFTI_DESCRIPTOR_HANDLE</code> | The FFT descriptor to copy. |

**Output Parameters**

| Name                          | Type                                | Description                     |
|-------------------------------|-------------------------------------|---------------------------------|
| <code>desc_handle_copy</code> | <code>DFTI_DESCRIPTOR_HANDLE</code> | The copy of the FFT descriptor. |
| <code>status</code>           | <code>MKL_LONG</code>               | Function completion status.     |

**Description**

This function makes a copy of an existing descriptor. The resulting descriptor `desc_handle_copy` and the existing descriptor `desc_handle_original` specify the same configuration of the transform, but do not have any memory areas in common ("deep copy").

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

**Prototype**

```
MKL_LONG DftiCopyDescriptor(DFTI_DESCRIPTOR_HANDLE, DFTI_DESCRIPTOR_HANDLE *);
```

## FFT Descriptor Configuration Functions

This category contains the following functions: the value setting function `DftiSetValue` sets one particular configuration parameter to an appropriate value, and the value getting function `DftiGetValue` reads the value of one particular configuration parameter. While all configuration parameters are readable, you cannot set a few of them. Some of these contain fixed information of a particular implementation such as version number, or dynamic information, which is derived by the implementation during execution of one of the functions. See [Configuration Settings](#) for details.

### DftiSetValue

*Sets one particular configuration parameter with the specified configuration value.*

---

#### Syntax

```
status = DftiSetValue(desc_handle, config_param, config_val);
```

#### Include Files

- mkl.h

#### Input Parameters

| Name                      | Type                                    | Description              |
|---------------------------|-----------------------------------------|--------------------------|
| <code>desc_handle</code>  | <code>DFTI_DESCRIPTOR_HANDLE</code>     | FFT descriptor.          |
| <code>config_param</code> | enum                                    | Configuration parameter. |
| <code>config_val</code>   | Depends on the configuration parameter. | Configuration value.     |

#### Output Parameters

| Name                     | Type                                | Description                 |
|--------------------------|-------------------------------------|-----------------------------|
| <code>desc_handle</code> | <code>DFTI_DESCRIPTOR_HANDLE</code> | Updated FFT descriptor.     |
| <code>status</code>      | <code>MKL_LONG</code>               | Function completion status. |

#### Description

This function sets one particular configuration parameter with the specified configuration value. Each configuration parameter is a named constant, and the configuration value must have the corresponding type, which can be a named constant or a native type. For available configuration parameters and the corresponding configuration values, see:

- `DFTI_PRECISION`
- `DFTI_FORWARD_DOMAIN`
- `DFTI_DIMENSION`, `DFTI_LENGTH`
- `DFTI_PLACEMENT`
- `DFTI_FORWARD_SCALE`, `DFTI_BACKWARD_SCALE`
- `DFTI_THREAD_LIMIT`
- `DFTI_INPUT_STRIDES`, `DFTI_OUTPUT_STRIDES`
- `DFTI_NUMBER_OF_TRANSFORMS`
- `DFTI_INPUT_DISTANCE`, `DFTI_OUTPUT_DISTANCE`

- `DFTI_COMPLEX_STORAGE`, `DFTI_REAL_STORAGE`, `DFTI_CONJUGATE_EVEN_STORAGE`
- `DFTI_PACKED_FORMAT`
- `DFTI_WORKSPACE`
- `DFTI_ORDERING`

The `DftiSetValue` function cannot be used to change configuration parameters `DFTI_FORWARD_DOMAIN`, `DFTI_PRECISION`, `DFTI_DIMENSION`, and `DFTI_LENGTHS`. Use the `DftiCreateDescriptor` function to set them.

Function calls needed to configure an FFT descriptor for a particular call to an FFT computation function are summarized in [Configuring and Computing an FFT in C C++](#).

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

## Prototype

```
MKL_LONG DftiSetValue(DFTI_DESCRIPTOR_HANDLE, DFTI_CONFIG_PARAM , ...);
```

## See Also

## FFT Computation Functions

This category contains the following functions: compute the forward transform and compute the backward transform.

### DftiComputeForward

*Computes the forward FFT.*

#### Syntax

```
status = DftiComputeForward(desc_handle, x_inout);
status = DftiComputeForward(desc_handle, x_in, y_out);
status = DftiComputeForward(desc_handle, xre_inout, xim_inout);
status = DftiComputeForward(desc_handle, xre_in, xim_in, yre_out, yim_out);
```

## Input Parameters

| Name                                              | Type                                                                                                                                                                     | Description                                                                                                                                                              |
|---------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>desc_handle</code>                          | <code>DFTI_DESCRIPTOR_HANDLE</code>                                                                                                                                      | FFT descriptor.                                                                                                                                                          |
| <code>x_inout, x_in</code>                        | Array of type <code>float</code> or <code>double</code> depending on the precision of the transform, specified in the <code>DFTI_PRECISION</code> configuration setting. | Data to be transformed in case of a real forward domain, specified in the <code>DFTI_FORWARD_DOMAIN</code> configuration setting.                                        |
| <code>xre_inout, xim_inout, xre_in, xim_in</code> | Array of type <code>float</code> or <code>double</code> depending on the precision of the transform.                                                                     | Real and imaginary parts of the data to be transformed in the case of a complex forward domain, specified in the <code>DFTI_FORWARD_DOMAIN</code> configuration setting. |

The suffix in parameter names corresponds to the value of the configuration parameter `DFTI_PLACEMENT` as follows:

- `_inout` to `DFTI_INPLACE`
- `_in` to `DFTI_NOT_INPLACE`

## Output Parameters

| Name                                                | Type                                                                                                 | Description                                                                                                                                                          |
|-----------------------------------------------------|------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>y_out</code>                                  | Array of type <code>float</code> or <code>double</code> depending on the precision of the transform. | The transformed data in case of a real backward domain, determined by the <code>DFTI_FORWARD_DOMAIN</code> configuration setting.                                    |
| <code>xre_inout, xim_inout, yre_out, yim_out</code> | Array of type <code>float</code> or <code>double</code> depending on the precision of the transform. | Real and imaginary parts of the transformed data in the case of a complex backward domain, determined by the <code>DFTI_FORWARD_DOMAIN</code> configuration setting. |
| <code>status</code>                                 | <code>MKL_LONG</code>                                                                                | Function completion status.                                                                                                                                          |

The suffix in parameter names corresponds to the value of the configuration parameter `DFTI_PLACEMENT` as follows:

- `_inout` to `DFTI_INPLACE`
- `_out` to `DFTI_NOT_INPLACE`

## Include Files

- `mkl.h`

## Description

The `DftiComputeForward` function accepts the descriptor handle parameter and one or more data parameters. Given a successfully configured and committed descriptor, this function computes the forward FFT, that is, the [transform](#) with the minus sign in the exponent,  $\delta = -1$ .

The `DFTI_COMPLEX_STORAGE`, `DFTI_REAL_STORAGE`, and `DFTI_CONJUGATE_EVEN_STORAGE` configuration parameters define the layout of the input and output data and must be properly set in a call to the `DftiSetValue` function.

The FFT descriptor must be properly configured prior to the function call. Function calls needed to configure an FFT descriptor for a particular call to an FFT computation function are summarized in [Configuring and Computing an FFT in C C++](#).

The number and types of the data parameters that the function requires may vary depending on the configuration of the descriptor. This variation is accommodated by variable parameters.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

## Prototype

```
MKL_LONG DftiComputeForward(DFTI_DESCRIPTOR_HANDLE, void*, ...);

### Configuring and Computing an FFT in C/C++

The table below summarizes information on configuring and computing an FFT in C/C++ for all kinds of transforms and possible combinations of input and output domains.

| FFT to Compute                                              | Input Data                  | Output Data                 | Required FFT Function Calls                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------|-----------------------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Complex-to-complex,<br>in-place,<br>forward or backward     | Interleaved complex numbers | Interleaved complex numbers | <pre> /* Configure a Descriptor */ status = DftiCreateDescriptor(&amp;hand, &lt;precision&gt;, DFTI_COMPLEX, &lt;dimension&gt;, &lt;sizes&gt;); status = DftiCommitDescriptor(hand);  /* Compute an FFT */ /* forward FFT */ status = DftiComputeForward(hand, X_inout); /* or backward FFT */ status = DftiComputeBackward(hand, X_inout);                     </pre>                                                                                              |

You can find C programs that illustrate configuring and computing FFTs in the `examples/dftc/` subdirectory of your Intel MKL directory.

## Status Checking Functions

All of the descriptor manipulation, FFT computation, and descriptor configuration functions return an integer value denoting the status of the operation. The functions in this category check that status. The first function is a logical function that checks whether the status reflects an error of a predefined class, and the second is an error message function that returns a character string.

### DftiErrorClass

*Checks whether the status reflects an error of a predefined class.*

#### Syntax

```
predicate = DftiErrorClass(status, error_class);
```

## Include Files

- `mk1.h`

## Input Parameters

| Name                     | Type                  | Description                           |
|--------------------------|-----------------------|---------------------------------------|
| <code>status</code>      | <code>MKL_LONG</code> | Completion status of an FFT function. |
| <code>error_class</code> | <code>MKL_LONG</code> | Predefined error class.               |

## Output Parameters

| Name                   | Type                  | Description         |
|------------------------|-----------------------|---------------------|
| <code>predicate</code> | <code>MKL_LONG</code> | Result of checking. |

## Description

The FFT interface in Intel MKL provides a set of predefined error classes listed in [Table "Predefined Error Classes"](#). They are named constants and have the type `MKL_LONG`.

### Predefined Error Classes

| Named Constants                              | Comments                                                                                                                                  |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <code>DFTI_NO_ERROR</code>                   | No error. The zero status belongs to this class.                                                                                          |
| <code>DFTI_MEMORY_ERROR</code>               | Usually associated with memory allocation                                                                                                 |
| <code>DFTI_INVALID_CONFIGURATION</code>      | Invalid settings of one or more configuration parameters                                                                                  |
| <code>DFTI_INCONSISTENT_CONFIGURATION</code> | Inconsistent configuration or input parameters                                                                                            |
| <code>DFTI_NUMBER_OF_THREADS_ERROR</code>    | Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function) |
| <code>DFTI_MULTITHREADED_ERROR</code>        | Usually associated with a value that OMP routines return in case of errors                                                                |
| <code>DFTI_BAD_DESCRIPTOR</code>             | Descriptor is unusable for computation                                                                                                    |
| <code>DFTI_UNIMPLEMENTED</code>              | Unimplemented legitimate settings; implementation dependent                                                                               |
| <code>DFTI_MKL_INTERNAL_ERROR</code>         | Internal library error                                                                                                                    |
| <code>DFTI_1D_LENGTH_EXCEEDS_INT32</code>    | Length of one of dimensions exceeds $2^{32} - 1$ (4 bytes).                                                                               |

The `DftiErrorClass` function returns a non-zero value if the status belongs to the predefined error class. To check whether a function call was successful, call `DftiErrorClass` with a specific error class. However, the zero value of the status belongs to the `DFTI_NO_ERROR` class and thus the zero status indicates successful completion of an operation. See [Example "Using Status Checking Functions"](#) for an illustration of correct use of the status checking functions.

#### NOTE

It is incorrect to directly compare a status with a predefined class.

## Prototype

```
MKL_LONG DftiErrorClass(MKL_LONG , MKL_LONG);
```

## DftiErrorMessage

*Generates an error message.*

### Syntax

```
error_message = DftiErrorMessage(status);
```

### Include Files

- mkl.h

### Input Parameters

| Name          | Type     | Description                      |
|---------------|----------|----------------------------------|
| <i>status</i> | MKL_LONG | Completion status of a function. |

### Output Parameters

| Name                 | Type          | Description                                  |
|----------------------|---------------|----------------------------------------------|
| <i>error_message</i> | Array of char | The character string with the error message. |

### Description

The error message function generates an error message character string. The function returns a pointer to a constant character string, that is, a character array with terminating '\0' character, and you do not need to free this pointer.

Example "Using Status Checking Function" shows how this function can be used.

### Prototype

```
char *DftiErrorMessage(MKL_LONG);
```

## Cluster FFT Functions

This section describes the cluster Fast Fourier Transform (FFT) functions implemented in Intel® MKL.

### NOTE

These functions are available only for Intel® 64 and Intel® Many Integrated Core architectures.

The cluster FFT function library was designed to perform fast Fourier transforms on a cluster, that is, a group of computers interconnected via a network. Each computer (node) in the cluster has its own memory and processor(s). Data interchanges between the nodes are provided by the network.

One or more processes may be running in parallel on each cluster node. To organize communication between different processes, the cluster FFT function library uses the Message Passing Interface (MPI). To avoid dependence on a specific MPI implementation (for example, MPICH, Intel® MPI, and others), the library works with MPI via a message-passing library for linear algebra called BLACS.

Cluster FFT functions of Intel MKL provide one-dimensional, two-dimensional, and multi-dimensional (up to the order of 7) functions and both Fortran and C interfaces for all transform functions.

To develop applications using the cluster FFT functions, you should have basic skills in MPI programming.

The interfaces for the Intel MKL cluster FFT functions are similar to the corresponding interfaces for the conventional Intel MKL [FFT functions](#), described earlier in this chapter. Refer there for details not explained in this section.

Table "Cluster FFT Functions in Intel MKL" lists cluster FFT functions implemented in Intel MKL:

**Cluster FFT Functions in Intel MKL**

| Function Name                       | Operation                                                                            |
|-------------------------------------|--------------------------------------------------------------------------------------|
| Descriptor Manipulation Functions   |                                                                                      |
| <code>DftiCreateDescriptorDM</code> | Allocates memory for the descriptor data structure and preliminarily initializes it. |
| <code>DftiCommitDescriptorDM</code> | Performs all initialization for the actual FFT computation.                          |
| <code>DftiFreeDescriptorDM</code>   | Frees memory allocated for a descriptor.                                             |
| FFT Computation Functions           |                                                                                      |
| <code>DftiComputeForwardDM</code>   | Computes the forward FFT.                                                            |
| <code>DftiComputeBackwardDM</code>  | Computes the backward FFT.                                                           |
| Descriptor Configuration Functions  |                                                                                      |
| <code>DftiSetValueDM</code>         | Sets one particular configuration parameter with the specified configuration value.  |
| <code>DftiGetValueDM</code>         | Gets the value of one particular configuration parameter.                            |

**Computing Cluster FFT**

The cluster FFT functions described later in this section are provided with Fortran and C interfaces.

Cluster FFT computation is performed by `DftiComputeForwardDM` and `DftiComputeBackwardDM` functions, called in a program using MPI, which will be referred to as MPI program. After an MPI program starts, a number of processes are created. MPI identifies each process by its rank. The processes are independent of one another and communicate via MPI. A function called in an MPI program is invoked in all the processes. Each process manipulates data according to its rank. Input or output data for a cluster FFT transform is a sequence of real or complex values. A cluster FFT computation function operates on the local part of the input data, that is, some part of the data to be operated in a particular process, as well as generates local part of the output data. While each process performs its part of computations, running in parallel and communicating through MPI, the processes perform the entire FFT computation. FFT computations using the Intel MKL cluster FFT functions are typically effected by a number of steps listed below:

1. Initiate MPI by calling `MPI_Init` (the function must be called prior to calling any FFT function and any MPI function).
2. Allocate memory for the descriptor and create it by calling `DftiCreateDescriptorDM`.
3. Specify one of several values of configuration parameters by one or more calls to `DftiSetValueDM`.
4. Obtain values of configuration parameters needed to create local data arrays; the values are retrieved by calling `DftiGetValueDM`.
5. Initialize the descriptor for the FFT computation by calling `DftiCommitDescriptorDM`.
6. Create arrays for local parts of input and output data and fill the local part of input data with values. (For more information, see [Distributing Data among Processes](#).)

7. Compute the transform by calling `DftiComputeForwardDM` or `DftiComputeBackwardDM`.
8. Gather local output data into the global array using MPI functions. (This step is optional because you may need to immediately employ the data differently.)
9. Release memory allocated for the descriptor by calling `DftiFreeDescriptorDM`.
10. Finalize communication through MPI by calling `MPI_Finalize` (the function must be called after the last call to a cluster FFT function and the last call to an MPI function).

Several code examples in the "Examples for Cluster FFT Functions" section in the Code Examples appendix illustrate cluster FFT computations.

## Distributing Data among Processes

The Intel MKL cluster FFT functions store all input and output multi-dimensional arrays (matrices) in one-dimensional arrays (vectors). The arrays are stored in the row-major order. For example, a two-dimensional matrix  $A$  of size  $(m,n)$  is stored in a vector  $B$  of size  $m*n$  so that

$$B[i*n+j]=A[i][j] \quad (i=0, \dots, m-1, j=0, \dots, n-1) .$$

---

### NOTE

Order of FFT dimensions is the same as the order of array dimensions in the programming language. For example, a 3-dimensional FFT with `Lengths=(m,n,l)` can be computed over an array `Ar[m][n][l]`.

---

All MPI processes involved in cluster FFT computation operate their own portions of data. These local arrays make up the virtual global array that the fast Fourier transform is applied to. It is your responsibility to properly allocate local arrays (if needed), fill them with initial data and gather resulting data into an actual global array or process the resulting data differently. To be able do this, see sections below on how the virtual global array is composed of the local ones.

## Multi-dimensional transforms

If the dimension of transform is greater than one, the cluster FFT function library splits data in the dimension whose index changes most slowly, so that the parts contain all elements with several consecutive values of this index. It is the first dimension in  $C$ . If the global array is two-dimensional, it gives each process several consecutive rows. Local arrays are placed in memory allocated for the virtual global array consecutively, in the order determined by process ranks. For example, in case of two processes, during the computation of a three-dimensional transform whose matrix has size  $(11,15,12)$ , the processes may store local arrays of sizes  $(6,15,12)$  and  $(5,15,12)$ , respectively.

If  $p$  is the number of MPI processes and the matrix of a transform to be computed has size  $(m,n,l)$ , each MPI process works with local data array of size  $(m_q, n, l)$ , where  $\sum m_q=m, q=0, \dots, p-1$ . Local input arrays must contain appropriate parts of the actual global input array, and then local output arrays will contain appropriate parts of the actual global output array. You can figure out which particular rows of the global array the local array must contain from the following configuration parameters of the cluster FFT interface: `CDFT_LOCAL_NX`, `CDFT_LOCAL_START_X`, and `CDFT_LOCAL_SIZE`. To retrieve values of the parameters, use the `DftiGetValueDM` function:

- `CDFT_LOCAL_NX` specifies how many rows of the global array the current process receives.
- `CDFT_LOCAL_START_X` specifies which row of the global input or output array corresponds to the first row of the local input or output array. If  $A$  is a global array and  $L$  is the appropriate local array, then

$$L[i][j][k]=A[i+cdft\_local\_start\_x][j][k], \text{ where } i=0, \dots, m_q-1, j=0, \dots, n-1, k=0, \dots, l-1.$$

Example "2D Out-of-place Cluster FFT Computation" in the Code Examples appendix shows how the data is distributed among processes for a two-dimensional cluster FFT computation.

## One-dimensional transforms

In this case, input and output data are distributed among processes differently and even the numbers of elements stored in a particular process before and after the transform may be different. Each local array stores a segment of consecutive elements of the appropriate global array. Such segment is determined by

the number of elements and a shift with respect to the first array element. So, to specify segments of the global input and output arrays that a particular process receives, *four* configuration parameters are needed: `CDFT_LOCAL_NX`, `CDFT_LOCAL_START_X`, `CDFT_LOCAL_OUT_NX`, and `CDFT_LOCAL_OUT_START_X`. Use the `DftiGetValueDM` function to retrieve their values. The meaning of the four configuration parameters depends upon the type of the transform, as shown in [Table "Data Distribution Configuration Parameters for 1D Transforms"](#):

#### Data Distribution Configuration Parameters for 1D Transforms

| Meaning of the Parameter           | Forward Transform                   | Backward Transform                  |
|------------------------------------|-------------------------------------|-------------------------------------|
| Number of elements in input array  | <code>CDFT_LOCAL_NX</code>          | <code>CDFT_LOCAL_OUT_NX</code>      |
| Elements shift in input array      | <code>CDFT_LOCAL_START_X</code>     | <code>CDFT_LOCAL_OUT_START_X</code> |
| Number of elements in output array | <code>CDFT_LOCAL_OUT_NX</code>      | <code>CDFT_LOCAL_NX</code>          |
| Elements shift in output array     | <code>CDFT_LOCAL_OUT_START_X</code> | <code>CDFT_LOCAL_START_X</code>     |

#### Memory size for local data

The memory size needed for local arrays cannot be just calculated from `CDFT_LOCAL_NX` (`CDFT_LOCAL_OUT_NX`), because the cluster FFT functions sometimes require allocating a little bit more memory for local data than just the size of the appropriate sub-array. The configuration parameter `CDFT_LOCAL_SIZE` specifies the size of the local input and output array in data elements. Each local input and output arrays must have size not less than `CDFT_LOCAL_SIZE*size_of_element`. Note that in the current implementation of the cluster FFT interface, data elements can be real or complex values, each complex value consisting of the real and imaginary parts. If you employ a user-defined workspace for in-place transforms (for more information, refer to [Table "Settable configuration Parameters"](#)), it must have the same size as the local arrays. [Example "1D In-place Cluster FFT Computations"](#) in the Code Examples appendix illustrates how the cluster FFT functions distribute data among processes in case of a one-dimensional FFT computation performed with a user-defined workspace.

#### Available Auxiliary Functions

If a global input array is located on one MPI process and you want to obtain its local parts or you want to gather the global output array on one MPI process, you can use functions `MKL_CDFT_ScatterData` and `MKL_CDFT_GatherData` to distribute or gather data among processes, respectively. These functions are defined in a file that is delivered with Intel MKL and located in the following subdirectory of the Intel MKL installation directory: `examples/cdftc/source/cdft_example_support.c`.

#### Restriction on Lengths of Transforms

The algorithm that the Intel MKL cluster FFT functions use to distribute data among processes imposes a restriction on lengths of transforms with respect to the number of MPI processes used for the FFT computation:

- For a multi-dimensional transform, lengths of the first two dimensions must be not less than the number of MPI processes.
- Length of a one-dimensional transform must be the product of two integers each of which is not less than the number of MPI processes.

Non-compliance with the restriction causes an error `CDFT_SPREAD_ERROR` (refer to [Error Codes](#) for details). To achieve the compliance, you can change the transform lengths and/or the number of MPI processes, which is specified at start of an MPI program. MPI-2 enables changing the number of processes during execution of an MPI program.

## Cluster FFT Interface

To use the cluster FFT functions, you need to access the header file `mkl_cdft.h` through "include".

The C interface provides a structure type `DFTI_DESCRIPTOR_DM_HANDLE` and a number of functions, some of which accept a different number of input arguments.

To provide communication between parallel processes through MPI, the following include statement must be present in your code:

- C/C++:  

```
#include "mpi.h"
```

There are three main categories of the cluster FFT functions in Intel MKL:

1. **Descriptor Manipulation** . There are three functions in this category. The `DftiCreateDescriptorDM` function creates an FFT descriptor whose storage is allocated dynamically. The `DftiCommitDescriptorDM` function "commits" the descriptor to all its settings. The `DftiFreeDescriptorDM` function frees up the memory allocated for the descriptor.
2. **FFT Computation** . There are two functions in this category. The `DftiComputeForwardDM` function performs the forward FFT computation, and the `DftiComputeBackwardDM` function performs the backward FFT computation.
3. **Descriptor Configuration** . There are two functions in this category. The `DftiSetValueDM` function sets one specific configuration value to one of the many configuration parameters. The `DftiGetValueDM` function gets the current value of any of these configuration parameters, all of which are readable. These parameters, though many, are handled one at a time.

## Cluster FFT Descriptor Manipulation Functions

There are three functions in this category: create a descriptor, commit a descriptor, and free a descriptor.

### DftiCreateDescriptorDM

*Allocates memory for the descriptor data structure and preliminarily initializes it.*

#### Syntax

```
status = DftiCreateDescriptorDM(comm, &handle, v1, v2, dim, size);
status = DftiCreateDescriptorDM(comm, &handle, v1, v2, dim, sizes);
```

#### Include Files

- `mkl_cdft.h`

#### Input Parameters

|                    |                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>comm</code>  | MPI communicator, e.g. <code>MPI_COMM_WORLD</code> .                                                                                                      |
| <code>v1</code>    | Precision of the transform.                                                                                                                               |
| <code>v2</code>    | Type of the forward domain. Must be <code>DFTI_COMPLEX</code> for complex-to-complex transforms or <code>DFTI_REAL</code> for real-to-complex transforms. |
| <code>dim</code>   | Dimension of the transform.                                                                                                                               |
| <code>size</code>  | Length of the transform in a one-dimensional case.                                                                                                        |
| <code>sizes</code> | Lengths of the transform in a multi-dimensional case.                                                                                                     |

## Output Parameters

*handle* Pointer to the descriptor handle of transform. If the function completes successfully, the pointer to the created handle is stored in the variable.

## Description

This function allocates memory in a particular MPI process for the descriptor data structure and instantiates it with default configuration settings with respect to the precision, domain, dimension, and length of the desired transform. The domain is understood to be the domain of the forward transform. The result is a pointer to the created descriptor. This function is slightly different from the "initialization" function `DftiCommitDescriptorDM` in a more traditional software packages or libraries used for computing the FFT. This function does not perform any significant computation work, such as twiddle factors computation, because the default configuration settings can still be changed using the function `DftiSetValueDM`.

The value of the parameter *vl* is specified through named constants `DFTI_SINGLE` and `DFTI_DOUBLE`. It corresponds to precision of input data, output data, and computation. A setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The parameter *dim* is a simple positive integer indicating the dimension of the transform.

For one-dimensional transforms, length is a single integer value of the parameter *size* having type `MKL_LONG`; for multi-dimensional transforms, length is supplied with the parameter *sizes*, which is an array of integers having type `MKL_LONG`.

## Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. In this case, the pointer to the created descriptor handle is stored in *handle*. If the function fails, it returns a value of another error class constant

## Prototype

```
MKL_LONG DftiCreateDescriptorDM(MPI_Comm,DFTI_DESCRIPTOR_DM_HANDLE*,
 enum DFTI_CONFIG_VALUE,enum DFTI_CONFIG_VALUE,MKL_LONG,...);
```

## DftiCommitDescriptorDM

*Performs all initialization for the actual FFT computation.*

## Syntax

```
status = DftiCommitDescriptorDM(handle);
```

## Include Files

- `mkl_cdft.h`

## Input Parameters

*handle* The descriptor handle. Must be valid, that is, created in a call to `DftiCreateDescriptorDM`.

## Description

The cluster FFT interface requires a function that completes initialization of a previously created descriptor before the descriptor can be used for FFT computations in a particular MPI process. The `DftiCommitDescriptorDM` function performs all initialization that facilitates the actual FFT computation. For the current implementation, it may involve exploring many different factorizations of the input length to search for highly efficient computation method.

Any changes of configuration parameters of a committed descriptor via the set value function (see [Descriptor Configuration Functions](#)) requires a re-committal of the descriptor before a computation function can be invoked. Typically, this committal function is called right before a computation function call (see [FFT Computation Functions](#)).

## Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

## Prototype

```
MKL_LONG DftiCommitDescriptorDM(DFTI_DESCRIPTOR_DM_HANDLE handle);
```

## DftiFreeDescriptorDM

*Frees memory allocated for a descriptor.*

## Syntax

```
status = DftiFreeDescriptorDM(&handle);
```

## Include Files

- `mkl_cdft.h`

## Input Parameters

*handle* The descriptor handle. Must be valid, that is, created in a call to [DftiCreateDescriptorDM](#).

## Output Parameters

*handle* The descriptor handle. Memory allocated for the handle is released on output.

## Description

This function frees up all memory allocated for a descriptor in a particular MPI process. Call the `DftiFreeDescriptorDM` function to delete the descriptor handle. Upon successful completion of `DftiFreeDescriptorDM` the descriptor handle is no longer valid.

## Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

## Prototype

```
MKL_LONG DftiFreeDescriptorDM(DFTI_DESCRIPTOR_DM_HANDLE *handle);
```

## Cluster FFT Computation Functions

There are two functions in this category: compute the forward transform and compute the backward transform.

### DftiComputeForwardDM

*Computes the forward FFT.*

#### Syntax

```
status = DftiComputeForwardDM(handle, in_X, out_X);
```

```
status = DftiComputeForwardDM(handle, in_out_X);
```

#### Include Files

- `mkl_cdft.h`

#### Input Parameters

|                             |                                                                                                                                                                        |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>handle</code>         | The descriptor handle.                                                                                                                                                 |
| <code>in_X, in_out_X</code> | Local part of input data. Array of complex values. Refer to the <a href="#">Distributing Data among Processes</a> section on how to allocate and initialize the array. |

#### Output Parameters

|                              |                                                                                                                                                          |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>out_X, in_out_X</code> | Local part of output data. Array of complex values. Refer to the <a href="#">Distributing Data among Processes</a> section on how to allocate the array. |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|

#### Description

The `DftiComputeForwardDM` function computes the forward FFT. Forward FFT is the transform using the factor  $e^{-i2\pi/n}$ .

Before you call the function, the valid descriptor, created by `DftiCreateDescriptorDM`, must be configured and committed using the `DftiCommitDescriptorDM` function.

The computation is carried out by calling the `DftiComputeForward` function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of `DftiComputeForward`.

Local part of input data, as well as local part of the output data, is an appropriate sequence of complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See the [Distributing Data Among Processes](#) section for details.

Refer to the [Configuration Settings](#) section for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter `DFTI_PRECISION` determines the precision of input data, output data, and transform: a setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The configuration parameter `DFTI_PLACEMENT` informs the function whether the computation should be in-place. If the value of this parameter is `DFTI_INPLACE` (default), you must call the function with two parameters, otherwise you must supply three parameters. If `DFTI_PLACEMENT = DFTI_INPLACE` and three parameters are supplied, then the third parameter is ignored.

## CAUTION

Even in case of an out-of-place transform, local array of input data *in\_X* may be changed. To save data, make its copy before calling `DftiComputeForwardDM`.

In case of an in-place transform, `DftiComputeForwardDM` dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

## NOTE

You can specify your own workspace of the same size through the configuration parameter `CDFT_WORKSPACE` to avoid redundant memory allocation.

## Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

## Prototype

```
MKL_LONG DftiComputeForwardDM(DFTI_DESCRIPTOR_DM_HANDLE handle, void *in_X, ...);
```

## DftiComputeBackwardDM

*Computes the backward FFT.*

### Syntax

```
status = DftiComputeBackwardDM(handle, in_X, out_X);
```

```
status = DftiComputeBackwardDM(handle, in_out_X);
```

### Include Files

- `mkl_cdft.h`

### Input Parameters

|                       |                                                                                                                                                                        |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>handle</i>         | The descriptor handle.                                                                                                                                                 |
| <i>in_X, in_out_X</i> | Local part of input data. Array of complex values. Refer to the <a href="#">Distributing Data among Processes</a> section on how to allocate and initialize the array. |

### Output Parameters

|                        |                                                                                                                                                          |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>out_X, in_out_X</i> | Local part of output data. Array of complex values. Refer to the <a href="#">Distributing Data among Processes</a> section on how to allocate the array. |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|

### Description

The `DftiComputeBackwardDM` function computes the backward FFT. Backward FFT is the transform using the factor  $e^{i2\pi/n}$ .

Before you call the function, the valid descriptor, created by `DftiCreateDescriptorDM`, must be configured and committed using the `DftiCommitDescriptorDM` function.

The computation is carried out by calling the `DftiComputeBackward` function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of `DftiComputeBackward`.

Local part of input data, as well as local part of the output data, is an appropriate sequence of complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See the [Distributing Data among Processes](#) section for details.

Refer to the [Configuration Settings](#) section for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter `DFTI_PRECISION` determines the precision of input data, output data, and transform: a setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The configuration parameter `DFTI_PLACEMENT` informs the function whether the computation should be in-place. If the value of this parameter is `DFTI_INPLACE` (default), you must call the function with two parameters, otherwise you must supply three parameters. If `DFTI_PLACEMENT = DFTI_INPLACE` and three parameters are supplied, then the third parameter is ignored.

---

### CAUTION

Even in case of an out-of-place transform, local array of input data `in_X` may be changed. To save data, make its copy before calling `DftiComputeBackwardDM`.

---

In case of an in-place transform, `DftiComputeBackwardDM` dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

---

### NOTE

You can specify your own workspace of the same size through the configuration parameter `CDFT_WORKSPACE` to avoid redundant memory allocation.

---

## Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

## Prototype

```
MKL_LONG DftiComputeBackwardDM(DFTI_DESCRIPTOR_DM_HANDLE handle, void *in_X,...);
```

## Cluster FFT Descriptor Configuration Functions

There are two functions in this category: the value setting function `DftiSetValueDM` sets one particular configuration parameter to an appropriate value, the value getting function `DftiGetValueDM` reads the value of one particular configuration parameter.

Some configuration parameters used by cluster FFT functions originate from the conventional FFT interface (see [Configuration Settings](#) subsection in the "FFT Functions" section for details).

Other configuration parameters are specific to the cluster FFT. Integer values of these parameters have type `MKL_LONG`. The exact type of the configuration parameters being floating-point scalars is `float` or `double`. The configuration parameters whose values are named constants have the `enum` type. They are defined in the `mkl_cdft.h` header file.

Names of the configuration parameters specific to the cluster FFT interface have prefix `CDFT`.

## DftiSetValueDM

Sets one particular configuration parameter with the specified configuration value.

### Syntax

```
status = DftiSetValueDM (handle, param, value);
```

### Include Files

- mkl\_cdft.h

### Input Parameters

|               |                                                                                                                                                                |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>handle</i> | The descriptor handle. Must be valid, that is, created in a call to <a href="#">DftiCreateDescriptorDM</a> .                                                   |
| <i>param</i>  | Name of a parameter to be set up in the descriptor handle. See <a href="#">Table "Settable Configuration Parameters"</a> for the list of available parameters. |
| <i>value</i>  | Value of the parameter.                                                                                                                                        |

### Description

This function sets one particular configuration parameter with the specified configuration value. The configuration parameter is one of the named constants listed in the table below, and the configuration value must have the corresponding type. See [Configuration Settings](#) for details of the meaning of each setting and for possible values of the parameters whose values are named constants.

### Settable Configuration Parameters

| Parameter Name      | Data Type                    | Description                                                                                     | Default Value                                                                                                                                                                                                                                 |
|---------------------|------------------------------|-------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DFTI_FORWARD_SCALE  | Floating-point scalar        | Scale factor of forward transform.                                                              | 1.0                                                                                                                                                                                                                                           |
| DFTI_BACKWARD_SCALE | Floating-point scalar        | Scale factor of backward transform.                                                             | 1.0                                                                                                                                                                                                                                           |
| DFTI_PLACEMENT      | Named constant               | Placement of the computation result.                                                            | DFTI_INPLACE                                                                                                                                                                                                                                  |
| DFTI_ORDERING       | Named constant               | Scrambling of data order.                                                                       | DFTI_ORDERED                                                                                                                                                                                                                                  |
| CDFT_WORKSPACE      | Array of an appropriate type | Auxiliary buffer, a user-defined workspace. Enables saving memory during in-place computations. | NULL (allocate workspace dynamically).                                                                                                                                                                                                        |
| DFTI_PACKED_FORMAT  | Named constant               | Packed format, real data.                                                                       | <ul style="list-style-type: none"> <li>• DFTI_PERM_FORMAT — default and the only available value for one-dimensional transforms</li> <li>• DFTI_CCE_FORMAT — default and the only available value for multi-dimensional transforms</li> </ul> |

| Parameter Name | Data Type      | Description                                                                                                                                                                                                                                                                                                                                          | Default Value          |
|----------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| DFTI_TRANSPOSE | Named constant | This parameter determines how the output data is located for multi-dimensional transforms. If the parameter value is <code>DFTI_NONE</code> , the data is located in a usual manner described in this document. If the value is <code>DFTI_ALLOW</code> , the last (first) global transposition is not performed for a forward (backward) transform. | <code>DFTI_NONE</code> |

### Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

### Prototype

```
MKL_LONG DftiSetValueDM(DFTI_DESCRIPTOR_DM_HANDLE handle, int param,...);
```

### DftiGetValueDM

*Gets the value of one particular configuration parameter.*

### Syntax

```
status = DftiGetValueDM(handle, param, &value);
```

### Include Files

- `mkl_cdft.h`

### Input Parameters

*handle* The descriptor handle. Must be valid, that is, created in a call to [DftiCreateDescriptorDM](#).

*param* Name of a parameter to be retrieved from the descriptor. See [Table "Retrievable Configuration Parameters"](#) for the list of available parameters.

### Output Parameters

*value* Value of the parameter.

### Description

This function gets the configuration value of one particular configuration parameter. The configuration parameter is one of the named constants listed in the table below, and the configuration value is the corresponding appropriate type, which can be a named constant or a native type. Possible values of the named constants can be found in [Table "Configuration Parameters"](#) and relevant subsections of the [Configuration Settings](#) section.

**Retrieval Configuration Parameters**

| Parameter Name         | Data Type                | Description                                                                                                                                                                                                |
|------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DFTI_PRECISION         | Named constant           | Precision of computation, input data and output data.                                                                                                                                                      |
| DFTI_DIMENSION         | Integer scalar           | Dimension of the transform                                                                                                                                                                                 |
| DFTI_LENGTHS           | Array of integer values  | Array of lengths of the transform. Number of lengths corresponds to the dimension of the transform.                                                                                                        |
| DFTI_FORWARD_SCALE     | Floating-point scalar    | Scale factor of forward transform.                                                                                                                                                                         |
| DFTI_BACKWARD_SCALE    | Floating-point scalar    | Scale factor of backward transform.                                                                                                                                                                        |
| DFTI_PLACEMENT         | Named constant           | Placement of the computation result.                                                                                                                                                                       |
| DFTI_COMMIT_STATUS     | Named constant           | Shows whether descriptor has been committed.                                                                                                                                                               |
| DFTI_FORWARD_DOMAIN    | Named constant           | Forward domain of transforms, has the value of DFTI_COMPLEX or DFTI_REAL.                                                                                                                                  |
| DFTI_ORDERING          | Named constant           | Scrambling of data order.                                                                                                                                                                                  |
| CDFT_MPI_COMM          | Type of MPI communicator | MPI communicator used for transforms.                                                                                                                                                                      |
| CDFT_LOCAL_SIZE        | Integer scalar           | Necessary size of input, output, and buffer arrays in data elements.                                                                                                                                       |
| CDFT_LOCAL_X_START     | Integer scalar           | Row/element number of the global array that corresponds to the first row/element of the local array. For more information, see <a href="#">Distributing Data among Processes</a> .                         |
| CDFT_LOCAL_NX          | Integer scalar           | The number of rows/elements of the global array stored in the local array. For more information, see <a href="#">Distributing Data among Processes</a> .                                                   |
| CDFT_LOCAL_OUT_X_START | Integer scalar           | Element number of the appropriate global array that corresponds to the first element of the input or output local array in a 1D case. For details, see <a href="#">Distributing Data among Processes</a> . |
| CDFT_LOCAL_OUT_NX      | Integer scalar           | The number of elements of the appropriate global array that are stored in the input or output local array in a 1D case. For details, see <a href="#">Distributing Data among Processes</a> .               |

**Return Values**

The function returns DFTI\_NO\_ERROR when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

## Prototype

```
MKL_LONG DftiGetValueDM(DFTI_DESCRIPTOR_DM_HANDLE handle, int param,...);
```

## Error Codes

All the cluster FFT functions return an integer value denoting the status of the operation. These values are identified by named constants. Each function returns `DFTI_NO_ERROR` if no errors were encountered during execution. Otherwise, a function generates an error code. In addition to FFT error codes, the cluster FFT interface has its own ones. Named constants specific to the cluster FFT interface have prefix "CDFT" in names. [Table "Error Codes that Cluster FFT Functions Return"](#) lists error codes that the cluster FFT functions may return.

### Error Codes that Cluster FFT Functions Return

| Named Constants                              | Comments                                                                                                                                   |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>DFTI_NO_ERROR</code>                   | No error.                                                                                                                                  |
| <code>DFTI_MEMORY_ERROR</code>               | Usually associated with memory allocation.                                                                                                 |
| <code>DFTI_INVALID_CONFIGURATION</code>      | Invalid settings of one or more configuration parameters.                                                                                  |
| <code>DFTI_INCONSISTENT_CONFIGURATION</code> | Inconsistent configuration or input parameters.                                                                                            |
| <code>DFTI_NUMBER_OF_THREADS_ERROR</code>    | Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function). |
| <code>DFTI_MULTITHREADED_ERROR</code>        | Usually associated with a value that OMP routines return in case of errors.                                                                |
| <code>DFTI_BAD_DESCRIPTOR</code>             | Descriptor is unusable for computation.                                                                                                    |
| <code>DFTI_UNIMPLEMENTED</code>              | Unimplemented legitimate settings; implementation dependent.                                                                               |
| <code>DFTI_MKL_INTERNAL_ERROR</code>         | Internal library error.                                                                                                                    |
| <code>DFTI_1D_LENGTH_EXCEEDS_INT32</code>    | Length of one of dimensions exceeds $2^{32} - 1$ (4 bytes).                                                                                |
| <code>CDFT_SPREAD_ERROR</code>               | Data cannot be distributed (For more information, see <a href="#">Distributing Data among Processes.</a> )                                 |
| <code>CDFT_MPI_ERROR</code>                  | MPI error. Occurs when calling MPI.                                                                                                        |

# PBLAS Routines

This chapter describes the Intel® Math Kernel Library implementation of the PBLAS (Parallel Basic Linear Algebra Subprograms) routines from the ScaLAPACK package for distributed-memory architecture. PBLAS is intended for using in vector-vector, matrix-vector, and matrix-matrix operations to simplify the parallelization of linear codes. The design of PBLAS is as consistent as possible with that of the BLAS. The routine descriptions are arranged in several sections according to the PBLAS level of operation:

- [PBLAS Level 1 Routines](#) (distributed vector-vector operations)
- [PBLAS Level 2 Routines](#) (distributed matrix-vector operations)
- [PBLAS Level 3 Routines](#) (distributed matrix-matrix operations)

Each section presents the routine and function group descriptions in alphabetical order by the routine group name; for example, the `p?asum` group, the `p?axpy` group. The question mark in the group name corresponds to a character indicating the data type (`s`, `d`, `c`, and `z` or their combination); see [Routine Naming Conventions](#).

---

## NOTE

PBLAS routines are provided only with Intel® MKL versions for Linux\* and Windows\* OSs.

---

Generally, PBLAS runs on a network of computers using MPI as a message-passing layer and a set of prebuilt communication subprograms (BLACS), as well as a set of PBLAS optimized for the target architecture. The Intel MKL version of PBLAS is optimized for Intel® processors. For the detailed system and environment requirements see *Intel® MKL Release Notes* and *Intel® MKL Developer Guide*.

For full reference on PBLAS routines and related information, see [http://www.netlib.org/scalapack/html/pblas\\_qref.html](http://www.netlib.org/scalapack/html/pblas_qref.html).

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## PBLAS Routines Overview

The model of the computing environment for PBLAS is represented as a one-dimensional array of processes or also a two-dimensional process grid. To use PBLAS, all global matrices or vectors must be distributed on this array or grid prior to calling the PBLAS routines.

PBLAS uses the two-dimensional block-cyclic data distribution as a layout for dense matrix computations. This distribution provides good work balance between available processors, as well as gives the opportunity to use PBLAS Level 3 routines for optimal local computations. Information about the data distribution that is required to establish the mapping between each global array and its corresponding process and memory location is contained in the so called *array descriptor* associated with each global array. [Table "Content of the array descriptor for dense matrices"](#) gives an example of an array descriptor structure.

## Content of Array Descriptor for Dense Matrices

| Array Element # | Name         | Definition                                                                    |
|-----------------|--------------|-------------------------------------------------------------------------------|
| 1               | <i>dtype</i> | Descriptor type ( =1 for dense matrices)                                      |
| 2               | <i>ctxt</i>  | BLACS context handle for the process grid                                     |
| 3               | <i>m</i>     | Number of rows in the global array                                            |
| 4               | <i>n</i>     | Number of columns in the global array                                         |
| 5               | <i>mb</i>    | Row blocking factor                                                           |
| 6               | <i>nb</i>    | Column blocking factor                                                        |
| 7               | <i>rsrc</i>  | Process row over which the first row of the global array is distributed       |
| 8               | <i>csrc</i>  | Process column over which the first column of the global array is distributed |
| 9               | <i>lld</i>   | Leading dimension of the local array                                          |

The number of rows and columns of a global dense matrix that a particular process in a grid receives after data distributing is denoted by *LOCr()* and *LOCc()*, respectively. To compute these numbers, you can use the ScaLAPACK tool routine *numroc*.

After the block-cyclic distribution of global data is done, you may choose to perform an operation on a submatrix of the global matrix *A*, which is contained in the global subarray *sub(A)*, defined by the following 6 values (for dense matrices):

|              |                                                                          |
|--------------|--------------------------------------------------------------------------|
| <i>m</i>     | The number of rows of <i>sub(A)</i>                                      |
| <i>n</i>     | The number of columns of <i>sub(A)</i>                                   |
| <i>a</i>     | A pointer to the local array containing the entire global array <i>A</i> |
| <i>ia</i>    | The row index of <i>sub(A)</i> in the global array                       |
| <i>ja</i>    | The column index of <i>sub(A)</i> in the global array                    |
| <i>desca</i> | The array descriptor for the global array <i>A</i>                       |

Intel MKL provides the PBLAS routines with interface similar to the interface used in the Netlib PBLAS (see [http://www.netlib.org/scalapack/html/pblas\\_qref.html](http://www.netlib.org/scalapack/html/pblas_qref.html)).

## PBLAS Routine Naming Conventions

The naming convention for PBLAS routines is similar to that used for BLAS routines (see [Routine Naming Conventions in Chapter 2](#)). A general rule is that each routine name in PBLAS, which has a BLAS equivalent, is simply the BLAS name prefixed by initial letter *p* that stands for "parallel".

The Intel MKL PBLAS routine names have the following structure:

```
p <character> <name> <mod> ()
```

The *<character>* field indicates the Fortran data type:

|   |                           |
|---|---------------------------|
| s | real, single precision    |
| c | complex, single precision |
| d | real, double precision    |
| z | complex, double precision |
| i | integer                   |

Some routines and functions can have combined character codes, such as *sc* or *dz*.

For example, the function *pscasum* uses a complex input array and returns a real value.

The *<name>* field, in PBLAS level 1, indicates the operation type. For example, the PBLAS level 1 routines *p?dot*, *p?swap*, *p?copy* compute a vector dot product, vector swap, and a copy vector, respectively.

In PBLAS level 2 and 3, *<name>* reflects the matrix argument type:

|           |                   |
|-----------|-------------------|
| <i>ge</i> | general matrix    |
| <i>sy</i> | symmetric matrix  |
| <i>he</i> | Hermitian matrix  |
| <i>tr</i> | triangular matrix |

In PBLAS level 3, the *<name>=tran* indicates the transposition of the matrix.

The *<mod>* field, if present, provides additional details of the operation. The PBLAS level 1 names can have the following characters in the *<mod>* field:

|          |                     |
|----------|---------------------|
| <i>c</i> | conjugated vector   |
| <i>u</i> | unconjugated vector |

The PBLAS level 2 names can have the following additional characters in the *<mod>* field:

|           |                                                                    |
|-----------|--------------------------------------------------------------------|
| <i>mv</i> | matrix-vector product                                              |
| <i>sv</i> | solving a system of linear equations with matrix-vector operations |
| <i>r</i>  | rank-1 update of a matrix                                          |
| <i>r2</i> | rank-2 update of a matrix.                                         |

The PBLAS level 3 names can have the following additional characters in the *<mod>* field:

|            |                                                                    |
|------------|--------------------------------------------------------------------|
| <i>mm</i>  | matrix-matrix product                                              |
| <i>sm</i>  | solving a system of linear equations with matrix-matrix operations |
| <i>rk</i>  | rank- <i>k</i> update of a matrix                                  |
| <i>r2k</i> | rank- <i>2k</i> update of a matrix.                                |

The examples below show how to interpret PBLAS routine names:

|               |                                                                                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>pddot</i>  | <i>&lt;p&gt;</i> <i>&lt;d&gt;</i> <i>&lt;dot&gt;</i> : double-precision real distributed vector-vector dot product                                                         |
| <i>pcdotc</i> | <i>&lt;p&gt;</i> <i>&lt;c&gt;</i> <i>&lt;dot&gt;</i> <i>&lt;c&gt;</i> : complex distributed vector-vector dot product, conjugated                                          |
| <i>pscsum</i> | <i>&lt;p&gt;</i> <i>&lt;sc&gt;</i> <i>&lt;asum&gt;</i> : sum of magnitudes of distributed vector elements, single precision real output and single precision complex input |
| <i>pcdotu</i> | <i>&lt;p&gt;</i> <i>&lt;c&gt;</i> <i>&lt;dot&gt;</i> <i>&lt;u&gt;</i> : distributed vector-vector dot product, unconjugated, complex                                       |
| <i>psgemv</i> | <i>&lt;p&gt;</i> <i>&lt;s&gt;</i> <i>&lt;ge&gt;</i> <i>&lt;mv&gt;</i> : distributed matrix-vector product, general matrix, single precision                                |
| <i>pztrmm</i> | <i>&lt;p&gt;</i> <i>&lt;z&gt;</i> <i>&lt;tr&gt;</i> <i>&lt;mm&gt;</i> : distributed matrix-matrix product, triangular matrix, double-precision complex.                    |

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## PBLAS Level 1 Routines

PBLAS Level 1 includes routines and functions that perform distributed vector-vector operations. [Table "PBLAS Level 1 Routine Groups and Their Data Types"](#) lists the PBLAS Level 1 routine groups and the data types associated with them.

### PBLAS Level 1 Routine Groups and Their Data Types

| Routine or Function Group | Data Types         | Description                                                                            |
|---------------------------|--------------------|----------------------------------------------------------------------------------------|
| <code>p?amax</code>       | s, d, c, z         | Calculates an index of the distributed vector element with maximum absolute value      |
| <code>p?asum</code>       | s, d, sc, dz       | Calculates sum of magnitudes of a distributed vector                                   |
| <code>p?axpy</code>       | s, d, c, z         | Calculates distributed vector-scalar product                                           |
| <code>p?copy</code>       | s, d, c, z         | Copies a distributed vector                                                            |
| <code>p?dot</code>        | s, d               | Calculates a dot product of two distributed real vectors                               |
| <code>p?dotc</code>       | c, z               | Calculates a dot product of two distributed complex vectors, one of them is conjugated |
| <code>p?dotu</code>       | c, z               | Calculates a dot product of two distributed complex vectors                            |
| <code>p?nrm2</code>       | s, d, sc, dz       | Calculates the 2-norm (Euclidean norm) of a distributed vector                         |
| <code>p?scal</code>       | s, d, c, z, cs, zd | Calculates a product of a distributed vector by a scalar                               |
| <code>p?swap</code>       | s, d, c, z         | Swaps two distributed vectors                                                          |

### `p?amax`

*Computes the global index of the element of a distributed vector with maximum absolute value.*

#### Syntax

```
void psamax (const MKL_INT *n , float *amax , MKL_INT *indx , const float *x , const
MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx);

void pdamax (const MKL_INT *n , double *amax , MKL_INT *indx , const double *x , const
MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx);
```

```

void pcamax (const MKL_INT *n , MKL_Complex8 *amax , MKL_INT *indx , const MKL_Complex8
*x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT
*incx);

void pzamax (const MKL_INT *n , MKL_Complex16 *amax , MKL_INT *indx , const
MKL_Complex16 *x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const
MKL_INT *incx);

```

### Include Files

- mkl\_pblas.h

### Description

The functions `p?amax` compute global index of the maximum element in absolute value of a distributed vector `sub(x)`,

where `sub(x)` denotes  $X(ix, jx:jx+n-1)$  if  $incx=m_x$ , and  $X(ix:ix+n-1, jx)$  if  $incx=1$ .

### Input Parameters

|                     |                                                                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>n</code>      | (global) The length of distributed vector <code>sub(x)</code> , $n \geq 0$ .                                                                                                    |
| <code>x</code>      | (local)<br>Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$ .<br>This array contains the entries of the distributed vector <code>sub(x)</code> .                                   |
| <code>ix, jx</code> | (global) The row and column indices in the distributed matrix <code>X</code> indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively. |
| <code>descx</code>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <code>X</code> .                                                                        |
| <code>incx</code>   | (global) Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and $m_x$ . <code>incx</code> must not be zero.              |

### Output Parameters

|                   |                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>amax</code> | (global).<br>Maximum absolute value (magnitude) of elements of the distributed vector only in its scope.                            |
| <code>indx</code> | (global) The global index of the maximum element in absolute value of the distributed vector <code>sub(x)</code> only in its scope. |

### p?asum

*Computes the sum of magnitudes of elements of a distributed vector.*

### Syntax

```

void psasum (const MKL_INT *n , float *asum , const float *x , const MKL_INT *ix ,
const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx);

void pdasum (const MKL_INT *n , double *asum , const double *x , const MKL_INT *ix ,
const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx);

```

```
void pscasum (const MKL_INT *n , float *asum , const MKL_Complex8 *x , const MKL_INT
*ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx);
```

```
void pdzasum (const MKL_INT *n , double *asum , const MKL_Complex16 *x , const MKL_INT
*ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx);
```

## Include Files

- mkl\_pblas.h

## Description

The functions `p?asum` compute the sum of the magnitudes of elements of a distributed vector `sub(x)`, where `sub(x)` denotes  $X(ix, jx:jx+n-1)$  if  $incx=m_x$ , and  $X(ix: ix+n-1, jx)$  if  $incx= 1$ .

## Input Parameters

|                     |                                                                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>n</code>      | (global) The length of distributed vector <code>sub(x)</code> , $n \geq 0$ .                                                                                                    |
| <code>x</code>      | (local)<br>Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$ .<br>This array contains the entries of the distributed vector <code>sub(x)</code> .                                   |
| <code>ix, jx</code> | (global) The row and column indices in the distributed matrix <code>X</code> indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively. |
| <code>descx</code>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <code>X</code> .                                                                        |
| <code>incx</code>   | (global) Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and $m_x$ . <code>incx</code> must not be zero.              |

## Output Parameters

|                   |                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>asum</code> | (local) and <code>p?casum</code> .<br>Contains the sum of magnitudes of elements of the distributed vector only in its scope. |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------|

## p?axpy

*Computes a distributed vector-scalar product and adds the result to a distributed vector.*

---

## Syntax

```
void psaxpy (const MKL_INT *n , const float *a , const float *x , const MKL_INT *ix ,
const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , float *y , const
MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy);
```

```
void pdaxpy (const MKL_INT *n , const double *a , const double *x , const MKL_INT *ix ,
const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , double *y , const
MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy);
```

```
void pcaxpy (const MKL_INT *n , const MKL_Complex8 *a , const MKL_Complex8 *x , const
MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx ,
MKL_Complex8 *y , const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const
MKL_INT *incy);
```

```
void pzaxpy (const MKL_INT *n , const MKL_Complex16 *a , const MKL_Complex16 *x , const
MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx ,
MKL_Complex16 *y , const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const
MKL_INT *incy);
```

## Include Files

- mkl\_pblas.h

## Description

The `p?axpy` routines perform the following operation with distributed vectors:

```
sub(y) := sub(y) + a*sub(x)
```

where:

$a$  is a scalar;

`sub(x)` and `sub(y)` are  $n$ -element distributed vectors.

`sub(x)` denotes  $X(ix, jx:jx+n-1)$  if  $incx=m_x$ , and  $X(ix: ix+n-1, jx)$  if  $incx= 1$ ;

`sub(y)` denotes  $Y(iy, jy:jy+n-1)$  if  $incy=m_y$ , and  $Y(iy: iy+n-1, jy)$  if  $incy= 1$ .

## Input Parameters

|          |                                                                                                                                                                      |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $n$      | (global) The length of distributed vectors, $n \geq 0$ .                                                                                                             |
| $a$      | (local)<br>Specifies the scalar $a$ .                                                                                                                                |
| $x$      | (local)<br>Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$ .<br>This array contains the entries of the distributed vector <code>sub(x)</code> .                        |
| $ix, jx$ | (global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively. |
| $descx$  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .                                                                        |
| $incx$   | (global) Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and $m_x$ . $incx$ must not be zero.              |
| $y$      | (local)<br>Array, size $(jy-1)*m_y + iy+(n-1)*abs(incy)$ .<br>This array contains the entries of the distributed vector <code>sub(y)</code> .                        |
| $iy, jy$ | (global) The row and column indices in the distributed matrix $Y$ indicating the first row and the first column of the submatrix <code>sub(Y)</code> , respectively. |
| $descy$  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $Y$ .                                                                        |
| $incy$   | (global) Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and $m_y$ . $incy$ must not be zero.              |

## Output Parameters

$y$  Overwritten by  $\text{sub}(y) := \text{sub}(y) + a * \text{sub}(x)$ .

## p?copy

*Copies one distributed vector to another vector.*

### Syntax

```
void picopy (const MKL_INT *n , const MKL_INT *x , const MKL_INT *ix , const MKL_INT
*jx , const MKL_INT *descx , const MKL_INT *incx , MKL_INT *y , const MKL_INT *iy ,
const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy);
```

```
void pscopy (const MKL_INT *n , const float *x , const MKL_INT *ix , const MKL_INT
*jx , const MKL_INT *descx , const MKL_INT *incx , float *y , const MKL_INT *iy ,
const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy);
```

```
void pdcopy (const MKL_INT *n , const double *x , const MKL_INT *ix , const MKL_INT
*jx , const MKL_INT *descx , const MKL_INT *incx , double *y , const MKL_INT *iy ,
const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy);
```

```
void pccopy (const MKL_INT *n , const MKL_Complex8 *x , const MKL_INT *ix , const
MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , MKL_Complex8 *y , const
MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy);
```

```
void pzcopy (const MKL_INT *n , const MKL_Complex16 *x , const MKL_INT *ix , const
MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , MKL_Complex16 *y , const
MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy);
```

### Include Files

- mkl\_pblas.h

### Description

The p?copy routines perform a copy operation with distributed vectors defined as

```
sub(y) = sub(x),
```

where  $\text{sub}(x)$  and  $\text{sub}(y)$  are  $n$ -element distributed vectors.

$\text{sub}(x)$  denotes  $X(ix, jx:jx+n-1)$  if  $incx=m_x$ , and  $X(ix: ix+n-1, jx)$  if  $incx= 1$ ;

$\text{sub}(y)$  denotes  $Y(iy, jy:jy+n-1)$  if  $incy=m_y$ , and  $Y(iy: iy+n-1, jy)$  if  $incy= 1$ .

### Input Parameters

$n$  (global) The length of distributed vectors,  $n \geq 0$ .

$x$  (local)  
 Array, size  $(jx-1) * m_x + ix + (n-1) * \text{abs}(incx)$ .  
 This array contains the entries of the distributed vector  $\text{sub}(x)$ .

$ix, jx$  (global) The row and column indices in the distributed matrix  $X$  indicating the first row and the first column of the submatrix  $\text{sub}(X)$ , respectively.

|               |                                                                                                                                                                  |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>descx</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .                                                                    |
| <i>incx</i>   | (global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m_x$ . <i>incx</i> must not be zero.         |
| <i>y</i>      | (local)<br>Array, size $(jy-1)*m_y + iy+(n-1)*\text{abs}(incy)$ .<br>This array contains the entries of the distributed vector $\text{sub}(y)$ .                 |
| <i>iy, jy</i> | (global) The row and column indices in the distributed matrix $Y$ indicating the first row and the first column of the submatrix $\text{sub}(Y)$ , respectively. |
| <i>descy</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $Y$ .                                                                    |
| <i>incy</i>   | (global) Specifies the increment for the elements of $\text{sub}(y)$ . Only two values are supported, namely 1 and $m_y$ . <i>incy</i> must not be zero.         |

## Output Parameters

|          |                                                           |
|----------|-----------------------------------------------------------|
| <i>y</i> | Overwritten with the distributed vector $\text{sub}(x)$ . |
|----------|-----------------------------------------------------------|

## p?dot

Computes the dot product of two distributed real vectors.

### Syntax

```
void psdot (const MKL_INT *n , float *dot , const float *x , const MKL_INT *ix , const
MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , const float *y , const
MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy);

void pddot (const MKL_INT *n , double *dot , const double *x , const MKL_INT *ix ,
const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , const double *y ,
const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy);
```

### Include Files

- `mkl_pblas.h`

### Description

The ?dot functions compute the dot product *dot* of two distributed real vectors defined as

$$\text{dot} = \text{sub}(x) \cdot \text{sub}(y)$$

where  $\text{sub}(x)$  and  $\text{sub}(y)$  are  $n$ -element distributed vectors.

$\text{sub}(x)$  denotes  $X(ix, jx:jx+n-1)$  if  $incx=m_x$ , and  $X(ix: ix+n-1, jx)$  if  $incx= 1$ ;

$\text{sub}(y)$  denotes  $Y(iy, jy:jy+n-1)$  if  $incy=m_y$ , and  $Y(iy: iy+n-1, jy)$  if  $incy= 1$ .

### Input Parameters

|          |                                                          |
|----------|----------------------------------------------------------|
| <i>n</i> | (global) The length of distributed vectors, $n \geq 0$ . |
|----------|----------------------------------------------------------|

|                     |                                                                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | (local)<br>Array, size $(j_x-1)*m_x + ix+(n-1)*abs(incx)$ .<br>This array contains the entries of the distributed vector <code>sub(x)</code> .                                  |
| <code>ix, jx</code> | (global) The row and column indices in the distributed matrix <code>X</code> indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively. |
| <code>descx</code>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <code>X</code> .                                                                        |
| <code>incx</code>   | (global) Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and $m_x$ . <code>incx</code> must not be zero.              |
| <code>y</code>      | (local)<br>Array, size $(j_y-1)*m_y + iy+(n-1)*abs(incy)$ .<br>This array contains the entries of the distributed vector <code>sub(y)</code> .                                  |
| <code>iy, jy</code> | (global) The row and column indices in the distributed matrix <code>Y</code> indicating the first row and the first column of the submatrix <code>sub(Y)</code> , respectively. |
| <code>descy</code>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <code>Y</code> .                                                                        |
| <code>incy</code>   | (global) Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and $m_y$ . <code>incy</code> must not be zero.              |

## Output Parameters

|                  |                                                                                            |

## p?dotc

*Computes the dot product of two distributed complex vectors, one of them is conjugated.*

---

### Syntax

```
void pcdotc (const MKL_INT *n , MKL_Complex8 *dotc , const MKL_Complex8 *x , const
MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , const
MKL_Complex8 *y , const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const
MKL_INT *incy);
```

```
void pzdorc (const MKL_INT *n , MKL_Complex16 *dotc , const MKL_Complex16 *x , const
MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , const
MKL_Complex16 *y , const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const
MKL_INT *incy);
```

### Include Files

- `mk1_pblas.h`

## Description

The `p?dotc` functions compute the dot product `dotc` of two distributed vectors, with one vector conjugated:

```
dotc = conjg(sub(x)')*sub(y)
```

where `sub(x)` and `sub(y)` are  $n$ -element distributed vectors.

`sub(x)` denotes  $X(ix, jx:jx+n-1)$  if  $incx=m\_x$ , and  $X(ix: ix+n-1, jx)$  if  $incx= 1$ ;

`sub(y)` denotes  $Y(iy, jy:jy+n-1)$  if  $incy=m\_y$ , and  $Y(iy: iy+n-1, jy)$  if  $incy= 1$ .

## Input Parameters

|                     |                                                                                                                                                                      |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>n</code>      | (global) The length of distributed vectors, $n \geq 0$ .                                                                                                             |
| <code>x</code>      | (local)<br>Array, size $(jx-1)*m\_x + ix+(n-1)*abs(incx)$ .<br>This array contains the entries of the distributed vector <code>sub(x)</code> .                       |
| <code>ix, jx</code> | (global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively. |
| <code>descx</code>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .                                                                        |
| <code>incx</code>   | (global) Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and $m\_x$ . <code>incx</code> must not be zero.  |
| <code>y</code>      | (local)<br>Array, size $(jy-1)*m\_y + iy+(n-1)*abs(incy)$ .<br>This array contains the entries of the distributed vector <code>sub(y)</code> .                       |
| <code>iy, jy</code> | (global) The row and column indices in the distributed matrix $Y$ indicating the first row and the first column of the submatrix <code>sub(Y)</code> , respectively. |
| <code>descy</code>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $Y$ .                                                                        |
| <code>incy</code>   | (global) Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and $m\_y$ . <code>incy</code> must not be zero.  |

## Output Parameters

|                   |                                                                                            |
|-------------------|--------------------------------------------------------------------------------------------|
| <code>dotc</code> | (local)<br>Dot product of <code>sub(x)</code> and <code>sub(y)</code> only in their scope. |
|-------------------|--------------------------------------------------------------------------------------------|

## p?dotu

Computes the dot product of two distributed complex vectors.

---

## Syntax

```
void pcdotu (const MKL_INT *n , MKL_Complex8 *dotu , const MKL_Complex8 *x , const
MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , const
MKL_Complex8 *y , const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const
MKL_INT *incy);
```

```
void pzdotu (const MKL_INT *n , MKL_Complex16 *dotu , const MKL_Complex16 *x , const
MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , const
MKL_Complex16 *y , const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const
MKL_INT *incy);
```

## Include Files

- mkl\_pblas.h

## Description

The `p?dotu` functions compute the dot product `dotu` of two distributed vectors defined as

$$\text{dotu} = \text{sub}(x)' * \text{sub}(y)$$

where `sub(x)` and `sub(y)` are  $n$ -element distributed vectors.

`sub(x)` denotes  $X(ix, jx:jx+n-1)$  if  $incx=m_x$ , and  $X(ix: ix+n-1, jx)$  if  $incx= 1$ ;

`sub(y)` denotes  $Y(iy, jy:jy+n-1)$  if  $incy=m_y$ , and  $Y(iy: iy+n-1, jy)$  if  $incy= 1$ .

## Input Parameters

|                     |                                                                                                                                                                      |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>n</code>      | (global) The length of distributed vectors, $n \geq 0$ .                                                                                                             |
| <code>x</code>      | (local)<br>Array, size $(jx-1) * m_x + ix + (n-1) * \text{abs}(incx)$ .<br>This array contains the entries of the distributed vector <code>sub(x)</code> .           |
| <code>ix, jx</code> | (global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively. |
| <code>descx</code>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .                                                                        |
| <code>incx</code>   | (global) Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and $m_x$ . <code>incx</code> must not be zero.   |
| <code>y</code>      | (local)<br>Array, size $(jy-1) * m_y + iy + (n-1) * \text{abs}(incy)$ .<br>This array contains the entries of the distributed vector <code>sub(y)</code> .           |
| <code>iy, jy</code> | (global) The row and column indices in the distributed matrix $Y$ indicating the first row and the first column of the submatrix <code>sub(Y)</code> , respectively. |
| <code>descy</code>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $Y$ .                                                                        |
| <code>incy</code>   | (global) Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and $m_y$ . <code>incy</code> must not be zero.   |

## Output Parameters

*dotu* (local)  
Dot product of  $\text{sub}(x)$  and  $\text{sub}(y)$  only in their scope.

## p?norm2

Computes the Euclidean norm of a distributed vector.

### Syntax

```
void psnorm2 (const MKL_INT *n , float *norm2 , const float *x , const MKL_INT *ix ,
const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx);
void pdnorm2 (const MKL_INT *n , double *norm2 , const double *x , const MKL_INT *ix ,
const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx);
void pscnorm2 (const MKL_INT *n , float *norm2 , const MKL_Complex8 *x , const MKL_INT
*ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx);
void pdznorm2 (const MKL_INT *n , double *norm2 , const MKL_Complex16 *x , const MKL_INT
*ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx);
```

### Include Files

- mkl\_pblas.h

### Description

The p?norm2 functions compute the Euclidean norm of a distributed vector  $\text{sub}(x)$ , where  $\text{sub}(x)$  is an  $n$ -element distributed vector.

$\text{sub}(x)$  denotes  $X(ix, jx:jx+n-1)$  if  $incx=m_x$ , and  $X(ix: ix+n-1, jx)$  if  $incx= 1$ .

### Input Parameters

*n* (global) The length of distributed vector  $\text{sub}(x)$ ,  $n \geq 0$ .

*x* (local)  
Array, size  $(jx-1)*m_x + ix+(n-1)*abs(incx)$ .  
This array contains the entries of the distributed vector  $\text{sub}(x)$ .

*ix, jx* (global) The row and column indices in the distributed matrix  $X$  indicating the first row and the first column of the submatrix  $\text{sub}(X)$ , respectively.

*descx* (global and local) array of dimension 9. The array descriptor of the distributed matrix  $X$ .

*incx* (global) Specifies the increment for the elements of  $\text{sub}(x)$ . Only two values are supported, namely 1 and  $m_x$ . *incx* must not be zero.

### Output Parameters

*norm2* (local) and pscnorm2.  
Contains the Euclidean norm of a distributed vector only in its scope.

## p?scal

Computes a product of a distributed vector by a scalar.

### Syntax

```
void pssscal (const MKL_INT *n , const float *a , float *x , const MKL_INT *ix , const
MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx);

void pdscal (const MKL_INT *n , const double *a , double *x , const MKL_INT *ix , const
MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx);

void pcscal (const MKL_INT *n , const MKL_Complex8 *a , MKL_Complex8 *x , const MKL_INT
*ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx);

void pzscal (const MKL_INT *n , const MKL_Complex16 *a , MKL_Complex16 *x , const
MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx);

void pcsscal (const MKL_INT *n , const float *a , MKL_Complex8 *x , const MKL_INT *ix ,
const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx);

void pdzscal (const MKL_INT *n , const double *a , MKL_Complex16 *x , const MKL_INT
*ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx);
```

### Include Files

### Description

The p?scal routines multiplies a  $n$ -element distributed vector  $\text{sub}(x)$  by the scalar  $a$ :

$\text{sub}(x) = a * \text{sub}(x)$ ,

where  $\text{sub}(x)$  denotes  $X(ix, jx:jx+n-1)$  if  $incx=m_x$ , and  $X(ix:ix+n-1, jx)$  if  $incx=1$ .

### Input Parameters

|          |                                                                                                                                                                  |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $n$      | (global) The length of distributed vector $\text{sub}(x)$ , $n \geq 0$ .                                                                                         |
| $a$      | (global) and pcsscal<br>Specifies the scalar $a$ .                                                                                                               |
| $x$      | (local)<br>Array, size $(jx-1) * m_x + ix + (n-1) * \text{abs}(incx)$ .<br>This array contains the entries of the distributed vector $\text{sub}(x)$ .           |
| $ix, jx$ | (global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix $\text{sub}(X)$ , respectively. |
| $descx$  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .                                                                    |
| $incx$   | (global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m_x$ . $incx$ must not be zero.              |

## Output Parameters

$x$  Overwritten by the updated distributed vector  $\text{sub}(x)$

## p?swap

*Swaps two distributed vectors.*

### Syntax

```
void psswap (const MKL_INT *n , float *x , const MKL_INT *ix , const MKL_INT *jx ,
const MKL_INT *descx , const MKL_INT *incx , float *y , const MKL_INT *iy , const
MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy);

void pdswap (const MKL_INT *n , double *x , const MKL_INT *ix , const MKL_INT *jx ,
const MKL_INT *descx , const MKL_INT *incx , double *y , const MKL_INT *iy , const
MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy);

void pcswap (const MKL_INT *n , MKL_Complex8 *x , const MKL_INT *ix , const MKL_INT
*jx , const MKL_INT *descx , const MKL_INT *incx , MKL_Complex8 *y , const MKL_INT
*iy , const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy);

void pzswap (const MKL_INT *n , MKL_Complex16 *x , const MKL_INT *ix , const MKL_INT
*jx , const MKL_INT *descx , const MKL_INT *incx , MKL_Complex16 *y , const MKL_INT
*iy , const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy);
```

### Include Files

- mkl\_pblas.h

### Description

Given two distributed vectors  $\text{sub}(x)$  and  $\text{sub}(y)$ , the p?swap routines return vectors  $\text{sub}(y)$  and  $\text{sub}(x)$  swapped, each replacing the other.

Here  $\text{sub}(x)$  denotes  $X(ix, jx:jx+n-1)$  if  $incx=m_x$ , and  $X(ix:ix+n-1, jx)$  if  $incx=1$ ;

$\text{sub}(y)$  denotes  $Y(iy, jy:jy+n-1)$  if  $incy=m_y$ , and  $Y(iy:iy+n-1, jy)$  if  $incy=1$ .

### Input Parameters

|          |                                                                                                                                                                  |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $n$      | (global) The length of distributed vectors, $n \geq 0$ .                                                                                                         |
| $x$      | (local)<br>Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$ .<br>This array contains the entries of the distributed vector $\text{sub}(x)$ .                        |
| $ix, jx$ | (global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix $\text{sub}(X)$ , respectively. |
| $descx$  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .                                                                    |
| $incx$   | (global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m_x$ . $incx$ must not be zero.              |
| $y$      | (local)                                                                                                                                                          |

Array, size  $(j_y-1)*m_y + i_y+(n-1)*abs(inc_y)$ .

This array contains the entries of the distributed vector  $sub(y)$ .

*i<sub>y</sub>*, *j<sub>y</sub>* (global) The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix  $sub(Y)$ , respectively.

*descy* (global and local) array of dimension 9. The array descriptor of the distributed matrix *Y*.

*incy* (global) Specifies the increment for the elements of  $sub(y)$ . Only two values are supported, namely 1 and *m<sub>y</sub>*. *incy* must not be zero.

### Output Parameters

*x* Overwritten by distributed vector  $sub(y)$ .

*y* Overwritten by distributed vector  $sub(x)$ .

## PBLAS Level 2 Routines

This section describes PBLAS Level 2 routines, which perform distributed matrix-vector operations. [Table "PBLAS Level 2 Routine Groups and Their Data Types"](#) lists the PBLAS Level 2 routine groups and the data types associated with them.

### PBLAS Level 2 Routine Groups and Their Data Types

| Routine Groups          | Data Types | Description                                                                    |

### Description

The `p?gemv` routines perform a distributed matrix-vector operation defined as

```
sub(y) := alpha*sub(A)*sub(x) + beta*sub(y),
```

or

```
sub(y) := alpha*sub(A)'*sub(x) + beta*sub(y),
```

or

```
sub(y) := alpha*conjg(sub(A)')*sub(x) + beta*sub(y),
```

where

*alpha* and *beta* are scalars,

*sub(A)* is a *m*-by-*n* submatrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$ ,

*sub(x)* and *sub(y)* are subvectors.

When *trans* = 'N' or 'n', *sub(x)* denotes  $X(\text{ix}, \text{jx}:\text{jx}+n-1)$  if *incx* = *m\_x*, and  $X(\text{ix}:\text{ix}+n-1, \text{jx})$  if *incx* = 1, *sub(y)* denotes  $Y(\text{iy}, \text{jy}:\text{jy}+m-1)$  if *incy* = *m\_y*, and  $Y(\text{iy}:\text{iy}+m-1, \text{jy})$  if *incy* = 1.

When *trans* = 'T' or 't', or 'C', or 'c', *sub(x)* denotes  $X(\text{ix}, \text{jx}:\text{jx}+m-1)$  if *incx* = *m\_x*, and  $X(\text{ix}:\text{ix}+m-1, \text{jx})$  if *incx* = 1, *sub(y)* denotes  $Y(\text{iy}, \text{jy}:\text{jy}+n-1)$  if *incy* = *m\_y*, and  $Y(\text{iy}:\text{iy}+m-1, \text{jy})$  if *incy* = 1.

## Input Parameters

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>trans</i>  | (global) Specifies the operation:<br>if <i>trans</i> = 'N' or 'n', then $\text{sub}(y) := \text{alpha} * \text{sub}(A)' * \text{sub}(x) + \text{beta} * \text{sub}(y)$ ;<br>if <i>trans</i> = 'T' or 't', then $\text{sub}(y) := \text{alpha} * \text{sub}(A)' * \text{sub}(x) + \text{beta} * \text{sub}(y)$ ;<br>if <i>trans</i> = 'C' or 'c', then $\text{sub}(y) := \text{alpha} * \text{conjg}(\text{sub}A)' * \text{sub}(x) + \text{beta} * \text{sub}(y)$ . |
| <i>m</i>      | (global) Specifies the number of rows of the distributed matrix <i>sub(A)</i> , $m \geq 0$ .                                                                                                                                                                                                                                                                                                                                                                       |
| <i>n</i>      | (global) Specifies the number of columns of the distributed matrix <i>sub(A)</i> , $n \geq 0$ .                                                                                                                                                                                                                                                                                                                                                                    |
| <i>alpha</i>  | (global)<br>Specifies the scalar <i>alpha</i> .                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>a</i>      | (local)<br>Array, size $(\text{lld}_a, \text{LOCq}(\text{ja}+n-1))$ . Before entry this array must contain the local pieces of the distributed matrix <i>sub(A)</i> .                                                                                                                                                                                                                                                                                              |
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.                                                                                                                                                                                                                                                                                                |

## Description

The `p?agemv` routines perform a distributed matrix-vector operation defined as

```
sub(y) := abs(alpha)*abs(sub(A)')*abs(sub(x)) + abs(beta*sub(y)),
```

or

```
sub(y) := abs(alpha)*abs(sub(A)')*abs(sub(x)) + abs(beta*sub(y)),
```

or

```
sub(y) := abs(alpha)*abs(conjg(sub(A)'))*abs(sub(x)) + abs(beta*sub(y)),
```

where

*alpha* and *beta* are scalars,

*sub(A)* is a *m*-by-*n* submatrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$ ,

*sub(x)* and *sub(y)* are subvectors.

When *trans* = 'N' or 'n',

*sub(x)* denotes  $X(\text{ix}:\text{ix}, \text{jx}:\text{jx}+n-1)$  if *incx* = *m<sub>x</sub>*, and

$X(\text{ix}:\text{ix}+n-1, \text{jx}:\text{jx})$  if *incx* = 1,

*sub(y)* denotes  $Y(\text{iy}:\text{iy}, \text{jy}:\text{jy}+m-1)$  if *incy* = *m<sub>y</sub>*, and

$Y(\text{iy}:\text{iy}+m-1, \text{jy}:\text{jy})$  if *incy* = 1.

When *trans* = 'T' or 't', or 'C', or 'c',

*sub(x)* denotes  $X(\text{ix}:\text{ix}, \text{jx}:\text{jx}+m-1)$  if *incx* = *m<sub>x</sub>*, and

$X(\text{ix}:\text{ix}+m-1, \text{jx}:\text{jx})$  if *incx* = 1,

*sub(y)* denotes  $Y(\text{iy}:\text{iy}, \text{jy}:\text{jy}+n-1)$  if *incy* = *m<sub>y</sub>*, and

$Y(\text{iy}:\text{iy}+m-1, \text{jy}:\text{jy})$  if *incy* = 1.

## Input Parameters

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>trans</i> | (global) Specifies the operation:<br>if <i>trans</i> = 'N' or 'n', then $\text{sub}(y) :=  \alpha  *  \text{sub}(A)  *  \text{sub}(x)  +  \beta * \text{sub}(y) $<br>if <i>trans</i> = 'T' or 't', then $\text{sub}(y) :=  \alpha  *  \text{sub}(A)'  *  \text{sub}(x)  +  \beta * \text{sub}(y) $<br>if <i>trans</i> = 'C' or 'c', then $\text{sub}(y) :=  \alpha  *  \text{sub}(A)'  *  \text{sub}(x)  +  \beta * \text{sub}(y) $ . |
| <i>m</i>     | (global) Specifies the number of rows of the distributed matrix <i>sub(A)</i> , $m \geq 0$ .                                                                                                                                                                                                                                                                                                                                          |

|               |                                                                                                                                                                                                                                          |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>      | (global) Specifies the number of columns of the distributed matrix $\text{sub}(A)$ , $n \geq 0$ .                                                                                                                                        |
| <i>alpha</i>  | (global)<br>Specifies the scalar <i>alpha</i> .                                                                                                                                                                                          |
| <i>a</i>      | (local)<br>Array, size $(lld\_a, \text{LOCq}(ja+n-1))$ . Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(A)$ .                                                                               |
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.                                                                    |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .                                                                                                                                       |
| <i>x</i>      | (local)<br>Array, size $(jx-1)*m\_x + ix+(n-1)*\text{abs}(incx)$ when <i>trans</i> = 'N' or 'n', and $(jx-1)*m\_x + ix+(m-1)*\text{abs}(incx)$ otherwise.<br>This array contains the entries of the distributed vector $\text{sub}(x)$ . |
| <i>ix, jx</i> | (global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix $\text{sub}(x)$ , respectively.                                                                    |
| <i>descx</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .                                                                                                                                       |
| <i>incx</i>   | (global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m\_x$ . <i>incx</i> must not be zero.                                                                                |
| <i>beta</i>   | (global)<br>Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then $\text{sub}(y)$ need not be set on input.                                                                                                           |
| <i>y</i>      | (local)<br>Array, size $(jy-1)*m\_y + iy+(m-1)*\text{abs}(incy)$ when <i>trans</i> = 'N' or 'n', and $(jy-1)*m\_y + iy+(n-1)*\text{abs}(incy)$ otherwise.<br>This array contains the entries of the distributed vector $\text{sub}(y)$ . |
| <i>iy, jy</i> | (global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix $\text{sub}(y)$ , respectively.                                                                    |
| <i>descy</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .                                                                                                                                       |
| <i>incy</i>   | (global) Specifies the increment for the elements of $\text{sub}(y)$ . Only two values are supported, namely 1 and $m\_y$ . <i>incy</i> must not be zero.                                                                                |

## Output Parameters

|          |                                                                 |
|----------|-----------------------------------------------------------------|
| <i>y</i> | Overwritten by the updated distributed vector $\text{sub}(y)$ . |
|----------|-----------------------------------------------------------------|

## p?ger

Performs a rank-1 update of a distributed general matrix.

### Syntax

```
void psgger (const MKL_INT *m , const MKL_INT *n , const float *alpha , const float *x ,

### Description

The p?ger routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{sub}(y)' + \text{sub}(A),$$

where:

*alpha* is a scalar,

sub(A) is a *m*-by-*n* distributed general matrix, sub(A)=A(*ia:ia+m-1*, *ja:ja+n-1*),

sub(x) is an *m*-element distributed vector, sub(y) is an *n*-element distributed vector,

sub(x) denotes X(*ix*, *jx:jx+m-1*) if *incx* = *m\_x*, and X(*ix: ix+m-1*, *jx*) if *incx* = 1,

sub(y) denotes Y(*iy*, *jy:jy+n-1*) if *incy* = *m\_y*, and Y(*iy: iy+n-1*, *jy*) if *incy* = 1.

### Input Parameters

|                       |                                                                                                                                                                                      |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>m</i>              | (global) Specifies the number of rows of the distributed matrix sub(A), <i>m</i> ≥ 0.                                                                                                |
| <i>n</i>              | (global) Specifies the number of columns of the distributed matrix sub(A), <i>n</i> ≥ 0.                                                                                             |
| <i>alpha</i>          | (global)<br>Specifies the scalar <i>alpha</i> .                                                                                                                                      |
| <i>x</i>              | (local)<br>Array, size at least ( <i>jx-1</i> ) * <i>m_x</i> + <i>ix</i> + ( <i>m-1</i> ) * abs( <i>incx</i> ).<br>This array contains the entries of the distributed vector sub(x). |
| <i>ix</i> , <i>jx</i> | (global) The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix sub(x), respectively.                                 |

|               |                                                                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>descx</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .                                                                  |
| <i>incx</i>   | (global) Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.         |
| <i>y</i>      | (local)<br>Array, size at least $(jy-1)*m_y + iy+(n-1)*abs(incy)$ .<br>This array contains the entries of the distributed vector <i>sub(y)</i> .                    |
| <i>iy, jy</i> | (global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <i>sub(y)</i> , respectively. |
| <i>descy</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .                                                                  |
| <i>incy</i>   | (global) Specifies the increment for the elements of <i>sub(y)</i> . Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.         |
| <i>a</i>      | (local)<br>Array, size $(lld_a, LOCq(ja+n-1))$ .<br>Before entry this array contains the local pieces of the distributed matrix <i>sub(A)</i> .                     |
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively. |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .                                                                  |

## Output Parameters

*a* Overwritten by the updated distributed matrix *sub(A)*.

## p?gerc

*Performs a rank-1 update (conjugated) of a distributed general matrix.*

### Syntax

```
void pcgerc (const MKL_INT *m , const MKL_INT *n , const MKL_Complex8 *alpha , const

## Description

The `p?gerc` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{conjg}(\text{sub}(y)') + \text{sub}(A),$$

where:

*alpha* is a scalar,

*sub(A)* is a *m*-by-*n* distributed general matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$ ,

*sub(x)* is an *m*-element distributed vector, *sub(y)* is an *n*-element distributed vector,

*sub(x)* denotes  $X(\text{ix}, \text{jx}:\text{jx}+m-1)$  if *incx* = *m\_x*, and  $X(\text{ix}:\text{ix}+m-1, \text{jx})$  if *incx* = 1,

*sub(y)* denotes  $Y(\text{iy}, \text{jy}:\text{jy}+n-1)$  if *incy* = *m\_y*, and  $Y(\text{iy}:\text{iy}+n-1, \text{jy})$  if *incy* = 1.

## Input Parameters

|               |                                                                                                                                                                                    |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>m</i>      | (global) Specifies the number of rows of the distributed matrix <i>sub(A)</i> , $m \geq 0$ .                                                                                       |
| <i>n</i>      | (global) Specifies the number of columns of the distributed matrix <i>sub(A)</i> , $n \geq 0$ .                                                                                    |
| <i>alpha</i>  | (global)<br>Specifies the scalar <i>alpha</i> .                                                                                                                                    |
| <i>x</i>      | (local)<br>Array, size at least $(\text{jx}-1) * m_x + \text{ix} + (n-1) * \text{abs}(\text{incx})$ .<br>This array contains the entries of the distributed vector <i>sub(x)</i> . |
| <i>ix, jx</i> | (global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix <i>sub(x)</i> , respectively.                |
| <i>descx</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .                                                                                 |
| <i>incx</i>   | (global) Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.                        |
| <i>y</i>      | (local)<br>Array, size at least $(\text{jy}-1) * m_y + \text{iy} + (n-1) * \text{abs}(\text{incy})$ .<br>This array contains the entries of the distributed vector <i>sub(y)</i> . |
| <i>iy, jy</i> | (global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <i>sub(y)</i> , respectively.                |
| <i>descy</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .                                                                                 |
| <i>incy</i>   | (global) Specifies the increment for the elements of <i>sub(y)</i> . Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.                        |

|               |                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>a</i>      | (local)<br>Array, size at least $(lld\_a, LOCq(ja+n-1))$ . Before entry this array contains the local pieces of the distributed matrix $sub(A)$ .         |
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix $A$ indicating the first row and the first column of the submatrix $sub(A)$ , respectively. |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $A$ .                                                             |

## Output Parameters

### Description

The p?hemv routines perform a distributed matrix-vector operation defined as

$$\text{sub}(y) := \alpha * \text{sub}(A) * \text{sub}(x) + \beta * \text{sub}(y),$$

where:

*alpha* and *beta* are scalars,

*sub(A)* is a *n*-by-*n* Hermitian distributed matrix,  $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ ,

*sub(x)* and *sub(y)* are distributed vectors.

*sub(x)* denotes  $X(ix, jx:jx+n-1)$  if *incx* = *m<sub>x</sub>*, and  $X(ix:ix+n-1, jx)$  if *incx* = 1,

*sub(y)* denotes  $Y(iy, jy:jy+n-1)$  if *incy* = *m<sub>y</sub>*, and  $Y(iy:iy+n-1, jy)$  if *incy* = 1.

### Input Parameters

|              |                                                                                                                                                                                                                                                                                                                          |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>uplo</i>  | (global) Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <i>sub(A)</i> is used:<br><br>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(A)</i> is used.<br><br>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(A)</i> is used. |

## Description

The p?ahemv routines perform a distributed matrix-vector operation defined as

$$\text{sub}(y) := \text{abs}(\alpha) * \text{abs}(\text{sub}(A)) * \text{abs}(\text{sub}(x)) + \text{abs}(\beta * \text{sub}(y)),$$

where:

*alpha* and *beta* are scalars,

*sub(A)* is a *n*-by-*n* Hermitian distributed matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ ,

*sub(x)* and *sub(y)* are distributed vectors.

*sub(x)* denotes  $X(\text{ix}, \text{jx}:\text{jx}+n-1)$  if *incx* = *m<sub>x</sub>*, and  $X(\text{ix}:\text{ix}+n-1, \text{jx})$  if *incx* = 1,

*sub(y)* denotes  $Y(\text{iy}, \text{jy}:\text{jy}+n-1)$  if *incy* = *m<sub>y</sub>*, and  $Y(\text{iy}:\text{iy}+n-1, \text{jy})$  if *incy* = 1.

## Input Parameters

## Description

The `p?her` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{conjg}(\text{sub}(x)') + \text{sub}(A),$$

where:

$\alpha$  is a real scalar,

$\text{sub}(A)$  is a  $n$ -by- $n$  distributed Hermitian matrix,  $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ ,

$\text{sub}(x)$  is distributed vector.

$\text{sub}(x)$  denotes  $X(ix, jx:jx+n-1)$  if  $incx = m_x$ , and  $X(ix:ix+n-1, jx)$  if  $incx = 1$ .

## Input Parameters

### Description

The p?her2 routines perform a distributed matrix-vector operation defined as

$$sub(A) := alpha * sub(x) * conj(sub(y)') + conj(alpha) * sub(y) * conj(sub(x)') + sub(A),$$

where:

*alpha* is a scalar,

$\text{sub}(A)$  is a  $n$ -by- $n$  distributed Hermitian matrix,  $\text{sub}(A)=A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ ,

$\text{sub}(x)$  and  $\text{sub}(y)$  are distributed vectors.

$\text{sub}(x)$  denotes  $X(\text{ix}, \text{jx}:\text{jx}+n-1)$  if  $\text{incx} = m_x$ , and  $X(\text{ix}:\text{ix}+n-1, \text{jx})$  if  $\text{incx} = 1$ ,

$\text{sub}(y)$  denotes  $Y(\text{iy}, \text{jy}:\text{jy}+n-1)$  if  $\text{incy} = m_y$ , and  $Y(\text{iy}:\text{iy}+n-1, \text{jy})$  if  $\text{incy} = 1$ .

## Input Parameters

|               |                                                                                                                                                                                                                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>uplo</i>   | (global) Specifies whether the upper or lower triangular part of the distributed Hermitian matrix $\text{sub}(A)$ is used:<br><br>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the $\text{sub}(A)$ is used.<br><br>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the $\text{sub}(A)$ is used. |
| <i>n</i>      | (global) Specifies the order of the distributed matrix $\text{sub}(A)$ , $n \geq 0$ .                                                                                                                                                                                                                                          |
| <i>alpha</i>  | (global)<br>Specifies the scalar <i>alpha</i> .                                                                                                                                                                                                                                                                                |
| <i>x</i>      | (local)<br>Array, size at least $(\text{jx}-1)*m_x + \text{ix}+(n-1)*\text{abs}(\text{incx})$ .<br>This array contains the entries of the distributed vector $\text{sub}(x)$ .                                                                                                                                                 |
| <i>ix, jx</i> | (global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix $\text{sub}(x)$ , respectively.                                                                                                                                                               |
| <i>descx</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .                                                                                                                                                                                                                                  |
| <i>incx</i>   | (global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m_x$ . <i>incx</i> must not be zero.                                                                                                                                                                       |
| <i>y</i>      | (local)<br>Array, size at least $(\text{jy}-1)*m_y + \text{iy}+(n-1)*\text{abs}(\text{incy})$ .<br>This array contains the entries of the distributed vector $\text{sub}(y)$ .                                                                                                                                                 |
| <i>iy, jy</i> | (global) The row and column indices in the distributed matrix $Y$ indicating the first row and the first column of the submatrix $\text{sub}(y)$ , respectively.                                                                                                                                                               |
| <i>descy</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $Y$ .                                                                                                                                                                                                                                  |
| <i>incy</i>   | (global) Specifies the increment for the elements of $\text{sub}(y)$ . Only two values are supported, namely 1 and $m_y$ . <i>incy</i> must not be zero.                                                                                                                                                                       |
| <i>a</i>      | (local)<br>Array, size $(\text{lld}_a, \text{LOCq}(\text{ja}+n-1))$ . This array contains the local pieces of the distributed matrix $\text{sub}(A)$ .                                                                                                                                                                         |

Before entry with `uplo = 'U'` or `'u'`, the  $n$ -by- $n$  upper triangular part of the distributed matrix `sub(A)` must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of `sub(A)` is not referenced, and with `uplo = 'L'` or `'l'`, the  $n$ -by- $n$  lower triangular part of the distributed matrix `sub(A)` must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of `sub(A)` is not referenced.

`ia, ja` (global) The row and column indices in the distributed matrix  $A$  indicating the first row and the first column of the submatrix `sub(A)`, respectively.

`desca` (global and local) array of dimension 9. The array descriptor of the distributed matrix  $A$ .

## Output Parameters

`a` With `uplo = 'U'` or `'u'`, the upper triangular part of the array  $a$  is overwritten by the upper triangular part of the updated distributed matrix `sub(A)`.

With `uplo = 'L'` or `'l'`, the lower triangular part of the array  $a$  is overwritten by the lower triangular part of the updated distributed matrix `sub(A)`.

## p?symv

*Computes a distributed matrix-vector product using a symmetric matrix.*

### Syntax

```
void pssymv (const char *uplo , const MKL_INT *n , const float *alpha , const float *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const float *x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , const float *beta , float *y , const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy);
```

```
void pdsymv (const char *uplo , const MKL_INT *n , const double *alpha , const double *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const double *x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , const double *beta , double *y , const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy);
```

### Description

The `p?symv` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(y) := \alpha * \text{sub}(A) * \text{sub}(x) + \beta * \text{sub}(y),$$

where:

$\alpha$  and  $\beta$  are scalars,

`sub(A)` is a  $n$ -by- $n$  symmetric distributed matrix, `sub(A)=A(ia:ia+n-1, ja:ja+n-1)`,

$\text{sub}(x)$  and  $\text{sub}(y)$  are distributed vectors.

$\text{sub}(x)$  denotes  $X(ix, jx:jx+n-1)$  if  $incx = m_x$ , and  $X(ix:ix+n-1, jx)$  if  $incx = 1$ ,

$\text{sub}(y)$  denotes  $Y(iy, jy:jy+n-1)$  if  $incy = m_y$ , and  $Y(iy:iy+n-1, jy)$  if  $incy = 1$ .

## Input Parameters

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <i>uplo</i>   | (global) Specifies whether the upper or lower triangular part of the symmetric distributed matrix $\text{sub}(A)$ is used:<br><br>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the $\text{sub}(A)$ is used.<br><br>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the $\text{sub}(A)$ is used.                                                                                                                                                                                                                                                                                                                                                                            |
| <i>n</i>      | (global) Specifies the order of the distributed matrix $\text{sub}(A)$ , $n \geq 0$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>alpha</i>  | (global)<br>Specifies the scalar <i>alpha</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>a</i>      | (local)<br>Array, size $(lld_a, LOCq(ja+n-1))$ . This array contains the local pieces of the distributed matrix $\text{sub}(A)$ .<br><br>Before entry when <i>uplo</i> = 'U' or 'u', the $n$ -by- $n$ upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and when <i>uplo</i> = 'L' or 'l', the $n$ -by- $n$ lower triangular part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced. |
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix $A$ indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $A$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>x</i>      | (local)<br>Array, size at least $(jx-1)*m_x + ix+(n-1)*abs(incx)$ .<br>This array contains the entries of the distributed vector $\text{sub}(x)$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>ix, jx</i> | (global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix $\text{sub}(x)$ , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>descx</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>incx</i>   | (global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m_x$ . <i>incx</i> must not be zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>beta</i>   | (global)<br>Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then $\text{sub}(y)$ need not be set on input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|               |                                                                                                                                                                |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>y</i>      | (local)<br>Array, size at least $(j_y-1)*m_y + i_y+(n-1)*abs(incy)$ .<br>This array contains the entries of the distributed vector $sub(y)$ .                  |
| <i>iy, jy</i> | (global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix $sub(y)$ , respectively. |
| <i>descy</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .                                                             |
| <i>incy</i>   | (global) Specifies the increment for the elements of $sub(y)$ . Only two values are supported, namely 1 and $m_y$ . <i>incy</i> must not be zero.              |

## Output Parameters

|          |                                                          |
|----------|----------------------------------------------------------|
| <i>y</i> | Overwritten by the updated distributed vector $sub(y)$ . |
|----------|----------------------------------------------------------|

## p?asymv

*Computes a distributed matrix-vector product using absolute values for a symmetric matrix.*

### Syntax

```
void psasymv (const char *uplo , const MKL_INT *n , const float *alpha , const float *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const float *x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , const float *beta , float *y , const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy);
```

```
void pdasymv (const char *uplo , const MKL_INT *n , const double *alpha , const double *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const double *x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , const double *beta , double *y , const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy);

### Description

The p?symv routines perform a distributed matrix-vector operation defined as

$$sub(y) := abs(alpha)*abs(sub(A))*abs(sub(x)) + abs(beta*sub(y)),$$

where:

*alpha* and *beta* are scalars,

*sub(A)* is a *n*-by-*n* symmetric distributed matrix,  $sub(A)=A(ia:ia+n-1, ja:ja+n-1)$ ,

*sub(x)* and *sub(y)* are distributed vectors.

*sub(x)* denotes  $X(ix, jx:jx+n-1)$  if *incx* =  $m_x$ , and  $X(ix: ix+n-1, jx)$  if *incx* = 1,

*sub(y)* denotes  $Y(iy, jy:jy+n-1)$  if *incy* =  $m_y$ , and  $Y(iy: iy+n-1, jy)$  if *incy* = 1.

## Input Parameters

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>uplo</i>   | (global) Specifies whether the upper or lower triangular part of the symmetric distributed matrix $\text{sub}(A)$ is used:<br><br>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the $\text{sub}(A)$ is used.<br><br>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the $\text{sub}(A)$ is used.                                                                                                                                                                                                                                                                                                                                                                             |
| <i>n</i>      | (global) Specifies the order of the distributed matrix $\text{sub}(A)$ , $n \geq 0$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>alpha</i>  | (global)<br>Specifies the scalar <i>alpha</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>a</i>      | (local)<br>Array, size $(lld\_a, LOCq(ja+n-1))$ . This array contains the local pieces of the distributed matrix $\text{sub}(A)$ .<br><br>Before entry when <i>uplo</i> = 'U' or 'u', the $n$ -by- $n$ upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and when <i>uplo</i> = 'L' or 'l', the $n$ -by- $n$ lower triangular part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced. |
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix $A$ indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $A$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>x</i>      | (local)<br>Array, size at least $(jx-1)*m\_x + ix+(n-1)*abs(incx)$ .<br>This array contains the entries of the distributed vector $\text{sub}(x)$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>ix, jx</i> | (global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix $\text{sub}(x)$ , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>descx</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>incx</i>   | (global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m\_x$ . <i>incx</i> must not be zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>beta</i>   | (global)<br>Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then $\text{sub}(y)$ need not be set on input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>y</i>      | (local)<br>Array, size at least $(jy-1)*m\_y + iy+(n-1)*abs(incy)$ .<br>This array contains the entries of the distributed vector $\text{sub}(y)$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|               |                                                                                                                                                                       |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>iy, jy</i> | (global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <i>sub(y)</i> , respectively.   |
| <i>descy</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .                                                                    |
| <i>incy</i>   | (global) Specifies the increment for the elements of <i>sub(y)</i> . Only two values are supported, namely 1 and <i>m<sub>y</sub></i> . <i>incy</i> must not be zero. |

## Output Parameters

|          |                                                               |
|----------|---------------------------------------------------------------|
| <i>y</i> | Overwritten by the updated distributed vector <i>sub(y)</i> . |
|----------|---------------------------------------------------------------|

## p?syr

Performs a rank-1 update of a distributed symmetric matrix.

### Syntax

```
void pssyr (const char *uplo , const MKL_INT *n , const float *alpha , const float *x ,

### Description

The `p?syr` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{sub}(x)' + \text{sub}(A),$$

where:

*alpha* is a scalar,

*sub(A)* is a *n*-by-*n* distributed symmetric matrix, *sub(A)* = *A*(*ia:ia+n-1, ja:ja+n-1*),

*sub(x)* is distributed vector.

*sub(x)* denotes *X*(*ix, jx:jx+n-1*) if *incx* = *m<sub>x</sub>*, and *X*(*ix: ix+n-1, jx*) if *incx* = 1,

### Input Parameters

|             |                                                                                                                                                                                                                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>uplo</i> | (global) Specifies whether the upper or lower triangular part of the symmetric distributed matrix <i>sub(A)</i> is used:<br><br>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(A)</i> is used.<br><br>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(A)</i> is used. |
| <i>n</i>    | (global) Specifies the order of the distributed matrix <i>sub(A)</i> , <i>n</i> ≥ 0.                                                                                                                                                                                                                                     |

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>alpha</i>  | (global)<br>Specifies the scalar <i>alpha</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>x</i>      | (local)<br>Array, size at least $(j_x-1)*m_x + ix+(n-1)*abs(incx)$ .<br>This array contains the entries of the distributed vector $sub(x)$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>ix, jx</i> | (global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix $sub(x)$ , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>descx</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>incx</i>   | (global) Specifies the increment for the elements of $sub(x)$ . Only two values are supported, namely 1 and $m_x$ . <i>incx</i> must not be zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>a</i>      | (local)<br>Array, size $(lld_a, LOCq(ja+n-1))$ . This array contains the local pieces of the distributed matrix $sub(A)$ .<br><br>Before entry with <i>uplo</i> = 'U' or 'u', the <i>n</i> -by- <i>n</i> upper triangular part of the distributed matrix $sub(A)$ must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of $sub(A)$ is not referenced, and with <i>uplo</i> = 'L' or 'l', the <i>n</i> -by- <i>n</i> lower triangular part of the distributed matrix $sub(A)$ must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of $sub(A)$ is not referenced. |
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $sub(A)$ , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Description

The p?syr2 routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{sub}(y)' + \alpha * \text{sub}(y) * \text{sub}(x)' + \text{sub}(A),$$

where:

*alpha* is a scalar,

*sub(A)* is a *n*-by-*n* distributed symmetric matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ ,

*sub(x)* and *sub(y)* are distributed vectors.

*sub(x)* denotes  $X(\text{ix}, \text{jx}:\text{jx}+n-1)$  if *incx* = *m<sub>x</sub>*, and  $X(\text{ix}:\text{ix}+n-1, \text{jx})$  if *incx* = 1,

*sub(y)* denotes  $Y(\text{iy}, \text{jy}:\text{jy}+n-1)$  if *incy* = *m<sub>y</sub>*, and  $Y(\text{iy}:\text{iy}+n-1, \text{jy})$  if *incy* = 1.

## Input Parameters

|               |                                                                                                                                                                                                                                                                                                                          |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>uplo</i>   | (global) Specifies whether the upper or lower triangular part of the distributed symmetric matrix <i>sub(A)</i> is used:<br><br>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(A)</i> is used.<br><br>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(A)</i> is used. |
| <i>n</i>      | (global) Specifies the order of the distributed matrix <i>sub(A)</i> , $n \geq 0$ .                                                                                                                                                                                                                                      |
| <i>alpha</i>  | (global)<br>Specifies the scalar <i>alpha</i> .                                                                                                                                                                                                                                                                          |
| <i>x</i>      | (local)<br>Array, size at least $(\text{jx}-1) * m_x + \text{ix} + (n-1) * \text{abs}(\text{incx})$ .<br>This array contains the entries of the distributed vector <i>sub(x)</i> .                                                                                                                                       |
| <i>ix, jx</i> | (global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix <i>sub(x)</i> , respectively.                                                                                                                                                      |
| <i>descx</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .                                                                                                                                                                                                                       |

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>incx</i>   | (global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m_x$ . <i>incx</i> must not be zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>y</i>      | (local)<br>Array, size at least $(jy-1)*m_y + iy + (n-1)*\text{abs}(incy)$ .<br>This array contains the entries of the distributed vector $\text{sub}(y)$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>iy, jy</i> | (global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix $\text{sub}(y)$ , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>descy</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>incy</i>   | (global) Specifies the increment for the elements of $\text{sub}(y)$ . Only two values are supported, namely 1 and $m_y$ . <i>incy</i> must not be zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>a</i>      | (local)<br>Array, size $(lld_a, \text{LOCq}(ja+n-1))$ . This array contains the local pieces of the distributed matrix $\text{sub}(A)$ .<br><br>Before entry with <i>uplo</i> = 'U' or 'u', the <i>n</i> -by- <i>n</i> upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the distributed symmetric matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and with <i>uplo</i> = 'L' or 'l', the <i>n</i> -by- <i>n</i> lower triangular part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the distributed symmetric matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced. |
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## p?trmv

Computes a distributed matrix-vector product using a triangular matrix.

### Syntax

```
void pstrmv (const char *uplo , const char *trans , const char *diag , const MKL_INT
*n , const float *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca ,
float *x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT
*incx);
```

```
void pdtrmv (const char *uplo , const char *trans , const char *diag , const MKL_INT
*n , const double *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca ,
double *x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const
MKL_INT *incx);
```

```
void pctrmv (const char *uplo , const char *trans , const char *diag , const MKL_INT
*n , const MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT
*desca , MKL_Complex8 *x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT
*descx , const MKL_INT *incx);
```

```
void pztrmv (const char *uplo , const char *trans , const char *diag , const MKL_INT

## Description

The `p?trmv` routines perform one of the following distributed matrix-vector operations defined as

$\text{sub}(x) := \text{sub}(A) * \text{sub}(x)$ , or  $\text{sub}(x) := \text{sub}(A)' * \text{sub}(x)$ , or  $\text{sub}(x) := \text{conjg}(\text{sub}(A)') * \text{sub}(x)$ ,

where:

$\text{sub}(A)$  is a  $n$ -by- $n$  unit, or non-unit, upper or lower triangular distributed matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ ,

$\text{sub}(x)$  is an  $n$ -element distributed vector.

$\text{sub}(x)$  denotes  $X(\text{ix}, \text{jx}:\text{jx}+n-1)$  if  $\text{incx} = m_x$ , and  $X(\text{ix}:\text{ix}+n-1, \text{jx})$  if  $\text{incx} = 1$ ,

## Input Parameters

|              |                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>uplo</i>  | (global) Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular:<br>if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular;<br>if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.                                                                                                                                              |
| <i>trans</i> | (global) Specifies the form of $\text{op}(\text{sub}(A))$ used in the matrix equation:<br>if <i>transa</i> = 'N' or 'n', then $\text{sub}(x) := \text{sub}(A) * \text{sub}(x)$ ;<br>if <i>transa</i> = 'T' or 't', then $\text{sub}(x) := \text{sub}(A)' * \text{sub}(x)$ ;<br>if <i>transa</i> = 'C' or 'c', then $\text{sub}(x) := \text{conjg}(\text{sub}(A)') * \text{sub}(x)$ . |
| <i>diag</i>  | (global) Specifies whether the matrix $\text{sub}(A)$ is unit triangular:<br>if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular;<br>if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.                                                                                                                                                                 |
| <i>n</i>     | (global) Specifies the order of the distributed matrix $\text{sub}(A)$ , $n \geq 0$ .                                                                                                                                                                                                                                                                                                |
| <i>a</i>     | (local)<br>Array, size at least $(\text{lld}_a, \text{LOCq}(1, \text{ja}+n-1))$ .                                                                                                                                                                                                                                                                                                    |

Before entry with *uplo* = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix *sub(A)*, and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix *sub(A)* is not referenced.

Before entry with *uplo* = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix *sub(A)*, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix *sub(A)* is not referenced.

When *diag* = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix *sub(A)* are not referenced either, but are assumed to be unity.

|               |                                                                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively. |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .                                                                  |
| <i>x</i>      | (local)<br>Array, size at least $(jx-1)*m_x + ix+(n-1)*abs(incx)$ .<br>This array contains the entries of the distributed vector <i>sub(x)</i> .                    |
| <i>ix, jx</i> | (global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix <i>sub(x)</i> , respectively. |
| <i>descx</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .                                                                  |
| <i>incx</i>   | (global) Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.         |

## Output Parameters

|          |                                                                   |
|----------|-------------------------------------------------------------------|
| <i>x</i> | Overwritten by the transformed distributed vector <i>sub(x)</i> . |
|----------|-------------------------------------------------------------------|

## p?atrmv

Computes a distributed matrix-vector product using absolute values for a triangular matrix.

### Syntax

```
void psatrmv (const char *uplo , const char *trans , const char *diag , const MKL_INT
*n , const float *alpha , const float *a , const MKL_INT *ia , const MKL_INT *ja ,
const MKL_INT *desca , const float *x , const MKL_INT *ix , const MKL_INT *jx , const
MKL_INT *descx , const MKL_INT *incx , const float *beta , float *y , const MKL_INT
*iy , const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy);
```

```
void pdatrmv (const char *uplo , const char *trans , const char *diag , const MKL_INT

## Description

The `p?atrmv` routines perform one of the following distributed matrix-vector operations defined as

$\text{sub}(y) := \text{abs}(\alpha) * \text{abs}(\text{sub}(A)) * \text{abs}(\text{sub}(x)) + \text{abs}(\beta * \text{sub}(y))$ , or

$\text{sub}(y) := \text{abs}(\alpha) * \text{abs}(\text{sub}(A)') * \text{abs}(\text{sub}(x)) + \text{abs}(\beta * \text{sub}(y))$ , or

$\text{sub}(y) := \text{abs}(\alpha) * \text{abs}(\text{conjg}(\text{sub}(A)')) * \text{abs}(\text{sub}(x)) + \text{abs}(\beta * \text{sub}(y))$ ,

where:

*alpha* and *beta* are scalars,

*sub(A)* is a *n*-by-*n* unit, or non-unit, upper or lower triangular distributed matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ ,

*sub(x)* is an *n*-element distributed vector.

*sub(x)* denotes  $X(\text{ix}, \text{jx}:\text{jx}+n-1)$  if *incx* = *m\_x*, and  $X(\text{ix}:\text{ix}+n-1, \text{jx})$  if *incx* = 1.

## Input Parameters

*uplo* (global) Specifies whether the distributed matrix *sub(A)* is upper or lower triangular:

if *uplo* = 'U' or 'u', then the matrix is upper triangular;

if *uplo* = 'L' or 'l', then the matrix is low triangular.

*trans* (global) Specifies the form of  $\text{op}(\text{sub}(A))$  used in the matrix equation:

if *trans* = 'N' or 'n', then  $\text{sub}(y) := |\alpha| * |\text{sub}(A)| * |\text{sub}(x)| + |\beta * \text{sub}(y)|$ ;

if *trans* = 'T' or 't', then  $\text{sub}(y) := |\alpha| * |\text{sub}(A)'| * |\text{sub}(x)| + |\beta * \text{sub}(y)|$ ;

if *trans* = 'C' or 'c', then  $\text{sub}(y) := |\alpha| * |\text{conjg}(\text{sub}(A)')| * |\text{sub}(x)| + |\beta * \text{sub}(y)|$ .

*diag* (global) Specifies whether the matrix *sub(A)* is unit triangular:

if *diag* = 'U' or 'u' then the matrix is unit triangular;

if *diag* = 'N' or 'n', then the matrix is not unit triangular.

---

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>x</i>      | (local)<br>Array, size at least $(jx-1)*m\_x + ix+(n-1)*abs(incx)$ .<br>This array contains the entries of the distributed vector $\text{sub}(x)$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>ix, jx</i> | (global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix $\text{sub}(x)$ , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>descx</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>incx</i>   | (global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m\_x$ . <i>incx</i> must not be zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>beta</i>   | (global)<br>Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then $\text{sub}(y)$ need not be set on input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>y</i>      | (local)<br>Array, size $(jy-1)*m\_y + iy+(m-1)*abs(incy)$ when <i>trans</i> = 'N' or 'n', and $(jy-1)*m\_y + iy+(n-1)*abs(incy)$ otherwise.<br>This array contains the entries of the distributed vector $\text{sub}(y)$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>iy, jy</i> | (global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix $\text{sub}(y)$ , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|              |                                                                                                                                                                       |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>descy</i> | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .                                                                    |
| <i>incy</i>  | (global) Specifies the increment for the elements of <i>sub(y)</i> . Only two values are supported, namely 1 and <i>m<sub>y</sub></i> . <i>incy</i> must not be zero. |

## Output Parameters

|          |                                                                   |
|----------|-------------------------------------------------------------------|
| <i>y</i> | Overwritten by the transformed distributed vector <i>sub(y)</i> . |
|----------|-------------------------------------------------------------------|

## p?trsv

*Solves a system of linear equations whose coefficients are in a distributed triangular matrix.*

### Syntax

```
void pstrsv (const char *uplo , const char *trans , const char *diag , const MKL_INT
*n , const float *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca ,
float *x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT
*incx);
```

```
void pdtrsv (const char *uplo , const char *trans , const char *diag , const MKL_INT
*n , const double *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca ,
double *x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const
MKL_INT *incx);
```

```
void pctrsv (const char *uplo , const char *trans , const char *diag , const MKL_INT
*n , const MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT
*desca , MKL_Complex8 *x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT
*descx , const MKL_INT *incx);
```

### Description

The p?trsv routines solve one of the systems of equations:

$$\text{sub}(A) * \text{sub}(x) = b, \text{ or } \text{sub}(A)' * \text{sub}(x) = b, \text{ or } \text{conjg}(\text{sub}(A)') * \text{sub}(x) = b,$$

where:

*sub(A)* is a *n*-by-*n* unit, or non-unit, upper or lower triangular distributed matrix, *sub(A)* = *A(ia:ia+n-1, ja:ja+n-1)*,

*b* and *sub(x)* are *n*-element distributed vectors,

*sub(x)* denotes *X(ix, jx:jx+n-1)* if *incx* = *m<sub>x</sub>*, and *X(ix: ix+n-1, jx)* if *incx* = 1,.

The routine does not test for singularity or near-singularity. Such tests must be performed before calling this routine.

## Input Parameters

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>uplo</i>   | (global) Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular:<br>if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular;<br>if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>trans</i>  | (global) Specifies the form of the system of equations:<br>if <i>transa</i> = 'N' or 'n', then $\text{sub}(A) * \text{sub}(x) = b$ ;<br>if <i>transa</i> = 'T' or 't', then $\text{sub}(A)' * \text{sub}(x) = b$ ;<br>if <i>transa</i> = 'C' or 'c', then $\text{conjg}(\text{sub}(A)') * \text{sub}(x) = b$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>diag</i>   | (global) Specifies whether the matrix $\text{sub}(A)$ is unit triangular:<br>if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular;<br>if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>n</i>      | (global) Specifies the order of the distributed matrix $\text{sub}(A)$ , $n \geq 0$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>a</i>      | (local)<br>Array, size at least $(lld\_a, LOCq(1, ja+n-1))$ .<br>Before entry with <i>uplo</i> = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix $\text{sub}(A)$ , and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix $\text{sub}(A)$ is not referenced.<br>Before entry with <i>uplo</i> = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix $\text{sub}(A)$ , and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix $\text{sub}(A)$ is not referenced .<br>When <i>diag</i> = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix $\text{sub}(A)$ are not referenced either, but are assumed to be unity. |
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix $A$ indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $A$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>x</i>      | (local)<br>Array, size at least $(jx-1) * m\_x + ix + (n-1) * \text{abs}(incx)$ .<br>This array contains the entries of the distributed vector $\text{sub}(x)$ . Before entry, $\text{sub}(x)$ must contain the $n$ -element right-hand side distributed vector $b$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>ix, jx</i> | (global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix $\text{sub}(x)$ , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>descx</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

*incx* (global) Specifies the increment for the elements of  $\text{sub}(x)$ . Only two values are supported, namely 1 and  $m_x$ . *incx* must not be zero.

## Output Parameters

*x* Overwritten with the solution vector.

## PBLAS Level 3 Routines

The PBLAS Level 3 routines perform distributed matrix-matrix operations. [Table "PBLAS Level 3 Routine Groups and Their Data Types"](#) lists the PBLAS Level 3 routine groups and the data types associated with them.

### PBLAS Level 3 Routine Groups and Their Data Types

| Routine Group           | Data Types | Description                                                         |
|-------------------------|------------|---------------------------------------------------------------------|

## Description

The `p?geadd` routines perform sum operation for two distributed general matrices. The operation is defined as

$$\text{sub}(C) := \text{beta} * \text{sub}(C) + \text{alpha} * \text{op}(\text{sub}(A)),$$

where:

$\text{op}(x)$  is one of  $\text{op}(x) = x$ , or  $\text{op}(x) = x'$ ,

$\text{alpha}$  and  $\text{beta}$  are scalars,

$\text{sub}(C)$  is an  $m$ -by- $n$  distributed matrix,  $\text{sub}(C) = C(\text{ic}:\text{ic}+m-1, \text{jc}:\text{jc}+n-1)$ .

$\text{sub}(A)$  is a distributed matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+m-1)$ .

## Input Parameters

|              |                                                                                                                                                                                                                                                                                                 |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>trans</i> | (global) Specifies the operation:<br>if <i>trans</i> = 'N' or 'n', then $\text{op}(\text{sub}(A)) := \text{sub}(A)$ ;<br>if <i>trans</i> = 'T' or 't', then $\text{op}(\text{sub}(A)) := \text{sub}(A)'$ ;<br>if <i>trans</i> = 'C' or 'c', then $\text{op}(\text{sub}(A)) := \text{sub}(A)'$ . |
| <i>m</i>     | (global) Specifies the number of rows of the distributed matrix $\text{sub}(C)$ and the number of columns of the submatrix $\text{sub}(A)$ , $m \geq 0$ .                                                                                                                                       |
| <i>n</i>     | (global) Specifies the number of columns of the distributed matrix $\text{sub}(C)$ and the number of rows of the submatrix $\text{sub}(A)$ , $n \geq 0$ .                                                                                                                                       |
| <i>alpha</i> | (global)<br>Specifies the scalar <i>alpha</i> .                                                                                                                                                                                                                                                 |
| <i>a</i>     | (local)<br>Array, size $(\text{lld}_a, \text{LOCq}(\text{ja}+m-1))$ . This array contains the local pieces of the distributed matrix $\text{sub}(A)$ .                                                                                                                                          |

|               |                                                                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively. |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .                                                                  |
| <i>beta</i>   | (global)<br>Specifies the scalar <i>beta</i> .<br>When <i>beta</i> is equal to zero, then <i>sub(C)</i> need not be set on input.                                   |
| <i>c</i>      | (local)<br>Array, size ( <i>lld_c</i> , <i>LOCq(jc+n-1)</i> ).<br>This array contains the local pieces of the distributed matrix <i>sub(C)</i> .                    |
| <i>ic, jc</i> | (global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <i>sub(C)</i> , respectively. |
| <i>descc</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .                                                                  |

## Output Parameters

| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $A$ .                                                                                                                                                                                                                 |
| <i>beta</i>   | (global)<br>Specifies the scalar <i>beta</i> .<br>When <i>beta</i> is equal to zero, then $\text{sub}(C)$ need not be set on input.                                                                                                                                                                           |
| <i>c</i>      | (local)<br>Array, size $(\text{lld}_c, \text{LOCq}(\text{jc}+n-1))$ .                                                                                                                                                                                                                                         |

This array contains the local pieces of the distributed matrix  $\text{sub}(C)$ .

*ic, jc* (global) The row and column indices in the distributed matrix  $C$  indicating the first row and the first column of the submatrix  $\text{sub}(C)$ , respectively.

*desc* (global and local) array of dimension 9. The array descriptor of the distributed matrix  $C$ .

## Output Parameters

*c* Overwritten by the updated submatrix.

## p?gemm

*Computes a scalar-matrix-matrix product and adds the result to a scalar-matrix product for distributed matrices.*

### Syntax

```
void psgemm (const char *transa , const char *transb , const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , const float *alpha , const float *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const float *b , const MKL_INT *ib , const MKL_INT *jb , const MKL_INT *descb , const float *beta , float *c , const MKL_INT *ic , const MKL_INT *jc , const MKL_INT *desc);
```

```

### Description

The `p?gemm` routines perform a matrix-matrix operation with general distributed matrices. The operation is defined as

$$\text{sub}(C) := \alpha * \text{op}(\text{sub}(A)) * \text{op}(\text{sub}(B)) + \beta * \text{sub}(C),$$

where:

$\text{op}(x)$  is one of  $\text{op}(x) = x$ , or  $\text{op}(x) = x'$ ,

*alpha* and *beta* are scalars,

$\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+k-1)$ ,  $\text{sub}(B) = B(\text{ib}:\text{ib}+k-1, \text{jb}:\text{jb}+n-1)$ , and  $\text{sub}(C) = C(\text{ic}:\text{ic}+m-1, \text{jc}:\text{jc}+n-1)$ , are distributed matrices.

### Input Parameters

|               |                                                                                                                                                                                                                                                                                                                                                            |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>transa</i> | (global) Specifies the form of $\text{op}(\text{sub}(A))$ used in the matrix multiplication:<br>if <i>transa</i> = 'N' or 'n', then $\text{op}(\text{sub}(A)) = \text{sub}(A)$ ;<br>if <i>transa</i> = 'T' or 't', then $\text{op}(\text{sub}(A)) = \text{sub}(A)'$ ;<br>if <i>transa</i> = 'C' or 'c', then $\text{op}(\text{sub}(A)) = \text{sub}(A)'$ . |
| <i>transb</i> | (global) Specifies the form of $\text{op}(\text{sub}(B))$ used in the matrix multiplication:<br>if <i>transb</i> = 'N' or 'n', then $\text{op}(\text{sub}(B)) = \text{sub}(B)$ ;<br>if <i>transb</i> = 'T' or 't', then $\text{op}(\text{sub}(B)) = \text{sub}(B)'$ ;<br>if <i>transb</i> = 'C' or 'c', then $\text{op}(\text{sub}(B)) = \text{sub}(B)'$ . |
| <i>m</i>      | (global) Specifies the number of rows of the distributed matrices $\text{op}(\text{sub}(A))$ and $\text{sub}(C)$ , $m \geq 0$ .                                                                                                                                                                                                                            |
| <i>n</i>      | (global) Specifies the number of columns of the distributed matrices $\text{op}(\text{sub}(B))$ and $\text{sub}(C)$ , $n \geq 0$ .<br><br>The value of <i>n</i> must be at least zero.                                                                                                                                                                     |
| <i>k</i>      | (global) Specifies the number of columns of the distributed matrix $\text{op}(\text{sub}(A))$ and the number of rows of the distributed matrix $\text{op}(\text{sub}(B))$ .<br><br>The value of <i>k</i> must be greater than or equal to 0.                                                                                                               |
| <i>alpha</i>  | (global)<br><br>Specifies the scalar <i>alpha</i> .<br><br>When <i>alpha</i> is equal to zero, then the local entries of the arrays <i>a</i> and <i>b</i> corresponding to the entries of the submatrices $\text{sub}(A)$ and $\text{sub}(B)$ respectively need not be set on input.                                                                       |
| <i>a</i>      | (local)<br><br>Array, size <i>lld_a</i> by <i>kla</i> , where <i>kla</i> is $\text{LOCc}(\text{ja}+k-1)$ when <i>transa</i> = 'N' or 'n', and is $\text{LOCq}(\text{ja}+m-1)$ otherwise. Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(A)$ .                                                                 |
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively                                                                                                                                                                                       |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .                                                                                                                                                                                                                                                         |
| <i>b</i>      | (local)<br><br>Array, size <i>lld_b</i> by <i>klb</i> , where <i>klb</i> is $\text{LOCc}(\text{jb}+n-1)$ when <i>transb</i> = 'N' or 'n', and is $\text{LOCq}(\text{jb}+k-1)$ otherwise. Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(B)$ .                                                                 |

|               |                                                                                                                                                                      |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ib, jb</i> | (global) The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix $\text{sub}(B)$ , respectively |
| <i>descb</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>B</i> .                                                                   |
| <i>beta</i>   | (global)<br>Specifies the scalar <i>beta</i> .<br>When <i>beta</i> is equal to zero, then $\text{sub}(C)$ need not be set on input.                                  |

### Description

The p?hemm routines perform a matrix-matrix operation with distributed matrices. The operation is defined as

```
sub(C) := alpha * sub(A) * sub(B) + beta * sub(C) ,
```

or

```
sub(C) := alpha*sub(B)*sub(A) + beta*sub(C),
```

where:

*alpha* and *beta* are scalars,

*sub(A)* is a Hermitian distributed matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+m-1)$ , if *side* = 'L', and  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ , if *side* = 'R'.

*sub(B)* and *sub(C)* are *m*-by-*n* distributed matrices.

$\text{sub}(B) = B(\text{ib}:\text{ib}+m-1, \text{jb}:\text{jb}+n-1)$ ,  $\text{sub}(C) = C(\text{ic}:\text{ic}+m-1, \text{jc}:\text{jc}+n-1)$ .

## Input Parameters

|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>side</i>   | (global) Specifies whether the Hermitian distributed matrix <i>sub(A)</i> appears on the left or right in the operation:<br><br>if <i>side</i> = 'L' or 'l', then $\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B) + \beta * \text{sub}(C)$ ;<br><br>if <i>side</i> = 'R' or 'r', then $\text{sub}(C) := \alpha * \text{sub}(B) * \text{sub}(A) + \beta * \text{sub}(C)$ .                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>uplo</i>   | (global) Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <i>sub(A)</i> is used:<br><br>if <i>uplo</i> = 'U' or 'u', then the upper triangular part is used;<br><br>if <i>uplo</i> = 'L' or 'l', then the lower triangular part is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>m</i>      | (global) Specifies the number of rows of the distribute submatrix <i>sub(C)</i> , $m \geq 0$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>n</i>      | (global) Specifies the number of columns of the distribute submatrix <i>sub(C)</i> , $n \geq 0$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>alpha</i>  | (global)<br>Specifies the scalar <i>alpha</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>a</i>      | (local)<br>Array, size $(\text{lld}_a, \text{LOCq}(\text{ja}+\text{na}-1))$ .<br><br>Before entry this array must contain the local pieces of the symmetric distributed matrix <i>sub(A)</i> , such that when <i>uplo</i> = 'U' or 'u', the <i>na</i> -by- <i>na</i> upper triangular part of the distributed matrix <i>sub(A)</i> must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of <i>sub(A)</i> is not referenced, and when <i>uplo</i> = 'L' or 'l', the <i>na</i> -by- <i>na</i> lower triangular part of the distributed matrix <i>sub(A)</i> must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of <i>sub(A)</i> is not referenced. |
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|               |                                                                                                                                                                |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>b</i>      | (local)<br>Array, size $(lld\_b, LOCq(jb+n-1))$ . Before entry this array must contain the local pieces of the distributed matrix $sub(B)$ .                   |
| <i>ib, jb</i> | (global) The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix $sub(B)$ , respectively. |
| <i>descb</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>B</i> .                                                             |
| <i>beta</i>   | (global)<br>Specifies the scalar <i>beta</i> .<br>When <i>beta</i> is set to zero, then $sub(C)$ need not be set on input.                                     |
| <i>c</i>      | (local)<br>Array, size $(lld\_c, LOCq(jc+n-1))$ . Before entry this array must contain the local pieces of the distributed matrix $sub(C)$ .                   |
| <i>ic, jc</i> | (global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix $sub(C)$ , respectively  |
| <i>desc</i>   | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .                                                             |

## Output Parameters

|          |                                                                       |
|----------|-----------------------------------------------------------------------|
| <i>c</i> | Overwritten by the <i>m</i> -by- <i>n</i> updated distributed matrix. |
|----------|-----------------------------------------------------------------------|

## p?herk

Performs a rank-*k* update of a distributed Hermitian matrix.

### Syntax

```
void pcherk (const char *uplo , const char *trans , const MKL_INT *n , const MKL_INT *k , const float *alpha , const MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const float *beta , MKL_Complex8 *c , const MKL_INT *ic , const MKL_INT *jc , const MKL_INT *desc) ;
```

```
void pzherk (const char *uplo , const char *trans , const MKL_INT *n , const MKL_INT *k , const double *alpha , const MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const double *beta , MKL_Complex16 *c , const MKL_INT *ic , const MKL_INT *jc , const MKL_INT *desc) ;
```

### Include Files

- mkl\_pblas.h

### Description

The p?herk routines perform a distributed matrix-matrix operation defined as

```
sub(C) := alpha * sub(A) * conjg(sub(A)') + beta * sub(C) ,
```

or

```
sub(C) := alpha*conjg(sub(A)')*sub(A) + beta*sub(C),
```

where:

*alpha* and *beta* are scalars,

*sub(C)* is an *n*-by-*n* Hermitian distributed matrix,  $\text{sub}(C) = C(\text{ic}:\text{ic}+n-1, \text{jc}:\text{jc}+n-1)$ .

*sub(A)* is a distributed matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+k-1)$ , if *trans* = 'N' or 'n', and  $\text{sub}(A) = A(\text{ia}:\text{ia}+k-1, \text{ja}:\text{ja}+n-1)$  otherwise.

## Input Parameters

|               |                                                                                                                                                                                                                                                                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>uplo</i>   | (global) Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <i>sub(C)</i> is used:<br><br>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(C)</i> is used.<br><br>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(C)</i> is used.                            |
| <i>trans</i>  | (global) Specifies the operation:<br><br>if <i>trans</i> = 'N' or 'n', then $\text{sub}(C) := \text{alpha} * \text{sub}(A) * \text{conjg}(\text{sub}(A)') + \text{beta} * \text{sub}(C)$ ;<br><br>if <i>trans</i> = 'C' or 'c', then $\text{sub}(C) := \text{alpha} * \text{conjg}(\text{sub}(A)') * \text{sub}(A) + \text{beta} * \text{sub}(C)$ . |
| <i>n</i>      | (global) Specifies the order of the distributed matrix <i>sub(C)</i> , $n \geq 0$ .                                                                                                                                                                                                                                                                 |
| <i>k</i>      | (global) On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the distributed matrix <i>sub(A)</i> , and on entry with <i>trans</i> = 'T' or 't' or 'C' or 'c', <i>k</i> specifies the number of rows of the distributed matrix <i>sub(A)</i> , $k \geq 0$ .                                                        |
| <i>alpha</i>  | (global)<br>Specifies the scalar <i>alpha</i> .                                                                                                                                                                                                                                                                                                     |
| <i>a</i>      | (local)<br>Array, size ( <i>lld_a</i> , <i>kla</i> ), where <i>kla</i> is $\text{LOCq}(\text{ja}+k-1)$ when <i>trans</i> = 'N' or 'n', and is $\text{LOCq}(\text{ja}+n-1)$ otherwise. Before entry with <i>trans</i> = 'N' or 'n', this array contains the local pieces of the distributed matrix <i>sub(A)</i> .                                   |
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.                                                                                                                                                                                 |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .                                                                                                                                                                                                                                                  |
| <i>beta</i>   | (global)<br>Specifies the scalar <i>beta</i> .                                                                                                                                                                                                                                                                                                      |
| <i>c</i>      | (local)<br>Array, size ( <i>lld_c</i> , $\text{LOCq}(\text{jc}+n-1)$ ).                                                                                                                                                                                                                                                                             |

Before entry with `uplo = 'U' or 'u'`, this array contains  $n$ -by- $n$  upper triangular part of the symmetric distributed matrix `sub(C)` and its strictly lower triangular part is not referenced.

Before entry with `uplo = 'L' or 'l'`, this array contains  $n$ -by- $n$  lower triangular part of the symmetric distributed matrix `sub(C)` and its strictly upper triangular part is not referenced.

`ic, jc` (global) The row and column indices in the distributed matrix `C` indicating the first row and the first column of the submatrix `sub(C)`, respectively.

`desc` (global and local) array of dimension 9. The array descriptor of the distributed matrix `C`.

## Output Parameters

`c` With `uplo = 'U' or 'u'`, the upper triangular part of `sub(C)` is overwritten by the upper triangular part of the updated distributed matrix.

With `uplo = 'L' or 'l'`, the lower triangular part of `sub(C)` is overwritten by the upper triangular part of the updated distributed matrix.

## p?her2k

Performs a rank-2k update of a Hermitian distributed matrix.

### Syntax

```
void pcher2k (const char *uplo , const char *trans , const MKL_INT *n , const MKL_INT *k , const MKL_Complex8 *alpha , const MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const MKL_Complex8 *b , const MKL_INT *ib , const MKL_INT *jb , const MKL_INT *descb , const float *beta , MKL_Complex8 *c , const MKL_INT *ic , const MKL_INT *jc , const MKL_INT *desc) ;
```

```
void pzher2k (const char *uplo , const char *trans , const MKL_INT *n , const MKL_INT *k , const MKL_Complex16 *alpha , const MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const MKL_Complex16 *b , const MKL_INT *ib , const MKL_INT *jb , const MKL_INT *descb , const double *beta , MKL_Complex16 *c , const MKL_INT *ic , const MKL_INT *jc , const MKL_INT *desc) ;
```

### Include Files

### Description

The `p?her2k` routines perform a distributed matrix-matrix operation defined as

$$\text{sub}(C) := \alpha * \text{sub}(A) * \text{conjg}(\text{sub}(B)') + \text{conjg}(\alpha) * \text{sub}(B) * \text{conjg}(\text{sub}(A)') + \beta * \text{sub}(C),$$

or

$$\text{sub}(C) := \alpha * \text{conjg}(\text{sub}(A)') * \text{sub}(A) + \text{conjg}(\alpha) * \text{conjg}(\text{sub}(B)') * \text{sub}(B) + \beta * \text{sub}(C),$$

where:

*alpha* and *beta* are scalars,

`sub(C)` is an  $n$ -by- $n$  Hermitian distributed matrix, `sub(C) = C(ic:ic+n-1, jc:jc+n-1)`.

$\text{sub}(A)$  is a distributed matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+k-1)$ , if  $\text{trans} = 'N'$  or  $'n'$ , and  $\text{sub}(A) = A(\text{ia}:\text{ia}+k-1, \text{ja}:\text{ja}+n-1)$  otherwise.

$\text{sub}(B)$  is a distributed matrix,  $\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+k-1)$ , if  $\text{trans} = 'N'$  or  $'n'$ , and  $\text{sub}(B) = B(\text{ib}:\text{ib}+k-1, \text{jb}:\text{jb}+n-1)$  otherwise.

## Input Parameters

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>uplo</i>   | (global) Specifies whether the upper or lower triangular part of the Hermitian distributed matrix $\text{sub}(C)$ is used:<br><br>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the $\text{sub}(C)$ is used.<br><br>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the $\text{sub}(C)$ is used.                                                                                                                                          |
| <i>trans</i>  | (global) Specifies the operation:<br><br>if <i>trans</i> = 'N' or 'n', then $\text{sub}(C) := \alpha * \text{sub}(A) * \text{conjg}(\text{sub}(B)') + \text{conjg}(\alpha) * \text{sub}(B) * \text{conjg}(\text{sub}(A)') + \beta * \text{sub}(C)$ ;<br><br>if <i>trans</i> = 'C' or 'c', then $\text{sub}(C) := \alpha * \text{conjg}(\text{sub}(A)') * \text{sub}(A) + \text{conjg}(\alpha) * \text{conjg}(\text{sub}(B)') * \text{sub}(B) + \beta * \text{sub}(C)$ . |
| <i>n</i>      | (global) Specifies the order of the distributed matrix $\text{sub}(C)$ , $n \geq 0$ .                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>k</i>      | (global) On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$ , and on entry with <i>trans</i> = 'C' or 'c', <i>k</i> specifies the number of rows of the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$ , $k \geq 0$ .                                                                                                                                          |
| <i>alpha</i>  | (global)<br>Specifies the scalar <i>alpha</i> .                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>a</i>      | (local)<br>Array, size $(\text{lld}_a, \text{kla})$ , where <i>kla</i> is $\text{LOCq}(\text{ja}+k-1)$ when <i>trans</i> = 'N' or 'n', and is $\text{LOCq}(\text{ja}+n-1)$ otherwise. Before entry with <i>trans</i> = 'N' or 'n', this array contains the local pieces of the distributed matrix $\text{sub}(A)$ .                                                                                                                                                     |
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.                                                                                                                                                                                                                                                                                                   |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .                                                                                                                                                                                                                                                                                                                                                                      |
| <i>b</i>      | (local)<br>Array, size $(\text{lld}_b, \text{k1b})$ , where <i>k1b</i> is $\text{LOCq}(\text{jb}+k-1)$ when <i>trans</i> = 'N' or 'n', and is $\text{LOCq}(\text{jb}+n-1)$ otherwise. Before entry with <i>trans</i> = 'N' or 'n', this array contains the local pieces of the distributed matrix $\text{sub}(B)$ .                                                                                                                                                     |
| <i>ib, jb</i> | (global) The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix $\text{sub}(B)$ , respectively.                                                                                                                                                                                                                                                                                                   |
| <i>descb</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>B</i> .                                                                                                                                                                                                                                                                                                                                                                      |
| <i>beta</i>   | (global)                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

Specifies the scalar *beta*.

*c*

(local)

Array, size (*lld\_c*, *LOCq(jc+n-1)*).

Before entry with *uplo* = 'U' or 'u', this array contains *n*-by-*n* upper triangular part of the symmetric distributed matrix *sub(C)* and its strictly lower triangular part is not referenced.

Before entry with *uplo* = 'L' or 'l', this array contains *n*-by-*n* lower triangular part of the symmetric distributed matrix *sub(C)* and its strictly upper triangular part is not referenced.

*ic, jc*

(global) The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix *sub(C)*, respectively.

*descc*

(global and local) array of dimension 9. The array descriptor of the distributed matrix *C*.

## Output Parameters

*c*

With *uplo* = 'U' or 'u', the upper triangular part of *sub(C)* is overwritten by the upper triangular part of the updated distributed matrix.

With *uplo* = 'L' or 'l', the lower triangular part of *sub(C)* is overwritten by the upper triangular part of the updated distributed matrix.

## p?symm

*Performs a scalar-matrix-matrix product (one matrix operand is symmetric) and adds the result to a scalar-matrix product for distribute matrices.*

### Syntax

```

## Description

The `p?symm` routines perform a matrix-matrix operation with distributed matrices. The operation is defined as

```
sub(C) := alpha*sub(A)*sub(B) + beta*sub(C) ,
```

or

```
sub(C) := alpha*sub(B)*sub(A) + beta*sub(C) ,
```

where:

*alpha* and *beta* are scalars,

*sub(A)* is a symmetric distributed matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+m-1)$ , if *side* = 'L', and  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ , if *side* = 'R'.

*sub(B)* and *sub(C)* are *m*-by-*n* distributed matrices.

$\text{sub}(B) = B(\text{ib}:\text{ib}+m-1, \text{jb}:\text{jb}+n-1)$ ,  $\text{sub}(C) = C(\text{ic}:\text{ic}+m-1, \text{jc}:\text{jc}+n-1)$ .

## Input Parameters

|              |                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>side</i>  | (global) Specifies whether the symmetric distributed matrix <i>sub(A)</i> appears on the left or right in the operation:<br>if <i>side</i> = 'L' or 'l', then $\text{sub}(C) := \text{alpha} * \text{sub}(A) * \text{sub}(B) + \text{beta} * \text{sub}(C)$ ;<br>if <i>side</i> = 'R' or 'r', then $\text{sub}(C) := \text{alpha} * \text{sub}(B) * \text{sub}(A) + \text{beta} * \text{sub}(C)$ . |
| <i>uplo</i>  | (global) Specifies whether the upper or lower triangular part of the symmetric distributed matrix <i>sub(A)</i> is used:<br>if <i>uplo</i> = 'U' or 'u', then the upper triangular part is used;<br>if <i>uplo</i> = 'L' or 'l', then the lower triangular part is used.                                                                                                                           |
| <i>m</i>     | (global) Specifies the number of rows of the distribute submatrix <i>sub(C)</i> , $m \geq 0$ .                                                                                                                                                                                                                                                                                                     |
| <i>n</i>     | (global) Specifies the number of columns of the distribute submatrix <i>sub(C)</i> , $m \geq 0$ .                                                                                                                                                                                                                                                                                                  |
| <i>alpha</i> | (global)<br>Specifies the scalar <i>alpha</i> .                                                                                                                                                                                                                                                                                                                                                    |
| <i>a</i>     | (local)<br>Array, size $(\text{lld}_a, \text{LOCq}(\text{ja}+\text{na}-1))$ .                                                                                                                                                                                                                                                                                                                      |

Before entry this array must contain the local pieces of the symmetric distributed matrix  $\text{sub}(A)$ , such that when  $\text{uplo} = 'U'$  or  $'u'$ , the  $na$ -by- $na$  upper triangular part of the distributed matrix  $\text{sub}(A)$  must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of  $\text{sub}(A)$  is not referenced, and when  $\text{uplo} = 'L'$  or  $'l'$ , the  $na$ -by- $na$  lower triangular part of the distributed matrix  $\text{sub}(A)$  must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of  $\text{sub}(A)$  is not referenced.

|               |                                                                                                                                                                  |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix $A$ indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively. |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $A$ .                                                                    |
| <i>b</i>      | (local)<br>Array, size $(\text{lld}_b, \text{LOCq}(jb+n-1))$ . Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(B)$ . |
| <i>ib, jb</i> | (global) The row and column indices in the distributed matrix $B$ indicating the first row and the first column of the submatrix $\text{sub}(B)$ , respectively. |
| <i>descb</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $B$ .                                                                    |
| <i>beta</i>   | (global)<br>Specifies the scalar <i>beta</i> .<br>When <i>beta</i> is set to zero, then $\text{sub}(C)$ need not be set on input.                                |
| <i>c</i>      | (local)<br>Array, size $(\text{lld}_c, \text{LOCq}(jc+n-1))$ . Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(C)$ . |
| <i>ic, jc</i> | (global) The row and column indices in the distributed matrix $C$ indicating the first row and the first column of the submatrix $\text{sub}(C)$ , respectively. |
| <i>descc</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix $C$ .                                                                    |

## Output Parameters

|          |                                                 |
|----------|-------------------------------------------------|
| <i>c</i> | Overwritten by the $m$ -by- $n$ updated matrix. |
|----------|-------------------------------------------------|

## p?syrk

Performs a rank- $k$  update of a symmetric distributed matrix.

### Syntax

```
void pssyrk (const char *uplo , const char *trans , const MKL_INT *n , const MKL_INT
*k , const float *alpha , const float *a , const MKL_INT *ia , const MKL_INT *ja ,
const MKL_INT *desca , const float *beta , float *c , const MKL_INT *ic , const MKL_INT
*jc , const MKL_INT *descc);
```

```

void pdsyrk (const char *uplo , const char *trans , const MKL_INT *n , const MKL_INT
*k , const double *alpha , const double *a , const MKL_INT *ia , const MKL_INT *ja ,
const MKL_INT *desca , const double *beta , double *c , const MKL_INT *ic , const
MKL_INT *jc , const MKL_INT *descc);

## Description

The p?syrk routines perform a distributed matrix-matrix operation defined as

$$\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(A)' + \beta * \text{sub}(C),$$

or

$$\text{sub}(C) := \alpha * \text{sub}(A)' * \text{sub}(A) + \beta * \text{sub}(C),$$

where:

*alpha* and *beta* are scalars,

*sub(C)* is an *n*-by-*n* symmetric distributed matrix,  $\text{sub}(C) = C(ic:ic+n-1, jc:jc+n-1)$ .

*sub(A)* is a distributed matrix,  $\text{sub}(A) = A(ia:ia+n-1, ja:ja+k-1)$ , if *trans* = 'N' or 'n', and  $\text{sub}(A) = A(ia:ia+k-1, ja:ja+n-1)$  otherwise.

## Input Parameters

|              |                                                                                                                                                                                                                                                                                                                          |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>uplo</i>  | (global) Specifies whether the upper or lower triangular part of the symmetric distributed matrix <i>sub(C)</i> is used:<br><br>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(C)</i> is used.<br><br>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(C)</i> is used. |
| <i>trans</i> | (global) Specifies the operation:<br><br>if <i>trans</i> = 'N' or 'n', then $\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(A)' + \beta * \text{sub}(C)$ ;<br><br>if <i>trans</i> = 'T' or 't', then $\text{sub}(C) := \alpha * \text{sub}(A)' * \text{sub}(A) + \beta * \text{sub}(C)$ .                          |
| <i>n</i>     | (global) Specifies the order of the distributed matrix <i>sub(C)</i> , $n \geq 0$ .                                                                                                                                                                                                                                      |
| <i>k</i>     | (global) On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the distributed matrix <i>sub(A)</i> , and on entry with <i>trans</i> = 'T' or 't', <i>k</i> specifies the number of rows of the distributed matrix <i>sub(A)</i> , $k \geq 0$ .                                           |

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>alpha</i>  | (global)<br>Specifies the scalar <i>alpha</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>a</i>      | (local)<br>Array, size $(l1d\_a, kla)$ , where <i>kla</i> is $LOCq(ja+k-1)$ when <i>trans</i> = 'N' or 'n', and is $LOCq(ja+n-1)$ otherwise. Before entry with <i>trans</i> = 'N' or 'n', this array contains the local pieces of the distributed matrix $sub(A)$ .                                                                                                                                                                                                                             |
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $sub(A)$ , respectively.                                                                                                                                                                                                                                                                                                                                  |

## Description

The `p?syr2k` routines perform a distributed matrix-matrix operation defined as

$$\text{sub}(C) := \alpha \text{sub}(A) * \text{sub}(B) + \alpha \text{sub}(B) * \text{sub}(A) + \beta \text{sub}(C),$$

or

$$\text{sub}(C) := \alpha \text{sub}(A) ' * \text{sub}(B) + \alpha \text{sub}(B) ' * \text{sub}(A) + \beta \text{sub}(C),$$

where:

*alpha* and *beta* are scalars,

*sub(C)* is an *n*-by-*n* symmetric distributed matrix,  $\text{sub}(C) = C(ic:ic+n-1, jc:jc+n-1)$ .

*sub(A)* is a distributed matrix,  $\text{sub}(A) = A(ia:ia+n-1, ja:ja+k-1)$ , if *trans* = 'N' or 'n', and  $\text{sub}(A) = A(ia:ia+k-1, ja:ja+n-1)$  otherwise.

*sub(B)* is a distributed matrix,  $\text{sub}(B) = B(ib:ib+n-1, jb:jb+k-1)$ , if *trans* = 'N' or 'n', and  $\text{sub}(B) = B(ib:ib+k-1, jb:jb+n-1)$  otherwise.

## Input Parameters

*uplo* (global) Specifies whether the upper or lower triangular part of the symmetric distributed matrix *sub(C)* is used:

If *uplo* = 'U' or 'u', then the upper triangular part of the *sub(C)* is used.

If *uplo* = 'L' or 'l', then the low triangular part of the *sub(C)* is used.

*trans* (global) Specifies the operation:

if *trans* = 'N' or 'n', then  $\text{sub}(C) := \alpha \text{sub}(A) * \text{sub}(B) + \alpha \text{sub}(B) * \text{sub}(A) + \beta \text{sub}(C);$

if *trans* = 'T' or 't', then  $\text{sub}(C) := \alpha \text{sub}(B) ' * \text{sub}(A) + \alpha \text{sub}(A) ' * \text{sub}(B) + \beta \text{sub}(C).$

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>      | (global) Specifies the order of the distributed matrix $\text{sub}(C)$ , $n \geq 0$ .                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>k</i>      | (global) On entry with $\text{trans} = 'N'$ or $'n'$ , $k$ specifies the number of columns of the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$ , and on entry with $\text{trans} = 'T'$ or $'t'$ , $k$ specifies the number of rows of the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$ , $k \geq 0$ .                                                                                                                                                                                   |
| <i>alpha</i>  | (global)<br>Specifies the scalar <i>alpha</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>a</i>      | (local)<br>Array, size $(\text{lld}_a, \text{kla})$ , where $\text{kla}$ is $\text{LOCq}(ja+k-1)$ when $\text{trans} = 'N'$ or $'n'$ , and is $\text{LOCq}(ja+n-1)$ otherwise. Before entry with $\text{trans} = 'N'$ or $'n'$ , this array contains the local pieces of the distributed matrix $\text{sub}(A)$ .                                                                                                                                                                                                |
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.                                                                                                                                                                                                                                                                                                                                            |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>b</i>      | (local)<br>Array, size $(\text{lld}_b, \text{k1b})$ , where $\text{k1b}$ is $\text{LOCq}(jb+k-1)$ when $\text{trans} = 'N'$ or $'n'$ , and is $\text{LOCq}(jb+n-1)$ otherwise. Before entry with $\text{trans} = 'N'$ or $'n'$ , this array contains the local pieces of the distributed matrix $\text{sub}(B)$ .                                                                                                                                                                                                |
| <i>ib, jb</i> | (global) The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix $\text{sub}(B)$ , respectively.                                                                                                                                                                                                                                                                                                                                            |
| <i>descb</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>B</i> .                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>beta</i>   | (global)<br>Specifies the scalar <i>beta</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>c</i>      | (local)<br>Array, size $(\text{lld}_c, \text{LOCq}(jc+n-1))$ .<br>Before entry with $\text{uplo} = 'U'$ or $'u'$ , this array contains $n$ -by- $n$ upper triangular part of the symmetric distributed matrix $\text{sub}(C)$ and its strictly lower triangular part is not referenced.<br>Before entry with $\text{uplo} = 'L'$ or $'l'$ , this array contains $n$ -by- $n$ lower triangular part of the symmetric distributed matrix $\text{sub}(C)$ and its strictly upper triangular part is not referenced. |
| <i>ic, jc</i> | (global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix $\text{sub}(C)$ , respectively.                                                                                                                                                                                                                                                                                                                                            |
| <i>desc</i>   | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .                                                                                                                                                                                                                                                                                                                                                                                                               |

## Output Parameters

*c* With *uplo* = 'U' or 'u', the upper triangular part of *sub(C)* is overwritten by the upper triangular part of the updated distributed matrix.  
 With *uplo* = 'L' or 'l', the lower triangular part of *sub(C)* is overwritten by the upper triangular part of the updated distributed matrix.

## p?tran

*Transposes a real distributed matrix.*

### Syntax

```
void pstran (const MKL_INT *m , const MKL_INT *n , const float *alpha , const float
*a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const float
*beta , float *c , const MKL_INT *ic , const MKL_INT *jc , const MKL_INT *descc);
```

```
void pdtran (const MKL_INT *m , const MKL_INT *n , const double *alpha , const double
*a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const double
*beta , double *c , const MKL_INT *ic , const MKL_INT *jc , const MKL_INT *descc);
```

### Include Files

- mkl\_pblas.h

### Description

The *p?tran* routines transpose a real distributed matrix. The operation is defined as

$$\text{sub}(C) := \text{beta} * \text{sub}(C) + \text{alpha} * \text{sub}(A)'$$

where:

*alpha* and *beta* are scalars,

*sub(C)* is an *m*-by-*n* distributed matrix,  $\text{sub}(C) = C(\text{ic}:\text{ic}+m-1, \text{jc}:\text{jc}+n-1)$ .

*sub(A)* is a distributed matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+m-1)$ .

### Input Parameters

|               |                                                                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>m</i>      | (global) Specifies the number of rows of the distributed matrix <i>sub(C)</i> , $m \geq 0$ .                                                                        |
| <i>n</i>      | (global) Specifies the number of columns of the distributed matrix <i>sub(C)</i> , $n \geq 0$ .                                                                     |
| <i>alpha</i>  | (global)<br>Specifies the scalar <i>alpha</i> .                                                                                                                     |
| <i>a</i>      | (local)<br>Array, size $(\text{lld}_a, \text{LOCq}(\text{ja}+m-1))$ . This array contains the local pieces of the distributed matrix <i>sub(A)</i> .                |
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively. |

|               |                                                                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .                                                                  |
| <i>beta</i>   | (global)<br>Specifies the scalar <i>beta</i> .<br>When <i>beta</i> is equal to zero, then <i>sub(C)</i> need not be set on input.                                   |
| <i>c</i>      | (local)<br>Array, size ( <i>lld_c</i> , <i>LOCq(jc+n-1)</i> ).<br>This array contains the local pieces of the distributed matrix <i>sub(C)</i> .                    |
| <i>ic, jc</i> | (global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <i>sub(C)</i> , respectively. |
| <i>descc</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .                                                                  |

## Output Parameters

|          |                                       |
|----------|---------------------------------------|
| <i>c</i> | Overwritten by the updated submatrix. |
|----------|---------------------------------------|

## p?tranu

*Transposes a distributed complex matrix.*

### Syntax

```
void pctranu (const MKL_INT *m , const MKL_INT *n , const MKL_Complex8 *alpha , const
MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const
MKL_Complex8 *beta , MKL_Complex8 *c , const MKL_INT *ic , const MKL_INT *jc , const
MKL_INT *descc);
```

```
void pztranu (const MKL_INT *m , const MKL_INT *n , const MKL_Complex16 *alpha , const
MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const
MKL_Complex16 *beta , MKL_Complex16 *c , const MKL_INT *ic , const MKL_INT *jc , const
MKL_INT *descc);
```

### Include Files

- `mk1_pblas.h`

### Description

The `p?tranu` routines transpose a complex distributed matrix. The operation is defined as

$$\text{sub}(C) := \text{beta} * \text{sub}(C) + \text{alpha} * \text{sub}(A)'$$

where:

*alpha* and *beta* are scalars,

*sub(C)* is an *m*-by-*n* distributed matrix,  $\text{sub}(C) = C(\text{ic}:\text{ic}+m-1, \text{jc}:\text{jc}+n-1)$ .

*sub(A)* is a distributed matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+m-1)$ .

## Input Parameters

|               |                                                                                                                                                                       |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>m</i>      | (global) Specifies the number of rows of the distributed matrix $\text{sub}(C)$ , $m \geq 0$ .                                                                        |
| <i>n</i>      | (global) Specifies the number of columns of the distributed matrix $\text{sub}(C)$ , $n \geq 0$ .                                                                     |
| <i>alpha</i>  | (global)<br>Specifies the scalar <i>alpha</i> .                                                                                                                       |
| <i>a</i>      | (local)<br>Array, size $(l1d\_a, \text{LOCq}(ja+m-1))$ . This array contains the local pieces of the distributed matrix $\text{sub}(A)$ .                             |
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively. |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .                                                                    |
| <i>beta</i>   | (global)<br>Specifies the scalar <i>beta</i> .<br>When <i>beta</i> is equal to zero, then $\text{sub}(C)$ need not be set on input.                                   |

## p?tranc

Transposes a complex distributed matrix, conjugated.

### Syntax

```
void pctranc (const MKL_INT *m , const MKL_INT *n , const MKL_Complex8 *alpha , const
MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const
MKL_Complex8 *beta , MKL_Complex8 *c , const MKL_INT *ic , const MKL_INT *jc , const
MKL_INT *descc);
```

```
void pztranc (const MKL_INT *m , const MKL_INT *n , const MKL_Complex16 *alpha , const
MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const
MKL_Complex16 *beta , MKL_Complex16 *c , const MKL_INT *ic , const MKL_INT *jc , const
MKL_INT *descc);
```

## Include Files

- `mkl_pblas.h`

## Description

The `p?tranc` routines transpose a complex distributed matrix. The operation is defined as

```
sub(C) := beta*sub(C) + alpha*conjg(sub(A)'),
```

where:

*alpha* and *beta* are scalars,

*sub(C)* is an *m*-by-*n* distributed matrix,  $sub(C) = C(ic:ic+m-1, jc:jc+n-1)$ .

*sub(A)* is a distributed matrix,  $sub(A) = A(ia:ia+n-1, ja:ja+m-1)$ .

## Input Parameters

|               |                                                                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>m</i>      | (global) Specifies the number of rows of the distributed matrix <i>sub(C)</i> , $m \geq 0$ .                                                                        |
| <i>n</i>      | (global) Specifies the number of columns of the distributed matrix <i>sub(C)</i> , $n \geq 0$ .                                                                     |
| <i>alpha</i>  | (global)<br>Specifies the scalar <i>alpha</i> .                                                                                                                     |
| <i>a</i>      | (local)<br>Array, size $(lld\_a, LOCq(ja+m-1))$ . This array contains the local pieces of the distributed matrix <i>sub(A)</i> .                                    |
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively. |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .                                                                  |
| <i>beta</i>   | (global)<br>Specifies the scalar <i>beta</i> .<br>When <i>beta</i> is equal to zero, then <i>sub(C)</i> need not be set on input.                                   |
| <i>c</i>      | (local)<br>Array, size $(lld\_c, LOCq(jc+n-1))$ .<br>This array contains the local pieces of the distributed matrix <i>sub(C)</i> .                                 |
| <i>ic, jc</i> | (global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <i>sub(C)</i> , respectively. |
| <i>desc</i>   | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .                                                                  |

## Output Parameters

|          |                                       |
|----------|---------------------------------------|
| <i>c</i> | Overwritten by the updated submatrix. |
|----------|---------------------------------------|

## p?trmm

Computes a scalar-matrix-matrix product (one matrix operand is triangular) for distributed matrices.

### Syntax

```
void pstrmm (const char *side , const char *uplo , const char *transa , const char
*diag , const MKL_INT *m , const MKL_INT *n , const float *alpha , const float *a ,
const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , float *b , const MKL_INT
*ib , const MKL_INT *jb , const MKL_INT *descb);
```

```
void pdtrmm (const char *side , const char *uplo , const char *transa , const char
*diag , const MKL_INT *m , const MKL_INT *n , const double *alpha , const double *a ,
const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , double *b , const
MKL_INT *ib , const MKL_INT *jb , const MKL_INT *descb);
```

```
void pctrmm (const char *side , const char *uplo , const char *transa , const char
*diag , const MKL_INT *m , const MKL_INT *n , const MKL_Complex8 *alpha , const
MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca ,
MKL_Complex8 *b , const MKL_INT *ib , const MKL_INT *jb , const MKL_INT *descb);
```

```
void pztrmm (const char *side , const char *uplo , const char *transa , const char
*diag , const MKL_INT *m , const MKL_INT *n , const MKL_Complex16 *alpha , const
MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca ,
MKL_Complex16 *b , const MKL_INT *ib , const MKL_INT *jb , const MKL_INT *descb);
```

### Include Files

- mkl\_pblas.h

### Description

The p?trmm routines perform a matrix-matrix operation using triangular matrices. The operation is defined as

$$\text{sub}(B) := \alpha * \text{op}(\text{sub}(A)) * \text{sub}(B)$$

or

$$\text{sub}(B) := \alpha * \text{sub}(B) * \text{op}(\text{sub}(A))$$

where:

$\alpha$  is a scalar,

$\text{sub}(B)$  is an  $m$ -by- $n$  distributed matrix,  $\text{sub}(B) = B(ib:ib+m-1, jb:jb+n-1)$ .

$A$  is a unit, or non-unit, upper or lower triangular distributed matrix,  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+m-1)$ , if  $side = 'L'$  or  $'l'$ , and  $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ , if  $side = 'R'$  or  $'r'$ .

$\text{op}(\text{sub}(A))$  is one of  $\text{op}(\text{sub}(A)) = \text{sub}(A)$ , or  $\text{op}(\text{sub}(A)) = \text{sub}(A)'$ , or  $\text{op}(\text{sub}(A)) = \text{conjg}(\text{sub}(A)')$ .

### Input Parameters

*side* (global) Specifies whether  $\text{op}(\text{sub}(A))$  appears on the left or right of  $\text{sub}(B)$  in the operation:  
 if  $side = 'L'$  or  $'l'$ , then  $\text{sub}(B) := \alpha * \text{op}(\text{sub}(A)) * \text{sub}(B)$ ;  
 if  $side = 'R'$  or  $'r'$ , then  $\text{sub}(B) := \alpha * \text{sub}(B) * \text{op}(\text{sub}(A))$ .

Before entry, this array contains the local pieces of the distributed matrix  $\text{sub}(B)$ .

*ib, jb* (global) The row and column indices in the distributed matrix  $B$  indicating the first row and the first column of the submatrix  $\text{sub}(B)$ , respectively.

*descb* (global and local) array of dimension 9. The array descriptor of the distributed matrix  $B$ .

## Output Parameters

*b* Overwritten by the transformed distributed matrix.

## p?trsm

*Solves a distributed matrix equation (one matrix operand is triangular).*

### Syntax

```

### Description

The `p?trsm` routines solve one of the following distributed matrix equations:

$$\text{op}(\text{sub}(A)) * X = \alpha * \text{sub}(B),$$

or

$$X * \text{op}(\text{sub}(A)) = \alpha * \text{sub}(B),$$

where:

$\alpha$  is a scalar,

$X$  and  $\text{sub}(B)$  are  $m$ -by- $n$  distributed matrices,  $\text{sub}(B) = B(ib:ib+m-1, jb:jb+n-1)$ ;

$A$  is a unit, or non-unit, upper or lower triangular distributed matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+m-1)$ , if  $\text{side} = 'L'$  or  $'l'$ , and  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ , if  $\text{side} = 'R'$  or  $'r'$ ;

$\text{op}(\text{sub}(A))$  is one of  $\text{op}(\text{sub}(A)) = \text{sub}(A)$ , or  $\text{op}(\text{sub}(A)) = \text{sub}(A)'$ , or  $\text{op}(\text{sub}(A)) = \text{conjg}(\text{sub}(A)')$ .

The distributed matrix  $\text{sub}(B)$  is overwritten by the solution matrix  $X$ .

## Input Parameters

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>side</i>   | (global) Specifies whether $\text{op}(\text{sub}(A))$ appears on the left or right of $X$ in the equation:<br>if $\text{side} = 'L'$ or $'l'$ , then $\text{op}(\text{sub}(A)) * X = \text{alpha} * \text{sub}(B)$ ;<br>if $\text{side} = 'R'$ or $'r'$ , then $X * \text{op}(\text{sub}(A)) = \text{alpha} * \text{sub}(B)$ .                                                                                                                                                                                                                                                 |
| <i>uplo</i>   | (global) Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular:<br>if $\text{uplo} = 'U'$ or $'u'$ , then the matrix is upper triangular;<br>if $\text{uplo} = 'L'$ or $'l'$ , then the matrix is low triangular.                                                                                                                                                                                                                                                                                                                              |
| <i>transa</i> | (global) Specifies the form of $\text{op}(\text{sub}(A))$ used in the matrix equation:<br>if $\text{transa} = 'N'$ or $'n'$ , then $\text{op}(\text{sub}(A)) = \text{sub}(A)$ ;<br>if $\text{transa} = 'T'$ or $'t'$ , then $\text{op}(\text{sub}(A)) = \text{sub}(A)'$ ;<br>if $\text{transa} = 'C'$ or $'c'$ , then $\text{op}(\text{sub}(A)) = \text{conjg}(\text{sub}(A)')$ .                                                                                                                                                                                              |
| <i>diag</i>   | (global) Specifies whether the matrix $\text{sub}(A)$ is unit triangular:<br>if $\text{diag} = 'U'$ or $'u'$ then the matrix is unit triangular;<br>if $\text{diag} = 'N'$ or $'n'$ , then the matrix is not unit triangular.                                                                                                                                                                                                                                                                                                                                                  |
| <i>m</i>      | (global) Specifies the number of rows of the distributed matrix $\text{sub}(B)$ , $m \geq 0$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>n</i>      | (global) Specifies the number of columns of the distributed matrix $\text{sub}(B)$ , $n \geq 0$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>alpha</i>  | (global)<br>Specifies the scalar <i>alpha</i> .<br>When <i>alpha</i> is zero, then <i>a</i> is not referenced and <i>b</i> need not be set before entry.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>a</i>      | (local)<br>Array, size <i>lld_a</i> by <i>ka</i> , where <i>ka</i> is at least $\text{LOCq}(1, \text{ja}+m-1)$ when $\text{side} = 'L'$ or $'l'$ and is at least $\text{LOCq}(1, \text{ja}+n-1)$ when $\text{side} = 'R'$ or $'r'$ .<br>Before entry with $\text{uplo} = 'U'$ or $'u'$ , this array contains the local entries corresponding to the entries of the upper triangular distributed matrix $\text{sub}(A)$ , and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix $\text{sub}(A)$ is not referenced. |

Before entry with *uplo* = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix *sub(A)*, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix *sub(A)* is not referenced .

When *diag* = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix *sub(A)* are not referenced either, but are assumed to be unity.

|               |                                                                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ia, ja</i> | (global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.       |
| <i>desca</i>  | (global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .                                                                        |
| <i>b</i>      | (local)<br>Array, size ( <i>lld_b</i> , <i>LOCq</i> (1, <i>jb+n-1</i> )).<br>Before entry, this array contains the local pieces of the distributed matrix <i>sub(B)</i> . |

# Partial Differential Equations Support

11

The Intel® Math Kernel Library (Intel® MKL) provides tools for solving Partial Differential Equations (PDE). These tools are Trigonometric Transform interface routines (see [Trigonometric Transform Routines](#)) and Poisson Solver (see [Fast Poisson Solver Routines](#)).

Poisson Solver is designed for fast solving of simple Helmholtz, Poisson, and Laplace problems. The solver is based on the Trigonometric Transform interface, which is, in turn, based on the Intel MKL Fast Fourier Transform (FFT) interface (refer to [Fourier Transform Functions](#)), optimized for Intel® processors.

Direct use of the Trigonometric Transform routines may be helpful to those who have already implemented their own solvers similar to the Intel MKL Poisson Solver. As it may be hard enough to modify the original code so as to make it work with Poisson Solver, you are encouraged to use fast (staggered) sine/cosine transforms implemented in the Trigonometric Transform interface to improve performance of your solver.

Both Trigonometric Transform and Poisson Solver routines can be called from C and Fortran.

## Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## Trigonometric Transform Routines

In addition to the Fast Fourier Transform (FFT) interface, described in chapter "[Fast Fourier Transforms](#)", Intel® MKL supports the Real Discrete Trigonometric Transforms (sometimes called real-to-real Discrete Fourier Transforms) interface. In this document, the interface is referred to as TT interface. It implements a group of routines (TT routines) used to compute sine/cosine, staggered sine/cosine, and twice staggered sine/cosine transforms (referred to as staggered2 sine/cosine transforms, for brevity). The TT interface provides much flexibility of use: you can adjust routines to your particular needs at the cost of manually tuning routine parameters or just call routines with default parameter values. The current Intel MKL implementation of the TT interface can be used in solving partial differential equations and contains routines that are helpful for Fast Poisson and similar solvers.

For the list of Trigonometric Transforms currently implemented in Intel MKL TT interface, see [Transforms Implemented](#).

If you have got used to the FFTW interface ([www.fftw.org](http://www.fftw.org)), you can call the TT interface functions through real-to-real FFTW to Intel MKL wrappers without changing FFTW function calls in your code (refer to [FFTW to Intel® MKL Wrappers for FFTW 3.x](#) for details). However, you are strongly encouraged to use the native TT interface for better performance. Another reason why you should use the wrappers cautiously is that TT and the real-to-real FFTW interfaces are not fully compatible and some features of the real-to-real FFTW, such as strides and multidimensional transforms, are not available through wrappers.

## Trigonometric Transforms Implemented

TT routines allow computing the following transforms:

## Forward sine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin \frac{ki\pi}{n}, k = 1, \dots, n-1$$

## Backward sine transform

$$f(i) = \sum_{k=1}^{n-1} F(k) \sin \frac{ki\pi}{n}, i = 1, \dots, n-1$$

## Forward staggered sine transform

$$F(k) = \frac{1}{n} \sin \frac{(2k-1)\pi}{2} f(n) + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin \frac{(2k-1)i\pi}{2n}, k = 1, \dots, n$$

## Backward staggered sine transform

$$f(i) = \sum_{k=1}^n F(k) \sin \frac{(2k-1)i\pi}{2n}, i = 1, \dots, n$$

## Forward staggered2 sine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^n f(i) \sin \frac{(2k-1)(2i-1)\pi}{4n}, k = 1, \dots, n$$

## Backward staggered2 sine transform

$$f(i) = \sum_{k=1}^n F(k) \sin \frac{(2k-1)(2i-1)\pi}{4n}, i = 1, \dots, n$$

## Forward cosine transform

$$F(k) = \frac{1}{n} [f(0) + f(n) \cos k\pi] + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \cos \frac{ki\pi}{n}, k = 0, \dots, n$$

## Backward cosine transform

$$f(i) = \frac{1}{2} [F(0) + F(n) \cos i\pi] + \sum_{k=1}^{n-1} F(k) \cos \frac{ki\pi}{n}, i = 0, \dots, n$$

## Forward staggered cosine transform

$$F(k) = \frac{1}{n} f(0) + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \cos \frac{(2k+1)i\pi}{2n}, k = 0, \dots, n-1$$

## Backward staggered cosine transform

$$f(i) = \sum_{k=0}^{n-1} F(k) \cos \frac{(2k+1)i\pi}{2n}, i = 0, \dots, n-1$$

## Forward staggered2 cosine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^n f(i) \cos \frac{(2k-1)(2i-1)\pi}{4n}, k = 1, \dots, n$$

## Backward staggered2 cosine transform

$$f(i) = \sum_{k=1}^n F(k) \cos \frac{(2k-1)(2i-1)\pi}{4n}, i = 1, \dots, n$$

**NOTE**

The size of the transform  $n$  can be any integer greater or equal to 2.

**Sequence of Invoking TT Routines**

Computation of a transform using TT interface is conceptually divided into four steps, each of which is performed via a dedicated routine. [Table "TT Interface Routines"](#) lists the routines and briefly describes their purpose and use.

Most TT routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with "s" and "d". The wildcard "?" stands for either of these symbols in routine names.

**TT Interface Routines**

| Routine                                                                         | Description                                                                                                                                          |
|---------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>?_init_trig_transform</code>                                              | Initializes basic data structures of Trigonometric Transforms.                                                                                       |
| <code>?_commit_trig_transform</code>                                            | Checks consistency and correctness of user-defined data and creates a data structure to be used by Intel MKL FFT interface <sup>1</sup> .            |
| <code>?_forward_trig_transform</code><br><code>?_backward_trig_transform</code> | Computes a forward/backward Trigonometric Transform of a specified type using the appropriate formula (see <a href="#">Transforms Implemented</a> ). |
| <code>free_trig_transform</code>                                                | Releases the memory used by a data structure needed for calling FFT interface <sup>1</sup> .                                                         |

<sup>1</sup>TT routines call Intel MKL FFT interface for better performance.

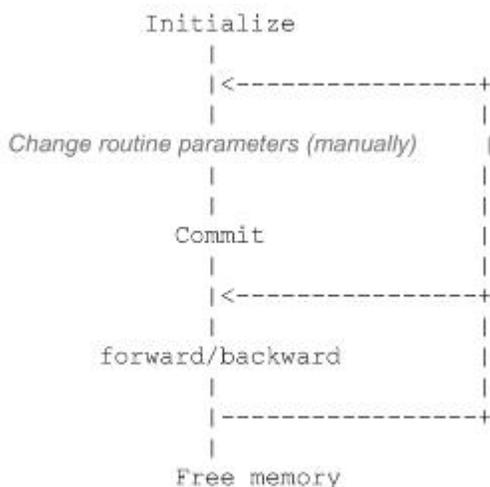

To find a transformed vector for a particular input vector only once, the Intel MKL TT interface routines are normally invoked in the order in which they are listed in [Table "TT Interface Routines"](#).

**NOTE**

Though the order of invoking TT routines may be changed, it is highly recommended to follow the above order of routine calls.

The diagram in [Figure "Typical Order of Invoking TT Interface Routines"](#) indicates the typical order in which TT interface routines can be invoked in a general case (prefixes and suffixes in routine names are omitted).

**Typical Order of Invoking TT Interface Routines**

A general scheme of using TT routines for double-precision computations is shown below. A similar scheme holds for single-precision computations with the only difference in the initial letter of routine names.

```
...
 d_init_trig_transform(&n, &tt_type, ipar, dpar, &ir);
/* Change parameters in ipar if necessary. */
/* Note that the result of the Transform will be in f. If you want to preserve the data stored in
f,
save it to another location before the function call below */
 d_commit_trig_transform(f, &handle, ipar, dpar, &ir);
 d_forward_trig_transform(f, &handle, ipar, dpar, &ir);
 d_backward_trig_transform(f, &handle, ipar, dpar, &ir);
 free_trig_transform(&handle, ipar, &ir);
/* here the user may clean the memory used by f, dpar, ipar */
...
```

You can find examples of code that uses TT interface routines to solve one-dimensional Helmholtz problem in the `examples\pdetttc\source` folder in your Intel MKL directory.

## Trigonometric Transform Interface Description

All types in this documentation are either standard C types `float` and `double` or `MKL_INT` integer type. For more information on the C types, refer to [C Datatypes Specific to Intel MKL](#) and the *Intel(R) MKL Developer Guide*. To better understand usage of the types, see examples in the `examples\pdetttc\source` folder in your Intel MKL directory.

### Routine Options

All TT routines use parameters to pass various options to one another. These parameters are arrays `ipar`, `dpar` and `spar`. Values for these parameters should be specified very carefully (see [Common Parameters](#)). You can change these values during computations to meet your needs.

---

#### WARNING

To avoid failure or incorrect results, you must provide correct and consistent parameters to the routines.

---

### User Data Arrays

TT routines take arrays of user data as input. For example, user arrays are passed to the routine `d_forward_trig_transform` to compute a forward Trigonometric Transform. To minimize storage requirements and improve the overall run-time efficiency, Intel MKL TT routines do not make copies of user input arrays.

---

#### NOTE

If you need a copy of your input data arrays, you must save them yourself.

---

For better performance, align your data arrays as recommended in the *Intel MKL Developer Guide* (search the document for coding techniques to improve performance).

## TT Routines

The section gives detailed description of TT routines, their syntax, parameters and values they return. Double-precision and single-precision versions of the same routine are described together.

TT routines call Intel MKL FFT interface (described in section "[FFT Functions](#)" in chapter "Fast Fourier Transforms"), which enhances performance of the routines.

## ?\_init\_trig\_transform

Initializes basic data structures of a Trigonometric Transform.

---

### Syntax

```
void d_init_trig_transform(MKL_INT *n, MKL_INT *tt_type, MKL_INT ipar[], double dpar[], MKL_INT *stat);
```

```
void s_init_trig_transform(MKL_INT *n, MKL_INT *tt_type, MKL_INT ipar[], float spar[], MKL_INT *stat);
```

### Include Files

- mkl.h

### Input Parameters

|                |                                                                                                                                                                                                                                                                                                                                                         |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>       | MKL_INT*. Contains the size of the problem, which should be a positive integer greater than 1. Note that data vector of the transform, which other TT routines will use, must have size $n+1$ for all but staggered2 transforms. Staggered2 transforms require the vector of size $n$ .                                                                 |
| <i>tt_type</i> | MKL_INT*. Contains the type of transform to compute, defined via a set of named constants. The following constants are available in the current implementation of TT interface: MKL_SINE_TRANSFORM, MKL_STAGGERED_SINE_TRANSFORM, MKL_STAGGERED2_SINE_TRANSFORM; MKL_COSINE_TRANSFORM, MKL_STAGGERED_COSINE_TRANSFORM, MKL_STAGGERED2_COSINE_TRANSFORM. |

### Output Parameters

|             |                                                                                                                                                     |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ipar</i> | MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.                                                   |
| <i>dpar</i> | double array of size $5n/2+2$ . Contains double-precision data needed for Trigonometric Transform computations.                                     |
| <i>spar</i> | float array of size $5n/2+2$ . Contains single-precision data needed for Trigonometric Transform computations.                                      |
| <i>stat</i> | MKL_INT*. Contains the routine completion status, which is also written to <i>ipar</i> [6]. The status should be 0 to proceed to other TT routines. |

### Description

The `?_init_trig_transform` routine initializes basic data structures for Trigonometric Transforms of appropriate precision. After a call to `?_init_trig_transform`, all subsequently invoked TT routines use values of *ipar* and *dpar* (*spar*) array parameters returned by `?_init_trig_transform`. The routine initializes the entire array *ipar*. In the *dpar* or *spar* array, `?_init_trig_transform` initializes elements that do not depend upon the type of transform. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the [Common Parameters](#) section. You can skip a call to the initialization routine in your code. For more information, see [Caveat on Parameter Modifications](#).

## Return Values

`stat= 0`

The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this `stat` value.

`stat= -99999`

The routine failed to complete the task.

## ?\_commit\_trig\_transform

*Checks consistency and correctness of user's data as well as initializes certain data structures required to perform the Trigonometric Transform.*

---

## Syntax

```
void d_commit_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], double dpar[], MKL_INT *stat);
```

```
void s_commit_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], float spar[], MKL_INT *stat);
```

## Include Files

## Input Parameters

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>    | <p>double for <code>d_commit_trig_transform</code>,<br/>float for <code>s_commit_trig_transform</code>,<br/>array of size <math>n</math> for staggered2 transforms and of size <math>n+1</math> for all other transforms, where <math>n</math> is the size of the problem. Contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors:</p> <ul style="list-style-type: none"> <li>• <math>f[0]</math> and <math>f[n]</math> for sine transforms</li> <li>• <math>f[n]</math> for staggered cosine transforms</li> <li>• <math>f[0]</math> for staggered sine transforms.</li> </ul> <p>Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. These restrictions meet the requirements of the Intel MKL Poisson Solver, which the TT interface is primarily designed for (for details, see <a href="#">Fast Poisson Solver Routines</a>).</p> |
| <code>ipar</code> | MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>dpar</code> | double array of size $5n/2+2$ . Contains double-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>spar</code> | float array of size $5n/2+2$ . Contains single-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Output Parameters

|               |                                                                                                                                                                                     |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>handle</i> | DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, refer to section " <a href="#">FFT Functions</a> " in chapter "Fast Fourier Transforms"). |
| <i>ipar</i>   | Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar[6]</i> is updated with the <i>stat</i> value.                                             |
| <i>dpar</i>   | Contains double-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.                                                         |
| <i>spar</i>   | Contains single-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.                                                         |
| <i>stat</i>   | MKL_INT*. Contains the routine completion status, which is also written to <i>ipar[6]</i> .                                                                                         |

## Description

The routine `?_commit_trig_transform` checks consistency and correctness of the parameters to be passed to the transform routines `?_forward_trig_transform` and/or `?_backward_trig_transform`. The routine also initializes the following data structures: *handle*, *dpar* in case of `d_commit_trig_transform`, and *spar* in case of `s_commit_trig_transform`. The `?_commit_trig_transform` routine initializes only those elements of *dpar* or *spar* that depend upon the type of transform, defined in the `?_init_trig_transform` routine and passed to `?_commit_trig_transform` with the *ipar* array. The size of the problem *n*, which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called `?_init_trig_transform` routine. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the [Common Parameters](#) section. The routine performs only a basic check for correctness and consistency of the parameters. If you are going to modify parameters of TT routines, see the [Caveat on Parameter Modifications](#) section. Unlike `?_init_trig_transform`, you must call the `?_commit_trig_transform` routine in your code.

## Return Values

|                    |                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>stat</i> = 11   | The routine produced some warnings and made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning <i>ipar[6]</i> =0 if you are sure that the parameters are correct. |
| <i>stat</i> = 10   | The routine made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning <i>ipar[6]</i> =0 if you are sure that the parameters are correct.                            |
| <i>stat</i> = 1    | The routine produced some warnings. You may proceed with computations by assigning <i>ipar[6]</i> =0 if you are sure that the parameters are correct.                                                                                         |
| <i>stat</i> = 0    | The routine completed the task normally.                                                                                                                                                                                                      |
| <i>stat</i> = -100 | The routine stopped for any of the following reasons: <ul style="list-style-type: none"> <li>• An error in the user's data was encountered.</li> </ul>                                                                                        |

- Data in *ipar*, *dpar* or *spar* parameters became incorrect and/or inconsistent as a result of modifications.

*stat*= -1000

The routine stopped because of an FFT interface error.

*stat*= -10000

The routine stopped because the initialization failed to complete or the parameter *ipar*[0] was altered by mistake.

---

## NOTE

Although positive values of *stat* usually indicate minor problems with the input data and Trigonometric Transform computations can be continued, you are highly recommended to investigate the problem first and achieve *stat*=0.

---

## ?\_forward\_trig\_transform

Computes the forward Trigonometric Transform of type specified by the parameter.

---

### Syntax

```
void d_forward_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], double dpar[], MKL_INT *stat);
```

```
void s_forward_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], float spar[], MKL_INT *stat);
```

### Include Files

- mkl.h

### Input Parameters

*f* double for `d_forward_trig_transform`,  
float for `s_forward_trig_transform`,  
array of size *n* for staggered2 transforms and of size *n*+1 for all other transforms, where *n* is the size of the problem. On input, contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors:

- *f*[0] and *f*[*n*] for sine transforms
- *f*[*n*] for staggered cosine transforms
- *f*[0] for staggered sine transforms.

Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. The above restrictions meet the requirements of the Intel MKL Poisson Solver, which the TT interface is primarily designed for (for details, see [Fast Poisson Solver Routines](#)).

*handle* DFTI\_DESCRIPTOR\_HANDLE\*. The data structure used by Intel MKL FFT interface (for details, see [FFT Functions](#)).

---

|             |                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------|
| <i>ipar</i> | MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.               |
| <i>dpar</i> | double array of size $5n/2+2$ . Contains double-precision data needed for Trigonometric Transform computations. |
| <i>spar</i> | float array of size $5n/2+2$ . Contains single-precision data needed for Trigonometric Transform computations.  |

## Output Parameters

|             |                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <i>f</i>    | Contains the transformed vector on output.                                                                                               |
| <i>ipar</i> | Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar</i> [6] is updated with the <i>stat</i> value. |
| <i>stat</i> | MKL_INT*. Contains the routine completion status, which is also written to <i>ipar</i> [6].                                              |

## Description

The routine computes the forward Trigonometric Transform of type defined in the `?_init_trig_transform` routine and passed to `?_forward_trig_transform` with the *ipar* array. The size of the problem *n*, which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called `?_init_trig_transform` routine. The other data that facilitates the computation is created by `?_commit_trig_transform` and supplied in *dpar* or *spar*. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the [Common Parameters](#) section. The routine has a commit step, which calls the `?_commit_trig_transform` routine. The transform is computed according to formulas given in the [Transforms Implemented](#) section. The routine replaces the input vector *f* with the transformed vector.

---

### NOTE

If you need a copy of the data vector *f* to be transformed, make the copy before calling the `?_forward_trig_transform` routine.

---

## Return Values

|                      |                                                                                                                                                                                                                                                                                                 |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>stat</i> = 0      | The routine completed the task normally.                                                                                                                                                                                                                                                        |
| <i>stat</i> = -100   | The routine stopped for any of the following reasons: <ul style="list-style-type: none"> <li>• An error in the user's data was encountered.</li> <li>• Data in <i>ipar</i>, <i>dpar</i> or <i>spar</i> parameters became incorrect and/or inconsistent as a result of modifications.</li> </ul> |
| <i>stat</i> = -1000  | The routine stopped because of an FFT interface error.                                                                                                                                                                                                                                          |
| <i>stat</i> = -10000 | The routine stopped because its commit step failed to complete or the parameter <i>ipar</i> [0] was altered by mistake.                                                                                                                                                                         |

## ?\_backward\_trig\_transform

Computes the backward Trigonometric Transform of type specified by the parameter.

### Syntax

```
void d_backward_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], double dpar[], MKL_INT *stat);
```

```
void s_backward_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], float spar[], MKL_INT *stat);
```

### Include Files

- mkl.h

### Input Parameters

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>f</i>      | double for <code>d_backward_trig_transform</code> ,<br>float for <code>s_backward_trig_transform</code> ,<br>array of size $n$ for staggered2 transforms and of size $n+1$ for all other transforms, where $n$ is the size of the problem. On input, contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors: <ul style="list-style-type: none"> <li>• <math>f[0]</math> and <math>f[n]</math> for sine transforms</li> <li>• <math>f[n]</math> for staggered cosine transforms</li> <li>• <math>f[0]</math> for staggered sine transforms.</li> </ul> Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. The above restrictions meet the requirements of the Intel MKL Poisson Solver, which the TT interface is primarily designed for (for details, see <a href="#">Fast Poisson Solver Routines</a> ). |
| <i>handle</i> | DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, see <a href="#">FFT Functions</a> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>ipar</i>   | MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>dpar</i>   | double array of size $5n/2+2$ . Contains double-precision data needed for Trigonometric Transform computations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>spar</i>   | float array of size $5n/2+2$ . Contains single-precision data needed for Trigonometric Transform computations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### Output Parameters

|             |                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <i>f</i>    | Contains the transformed vector on output.                                                                                               |
| <i>ipar</i> | Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar</i> [6] is updated with the <i>stat</i> value. |
| <i>stat</i> | MKL_INT*. Contains the routine completion status, which is also written to <i>ipar</i> [6].                                              |

## Description

The routine computes the backward Trigonometric Transform of type defined in the `?_init_trig_transform` routine and passed to `?_backward_trig_transform` with the `ipar` array. The size of the problem  $n$ , which determines sizes of the array parameters, is also passed to the routine with the `ipar` array and defined in the previously called `?_init_trig_transform` routine. The other data that facilitates the computation is created by `?_commit_trig_transform` and supplied in `dpar` or `spar`. For a detailed description of arrays `ipar`, `dpar` and `spar`, refer to the [Common Parameters](#) section. The routine has a commit step, which calls the `?_commit_trig_transform` routine. The transform is computed according to formulas given in the [Transforms Implemented](#) section. The routine replaces the input vector  $f$  with the transformed vector.

---

### NOTE

If you need a copy of the data vector  $f$  to be transformed, make the copy before calling the `?_backward_trig_transform` routine.

---

## Return Values

|                           |                                                                                                                                                                                                                                                                                                                   |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>stat= 0</code>      | The routine completed the task normally.                                                                                                                                                                                                                                                                          |
| <code>stat= -100</code>   | The routine stopped for any of the following reasons: <ul style="list-style-type: none"> <li>• An error in the user's data was encountered.</li> <li>• Data in <code>ipar</code>, <code>dpar</code> or <code>spar</code> parameters became incorrect and/or inconsistent as a result of modifications.</li> </ul> |
| <code>stat= -1000</code>  | The routine stopped because of an FFT interface error.                                                                                                                                                                                                                                                            |
| <code>stat= -10000</code> | The routine stopped because its commit step failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.                                                                                                                                                                                      |

## free\_trig\_transform

*Cleans the memory allocated for the data structure used by the FFT interface.*

---

## Syntax

```
void free_trig_transform(DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], MKL_INT *stat);
```

## Include Files

- `mkl.h`

## Input Parameters

|                     |                                                                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ipar</code>   | MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.                                                                                   |
| <code>handle</code> | DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, refer to section " <a href="#">FFT Functions</a> " in chapter "Fast Fourier Transforms"). |

## Output Parameters

|               |                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <i>handle</i> | The data structure used by Intel MKL FFT interface. Memory allocated for the structure is released on output.                           |
| <i>ipar</i>   | Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar[6]</i> is updated with the <i>stat</i> value. |
| <i>stat</i>   | MKL_INT*. Contains the routine completion status, which is also written to <i>ipar[6]</i> .                                             |

## Description

The `free_trig_transform` routine cleans the memory used by the *handle* structure, needed for Intel MKL FFT functions. To release the memory allocated for other parameters, include cleaning of the memory in your code.

## Return Values

|                      |                                                        |
|----------------------|--------------------------------------------------------|
| <i>stat</i> = 0      | The routine completed the task normally.               |
| <i>stat</i> = -1000  | The routine stopped because of an FFT interface error. |
| <i>stat</i> = -99999 | The routine failed to complete the task.               |

## Common Parameters of the Trigonometric Transforms

This section provides description of array parameters that hold TT routine options: *ipar*, *dpar* and *spar*.

---

### NOTE

Initial values are assigned to the array parameters by the appropriate `?_init_trig_transform` and `?_commit_trig_transform` routines.

---

| 3 through 4    | Reserved for future use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 5              | Contains the type of the transform. The <code>?_init_trig_transform</code> routine sets <i>ipar[5]=tt_type</i> , and all subsequently called TT routines use <i>ipar[5]</i> as the type of the transform.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 6              | Contains the <i>stat</i> value returned by the last completed TT routine. Used to check that the previous call to a TT routine completed with <i>stat</i> =0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 7              | <p>Informs the <code>?_commit_trig_transform</code> routines whether to initialize data structures <i>dpar</i> (<i>spar</i>) and <i>handle</i>. <i>ipar[7]=0</i> indicates that the routine should skip the initialization and only check correctness and consistency of the parameters. Otherwise, the routine initializes the data structures. The default value is 1.</p> <p>The possibility to check correctness and consistency of input data without initializing data structures <i>dpar</i>, <i>spar</i> and <i>handle</i> enables avoiding performance losses in a repeated use of the same transform for different data vectors. Note that you can benefit from the opportunity that <i>ipar[7]</i> gives only if you are sure to have supplied proper tolerance value in the <i>dpar</i> or <i>spar</i> array. Otherwise, avoid tuning this parameter.</p>                                                                                         |
| 8              | <p>Contains message style options for TT routines. Specifically, if <i>ipar[8]</i> is non-zero, TT routines print the messages in C-style notations. The default value is 1.</p> <p>When specifying message style options, be aware that by default, numbering of elements in C arrays starts at 0. For example, "<i>parameter ipar[0]=3 should be an even integer</i>" is a C-style message. The use of <i>ipar[8]</i> enables you to view messages in a more convenient style.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 9              | Specifies the number of OpenMP threads to run TT routines in the OpenMP environment of the Intel MKL Poisson Solver. The default value is 1. You are highly recommended not to alter this value. See also <a href="#">Caveat on Parameter Modifications</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 10             | Specifies the mode of compatibility with FFTW. The default value is 0. Set the value to 1 to invoke compatibility with FFTW. In the latter case, results will not be normalized, because FFTW does not do this. It is highly recommended not to alter this value, but rather use real-to-real FFTW to MKL wrappers, described in <a href="#">FFTW to Intel® MKL Wrappers for FFTW 3.x</a> . See also <a href="#">Caveat on Parameter Modifications</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 11 through 127 | Reserved for future use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**NOTE**

While you can declare the *ipar* array as `MKL_INT ipar[11]`, for future compatibility you should declare *ipar* as `MKL_INT ipar[128]`.

Arrays *dpar* and *spar* are the same except in the data precision:

- dpar*                      double array of size  $5n/2+2$ , holds data needed for double-precision routines to perform TT computations. This array is initialized in the `d_init_trig_transform` and `d_commit_trig_transform` routines.
- spar*                      float array of size  $5n/2+2$ , holds data needed for single-precision routines to perform TT computations. This array is initialized in the `s_init_trig_transform` and `s_commit_trig_transform` routines.

As *dpar* and *spar* have similar elements in respective positions, the elements are described together in [Table "Elements of the dpar and spar Arrays"](#):

**Elements of the dpar and spar Arrays**

| Index              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                  | Contains the first absolute tolerance used by the appropriate <code>?_commit_trig_transform</code> routine. For a staggered cosine or a sine transform, $f[n]$ should be equal to 0.0 and for a staggered sine or a sine transform, $f[0]$ should be equal to 0.0. The <code>?_commit_trig_transform</code> routine checks whether absolute values of these parameters are below $dpar[0]*n$ or $spar[0]*n$ , depending on the routine precision. To suppress warnings resulting from tolerance checks, set $dpar[0]$ or $spar[0]$ to a sufficiently large number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 1                  | Reserved for future use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 2 through $5n/2+1$ | Contain tabulated values of trigonometric functions. Contents of the elements depend upon the type of transform <i>tt_type</i> , set up in the <code>?_commit_trig_transform</code> routine: <ul style="list-style-type: none"> <li>• If <i>tt_type</i>=<code>MKL_SINE_TRANSFORM</code>, the transform uses only the first <math>n/2</math> array elements, which contain tabulated sine values.</li> <li>• If <i>tt_type</i>=<code>MKL_STAGGERED_SINE_TRANSFORM</code>, the transform uses only the first <math>3n/2</math> array elements, which contain tabulated sine and cosine values.</li> <li>• If <i>tt_type</i>=<code>MKL_STAGGERED2_SINE_TRANSFORM</code>, the transform uses all the <math>5n/2</math> array elements, which contain tabulated sine and cosine values.</li> <li>• If <i>tt_type</i>=<code>MKL_COSINE_TRANSFORM</code>, the transform uses only the first <math>n</math> array elements, which contain tabulated cosine values.</li> <li>• If <i>tt_type</i>=<code>MKL_STAGGERED_COSINE_TRANSFORM</code>, the transform uses only the first <math>3n/2</math> elements, which contain tabulated sine and cosine values.</li> <li>• If <i>tt_type</i>=<code>MKL_STAGGERED2_COSINE_TRANSFORM</code>, the transform uses all the <math>5n/2</math> elements, which contain tabulated sine and cosine values.</li> </ul> |

**NOTE**

To save memory, you can define the array size depending upon the type of transform.

**Caveat on Parameter Modifications**

Flexibility of the TT interface enables you to skip a call to the `?_init_trig_transform` routine and to initialize the basic data structures explicitly in your code. You may also need to modify the contents of *ipar*, *dpar* and *spar* arrays after initialization. When doing so, provide correct and consistent data in the arrays.

Mistakenly altered arrays cause errors or wrong computation. You can perform a basic check for correctness and consistency of parameters by calling the `?_commit_trig_transform` routine; however, this does not ensure the correct result of a transform but only reduces the chance of errors or wrong results.

**NOTE**

To supply correct and consistent parameters to TT routines, you should have considerable experience in using the TT interface and good understanding of elements that the `ipar`, `spar` and `dpar` arrays contain and dependencies between values of these elements.

However, in rare occurrences, even advanced users might fail to compute a transform using TT routines after the parameter modifications. In cases like these, refer for technical support at <http://www.intel.com/software/products/support/>.

**WARNING**

The only way that ensures proper computation of the Trigonometric Transforms is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of `ipar`, `dpar` and `spar` arrays unless a strong need arises.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

**Trigonometric Transform Implementation Details**

Several aspects of the Intel MKL TT interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, Intel MKL provides you with the TT language-specific header file to include in your code:

- `mkl_trig_transforms.h`, to be used together with `mkl_dfti.h`.

**NOTE**

- Use of the Intel MKL TT software without including the above language-specific header files is not supported.

**Header File**

The header file below defines the following function prototypes:

```
void d_init_trig_transform(MKL_INT *, MKL_INT *, MKL_INT *, double *, MKL_INT *);
void d_commit_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, double *, MKL_INT *);
void d_forward_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, double *, MKL_INT *);
void d_backward_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, double *, MKL_INT *);

void s_init_trig_transform(MKL_INT *, MKL_INT *, MKL_INT *, float *, MKL_INT *);
void s_commit_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, float *, MKL_INT *);
```

```
void s_forward_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, float *, MKL_INT *);
void s_backward_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, float *, MKL_INT *);

void free_trig_transform(DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, MKL_INT *);
```

## Fast Poisson Solver Routines

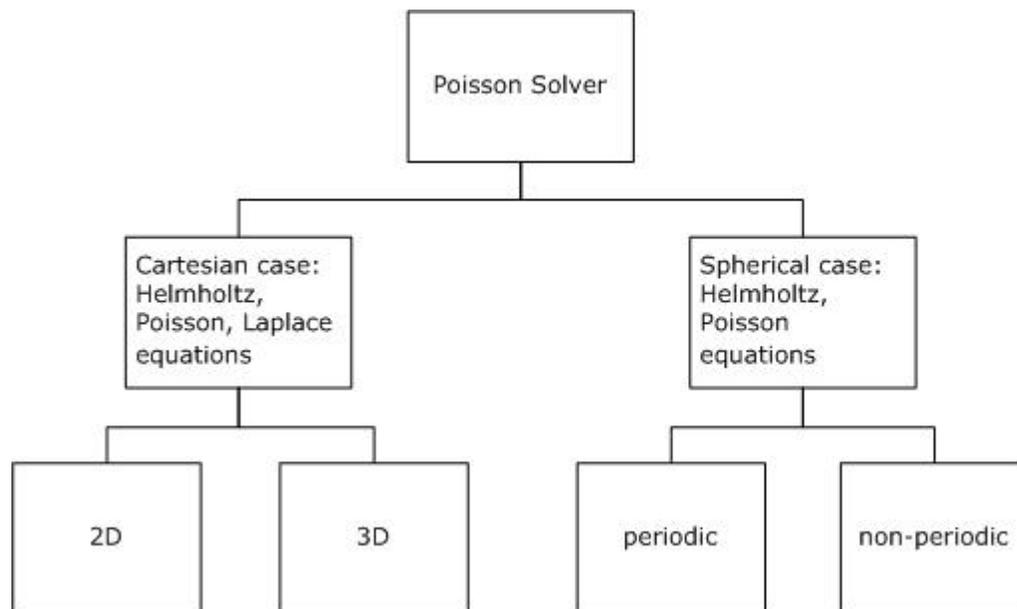

In addition to the Real Discrete Trigonometric Transforms (TT) interface (refer to [Trigonometric Transform Routines](#)), Intel MKL supports the the Poisson Solver interface. This interface implements a group of routines (Poisson Solver routines) used to compute a solution of Laplace, Poisson, and Helmholtz problems of a special kind using discrete Fourier transforms. Laplace and Poisson problems are special cases of a more general Helmholtz problem. The problems that are solved by the Poisson Solver interface are defined more exactly in the [Poisson Solver Implementation](#) subsection. The Poisson Solver interface provides much flexibility of use: you can call routines with the default parameter values or adjust routines to your particular needs by manually tuning routine parameters. You can adjust the style of error and warning messages to a C notation by setting up a dedicated parameter. This adds convenience to debugging, because you can read information in the way that is natural for your code. The Intel MKL Poisson Solver interface currently contains only routines that implement the following solvers:

- Fast Laplace, Poisson and Helmholtz solvers in a Cartesian coordinate system
- Fast Poisson and Helmholtz solvers in a spherical coordinate system.

### Poisson Solver Implementation

Poisson Solver routines enable approximate solving of certain two-dimensional and three-dimensional problems. [Figure "Structure of the Poisson Solver"](#) shows the general structure of the Poisson Solver.

#### Structure of the Poisson Solver

#### NOTE

Although in the Cartesian case, both periodic and non-periodic solvers are also supported, they use the same interfaces.

Sections below provide details of the problems that can be solved using Intel MKL Poisson Solver.

### Two-Dimensional Problems

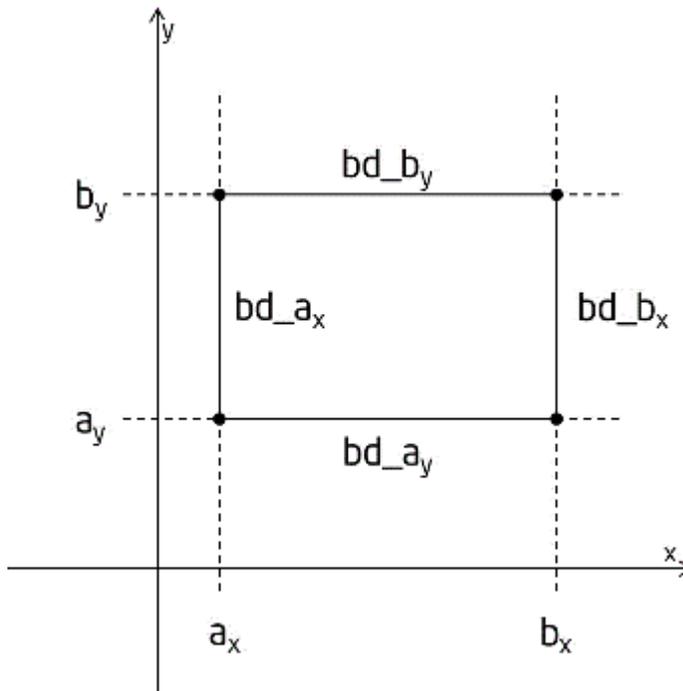

#### Notational Conventions

The Poisson Solver interface description uses the following notation for boundaries of a rectangular domain  $a_x < x < b_x, a_y < y < b_y$  on a Cartesian plane:

$$bd\_a_x = \{x = a_x, a_y \leq y \leq b_y\}, \quad bd\_b_x = \{x = b_x, a_y \leq y \leq b_y\}$$

$$bd\_a_y = \{a_x \leq x \leq b_x, y = a_y\}, \quad bd\_b_y = \{a_x \leq x \leq b_x, y = b_y\}.$$

The following figure shows these boundaries:

The wildcard "+" may stand for any of the symbols  $a_x, b_x, a_y, b_y$ , so  $bd\_+$  denotes any of the above boundaries.

The Poisson Solver interface description uses the following notation for boundaries of a rectangular domain  $a_\varphi < \varphi < b_\varphi, a_\theta < \theta < b_\theta$  on a sphere  $0 \leq \varphi \leq 2\pi, 0 \leq \theta \leq \pi$ :

$$bd\_a_\varphi = \{\varphi = a_\varphi, a_\theta \leq \theta \leq b_\theta\}, \quad bd\_b_\varphi = \{\varphi = b_\varphi, a_\theta \leq \theta \leq b_\theta\},$$

$$bd\_a_\theta = \{a_\varphi \leq \varphi \leq b_\varphi, \theta = a_\theta\}, \quad bd\_b_\theta = \{a_\varphi \leq \varphi \leq b_\varphi, \theta = b_\theta\}.$$

The wildcard "~" may stand for any of the symbols  $a_\varphi, b_\varphi, a_\theta, b_\theta$ , so  $bd\_~$  denotes any of the above boundaries.

#### Two-dimensional Helmholtz problem on a Cartesian plane

The two-dimensional (2D) Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} + qu = f(x, y), \quad q = const \geq 0$$

in a rectangle, that is, a rectangular domain  $a_x < x < b_x, a_y < y < b_y$ , with one of the following boundary conditions on each boundary  $bd\_+$ :

- The Dirichlet boundary condition

$$u(x, y) = G(x, y)$$

- The Neumann boundary condition

$$\frac{\partial u}{\partial n}(x, y) = g(x, y)$$

where

$$n = -x \text{ on } bd\_a_x, n = x \text{ on } bd\_b_x,$$

$$n = -y \text{ on } bd\_a_y, n = y \text{ on } bd\_b_y.$$

- Periodic boundary conditions

$$u(a_x, y) = u(b_x, y), \frac{\partial}{\partial x} u(a_x, y) = \frac{\partial}{\partial x} u(b_x, y),$$

$$u(x, a_y) = u(x, b_y), \frac{\partial}{\partial y} u(x, a_y) = \frac{\partial}{\partial y} u(x, b_y).$$

## Two-dimensional Poisson problem on a Cartesian plane

The Poisson problem is a special case of the Helmholtz problem, when  $q=0$ . The 2D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} = f(x, y)$$

in a rectangle  $a_x < x < b_x, a_y < y < b_y$  with the Dirichlet, Neumann, or periodic boundary conditions on each boundary  $bd\_+$ . In case of a problem with the Neumann boundary condition on the entire boundary, you can find the solution of the problem only up to a constant. In this case, the Poisson Solver will compute the solution that provides the minimal Euclidean norm of a residual.

## Two-dimensional (2D) Laplace problem on a Cartesian plane

The Laplace problem is a special case of the Helmholtz problem, when  $q=0$  and  $f(x, y)=0$ . The 2D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$$

in a rectangle  $a_x < x < b_x, a_y < y < b_y$  with the Dirichlet, Neumann, or periodic boundary conditions on each boundary  $bd\_+$ .

## Helmholtz problem on a sphere

The Helmholtz problem on a sphere is to find an approximate solution of the Helmholtz equation

$$-\Delta_s u + qu = f, q = const \geq 0,$$

$$\Delta_s = \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \phi^2} + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left( \sin \theta \frac{\partial}{\partial \theta} \right)$$

in a domain bounded by angles  $a_\phi \leq \phi \leq b_\phi, a_\theta \leq \theta \leq b_\theta$  (spherical rectangle), with boundary conditions for particular domains listed in [Table "Details of Helmholtz Problem on a Sphere"](#).

## Details of Helmholtz Problem on a Sphere

| Domain on a sphere | Boundary condition                                                 | Periodic/non-periodic case |
|--------------------|--------------------------------------------------------------------|----------------------------|
|                    | Homogeneous Dirichlet boundary conditions on each boundary $bd\_~$ | <i>non-periodic</i>        |

| Domain on a sphere                                                                             | Boundary condition                                                                                                                                         | Periodic/non-periodic case |
|------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------|
| Rectangular, that is, $b_\phi - a_\phi < 2\pi$ and $b_\theta - a_\theta < \pi$                 |                                                                                                                                                            |                            |
| Where $a_\phi = 0$ , $b_\phi = 2\pi$ , and $b_\theta - a_\theta < \pi$                         | Homogeneous Dirichlet boundary conditions on the boundaries $bd_{a_\theta}$ and $bd_{b_\theta}$                                                            | <i>periodic</i>            |
| Entire sphere, that is, $a_\phi = 0$ , $b_\phi = 2\pi$ , $a_\theta = 0$ , and $b_\theta = \pi$ | Boundary condition $\left(\sin\theta \frac{\partial u}{\partial \theta}\right) = 0$ at $\theta \rightarrow 0$ and $\theta \rightarrow \pi$<br>at the poles | <i>periodic</i>            |

**Poisson problem on a sphere**

The Poisson problem is a special case of the Helmholtz problem, when  $q=0$ . The Poisson problem on a sphere is to find an approximate solution of the Poisson equation

$$-\Delta_s u = f, \Delta_s = \frac{1}{\sin^2\theta} \frac{\partial^2}{\partial \phi^2} + \frac{1}{\sin\theta} \frac{\partial}{\partial \theta} \left( \sin\theta \frac{\partial}{\partial \theta} \right)$$

in a spherical rectangle  $a_\phi \leq \phi \leq b_\phi$ ,  $a_\theta \leq \theta \leq b_\theta$  in cases listed in [Table "Details of Helmholtz Problem on a Sphere"](#). The solution to the Poisson problem on the entire sphere can be found up to a constant only. In this case, Poisson Solver will compute the solution that provides the minimal Euclidean norm of a residual.

**Approximation of 2D problems**

To find an approximate solution for any of the 2D problems, in the rectangular domain a uniform mesh can be defined for the Cartesian case as:

$$\{x_i = a_x + ih_x, y_j = a_y + jh_y\},$$

$$i = 0, \dots, n_x, j = 0, \dots, n_y, h_x = \frac{b_x - a_x}{n_x}, h_y = \frac{b_y - a_y}{n_y}$$

and for the spherical case as:

$$\{\phi_i = a_\phi + ih_\phi, \theta_j = a_\theta + jh_\theta\},$$

$$i = 0, \dots, n_\phi, j = 0, \dots, n_\theta, h_\phi = \frac{b_\phi - a_\phi}{n_\phi}, h_\theta = \frac{b_\theta - a_\theta}{n_\theta}.$$

The Poisson Solver uses the standard five-point finite difference approximation on this mesh to compute the approximation to the solution:

- In the Cartesian case, the values of the approximate solution will be computed in the mesh points  $(x_i, y_j)$  provided that you can supply the values of the right-hand side  $f(x, y)$  in these points and the values of the appropriate boundary functions  $G(x, y)$  and/or  $g(x, y)$  in the mesh points laying on the boundary of the rectangular domain.
- In the spherical case, the values of the approximate solution will be computed in the mesh points  $(\phi_i, \theta_j)$  provided that you can supply the values of the right-hand side  $f(\phi, \theta)$  in these points.

**NOTE**

The number of mesh intervals  $n_\phi$  in the  $\phi$  direction of a spherical mesh must be even in the periodic case. The Poisson Solver does not support spherical meshes that do not meet this condition.

**Three-Dimensional Problems**

**Notational Conventions**

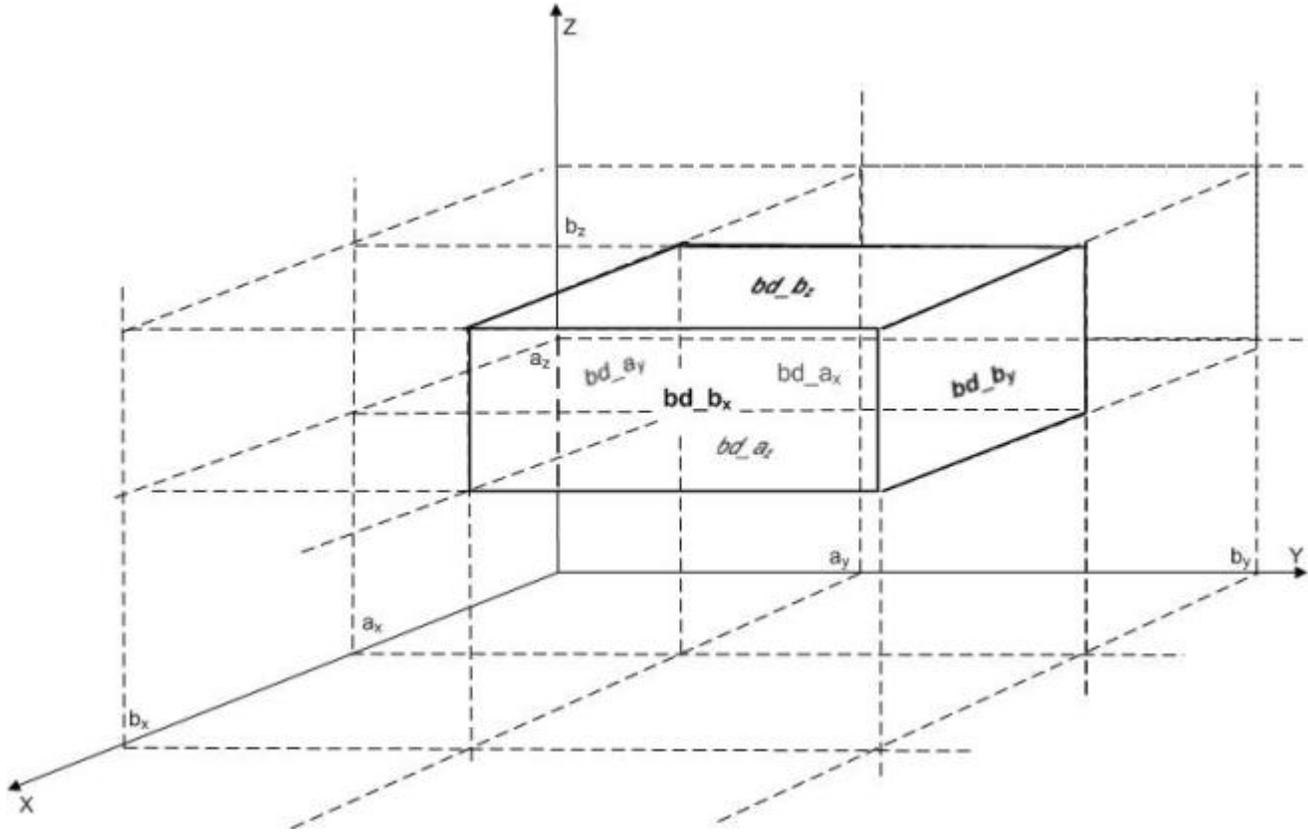

The Poisson Solver interface description uses the following notation for boundaries of a parallelepiped domain  $a_x < x < b_x, a_y < y < b_y, a_z < z < b_z$ :

$$bd\_a_x = \{x = a_x, a_y \leq y \leq b_y, a_z \leq z \leq b_z\}, bd\_b_x = \{x = b_x, a_y \leq y \leq b_y, a_z \leq z \leq b_z\},$$

$$bd\_a_y = \{a_x \leq x \leq b_x, y = a_y, a_z \leq z \leq b_z\}, bd\_b_y = \{a_x \leq x \leq b_x, y = b_y, a_z \leq z \leq b_z\},$$

$$bd\_a_z = \{a_x \leq x \leq b_x, a_y \leq y \leq b_y, z = a_z\}, bd\_b_z = \{a_x \leq x \leq b_x, a_y \leq y \leq b_y, z = b_z\}.$$

The following figure shows these boundaries:

The wildcard "+" may stand for any of the symbols  $a_x, b_x, a_y, b_y, a_z, b_z$ , so  $bd\_+$  denotes any of the above boundaries.

### Three-dimensional (3D) Helmholtz problem

The 3D Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} - \frac{\partial^2 u}{\partial z^2} + qu = f(x, y, z), \quad q = const \geq 0$$

in a parallelepiped, that is, a parallelepiped domain  $a_x < x < b_x, a_y < y < b_y, a_z < z < b_z$ , with one of the following boundary conditions on each boundary  $bd\_+$ :

- The Dirichlet boundary condition

$$u(x, y, z) = G(x, y, z)$$

- The Neumann boundary condition

$$\frac{\partial u}{\partial n}(x, y, z) = g(x, y, z)$$

where

$$n = -x \text{ on } bd\_a_x, n = x \text{ on } bd\_b_x,$$

$$n = -y \text{ on } bd_{a_y}, n = y \text{ on } bd_{b_y},$$

$$n = -z \text{ on } bd_{a_z}, n = z \text{ on } bd_{b_z}.$$

- Periodic boundary conditions

$$u(a_x, y, z) = u(b_x, y, z), \quad \frac{\partial}{\partial x} u(a_x, y, z) = \frac{\partial}{\partial x} u(b_x, y, z),$$

$$u(x, a_y, z) = u(x, b_y, z), \quad \frac{\partial}{\partial y} u(x, a_y, z) = \frac{\partial}{\partial y} u(x, b_y, z),$$

$$u(x, y, a_z) = u(x, y, b_z), \quad \frac{\partial}{\partial z} u(x, y, a_z) = \frac{\partial}{\partial z} u(x, y, b_z).$$

### Three-dimensional (3D) Poisson problem

The Poisson problem is a special case of the Helmholtz problem, when  $q=0$ . The 3D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} - \frac{\partial^2 u}{\partial z^2} = f(x, y, z)$$

in a parallelepiped  $a_x < x < b_x$ ,  $a_y < y < b_y$ ,  $a_z < z < b_z$  with the Dirichlet, Neumann, or periodic boundary conditions on each boundary  $bd_{\pm}$ .

### Three-dimensional (3D) Laplace problem

The Laplace problem is a special case of the Helmholtz problem, when  $q=0$  and  $f(x, y, z)=0$ . The 3D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0$$

in a parallelepiped  $a_x < x < b_x$ ,  $a_y < y < b_y$ ,  $a_z < z < b_z$  with the Dirichlet, Neumann, or periodic boundary conditions on each boundary  $bd_{\pm}$ .

### Approximation of 3D problems

To find an approximate solution for each of the 3D problems, a uniform mesh can be defined in the parallelepiped domain as:

$$\{x_i = a_x + ih_x, y_j = a_y + jh_y, z_k = a_z + kh_z\},$$

where

$$i = 0, \dots, n_x, \quad j = 0, \dots, n_y, \quad k = 0, \dots, n_z,$$

$$h_x = \frac{b_x - a_x}{n_x}, \quad h_y = \frac{b_y - a_y}{n_y}, \quad h_z = \frac{b_z - a_z}{n_z}.$$

The Poisson Solver uses the standard seven-point finite difference approximation on this mesh to compute the approximation to the solution. The values of the approximate solution will be computed in the mesh points  $(x_i, y_j, z_k)$ , provided that you can supply the values of the right-hand side  $f(x, y, z)$  in these points and the values of the appropriate boundary functions  $G(x, y, z)$  and/or  $g(x, y, z)$  in the mesh points laying on the boundary of the parallelepiped domain.

## Sequence of Invoking Poisson Solver Routines

### NOTE

This description always shows the solution process for the Helmholtz problem, because Fast Poisson Solvers and Fast Laplace Solvers are special cases of Fast Helmholtz Solvers (see [Poisson Solver Implementation](#)).

The Poisson Solver interface enables you to compute a solution of the Helmholtz problem in four steps. Each step is performed by a dedicated routine. [Table "Poisson Solver Interface Routines"](#) lists the routines and briefly describes their purpose.

Most Poisson Solver routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with "s" and "d". The wildcard "?" stands for either of these symbols in routine names. The routines for the Cartesian coordinate system have 2D and 3D versions. Their names end respectively in "2D" and "3D". The routines for spherical coordinate system have periodic and non-periodic versions. Their names end respectively in "p" and "np".

### Poisson Solver Interface Routines

| Routine                                                                                 | Description                                                                                                                                                             |
|-----------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np</code>         | Initializes basic data structures for Fast Helmholtz Solver in the 2D/3D/periodic/non-periodic case, respectively.                                                      |
| <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np</code> | Checks consistency and correctness of input data and initializes data structures for the solver, including those used by the Intel MKL FFT interface <sup>1</sup> .     |
| <code>?_Helmholtz_2D/?_Helmholtz_3D/?_sph_p/?_sph_np</code>                             | Computes an approximate solution of the 2D/3D/periodic/non-periodic Helmholtz problem (see <a href="#">Poisson Solver Implementation</a> ) specified by the parameters. |
| <code>free_Helmholtz_2D/free_Helmholtz_3D/free_sph_p/free_sph_np</code>                 | Releases the memory used by the data structures needed for calling the Intel MKL FFT interface <sup>1</sup> .                                                           |

<sup>1</sup> Poisson Solver routines call the Intel MKL FFT interface for better performance.

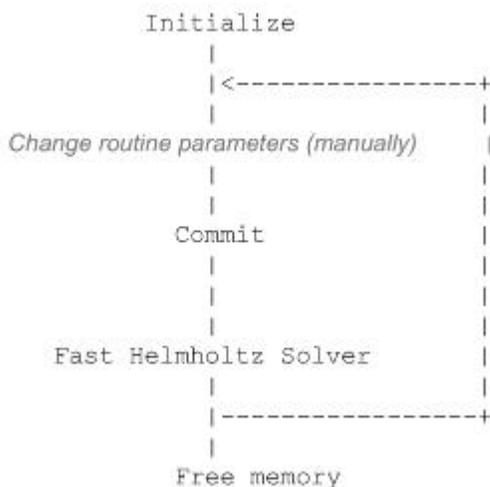

To find an approximate solution of Helmholtz problem only once, the Intel MKL Poisson Solver interface routines are normally invoked in the order in which they are listed in [Table "Poisson Solver Interface Routines"](#).

### NOTE

Though the order of invoking Poisson Solver routines may be changed, it is highly recommended to follow the above order of routine calls.

The diagram in [Figure "Typical Order of Invoking Poisson Solver Routines"](#) indicates the typical order in which Poisson Solver routines can be invoked in a general case.

### Typical Order of Invoking Poisson Solver Routines

A general scheme of using Poisson Solver routines for double-precision computations in a 3D Cartesian case is shown below. You can change this scheme to a scheme for single-precision computations by changing the initial letter of the Poisson Solver routine names from "d" to "s". You can also change the scheme below from the 3D to 2D case by changing the ending of the Poisson Solver routine names.

```

...
d_init_Helmholtz_3D(&ax, &bx, &ay, &by, &az, &bz, &nx, &ny, &nz, Bctype, ipar, dpar, &stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f. If you want to keep the data
that is stored in f, save it to another location before the function call below */
d_commit_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar, dpar,
&stat);
d_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar, dpar, &stat);
free_Helmholtz_3D (&xhandle, &yhandle, ipar, &stat);
/* here you may clean the memory used by f, dpar, ipar */
...

```

A general scheme of using Poisson Solver routines for double-precision computations in a spherical periodic case is shown below. You can change this scheme to a scheme for single-precision computations by changing the initial letter of the Poisson Solver routine names from "d" to "s". You can also change the scheme below to a scheme for a non-periodic case by changing the ending of the Poisson Solver routine names from "p" to "np".

```

...
d_init_sph_p(&ap, &bp, &at, &bt, &np, &nt, &q, ipar, dpar, &stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f. If you want to keep the data
that is stored in f, save it to another location before the function call below */
d_commit_sph_p(f, &handle_s, &handle_c, ipar, dpar, &stat);
d_sph_p(f, &handle_s, &handle_c, ipar, dpar, &stat);
free_sph_p(&handle_s, &handle_c, ipar, &stat);
/* here you may clean the memory used by f, dpar, ipar */
...

```

You can find examples of code that uses Poisson Solver routines to solve Helmholtz problem (in both Cartesian and spherical cases) in the `examples\pdepoissonc\source` folder in your Intel MKL directory.

## Fast Poisson Solver Interface Description

All numerical types in this section are either standard C types `float` and `double` or `MKL_INT` integer type. For more information on the C types, refer to [C Datatypes Specific to Intel MKL](#) and the *Intel(R) MKL Developer Guide*. To better understand usage of the types, see examples in the `examples\pdepoissonc\source` folder in your Intel MKL directory.

### Routine Options

All Poisson Solver routines use parameters for passing various options to the routines. These parameters are arrays `ipar`, `dpar`, and `spar`. Values for these parameters should be specified very carefully (see [Common Parameters](#)). You can change these values during computations to meet your needs. For more details, see the descriptions of specific routines.

---

**WARNING**

To avoid failure or incorrect results, you must provide correct and consistent parameters to the routines.

---

### User Data Arrays

Poisson Solver routines take arrays of user data as input. For example, the `d_Helmholtz_3D` routine takes user arrays to compute an approximate solution to the 3D Helmholtz problem. To minimize storage requirements and improve the overall run-time efficiency, Intel MKL Poisson Solver routines do not make copies of user input arrays.

---

**NOTE**

If you need a copy of your input data arrays, you must save them yourself.

---

For better performance, align your data arrays as recommended in the *Intel MKL Developer Guide* (search the document for coding techniques to improve performance).

## Routines for the Cartesian Solver

The section describes Poisson Solver routines for the Cartesian case, their syntax, parameters, and return values. All flavors of the same routine are described together: single- and double-precision and 2D and 3D.

---

**NOTE**

Some of the routine parameters are used only in the 3D Fast Helmholtz Solver.

---

Poisson Solver routines call Intel MKL FFT routines (described in section "[FFT Functions](#)" in chapter "Fast Fourier Transforms"), which enhance performance of the Poisson Solver routines.

### ?\_init\_Helmholtz\_2D/?\_init\_Helmholtz\_3D

*Initializes basic data structures of the Fast 2D/3D Helmholtz Solver.*

---

#### Syntax

```
void d_init_Helmholtz_2D (const double * ax, const double * bx, const double * ay,

|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>nz</i>     | MKL_INT*. The number of mesh intervals along the z-axis. This parameter is needed only for the <code>?_init_Helmholtz_3D</code> routine.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>BCtype</i> | char*. Contains the type of boundary conditions on each boundary. Must contain four characters for <code>?_init_Helmholtz_2D</code> and six characters for <code>?_init_Helmholtz_3D</code> . Each of the characters can be 'N' (Neumann boundary condition), 'D' (Dirichlet boundary condition), or 'P' (periodic boundary conditions). Specify the types of boundary conditions for the boundaries in the following order: <i>bd_ax</i> , <i>bd_bx</i> , <i>bd_ay</i> , <i>bd_by</i> , <i>bd_az</i> , and <i>bd_bz</i> . Specify periodic boundary conditions on the respective boundaries in pairs (for example, 'PPDD' or 'NNPP' in the 2D case). The types of boundary conditions for the last two boundaries are needed only in the 3D case. |
| <i>q</i>      | double* for <code>d_init_Helmholtz_2D/d_init_Helmholtz_3D</code> ,<br>float* for <code>s_init_Helmholtz_2D/s_init_Helmholtz_3D</code> .<br><br>The constant Helmholtz coefficient. Note that to solve Poisson or Laplace problem, you should set the value of <i>q</i> to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Output Parameters

|             |                                                                                                                                                                                                                                               |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ipar</i> | MKL_INT array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to <a href="#">ipar</a> ).                                                                                                           |
| <i>dpar</i> | double array of size $5 * n_x / 2 + 7$ in the 2D case or $5 * (n_x + n_y) / 2 + 9$ in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to <a href="#">dpar</a> and <a href="#">spar</a> ). |
| <i>spar</i> | float array of size $5 * n_x / 2 + 7$ in the 2D case or $5 * (n_x + n_y) / 2 + 9$ in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to <a href="#">dpar</a> and <a href="#">spar</a> ).  |
| <i>stat</i> | MKL_INT*. Routine completion status, which is also written to <code>ipar[0]</code> . Continue to call other Poisson Solver routines only if the status is 0.                                                                                  |

## Description

The `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routines initialize basic data structures for Poisson Solver computations of the appropriate precision. All routines invoked after a call to a `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine use values of the *ipar*, *dpar* and *spar* array parameters returned by the routine. Detailed description of the array parameters can be found in [Common Parameters](#).

---

### CAUTION

Data structures initialized and created by 2D flavors of the routine cannot be used by 3D flavors of any Poisson Solver routines, and vice versa.

---

You can skip calls to these routines in your code. However, see [Caveat on Parameter Modifications](#) for information on initializing the data structures.

## Return Values

`stat= 0`

The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this `stat` value.

`stat= -99999`

The routine failed to complete the task because of a fatal error.

## `_commit_Helmholtz_2D/?_commit_Helmholtz_3D`

*Checks consistency and correctness of input data and initializes certain data structures required to solve 2D/3D Helmholtz problem.*

## Syntax

```
void d_commit_Helmholtz_2D (double * f, const double * bd_ax, const double * bd_bx,
const double * bd_ay, const double * bd_by, DFTI_DESCRIPTOR_HANDLE * xhandle, MKL_INT *
ipar, double * dpar, MKL_INT * stat);
```

```
void s_commit_Helmholtz_2D (float * f, const float * bd_ax, const float * bd_bx, const
float * bd_ay, const float * bd_by, DFTI_DESCRIPTOR_HANDLE * xhandle, MKL_INT * ipar,
float * spar, MKL_INT * stat);
```

```
void d_commit_Helmholtz_3D (double * f, const double * bd_ax, const double * bd_bx,
const double * bd_ay, const double * bd_by, const double * bd_az, const double * bd_bz,
DFTI_DESCRIPTOR_HANDLE * xhandle, DFTI_DESCRIPTOR_HANDLE * yhandle, MKL_INT * ipar,
double * dpar, MKL_INT * stat);
```

```
void s_commit_Helmholtz_3D (float * f, const float * bd_ax, const float * bd_bx, const
float * bd_ay, const float * bd_by, const float * bd_az, const float * bd_bz,
DFTI_DESCRIPTOR_HANDLE * xhandle, DFTI_DESCRIPTOR_HANDLE * yhandle, MKL_INT * ipar,
float * spar, MKL_INT * stat);
```

## Include Files

- `mk1.h`

## Input Parameters

`f` double\* for `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D`,  
float\* for `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D`.

Contains the right-hand side of the problem packed in a single vector:

- 2D problem: The size of the vector for the is  $(n_x+1)*(n_y+1)$ . The value of the right-hand side in the mesh point  $(i, j)$  is stored in  $f[i+j*(n_x+1)]$ .
- 3D problem: The size of the vector for the is  $(n_x+1)*(n_y+1)*(n_z+1)$ . The value of the right-hand side in the mesh point  $(i, j, k)$  is stored in  $f[i+j*(n_x+1)+k*(n_x+1)*(n_y+1)]$ .

Note that to solve the Laplace problem, you should set all the elements of the array `f` to 0.

Note also that the array `f` may be altered by the routine. To preserve the `f` vector, save it to another memory location.

|              |                                                                                                                                                                                                                                                                                                                                                                              |

| <i>bd_az</i> | <p>double* for d_commit_Helmholtz_3D,<br/>float* for s_commit_Helmholtz_3D.</p> <p>Used only by ?_commit_Helmholtz_3D. Contains values of the boundary condition on the leftmost boundary of the domain along the z-axis (for more information, refer to <a href="#">a detailed description of bd_az</a>).</p>                                                               |
| <i>bd_bz</i> | <p>double* for d_commit_Helmholtz_3D,<br/>float* for s_commit_Helmholtz_3D.</p>                                                                                                                                                                                                                                                                                              |

Used only by `?_commit_Helmholtz_3D`. Contains values of the boundary condition on the rightmost boundary of the domain along the z-axis (for more information, refer to [a detailed description of `bd\_bz`](#)).

## Output Parameters

|                               |                                                                                                                                                                                                                                                                              |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>                | Contains right-hand side of the problem, possibly altered on output.                                                                                                                                                                                                         |
| <code>ipar</code>             | Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in <a href="#">ipar</a> .                                                                                                                                                         |
| <code>dpar</code>             | Contains double-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in <a href="#">dpar</a> and <a href="#">spar</a> .                                                                                                                       |
| <code>spar</code>             | Contains single-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in <a href="#">dpar</a> and <a href="#">spar</a> .                                                                                                                       |
| <code>xhandle, yhandle</code> | <code>DFTI_DESCRIPTOR_HANDLE*</code> . Data structures used by the Intel MKL FFT interface (for details, refer to section " <a href="#">FFT Functions</a> " in chapter "Fast Fourier Transforms"). <code>yhandle</code> is used only by <code>?_commit_Helmholtz_3D</code> . |
| <code>stat</code>             | <code>MKL_INT*</code> . Routine completion status, which is also written to <code>ipar[0]</code> . Continue to call other Poisson Solver routines only if the status is 0.                                                                                                   |

## Description

The `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routines check the consistency and correctness of the parameters to be passed to the solver routines `?_Helmholtz_2D/?_Helmholtz_3D`. They also initialize the `xhandle` and `yhandle` data structures, `ipar` array, and `dpar` or `spar` array, depending upon the routine precision. Refer to [Common Parameters](#) to find out which particular array elements the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routines initialize and to what values these elements are initialized.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of Poisson Solver routines, see [Caveat on Parameter Modifications](#). Unlike `?_init_Helmholtz_2D/?_init_Helmholtz_3D`, you must call the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routines in your code. Values of `ax`, `bx`, `ay`, `by`, `az`, and `bz` are passed to the routines with the `spar/dpar` array, and values of `nx`, `ny`, `nz`, and `BCTYPE` are passed with the `ipar` array.

## Return Values

|                           |                                                                                                                                                                                 |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>stat= 1</code>      | The routine completed without errors but with warnings.                                                                                                                         |
| <code>stat= 0</code>      | The routine successfully completed the task.                                                                                                                                    |
| <code>stat= -100</code>   | The routine stopped because an error in the input data was found, or the data in the <code>dpar</code> , <code>spar</code> , or <code>ipar</code> array was altered by mistake. |
| <code>stat= -1000</code>  | The routine stopped because of an Intel MKL FFT or TT interface error.                                                                                                          |
| <code>stat= -10000</code> | The routine stopped because the initialization failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.                                                 |

`stat= -99999`

The routine failed to complete the task because of a fatal error.

## ?\_Helmholtz\_2D/?\_Helmholtz\_3D

Computes the solution of the 2D/3D Helmholtz problem specified by the parameters.

### Syntax

```
void d_Helmholtz_2D (double * f, const double * bd_ax, const double * bd_bx, const
double * bd_ay, const double *bd_by, DFTI_DESCRIPTOR_HANDLE * xhandle, MKL_INT * ipar,
const double * dpar, MKL_INT * stat);

void s_Helmholtz_2D (float * f, const float * bd_ax, const float * bd_bx, const float *
bd_ay, const float * bd_by, DFTI_DESCRIPTOR_HANDLE * xhandle, MKL_INT * ipar, const
float * spar, MKL_INT * stat);

void d_Helmholtz_3D (double * f, const double * bd_ax, const double * bd_bx, const
double * bd_ay, const double *bd_by, const double * bd_az, const double * bd_bz,
DFTI_DESCRIPTOR_HANDLE * xhandle, DFTI_DESCRIPTOR_HANDLE * yhandle, MKL_INT * ipar,
const double * dpar, MKL_INT * stat);

void s_Helmholtz_3D (float * f, const float * bd_ax, const float * bd_bx, const float *
bd_ay, const float * bd_by, const float * bd_az, const float * bd_bz,
DFTI_DESCRIPTOR_HANDLE * xhandle, DFTI_DESCRIPTOR_HANDLE * yhandle, MKL_INT * ipar,
const float * spar, MKL_INT * stat);
```

### Include Files

- `mkl.h`

### Input Parameters

`f` double\* for `d_Helmholtz_2D/d_Helmholtz_3D`,  
float\* for `s_Helmholtz_2D/s_Helmholtz_3D`.

Contains the right-hand side of the problem packed in a single vector and modified by the appropriate `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine. Note that an attempt to substitute the original right-hand side vector, which was passed to the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine, at this point results in an incorrect solution.

- 2D problem: the size of the vector is  $(n_x+1)*(n_y+1)$ . The value of the modified right-hand side in the mesh point  $(i, j)$  is stored in  $f[i+j*(n_x+1)]$ .
- 3D problem: the size of the vector is  $(n_x+1)*(n_y+1)*(n_z+1)$ . The value of the modified right-hand side in the mesh point  $(i, j, k)$  is stored in  $f[i+j*(n_x+1)+k*(n_x+1)*(n_y+1)]$ .

`xhandle, yhandle` DFTI\_DESCRIPTOR\_HANDLE\*. Data structures used by the Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). `yhandle` is used only by `?_Helmholtz_3D`.

|              |                                                                                                                                                                                                                                                                                                                                                                          |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ipar</i>  | MKL_INT array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to <a href="#">ipar</a> ).                                                                                                                                                                                                                                      |
| <i>dpar</i>  | <p>double array of size depending on the dimension of the problem:</p> <ul style="list-style-type: none"> <li>• 2D problem: <math>5 \cdot n_x / 2 + 7</math></li> <li>• 3D problem: <math>5 \cdot (n_x + n_y) / 2 + 9</math></li> </ul> <p>Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to <a href="#">dpar and spar</a>).</p> |
| <i>spar</i>  | <p>float array of size depending on the dimension of the problem:</p> <ul style="list-style-type: none"> <li>• 2D problem: <math>5 \cdot n_x / 2 + 7</math></li> <li>• 3D problem: <math>5 \cdot (n_x + n_y) / 2 + 9</math></li> </ul> <p>Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to <a href="#">dpar and spar</a>).</p>  |
| <i>bd_ax</i> | <p>double* for d_Helmholtz_2D/d_Helmholtz_3D,<br/>float* for s_Helmholtz_2D/s_Helmholtz_3D.</p> <p>Contains values of the boundary condition on the leftmost boundary of the domain along the x-axis (for more information, refer to <a href="#">a detailed description of bd_ax</a>).</p>                                                                               |
| <i>bd_bx</i> | <p>double* for d_Helmholtz_2D/d_Helmholtz_3D,<br/>float* for s_Helmholtz_2D/s_Helmholtz_3D.</p> <p>Contains values of the boundary condition on the rightmost boundary of the domain along the x-axis (for more information, refer to <a href="#">a detailed description of bd_bx</a>).</p>                                                                              |
| <i>bd_ay</i> | <p>double* for d_Helmholtz_2D/d_Helmholtz_3D,<br/>float* for s_Helmholtz_2D/s_Helmholtz_3D.</p> <p>Contains values of the boundary condition on the leftmost boundary of the domain along the y-axis for more information, refer to <a href="#">a detailed description of bd_ay</a>).</p>                                                                                |
| <i>bd_by</i> | <p>double* for d_Helmholtz_2D/d_Helmholtz_3D,<br/>float* for s_Helmholtz_2D/s_Helmholtz_3D.</p> <p>Contains values of the boundary condition on the rightmost boundary of the domain along the y-axis (for more information, refer to <a href="#">a detailed description of bd_by</a>).</p>                                                                              |
| <i>bd_az</i> | <p>double* for d_Helmholtz_3D,<br/>float* for s_Helmholtz_3D.</p> <p>Used only by ?_Helmholtz_3D. Contains values of the boundary condition on the leftmost boundary of the domain along the z-axis (for more information, refer to <a href="#">a detailed description of bd_az</a>).</p>                                                                                |
| <i>bd_bz</i> | <p>double* for d_Helmholtz_3D,<br/>float* for s_Helmholtz_3D.</p>                                                                                                                                                                                                                                                                                                        |

Used only by `?_Helmholtz_3D`. Contains values of the boundary condition on the rightmost boundary of the domain along the z-axis (for more information, refer to [a detailed description of `bd\_bz`](#)).

---

**NOTE**

To avoid incorrect computation results, do not change arrays `bd_ax`, `bd_bx`, `bd_ay`, `bd_by`, `bd_az`, `bd_bz` between a call to the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine and a subsequent call to the appropriate `?_Helmholtz_2D/?_Helmholtz_3D` routine.

---

## Output Parameters

|                               |                                                                                                                                                              |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>                | On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input.                   |
| <code>xhandle, yhandle</code> | Data structures used by the Intel MKL FFT interface. Although the addresses do not change, the structures are modified on output.                            |
| <code>ipar</code>             | Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in <a href="#">ipar</a> .                                         |
| <code>stat</code>             | MKL_INT*. Routine completion status, which is also written to <code>ipar[0]</code> . Continue to call other Poisson Solver routines only if the status is 0. |

## Description

The `?_Helmholtz_2D/?_Helmholtz_3D` routines compute the approximate solution of the Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to formulas given in the [Poisson Solver Implementation](#) section. The `f` parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of `ax`, `bx`, `ay`, `by`, `az`, and `bz` are passed to the routines with the `spar/dpar` array, and values of `nx`, `ny`, `nz`, and `Bctype` are passed with the `ipar` array.

## Return Values

|                          |                                                                                                                                                                                |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>stat= 1</code>     | The routine completed without errors but with some warnings.                                                                                                                   |
| <code>stat= 0</code>     | The routine successfully completed the task.                                                                                                                                   |
| <code>stat= -2</code>    | The routine stopped because division by zero occurred. It usually happens if the data in the <code>dpar</code> or <code>spar</code> array was altered by mistake.              |
| <code>stat= -3</code>    | The routine stopped because the sufficient memory was unavailable for the computations.                                                                                        |
| <code>stat= -100</code>  | The routine stopped because an error in the input data was found or the data in the <code>dpar</code> , <code>spar</code> , or <code>ipar</code> array was altered by mistake. |
| <code>stat= -1000</code> | The routine stopped because of the Intel MKL FFT or TT interface error.                                                                                                        |

`stat= -10000`

The routine stopped because the initialization failed to complete or the parameter `ipar[0]` was altered by mistake.

`stat= -99999`

The routine failed to complete the task because of a fatal error.

## free\_Helmholtz\_2D/free\_Helmholtz\_3D

Releases the memory allocated for the data structures used by the FFT interface.

### Syntax

```
void free_Helmholtz_2D(DFTI_DESCRIPTOR_HANDLE* xhandle, MKL_INT* ipar, MKL_INT* stat);
void free_Helmholtz_3D(DFTI_DESCRIPTOR_HANDLE* xhandle, DFTI_DESCRIPTOR_HANDLE*
yhandle, MKL_INT* ipar, MKL_INT* stat);
```

### Include Files

- `mkl.h`

### Input Parameters

`xhandle, yhandle`

`DFTI_DESCRIPTOR_HANDLE*`. Data structures used by the Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). The structure `yhandle` is used only by `free_Helmholtz_3D`.

`ipar`

`MKL_INT` array of size 128. Contains integer data used by Fast Helmholtz Solver (for details, refer to `ipar`).

### Output Parameters

`xhandle, yhandle`

Data structures used by the Intel MKL FFT interface. Memory allocated for the structures is released on output.

`ipar`

Contains integer data used by Fast Helmholtz Solver. On output, the status of the routine call is written to `ipar[0]`.

`stat`

`MKL_INT*`. Routine completion status, which is also written to `ipar[0]`.

### Description

The `free_Helmholtz_2D-free_Helmholtz_3D` routine releases the memory used by the `xhandle` and `yhandle` structures, which are needed for calling the Intel MKL FFT functions. To release memory allocated for other parameters, include memory release statements in your code.

### Return Values

`stat= 0`

The routine successfully completed the task.

`stat= -1000`

The routine stopped because of an Intel MKL FFT or TT interface error.

`stat= -99999`

The routine failed to complete the task because of a fatal error.

## Routines for the Spherical Solver

The section describes Poisson Solver routines for the spherical case, their syntax, parameters, and return values. All flavors of the same routine are described together: single- and double-precision and periodic (having names ending in "p") and non-periodic (having names ending in "np").

These Poisson Solver routines also call the Intel MKL FFT routines (described in section "FFT Functions" in chapter "Fast Fourier Transforms"), which enhance the performance of the Poisson Solver routines.

### ?\_init\_sph\_p/?\_init\_sph\_np

*Initializes basic data structures of the periodic and non-periodic Fast Helmholtz Solver on a sphere.*

---

#### Syntax

```
void d_init_sph_p (const double * ap, const double * at, const double * bp, const
double * bt, const MKL_INT * np, const MKL_INT * nt, const double * q, MKL_INT * ipar,
double * dpar, MKL_INT * stat);
```

```
void s_init_sph_p (const float * ap, const float * at, const float * bp, const float *
bt, const MKL_INT * np, const MKL_INT * nt, const float * q, MKL_INT * ipar, float *
spar, MKL_INT * stat);
```

```
void d_init_sph_np (const double * ap, const double * at, const double * bp, const
double * bt, const MKL_INT * np, const MKL_INT * nt, const double * q, MKL_INT * ipar,
double * dpar, MKL_INT * stat);
```

```
void s_init_sph_np (const float * ap, const float * at, const float * bp, const float *
bt, const MKL_INT * np, const MKL_INT * nt, const float * q, MKL_INT * ipar, float *
spar, MKL_INT * stat);
```

#### Include Files

- `mkl.h`

#### Input Parameters

|                 |                                                                                                                                                                                                                                |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ap</code> | <p>double* for <code>d_init_sph_p/d_init_sph_np</code>,<br/>float* for <code>s_init_sph_p/s_init_sph_np</code>.</p> <p>The coordinate (angle) of the leftmost boundary of the domain along the <math>\varphi</math>-axis.</p>  |
| <code>bp</code> | <p>double* for <code>d_init_sph_p/d_init_sph_np</code>,<br/>float* for <code>s_init_sph_p/s_init_sph_np</code>.</p> <p>The coordinate (angle) of the rightmost boundary of the domain along the <math>\varphi</math>-axis.</p> |
| <code>at</code> | <p>double* for <code>d_init_sph_p/d_init_sph_np</code>,<br/>float* for <code>s_init_sph_p/s_init_sph_np</code>.</p>                                                                                                            |

|           |                                                                                                                                                                                                                        |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | The coordinate (angle) of the leftmost boundary of the domain along the $\theta$ -axis.                                                                                                                                |
| <i>bt</i> | double* for <code>d_init_sph_p/d_init_sph_np</code> ,<br>float* for <code>s_init_sph_p/s_init_sph_np</code> .<br><br>The coordinate (angle) of the rightmost boundary of the domain along the $\theta$ -axis.          |
| <i>np</i> | MKL_INT*. The number of mesh intervals along the $\varphi$ -axis. Must be even in the periodic case.                                                                                                                   |
| <i>nt</i> | MKL_INT*. The number of mesh intervals along the $\theta$ -axis.                                                                                                                                                       |
| <i>q</i>  | double* for <code>d_init_sph_p/d_init_sph_np</code> ,<br>float* for <code>s_init_sph_p/s_init_sph_np</code> .<br><br>The constant Helmholtz coefficient. To solve the Poisson problem, set the value of <i>q</i> to 0. |

## Output Parameters

|             |                                                                                                                                                                                              |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ipar</i> | MKL_INT array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to <a href="#">ipar</a> ).                                              |
| <i>dpar</i> | double array of size $5*np/2+nt+10$ . Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to <a href="#">dpar</a> and <a href="#">spar</a> ). |
| <i>spar</i> | float array of size $5*np/2+nt+10$ . Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to <a href="#">dpar</a> and <a href="#">spar</a> ).  |
| <i>stat</i> | MKL_INT*. Routine completion status, which is also written to <code>ipar[0]</code> . Continue to call other Poisson Solver routines only if the status is 0.                                 |

## Description

The `?_init_sph_p/?_init_sph_np` routines initialize basic data structures for Poisson Solver computations. All routines invoked after a call to a `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine use values of the *ipar*, *dpar*, and *spar* array parameters returned by the routine. A detailed description of the array parameters can be found in [Common Parameters](#).

---

### CAUTION

Data structures initialized and created by periodic flavors of the routine cannot be used by non-periodic flavors of any Poisson Solver routines for Helmholtz Solver on a sphere, and vice versa.

---

You can skip calls to these routines in your code. However, see [Caveat on Parameter Modifications](#) for information on initializing the data structures.

## Return Values

|                           |                                                                                                                                                       |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>stat= 0</code>      | The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this <code>stat</code> value. |
| <code>stat= -99999</code> | The routine failed to complete the task because of fatal error.                                                                                       |

## ?\_commit\_sph\_p/?\_commit\_sph\_np

*Checks consistency and correctness of input data and initializes certain data structures required to solve the periodic/non-periodic Helmholtz problem on a sphere.*

## Syntax

```
void d_commit_sph_p(double* f, DFTI_DESCRIPTOR_HANDLE* handle_s,
DFTI_DESCRIPTOR_HANDLE* handle_c, MKL_INT* ipar, double* dpar, MKL_INT* stat);
void s_commit_sph_p(float* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE*
handle_c, MKL_INT* ipar, float* spar, MKL_INT* stat);
void d_commit_sph_np(double* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, double*
dpar, MKL_INT* stat);
void s_commit_sph_np(float* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, float*
spar, MKL_INT* stat);
```

## Input Parameters

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>    | <p>double* for <code>d_commit_sph_p/d_commit_sph_np</code>,<br/>float* for <code>s_commit_sph_p/s_commit_sph_np</code>.</p> <p>Contains the right-hand side of the problem packed in a single vector. The size of the vector is <math>(np+1)*(nt+1)</math> and value of the right-hand side in the mesh point <math>(i, j)</math> is stored in <math>f[i+j*(np+1)]</math>.</p> <p>Note that the array <code>f</code> may be altered by the routine. Save this vector to another memory location if you want to preserve it.</p> |
| <code>ipar</code> | MKL_INT array of size 128. Contains integer data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to <a href="#">ipar</a> ).                                                                                                                                                                                                                                                                                                                                                                             |
| <code>dpar</code> | double array of size $5*np/2+nt+10$ . Contains double-precision data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to <a href="#">dpar</a> and <a href="#">spar</a> ).                                                                                                                                                                                                                                                                                                                                |
| <code>spar</code> | float array of size $5*np/2+nt+10$ . Contains single-precision data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to <a href="#">dpar</a> and <a href="#">spar</a> ).                                                                                                                                                                                                                                                                                                                                 |

## Output Parameters

|                                   |                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>f</i>                          | Contains the right-hand side of the problem, possibly altered on output.                                                                                                                                                                                                                                                               |
| <i>ipar</i>                       | Contains integer data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in <a href="#">ipar</a> .                                                                                                                                                                                                   |
| <i>dpar</i>                       | Contains double-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in <a href="#">dpar</a> and <a href="#">spar</a> .                                                                                                                                                                 |
| <i>spar</i>                       | Contains single-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in <a href="#">dpar</a> and <a href="#">spar</a> .                                                                                                                                                                 |
| <i>handle_s, handle_c, handle</i> | DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section " <a href="#">FFT Functions</a> " in chapter "Fast Fourier Transforms"). <i>handle_s</i> and <i>handle_c</i> are used only in <code>?_commit_sph_p</code> and <i>handle</i> is used only in <code>?_commit_sph_np</code> . |
| <i>stat</i>                       | MKL_INT*. Routine completion status, which is also written to <i>ipar</i> [0]. Continue to call other Poisson Solver routines only if the status is 0.                                                                                                                                                                                 |

## Description

The `?_commit_sph_p/?_commit_sph_np` routines check consistency and correctness of the parameters to be passed to the solver routines `?_sph_p/?_sph_np`, respectively. They also initialize certain data structures. The routine `?_commit_sph_p` initializes structures *handle\_s* and *handle\_c*, and `?_commit_sph_np` initializes *handle*. The routines also initialize the *ipar* array and *dpar* or *spar* array, depending upon the routine precision. Refer to [Common Parameters](#) to find out which particular array elements the `?_commit_sph_p/?_commit_sph_np` routines initialize and to what values these elements are initialized.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of Poisson Solver routines, see [Caveat on Parameter Modifications](#). Unlike `?_init_sph_p/?_init_sph_np`, you must call the `?_commit_sph_p/?_commit_sph_np` routines. Values of *np* and *nt* are passed to each of the routines with the *ipar* array.

## Return Values

|                      |                                                                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>stat</i> = 1      | The routine completed without errors but with warnings.                                                                                                      |
| <i>stat</i> = 0      | The routine successfully completed the task.                                                                                                                 |
| <i>stat</i> = -100   | The routine stopped because an error in the input data was found or the data in the <i>dpar</i> , <i>spar</i> , or <i>ipar</i> array was altered by mistake. |
| <i>stat</i> = -1000  | The routine stopped because of an Intel MKL FFT or TT interface error.                                                                                       |
| <i>stat</i> = -10000 | The routine stopped because the initialization failed to complete or the parameter <i>ipar</i> [0] was altered by mistake.                                   |
| <i>stat</i> = -99999 | The routine failed to complete the task because of a fatal error.                                                                                            |

## ?\_sph\_p/?\_sph\_np

Computes the solution of the spherical Helmholtz problem specified by the parameters.

### Syntax

```
void d_sph_p(double* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE* handle_c, MKL_INT* ipar, double* dpar, MKL_INT* stat);
```

```
void s_sph_p(float* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE* handle_c, MKL_INT* ipar, float* spar, MKL_INT* stat);
```

```
void d_sph_np(double* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, double* dpar, MKL_INT* stat);
```

```
void s_sph_np(float* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, float* spar, MKL_INT* stat);
```

|----------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <i>f</i> | On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input. |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------|

|                                                      |                                                                                                                                                                        |
|------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>handle_s</i> , <i>handle_c</i> ,<br><i>handle</i> | Data structures used by the Intel MKL FFT interface.                                                                                                                   |
| <i>ipar</i>                                          | Contains integer data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in <a href="#">ipar</a> .                                   |
| <i>dpar</i>                                          | Contains double-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in <a href="#">dpar</a> and <a href="#">spar</a> . |
| <i>spar</i>                                          | Contains single-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in <a href="#">dpar</a> and <a href="#">spar</a> . |
| <i>stat</i>                                          | MKL_INT*. Routine completion status, which is also written to <i>ipar[0]</i> . Continue to call other Poisson Solver routines only if the status is 0.                 |

## Description

The *sph\_p/sph\_np* routines compute the approximate solution on a sphere of the Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to the formulas given in the [Poisson Solver Implementation](#) section. The *f* parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of *np* and *nt* are passed to each of the routines with the *ipar* array.

## Return Values

|                      |                                                                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>stat</i> = 1      | The routine completed without errors but with warnings.                                                                                                      |
| <i>stat</i> = 0      | The routine successfully completed the task.                                                                                                                 |
| <i>stat</i> = -2     | The routine stopped because division by zero occurred. It usually happens if the data in the <i>dpar</i> or <i>spar</i> array was altered by mistake.        |
| <i>stat</i> = -3     | The routine stopped because the memory was insufficient to complete the computations.                                                                        |
| <i>stat</i> = -100   | The routine stopped because an error in the input data was found or the data in the <i>dpar</i> , <i>spar</i> , or <i>ipar</i> array was altered by mistake. |
| <i>stat</i> = -1000  | The routine stopped because of an Intel MKL FFT or TT interface error.                                                                                       |
| <i>stat</i> = -10000 | The routine stopped because the initialization failed to complete or the parameter <i>ipar[0]</i> was altered by mistake.                                    |
| <i>stat</i> = -99999 | The routine failed to complete the task because of a fatal error.                                                                                            |

## **free\_sph\_p/free\_sph\_np**

*Releases the memory allocated for the data structures used by the FFT interface.*

---

## Syntax

```
void free_sph_p(DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE* handle_c,
MKL_INT* ipar, MKL_INT* stat);
```

```
void free_sph_np(DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, MKL_INT* stat);
```

## Include Files

- mkl.h

## Input Parameters

*handle\_s*, *handle\_c*,  
*handle*                    DFTI\_DESCRIPTOR\_HANDLE\*. Data structures used by the Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). The structures *handle\_s* and *handle\_c* are used only in *free\_sph\_p*, and *handle* is used only in *free\_sph\_np*.

*ipar*                      MKL\_INT array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to [ipar](#)).

## Output Parameters

*handle\_s*, *handle\_c*,  
*handle*                    Data structures used by the Intel MKL FFT interface. Memory allocated for the structures is released on output.

*ipar*                      Contains integer data to be used by Fast Helmholtz Solver on a sphere. On output, the status of the routine call is written to *ipar[0]*.

*stat*                      MKL\_INT\*. Routine completion status, which is also written to *ipar[0]*.

## Description

The *free\_sph\_p/free\_sph\_np* routine releases the memory used by the *handle\_s*, *handle\_c* or *handle* structures, needed for calling the Intel MKL FFT functions. To release memory allocated for other parameters, include memory release statements in your code.

## Return Values

|                      |                                                                        |
|----------------------|------------------------------------------------------------------------|
| <i>stat</i> = 0      | The routine successfully completed the task.                           |
| <i>stat</i> = -1000  | The routine stopped because of an Intel MKL FFT or TT interface error. |
| <i>stat</i> = -99999 | The routine failed to complete the task because of a fatal error.      |

## Common Parameters for the Poisson Solver

### *ipar*

*ipar*                      MKL\_INT array of size 128, holds integer data needed for Fast Helmholtz Solver (both for Cartesian and spherical coordinate systems). Its elements are described in [Table "Elements of the ipar Array"](#):

**NOTE**

Initial values are assigned to the array parameters by the appropriate `?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np` and `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np` routines.

**Elements of the ipar Array**

| Index | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | <p>Contains status value of the last Poisson Solver routine called. In general, it should be 0 on exit from a routine to proceed with the Fast Helmholtz Solver. The element has no predefined values. This element can also be used to inform the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np</code> routines of how the Commit step of the computation should be carried out (see <a href="#">Figure "Typical Order of Invoking Poisson Solver Routines"</a>). A non-zero value of <code>ipar[0]</code> with decimal representation</p> $\overline{abc} = 100a + 10b + c$ <p>=100a+10b+c, where each of <i>a</i>, <i>b</i>, and <i>c</i> is equal to 0 or 9, indicates that some parts of the Commit step should be omitted.</p> <ul style="list-style-type: none"> <li>• If <i>c</i>=9, the routine omits checking of parameters and initialization of the data structures.</li> <li>• If <i>b</i>=9,             <ul style="list-style-type: none"> <li>• In the Cartesian case, the routine omits the adjustment of the right-hand side vector <i>f</i> to the Neumann boundary condition (multiplication of boundary values by 0.5 as well as incorporation of the boundary function <i>g</i>) and/or the Dirichlet boundary condition (setting boundary values to 0 as well as incorporation of the boundary function <i>G</i>).</li> <li>• For the Helmholtz solver on a sphere, the routine omits computation of the spherical weights for the <code>dpar/spar</code> array.</li> </ul> </li> <li>• If <i>a</i>=9, the routine omits the normalization of the right-hand side vector <i>f</i>. Depending on the solver, the normalization means:             <ul style="list-style-type: none"> <li>• 2D Cartesian case: multiplication by <math>h_y^2</math>, where <math>h_y</math> is the mesh size in the <i>y</i> direction (for details, see <a href="#">Poisson Solver Implementation</a>).</li> <li>• 3D (Cartesian) case: multiplication by <math>h_z^2</math>, where <math>h_z</math> is the mesh size in the <i>z</i> direction.</li> <li>• Helmholtz solver on a sphere: multiplication by <math>h_\theta^2</math>, where <math>h_\theta</math> is the mesh size in the <math>\theta</math> direction (for details, see <a href="#">Poisson Solver Implementation</a>).</li> </ul> </li> </ul> <p>Using <code>ipar[0]</code> you can adjust the routine to your needs and improve efficiency in solving multiple Helmholtz problems that differ only in the right-hand side. You must be cautious when using this method, because any misunderstanding of the commit process may cause incorrect results or program failure (see also <a href="#">Caveat on Parameter Modifications</a>).</p> |
| 1     | <p>Contains error messaging options:</p> <ul style="list-style-type: none"> <li>• <code>ipar[1]=-1</code> indicates that all error messages are printed to the <code>MKL_Poisson_Library_log.txt</code> file in the folder from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device (usually, screen).</li> <li>• <code>ipar[1]=0</code> indicates that no error messages will be printed.</li> <li>• <code>ipar[1]=1</code> is the default value. It indicates that all error messages are printed to the standard output device.</li> </ul> <p>In case of errors, the <code>stat</code> parameter contains a non-zero value on exit from a routine regardless of the <code>ipar[1]</code> setting.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| 9                                                           | Takes this value: <ul style="list-style-type: none"> <li>• 2, if <i>BCtype[5]='P'</i></li> <li>• 1, if <i>BCtype[5]='N'</i></li> <li>• 0, if <i>BCtype[5]='D'</i></li> <li>• -1, otherwise</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Index | Description                                                                                                                                                                                                                                                                                         |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10    | Takes the value of <ul style="list-style-type: none"> <li><math>n_x</math>, that is, the number of intervals along the <math>x</math>-axis, in the Cartesian case.</li> <li><math>n_p</math>, that is, the number of intervals along the <math>\phi</math>-axis, in the spherical case.</li> </ul>  |
| 11    | Takes the value of <ul style="list-style-type: none"> <li><math>n_y</math>, that is, the number of intervals along the <math>y</math>-axis, in the Cartesian case</li> <li><math>n_t</math>, that is, the number of intervals along the <math>\theta</math>-axis, in the spherical case.</li> </ul> |
| 12    | Takes the value of $n_z$ , the number of intervals along the $z$ -axis. This parameter is used only in the 3D case (Cartesian).                                                                                                                                                                     |
| 13    | Has the value of 6, which specifies the internal partitioning of the $dpar/spar$ array.                                                                                                                                                                                                             |
| 14    | Takes the value of $ipar[13]+ipar[10]+1$ , which specifies the internal partitioning of the $dpar/spar$ array.                                                                                                                                                                                      |

The values of  $ipar[15] - ipar[20]$  depend on the dimension of the problem for the Cartesian solver or on whether the solver on a sphere is periodic.

|    | Cartesian Solver                                                                                                   |                                                                                                                    | Spherical Solver                                                                                                   |                                                                                                                    |

| 40<br>through<br>59   | Contain the first twenty elements of the <code>ipar</code> array of the first Trigonometric Transform that the solver uses. (For details, see <a href="#">Common Parameters</a> in the "Trigonometric Transform Routines" section.)                                                                                                    |
| 60<br>through<br>79   | Contain the first twenty elements of the <code>ipar</code> array of the second Trigonometric Transform that the 3D Cartesian and periodic spherical solvers use. (For details, see <a href="#">Common Parameters</a> in the "Trigonometric Transform Routines" section.)                                                               |
| 80<br>through<br>99   | Contain the first twenty elements of the <code>ipar</code> array of the third Trigonometric Transform that the solver uses in case of periodic boundary conditions along the <i>x</i> -axis. (For details, see <a href="#">Common Parameters</a> in the "Trigonometric Transform Routines" section.)                                   |
| 100<br>through<br>119 | Contain the first twenty elements of the <code>ipar</code> array of the fourth Trigonometric Transform used by periodic spherical solvers and 3D Cartesian solvers with periodic boundary conditions along the <i>y</i> -axis. (For details, see <a href="#">Common Parameters</a> in the "Trigonometric Transform Routines" section.) |

**NOTE**

While you can declare the `ipar` array as `MKL_INT ipar[120]`, for future compatibility you should declare `ipar` as `MKL_INT ipar[128]`.

**dpar and spar**

Arrays `dpar` and `spar` are the same except in the data precision:

- `dpar` Holds data needed for double-precision Fast Helmholtz Solver computations.
- For the Cartesian solver, `double` array of size  $5 \cdot n_x / 2 + 7$  in the 2D case or  $5 \cdot (n_x + n_y) / 2 + 9$  in the 3D case; initialized in the `d_init_Helmholtz_2D/`, `d_init_Helmholtz_3D` and `d_commit_Helmholtz_2D/`, `d_commit_Helmholtz_3D` routines.

- For the spherical solver, `double` array of size  $5*nx/2+nt+10$ ; initialized in the `d_init_sph_p/d_init_sph_np` and `d_commit_sph_p/d_commit_sph_np` routines.

*spar*

Holds data needed for single-precision Fast Helmholtz Solver computations.

- For the Cartesian solver, `float` array of size  $5*nx/2+7$  in the 2D case or  $5*(nx+ny)/2+9$  in the 3D case; initialized in the `s_init_Helmholtz_2D/s_init_Helmholtz_3D` and `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D` routines.
- For the spherical solver, `float` array of size  $5*nx/2+nt+10$ ; initialized in the `s_init_sph_p/s_init_sph_np` and `s_commit_sph_p/s_commit_sph_np` routines.

Because *dpar* and *spar* have similar elements in each position, the elements are described together in [Table "Elements of the dpar and spar Arrays"](#):

**Elements of the dpar and spar Arrays**

| Index | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**NOTE**

You may define the array size depending upon the type of the problem to solve.

## Caveat on Parameter Modifications

Flexibility of the Poisson Solver interface enables you to skip calls to the `?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np` routine and to initialize the basic data structures explicitly in your code. You may also need to modify contents of the `ipar`, `dpar`, and `spar` arrays after initialization. When doing so, provide correct and consistent data in the arrays. Mistakenly altered arrays cause errors or incorrect results. You can perform a basic check for correctness and consistency of parameters by calling the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine; however, this does not ensure the correct solution but only reduces the chance of errors or wrong results.

---

### NOTE

To supply correct and consistent parameters to Poisson Solver routines, you should have considerable experience in using the Poisson Solver interface and good understanding of the solution process, as well as elements contained in the `ipar`, `spar`, and `dpar` arrays and dependencies between values of these elements.

---

In rare occurrences when you fail in tuning parameters for the Fast Helmholtz Solver, refer for technical support at <http://www.intel.com/software/products/support/>.

---

### WARNING

The only way that ensures a proper solution of a Helmholtz problem is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of `ipar`, `dpar`, and `spar` arrays unless it is necessary.

---

## Parameters That Define Boundary Conditions

Poisson Solver routines for the Cartesian solver use the following common parameters to define the boundary conditions.

### Parameters to Define Boundary Conditions for the Cartesian Solver

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

---

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

---

The values are packed in the array so that the value corresponding to indices  $(j, k)$  is placed in  $bd\_ax[j+k*(ny+1)]$ .

For periodic boundary conditions (the value of  $BCtype[0]$  is 'P'), this parameter is not used, so it can accept a dummy pointer.

*bd\_bx* double\* for `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D` and `d_Helmholtz_2D/d_Helmholtz_3D`,

float\* for `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D` and `s_Helmholtz_2D/s_Helmholtz_3D`.

Contains values of the boundary condition on the rightmost boundary of the domain along the x-axis.

- 2D problem: the size of the array is  $ny+1$ . Its contents depend on the boundary conditions as follows:
  - Dirichlet boundary condition (value of  $BCtype[1]$  is 'D'): values of the function  $G(bx, y_j), j=0, \dots, ny$ .
  - Neumann boundary condition (value of  $BCtype[1]$  is 'N'): values of the function  $g(bx, y_j), j=0, \dots, ny$ .

The value corresponding to the index  $j$  is placed in  $bd\_bx[j]$ .

- 3D problem: the size of the array is  $(ny+1)*(nz+1)$ . Its contents depend on the boundary conditions as follows:
  - Dirichlet boundary condition (value of  $BCtype[1]$  is 'D'): values of the function  $G(bx, y_j, z_k), j=0, \dots, ny, k=0, \dots, nz$ .
  - Neumann boundary condition (value of  $BCtype[1]$  is 'N'): values of the function  $g(bx, y_j, z_k), j=0, \dots, ny, k=0, \dots, nz$ .

The values are packed in the array so that the value corresponding to indices  $(j, k)$  is placed in  $bd\_bx[j+k*(ny+1)]$ .

For periodic boundary conditions (the value of  $BCtype[1]$  is 'P'), this parameter is not used, so it can accept a dummy pointer.

*bd\_ay* double\* for `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D` and `d_Helmholtz_2D/d_Helmholtz_3D`,

float\* for `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D` and `s_Helmholtz_2D/s_Helmholtz_3D`.

Contains values of the boundary condition on the leftmost boundary of the domain along the y-axis.

- 2D problem: the size of the array is  $nx+1$ . Its contents depend on the boundary conditions as follows:
  - Dirichlet boundary condition (value of  $BCtype[2]$  is 'D'): values of the function  $G(x_i, ay), i=0, \dots, nx$ .
  - Neumann boundary condition (value of  $BCtype[2]$  is 'N'): values of the function  $g(x_i, ay), i=0, \dots, nx$ .

The value corresponding to the index  $i$  is placed in  $bd\_ay[i]$ .

- 3D problem: the size of the array is  $(nx+1)*(nz+1)$ . Its contents depend on the boundary conditions as follows:
  - Dirichlet boundary condition (value of  $BCtype[2]$  is 'D'): values of the function  $G(x_i, ay, z_k), i=0, \dots, nx, k=0, \dots, nz$ .
  - Neumann boundary condition (value of  $BCtype[2]$  is 'N'): values of the function  $g(x_i, ay, z_k), i=0, \dots, nx, k=0, \dots, nz$ .

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

### Poisson Solver Implementation Details

Several aspects of the Intel MKL Poisson Solver interface are platform-specific and language-specific. To promote portability of the Intel MKL Poisson Solver interface across platforms and ease of use across different languages, Intel MKL provides you with the Poisson Solver language-specific header file to include in your code:

- `mkl_poisson.h`, to be used together with `mkl_dfti.h`.

#### NOTE

- Use of the Intel MKL Poisson Solver software without including the above language-specific header files is not supported.

### Header File

The header file defines the function prototypes for the Cartesian and spherical solver available in specific function descriptions.

# Nonlinear Optimization Problem Solvers

# 12

Intel® Math Kernel Library (Intel® MKL) provides tools for solving nonlinear least squares problems using the Trust-Region (TR) algorithms. The solver routines are grouped according to their purpose as follows:

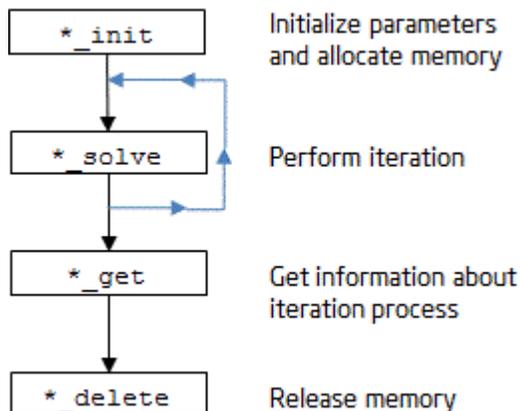

- [Nonlinear Least Squares Problem without Constraints](#)
- [Nonlinear Least Squares Problem with Linear \(Boundary\) Constraints](#)
- [Jacobian Matrix Calculation Routines](#)

For more information on the key concepts required to understand the use of the Intel MKL nonlinear least squares problem solver routines, see [\[Conn00\]](#).

## Nonlinear Solver Organization and Implementation

The Intel MKL solver routines for nonlinear least squares problems use reverse communication interfaces (RCI). That means you need to provide the solver with information required for the iteration process, for example, the corresponding Jacobian matrix, or values of the objective function. RCI removes the dependency of the solver on specific implementation of the operations. However, it does require that you organize a computational loop.

### Typical order for invoking RCI solver routines

The nonlinear least squares problem solver routines, or Trust-Region (TR) solvers, are implemented with threading support. You can manage the threads using [Threading Control Functions](#). The TR solvers use BLAS and LAPACK routines, and offer the same parallelism as those domains. The `?jacobi` and `?jacobix` routines of Jacobian matrix calculations are parallel. These routines (`?jacobi` and `?jacobix`) make calls to the user-supplied functions with different  $x$  parameters for multiple threads.

### Memory Allocation and Handles

To make the TR solver routines easy to use, you are not required to allocate temporary working storage. The solver allocates any required memory. To allow multiple users to access the solver simultaneously, the solver keeps track of the storage allocated for a particular application by using a data object called a *handle*. Each TR solver routine creates, uses, or deletes a handle. To declare a handle, include `mk1.h`.

Declare a handle as one of the following:

```
#include "mkl.h"
_TRNSP_HANDLE_t handle;
```

or

```
_TRNSPBC_HANDLE_t handle;
```

The first declaration is used for nonlinear least squares problems without boundary constraints, and the second is used for nonlinear least squares problems with boundary constraints.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## Nonlinear Solver Routine Naming Conventions

The TR routine names have the following structure:

```
<character><name>_<action>()
```

where

- *<character>* indicates the data type:

|   |        |
|---|--------|
| s | float  |
| d | double |

- *<name>* indicates the task type:

|          |                                                              |
|----------|--------------------------------------------------------------|
| trnlsp   | nonlinear least squares problem without constraints          |
| trnlspbc | nonlinear least squares problem with boundary constraints    |
| jacobi   | computation of the Jacobian matrix using central differences |

- *<action>* indicates an action on the task:

|        |                                                                                                      |
|--------|------------------------------------------------------------------------------------------------------|
| init   | initializes the solver                                                                               |
| check  | checks correctness of the input parameters                                                           |
| solve  | solves the problem                                                                                   |
| get    | retrieves the number of iterations, the stop criterion, the initial residual, and the final residual |
| delete | releases the allocated data                                                                          |

## Nonlinear Least Squares Problem without Constraints

The nonlinear least squares problem without constraints can be described as follows:

$$\min_{x \in \mathbb{R}^n} \|F(x)\|_2^2 = \min_{x \in \mathbb{R}^n} \|y - f(x)\|_2^2, y \in \mathbb{R}^m, x \in \mathbb{R}^n, f: \mathbb{R}^n \rightarrow \mathbb{R}^m, m \geq n,$$

where

$F(x) : \mathbb{R}^n \rightarrow \mathbb{R}^m$  is a twice differentiable function in  $\mathbb{R}^n$ .

Solving a nonlinear least squares problem means searching for the best approximation to the vector  $y$  with the model function  $f_i(x)$  and nonlinear variables  $x$ . The best approximation means that the sum of squares of residuals  $y_i - f_i(x)$  is the minimum.

See usage examples in the `examples\solverc\source` folder of your Intel MKL directory. Specifically, see `ex_nlsqp_c.c`.

### RCI TR Routines

| Routine Name                | Operation                                                                                 |
|-----------------------------|-------------------------------------------------------------------------------------------|
| <code>?trnlsp_init</code>   | Initializes the solver.                                                                   |
| <code>?trnlsp_check</code>  | Checks correctness of the input parameters.                                               |
| <code>?trnlsp_solve</code>  | Solves a nonlinear least squares problem using the Trust-Region algorithm.                |
| <code>?trnlsp_get</code>    | Retrieves the number of iterations, stop criterion, initial residual, and final residual. |
| <code>?trnlsp_delete</code> | Releases allocated data.                                                                  |

### ?trnlsp\_init

Initializes the solver of a nonlinear least squares problem.

#### Syntax

```
MKL_INT strnlsp_init (_TRNSP_HANDLE_t* &handle, const MKL_INT* &n, const MKL_INT* &m,
const float* x, const float* &eps, const MKL_INT* &iter1, const MKL_INT* &iter2, const
float* &rs);
```

```
MKL_INT dtrnlsp_init (_TRNSP_HANDLE_t* &handle, MKL_INT* &n, const MKL_INT* &m, const
double* x, const double* &eps, const MKL_INT* &iter1, const MKL_INT* &iter2, const
double* &rs);
```

#### Include Files

- `mkl.h`

#### Description

The `?trnlsp_init` routine initializes the solver.

After initialization, all subsequent invocations of the `?trnlsp_solve` routine should use the values of the `handle` returned by `?trnlsp_init`.

The `eps` array contains a number indicating the stopping criteria:

| <i>eps</i> Value | Description                                                                                                                 |
|------------------|-----------------------------------------------------------------------------------------------------------------------------|
| 0                | $\Delta < eps[0]$                                                                                                           |
| 1                | $  F(x)  _2 < eps[1]$                                                                                                       |
| 2                | The Jacobian matrix is singular.<br>$  J(x)_{[m*(j-1)...m*j-1]}  _2 < eps[2], j = 1, \dots, n$                              |
| 3                | $  s  _2 < eps[3]$                                                                                                          |
| 4                | $  F(x)  _2 -   F(x) - J(x)s  _2 < eps[4]$                                                                                  |
| 5                | The trial step precision. If $eps[5] = 0$ , then the trial step meets the required precision ( $\leq 1.0 \cdot 10^{-10}$ ). |

**Note:**

- $J(x)$  is the Jacobian matrix.
- $\Delta$  is the trust-region area.
- $F(x)$  is the value of the functional.
- $s$  is the trial step.

### Input Parameters

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>     | Length of $x$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>m</i>     | Length of $F(x)$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>x</i>     | Array of size $n$ . Initial guess.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>eps</i>   | Array of size 6; contains stopping criteria. See the values in the Description section.                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>iter1</i> | Specifies the maximum number of iterations.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>iter2</i> | Specifies the maximum number of iterations of trial step calculation.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>rs</i>    | Definition of initial size of the trust region (boundary of the trial step). The recommend minimum value is 0.1, and the recommended maximum value is 100.0. Based on your knowledge of the objective function and initial guess you can increase or decrease the initial trust region. It can influence the iteration process, for example, the direction of the iteration process and the number of iterations. If you set <i>rs</i> to 0.0, the solver uses the default value, which is 100.0. |

### Output Parameters

|               |                                                                                                                                                                                                                                                                                                                                               |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>handle</i> | Type <code>_TRNSP_HANDLE_t</code> .                                                                                                                                                                                                                                                                                                           |
| <i>res</i>    | Indicates task completion status. <ul style="list-style-type: none"> <li>• <math>res = TR\_SUCCESS</math> - the routine completed the task normally.</li> <li>• <math>res = TR\_INVALID\_OPTION</math> - there was an error in the input parameters.</li> <li>• <math>res = TR\_OUT\_OF\_MEMORY</math> - there was a memory error.</li> </ul> |

TR\_SUCCESS, TR\_INVALID\_OPTION, and TR\_OUT\_OF\_MEMORY are defined in the mkl\_rci.h include file.

**See Also**

?trnlsp\_solve

**?trnlsp\_check**

Checks the correctness of handle and arrays containing Jacobian matrix, objective function, and stopping criteria.

**Syntax**

```
MKL_INT strnlsp_check (_TRNSP_HANDLE_t* &handle, const MKL_INT* &n, const MKL_INT* &m,
const float* fjac, const float* fvec, const float* eps, MKL_INT* info);
```

```
MKL_INT dtrnlsp_check (_TRNSP_HANDLE_t* &handle, const MKL_INT* &n, const MKL_INT* &m,
const double* fjac, const double* fvec, const double* eps, MKL_INT* info);
```

**Include Files**

- mkl.h

**Description**

The ?trnlsp\_check routine checks the arrays passed into the solver as input parameters. If an array contains any INF or NaN values, the routine sets the flag in output array info (see the description of the values returned in the Output Parameters section for the info array).

**Input Parameters**

|               |                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------|
| <i>handle</i> | Type <code>_TRNSPBC_HANDLE_t</code> .                                                                        |
| <i>n</i>      | Length of <i>x</i> .                                                                                         |
| <i>m</i>      | Length of <i>F(x)</i> .                                                                                      |
| <i>fjac</i>   | Array of size <i>m</i> by <i>n</i> . Contains the Jacobian matrix of the function.                           |
| <i>fvec</i>   | Array of size <i>m</i> . Contains the function values at <i>x</i> , where $fvec[i] = (y_i - \hat{f}_i(x))$ . |
| <i>eps</i>    | Array of size 6; contains stopping criteria. See the values in the Description section of the ?trnlsp_init.  |

**Output Parameters**

*info* Array of size 6.  
Results of input parameter checking:

| Parameter       | Used for                | Value | Description                  |
|-----------------|-------------------------|-------|------------------------------|
| <i>info</i> [0] | Flags for <i>handle</i> | 0     | The handle is valid.         |
|                 |                         | 1     | The handle is not allocated. |

| Parameter       | Used for              | Value | Description                                                       |
|-----------------|-----------------------|-------|-------------------------------------------------------------------|
| <i>info</i> [1] | Flags for <i>fjac</i> | 0     | The <i>fjac</i> array is valid.                                   |

|                 |                       | 2     | The <i>fjac</i> array contains NaN.                               |
|                 |                       | 3     | The <i>fjac</i> array contains Inf.                               |
| <i>info</i> [2] | Flags for <i>fvec</i> | 0     | The <i>fvec</i> array is valid.                                   |
|                 |                       | 1     | The <i>fvec</i> array is not allocated                            |
|                 |                       | 2     | The <i>fvec</i> array contains NaN.                               |
|                 |                       | 3     | The <i>fvec</i> array contains Inf.                               |
| <i>info</i> [3] | Flags for <i>eps</i>  | 0     | The <i>eps</i> array is valid.                                    |
|                 |                       | 1     | The <i>eps</i> array is not allocated                             |
|                 |                       | 2     | The <i>eps</i> array contains NaN.                                |
|                 |                       | 3     | The <i>eps</i> array contains Inf.                                |
|                 |                       | 4     | The <i>eps</i> array contains a value less than or equal to zero. |

*res*

Information about completion of the task.

*res* = TR\_SUCCESS - the routine completed the task normally.

TR\_SUCCESS is defined in the `mkl_rci.h` include file.

## ?trnlsp\_solve

Solves a nonlinear least squares problem using the TR algorithm.

### Syntax

```
MKL_INT strnlsp_solve (_TRNSP_HANDLE_t* &handle, float* fvec, float* fjac, MKL_INT* &RCI_Request);
```

```
MKL_INT dtrnlsp_solve (_TRNSP_HANDLE_t* &handle, double* fvec, double* fjac, MKL_INT* &RCI_Request);
```

### Include Files

- `mkl.h`

### Description

The ?trnlsp\_solve routine uses the TR algorithm to solve nonlinear least squares problems.

The problem is stated as follows:

$$\min_{x \in \mathbb{R}^n} \|F(x)\|_2^2 = \min_{x \in \mathbb{R}^n} \|y - f(x)\|_2^2, y \in \mathbb{R}^m, x \in \mathbb{R}^n, f: \mathbb{R}^n \rightarrow \mathbb{R}^m, m \geq n,$$

where

- $F(x) : \mathbb{R}^n \rightarrow \mathbb{R}^m$
- $m \geq n$

From a current point  $x_{current}$ , the algorithm uses the trust-region approach:

$$\min_{x \in \mathbb{R}^n} \left\| F(x_{current}) + J(x_{current})(x_{new} - x_{current}) \right\|_2^2 \quad \text{subject to} \quad \|x_{new} - x_{current}\| \leq \Delta_{current}$$

to get  $x_{new} = x_{current} + s$  that satisfies

$$\min_{s \in \mathbb{R}^n} \left\| J^T(x)J(x)s + J^T F(x) \right\|_2^2$$

where

- $J(x)$  is the Jacobian matrix
- $s$  is the trial step
- $\|s\|_2 \leq \Delta_{current}$

The *RCI\_Request* parameter provides additional information:

| <i>RCI_Request</i> Value | Description                                                                                                             |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------|
| 2                        | Request to calculate the Jacobian matrix and put the result into <i>fjac</i>                                            |
| 1                        | Request to recalculate the function at vector $x$ and put the result into <i>fvec</i>                                   |
| 0                        | One successful iteration step on the current trust-region radius (that does not mean that the value of $x$ has changed) |
| -1                       | The algorithm has exceeded the maximum number of iterations                                                             |
| -2                       | $\Delta < eps[0]$                                                                                                       |
| -3                       | $\ F(x)\ _2 < eps[1]$                                                                                                   |
| -4                       | The Jacobian matrix is singular.<br>$\ J(x)_{[m*(j-1)...m*j-1]}\ _2 < eps[2], j = 1, \dots, n$                          |
| -5                       | $\ s\ _2 < eps[3]$                                                                                                      |
| -6                       | $\ F(x)\ _2 - \ F(x) - J(x)s\ _2 < eps[4]$                                                                              |

Note:

- $J(x)$  is the Jacobian matrix.
- $\Delta$  is the trust-region area.
- $F(x)$  is the value of the functional.
- $s$  is the trial step.

## Input Parameters

|               |                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------|
| <i>handle</i> | Type <code>_TRNSP_HANDLE_t</code> .                                                                    |
| <i>fvec</i>   | Array of size <i>m</i> . Contains the function values at <i>x</i> , where $fvec[i] = (y_i - f_i(x))$ . |
| <i>fjac</i>   | Array of size <i>m</i> by <i>n</i> . Contains the Jacobian matrix of the function.                     |

## Output Parameters

|                    |                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>fvec</i>        | Array of size <i>m</i> . Updated function evaluated at <i>x</i> .                                                                                                                                                  |
| <i>RCI_Request</i> | <p>Informs about the task stage.</p> <p>See the Description section for the parameter values and their meaning.</p>                                                                                                |
| <i>res</i>         | <p>Indicates the task completion.</p> <p><i>res</i> = <code>TR_SUCCESS</code> - the routine completed the task normally.</p> <p><code>TR_SUCCESS</code> is defined in the <code>mkl_rci.h</code> include file.</p> |

## ?trnlsp\_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

### Syntax

```
MKL_INT strnlsp_get(_TRNSP_HANDLE_t* &handle, MKL_INT* &iter, MKL_INT* &st_cr, float* &r1, float* &r2);
```

```
MKL_INT dtrnlsp_get (_TRNSP_HANDLE_t* &handle, MKL_INT* &iter, MKL_INT* &st_cr, double* &r1, double* &r2);
```

### Include Files

- `mkl.h`

### Description

The routine retrieves the current number of iterations, the stop criterion, the initial residual, and final residual.

The initial residual is the value of the functional  $(\|y - f(x)\|)$  of the initial *x* values provided by the user.

The final residual is the value of the functional  $(\|y - f(x)\|)$  of the final *x* resulting from the algorithm operation.

The *st\_cr* parameter contains a number indicating the stop criterion:

| <i>st_cr</i> Value | Description                                                 |
|--------------------|-------------------------------------------------------------|
| 1                  | The algorithm has exceeded the maximum number of iterations |
| 2                  | $\Delta < eps[0]$                                           |
| 3                  | $\ F(x)\ _2 < eps[1]$                                       |
| 4                  | The Jacobian matrix is singular.                            |

| <i>st_cr</i> Value | Description                                                |
|--------------------|------------------------------------------------------------|
|                    | $  J(x)_{[m*(j-1)...m*j-1]}  _2 < eps[2], j = 1, \dots, n$ |
| 5                  | $  s  _2 < eps[3]$                                         |
| 6                  | $  F(x)  _2 -   F(x) - J(x)s  _2 < eps[4]$                 |

Note:

- $J(x)$  is the Jacobian matrix.
- $\Delta$  is the trust-region area.
- $F(x)$  is the value of the functional.
- $s$  is the trial step.

### Input Parameters

*handle* Type `_TRNSP_HANDLE_t`.

### Output Parameters

*iter* Contains the current number of iterations.

*st\_cr* Contains the stop criterion.  
See the Description section for the parameter values and their meanings.

*r1* Contains the residual,  $(||y - f(x)||)$  given the initial  $x$ .

*r2* Contains the final residual, that is, the value of the functional  $(||y - f(x)||)$  of the final  $x$  resulting from the algorithm operation.

*res* Indicates the task completion.  
`res = TR_SUCCESS` - the routine completed the task normally.  
`TR_SUCCESS` is defined in the `mkl_rci.h` include file.

### ?trnlsp\_delete

*Releases allocated data.*

#### Syntax

```
MKL_INT strnlsp_delete(_TRNSP_HANDLE_t* &handle);
MKL_INT dtrnlsp_delete(_TRNSP_HANDLE_t* &handle);
```

#### Include Files

- `mkl.h`

#### Description

The `?trnlsp_delete` routine releases all memory allocated for the handle.

This routine flags memory as not used, but to actually release all memory you must call the support function [mkl\\_free\\_buffers](#).

## Input Parameters

*handle* Type `_TRNSP_HANDLE_t`.

## Output Parameters

*res* Indicates the task completion.  
*res* = `TR_SUCCESS` means the routine completed the task normally.  
`TR_SUCCESS` is defined in the `mkl_rci.h` include file.

# Nonlinear Least Squares Problem with Linear (Bound) Constraints

The nonlinear least squares problem with linear bound constraints is very similar to the [nonlinear least squares problem without constraints](#) but it has the following constraints:

$$l_i \leq x_i \leq u_i, i = 1, \dots, n, \quad l, u \in R^n.$$

See usage examples in the `examples\solverc\source` folder of your Intel MKL directory. Specifically, see `ex_nlsqp_bc_c.c`.

## RCI TR Routines for Problem with Bound Constraints

| Routine Name                  | Operation                                                                                 |
|-------------------------------|-------------------------------------------------------------------------------------------|
| <code>?trnlspsc_init</code>   | Initializes the solver.                                                                   |
| <code>?trnlspsc_check</code>  | Checks correctness of the input parameters.                                               |
| <code>?trnlspsc_solve</code>  | Solves a nonlinear least squares problem using RCI and the Trust-Region algorithm.        |
| <code>?trnlspsc_get</code>    | Retrieves the number of iterations, stop criterion, initial residual, and final residual. |
| <code>?trnlspsc_delete</code> | Releases allocated data.                                                                  |

### ?trnlspsc\_init

*Initializes the solver of nonlinear least squares problem with linear (boundary) constraints.*

#### Syntax

```
MKL_INT strnlspsc_init (_TRNSPBC_HANDLE_t* &handle, const MKL_INT* &n, const MKL_INT* &m, const float* x, const float* LW, const float* UP, const float* eps, const MKL_INT* &iter1, const MKL_INT* &iter2, const float* &rs);

MKL_INT dtrnlspsc_init (_TRNSPBC_HANDLE_t* &handle, const MKL_INT* &n, const MKL_INT* &m, const double* x, const double* LW, const double* UP, const double* eps, const MKL_INT* &iter1, const MKL_INT* &iter2, const double* &rs);
```

## Include Files

- `mkl.h`

## Description

The `?trnlspbc_init` routine initializes the solver.

After initialization all subsequent invocations of the `?trnlspbc_solve` routine should use the values of the handle returned by `?trnlspbc_init`.

The `eps` array contains a number indicating the stopping criteria:

| <code>eps</code> Value | Description                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| 0                      | $\Delta < eps[0]$                                                                                                           |
| 1                      | $\ F(x)\ _2 < eps[1]$                                                                                                       |
| 2                      | The Jacobian matrix is singular.<br>$\ J(x)_{[m*(j-1)...m*j-1]}\ _2 < eps[2], j = 1, \dots, n$                              |
| 3                      | $\ s\ _2 < eps[3]$                                                                                                          |
| 4                      | $\ F(x)\ _2 - \ F(x) - J(x)s\ _2 < eps[4]$                                                                                  |
| 5                      | The trial step precision. If $eps[5] = 0$ , then the trial step meets the required precision ( $\leq 1.0 \cdot 10^{-10}$ ). |

Note:

- $J(x)$  is the Jacobian matrix.
- $\Delta$  is the trust-region area.
- $F(x)$  is the value of the functional.
- $s$  is the trial step.

## Input Parameters

|                    |                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------|
| <code>n</code>     | Length of $x$ .                                                                         |
| <code>m</code>     | Length of $F(x)$ .                                                                      |
| <code>x</code>     | Array of size $n$ . Initial guess.                                                      |
| <code>LW</code>    | Array of size $n$ .<br>Contains low bounds for $x$ ( $lw_i < x_i$ ).                    |
| <code>UP</code>    | Array of size $n$ .<br>Contains upper bounds for $x$ ( $up_i > x_i$ ).                  |
| <code>eps</code>   | Array of size 6; contains stopping criteria. See the values in the Description section. |
| <code>iter1</code> | Specifies the maximum number of iterations.                                             |
| <code>iter2</code> | Specifies the maximum number of iterations of trial step calculation.                   |

*rs* Definition of initial size of the trust region (boundary of the trial step). The recommended minimum value is 0.1, and the recommended maximum value is 100.0. Based on your knowledge of the objective function and initial guess you can increase or decrease the initial trust region. It can influence the iteration process, for example, the direction of the iteration process and the number of iterations. If you set *rs* to 0.0, the solver uses the default value, which is 100.0.

## Output Parameters

*handle* Type `_TRNSPBC_HANDLE_t`.

*res* Informs about the task completion.

- *res* = `TR_SUCCESS` - the routine completed the task normally.
- *res* = `TR_INVALID_OPTION` - there was an error in the input parameters.
- *res* = `TR_OUT_OF_MEMORY` - there was a memory error.

`TR_SUCCESS`, `TR_INVALID_OPTION`, and `TR_OUT_OF_MEMORY` are defined in the `mkl_rci.h` include file.

## ?trnlspsc\_check

*Checks the correctness of handle and arrays containing Jacobian matrix, objective function, lower and upper bounds, and stopping criteria.*

---

### Syntax

```
MKL_INT strnlspsc_check (_TRNSPBC_HANDLE_t* &handle, const MKL_INT* &n, const MKL_INT* &m, const float* fjac, const float* fvec, const float* LW, const float* UP, const float* eps, MKL_INT* info);
```

```
MKL_INT dtrnlspsc_check (_TRNSPBC_HANDLE_t* &handle, const MKL_INT* &n, const MKL_INT* &m, const double* fjac, const double* fvec, const double* LW, const double* UP, const double* eps, MKL_INT* info);
```

### Include Files

- `mkl.h`

### Description

The `?trnlspsc_check` routine checks the arrays passed into the solver as input parameters. If an array contains any `INF` or `NaN` values, the routine sets the flag in output array *info* (see the description of the values returned in the Output Parameters section for the *info* array).

### Input Parameters

*handle* Type `_TRNSPBC_HANDLE_t`.

*n* Length of *x*.

*m* Length of *F(x)*.

*fjac* Array of size *m* by *n*. Contains the Jacobian matrix of the function.

|             |                                                                                                                                |
|-------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>fvec</i> | Array of size $m$ . Contains the function values at $x$ , where $fvec[i] = (y_i - f_i(x))$ .                                   |
| <i>LW</i>   | Array of size $n$ .<br>Contains low bounds for $x$ ( $lw_i < x_i$ ).                                                           |
| <i>UP</i>   | Array of size $n$ .<br>Contains upper bounds for $x$ ( $up_i > x_i$ ).                                                         |
| <i>eps</i>  | Array of size 6; contains stopping criteria. See the values in the Description section of the <a href="#">?trnlspbc_init</a> . |

## Output Parameters

*info* Array of size 6.  
Results of input parameter checking:

| Parameter       | Used for                | Value | Description                                      |

|                 |                      | 1     | The <i>eps</i> array is not allocated                             |
|                 |                      | 2     | The <i>eps</i> array contains NaN.                                |
|                 |                      | 3     | The <i>eps</i> array contains Inf.                                |
|                 |                      | 4     | The <i>eps</i> array contains a value less than or equal to zero. |

*res*

Information about completion of the task.

*res* = TR\_SUCCESS - the routine completed the task normally.

TR\_SUCCESS is defined in the `mkl_rci.h` include file.

## ?trnlspbc\_solve

Solves a nonlinear least squares problem with linear (bound) constraints using the Trust-Region algorithm.

### Syntax

```
MKL_INT strnlspbc_solve (_TRNSPBC_HANDLE_t* &handle, float* fvec, float* fjac, MKL_INT* &RCI_Request);
```

```
MKL_INT dtrnlspbc_solve (_TRNSPBC_HANDLE_t* &handle, double* fvec, double* fjac, MKL_INT* &RCI_Request);
```

### Include Files

- `mkl.h`

### Description

The `?trnlspbc_solve` routine, based on RCI, uses the Trust-Region algorithm to solve nonlinear least squares problems with linear (bound) constraints. The problem is stated as follows:

$$\min_{x \in \mathbb{R}^n} \|F(x)\|_2^2 = \min_{x \in \mathbb{R}^n} \|y - f(x)\|_2^2, y \in \mathbb{R}^m, x \in \mathbb{R}^n, f: \mathbb{R}^n \rightarrow \mathbb{R}^m, m \geq n$$

where

$$l_i \leq x_i \leq u_i$$

$$i = 1, \dots, n.$$

The `RCI_Request` parameter provides additional information:

| <i>RCI_Request</i> Value | Description                                                                                                                  |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------|
| 2                        | Request to calculate the Jacobian matrix and put the result into <i>fjac</i>                                                 |
| 1                        | Request to recalculate the function at vector <i>x</i> and put the result into <i>fvec</i>                                   |
| 0                        | One successful iteration step on the current trust-region radius (that does not mean that the value of <i>x</i> has changed) |
| -1                       | The algorithm has exceeded the maximum number of iterations                                                                  |
| -2                       | $\Delta < eps[0]$                                                                                                            |
| -3                       | $  F(x)  _2 < eps[1]$                                                                                                        |
| -4                       | The Jacobian matrix is singular.<br>$  J(x)_{[m*(j-1)...m*j-1]}  _2 < eps[2], j = 1, \dots, n$                               |
| -5                       | $  s  _2 < eps[3]$                                                                                                           |
| -6                       | $  F(x)  _2 -   F(x) - J(x)s  _2 < eps[4]$                                                                                   |

Note:

- $J(x)$  is the Jacobian matrix.
- $\Delta$  is the trust-region area.
- $F(x)$  is the value of the functional.
- $s$  is the trial step.

### Input Parameters

|               |                                                                                              |
|---------------|----------------------------------------------------------------------------------------------|
| <i>handle</i> | Type <code>_TRNSPBC_HANDLE_t</code> .                                                        |
| <i>fvec</i>   | Array of size $m$ . Contains the function values at $x$ , where $fvec[i] = (y_i - f_i(x))$ . |
| <i>fjac</i>   | Array of size $m$ by $n$ . Contains the Jacobian matrix of the function.                     |

### Output Parameters

|                    |                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>fvec</i>        | Array of size $m$ . Updated function evaluated at $x$ .                                                                                                                                                               |
| <i>RCI_Request</i> | <p>Informs about the task stage.</p> <p>See the Description section for the parameter values and their meaning.</p>                                                                                                   |
| <i>res</i>         | <p>Informs about the task completion.</p> <p><math>res = TR\_SUCCESS</math> means the routine completed the task normally.</p> <p><code>TR\_SUCCESS</code> is defined in the <code>mkl_rci.h</code> include file.</p> |

### ?trnlspsc\_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

`res = TR_SUCCESS` - the routine completed the task normally.

`TR_SUCCESS` is defined in the `mkl_rci.h` include file.

## ?trnlspsc\_delete

*Releases allocated data.*

### Syntax

```
MKL_INT strnlspsc_delete (_TRNSPBC_HANDLE_t* &handle);
```

```
MKL_INT dtrnlspsc_delete (_TRNSPBC_HANDLE_t* &handle);
```

### Include Files

- `mkl.h`

### Description

The `?trnlspsc_delete` routine releases all memory allocated for the handle.

#### NOTE

This routine flags memory as not used, but to actually release all memory you must call the support function `mkl_free_buffers`.

### Input Parameters

`handle` Type `_TRNSPBC_HANDLE_t`.

### Output Parameters

`res` Informs about the task completion.  
`res = TR_SUCCESS` means the routine completed the task normally.  
`TR_SUCCESS` is defined in the `mkl_rci.h` include file.

## Jacobian Matrix Calculation Routines

This section describes routines that compute the Jacobian matrix using the central difference algorithm. Jacobian matrix calculation is required to solve a nonlinear least squares problem and systems of nonlinear equations (with or without linear bound constraints). Routines for calculation of the Jacobian matrix have the "Black-Box" interfaces, where you pass the objective function via parameters. Your objective function must have a fixed interface.

### Jacobian Matrix Calculation Routines

| Routine Name                | Operation                                                                                                |
|-----------------------------|----------------------------------------------------------------------------------------------------------|
| <code>?jacobi_init</code>   | Initializes the solver.                                                                                  |
| <code>?jacobi_solve</code>  | Computes the Jacobian matrix of the function on the basis of RCI using the central difference algorithm. |
| <code>?jacobi_delete</code> | Removes data.                                                                                            |

| Routine Name          | Operation                                                                                                                                 |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <code>?jacobi</code>  | Computes the Jacobian matrix of the <code>fcn</code> function using the central difference algorithm.                                     |
| <code>?jacobix</code> | Presents an alternative interface for the <code>?jacobi</code> function enabling you to pass additional data into the objective function. |

## `?jacobi_init`

Initializes the solver for Jacobian calculations.

### Syntax

```
MKL_INT sjacobi_init (_JACOBIHANDLE_t* &handle, const MKL_INT* &n, const MKL_INT* &m, const float* x, const float* fjac, const float* &eps);
```

```
MKL_INT djacobi_init (_JACOBIHANDLE_t* &handle, const MKL_INT* &n, const MKL_INT* &m, const double* x, const double* fjac, const double* &eps);
```

### Include Files

- `mkl.h`

### Description

The routine initializes the solver.

### Input Parameters

|                   |                                                                          |
|-------------------|--------------------------------------------------------------------------|
| <code>n</code>    | Length of $x$ .                                                          |
| <code>m</code>    | Length of $F$ .                                                          |
| <code>x</code>    | Array of size $n$ . Vector, at which the function is evaluated.          |
| <code>eps</code>  | Precision of the Jacobian matrix calculation.                            |
| <code>fjac</code> | Array of size $m$ by $n$ . Contains the Jacobian matrix of the function. |

### Output Parameters

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>handle</code> | Data object of the <code>_JACOBIHANDLE_t</code> type.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>res</code>    | Indicates task completion status. <ul style="list-style-type: none"> <li>• <code>res = TR_SUCCESS</code> - the routine completed the task normally.</li> <li>• <code>res = TR_INVALID_OPTION</code> - there was an error in the input parameters.</li> <li>• <code>res = TR_OUT_OF_MEMORY</code> - there was a memory error.</li> </ul> <p><code>TR_SUCCESS</code>, <code>TR_INVALID_OPTION</code>, and <code>TR_OUT_OF_MEMORY</code> are defined in the <code>mkl_rci.h</code> include file.</p> |

## `?jacobi_solve`

Computes the Jacobian matrix of the function using RCI and the central difference algorithm.

## Syntax

```
MKL_INT sjacobi_solve (_JACOBI_MATRIX_HANDLE_t* &handle, float* f1, float* f2, MKL_INT*
&RCI_Request);
```

```
MKL_INT djacobi_solve (_JACOBI_MATRIX_HANDLE_t* &handle, double* f1, double* f2,
MKL_INT* &RCI_Request);
```

## Include Files

- mkl.h

## Description

The `?jacobi_solve` routine computes the Jacobian matrix of the function using RCI and the central difference algorithm.

See usage examples in the `examples\solverc\source` folder of your Intel MKL directory. Specifically, see `sjacobi_rci_c.c` and `djacobi_rci_c.c`.

## Input Parameters

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <i>handle</i>      | Type <code>_JACOBI_MATRIX_HANDLE_t</code> .                    |
| <i>RCI_Request</i> | Set to 0 before the first call to <code>?jacobi_solve</code> . |

## Output Parameters

|                    |                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>f1</i>          | Contains the updated function values at $x + \text{eps}$ .                                                                                                                                                                                                                                                                                                                                                |
| <i>f2</i>          | Array of size $m$ . Contains the updated function values at $x - \text{eps}$ .                                                                                                                                                                                                                                                                                                                            |
| <i>RCI_Request</i> | Provides information about the task completion. When equal to 0, the task has completed successfully.<br><br><i>RCI_Request</i> = 1 indicates that you should compute the function values at the current $x$ point and put the results into <i>f1</i> .<br><br><i>RCI_Request</i> = 2 indicates that you should compute the function values at the current $x$ point and put the results into <i>f2</i> . |
| <i>res</i>         | Indicates the task completion status. <ul style="list-style-type: none"> <li>• <i>res</i> = <code>TR_SUCCESS</code> - the routine completed the task normally.</li> <li>• <i>res</i> = <code>TR_INVALID_OPTION</code> - there was an error in the input parameters.</li> </ul> <p><code>TR_SUCCESS</code> and <code>TR_INVALID_OPTION</code> are defined in the <code>mkl_rci.h</code> include file.</p>  |

## ?jacobi\_delete

*Releases allocated data.*

---

## Syntax

```
MKL_INT sjacobi_delete (_JACOBI_MATRIX_HANDLE_t* &handle);
```

| Parameter         | Type | Description                                                                                                                     |
|-------------------|------|---------------------------------------------------------------------------------------------------------------------------------|
| $m$               |      | Length of $f$                                                                                                                   |
| $n$               |      | Length of $x$                                                                                                                   |
| $x$               |      | Array of size $n$ . Vector, at which the function is evaluated. The <code>fcn</code> function should not change this parameter. |
| Output Parameters |      |                                                                                                                                 |
| $f$               |      | Array of size $m$ ; contains the function values at $x$ .                                                                       |

You need to declare `fcn` as `extern` in the calling program.

|       |                                                                |
|-------|----------------------------------------------------------------|
| $n$   | Length of $X$ .                                                |
| $m$   | Length of $F$ .                                                |
| $x$   | Array of size $n$ . Vector at which the function is evaluated. |
| $eps$ | Precision of the Jacobian matrix calculation.                  |

## Output Parameters

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $fjac$ | Array of size $m$ by $n$ . Contains the Jacobian matrix of the function.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| $res$  | Indicates task completion status. <ul style="list-style-type: none"> <li><math>res = TR\_SUCCESS</math> - the routine completed the task normally.</li> <li><math>res = TR\_INVALID\_OPTION</math> - there was an error in the input parameters.</li> <li><math>res = TR\_OUT\_OF\_MEMORY</math> - there was a memory error.</li> </ul> <p><code>TR_SUCCESS</code>, <code>TR_INVALID_OPTION</code>, and <code>TR_OUT_OF_MEMORY</code> are defined in the <code>mkl_rci.h</code> include file.</p> |

## See Also

[?jacobix](#)

## ?jacobix

Alternative interface for `?jacobi` function for passing additional data into the objective function.

### Syntax

```
MKL_INT sjacobix (USRFCNXS fcn, const MKL_INT* &n, const MKL_INT * &m, float* fjac,
float* x, float* &eps, void* user_data);
```

```
MKL_INT djacobix (USRFCNXD fcn, const MKL_INT* &n, const MKL_INT * &m, double* fjac,
double* x, double* &eps, void* user_data);
```

### Include Files

- `mkl.h`

## Description

The `?jacobix` routine presents an alternative interface for the `?jacobi` function that enables you to pass additional data into the objective function `fcn`.

See calling and usage examples in the `examples\solverc\source` folder of your Intel MKL directory. Specifically, see `ex_nlsqp_c_x.c` and `ex_nlsqp_bc_c_x.c`.

## Input Parameters

`fcn`

User-supplied subroutine to evaluate the function that defines the least squares problem. Call `fcn (&m, &n, x, f, user_data)` with the following parameters:

| Parameter              | Description                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Input Parameters       |                                                                                                                                            |
| <code>m</code>         | Length of <code>f</code>                                                                                                                   |
| <code>n</code>         | Length of <code>x</code>                                                                                                                   |
| <code>x</code>         | Array of size <code>n</code> . Vector, at which the function is evaluated. The <code>fcn</code> function should not change this parameter. |
| <code>user_data</code> | Pointer to your additional data, if any. Otherwise, a dummy argument.                                                                      |
| Output Parameters      |                                                                                                                                            |
| <code>f</code>         | Array of size <code>m</code> ; contains the function values at <code>x</code> .                                                            |

You need to declare `fcn` as `extern` in the calling program.

`n`

Length of `X`.

`m`

Length of `F`.

`x`

Array of size `n`. Vector at which the function is evaluated.

`eps`

Precision of the Jacobian matrix calculation.

`user_data`

Pointer to your additional data. If there is no additional data, this is a dummy argument.

## Output Parameters

`fjac`

Array of size `m` by `n`). Contains the Jacobian matrix of the function.

`res`

Indicates task completion status.

- `res = TR_SUCCESS` - the routine completed the task normally.
- `res = TR_INVALID_OPTION` - there was an error in the input parameters.
- `res = TR_OUT_OF_MEMORY` - there was a memory error.

`TR_SUCCESS`, `TR_INVALID_OPTION`, and `TR_OUT_OF_MEMORY` are defined in the `mkl_rci.h` include file.

# Support Functions

Intel® Math Kernel Library (Intel® MKL) support functions are subdivided into the following groups according to their purpose:

Version Information

Threading Control

Error Handling

Character Equality Testing

Timing

Memory Management

Single Dynamic Library Control

Intel® Many Integrated Core (Intel® MIC) Architecture Support

Conditional Numerical Reproducibility Control

Miscellaneous

The following table lists Intel MKL support functions.

## Intel MKL Support Functions

| Function Name                           | Operation                                                                                                                      |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| Version Information                     |                                                                                                                                |
| <code>mkl_get_version</code>            | Returns the Intel MKL version.                                                                                                 |
| <code>mkl_get_version_string</code>     | Returns the Intel MKL version in a character string.                                                                           |
| Threading Control                       |                                                                                                                                |
| <code>mkl_set_num_threads</code>        | Specifies the number of OpenMP* threads to use.                                                                                |
| <code>mkl_domain_set_num_threads</code> | Specifies the number of OpenMP* threads for a particular function domain.                                                      |
| <code>mkl_set_num_threads_local</code>  | Specifies the number of OpenMP* threads for all Intel MKL functions on the current execution thread.                           |
| <code>mkl_set_dynamic</code>            | Enables Intel MKL to dynamically change the number of OpenMP* threads.                                                         |
| <code>mkl_get_max_threads</code>        | Gets the number of OpenMP* threads targeted for parallelism.                                                                   |
| <code>mkl_domain_get_max_threads</code> | Gets the number of OpenMP* threads targeted for parallelism for a particular function domain.                                  |
| <code>mkl_get_dynamic</code>            | Determines whether Intel MKL is enabled to dynamically change the number of OpenMP* threads.                                   |
| <code>mkl_set_num_stripes</code>        | Specifies the number of partitions along the leading dimension of the output matrix for parallel <code>?gemm</code> functions. |

| Function Name                          | Operation                                                                                                                       |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <code>mkl_get_num_stripes</code>       | Gets the number of partitions along the leading dimension of the output matrix for parallel ?gemm functions.                    |
| <b>Error Handling</b>                  |                                                                                                                                 |
| <code>xerbla</code>                    | Error handling function called by BLAS, LAPACK, Vector Math, and Vector Statistics functions.                                   |
| <code>pxerbla</code>                   | Handles error conditions for the ScaLAPACK routines.                                                                            |
| <code>LAPACKE_xerbla</code>            | Error handling function called by the C interface to LAPACK functions.                                                          |
| <code>mkl_set_exit_handler</code>      | Sets the custom handler of fatal errors.                                                                                        |
| <b>Character Equality Testing</b>      |                                                                                                                                 |
| <code>lsame</code>                     | Tests two characters for equality regardless of the case.                                                                       |
| <code>lsamen</code>                    | Tests two character strings for equality regardless of the case.                                                                |
| <b>Timing</b>                          |                                                                                                                                 |
| <code>second/dsecnd</code>             | Returns elapsed time in seconds. Use to estimate real time between two calls to this function.                                  |
| <code>mkl_get_cpu_clocks</code>        | Returns elapsed CPU clocks.                                                                                                     |
| <code>mkl_get_cpu_frequency</code>     | Returns CPU frequency value in GHz.                                                                                             |
| <code>mkl_get_max_cpu_frequency</code> | Returns the maximum CPU frequency value in GHz.                                                                                 |
| <code>mkl_get_clocks_frequency</code>  | Returns the frequency value in GHz based on constant-rate Time Stamp Counter.                                                   |
| <b>Memory Management</b>               |                                                                                                                                 |
| <code>mkl_free_buffers</code>          | Frees unused memory allocated by the Intel MKL Memory Allocator.                                                                |
| <code>mkl_thread_free_buffers</code>   | Frees unused memory allocated by the Intel MKL Memory Allocator in the current thread.                                          |
| <code>mkl_mem_stat</code>              | Reports the status of the Intel MKL Memory Allocator.                                                                           |
| <code>mkl_peak_mem_usage</code>        | Reports the peak memory allocated by the Intel MKL Memory Allocator.                                                            |
| <code>mkl_disable_fast_mm</code>       | Turns off the Intel MKL Memory Allocator for Intel MKL functions to directly use the system <code>malloc/free</code> functions. |
| <code>mkl_malloc</code>                | Allocates an aligned memory buffer.                                                                                             |
| <code>mkl_calloc</code>                | Allocates and initializes an aligned memory buffer.                                                                             |
| <code>mkl_realloc</code>               | Changes the size of memory buffer allocated by <code>mkl_malloc/mkl_calloc</code> .                                             |
| <code>mkl_free</code>                  | Frees the aligned memory buffer allocated by <code>mkl_malloc/mkl_calloc</code> .                                               |

| Function Name                               | Operation                                                                                                                                                                                |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mkl_set_memory_limit</code>           | On Linux, sets the limit of memory that Intel MKL can allocate for a specified type of memory.                                                                                           |
| Single Dynamic Library (SDL) Control        |                                                                                                                                                                                          |
| <code>mkl_set_interface_layer</code>        | Sets the interface layer for Intel MKL at run time.                                                                                                                                      |
| <code>mkl_set_threading_layer</code>        | Sets the threading layer for Intel MKL at run time.                                                                                                                                      |
| <code>mkl_set_xerbla</code>                 | Replaces the error handling routine. Use with the Single Dynamic Library on Windows*.                                                                                                    |
| <code>mkl_set_progress</code>               | Replaces the progress information routine.                                                                                                                                               |
| <code>mkl_set_pardiso_pivot</code>          | Replaces the routine handling Intel MKL PARDISO pivots with a user-defined routine. Use with the Single Dynamic Library (SDL).                                                           |
| Intel MIC Architecture Support              |                                                                                                                                                                                          |
| <code>mkl_mic_enable</code>                 | Enables Automatic Offload mode.                                                                                                                                                          |
| <code>mkl_mic_disable</code>                | Disables Automatic Offload mode.                                                                                                                                                         |
| <code>mkl_mic_get_device_count</code>       | Returns the number of Intel® Xeon Phi™ coprocessors on the system when called on the host CPU.                                                                                           |
| <code>mkl_mic_set_workdivision</code>       | For computations in the Automatic Offload mode, sets the fraction of the work for the specified coprocessor or host CPU to do.                                                           |
| <code>mkl_mic_get_workdivision</code>       | For computations in the Automatic Offload mode, retrieves the fraction of the work for the specified coprocessor or host CPU to do.                                                      |
| <code>mkl_mic_set_max_memory</code>         | Sets the maximum amount of coprocessor memory reserved for Automatic Offload computations.                                                                                               |
| <code>mkl_mic_free_memory</code>            | Frees the coprocessor memory reserved for Automatic Offload computations.                                                                                                                |
| <code>mkl_mic_register_memory</code>        | Enables/disables the <code>mkl_malloc</code> function running in Automatic Offload mode to register allocated memory.                                                                    |
| <code>mkl_mic_set_device_num_threads</code> | Sets the maximum number of OpenMP* threads to use on an Intel Xeon Phi coprocessor for the Automatic Offload computations.                                                               |
| <code>mkl_mic_set_resource_limit</code>     | For computations in the Automatic Offload mode, sets the maximum fraction of available Intel Xeon Phi coprocessor computational resources (cores) that the calling process can use.      |
| <code>mkl_mic_get_resource_limit</code>     | For computations in the Automatic Offload mode, retrieves the maximum fraction of available Intel Xeon Phi coprocessor computational resources (cores) that the calling process can use. |
| <code>mkl_mic_set_offload_report</code>     | Turns on/off reporting of Automatic Offload profiling.                                                                                                                                   |
| <code>mkl_mic_set_flags</code>              | Sets flags to control the behavior of computations in the Automatic Offload mode.                                                                                                        |
| <code>mkl_mic_get_flags</code>              | Retrieves flags that control the behavior of computations in the Automatic Offload mode.                                                                                                 |
| <code>mkl_mic_get_status</code>             | For the Automatic Offload mode, returns the status of the latest call to an Intel MKL function.                                                                                          |

| Function Name                                       | Operation                                                                                                                   |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>mkl_mic_clear_status</code>                   | For the Automatic Offload mode, clears the status of the latest call to an Intel MKL function.                              |
| <code>mkl_mic_get_meminfo</code>                    | Retrieves the amount of total and free memory for the specified coprocessor or host CPU.                                    |
| <code>mkl_mic_get_cpuinfo</code>                    | Retrieves the number of cores, hardware threads, and frequency for the specified coprocessor or host CPU.                   |
| Conditional Numerical Reproducibility (CNR) Control |                                                                                                                             |
| <code>mkl_cbwr_set</code>                           | Configures the CNR mode of Intel MKL.                                                                                       |
| <code>mkl_cbwr_get</code>                           | Returns the current CNR settings.                                                                                           |
| <code>mkl_cbwr_get_auto_branch</code>               | Automatically detects the CNR code branch for your platform.                                                                |
| Miscellaneous                                       |                                                                                                                             |
| <code>mkl_progress</code>                           | Provides progress information.                                                                                              |
| <code>mkl_enable_instructions</code>                | Enables dispatching for new Intel® architectures or restricts the set of Intel® instruction sets available for dispatching. |
| <code>mkl_set_env_mode</code>                       | Sets up the mode that ignores environment settings specific to Intel MKL.                                                   |
| <code>mkl_verbose</code>                            | Enables or disables Intel MKL Verbose mode.                                                                                 |
| <code>mkl_set_mpi</code>                            | Sets the implementation of the message-passing interface to be used by Intel MKL.                                           |
| <code>mkl_finalize</code>                           | Terminates Intel MKL execution environment and frees resources allocated by the library.                                    |

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## Version Information

Intel® MKL provides two methods for extracting information about the library version number:

- extracting a version string using the `mkl_get_version_string` function
- using the `mkl_get_version` function to obtain an `MKLVersion` structure that contains the version information

A makefile is also provided to automatically build the examples and output summary files containing the version information for the current library.

## mkl\_get\_version

Returns the Intel MKL version.

### Syntax

```
void mkl_get_version(MKLVersion* pVersion);
```

### Include Files

- mkl.h

### Output Parameters

*pVersion*                      Pointer to the `MKLVersion` structure.

### Description

The `mkl_get_version` function collects information about the active C version of the Intel MKL software and returns this information in a structure of `MKLVersion` type by the *pVersion* address. The `MKLVersion` structure type is defined in the `mkl_types.h` file. The following fields of the `MKLVersion` structure are available:

|                            |                                                                                                                                                                                                                                                                                                                         |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>MajorVersion</code>  | is the major number of the current library version.                                                                                                                                                                                                                                                                     |
| <code>MinorVersion</code>  | is the minor number of the current library version.                                                                                                                                                                                                                                                                     |
| <code>UpdateVersion</code> | is the update number of the current library version.                                                                                                                                                                                                                                                                    |
| <code>ProductStatus</code> | is the status of the current library version. Possible variants are "Beta" or "Product".                                                                                                                                                                                                                                |
| <code>Build</code>         | is the string that contains the build date and the internal build number.                                                                                                                                                                                                                                               |
| <code>Platform</code>      | is the string that contains the current architecture. Possible variants are "IA-32 architecture" or "Intel(R) 64 architecture".                                                                                                                                                                                         |
| <code>Processor</code>     | is the processor optimization. Normally it is targeted for the processor installed on your system and based on the detection of the Intel MKL library that is optimal for the installed processor. In the Conditional Numerical Reproducibility (CNR) mode, the processor optimization matches the selected CNR branch. |

#### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## mkl\_get\_version Usage

---

```

#include <stdio.h>
#include <stdlib.h>
#include "mkl.h"

int main(void)
{
 MKLVersion Version;

 mkl_get_version(&Version);

 printf("Major version: %d\n",Version.MajorVersion);
 printf("Minor version: %d\n",Version.MinorVersion);
 printf("Update version: %d\n",Version.UpdateVersion);
 printf("Product status: %s\n",Version.ProductStatus);
 printf("Build: %s\n",Version.Build);
 printf("Platform: %s\n",Version.Platform);
 printf("Processor optimization: %s\n",Version.Processor);
 printf("=====\n");
 printf("\n");

 return 0;
}

```

### Output:

|                        |                                |
|------------------------|--------------------------------|
| Major Version          | 11                             |
| Minor Version          | 0                              |
| Update Version         | 2                              |
| Product status         | Product                        |
| Build                  | 20121113                       |
| Platform               | Intel(R) 64 architecture       |
| Processor optimization | Intel(R) Core(TM) i7 Processor |

## mkl\_get\_version\_string

*Returns the Intel MKL version in a character string.*

### Syntax

```
void mkl_get_version_string (char* buf, int len);
```

### Include Files

- mkl.h

## Output Parameters

| Name             | Type               | Description                 |
|------------------|--------------------|-----------------------------|
| <code>buf</code> | <code>char*</code> | Source string               |
| <code>len</code> | <code>int</code>   | Length of the source string |

## Description

The function returns a string that contains the Intel MKL version.

For usage details, see the code example below:

## Example

```
#include <stdio.h>
#include "mkl.h"

int main(void)
{
 int len=198;
 char buf[198];
 mkl_get_version_string(buf, len);
 printf("%s\n",buf);
 printf("\n");
 return 0;
}
```

## Threading Control

Intel® MKL provides functions for OpenMP\* threading control, discussed in this section.

### Important

If Intel MKL operates within the Intel® Threading Building Blocks (Intel® TBB) execution environment, the environment variables for OpenMP\* threading control, such as `OMP_NUM_THREADS`, and Intel MKL functions discussed in this section have no effect. If the Intel TBB threading technology is used, control the number of threads through the Intel TBB application programming interface. Read the documentation for the `tbb::task_scheduler_init` class at <https://www.threadingbuildingblocks.org/documentation> to find out how to specify the number of Intel TBB threads.

If Intel® MKL operates within an OpenMP\* execution environment, you can control the number of threads for Intel MKL using OpenMP\* run-time library routines and environment variables (see the OpenMP\* specification for details). Additionally Intel MKL provides *optional* threading control functions and environment variables that enable you to specify the number of threads for Intel MKL and to control dynamic adjustment of the number of threads *independently* of the OpenMP\* settings. The settings made with the Intel MKL threading control functions and environment variables do not affect OpenMP\* settings but take precedence over them.

If none of the threading control functions is used, Intel MKL environment variables may control Intel MKL threading. For details of those environment variables, see the *Intel MKL Developer Guide*.

You can specify the number of threads for Intel MKL function domains with the `mkl_set_num_threads` or `mkl_domain_set_num_threads` function. While `mkl_set_num_threads` specifies the number of threads for the entire Intel MKL, `mkl_domain_set_num_threads` does it for a specific function domain. The following table lists the function domains that support independent threading control. The table also provides named constants to pass to threading control functions as a parameter that specifies the function domain.

**Intel MKL Function Domains**

| Function Domain                                                                                             | Named Constant     |
|-------------------------------------------------------------------------------------------------------------|--------------------|
| Basic Linear Algebra Subroutines (BLAS)                                                                     | MKL_DOMAIN_BLAS    |
| Fast Fourier Transform (FFT) functions, except Cluster FFT functions                                        | MKL_DOMAIN_FFT     |
| Vector Math (VM) functions                                                                                  | MKL_DOMAIN_VML     |
| Parallel Direct Solver (PARDISO) functions                                                                  | MKL_DOMAIN_PARDISO |
| All Intel MKL functions except the functions from the domains where the number of threads is set explicitly | MKL_DOMAIN_ALL     |

**WARNING**

Do not increase the number of OpenMP threads used for Intel MKL PARDISO between the first call to `pardiso` and the factorization or solution phase. Because the minimum amount of memory required for out-of-core execution depends on the number of OpenMP threads, increasing it after the initial call can cause incorrect results.

Both `mkl_set_num_threads` and `mkl_domain_set_num_threads` functions set the number of threads for all subsequent calls to Intel MKL from all applications threads. Use the `mkl_set_num_threads_local` function to specify different numbers of threads for Intel MKL on different execution threads of your application. The thread-local settings take precedence over the global settings. However, the thread-local settings may have undesirable side effects (see the description of the `mkl_set_num_threads_local` function for details).

By default, Intel MKL can adjust the specified number of threads dynamically. For example, Intel MKL may use fewer threads if the size of the computation is not big enough or not create parallel regions when running within an OpenMP\* parallel region. Although Intel MKL may actually use a different number of threads from the number specified, the library does not create parallel regions with more threads than specified. If dynamic adjustment of the number of threads is disabled, Intel MKL attempts to use the specified number of threads in internal parallel regions (for more information, see the *Intel MKL Developer Guide*). Use the `mkl_set_dynamic` function to control dynamic adjustment of the number of threads.

**mkl\_set\_num\_threads**

*Specifies the number of OpenMP\* threads to use.*

**Syntax**

```
void mkl_set_num_threads(int nt);
```

**Include Files**

- `mkl.h`

**Input Parameters**

| Name            | Type             | Description                                                                                                                     |
|-----------------|------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <code>nt</code> | <code>int</code> | <code>nt &gt; 0</code> - The number of threads suggested by the user.<br><code>nt ≤ 0</code> - Invalid value, which is ignored. |

**Description**

This function enables you to specify how many OpenMP threads Intel MKL should use for internal parallel regions. If this number is not set (default), Intel MKL functions use the default number of threads for the OpenMP run-time library. The specified number of threads applies:

- To all Intel MKL functions except the functions from the domains where the number of threads is set with [mkl\\_domain\\_set\\_num\\_threads](#)
- To all execution threads except the threads where the number of threads is set with [mkl\\_set\\_num\\_threads\\_local](#)

The number specified is a hint, and Intel MKL may actually use a smaller number.

---

**NOTE**

This function takes precedence over the `MKL_NUM_THREADS` environment variable.

---

## Example

```
#include "mkl.h"
...
mkl_set_num_threads(4);
my_compute_using_mkl(); // Intel MKL uses up to 4 OpenMP threads
```

## mkl\_domain\_set\_num\_threads

*Specifies the number of OpenMP\* threads for a particular function domain.*

---

### Syntax

```
int mkl_domain_set_num_threads (int nt, int domain);
```

### Include Files

- `mkl.h`

### Input Parameters

| Name          | Type             | Description                                                                                                                                                                                                             |
|---------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>nt</i>     | <code>int</code> | <p><i>nt</i> &gt; 0 - The number of threads suggested by the user.</p> <p><i>nt</i> = 0 - The default number of threads for the OpenMP run-time library.</p> <p><i>nt</i> &lt; 0 - Invalid value, which is ignored.</p> |
| <i>domain</i> | <code>int</code> | The named constant that defines the targeted domain.                                                                                                                                                                    |

### Description

This function specifies how many OpenMP threads a particular function domain of Intel MKL should use. If this number is not set (default) or if it is set to zero in a call to this function, Intel MKL uses the default number of threads for the OpenMP run-time library. The number of threads specified applies to the specified function domain on all execution threads except the threads where the number of threads is set with [mkl\\_set\\_num\\_threads\\_local](#). For a list of supported values of the *domain* argument, see [Table "Intel MKL Function Domains"](#).

The number of threads specified is only a hint, and Intel MKL may actually use a smaller number.

---

**NOTE**

This function takes precedence over the `MKL_DOMAIN_NUM_THREADS` environment variable.

---

## Return Values

| Name              | Type             | Description                                                                                                                |
|-------------------|------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>ierr</code> | <code>int</code> | 1 - Indicates no error, execution is successful.<br>0 - Indicates a failure, possibly because of invalid input parameters. |

## Example

```
#include "mkl.h"
...
mkl_domain_set_num_threads(4, MKL_DOMAIN_BLAS);
my_compute_using_mkl_blas(); // Intel MKL BLAS functions use up to 4 threads
my_compute_using_mkl_dft(); // Intel MKL FFT functions use the default number of threads
```

## mkl\_set\_num\_threads\_local

*Specifies the number of OpenMP\* threads for all Intel MKL functions on the current execution thread.*

### Syntax

```
int mkl_set_num_threads_local(int nt);
```

### Include Files

- `mkl.h`

### Input Parameters

| Name            | Type             | Description                                                                                                                                                                                                              |
|-----------------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>nt</code> | <code>int</code> | <code>nt &gt; 0</code> - The number of threads for Intel MKL functions to use on the current execution thread.<br><code>nt = 0</code> - A request to reset the thread-local number of threads and use the global number. |

### Description

This function sets the number of OpenMP threads that Intel MKL functions should request for parallel computation. The number of threads is thread-local, which means that it only affects the current execution thread of the application. If the thread-local number is not set or if this number is set to zero in a call to this function, Intel MKL functions use the global number of threads. You can set the global number of threads using the [mkl\\_set\\_num\\_threads](#) or [mkl\\_domain\\_set\\_num\\_threads](#) function.

The thread-local number of threads takes precedence over the global number: if the thread-local number is non-zero, changes to the global number of threads have no effect on the current thread.

#### CAUTION

If your application is threaded with OpenMP\* and parallelization of Intel MKL is based on nested OpenMP parallelism, different OpenMP parallel regions reuse OpenMP threads. Therefore a thread-local setting in one OpenMP parallel region may continue to affect not only the master thread after the parallel region ends, but also subsequent parallel regions. To avoid performance implications of this side effect, reset the thread-local number of threads before leaving the OpenMP parallel region (see [Examples](#) for how to do it).

## Return Values

| Name                 | Type             | Description                                                                                                                                     |
|----------------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>save_nt</code> | <code>int</code> | The value of the thread-local number of threads that was used before this function call. Zero means that the global number of threads was used. |

## Examples

This example shows how to avoid the side effect of a thread-local number of threads by reverting to the global setting:

```
#include "omp.h"
#include "mkl.h"
...
mkl_set_num_threads(16);
my_compute_using_mkl(); // Intel MKL functions use up to 16 threads
#pragma omp parallel num_threads(2)
{
 if (0 == omp_get_thread_num())
 mkl_set_num_threads_local(4);
 else
 mkl_set_num_threads_local(12);

 my_compute_using_mkl(); // Intel MKL functions use up to 4 threads on thread 0
 // and up to 12 threads on thread 1
}
my_compute_using_mkl(); // Intel MKL functions use up to 4 threads (!)
mkl_set_num_threads_local(0); // make master thread use global setting
my_compute_using_mkl(); // Intel MKL functions use up to 16 threads
```

This example shows how to avoid the side effect of a thread-local number of threads by saving and restoring the existing setting:

```
#include "mkl.h"
void my_compute(int nt)
{
 int save = mkl_set_num_threads_local(nt); // save the Intel MKL number of threads
 my_compute_using_mkl(); // Intel MKL functions use up to nt threads on this thread
 mkl_set_num_threads_local(save); // restore the Intel MKL number of threads
}
```

## **mkl\_set\_dynamic**

*Enables Intel MKL to dynamically change the number of OpenMP\* threads.*

### Syntax

```
void mkl_set_dynamic (int flag);
```

### Include Files

- `mkl.h`

## Input Parameters

| Name        | Type | Description                                                                                                                                                                      |
|-------------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>flag</i> | int  | <p><i>flag</i> = 0 - Requests disabling dynamic adjustment of the number of threads.</p> <p><i>flag</i> ≠ 0 - Requests enabling dynamic adjustment of the number of threads.</p> |

## Description

This function indicates whether Intel MKL can dynamically change the number of OpenMP threads or should avoid doing this. The setting applies to all Intel MKL functions on all execution threads. This function takes precedence over the `MKL_DYNAMIC` environment variable.

Dynamic adjustment of the number of threads is enabled by default. Specifically, Intel MKL may use fewer threads in parallel regions than the number returned by the [mkl\\_get\\_max\\_threads](#) function. Disabling dynamic adjustment of the number of threads does not ensure that Intel MKL actually uses the specified number of threads, although the library attempts to use that number.

### TIP

If you call Intel MKL from within an OpenMP parallel region and want to create internal parallel regions, either disable dynamic adjustment of the number of threads or set the thread-local number of threads (see [mkl\\_set\\_num\\_threads\\_local](#) for how to do it).

## Example

```
#include "mkl.h"
...
mkl_set_num_threads(8);
#pragma omp parallel
{
 my_compute_with_mkl(); // Intel MKL uses 1 thread, being called from OpenMP parallel region
 mkl_set_dynamic(0); // disable adjustment of the number of threads
 my_compute_with_mkl(); // Intel MKL uses 8 threads
}
```

## mkl\_get\_max\_threads

*Gets the number of OpenMP\* threads targeted for parallelism.*

### Syntax

```
int mkl_get_max_threads (void);
```

### Include Files

- `mkl.h`

### Description

This function returns the number of OpenMP threads for Intel MKL to use in internal parallel regions. This number depends on whether dynamic adjustment of the number of threads by Intel MKL is disabled (by an environment setting or in a function call):

- If the dynamic adjustment is disabled, the function inspects the environment settings and return values of the function calls below in the order they are listed until it finds a non-zero value:

- A call to [mkl\\_set\\_num\\_threads\\_local](#)
- The last of the calls to [mkl\\_set\\_num\\_threads](#) or [mkl\\_domain\\_set\\_num\\_threads](#)( ..., MKL\_DOMAIN\_ALL)
- The MKL\_DOMAIN\_NUM\_THREADS environment variable with the MKL\_DOMAIN\_ALL tag
- The MKL\_NUM\_THREADS environment variable
- A call to [omp\\_set\\_num\\_threads](#)
- The OMP\_NUM\_THREADS environment variable
- If the dynamic adjustment is enabled, the function returns the number of physical cores on your system.

The number of threads returned by this function is a hint, and Intel MKL may actually use a different number.

## Return Values

| Name      | Type | Description                                                                                |
|-----------|------|--------------------------------------------------------------------------------------------|
| <i>nt</i> | int  | The maximum number of threads for Intel MKL functions to use in internal parallel regions. |

## Example

```
#include "mkl.h"
...
if (1 == mkl_get_max_threads()) puts("Intel MKL does not employ threading");
```

## See Also

[mkl\\_set\\_dynamic](#)  
[mkl\\_get\\_dynamic](#)

## mkl\_domain\_get\_max\_threads

*Gets the number of OpenMP\* threads targeted for parallelism for a particular function domain.*

## Syntax

```
int mkl_domain_get_max_threads (int domain);
```

## Include Files

- mkl.h

## Input Parameters

| Name          | Type | Description                                          |
|---------------|------|------------------------------------------------------|
| <i>domain</i> | int  | The named constant that defines the targeted domain. |

## Description

Computational functions of the Intel MKL function domain defined by the *domain* parameter use the value returned by this function as a limit of the number of OpenMP threads they should request for parallel computations. The [mkl\\_domain\\_get\\_max\\_threads](#) function returns the thread-local number of threads or, if that value is zero or not set, the global number of threads. To determine this number, the function inspects the environment settings and return values of the function calls below in the order they are listed until it finds a non-zero value:

- A call to [mkl\\_set\\_num\\_threads\\_local](#)
- The last of the calls to [mkl\\_set\\_num\\_threads](#) or [mkl\\_domain\\_set\\_num\\_threads](#)( ..., MKL\_DOMAIN\_ALL)
- A call to [mkl\\_domain\\_set\\_num\\_threads](#)( ..., *domain*)

- The `MKL_DOMAIN_NUM_THREADS` environment variable with the `MKL_DOMAIN_ALL` tag
- The `MKL_DOMAIN_NUM_THREADS` environment variable (with the specific domain tag)
- The `MKL_NUM_THREADS` environment variable
- A call to `omp_set_num_threads`
- The `OMP_NUM_THREADS` environment variable

Actual number of threads used by the Intel MKL computational functions may vary depending on the problem size and on whether dynamic adjustment of the number of threads is enabled (see the description of [mkl\\_set\\_dynamic](#)). For a list of supported values of the `domain` argument, see [Table "Intel MKL Function Domains"](#).

## Return Values

| Name            | Type             | Description                                                                                                                                                                                                                                              |
|-----------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>nt</code> | <code>int</code> | The maximum number of threads for Intel MKL functions from a given domain to use in internal parallel regions.<br><br>If an invalid value of <code>domain</code> is supplied, the function returns the number of threads for <code>MKL_DOMAIN_ALL</code> |

## Example

```
#include "mkl.h"
...
if (1 < mkl_domain_get_max_threads(MKL_DOMAIN_BLAS))
puts("Intel MKL BLAS functions employ threading");
```

## [mkl\\_get\\_dynamic](#)

*Determines whether Intel MKL is enabled to dynamically change the number of OpenMP\* threads.*

### Syntax

```
int mkl_get_dynamic(void);
```

### Include Files

- `mkl.h`

### Description

This function returns the status of dynamic adjustment of the number of OpenMP\* threads. To determine this status, the function inspects the return value of the following function call and if it is undefined, inspects the environment setting below:

- A call to [mkl\\_set\\_dynamic](#)
- The `MKL_DYNAMIC` environment variable

---

#### NOTE

Dynamic adjustment of the number of threads is enabled by default.

---

The dynamic adjustment works as follows. Suppose that the [mkl\\_get\\_max\\_threads](#) function returns the number of threads equal to  $N$ . If dynamic adjustment is enabled, Intel MKL may request up to  $N$  threads, depending on the size of the problem. If dynamic adjustment is disabled, Intel MKL requests exactly  $N$

threads for internal parallel regions (provided it uses a threaded algorithm with at least  $N$  computations that can be done in parallel). However, the OpenMP\* run-time library may be configured to supply fewer threads than Intel MKL requests, depending on the OpenMP\* setting of dynamic adjustment.

## Return Values

| Name             | Type             | Description                                                                                                                 |
|------------------|------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>ret</code> | <code>int</code> | 0 - Dynamic adjustment of the number of threads is disabled.<br>1 - Dynamic adjustment of the number of threads is enabled. |

## Example

```
#include "mkl.h"
...
int nt = mkl_get_max_threads();
if (1 == mkl_get_dynamic())
printf("Intel MKL may use less than %i threads for a large problem", nt);
else
printf("Intel MKL should use %i threads for a large problem", nt);
```

## mkl\_set\_num\_stripes

*Specifies the number of partitions along the leading dimension of the output matrix for parallel ?gemm functions.*

### Syntax

```
void mkl_set_num_stripes(int ns);
```

### Include Files

- `mkl.h`

### Input Parameters

| Name            | Type             | Description                                                                                                                                                              |
|-----------------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ns</code> | <code>int</code> | $ns > 0$ - Specifies the number of partitions to use.<br>$ns = 0$ - Instructs Intel MKL to use the default partitioning algorithm.<br>$ns < 0$ - Invalid value; ignored. |

### Description

This function enables you to specify the number of stripes, or partitions along the leading dimension of the output matrix, for parallel ?gemm functions. If this number is not set (default) or if it is set to zero, Intel MKL ?gemm functions use the default partitioning algorithm. The specified number of partitions only applies to ?gemm functions.

The number specified is a hint, and Intel MKL may actually use a smaller number.

#### NOTE

This function takes precedence over the `MKL_NUM_STRIPES` environment variable.

## Example

```
#include "mkl.h"
...
mkl_set_num_stripes(4);
dgemm(...); // Intel MKL uses up to 4 stripes for dgemm
```

## See Also

[mkl\\_get\\_num\\_stripes](#)

## mkl\_get\_num\_stripes

*Gets the number of partitions along the leading dimension of the output matrix for parallel ?gemm functions.*

## Syntax

```
int mkl_get_num_stripes(void);
```

## Include Files

- mkl.h

## Description

This function returns the number of stripes, that is, partitions along the leading dimension of the output matrix, for parallel ?gemm functions. The number of partitions only applies to ?gemm functions.

The number returned is a hint, and Intel MKL may actually use a smaller number.

## Return Values

| Name      | Type | Description                                                 |
|-----------|------|-------------------------------------------------------------|
| <i>ns</i> | int  | The number of stripes for Intel MKL ?gemm functions to use. |

## Example

```
#include "mkl.h"
...
int ns = mkl_get_num_stripes();
if (ns > 0) printf("Intel MKL uses %d number of stripes\n", ns);
```

# Error Handling

## Error Handling for Linear Algebra Routines

### xerbla

*Error handling function called by BLAS, LAPACK, Vector Math, and Vector Statistics functions.*

## Syntax

```
void xerbla(const char * sname, const int* info, const int len);
```

## Include Files

- `mkl.h`

## Input Parameters

| Name               | Type                     | Description                                                                                          |
|--------------------|--------------------------|------------------------------------------------------------------------------------------------------|
| <code>sname</code> | <code>const char*</code> | The name of the routine that called <code>xerbla</code>                                              |
| <code>info</code>  | <code>const int*</code>  | The position of the invalid parameter in the parameter list of the calling function or an error code |
| <code>len</code>   | <code>const int</code>   | Length of the source string                                                                          |

## Description

The `xerbla` function is an error handler for Intel MKL BLAS, LAPACK, Vector Math, and Vector Statistics functions. These functions call `xerbla` if an issue is encountered on entry or during the function execution.

`xerbla` operates as follows:

1. Prints a message that depends on the value of the `info` parameter as explained in the [Error Messages Printed by `xerbla`](#) table.

---

### NOTE

A specific message can differ from the listed messages in numeric values and/or function names.

---

2. Returns to the calling application.

Comments in the Netlib LAPACK reference code ([http://www.netlib.org/lapack/explore-html/d1/dc0/\\_b\\_l\\_a\\_s\\_2\\_s\\_r\\_c\\_2xerbla\\_8f.html](http://www.netlib.org/lapack/explore-html/d1/dc0/_b_l_a_s_2_s_r_c_2xerbla_8f.html)) suggest this behavior although the LAPACK User's Guide recommends that the execution should stop when an error occurs.

## Error Messages Printed by `xerbla`

| Value of <code>info</code> | Error Message                                                                  |
|----------------------------|--------------------------------------------------------------------------------|
| 1001                       | Intel MKL ERROR: Incompatible optional parameters on entry to DGEMM.           |
| 1212                       | Intel MKL INTERNAL ERROR: Issue accessing coprocessor in function CGEEV.       |
| 1000 or 1089               | Intel MKL INTERNAL ERROR: Insufficient workspace available in function CGELSD. |
| < 0                        | Intel MKL INTERNAL ERROR: Condition 1 detected in function DLASD8.             |
| Other                      | Intel MKL ERROR: Parameter 6 was incorrect on entry to DGEMM.                  |

Note that `xerbla` is an internal function. You can change or disable printing of an error message by providing your own `xerbla` function. The following examples illustrate usage of `xerbla`.

## Example

```
void xerbla(char* sname, int* info, int len){
// sname - name of the function that called xerbla
// info - position of the invalid parameter in the parameter list
```

```
// len - length of the name in bytes
printf("\nXERBLA is called :%s: %d\n",srname,*info);
}
```

## See Also

[mkl\\_set\\_xerbla](#)

## pxerbla

*Error handling routine called by ScaLAPACK routines.*

## Syntax

```
void pxerbla (MKL_INT* ictxt, char* srname, MKL_INT* info, MKL_INT srname_len);
```

## Include Files

- `mkl_scalapack.h`

## Input Parameters

|                   |                      |                                                                                                         |
|-------------------|----------------------|---------------------------------------------------------------------------------------------------------|
| <i>ictxt</i>      | (local)<br>MKL_INT*  | The BLACS context handle, indicating the global context of the operation. The context itself is global. |
| <i>srname</i>     | (global)<br>char*    | The name of the routine that called <code>pxerbla</code> .                                              |
| <i>info</i>       | (global)<br>MKL_INT* | The position of the invalid parameter in the parameter list of the calling routine.                     |
| <i>srname_len</i> | (global)<br>MKL_INT  | The length of the calling routine name.                                                                 |

## Description

This routine is an error handler for the *ScaLAPACK* routines. It is called if an input parameter has an invalid value. A message is printed and program execution continues. For *ScaLAPACK* driver and computational routines, a `RETURN` statement is issued following the call to `pxerbla`.

Control returns to the higher-level calling routine, and you can determine how the program should proceed. However, in the specialized low-level *ScaLAPACK* routines (auxiliary routines that are Level 2 equivalents of computational routines), the call to `pxerbla()` is immediately followed by a call to `BLACS_ABORT()` to terminate program execution since recovery from an error at this level in the computation is not possible.

It is always good practice to check for a non-zero value of *info* on return from a *ScaLAPACK* routine. Installers may consider modifying this routine in order to call system-specific exception-handling facilities.

## LAPACKE\_xerbla

Error handling function called by the C interface to LAPACK functions.

---

### Syntax

```
void LAPACKE_xerbla(const char * name, lapack_int info);
```

### Include Files

- mkl.h

### Input Parameters

| Name        | Type        | Description                                                                                          |
|-------------|-------------|------------------------------------------------------------------------------------------------------|
| <i>name</i> | const char* | The name of the routine that called LAPACKE_xerbla                                                   |
| <i>info</i> | lapack_int  | The position of the invalid parameter in the parameter list of the calling function or an error code |

### Description

The LAPACKE\_xerbla function is an error handler for Intel MKL LAPACKE functions (the C interface to LAPACK functionality). If a LAPACKE function encounters an issue on entry or during the function execution, it calls LAPACKE\_xerbla to print an error message and return an error code.

---

**NOTE**

The LAPACKE\_xerbla routine does not replace the xerbla routine. For instance, if an issue occurs when a LAPACK function is called by a LAPACKE function, the LAPACK function calls xerbla.

---

### Error Messages Printed by LAPACKE\_xerbla

---

| Value of <i>info</i>          | Example Error Message                                        |
|-------------------------------|--------------------------------------------------------------|
| LAPACK_WORK_MEMORY_ERROR      | Not enough memory to allocate work array in LAPACKE_dgees    |
| LAPACK_TRANSPOSE_MEMORY_ERROR | Not enough memory to transpose matrix in LAPACKE_dgetrf_work |
| < 0                           | Wrong parameter 1 in LAPACKE_dgetrf                          |

---

---

**NOTE**

LAPACKE\_xerbla is an internal function. You can change or disable printing of an error message by providing your own LAPACKE\_xerbla function. Intel MKL does not provide functionality for dynamic replacement of LAPACKE\_xerbla.

---

### See Also

xerbla

### Handling Fatal Errors

A fatal error is a circumstance under which Intel MKL cannot continue the computation. For example, a fatal error occurs when Intel MKL cannot load a dynamic library or confronts an unsupported CPU type. In case of a fatal error, the default Intel MKL behavior is to print an explanatory message to the console and call an

internal function that terminates the application with a call to the system `exit()` function. Intel MKL enables you to override this behavior by setting a custom handler of fatal errors. The custom error handler can be configured to throw a C++ exception, set a global variable indicating the failure, or otherwise handle cannot-continue situations. It is not necessary for the custom error handler to call the system `exit()` function. Once execution of the error handler completes, a call to Intel MKL returns to the calling program without performing any computations and leaves no memory allocated by Intel MKL and no thread synchronization pending on return.

To specify a custom fatal error handler, call the `mkl_set_exit_handler` function.

## `mkl_set_exit_handler`

*Sets the custom handler of fatal errors.*

---

### Syntax

```
int mkl_set_exit_handler (MKLExitHandler myexit);
```

### Include Files

- `mkl.h`

### Input Parameters

| Name                | Prototype                             | Description               |
|---------------------|---------------------------------------|---------------------------|
| <code>myexit</code> | <code>void (*myexit)(int why);</code> | The error handler to set. |

### Description

This function sets the custom handler of fatal errors. If the input parameter is `NULL`, the system `exit()` function is set.

The following example shows how to use a custom handler of fatal errors in your C++ application:

```
#include "mkl.h"
void my_exit(int why){
 throw my_exception();
}
int ComputationFunction()
{
 mkl_set_exit_handler(my_exit);
 try {
 compute_using_mkl();
 }
 catch (const my_exception& e) {
 handle_exception();
 }
}
```

---

## Character Equality Testing

---

### `lsame`

*Tests two characters for equality regardless of the case.*

---

## Syntax

```
int lsame(const char* ca, const char* cb, int lca, int lcb);
```

## Include Files

- mkl.h

## Input Parameters

| Name            | Type        | Description                                           |
|-----------------|-------------|-------------------------------------------------------|
| <i>ca, cb</i>   | const char* | Pointers to the single characters to be compared      |
| <i>lca, lcb</i> | int         | Lengths of the input character strings, equal to one. |

## Description

This logical function checks whether two characters are equal regardless of the case.

## Return Values

| Name       | Type | Description                                                                                                                                                                                                                                                  |
|------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>val</i> | int  | Result of the comparison: <ul style="list-style-type: none"> <li>• a non-zero value if <i>ca</i> is the same letter as <i>cb</i>, maybe except for the case.</li> <li>• zero if <i>ca</i> and <i>cb</i> are different letters for whatever cases.</li> </ul> |

## lsamen

*Tests two character strings for equality regardless of the case.*

---

## Syntax

```
MKL_INT lsamen(const MKL_INT* n, const char* ca, const char* cb);
```

## Include Files

- mkl.h

## Input Parameters

| Name          | Type           | Description                                                                                                                       |
|---------------|----------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>      | const MKL_INT* | Pointer to the number of characters in <i>ca</i> and <i>cb</i> to be compared.                                                    |
| <i>ca, cb</i> | const char*    | Character strings of length at least <i>n</i> to be compared. Only the first <i>n</i> characters of each string will be accessed. |

## Description

This logical function tests whether the first *n* letters of one string are the same as the first *n* letters of the other string, regardless of the case.

## Return Values

| Name             | Type                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>val</code> | <code>MKL_INT</code> | Result of the comparison: <ul style="list-style-type: none"><li>• a non-zero value if the first <math>n</math> letters in <math>ca</math> and <math>cb</math> character strings are equal, maybe except for the case, or if the length of character string <math>ca</math> or <math>cb</math> is less than <math>n</math>.</li><li>• zero if the first <math>n</math> letters in <math>ca</math> and <math>cb</math> character strings are different for whatever cases.</li></ul> |

## Timing

---

### `second/dsecnd`

Returns elapsed time in seconds. Use to estimate real time between two calls to this function.

---

#### Syntax

```
float second(void);
double dsecnd(void);
```

#### Include Files

- `mkl.h`

#### Description

The `second/dsecnd` function returns time in seconds to be used to estimate real time between two calls to the function. The difference between these functions is in the precision of the floating-point type of the result: while `second` returns the single-precision type, `dsecnd` returns the double-precision type.

Use these functions to measure durations. To do this, call each of these functions twice. For example, to measure performance of a routine, call the appropriate function directly before a call to the routine to be measured, and then after the call of the routine. The difference between the returned values shows real time spent in the routine.

Initializations may take some time when the `second/dsecnd` function runs for the first time. To eliminate the effect of this extra time on your measurements, make the first call to `second/dsecnd` in advance.

Do not use `second` to measure short time intervals because the single-precision format is not capable of holding sufficient timer precision.

#### Return Values

| Name             | Type                                                                                      | Description                  |
|------------------|-------------------------------------------------------------------------------------------|------------------------------|
| <code>val</code> | <code>float</code> for <code>second</code><br><code>double</code> for <code>dsecnd</code> | Elapsed real time in seconds |

### `mkl_get_cpu_clocks`

Returns elapsed CPU clocks.

---

## Syntax

```
void mkl_get_cpu_clocks (unsigned MKL_INT64 *clocks);
```

## Include Files

- mkl.h

## Output Parameters

| Name                | Type               | Description        |
|---------------------|--------------------|--------------------|
| <code>clocks</code> | unsigned MKL_INT64 | Elapsed CPU clocks |

## Description

The `mkl_get_cpu_clocks` function returns the elapsed CPU clocks.

This may be useful when timing short intervals with high resolution. The `mkl_get_cpu_clocks` function is also applied in pairs like `second/dsecond`. Note that out-of-order code execution on IA-32 or Intel® 64 architecture processors may disturb the exact elapsed CPU clocks value a little bit, which may be important while measuring extremely short time intervals.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## `mkl_get_cpu_frequency`

*Returns the current CPU frequency value in GHz.*

## Syntax

```
double mkl_get_cpu_frequency(void);
```

## Include Files

- mkl.h

## Description

The function `mkl_get_cpu_frequency` returns the current CPU frequency in GHz.

### NOTE

The returned value may vary from run to run if power management or Intel® Turbo Boost Technology is enabled.

## Return Values

| Name        | Type   | Description                        |
|-------------|--------|------------------------------------|
| <i>freq</i> | double | Current CPU frequency value in GHz |

## mkl\_get\_max\_cpu\_frequency

Returns the maximum CPU frequency value in GHz.

---

### Syntax

```
double mkl_get_max_cpu_frequency(void);
```

### Include Files

- mkl.h

### Description

The function `mkl_get_max_cpu_frequency` returns the maximum CPU frequency in GHz.

## Return Values

| Name        | Type   | Description                        |
|-------------|--------|------------------------------------|
| <i>freq</i> | double | Maximum CPU frequency value in GHz |

## mkl\_get\_clocks\_frequency

Returns the frequency value in GHz based on constant-rate Time Stamp Counter.

---

### Syntax

```
double mkl_get_clocks_frequency (void);
```

### Include Files

- mkl.h

### Description

The function `mkl_get_clocks_frequency` returns the CPU frequency value (in GHz) based on constant-rate Time Stamp Counter (TSC). Use of the constant-rate TSC ensures that each clock tick is constant even if the CPU frequency changes. Therefore, the returned frequency is constant.

---

#### NOTE

Obtaining the frequency may take some time when `mkl_get_clocks_frequency` is called for the first time. The same holds for functions `second/dsecnd`, which call `mkl_get_clocks_frequency`.

---

## Return Values

| Name        | Type   | Description            |
|-------------|--------|------------------------|
| <i>freq</i> | double | Frequency value in GHz |

**See Also**

second/dsecnd

## Memory Management

This section describes the Intel MKL memory functions. See the *Intel® MKL Developer Guide* for more memory usage information.

### mkl\_free\_buffers

*Frees unused memory allocated by the Intel MKL Memory Allocator.*

#### Syntax

```
void mkl_free_buffers (void);
```

#### Include Files

- mkl.h

#### Description

To improve performance of Intel MKL, the Memory Allocator uses per-thread memory pools where buffers may be collected for fast reuse. The `mkl_free_buffers` function frees unused memory allocated by the Memory Allocator.

See the *Intel MKL Developer Guide* for details.

You should call `mkl_free_buffers` after the last call to Intel MKL functions. In large applications, if you suspect that the memory may get insufficient, you may call this function earlier, but anticipate a drop in performance that may occur due to reallocation of buffers for subsequent calls to Intel MKL functions.

In a threaded application, avoid calling `mkl_free_buffers` from each thread because the function has a global effect. Call `mkl_thread_free_buffers` instead.

#### Usage of mkl\_free\_buffers with FFT Functions

```
DFTI_DESCRIPTOR_HANDLE hand1;
DFTI_DESCRIPTOR_HANDLE hand2;
void mkl_free_buffers(void);
.
/* Using MKL FFT */
Status = DftiCreateDescriptor(&hand1, DFTI_SINGLE, DFTI_COMPLEX, dim, m1);
Status = DftiCommitDescriptor(hand1);
Status = DftiComputeForward(hand1, s_array1);
.
Status = DftiCreateDescriptor(&hand2, DFTI_SINGLE, DFTI_COMPLEX, dim, m2);
Status = DftiCommitDescriptor(hand2);
.
Status = DftiFreeDescriptor(&hand1);
/* Do not call mkl_free_buffers() here because the hand2 descriptor will be corrupted! */
.
Status = DftiComputeBackward(hand2, s_array2));
Status = DftiFreeDescriptor(&hand2);
/* Here you finish using Intel MKL FFT */
/* Memory leak will be triggered by any memory control tool */
/* Use mkl_free_buffers() to avoid memory leaking */
mkl_free_buffers();
```

## **mkl\_thread\_free\_buffers**

*Frees unused memory allocated by the Intel MKL Memory Allocator in the current thread.*

---

### **Syntax**

```
void mkl_thread_free_buffers (void);
```

### **Include Files**

- `mkl.h`

### **Description**

To improve performance of Intel MKL, the Memory Allocator uses per-thread memory pools where buffers may be collected for fast reuse. The `mkl_thread_free_buffers` function frees unused memory allocated by the Memory Allocator in the current thread only.

You should call `mkl_thread_free_buffers` after the last call to Intel MKL functions in the current thread. In large applications, if you suspect that the memory may get insufficient, you may call this function earlier, but anticipate a drop in performance that may occur due to reallocation of buffers for subsequent calls to Intel MKL functions.

### **See Also**

[mkl\\_free\\_buffers](#)

## **mkl\_disable\_fast\_mm**

*Turns off the Intel MKL Memory Allocator for Intel MKL functions to directly use the system `malloc/free` functions.*

---

### **Syntax**

```
int mkl_disable_fast_mm (void);
```

### **Include Files**

- `mkl.h`

### **Description**

The `mkl_disable_fast_mm` function turns the Intel MKL Memory Allocator off for Intel MKL functions to directly use the system `malloc/free` functions. Intel MKL Memory Allocator uses per-thread memory pools where buffers may be collected for fast reuse. The Memory Allocator is turned on by default for better performance. To turn it off, you can use the `mkl_disable_fast_mm` function or the `MKL_DISABLE_FAST_MM` environment variable (See the *Intel MKL Developer Guide* for details.) Call `mkl_disable_fast_mm` before calling any Intel MKL functions that require allocation of memory buffers.

---

#### **NOTE**

Turning the Memory Allocator off negatively impacts performance of some Intel MKL routines, especially for small problem sizes.

---

## Return Values

| Name      | Type | Description                                                                                          |
|-----------|------|------------------------------------------------------------------------------------------------------|
| <i>mm</i> | int  | 1 - The Memory Allocator is successfully turned off.<br>0 - Turning the Memory Allocator off failed. |

## mkl\_mem\_stat

*Reports the status of the Intel MKL Memory Allocator.*

### Syntax

```
MKL_INT64 mkl_mem_stat (int* AllocatedBuffers);
```

### Include Files

- `mkl.h`

### Output Parameters

| Name                    | Type | Description                                   |
|-------------------------|------|-----------------------------------------------|
| <i>AllocatedBuffers</i> | int  | The number of buffers allocated by Intel MKL. |

### Description

The function returns the number of buffers allocated by Intel MKL and the amount of memory in these buffers. Intel MKL can allocate the memory buffers internally or in a call to [mkl\\_malloc/mkl\\_calloc](#). If no buffers are allocated at the moment, the `mkl_mem_stat` function returns 0. Call `mkl_mem_stat` to check the Intel MKL memory status.

---

#### NOTE

If you free all the memory allocated in calls to `mkl_malloc` or `mkl_calloc` and then call `mkl_free_buffers`, a subsequent call to `mkl_mem_stat` normally returns 0.

---

## Return Values

| Name                  | Type      | Description                                |
|-----------------------|-----------|--------------------------------------------|
| <i>AllocatedBytes</i> | MKL_INT64 | The amount of allocated memory (in bytes). |

## mkl\_peak\_mem\_usage

*Reports the peak memory allocated by the Intel MKL Memory Allocator.*

### Syntax

```
MKL_INT64 mkl_peak_mem_usage (intmode);
```

## Include Files

- `mk1.h`

## Input Parameters

| Name              | Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mode</code> | <code>int</code> | Requested mode of the function's operation.<br>Possible values: <ul style="list-style-type: none"> <li>• <code>MKL_PEAK_MEM_ENABLE</code> - start gathering the peak memory data</li> <li>• <code>MKL_PEAK_MEM_DISABLE</code> - stop gathering the peak memory data</li> <li>• <code>MKL_PEAK_MEM</code> - return the peak memory</li> <li>• <code>MKL_PEAK_MEM_RESET</code> - return the peak memory and reset the counter to start gathering the peak memory data from scratch</li> </ul> |

## Description

The `mk1_peak_mem_usage` function reports the peak memory allocated by the Intel MKL Memory Allocator.

Gathering the peak memory data is turned off by default. If you need to know the peak memory, explicitly turn the data gathering mode on by calling the function with the `MKL_PEAK_MEM_ENABLE` value of the parameter. Use the `MKL_PEAK_MEM` and `MKL_PEAK_MEM_RESET` values only when the data gathering mode is turned on. Otherwise the function returns -1. The data gathering mode leads to performance degradation, so when the mode is turned on, you can turn it off by calling the function with the `MKL_PEAK_MEM_DISABLE` value of the parameter.

- 
- If Intel MKL is running in a threaded mode, the `mk1_peak_mem_usage` function may return different amounts of memory from run to run.
  - The function reports the peak memory for the entire application, not just for the calling thread.
- 

## Return Values

| Name                        | Type                   | Description                                                                           |
|-----------------------------|------------------------|---------------------------------------------------------------------------------------|
| <code>AllocatedBytes</code> | <code>MKL_INT64</code> | The peak memory allocated by the Memory Allocator (in bytes) or -1 in case of errors. |

## `mk1_malloc`

*Allocates an aligned memory buffer.*

---

## Syntax

```
void* mk1_malloc (size_t alloc_size, int alignment);
```

## Include Files

- `mk1.h`

## Input Parameters

| Name                    | Type                | Description                         |
|-------------------------|---------------------|-------------------------------------|
| <code>alloc_size</code> | <code>size_t</code> | Size of the buffer to be allocated. |
| <code>alignment</code>  | <code>int</code>    | Alignment of the buffer.            |

## Description

The function allocates an `alloc_size`-byte buffer aligned on the `alignment`-byte boundary.

If `alignment` is not a power of 2, the 32-byte alignment is used.

## Return Values

| Name               | Type               | Description                                                                                                 |
|--------------------|--------------------|-------------------------------------------------------------------------------------------------------------|
| <code>a_ptr</code> | <code>void*</code> | Pointer to the allocated buffer if <code>alloc_size</code> $\geq$ 1, NULL if <code>alloc_size</code> $<$ 1. |

## See Also

## mkl\_calloc

*Allocates and initializes an aligned memory buffer.*

## Syntax

```
void* mkl_calloc (size_t num, size_t size, int alignment);
```

## Include Files

- `mkl.h`

## Input Parameters

| Name                   | Type                | Description                                           |
|------------------------|---------------------|-------------------------------------------------------|
| <code>num</code>       | <code>size_t</code> | The number of elements in the buffer to be allocated. |
| <code>size</code>      | <code>size_t</code> | The size of the element.                              |
| <code>alignment</code> | <code>int</code>    | Alignment of the buffer.                              |

## Description

The function allocates a `num*size`-byte buffer, aligned on the `alignment`-byte boundary, and initializes the buffer with zeros.

If `alignment` is not a power of 2, the 64-byte alignment is used.

## Return Values

| Name               | Type               | Description                                                    |
|--------------------|--------------------|----------------------------------------------------------------|
| <code>a_ptr</code> | <code>void*</code> | Pointer to the allocated buffer if <code>size</code> $\geq$ 1, |

---

| Name | Type | Description              |
|------|------|--------------------------|
|      |      | NULL if <i>size</i> < 1. |

## mkl\_realloc

*Changes the size of memory buffer allocated by mkl\_malloc/mkl\_calloc.*

---

### Syntax

```
void* mkl_realloc (void *ptr, size_t size);
```

### Include Files

- `mkl.h`

### Input Parameters

| Name        | Type   | Description                                                                                                                  |
|-------------|--------|------------------------------------------------------------------------------------------------------------------------------|
| <i>ptr</i>  | void*  | Pointer to the memory buffer allocated by the <code>mkl_malloc</code> or <code>mkl_calloc</code> function or a NULL pointer. |
| <i>size</i> | size_t | New size of the buffer.                                                                                                      |

### Description

The function changes the size of the memory buffer allocated by the `mkl_malloc` or `mkl_calloc` function to *size* bytes. The first bytes of the returned buffer up to the minimum of the old and new sizes keep the content of the input buffer. The returned memory buffer can have a different location than the input one. If *ptr* is NULL, the function works as `mkl_malloc`.

### Return Values

| Name         | Type  | Description                                                                                                                                                           |
|--------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>a_ptr</i> | void* | <ul style="list-style-type: none"><li>• Pointer to the re-allocated buffer if re-allocation is successful.</li><li>• NULL if re-allocation is unsuccessful.</li></ul> |

### Description

This function sets the limit for the amount of memory that Intel MKL can allocate for the specified memory type. The limit bounds both internal allocations (inside Intel MKL computation routines) and external allocations (in a call to `mkl_malloc`, `mkl_calloc`, or `mkl_realloc`). By default no limit is set for memory allocation.

Call `mkl_set_memory_limit` at most once, prior to calling any other Intel MKL function in your application except `mkl_set_interface_layer` and `mkl_set_threading_layer`.

- Allocation in MCDRAM requires `libmemkind` and `libjemalloc` dynamic libraries which are a part of Intel® Manycore Platform Software Package (Intel® MPSP) for Linux\*.
- The `mkl_set_memory_limit` function takes precedence over the `MKL_FAST_MEMORY_LIMIT` environment variable.

## Return Values

| Type | Description                                                                                                                                     |

|------|------|-------------------------------------------------------------------------------------------------|
|      |      | MKL_INTERFACE_LP64+MKL_INTERFACE_GNU or<br>MKL_INTERFACE_GNU for the GNU interface on Linux OS. |

## Description

If you are using the Single Dynamic Library (SDL), the `mkl_set_interface_layer` function sets the specified interface layer for Intel MKL at run time.

Call this function prior to calling any other Intel MKL function in your application except `mkl_set_threading_layer`. You can call `mkl_set_interface_layer` and `mkl_set_threading_layer` in any order.

The `mkl_set_interface_layer` function takes precedence over the `MKL_INTERFACE_LAYER` environment variable.

See *Intel MKL Developer Guide* for the layered model concept and usage details of the SDL.

## Return Values

| Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                        |

*Sets the threading layer for Intel MKL at run time. Use with the Single Dynamic Library (SDL).*

---

## Syntax

```
int mkl_set_threading_layer (int required_threading);
```

## Include Files

- `mkl.h`

## Input Parameters

| Name                            | Type             | Description                                                                                                                                                                                                                                                                         |
|---------------------------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>required_threading</code> | <code>int</code> | Determines the threading layer. Possible values:<br><code>MKL_THREADING_INTEL</code> for Intel threading.<br><code>MKL_THREADING_SEQUENTIAL</code> for the sequential mode of Intel MKL.<br><code>MKL_THREADING_TBB</code> for threading with the Intel® Threading Building Blocks. |

| Name | Type | Description                                                                                                                                                                    |
|------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|      |      | MKL_THREADING_PGI for PGI threading on Windows* or Linux* operating system only. Do not use this value with the SDL for Intel® Many Integrated Core (Intel® MIC) Architecture. |
|      |      | MKL_THREADING_GNU for GNU threading on Linux* operating system only. Do not use this value with the SDL for Intel MIC Architecture.                                            |

## Description

If you are using the Single Dynamic Library (SDL), the `mkl_set_threading_layer` function sets the specified threading layer for Intel MKL at run time.

Call this function prior to calling any other Intel MKL function in your application except `mkl_set_interface_layer`.

You can call `mkl_set_threading_layer` and `mkl_set_interface_layer` in any order.

The `mkl_set_threading_layer` function takes precedence over the `MKL_THREADING_LAYER` environment variable.

See *Intel MKL Developer Guide* for the layered model concept and usage details of the SDL.

## Return Values

| Type             | Description                                                                                                                                                                                                                                                                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>int</code> | <ul style="list-style-type: none"> <li>Current threading layer if it is set in a call to <code>mkl_set_threading_layer</code> or specified by environment variables or defaults. Possible values are specified in <a href="#">Input Parameters</a>.</li> <li>-1, if the layer was not specified prior to the call and the input parameter is incorrect.</li> </ul> |

## mkl\_set\_xerbla

*Replaces the error handling routine. Use with the Single Dynamic Library on Windows\*.*

## Syntax

```
XerblaEntry mkl_set_xerbla (XerblaEntry new_xerbla_ptr);
```

## Include Files

- `mkl.h`

## Input Parameters

| Name                        | Type                     | Description                                       |
|-----------------------------|--------------------------|---------------------------------------------------|
| <code>new_xerbla_ptr</code> | <code>XerblaEntry</code> | Pointer to the error handling routine to be used. |

## Description

If you are linking with the Single Dynamic Library (SDL) `mkl_rt.lib` on Windows\*, the `mkl_set_xerbla` function replaces the error handling routine that is called by Intel MKL functions with the routine specified by the parameter.

See *Intel MKL Developer Guide* for details of SDL.

## Return Values

The function returns the pointer to the replaced error handling routine.

## See Also

[xerbla](#)

## **mkl\_set\_progress**

*Replaces the progress information routine.*

---

### Syntax

```
ProgressEntry mkl_set_progress (ProgressEntry new_progress_ptr);
```

### Include Files

- `mkl.h`

### Input Parameters

| Name                          | Type                       | Description                                             |
|-------------------------------|----------------------------|---------------------------------------------------------|
| <code>new_progress_ptr</code> | <code>ProgressEntry</code> | Pointer to the progress information routine to be used. |

### Description

The `mkl_set_progress` function replaces the currently used progress information routine with the routine specified by the parameter.

Usually a user-supplied `mkl_progress` function redefines the default `mkl_progress` function automatically. However, you must call `mkl_set_progress` to replace the default `mkl_progress` on Windows\* in any of the following cases:

- You are using the Single Dynamic Library (SDL) `mkl_rt.lib`.
- You link dynamically with ScaLAPACK.

See *Intel MKL Developer Guide* for details of SDL.

### Return Values

The function returns the pointer to the replaced progress information routine.

## See Also

[mkl\\_progress](#)

## **mkl\_set\_pardiso\_pivot**

*Replaces the routine handling Intel MKL PARDISO pivots with a user-defined routine. Use with the Single Dynamic Library (SDL).*

---

### Syntax

```
PardisopivotEntry mkl_set_pardiso_pivot (PardisopivotEntry new_pardiso_pivot_ptr);
```

### Include Files

- `mkl.h`

## Input Parameters

| Name                               | Type                           | Description                                      |
|------------------------------------|--------------------------------|--------------------------------------------------|
| <code>new_pardiso_pivot_ptr</code> | <code>PardisoPivotEntry</code> | Pointer to the pivot setting routine to be used. |

## Description

If you are using the Single Dynamic Library (SDL), the `mkl_set_pardiso_pivot` function replaces the pivot setting routine that is called by Intel MKL functions with the routine specified by the parameter.

See *Intel MKL Developer Guide* for usage details of the SDL.

## Return Values

| Type                           | Description                                    |
|--------------------------------|------------------------------------------------|
| <code>PardisoPivotEntry</code> | Pointer to the replaced pivot setting routine. |

## See Also

# Intel Many Integrated Core Architecture Support

This section describes Intel MKL functions to support the use of Intel Xeon Phi coprocessors and especially Automatic Offload mode, when the computations are automatically offloaded to the coprocessors.

The `mkl_mic_enable` function enables Intel MKL to offload computations to Intel Xeon Phi coprocessors automatically, while the `mkl_mic_disable` function disables automatic offloading.

### Important

Automatic Offload supports only OpenMP\* threaded Intel MKL.

Optional work-division control functions enable you to specify the fractional amount of work to distribute between the host CPU and the coprocessors in the Automatic Offload mode. Work division is a fractional measure ranging from 0.0 to 1.0. For example, setting work division for the host CPU to 0.5 means to keep half of the computational work on the host CPU and move half to the coprocessor(s). Setting work division to 0.25 for a coprocessor means to offload a quarter of the computational work to this coprocessor while leaving the rest on the host CPU.

Other functions enable more control over computational resources of Intel Xeon Phi coprocessors.

### NOTE

The support functions for Intel MIC Architecture take precedence over the respective environment variables.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

**Optimization Notice**

Notice revision #20110804

**mkl\_mic\_enable***Enables Automatic Offload mode.***Syntax**

```
int mkl_mic_enable();
```

**Include Files**

- mkl.h

**Description**

The `mkl_mic_enable` function enables Automatic Offload mode and initializes Intel Xeon Phi coprocessors available on your system. This function takes precedence over the `MKL_MIC_ENABLE` environment variable. Unlike the function, the environment variable enables Automatic Offload mode, but the initialization is delayed until a call to an Intel MKL function supporting Automatic Offload. For functions supporting Automatic Offload, see the *Intel MKL Release Notes*.

**Return Values**

| Name              | Type             | Description                                                                                                                                       |
|-------------------|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ierr</code> | <code>int</code> | Result status:<br>= 0 Indicates that Automatic Offload mode is successfully enabled.<br>< 0 Indicates a failure to enable Automatic Offload mode. |

**mkl\_mic\_disable***Disables Automatic Offload mode.***Syntax**

```
int mkl_mic_disable();
```

**Include Files**

- mkl.h

**Description**

The `mkl_mic_disable` function disables Automatic Offload mode. To enable Automatic Offload mode back, use the `mkl_mic_enable` function.

**NOTE**

If Automatic Offload mode is not enabled, a call to `mkl_mic_disable` completes successfully if Intel Xeon Phi coprocessors are available on your system.

## Return Values

| Name              | Type             | Description                                                                                                                                                           |
|-------------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ierr</code> | <code>int</code> | <p>Result status:</p> <p>= 0 Indicates that Automatic Offload mode is successfully disabled.</p> <p>&lt; 0 Indicates a failure to disable Automatic Offload mode.</p> |

## `mkl_mic_get_device_count`

Returns the number of Intel Xeon Phi coprocessors on the system when called on the host CPU.

### Syntax

```
int mkl_mic_get_device_count();
```

### Include Files

- `mkl.h`

### Description

The `mkl_get_device_count` function returns the number of Intel Xeon Phi coprocessors on your system. You may need this number to specify a custom work-division scheme.

---

#### CAUTION

Call this function only on the host CPU.

---

## Return Values

| Name                  | Type             | Description                                                                                       |
|-----------------------|------------------|---------------------------------------------------------------------------------------------------|
| <code>ndevices</code> | <code>int</code> | The number of Intel Xeon Phi coprocessors available on the system. Equals zero if there are none. |

### See Also

[mkl\\_mic\\_enable](#)

## `mkl_mic_set_workdivision`

For computations in the Automatic Offload mode, sets the fraction of the work for the specified coprocessor or host CPU to do.

### Syntax

```
int mkl_mic_set_workdivision (MKL_MIC_TARGET_TYPE target_type, int target_number, double wd);
```

### Include Files

- `mkl.h`

## Input Parameters

| Name                       | Type                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>target_type</code>   | <code>MKL_MIC_TARGET_TYPE</code> | Type of the target device. Use one of the following values: <ul style="list-style-type: none"> <li><code>MKL_TARGET_HOST</code> - host CPU</li> <li><code>MKL_TARGET_MIC</code> - Intel Xeon Phi coprocessor, default</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>target_number</code> | <code>int</code>                 | The device to set the fraction of work for. Takes the following values: <ul style="list-style-type: none"> <li><math>\geq 0</math>. Specifies execution on a specific coprocessor. The coprocessor is determined by <code>target_number</code> modulo the number of Intel Xeon Phi coprocessors on the system as returned by <code>mkl_mic_get_device_count()</code>. For example: for a system with 4 Intel Xeon Phi coprocessors, <code>target_number = 6</code> determines the coprocessor number 2.</li> <li><math>&lt; 0</math>. Reserved.</li> </ul> <p>If <code>target_type = MKL_TARGET_HOST</code>, the function ignores the <code>target_number</code> parameter, which may have any value.</p> |
| <code>wd</code>            | <code>double</code>              | The fractional amount of the work that the specified device should do, where $0.0 \leq wd \leq 1.0$ .<br>Specifying <code>MKL_MIC_AUTO_WORKDIVISION</code> for <code>wd</code> indicates that Intel MKL should determine the amount of the work for the specified device.                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Description

If you are using Intel MKL in Automatic Offload mode, the `mkl_mic_set_workdivision` function specifies how much work each Intel Xeon Phi coprocessor or the host CPU should do. This function takes precedence over the `MKL_HOST_WORKDIVISION`, `MKL_MIC_WORKDIVISION`, and `MKL_MIC_<number>_WORKDIVISION` environment variables (see the *Intel MKL Developer Guide* for details).

- 
- Intel MKL interprets the fraction of work set by the `mkl_mic_set_workdivision` function as guidance toward dividing work between coprocessors, but the library may choose a different work division if necessary.
  - Intel MKL resolves the collision that arises if the sum of all the work-division fractions does not equal one.
  - For LAPACK routines, setting the fraction of work to any value other than 0.0 enables the specified processor for Automatic Offload mode. However Intel MKL LAPACK does not use the value specified to divide the workload. For example, setting the fraction to 0.5 has the same effect as setting the fraction to 1.0.
-

## Return Values

| Name              | Type             | Description                                                                                                                                                                           |
|-------------------|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ierr</code> | <code>int</code> | <p>Result status:</p> <ul style="list-style-type: none"> <li>= 0 Indicates that the fraction is successfully set.</li> <li>&lt; 0 Indicates a failure to set the fraction.</li> </ul> |

## mkl\_mic\_get\_workdivision

For computations in the Automatic Offload mode, retrieves the fraction of the work for the specified coprocessor or host CPU to do.

## Syntax

```
int mkl_mic_get_workdivision (MKL_MIC_TARGET_TYPE target_type, int target_number,
double *wd);
```

## Include Files

- `mkl.h`

## Input Parameters

| Name                       | Type                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

Reserved.</li> </ul> <p>For the <code>target_number</code> device, the amount of memory in kilobytes to reserve for Automatic Offload computations. Intel MKL attempts to not exceed the specified memory size for Automatic Offload computations.</p> |

## Description

The `mkl_mic_set_max_memory` function enables you to limit coprocessor memory used by the Automatic Offload computations. Intel MKL reserves the specified memory on Intel Xeon Phi coprocessors. This can improve the performance of Automatic Offload computations by reducing the cost of buffer initialization and data transfer. The specified memory is reserved for the calling process, and the threads of a process share the specified memory. Intel MKL allocates additional memory for each process that performs Automatic Offload computations.

This function takes precedence over the `MKL_MIC_MAX_MEMORY` and `MKL_MIC_<number>_MAX_MEMORY` environment variables (see the *Intel MKL Developer Guide* for details).

- 
- Call `mkl_mic_set_max_memory` before any Intel MKL functions that do Automatic Offload computations.
  - Use `mkl_mic_free_memory` to free the coprocessor memory reserved for the Automatic Offload computations.
- 

## Return Values

| Name              | Type             | Description                                                                                                                                                                                                                    |

| <i>target_number</i> | int                 | The coprocessor number for which the memory reserved for Automatic Offload computations is freed. Takes the following values: <ul style="list-style-type: none"> <li>• <math>\geq 0</math>. Specifies execution on a specific coprocessor. The coprocessor is determined by <i>target_number</i> modulo the number of Intel Xeon Phi coprocessors on the system as returned by <code>mkl_mic_get_device_count()</code>. For example: for a system with 4 Intel Xeon Phi coprocessors, <i>target_number</i> = 6 determines the coprocessor number 2.</li> <li>• <math>&lt; 0</math>. Reserved.</li> </ul> |

## Description

The `mkl_mic_free_memory` function frees the coprocessor memory reserved for the Automatic Offload computations. If you call `mkl_mic_set_max_memory` to specify the maximum coprocessor memory for Automatic Offload computations, Intel MKL reserves and reuses the specified coprocessor memory during multiple Automatic Offload calls. You can reclaim the coprocessor memory by calling `mkl_mic_free_memory`.

- 
- Currently, Intel MKL reserves the coprocessor memory only if the `mkl_mic_set_max_memory` function is called. Therefore, `mkl_mic_free_memory` has no effect unless there is a prior call to the `mkl_mic_set_max_memory` function.
  - If you do not call `mkl_mic_free_memory`, Intel MKL frees the coprocessor memory at the program exit.
- 

## Return Values

| Name        | Type | Description                                                                                                                                                                                     |
|-------------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## **mkl\_mic\_register\_memory**

*Enables/disables the `mkl_malloc` function running in Automatic Offload mode to register allocated memory.*

### **Syntax**

```
void mkl_mic_register_memory (int control);
```

### **Include Files**

- `mkl.h`

### **Input Parameters**

| <b>Name</b>          | <b>Type</b>      | <b>Description</b>                                                                                                                                                                           |
|----------------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>control</code> | <code>int</code> | Desired behavior of <code>mkl_malloc</code> .<br>Possible values:<br>0 - not register allocated memory, default.<br>1 - register allocated memory if Automatic Offload (AO) mode is enabled. |

### **Description**

The `mkl_mic_register_memory` function enables or disables the `mkl_malloc` function to register allocated memory when `mkl_malloc` runs in AO mode.

Registration of memory may reduce the overhead introduced by the operating system during data transfers between Intel Xeon Phi coprocessors and the host CPU.

This function takes precedence over the `MKL_MIC_REGISTER_MEMORY` environment variable.

If AO mode is disabled, the function has no effect.

### **See Also**

## Description

The `mkl_mic_set_device_num_threads` function enables you to limit the number of OpenMP threads to use for Automatic Offload computations on a specific Intel Xeon Phi coprocessor.

This function takes precedence over the `MIC_OMP_NUM_THREADS` and `MKL_MIC_<number>_OMP_NUM_THREADS` environment variables (see the *Intel MKL Developer Guide* for details).

Unless the maximum number of threads is set by the environment variables or this function, Intel MKL uses all coprocessor cores.

Call `mkl_mic_set_device_num_threads` before initialization of Automatic Offload mode. Otherwise the function returns -1 without setting the number of threads.

---

### NOTE

Automatic Offload mode can be initialized as follows:

- *explicitly*, in a call to the `mkl_mic_enable` function.
  - *implicitly*, in the first call to an Intel MKL function that does Automatic Offload computations (for example: `?GEMM`). See the *Intel MKL Release Notes* for which functions support Automatic Offload mode.
- 

The `mkl_mic_set_device_num_threads` function sets the maximum number of threads to use for the Automatic Offload computations on Intel Xeon Phi coprocessors only. To control host CPU threading, use general threading control functions and see "Using Additional Threading Control" in the *Intel MKL Developer Guide* for more information.

## Return Values

| Name              | Type | Description    |
|-------------------|------|----------------|
| <code>ierr</code> | int  | Result status: |

| Name | Type | Description                                                   |
|------|------|---------------------------------------------------------------|
|      |      | = 0 Indicates that the number of threads is set successfully. |
|      |      | < 0 Indicates a failure to set the number of threads.         |

*For computations in the Automatic Offload mode, sets the maximum fraction of available Intel Xeon Phi coprocessor computational resources (cores) that the calling process can use.*

### Syntax

```
int mkl_mic_set_resource_limit (double fraction);
```

### Include Files

- `mkl.h`

### Input Parameters

| Name            | Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>fraction</i> | double | <p>The fractional amount of Intel Xeon Phi coprocessor computational resources that the calling process can use for Automatic Offload (AO).</p> <p>Possible values: <math>0.0 \leq \textit{fraction} \leq 1.0</math>.</p> <p>Special values:</p> <ul style="list-style-type: none"> <li>• 0.0 - you need to manage the coprocessors explicitly using the <a href="#">mkl_mic_set_device_num_threads</a> function or the <code>MIC_KMP_AFFINITY</code> environment variable. Default.</li> <li>• <code>MKL_MPI_PPN</code> constant - enables a fully automated mode for message-passing interface (MPI) applications. In this mode, Intel MKL tries to read the number of MPI processes per node (<i>ppn</i>) from the environment variables passed to the process by MPI. If this attempt is successful, Intel MKL sets the actual value of the fractional amount to <math>1.0/\textit{ppn}</math>.</li> </ul> |

#### NOTE

For Intel® MPI Library, Open MPI, and IBM Platform MPI, Intel MKL automatically detects *ppn*. For other MPI implementations, use the `MKL_MPI_PPN` environment variable to set *ppn*.

## Description

If you are using Intel MKL in the AO mode, the `mkl_mic_set_resource_limit` function specifies how much of the computational resources of Intel Xeon Phi coprocessors can be used by the calling process. Use this function if you need to share coprocessor cores automatically across multiple processes that call Intel MKL in the AO mode. For example, this might be useful in MPI applications.

You can also enable this functionality using the `MKL_MIC_RESOURCE_LIMIT` environment variable (see the *Intel MKL Developer Guide* for details), but the `mkl_mic_set_resource_limit` function take precedence over the environment variable.

If *fraction* is set to a valid non-zero value, Intel MKL enables automatic reservation of Intel Xeon Phi coprocessor cores.

Actual reservation is made during a call to an Intel MKL AO function and works as follows:

1. Intel MKL converts *fraction* to a number of Intel Xeon Phi coprocessor cores and tries to find cores that are not reserved by other processes.

The number of available cores can be less than the requested number. Intel MKL considers cores of all available coprocessors as a single space and can find cores on different coprocessors. However, Intel MKL tends to reserve as many cores as were requested and to reserve cores compactly (using as few coprocessors as possible).

2. Intel MKL exclusively reserves cores found in the previous step.

Intel MKL makes reservation safely across a persistent shared memory region using semaphores.

3. Intel MKL performs AO computations on reserved cores only.

You do not need to set any threading parameters for Intel Xeon Phi coprocessors, such as `MIC_OMP_NUM_THREADS` or `MIC_KMP_AFFINITY` (these settings are ignored when automatic resource sharing is enabled).

4. Upon completion of an AO call, Intel MKL releases reserved cores.

Be aware of the following features of the automatic reservation:

- Execution of Intel MKL AO functions falls back to the host if Intel MKL fails to reserve the minimum number of Intel Xeon Phi coprocessor cores that provide a benefit over executing on the host.
- The last core of Intel Xeon Phi coprocessors cannot be reserved because it is used for system processes.
- Reservation works only within a space of a single user. In other words, Intel MKL cannot share Intel Xeon Phi coprocessor resources across processes from different users.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## Examples

1. One Intel Xeon Phi coprocessor with 61 cores is available on the system. One process calls `mkl_mic_set_resource_limit(1.0)` and then calls `dgemm` in AO mode. As a result, 60 Intel Xeon Phi coprocessor cores are reserved at the beginning of AO `dgemm`. Then `mkl_mic_set_resource_limit(0.3)` is invoked and AO `dgemm` is called one more time. As a result,

`dgemm` is run on 18 Intel Xeon Phi coprocessor cores. During this run of AO `dgemm`, another process calls `mkl_mic_set_resource_limit(1.0)` and invokes AO `dgetrf`. Because 18 cores are reserved by the first process, only 42 cores are reserved for AO `dgetrf`.

2. Two Intel Xeon Phi coprocessors with 61 cores each are available on the system. Three processes simultaneously call `mkl_mic_set_resource_limit(0.34)` and then call `dpotrf` in AO mode. As a result, one process receives 40 cores from coprocessor 1, another process receives 40 cores from coprocessor 2, and the remaining process is given 20 cores from each of the two coprocessors for a total of 40 cores.
3. Two Intel Xeon Phi coprocessors with 58 cores each are available on the system. The user sets `MKL_MIC_PPN=4` and runs an MPI application with 4 MPI ranks. The following sequence of functions is called in each MPI process:

```
mkl_mic_set_workdivision(MKL_TARGET_MIC, 2, 0.0);
mkl_mic_set_resource_limit(MKL_MIC_PPN);
MPI_Init(...);
//calls to Intel MKL AO functions;
MPI_Finalize(...);
```

As a result, actual *fraction* is set to 0.25 for each MPI process, and each MPI process receives 14 cores on Intel Xeon Phi coprocessor 1 (because the user excluded co-processor 2 from computations by setting zero workdivision for it).

## Return Values

| Name              | Type             | Description                                                                                                            |
|-------------------|------------------|------------------------------------------------------------------------------------------------------------------------|
| <code>ierr</code> | <code>int</code> | Result status:<br>= 0 Indicates that the fraction is set successfully.<br>< 0 Indicates a failure to set the fraction. |

## **mkl\_mic\_set\_offload\_report**

*Turns on/off reporting of Automatic Offload profiling.*

## Syntax

```
int mkl_mic_set_offload_report (int enabled);
```

## Include Files

- `mkl.h`

## Input Parameters

| Name                 | Type             | Description                                                                                                                                                                                                                                                                                                |
|----------------------|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>enabled</code> | <code>int</code> | This parameter specifies whether to turn the reporting on or off. Takes values with boolean semantics: <ul style="list-style-type: none"> <li>• 0 - Reporting of Automatic Offload profiling should be turned off.</li> <li>• 1 - Reporting of Automatic Offload profiling should be turned on.</li> </ul> |

## Description

If the `OFFLOAD_REPORT` environment variable has the value of 1 or 2, the `mkl_mic_set_offload_report` function turns on/off reporting of the Automatic Offload profiling at run time. If the `OFFLOAD_REPORT` environment variable is not set or is set to a value different from 1 and 2, the function has no effect. If `OFFLOAD_REPORT` is set to 1 or 2, the reporting is turned on at a program startup. The `mkl_mic_set_offload_report` function does not change the reporting level or the value of the environment variable. Instead, it determines which Intel MKL functions called in the Automatic Offload mode produce profiling reports.

For details of the reporting level and `OFFLOAD_REPORT` environment variable, see the *Intel MKL Developer Guide*.

## Return Values

| Name               | Type             | Description                                                             |
|--------------------|------------------|-------------------------------------------------------------------------|
| <code>iprev</code> | <code>int</code> | The previous value that determined whether the reporting was on or off. |

## `mkl_mic_set_flags`

Sets flags to control the behavior of computations in the Automatic Offload mode.

### Syntax

```
int mkl_mic_set_flags (int flags);
```

### Include Files

- `mkl.h`

### Input Parameters

| Name               | Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>flags</code> | <code>int</code> | <p>The settings requested:</p> <ul style="list-style-type: none"> <li>• <code>MKL_MIC_DEFAULT_FLAGS</code> - The default Automatic Offload (AO) mode, when computations fall back to host in the case of any AO error, such as lack of memory or other resources on the Intel Xeon Phi coprocessor.</li> <li>• <code>MKL_MIC_DISABLE_HOST_FALLBACK</code> - The mode when computations do not fall back to host in the case of an AO error, but the AO function immediately returns control to the calling program without completing the computations.</li> </ul> |

### Description

This function sets flags to control the behavior of computations in the AO mode. Depending on the flags set, the AO program may silently return to the calling program in the case of an AO error. To check whether the AO call is successful, call the `mkl_mic_get_status` function and check whether the return value is non-negative. For more details of `mkl_mic_get_status` and in particular, for a sequence of function calls that enables checking the status of an AO call, see [mkl\\_mic\\_get\\_status](#).

### Return Values

| Name                   | Type             | Description               |
|------------------------|------------------|---------------------------|
| <code>old_flags</code> | <code>int</code> | The previously set flags. |

### See Also

[mkl\\_mic\\_get\\_flags](#)

## mkl\_mic\_get\_flags

Retrieves flags that control the behavior of computations in the Automatic Offload mode.

---

### Syntax

```
int mkl_mic_get_flags (void);
```

### Include Files

- mkl.h

### Description

This function retrieves flags that control the behavior of computations in the Automatic Offload (AO) mode. These flags are either the default flags for the AO mode or the flags set in a call to the `mkl_mic_set_flags` function.

---

#### NOTE

Depending on the flags set, the AO program may silently return to the calling program in the case of an AO error. To check whether the AO call is successful, call the `mkl_mic_get_status` function and check whether the return value is non-negative. For more details of `mkl_mic_get_status` and in particular, for a sequence of function calls that enables checking the status of an AO call, see [mkl\\_mic\\_get\\_status](#).

---

### Return Values

| Name               | Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>flags</code> | <code>int</code> | The flags returned, which can be one of the following: <ul style="list-style-type: none"><li>• <code>MKL_MIC_DEFAULT_FLAGS</code> - The default AO mode, when computations fall back to host in the case of any AO error, such as lack of memory or other resources on the Intel Xeon Phi coprocessor.</li><li>• <code>MKL_MIC_DISABLE_HOST_FALLBACK</code> - The mode when computations do not fall back to host in the case of an AO error, but the AO function immediately returns control to the calling program without completing the computations.</li></ul> |

## mkl\_mic\_get\_status

For the Automatic Offload mode, returns the status of the latest call to an Intel MKL function.

---

### Syntax

```
int mkl_mic_get_status (void);
```

## Include Files

- `mkl.h`

## Description

This function returns the status of the latest call to an Intel MKL function done in the Automatic Offload (AO) mode. The sign of the returned value characterizes the status of the AO computations at a high level:

- = 0 - The computations completed successfully using AO
- > 0 - The computations were done without using AO
- < 0 - The computations were not completed at all

In an AO call to an Intel MKL function, offloading computations as expected may not be possible for various reasons, such as:

- Lack of available memory or computation cores on an Intel Xeon Phi coprocessor
- Incorrect environment settings (which result in a failure to locate or load a coprocessor driver or libraries)
- Communication error during data transfer to or from a coprocessor (for example, a remote process dies unexpectedly)
- Other unexpected error

The status returned helps you to find out the reason of offload failure.

Because the status is a thread-local value, to be able to check the status of an Intel MKL AO function, the following sequence of function calls in the same thread is required:

1. `mkl_mic_clear_status`
2. Intel MKL function
3. `mkl_mic_get_status`

## Return Values

| Name                | Type             |
|---------------------|------------------|
| <code>status</code> | <code>int</code> |

### Description

The thread-local value of the status:

- `MKL_MIC_SUCCESS` (0) - The computations successfully completed with offloading to Intel Xeon Phi coprocessors.
- `MKL_MIC_NOT_IMPL` (1) - The computations successfully completed only on the host because AO is not implemented for this function or for the combination of input parameters of the function.
- `MKL_MIC_HOST_FALLBACK` (2) - The computations successfully completed only on the host because AO could not start. Possible reasons: the environment path does not include required system libraries, resources are insufficient, memory allocation failed on a coprocessor, and so on.
- `MKL_MIC_DISABLED` (3) - The computations successfully completed only on the host because AO is disabled.
- `MKL_MIC_FAILED` (-1) - The computations were not completed. AO could start, but an error occurred during the computations. Note that the function output data may be corrupted in this case.
- `MKL_MIC_HOST_FALLBACK_DISABLED` (-2) - The computations were not completed because AO could not start. Possible reasons: the environment path does not

| Name | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|      |      | include required system libraries, resources are insufficient, memory allocation failed on a coprocessor, and so on. Unlike <code>MKL_MIC_HOST_FALLBACK</code> , the <code>mkl_mic_get_status</code> function can return this status only if the <code>mkl_mic_set_flags</code> function disabled falling back to host. Unlike for <code>MKL_MIC_FAILED</code> status, the function input and output data remain untouched. |

#### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. ### **mkl\_mic\_clear\_status**

*For the Automatic Offload mode, clears the status of the latest call to an Intel MKL function.*

#### Syntax

```
int mkl_mic_clear_status (void);
```

#### Include Files

- `mkl.h`

#### Description

This function clears the status of the latest call to an Intel MKL function done in the Automatic Offload (AO) mode. Call `mkl_mic_clear_status` before calling an Intel MKL function in the AO mode to be able to check the status of the AO call. Because the status is a thread-local value, getting the status for an Intel MKL function requires the following sequence of function calls in the same thread:

1. `mkl_mic_clear_status`
2. Intel MKL function
3. `mkl_mic_get_status`

#### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-

**Optimization Notice**

## Conditional Numerical Reproducibility Control

The CNR mode of Intel MKL ensures bitwise reproducible results from run to run of Intel MKL functions on a fixed number of threads for a specific Intel instruction set architecture (ISA) under the following conditions:

- Calls to Intel MKL occur in a single executable
- The number of computational threads used by the library does not change in the run

Intel MKL offers both functions and environment variables to support conditional numerical reproducibility. See the *Intel MKL Developer Guide* for more information on bitwise reproducible results of computations and for details about the environment variables.

The support functions enable you to configure the CNR mode and also provide information on the current and optimal CNR branch on your system. [Usage Examples for CNR Support Functions](#) illustrate usage of these functions.

---

### Important

Call the functions that define the behavior of CNR before any of the math library functions that they control.

---

Intel MKL provides named constants for use as input and output parameters of the functions instead of integer values. See [Named Constants for CNR Control](#) for a list of the named constants.

Although you can configure the CNR mode using either the support functions or the environment variables, the functions offer more flexible configuration and control than the environment variables. Settings specified by the functions take precedence over the settings specified by the environment variables.

Use Intel MKL in the CNR mode only in case a need for bitwise reproducible results is critical. Otherwise, run Intel MKL as usual to avoid performance degradation.

While you can supply unaligned input and output data to Intel MKL functions running in the CNR mode, use of aligned data is recommended. Refer to [Reproducibility Conditions](#) for more details.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## [mkl\\_cbwr\\_set](#)

*Configures the CNR mode of Intel MKL.*

---

### Syntax

```
int mkl_cbwr_set (int setting);
```

### Include Files

- `mkl.h`

### Input Parameters

| Name                 | Type             | Description                                                                                                                     |
|----------------------|------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <code>setting</code> | <code>int</code> | CNR branch to set. See <a href="#">Named Constants for CNR Control</a> for a list of named constants that specify the settings. |

### Description

The `mkl_cbwr_set` function configures the CNR mode. In this release, it sets the CNR branch and turns on the CNR mode.

**NOTE**

Settings specified by the `mkl_cbwr_set` function take precedence over the settings specified by the `MKL_CBWR` environment variable.

**Return Values**

| Name                | Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>status</code> | <code>int</code> | <p>The status of the function completion:</p> <ul style="list-style-type: none"> <li><code>MKL_CBWR_SUCCESS</code> - the function completed successfully.</li> <li><code>MKL_CBWR_ERR_INVALID_INPUT</code> - an invalid setting is requested.</li> <li><code>MKL_CBWR_ERR_UNSUPPORTED_BRANCH</code> - the input value of the branch does not match the instruction set architecture (ISA) of your system. See <a href="#">Named Constants for CNR Control</a> for more details.</li> <li><code>MKL_CBWR_ERR_MODE_CHANGE_FAILURE</code> - the <code>mkl_cbwr_set</code> function requested to change the current CNR branch after a call to some Intel MKL function other than a CNR function.</li> </ul> |

**See Also**

[Usage Examples for CNR Support Functions](#)

**mkl\_cbwr\_get**

*Returns the current CNR settings.*

**Syntax**

```
int mkl_cbwr_get (int option);
```

**Include Files**

- `mkl.h`

**Input Parameters**

| Name                | Type             | Description                                                                                                                                                                                                                                                                                                            |
|---------------------|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>option</code> | <code>int</code> | <p>Specifies what kind of settings is requested. Named constants define possible values of <code>option</code>:</p> <ul style="list-style-type: none"> <li><code>MKL_CBWR_BRANCH</code> - indicates the setting of the CNR branch.</li> <li><code>MKL_CBWR_ALL</code> - indicates all CNR-related settings.</li> </ul> |

**NOTE**

This release supports no CNR settings other than branch.

## Description

The `mkl_cbwr_get` function returns the requested CNR settings. If the function completes successfully and the CNR mode is turned on, `mkl_cbwr_get` returns the *specific* CNR branch.

### NOTE

To turn the CNR mode on, use the `mkl_cbwr_set` function or environment variables. For more details, see the *Intel MKL Developer Guide*.

## Return Values

## Named Constants for CNR Control

Intel MKL provides reproducible results for a certain code branch, determined by the instruction set architecture (ISA). To define CNR code branches, use the following named constants as input/output for conditional numerical reproducibility support functions. Pass named constants to the functions instead of their values.

| Named Constant                   | Value | Description                                                                                                                                                                                            |
|----------------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>MKL_CBWR_AUTO</code>       | 2     | CNR mode uses the standard ISA-based dispatching model while ensuring fixed cache sizes, deterministic reductions, and static scheduling<br><br><b>CNR mode uses the branch for the following ISA:</b> |
| <code>MKL_CBWR_COMPATIBLE</code> | 3     | Intel® Streaming SIMD Extensions 2 (Intel® SSE2) without <code>rcpps/rsqrtps</code> instructions                                                                                                       |
| <code>MKL_CBWR_SSE2</code>       | 4     | Intel SSE2                                                                                                                                                                                             |
| <code>MKL_CBWR_SSE3</code>       | 5     | DEPRECATED. Intel® Streaming SIMD Extensions 3 (Intel® SSE3). This setting is kept for backward compatibility and is equivalent to <code>MKL_CBWR_SSE2</code> .                                        |
| <code>MKL_CBWR_SSSE3</code>      | 6     | Supplemental Streaming SIMD Extensions 3 (SSSE3)                                                                                                                                                       |
| <code>MKL_CBWR_SSE4_1</code>     | 7     | Intel® Streaming SIMD Extensions 4-1 (SSE4-1)                                                                                                                                                          |
| <code>MKL_CBWR_SSE4_2</code>     | 8     | Intel® Streaming SIMD Extensions 4-2 (SSE4-2)                                                                                                                                                          |
| <code>MKL_CBWR_AVX</code>        | 9     | Intel® Advanced Vector Extensions (Intel® AVX)                                                                                                                                                         |
| <code>MKL_CBWR_AVX2</code>       | 10    | Intel® Advanced Vector Extensions 2 (Intel® AVX2)                                                                                                                                                      |

When specifying the CNR branch with the named constants, be aware of the following:

- Reproducible results are provided under [Reproducibility Conditions](#).
- Settings other than `MKL_CBWR_AUTO` or `MKL_CBWR_COMPATIBLE` are available only for Intel processors.
- Intel and Intel compatible CPUs have a few instructions, such as approximation instructions `rcpps/rsqrtps`, that may return different results. Setting the branch to `MKL_CBWR_COMPATIBLE` ensures that Intel MKL does not use these instructions and forces a single Intel SSE2 only code path to be executed.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain

**Optimization Notice**

optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

**Reproducibility Conditions**

To get reproducible results from run to run, ensure that the number of threads is fixed and constant. Specifically:

- If you are running your program with OpenMP\* parallelization on different processors, explicitly specify the number of threads.
- To ensure that your application has deterministic behavior with OpenMP\* parallelization and does not adjust the number of threads dynamically at run time, set `MKL_DYNAMIC` and `OMP_DYNAMIC` to `FALSE`. This is especially needed if you are running your program on different systems.
- If you are running your program with the Intel® Threading Building Blocks parallelization, numerical reproducibility is not guaranteed.
 

---

  - As usual, you should align your data, even in CNR mode, to obtain the best possible performance. While CNR mode also fully supports unaligned input and output data, the use of it might reduce the performance of some Intel MKL functions on earlier Intel processors. To ensure proper alignment of arrays, allocate memory for them using `mkl_malloc/mkl_calloc`.
  - Conditional Numerical Reproducibility does not ensure that bitwise-identical NaN values are generated when the input data contains NaN values.
  - If dynamic memory allocation fails on one run but succeeds on another run, you may fail to get reproducible results between these two runs.

**Usage Examples for CNR Support Functions**

The following examples illustrate usage of support functions for conditional numerical reproducibility.

**Setting Automatically Detected CNR Branch**

```
#include <mkl.h>
int main(void) {
 int my_cbwr_branch;
 /* Find the available MKL_CBWR_BRANCH automatically */
 my_cbwr_branch = mkl_cbwr_get_auto_branch();
 /* User code without Intel MKL calls */
 /* Piece of the code where CNR of Intel MKL is needed */
 /* The performance of Intel MKL functions might be reduced for CNR mode */
 if (mkl_cbwr_set(my_cbwr_branch) != MKL_CBWR_SUCCESS) {
 printf("Error in setting MKL_CBWR_BRANCH! Aborting...\n");
 return;
 }
}
```

```

}
/* CNR calls to Intel MKL + any other code */
}

```

## Use of the `mkl_cbwr_get` Function

```

#include <mkl.h>
int main(void) {
 int my_cbwr_branch;
 /* Piece of the code where CNR of Intel MKL is analyzed */
 my_cbwr_branch = mkl_cbwr_get(MKL_CBWR_BRANCH);
 switch (my_cbwr_branch) {
 case MKL_CBWR_AUTO:
 /* actions in case of automatic mode */
 break;
 case MKL_CBWR_SSSE3:
 /* actions for SSSE3 code */
 break;
 default:
 /* all other cases */
 }
 /* User code */
}

```

## Miscellaneous

---

### `mkl_progress`

*Provides progress information.*

#### Syntax

```
int mkl_progress (int* thread_process, int* step, char* stage, int lstage);
```

#### Include Files

- `mkl.h`

#### Input Parameters

| Name                        | Type                    | Description                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>thread_process</code> | <code>const int*</code> | Indicates the number of thread or process the progress routine is called from: <ul style="list-style-type: none"> <li>• The thread number for non-cluster components linked with OpenMP threading layer</li> <li>• Zero for non-cluster components linked with sequential threading layer</li> <li>• The process number (MPI rank) for non-cluster components</li> </ul> |
| <code>step</code>           | <code>const int*</code> | Pointer to the linear progress indicator that shows the amount of work done. Increases from 0 to the linear size of the problem during the computation.                                                                                                                                                                                                                  |

| Name          | Type        | Description                                                                                                          |
|---------------|-------------|----------------------------------------------------------------------------------------------------------------------|
| <i>stage</i>  | const char* | Message indicating the name of the routine or the name of the computation stage the progress routine is called from. |
| <i>lstage</i> | int         | The length of a stage string excluding the trailing NULL character.                                                  |

## Description

The `mkl_progress` function is intended to track progress of a lengthy computation and/or interrupt the computation. By default this routine does nothing but the user application can redefine it to obtain the computation progress information. You can set it to perform certain operations during the routine computation, for instance, to print a progress indicator. A non-zero return value may be supplied by the redefined function to break the computation.

Some Intel MKL functions from LAPACK, ScaLAPACK, DSS/PARDISO, and Parallel Direct Sparse Solver for Clusters regularly call the `mkl_progress` function during the computation. Refer to the description of a specific function from those domains to see whether the function supports this feature or not.

If a LAPACK function returns `info=-1002`, the function was interrupted by `mkl_progress`. Because ScaLAPACK does not support interruption of the computation, Intel MKL ignores any value returned by `mkl_progress`.

While a user-supplied `mkl_progress` function usually redefines the default `mkl_progress` function automatically, some configurations require calling the `mkl_set_progress` function to replace the default `mkl_progress` function. Call `mkl_set_progress` to replace the default `mkl_progress` on Windows\* in any of the following cases:

- You are using the Single Dynamic Library (SDL) `mkl_rt.lib`.
- You link dynamically with ScaLAPACK.

---

### WARNING

The `mkl_progress` function only supports OpenMP\* threading and sequential execution.

---

## Return Values

| Name            | Type | Description                                                                                                         |
|-----------------|------|---------------------------------------------------------------------------------------------------------------------|
| <i>stopflag</i> | int  | The stopping flag. A non-zero flag forces the routine to be interrupted. The zero flag is the default return value. |

## Example

The following example prints the progress information to the standard output device:

```
#include <stdio.h>
#include <string.h>
#define BUFLLEN 16
int mkl_progress(int* thread_process, int* step, char* stage, int lstage)
{
 char buf[BUFLLEN];
 if(lstage >= BUFLLEN) lstage = BUFLLEN-1;
 strncpy(buf, stage, lstage);
 buf[lstage] = '\0';
 printf("In thread %i, at stage %s, steps passed %i\n", *thread_process, buf, *step);
 return 0;
}
```

## mkl\_enable\_instructions

Enables dispatching for new Intel® architectures or restricts the set of Intel® instruction sets available for dispatching.

### Syntax

```
int mkl_enable_instructions (int isa);
```

### Include Files

- mkl.h

### Input Parameters

| Name             | Type             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>isa</code> | <code>int</code> | <p>The latest Intel® instruction-set architecture (ISA) for Intel MKL to dispatch.</p> <p>Possible values, in the order from the latest to the earliest instruction set:</p> <ul style="list-style-type: none"> <li><code>MKL_ENABLE_AVX512</code> Intel® Advanced Vector Extensions 512 (Intel® AVX-512) on Intel® Xeon® processors.</li> <li><code>MKL_ENABLE_AVX512_MIC</code> Intel AVX-512 on Intel® Xeon Phi™ processors and coprocessors.</li> <li><code>MKL_ENABLE_AVX2</code> Intel® Advanced Vector Extensions 2 (Intel® AVX2).</li> <li><code>MKL_ENABLE_AVX</code> Intel® Advanced Vector Extensions (Intel® AVX).</li> <li><code>MKL_ENABLE_SSE4_2</code> Intel® Streaming SIMD Extensions 4-2 (Intel® SSE4-2).</li> </ul> |

### Description

Intel MKL does run-time processor dispatching to identify appropriate internal code paths to traverse for Intel MKL functions called by the application. The `mkl_enable_instructions` function controls the behavior of the dispatcher to do either of the following:

- Enable dispatching for new Intel architectures.

Intel MKL does not dispatch instruction sets that do not have silicon available at time of the product launch. Call `mkl_enable_instructions` to enable dispatching the code path for such an ISA in a simulator environment or on hardware that supports this ISA.

- Restrict the set of Intel instruction sets available for dispatching.

Call `mkl_enable_instructions` to restrict dispatching to code paths for earlier ISA. For example, if the hardware supports Intel AVX, a call to `mkl_enable_instructions` with the `MKL_ENABLE_SSE4_2` parameter forces the dispatcher to use the Intel SSE4-2 code path.

If the system does not support the instruction set specified by the `isa` parameter or the system is based on a non-Intel architecture, `mkl_enable_instructions` does nothing and returns zero.

Settings specified by the `mkl_enable_instructions` function set an upper limit to settings specified by the `mkl_cbwr_set` function.

You can use the `MKL_ENABLE_INSTRUCTIONS` environment variable instead of calling `mkl_enable_instructions` (for more details, see the *Intel MKL Developer Guide*), but the settings specified by the function take precedence over the settings specified by the environment variable.

## Return Values

| Name             | Type             | Description                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>irc</code> | <code>int</code> | <p>Function completion status:</p> <p>1 - Intel MKL dispatches the code path for the specified ISA by default.</p> <p>0 - The request is rejected. Usually this occurs if <code>mkl_enable_instructions</code> was called:</p> <ul style="list-style-type: none"> <li>• After another Intel MKL function</li> <li>• On a non-Intel architecture</li> <li>• With an incompatible ISA specified</li> </ul> |

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## `mkl_set_env_mode`

*Sets up the mode that ignores environment settings specific to Intel MKL.*

### Syntax

```
int mkl_set_env_mode(int mode);
```

### Include Files

- `mkl.h`

### Input Parameters

| Name              | Type             | Description                                                                                                                                                                                                                        |
|-------------------|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mode</code> | <code>int</code> | <p>Specifies what mode to set. For details, see <a href="#">Description</a>. Possible values:</p> <ul style="list-style-type: none"> <li>• 0 - Do nothing.</li> </ul> <p>Use this value to query the current environment mode.</p> |

| Name | Type | Description                                                                                                               |
|------|------|---------------------------------------------------------------------------------------------------------------------------|
|      |      | <ul style="list-style-type: none"> <li>1 - Make Intel MKL ignore environment settings specific to the library.</li> </ul> |

## Description

In the default *environment mode*, Intel MKL can control its behavior using environment variables for threading, memory management, Conditional Numerical Reproducibility, automatic offload, and so on. The `mkl_set_env_mode` function sets up the environment mode that ignores all settings specified by Intel MKL environment variables except `MIC_LD_LIBRARY_PATH` and `MKLROOT`.

## Return Values

| Name                      | Type             | Description                                                                                                                                                                            |
|---------------------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>current_mode</code> | <code>int</code> | Environment mode that was used before the function call: <ul style="list-style-type: none"> <li>0 - Default</li> <li>1 - Ignore environment settings specific to Intel MKL.</li> </ul> |

## `mkl_verbose`

*Enables or disables Intel MKL Verbose mode.*

## Syntax

```
int mkl_verbose (int enable);
```

## Include Files

- `mkl.h`

## Input Parameters

| Name                | Type             | Description                                                                                                                                                                                                                                                                    |
|---------------------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>enable</code> | <code>int</code> | Desired state of the Intel MKL Verbose mode. Indicates whether printing Intel MKL function call information should be turned on or off. Possible values: <ul style="list-style-type: none"> <li>0 - disable the Verbose mode.</li> <li>1 - enable the Verbose mode.</li> </ul> |

## Description

This function enables or disables the Intel MKL Verbose mode, in which computational functions print call description information. For details of the Verbose mode, see the *Intel MKL Developer Guide*, available in the Intel® Software Documentation Library.

---

### NOTE

The setting for the Verbose mode specified by the `mkl_verbose` function takes precedence over the setting specified by the `MKL_VERBOSE` environment variable.

---

## Return Values

### Description

Call this function to set the MPI implementation to be used by Intel MKL on Windows\* OS when dynamic Intel MKL libraries are used. For all other configurations, the function returns an error indicating that you cannot set the MPI implementation. You can specify your own prebuilt dynamic BLACS library for a custom MPI by setting `vendor` to `MKL_BLACS_CUSTOM` and optionally passing the name of the custom BLACS dynamic library. If the `custom_library_path` parameter is `NULL` or an empty string, Intel MKL uses the default platform-specific library name: `mkl_blacs_custom_lp64.dll` or `mkl_blacs_custom_ilp64.dll`, depending on whether the BLACS interface linked against your application is LP64 or ILP64.

## Return Values

| Name                | Type             | Description                                                                                                                                                                                                                                                                                                                  |
|---------------------|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>status</code> | <code>int</code> | <p>The return status:</p> <ul style="list-style-type: none"> <li>• 0 - The function completed successfully.</li> <li>• -1 - The <code>vendor</code> parameter is invalid.</li> <li>• -2 - The <code>custom_library_name</code> parameter is invalid.</li> <li>• -3 - The MPI library cannot be set at this point.</li> </ul> |

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Notice revision #20110804

## mkl\_finalize

*Terminates Intel MKL execution environment and frees resources allocated by the library.*

### Syntax

```
void mkl_finalize(void);
```

### Include Files

- `mkl.h`

### Description

This function frees resources allocated by Intel MKL. Once this function is called, the application can no longer call Intel MKL functions other than `mkl_finalize`.

In particular, the `mkl_finalize` function enables you to free resources when a third-party shared library is statically linked to Intel MKL. To avoid resource leaks that may happen when a shared library is loaded and unloaded multiple times, call `mkl_finalize` each time the library is unloaded. The recommended method to do this depends on the operating system:

- On Linux\* or macOS\*, place the call into a shared library destructor.
- On Windows\*, call `mkl_finalize` from the `DLL_PROCESS_DETACH` handler of `DllMain`.

### NOTE

Intel MKL shared libraries automatically perform finalization when they are unloaded. If an application is statically linked to Intel MKL, the operating system frees all resources allocated by Intel MKL during termination of the process associated with the application.

# BLACS Routines

This chapter describes the Intel® Math Kernel Library implementation of FORTRAN 77 routines from the BLACS (Basic Linear Algebra Communication Subprograms) package. These routines are used to support a linear algebra oriented message passing interface that may be implemented efficiently and uniformly across a large range of distributed memory platforms.

The BLACS routines make linear algebra applications both easier to program and more portable. For this purpose, they are used in Intel MKL intended for the Linux\* and Windows\* OSs as the communication layer of ScaLAPACK and Cluster FFT.

On computers, a linear algebra matrix is represented by a two dimensional array (2D array), and therefore the BLACS operate on 2D arrays. See description of the basic [matrix shapes](#) in a special section.

The BLACS routines implemented in Intel MKL are of four categories:

- Combines
- Point to Point Communication
- Broadcast
- Support.

The [Combines](#) take data distributed over processes and combine the data to produce a result. The [Point to Point](#) routines are intended for point-to-point communication and [Broadcast](#) routines send data possessed by one process to all processes within a scope.

The [Support routines](#) perform distinct tasks that can be used for initialization, destruction, information, and miscellaneous tasks.

## Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## Matrix Shapes

The BLACS routines recognize the two most common classes of matrices for dense linear algebra. The first of these classes consists of general rectangular matrices, which in machine storage are 2D arrays consisting of  $m$  rows and  $n$  columns, with a leading dimension,  $lda$ , that determines the distance between successive columns in memory.

The *general rectangular* matrices take the following parameters as input when determining what array to operate on:

- |     |                                                                                                                                       |
|-----|---------------------------------------------------------------------------------------------------------------------------------------|
| $m$ | (input) INTEGER. The number of matrix rows to be operated on.                                                                         |
| $n$ | (input) INTEGER. The number of matrix columns to be operated on.                                                                      |
| $a$ | (input/output) TYPE (depends on routine), array of dimension $(lda, n)$ .<br>A pointer to the beginning of the (sub)array to be sent. |

*lda* (input) INTEGER. The distance between two elements in matrix row.

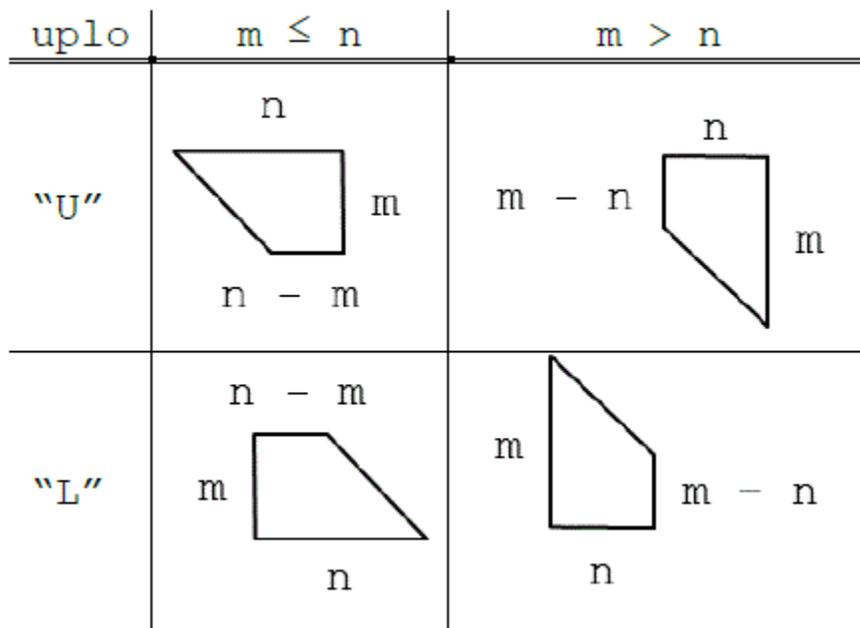

The second class of matrices recognized by the BLACS are *trapezoidal* matrices (triangular matrices are a sub-class of trapezoidal). Trapezoidal arrays are defined by *m*, *n*, and *lda*, as above, but they have two additional parameters as well. These parameters are:

*uplo* (input) CHARACTER\*1 . Indicates whether the matrix is upper or lower trapezoidal, as discussed below.

*diag* (input) CHARACTER\*1 . Indicates whether the diagonal of the matrix is unit diagonal (will not be operated on) or otherwise (will be operated on).

The shape of the trapezoidal arrays is determined by these parameters as follows:

**Trapezoidal Arrays Shapes**

The packing of arrays, if required, so that they may be sent efficiently is hidden, allowing the user to concentrate on the logical matrix, rather than on how the data is organized in the system memory.

**Repeatability and Coherence**

Floating point computations are not exact on almost all modern architectures. This lack of precision is particularly problematic in parallel operations. Since floating point computations are inexact, algorithms are classified according to whether they are *repeatable* and to what degree they guarantee *coherence*.

- Repeatable: a routine is repeatable if it is guaranteed to give the same answer if called multiple times with the same parallel configuration and input.
- Coherent: a routine is coherent if all processes selected to receive the answer get identical results.

**NOTE**

Repeatability and coherence do not effect correctness. A routine may be both incoherent and non-repeatable, and still give correct output. But inaccuracies in floating point calculations may cause the routine to return differing values, all of which are equally valid.

## Repeatability

Because the precision of floating point arithmetic is limited, it is not truly associative:  $(a + b) + c$  might not be the same as  $a + (b + c)$ . The lack of exact arithmetic can cause problems whenever the possibility for reordering of floating point calculations exists. This problem becomes prevalent in parallel computing due to race conditions in message passing. For example, consider a routine which sums numbers stored on different processes. Assume this routine runs on four processes, with the numbers to be added being the process numbers themselves. Therefore, process 0 has the value 0:0, process 1 has the value 1:0, and so on.

One algorithm for the computation of this result is to have all processes send their process numbers to process 0; process 0 adds them up, and sends the result back to all processes. So, process 0 would add a number to 0:0 in the first step. If receiving the process numbers is ordered so that process 0 always receives the message from process 1 first, then 2, and finally 3, this results in a repeatable algorithm, which evaluates the expression  $((0:0 + 1:0) + 2:0) + 3:0$ .

However, to get the best parallel performance, it is better not to require a particular ordering, and just have process 0 add the first available number to its value and continue to do so until all numbers have been added in. Using this method, a race condition occurs, because the order of the operation is determined by the order in which process 0 receives the messages, which can be effected by any number of things. This implementation is not repeatable, because the answer can vary between invocations, even if the input is the same. For instance, one run might produce the sequence  $((0:0 + 1:0) + 2:0) + 3:0$ , while a subsequent run could produce  $((0:0 + 2:0) + 1:0) + 3:0$ . Both of these results are correct summations of the given numbers, but because of floating point roundoff, they might be different.

## Coherence

A routine produces coherent output if all processes are guaranteed to produce the exact same results. Obviously, almost no algorithm involving communication is coherent if communication can change the values being communicated. Therefore, if the parallel system being studied cannot guarantee that communication between processes preserves values, no routine is guaranteed to produce coherent results.

If communication is assumed to be coherent, there are still various levels of coherent algorithms. Some algorithms guarantee coherence only if floating point operations are done in the exact same order on every node. This is *homogeneous coherence*: the result will be coherent if the parallel machine is homogeneous in its handling of floating point operations.

A stronger assertion of coherence is *heterogeneous coherence*, which does not require all processes to have the same handling of floating point operations.

In general, a routine that is homogeneous coherent performs computations redundantly on all nodes, so that all processes get the same answer only if all processes perform arithmetic in the exact same way, whereas a routine which is heterogeneous coherent is usually constrained to having one process calculate the final result, and broadcast it to all other processes.

## Example of Incoherence

An incoherent algorithm is one which does not guarantee that all processes get the same result even on a homogeneous system with coherent communication. The previous example of summing the process numbers demonstrates this kind of behavior. One way to perform such a sum is to have every process broadcast its number to all other processes. Each process then adds these numbers, starting with its own. The calculations performed by each process receives would then be:

- Process 0 :  $((0:0 + 1:0) + 2:0) + 3:0$
- Process 1 :  $((1:0 + 2:0) + 3:0) + 0:0$
- Process 2 :  $((2:0 + 3:0) + 0:0) + 1:0$
- Process 3 :  $((3:0 + 0:0) + 1:0) + 0:0$

All of these results are equally valid, and since all the results might be different from each other, this algorithm is incoherent. Notice, however, that this algorithm is repeatable: each process will get the same result if the algorithm is called again on the same data.

## Example of Homogeneous Coherence

Another way to perform this summation is for all processes to send their data to all other processes, and to ensure the result is not incoherent, enforce the ordering so that the calculation each node performs is  $((0:0 + 1:0) + 2:0) + 3:0$ . This answer is the same for all processes only if all processes do the floating point arithmetic in the same way. Otherwise, each process may make different floating point errors during the addition, leading to incoherence of the output. Notice that since there is a specific ordering to the addition, this algorithm is repeatable.

## Example of Heterogeneous Coherence

In the final example, all processes send the result to process 0, which adds the numbers and broadcasts the result to the rest of the processes. Since one process does all the computation, it can perform the operations in any order and it will give coherent results as long as communication is itself coherent. If a particular order is not forced on the the addition, the algorithm will not be repeatable. If a particular order is forced, it will be repeatable.

## Summary

Repeatability and coherence are separate issues which may occur in parallel computations. These concepts may be summarized as:

- **Repeatability:** The routine will yield the exact same result if it run multiple times on an identical problem. Each process may get a different result than the others (i.e., repeatability does not imply coherence), but that value will not change if the routine is invoked multiple times.
- **Homogeneous coherence:** All processes selected to possess the result will receive the exact same answer if:
  - Communication does not change the value of the communicated data.
  - All processes perform floating point arithmetic exactly the same.
- **Heterogeneous coherence:** All processes will receive the exact same answer if communication does not change the value of the communicated data.

In general, lack of the associative property for floating point calculations may cause both incoherence and non-repeatability. Algorithms that rely on redundant computations are at best homogeneous coherent, and algorithms in which one process broadcasts the result are heterogeneous coherent. Repeatability does not imply coherence, nor does coherence imply repeatability.

Since these issues do not effect the correctness of the answer, they can usually be ignored. However, in very specific situations, these issues may become very important. A stopping criteria should not be based on incoherent results, for instance. Also, a user creating and debugging a parallel program may wish to enforce repeatability so the exact same program sequence occurs on every run.

In the BLACS, coherence and repeatability apply only in the context of the combine operations. As mentioned above, it is possible to have communication which is incoherent (for instance, two machines which store floating point numbers differently may easily produce incoherent communication, since a number stored on machine A may not have a representation on machine B). However, the BLACS cannot control this issue. Communication is assumed to be coherent, which for communication implies that it is also repeatable.

For combine operations, the BLACS allow you to set flags indicating that you would like combines to be repeatable and/or heterogeneous coherent (see [blacs\\_get](#) and [blacs\\_set](#) for details on setting these flags).

If the BLACS are instructed to guarantee heterogeneous coherency, the BLACS restrict the topologies which can be used so that one process calculates the final result of the combine, and if necessary, broadcasts the answer to all other processes.

If the BLACS are instructed to guarantee repeatability, orderings will be enforced in the topologies which are selected. This may result in loss of performance which can range from negligible to serious depending on the application.

A couple of additional notes are in order. Incoherence and nonrepeatability can arise as a result of floating point errors, as discussed previously. This might lead you to suspect that integer calculations are always repeatable and coherent, since they involve exact arithmetic. This is true if overflow is ignored. With overflow taken into consideration, even integer calculations can display incoherence and non-repeatability. Therefore, if the repeatability or coherence flags are set, the BLACS treats integer combines the same as floating point combines in enforcing repeatability and coherence guards.

By their nature, maximization and minimization should always be repeatable. In the complex precisions, however, the real and imaginary parts must be combined in order to obtain a magnitude value used to do the comparison (this is typically  $|r| + |i|$  or  $\text{sqr}(r^2 + i^2)$ ). This allows for the possibility of heterogeneous incoherence. The BLACS therefore restrict which topologies are used for maximization and minimization in the complex routines when the heterogeneous coherence flag is set.

## BLACS Combine Operations

This section describes BLACS routines that combine the data to produce a result.

In a combine operation, each participating process contributes data that is combined with other processes' data to produce a result. This result can be given to a particular process (called the *destination* process), or to all participating processes. If the result is given to only one process, the operation is referred to as a *leave-on-one* combine, and if the result is given to all participating processes the operation is referenced as a *leave-on-all* combine.

At present, three kinds of combines are supported. They are:

- element-wise summation
- element-wise absolute value maximization
- element-wise absolute value minimization

of general rectangular arrays.

Note that a combine operation combines data between processes. By definition, a combine performed across a scope of only one process does not change the input data. This is why the operations (*max/min/sum*) are specified as *element-wise*. Element-wise indicates that each element of the input array will be combined with the corresponding element from all other processes' arrays to produce the result. Thus, a 4 x 2 array of inputs produces a 4 x 2 answer array.

When the *max/min* comparison is being performed, absolute value is used. For example, -5 and 5 are equivalent. However, the returned value is unchanged; that is, it is not the absolute value, but is a signed value instead. Therefore, if you performed a BLACS absolute value maximum combine on the numbers -5, 3, 1, 8 the result would be -8.

The initial symbol ? in the routine names below masks the data type:

|   |                           |
|---|---------------------------|
| i | integer                   |
| s | single precision real     |
| d | double precision real     |
| c | single precision complex  |
| z | double precision complex. |

### BLACS Combines

| Routine name           | Results of operation                                                                                |
|------------------------|-----------------------------------------------------------------------------------------------------|
| <a href="#">gamx2d</a> | Entries of result matrix will have the value of the greatest absolute value found in that position. |
| <a href="#">gamn2d</a> | Entries of result matrix will have the value of the smallest absolute value found in that position. |

| Routine name        | Results of operation                                               |
|---------------------|--------------------------------------------------------------------|
| <code>gsum2d</code> | Entries of result matrix will have the summation of that position. |

## ?gamx2d

*Performs element-wise absolute value maximization.*

### Syntax

```
call igamx2d(icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest)
call sgamx2d(icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest)
call dgamx2d(icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest)
call cgamx2d(icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest)
call zgamx2d(icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest)
```

### Input Parameters

|                      |                                                                                                                                                                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>icontxt</code> | INTEGER. Integer handle that indicates the context.                                                                                                                                                                                       |
| <code>scope</code>   | CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.                                                                                                                                          |
| <code>top</code>     | CHARACTER*1. Communication pattern to use during the combine operation.                                                                                                                                                                   |
| <code>m</code>       | INTEGER. The number of matrix rows to be combined.                                                                                                                                                                                        |
| <code>n</code>       | INTEGER. The number of matrix columns to be combined.                                                                                                                                                                                     |
| <code>a</code>       | TYPE array ( <code>lda</code> , <code>n</code> ). Matrix to be compared with to produce the maximum.                                                                                                                                      |
| <code>lda</code>     | INTEGER. The leading dimension of the matrix <i>A</i> , that is, the distance between two successive elements in a matrix row.                                                                                                            |
| <code>rcflag</code>  | INTEGER.<br>If <code>rcflag = -1</code> , the arrays <code>ra</code> and <code>ca</code> are not referenced and need not exist. Otherwise, <code>rcflag</code> indicates the leading dimension of these arrays, and so must be $\geq m$ . |
| <code>rdest</code>   | INTEGER.<br>The process row coordinate of the process that should receive the result. If <code>rdest</code> or <code>cdest = -1</code> , all processes within the indicated scope receive the answer.                                     |
| <code>cdest</code>   | INTEGER.<br>The process column coordinate of the process that should receive the result. If <code>rdest</code> or <code>cdest = -1</code> , all processes within the indicated scope receive the answer.                                  |

## Output Parameters

|           |                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>a</i>  | TYPE array ( <i>lda</i> , <i>n</i> ). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.                                                                                                                                                                                                           |
| <i>ra</i> | INTEGER array ( <i>rcflag</i> , <i>n</i> ).<br>If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> × <i>n</i> ) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results. |
| <i>ca</i> | INTEGER array ( <i>rcflag</i> , <i>n</i> ).<br>If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> × <i>n</i> ) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results. |

## Description

This routine performs element-wise absolute value maximization, that is, each element of matrix *A* is compared with the corresponding element of the other process's matrices. Note that the value of *A* is returned, but the absolute value is used to determine the maximum (the 1-norm is used for complex numbers). Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

## BLACS Point To Point Communication

This section describes BLACS routines for point to point communication.

Point to point communication requires two complementary operations. The *send* operation produces a message that is then consumed by the *receive* operation. These operations have various resources associated with them. The main such resource is the buffer that holds the data to be sent or serves as the area where the incoming data is to be received. The level of *blocking* indicates what correlation the return from a send/receive operation has with the availability of these resources and with the status of message.

### Non-blocking

The return from the *send* or *receive* operations does not imply that the resources may be reused, that the message has been sent/received or that the complementary operation has been called. Return means only that the send/receive has been started, and will be completed at some later date. Polling is required to determine when the operation has finished.

In non-blocking message passing, the concept of *communication/computation overlap* (abbreviated C/C overlap) is important. If a system possesses C/C overlap, independent computation can occur at the same time as communication. That means a nonblocking operation can be posted, and unrelated work can be done while the message is sent/received in parallel. If C/C overlap is not present, after returning from the routine call, computation will be interrupted at some later date when the message is actually sent or received.

### Locally-blocking

Return from the *send* or *receive* operations indicates that the resources may be reused. However, since this only depends on local information, it is unknown whether the complementary operation has been called. There are no locally-blocking receives: the send must be completed before the receive buffer is available for re-use.

If a receive has not been posted at the time a locally-blocking send is issued, buffering will be required to avoid losing the message. Buffering can be done on the sending process, the receiving process, or not done at all, losing the message.

### Globally-blocking

Return from a globally-blocking procedure indicates that the operation resources may be reused, and that complement of the operation has at least been posted. Since the receive has been posted, there is no buffering required for globally-blocking sends: the message is always sent directly into the user's receive buffer.

Almost all processors support non-blocking communication, as well as some other level of blocking sends. What level of blocking the send possesses varies between platforms. For instance, the Intel® processors support locally-blocking sends, with buffering done on the receiving process. This is a very important distinction, because codes written assuming locally-blocking sends will hang on platforms with globally-blocking sends. Below is a simple example of how this can occur:

```
IAM = MY_PROCESS_ID()
IF (IAM .EQ. 0) THEN
 SEND TO PROCESS 1
 RECV FROM PROCESS 1
ELSE IF (IAM .EQ. 1) THEN
 SEND TO PROCESS 0
 RECV FROM PROCESS 0
END IF
```

If the send is globally-blocking, process 0 enters the send, and waits for process 1 to start its receive before continuing. In the meantime, process 1 starts to send to 0, and waits for 0 to receive before continuing. Both processes are now waiting on each other, and the program will never continue.

The solution for this case is obvious. One of the processes simply reverses the order of its communication calls and the hang is avoided. However, when the communication is not just between two processes, but rather involves a hierarchy of processes, determining how to avoid this kind of difficulty can become problematic.

For this reason, it was decided the BLACS would support locally-blocking sends. On systems natively supporting globally-blocking sends, non-blocking sends coupled with buffering is used to simulate locally-blocking sends. The BLACS support globally-blocking receives.

In addition, the BLACS specify that point to point messages between two given processes will be strictly ordered. If process 0 sends three messages (label them *A*, *B*, and *C*) to process 1, process 1 must receive *A* before it can receive *B*, and message *C* can be received only after both *A* and *B*. The main reason for this restriction is that it allows for the computation of message identifiers.

Note, however, that messages from different processes are not ordered. If processes 0, . . . , 3 send messages *A*, . . . , *D* to process 4, process 4 may receive these messages in any order that is convenient.

### Convention

The convention used in the communication routine names follows the template `?xxyy2d`, where the letter in the ? position indicates the data type being sent, `xx` is replaced to indicate the shape of the matrix, and the `yy` positions are used to indicate the type of communication to perform:

|                 |                                                                        |
|-----------------|------------------------------------------------------------------------|
| <code>i</code>  | integer                                                                |
| <code>s</code>  | single precision real                                                  |
| <code>d</code>  | double precision real                                                  |
| <code>c</code>  | single precision complex                                               |
| <code>z</code>  | double precision complex                                               |
| <code>ge</code> | The data to be communicated is stored in a general rectangular matrix. |
| <code>tr</code> | The data to be communicated is stored in a trapezoidal matrix.         |
| <code>sd</code> | Send. One process sends to another.                                    |
| <code>rv</code> | Receive. One process receives from another.                            |

### BLACS Point To Point Communication

| Routine name        | Operation performed                                               |
|---------------------|-------------------------------------------------------------------|
| <code>gesd2d</code> | Take the indicated matrix and send it to the destination process. |
| <code>trsd2d</code> |                                                                   |
| <code>gerv2d</code> | Receive a message from the process into the matrix.               |
| <code>trrv2d</code> |                                                                   |

As a simple example, the pseudo code given above is rewritten below in terms of the BLACS. It is further specified that the data being exchanged is the double precision vector *X*, which is 5 elements long.

```
CALL GRIDINFO(NPROW, NPCOL, MYPROW, MYPCOL)
IF (MYPROW.EQ.0 .AND. MYPCOL.EQ.0) THEN
 CALL DGESD2D(5, 1, X, 5, 1, 0)
 CALL DGERV2D(5, 1, X, 5, 1, 0)
ELSE IF (MYPROW.EQ.1 .AND. MYPCOL.EQ.0) THEN
```

```
CALL DGESD2D(5, 1, X, 5, 0, 0)
CALL DGERV2D(5, 1, X, 5, 0, 0)
END IF
```

## ?gesd2d

*Takes a general rectangular matrix and sends it to the destination process.*

### Syntax

```
call igesd2d(icontxt, m, n, a, lda, rdest, cdest)
call sgesd2d(icontxt, m, n, a, lda, rdest, cdest)
call dgesd2d(icontxt, m, n, a, lda, rdest, cdest)
call cgesd2d(icontxt, m, n, a, lda, rdest, cdest)
call zgesd2d(icontxt, m, n, a, lda, rdest, cdest)
```

### Input Parameters

|                     |                                                                                  |
|---------------------|----------------------------------------------------------------------------------|
| <i>icontxt</i>      | INTEGER. Integer handle that indicates the context.                              |
| <i>m, n, a, lda</i> | Describe the matrix to be sent. See <a href="#">Matrix Shapes</a> for details.   |
| <i>rdest</i>        | INTEGER.<br>The process row coordinate of the process to send the message to.    |
| <i>cdest</i>        | INTEGER.<br>The process column coordinate of the process to send the message to. |

### Description

This routine takes the indicated general rectangular matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix A) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

## ?trsd2d

*Takes a trapezoidal matrix and sends it to the destination process.*

### Syntax

```
call itrdsd2d(icontxt, uplo, diag, m, n, a, lda, rdest, cdest)
call strsd2d(icontxt, uplo, diag, m, n, a, lda, rdest, cdest)
call dtrsd2d(icontxt, uplo, diag, m, n, a, lda, rdest, cdest)
call ctrsd2d(icontxt, uplo, diag, m, n, a, lda, rdest, cdest)
call ztrsd2d(icontxt, uplo, diag, m, n, a, lda, rdest, cdest)
```

## Input Parameters

|                                 |                                                                                  |
|---------------------------------|----------------------------------------------------------------------------------|
| <i>icontxt</i>                  | INTEGER. Integer handle that indicates the context.                              |
| <i>uplo, diag, m, n, a, lda</i> | Describe the matrix to be sent. See <a href="#">Matrix Shapes</a> for details.   |
| <i>rdest</i>                    | INTEGER.<br>The process row coordinate of the process to send the message to.    |
| <i>cdest</i>                    | INTEGER.<br>The process column coordinate of the process to send the message to. |

## Description

This routine takes the indicated trapezoidal matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix *A*) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

## ?gerv2d

*Receives a message from the process into the general rectangular matrix.*

## Syntax

```
call igerv2d(icontxt, m, n, a, lda, rsrc, csrc)
call sgerv2d(icontxt, m, n, a, lda, rsrc, csrc)
call dgerv2d(icontxt, m, n, a, lda, rsrc, csrc)
call cgerv2d(icontxt, m, n, a, lda, rsrc, csrc)
call zgerv2d(icontxt, m, n, a, lda, rsrc, csrc)
```

## Input Parameters

|                  |                                                                                |
|------------------|--------------------------------------------------------------------------------|
| <i>icontxt</i>   | INTEGER. Integer handle that indicates the context.                            |
| <i>m, n, lda</i> | Describe the matrix to be sent. See <a href="#">Matrix Shapes</a> for details. |
| <i>rsrc</i>      | INTEGER.<br>The process row coordinate of the source of the message.           |
| <i>csrc</i>      | INTEGER.<br>The process column coordinate of the source of the message.        |

## Output Parameters

|          |                                                                        |
|----------|------------------------------------------------------------------------|
| <i>a</i> | An array of dimension $(lda, n)$ to receive the incoming message into. |
|----------|------------------------------------------------------------------------|

## Description

This routine receives a message from process {RSRC, CSRC} into the general rectangular matrix *A*. This routine is globally-blocking, that is, return from the routine indicates that the message has been received into *A*.

## See Also

Examples of BLACS Routines Usage

## ?trrv2d

Receives a message from the process into the trapezoidal matrix.

---

### Syntax

```
call itrrv2d(ictxt, uplo, diag, m, n, a, lda, rsrc, csrc)
call strrv2d(ictxt, uplo, diag, m, n, a, lda, rsrc, csrc)
call dtrrv2d(ictxt, uplo, diag, m, n, a, lda, rsrc, csrc)
call ctrrv2d(ictxt, uplo, diag, m, n, a, lda, rsrc, csrc)
call ztrrv2d(ictxt, uplo, diag, m, n, a, lda, rsrc, csrc)
```

### Input Parameters

|                              |                                                                                |
|------------------------------|--------------------------------------------------------------------------------|
| <i>ictxt</i>                 | INTEGER. Integer handle that indicates the context.                            |
| <i>uplo, diag, m, n, lda</i> | Describe the matrix to be sent. See <a href="#">Matrix Shapes</a> for details. |
| <i>rsrc</i>                  | INTEGER.<br>The process row coordinate of the source of the message.           |
| <i>csrc</i>                  | INTEGER.<br>The process column coordinate of the source of the message.        |

### Output Parameters

|          |                                                                        |
|----------|------------------------------------------------------------------------|
| <i>a</i> | An array of dimension $(lda, n)$ to receive the incoming message into. |
|----------|------------------------------------------------------------------------|

### Description

This routine receives a message from process {RSRC, CSRC} into the trapezoidal matrix A. This routine is globally-blocking, that is, return from the routine indicates that the message has been received into A.

## BLACS Broadcast Routines

---

This section describes BLACS broadcast routines.

A broadcast sends data possessed by one process to all processes within a scope. Broadcast, much like point to point communication, has two complementary operations. The process that owns the data to be broadcast issues a *broadcast/send*. All processes within the same scope must then issue the complementary *broadcast/receive*.

The BLACS define that both broadcast/send and broadcast/receive are *globally-blocking*. Broadcasts/receives cannot be locally-blocking since they must post a receive. Note that receives cannot be locally-blocking. When a given process can leave, a broadcast/receive operation is topology dependent, so, to avoid a hang as topology is varied, the broadcast/receive must be treated as if no process can leave until all processes have called the operation.

Broadcast/sends could be defined to be *locally-blocking*. Since no information is being received, as long as locally-blocking point to point sends are used, the broadcast/send will be locally blocking. However, defining one process within a scope to be locally-blocking while all other processes are globally-blocking adds little to the programmability of the code. On the other hand, leaving the option open to have globally-blocking broadcast/sends may allow for optimization on some platforms.

The fact that broadcasts are defined as globally-blocking has several important implications. The first is that scoped operations (broadcasts or combines) must be strictly ordered, that is, all processes within a scope must agree on the order of calls to separate scoped operations. This constraint falls in line with that already in place for the computation of message IDs, and is present in point to point communication as well.

A less obvious result is that scoped operations with `SCOPE = 'ALL'` must be ordered with respect to any other scoped operation. This means that if there are two broadcasts to be done, one along a column, and one involving the entire process grid, all processes within the process column issuing the column broadcast must agree on which broadcast will be performed first.

The convention used in the communication routine names follows the template `?xxyy2d`, where the letter in the `?` position indicates the data type being sent, `xx` is replaced to indicate the shape of the matrix, and the `yy` positions are used to indicate the type of communication to perform:

|    |                                                                                                |
|----|------------------------------------------------------------------------------------------------|
| i  | integer                                                                                        |
| s  | single precision real                                                                          |
| d  | double precision real                                                                          |
| c  | single precision complex                                                                       |
| z  | double precision complex                                                                       |
| ge | The data to be communicated is stored in a general rectangular matrix.                         |
| tr | The data to be communicated is stored in a trapezoidal matrix.                                 |
| bs | Broadcast/send. A process begins the broadcast of data within a scope.                         |
| br | Broadcast/receive A process receives and participates in the broadcast of data within a scope. |

### BLACS Broadcast Routines

| Routine name           | Operation performed                                   |
|------------------------|-------------------------------------------------------|
| <a href="#">gebs2d</a> | Start a broadcast along a scope.                      |
| <a href="#">trbs2d</a> |                                                       |
| <a href="#">gebr2d</a> | Receive and participate in a broadcast along a scope. |
| <a href="#">trbr2d</a> |                                                       |

#### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## ?gebs2d

Starts a broadcast along a scope for a general rectangular matrix.

---

### Syntax

```
call igebs2d(icontxt, scope, top, m, n, a, lda)
call sgebs2d(icontxt, scope, top, m, n, a, lda)
call dgebs2d(icontxt, scope, top, m, n, a, lda)
call cgebs2d(icontxt, scope, top, m, n, a, lda)
call zgebs2d(icontxt, scope, top, m, n, a, lda)
```

### Input Parameters

|                     |                                                                                                          |
|---------------------|----------------------------------------------------------------------------------------------------------|
| <i>icontxt</i>      | INTEGER. Integer handle that indicates the context.                                                      |
| <i>scope</i>        | CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'. |
| <i>top</i>          | CHARACTER*1. Indicates the communication pattern to use for the broadcast.                               |
| <i>m, n, a, lda</i> | Describe the matrix to be sent. See <a href="#">Matrix Shapes</a> for details.                           |

### Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix *A*.

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

## ?trbs2d

Starts a broadcast along a scope for a trapezoidal matrix.

---

### Syntax

```
call itrbs2d(icontxt, scope, top, uplo, diag, m, n, a, lda)
call strbs2d(icontxt, scope, top, uplo, diag, m, n, a, lda)
call dtrbs2d(icontxt, scope, top, uplo, diag, m, n, a, lda)
call ctrbs2d(icontxt, scope, top, uplo, diag, m, n, a, lda)
call ztrbs2d(icontxt, scope, top, uplo, diag, m, n, a, lda)
```

### Input Parameters

|                |                                                     |
|----------------|-----------------------------------------------------|
| <i>icontxt</i> | INTEGER. Integer handle that indicates the context. |
|----------------|-----------------------------------------------------|

|                                 |                                                                                                          |
|---------------------------------|----------------------------------------------------------------------------------------------------------|
| <i>scope</i>                    | CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'. |
| <i>top</i>                      | CHARACTER*1. Indicates the communication pattern to use for the broadcast.                               |
| <i>uplo, diag, m, n, a, lda</i> | Describe the matrix to be sent. See <a href="#">Matrix Shapes</a> for details.                           |

## Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix *A*.

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

## ?gebr2d

*Receives and participates in a broadcast along a scope for a general rectangular matrix.*

---

## Syntax

```
call igebr2d(icontxt, scope, top, m, n, a, lda, rsrc, csrc)
call sgebr2d(icontxt, scope, top, m, n, a, lda, rsrc, csrc)
call dgebr2d(icontxt, scope, top, m, n, a, lda, rsrc, csrc)
call cgebr2d(icontxt, scope, top, m, n, a, lda, rsrc, csrc)
call zgebr2d(icontxt, scope, top, m, n, a, lda, rsrc, csrc)
```

## Input Parameters

|                  |                                                                                                          |
|------------------|----------------------------------------------------------------------------------------------------------|
| <i>icontxt</i>   | INTEGER. Integer handle that indicates the context.                                                      |
| <i>scope</i>     | CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'. |
| <i>top</i>       | CHARACTER*1. Indicates the communication pattern to use for the broadcast.                               |
| <i>m, n, lda</i> | Describe the matrix to be sent. See <a href="#">Matrix Shapes</a> for details.                           |
| <i>rsrc</i>      | INTEGER.<br>The process row coordinate of the process that called broadcast/send.                        |
| <i>csrc</i>      | INTEGER.<br>The process column coordinate of the process that called broadcast/send.                     |

## Output Parameters

|          |                                                                        |
|----------|------------------------------------------------------------------------|
| <i>a</i> | An array of dimension $(lda, n)$ to receive the incoming message into. |
|----------|------------------------------------------------------------------------|

## Description

This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix  $A$ . Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

call ctrbr2d(icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc)
call ztrbr2d(icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc)
```

## Input Parameters

|                              |                                                                                                          |
|------------------------------|----------------------------------------------------------------------------------------------------------|
| <i>icontxt</i>               | INTEGER. Integer handle that indicates the context.                                                      |
| <i>scope</i>                 | CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'. |
| <i>top</i>                   | CHARACTER*1. Indicates the communication pattern to use for the broadcast.                               |
| <i>uplo, diag, m, n, lda</i> | Describe the matrix to be sent. See <a href="#">Matrix Shapes</a> for details.                           |
| <i>rsrc</i>                  | INTEGER.<br>The process row coordinate of the process that called broadcast/send.                        |
| <i>csrc</i>                  | INTEGER.<br>The process column coordinate of the process that called broadcast/send.                     |

## Output Parameters

|          |                                                                        |
|----------|------------------------------------------------------------------------|
| <i>a</i> | An array of dimension $(lda, n)$ to receive the incoming message into. |
|----------|------------------------------------------------------------------------|

## Description

This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix  $A$ . Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

## blacs\_setup

*Allocates virtual machine and spawns processes.*

---

### Syntax

```
call blacs_setup(mypnum, nprocs)
```

### Input Parameters

*nprocs* INTEGER. On the process spawned from the keyboard rather than from `pvmspawn`, this parameter indicates the number of processes to create when building the virtual machine.

### Output Parameters

*mypnum* INTEGER. An integer between 0 and (*nprocs* - 1) that uniquely identifies each process.

*nprocs* INTEGER. For all processes other than spawned from the keyboard, this parameter means the number of processes available for BLACS use.

### Description

This routine only accomplishes meaningful work in the PVM BLACS. On all other platforms, it is functionally equivalent to `blacs_pinfo`. The BLACS assume a static system, that is, the given number of processes does not change. PVM supplies a dynamic system, allowing processes to be added to the system on the fly.

`blacs_setup` is used to allocate the virtual machine and spawn off processes. It reads in a file called `blacs_setup.dat`, in which the first line must be the name of your executable. The second line is optional, but if it exists, it should be a PVM spawn flag. Legal values at this time are 0 (`PvmTaskDefault`), 4 (`PvmTaskDebug`), 8 (`PvmTaskTrace`), and 12 (`PvmTaskDebug + PvmTaskTrace`). The primary reason for this line is to allow the user to easily turn on and off PVM debugging. Additional lines, if any, specify what machines should be added to the current configuration before spawning *nprocs*-1 processes to the machines in a round robin fashion.

*nprocs* is input on the process which has no PVM parent (that is, *mypnum*=0), and both parameters are output for all processes. So, on PVM systems, the call to `blacs_pinfo` informs you that the virtual machine has not been set up, and a call to `blacs_setup` then sets up the machine and returns the real values for *mypnum* and *nprocs*.

Note that if the file `blacs_setup.dat` does not exist, the BLACS prompt the user for the executable name, and processes are spawned to the current PVM configuration.

## blacs\_get

*Gets values that BLACS use for internal defaults.*

---

### Syntax

```
call blacs_get(icontxt, what, val)
```

### Input Parameters

*icontxt* INTEGER. On values of *what* that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.

*what* INTEGER. Indicates what BLACS internal(s) should be returned in *val*. Present options are:

- *what* = 0 : Handle indicating default system context.
- *what* = 1 : The BLACS message ID range.
- *what* = 2 : The BLACS debug level the library was compiled with.
- *what* = 10 : Handle indicating the system context used to define the BLACS context whose handle is *icontxt*.
- *what* = 11 : Number of rings multiring broadcast topology is presently using.
- *what* = 12 : Number of branches general tree broadcast topology is presently using.
- *what* = 13 : Number of rings multiring combine topology is presently using.
- *what* = 14 : Number of branches general tree combine topology is presently using.
- *what* = 15 : Whether topologies are forced to be repeatable or not. A non-zero return value indicates that topologies are being forced to be repeatable. See [Repeatability and Coherence](#) for more information about repeatability.
- *what* = 16 : Whether topologies are forced to be heterogenous coherent or not. A non-zero return value indicates that topologies are being forced to be heterogenous coherent. See [Repeatability and Coherence](#) for more information about coherence.

## Output Parameters

*val* INTEGER. The value of the BLACS internal.

## Description

This routine gets the values that the BLACS are using for internal defaults. Some values are tied to a BLACS context, and some are more general. The most common use is in retrieving a default system context for input into `blacs_gridinit` or `blacs_gridmap`.

Some systems, such as MPI\*, supply their own version of context. For those users who mix system code with BLACS code, a BLACS context should be formed in reference to a system context. Thus, the grid creation routines take a system context as input. If you wish to have strictly portable code, you may use `blacs_get` to retrieve a default system context that will include all available processes. This value is not tied to a BLACS context, so the parameter *icontxt* is unused.

`blacs_get` returns information on three quantities that are tied to an individual BLACS context, which is passed in as *icontxt*. The information that may be retrieved is:

- The handle of the system context upon which this BLACS context was defined
- The number of rings for TOP = 'M' (multiring broadcast/combine)
- The number of branches for TOP = 'T' (general tree broadcast/general tree gather).
- Whether topologies are being forced to be repeatable or heterogenous coherent.

## `blacs_set`

*Sets values that BLACS use for internal defaults.*

---

## Syntax

call `blacs_set( ictxt, what, val )`

## Input Parameters

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ictxt</i> | INTEGER. For values of <i>what</i> that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>what</i>  | <p>INTEGER. Indicates what BLACS internal(s) should be set. Present values are:</p> <ul style="list-style-type: none"> <li>• 1 = Set the BLACS message ID range</li> <li>• 11 = Number of rings for multiring broadcast topology to use</li> <li>• 12 = Number of branches for general tree broadcast topology to use</li> <li>• 13 = Number of rings for multiring combine topology to use</li> <li>• 14 = Number of branches for general tree combine topology to use</li> <li>• 15 = Force topologies to be repeatable or not</li> <li>• 16 = Force topologies to be heterogenous coherent or not</li> </ul> |
| <i>val</i>   | INTEGER. Array of dimension (*). Indicates the value(s) the internals should be set to. The specific meanings depend on <i>what</i> values, as discussed in Description below.                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Description

This routine sets the BLACS internal defaults depending on *what* values:

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>what</i> = 1  | <p>Setting the BLACS message ID range.</p> <p>If you wish to mix the BLACS with other message-passing packages, restrict the BLACS to a certain message ID range not to be used by the non-BLACS routines. The message ID range must be set before the first call to <code>blacs_gridinit</code> or <code>blacs_gridmap</code>. Subsequent calls will have no effect. Because the message ID range is not tied to a particular context, the parameter <i>ictxt</i> is ignored, and <i>val</i> is defined as:</p> <p>VAL (input) INTEGER array of dimension (2)</p> <p>VAL(1) : The smallest message ID (also called message type or message tag) the BLACS should use.</p> <p>VAL(2) : The largest message ID (also called message type or message tag) the BLACS should use.</p> |
| <i>what</i> = 11 | <p>Set number of rings for TOP = 'M' (multiring broadcast). This quantity is tied to a context, so <i>ictxt</i> is used, and <i>val</i> is defined as:</p> <p>VAL (input) INTEGER array of dimension (1)</p> <p>VAL(1) : The number of rings for multiring topology to use.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>what</i> = 12 | <p>Set number of branches for TOP = 'T' (general tree broadcast). This quantity is tied to a context, so <i>ictxt</i> is used, and <i>val</i> is defined as:</p> <p>VAL (input) INTEGER array of dimension (1)</p> <p>VAL(1) : The number of branches for general tree topology to use.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>what</i> = 13 | <p>Set number of rings for TOP = 'M' (multiring combine). This quantity is tied to a context, so <i>icontxt</i> is used, and <i>val</i> is defined as:</p> <p>VAL (input) INTEGER array of dimension (1)</p> <p>VAL(1) : The number of rings for multiring topology to use.</p>                                                                                                                                                |
| <i>what</i> = 14 | <p>Set number of branches for TOP = 'T' (general tree gather). This quantity is tied to a context, so <i>icontxt</i> is used, and <i>val</i> is defined as:</p> <p>VAL (input) INTEGER array of dimension (1)</p> <p>VAL(1) : The number of branches for general tree topology to use.</p>                                                                                                                                     |
| <i>what</i> = 15 | <p>Force topologies to be repeatable or not (see <a href="#">Repeatability and Coherence</a> for more information about repeatability).</p> <p>VAL (input) INTEGER array of dimension (1)</p> <p>VAL(1) = 0 (default)      Topologies are not required to be repeatable.</p> <p>VAL(1) ≠ 0                All used topologies are required to be repeatable, which might degrade performance.</p>                              |
| <i>what</i> = 16 | <p>Force topologies to be heterogenous coherent or not (see <a href="#">Repeatability and Coherence</a> for more information about coherence).</p> <p>VAL (input) INTEGER array of dimension (1)</p> <p>VAL(1) = 0 (default)      Topologies are not required to be heterogenous coherent.</p> <p>VAL(1) ≠ 0                All used topologies are required to be heterogenous coherent, which might degrade performance.</p> |

## blacs\_gridinit

Assigns available processes into BLACS process grid.

### Syntax

call blacs\_gridinit( *icontxt*, *layout*, *nprow*, *npcol* )

### Input Parameters

|                |                                                                                                                                                                                                                                                                             |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>icontxt</i> | <p>INTEGER. Integer handle indicating the system context to be used in creating the BLACS context. Call <code>blacs_get</code> to obtain a default system context.</p>                                                                                                      |
| <i>layout</i>  | <p>CHARACTER*1. Indicates how to map processes to BLACS grid. Options are:</p> <ul style="list-style-type: none"> <li>• 'R' : Use row-major natural ordering</li> <li>• 'C' : Use column-major natural ordering</li> <li>• ELSE : Use row-major natural ordering</li> </ul> |
| <i>nprow</i>   | <p>INTEGER. Indicates how many process rows the process grid should contain.</p>                                                                                                                                                                                            |

*npcol* INTEGER. Indicates how many process columns the process grid should contain.

## Output Parameters

*icontxt* INTEGER. Integer handle to the created BLACS context.

## Description

All BLACS codes must call this routine, or its sister routine `blacs_gridmap`. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine `blacs_setup` should be used to create the virtual machine.

This routine creates a simple  $nprow \times npcold$  process grid. This process grid uses the first  $nprow * npcold$  processes, and assigns them to the grid in a row- or column-major natural ordering. If these process-to-grid mappings are unacceptable, call `blacs_gridmap`.

## **blacs\_gridmap**

*Maps available processes into BLACS process grid.*

---

## Syntax

```
call blacs_gridmap(icontxt, usermap, ldumap, nprow, npcold)
```

## Input Parameters

*icontxt* INTEGER. Integer handle indicating the system context to be used in creating the BLACS context. Call `blacs_get` to obtain a default system context.

*usermap* INTEGER. Array, dimension  $(ldumap, npcold)$ , indicating the process-to-grid mapping.

*ldumap* INTEGER. Leading dimension of the 2D array *usermap*.  $ldumap \geq nprow$ .

*nprow* INTEGER. Indicates how many process rows the process grid should contain.

*npcol* INTEGER. Indicates how many process columns the process grid should contain.

## Output Parameters

*icontxt* INTEGER. Integer handle to the created BLACS context.

## Description

All BLACS codes must call this routine, or its sister routine `blacs_gridinit`. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are actual processors (hardware), and they are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine `blacs_setup` should be used to create the virtual machine.

This routine allows the user to map processes to the process grid in an arbitrary manner. `usermap(i,j)` holds the process number of the process to be placed in  $\{i, j\}$  of the process grid. On most distributed systems, this process number is a machine defined number between  $0 \dots nprow-1$ . For PVM, these node numbers are the PVM TIDS (Task IDs). The `blacs_gridmap` routine is intended for an experienced user. The `blacs_gridinit` routine is much simpler. `blacs_gridinit` simply performs a `gridmap` where the first  $nprow * npcold$  processes are mapped into the current grid in a row-major natural ordering. If you are an experienced user, `blacs_gridmap` allows you to take advantage of your system's actual layout. That is, you can map nodes that are physically connected to be neighbors in the BLACS grid, etc. The `blacs_gridmap` routine also opens the way for *multigridding*: you can separate your nodes into arbitrary grids, join them together at some later date, and then re-split them into new grids. `blacs_gridmap` also provides the ability to make arbitrary grids or subgrids (for example, a "nearest neighbor" grid), which can greatly facilitate operations among processes that do not fall on a row or column of the main process grid.

## Destruction Routines

This section describes BLACS routines that destroy grids, abort processes, and free resources.

### BLACS Destruction Routines

| Routine name                   | Operation performed    |
|--------------------------------|------------------------|
| <a href="#">blacs_freebuff</a> | Frees BLACS buffer.    |
| <a href="#">blacs_gridexit</a> | Frees a BLACS context. |

| Routine name             | Operation performed                                         |
|--------------------------|-------------------------------------------------------------|
| <code>blacs_abort</code> | Aborts all processes.                                       |
| <code>blacs_exit</code>  | Frees all BLACS contexts and releases all allocated memory. |

## **blacs\_freebuff**

*Frees BLACS buffer.*

### **Syntax**

call `blacs_freebuff( ictxt, wait )`

### **Input Parameters**

|                    |                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ictxt</code> | INTEGER. Integer handle that indicates the BLACS context.                                                                                                                                                       |
| <code>wait</code>  | INTEGER. Parameter indicating whether to wait for non-blocking operations or not. If equals 0, the operations should not be waited for; free only unused buffers. Otherwise, wait in order to free all buffers. |

### **Description**

This routine releases the BLACS buffer.

The BLACS have at least one internal buffer that is used for packing messages. The number of internal buffers depends on what platform you are running the BLACS on. On systems where memory is tight, keeping this buffer or buffers may become expensive. Call `freebuff` to release the buffer. However, the next call of a communication routine that requires packing reallocates the buffer.

The `wait` parameter determines whether the BLACS should wait for any non-blocking operations to be completed or not. If `wait = 0`, the BLACS free any buffers that can be freed without waiting. If `wait` is not 0, the BLACS free all internal buffers, even if non-blocking operations must be completed first.

## **blacs\_gridexit**

*Frees a BLACS context.*

### **Syntax**

call `blacs_gridexit( ictxt )`

### **Input Parameters**

|                    |                                                                       |
|--------------------|-----------------------------------------------------------------------|
| <code>ictxt</code> | INTEGER. Integer handle that indicates the BLACS context to be freed. |
|--------------------|-----------------------------------------------------------------------|

### **Description**

This routine frees a BLACS context.

Release the resources when contexts are no longer needed. After freeing a context, the context no longer exists, and its handle may be re-used if new contexts are defined.

## **blacs\_abort**

*Aborts all processes.*

### **Syntax**

call `blacs_abort( ictxt, errornum )`

## Input Parameters

|                 |                                                                         |
|-----------------|-------------------------------------------------------------------------|
| <i>icontxt</i>  | INTEGER. Integer handle that indicates the BLACS context to be aborted. |
| <i>errornum</i> | INTEGER. User-defined integer error number.                             |

## Description

This routine aborts all the BLACS processes, not only those confined to a particular context.

Use `blacs_abort` to abort all the processes in case of a serious error. Note that both parameters are input, but the routine uses them only in printing out the error message. The context handle passed in is not required to be a valid context handle.

## `blacs_exit`

*Frees all BLACS contexts and releases all allocated memory.*

---

## Syntax

```
call blacs_exit(continue)
```

## Input Parameters

|                 |                                                                                                                                                                                                                                                                         |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>continue</i> | INTEGER. Flag indicating whether message passing continues after the BLACS are done. If <i>continue</i> is non-zero, the user is assumed to continue using the machine after completing the BLACS. Otherwise, no message passing is assumed after calling this routine. |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Description

This routine frees all BLACS contexts and releases all allocated memory.

This routine should be called when a process has finished all use of the BLACS. The *continue* parameter indicates whether the user will be using the underlying communication platform after the BLACS are finished. This information is most important for the PVM BLACS. If *continue* is set to 0, then `pvm_exit` is called; otherwise, it is not called. Setting *continue* not equal to 0 indicates that explicit PVM `send/recvs` will be called after the BLACS routines are used. Make sure your code calls `pvm_exit`. PVM users should either call `blacs_exit` or explicitly call `pvm_exit` to avoid PVM problems.

## Informational Routines

This section describes BLACS routines that return information involving the process grid.

### BLACS Informational Routines

---

| Routine name                | Operation performed                                                   |
|-----------------------------|-----------------------------------------------------------------------|
| <code>blacs_gridinfo</code> | Returns information on the current grid.                              |
| <code>blacs_pnum</code>     | Returns the system process number of the process in the process grid. |
| <code>blacs_pcoord</code>   | Returns the row and column coordinates in the process grid.           |

---

## Syntax

```
call blacs_pcoord(icontxt, pnum, prow, pcol)
```

## Input Parameters

*icontxt*                                    INTEGER. Integer handle that indicates the context.

*pnum*                                        INTEGER. Process number the coordinates of which are to be determined. This parameter stand for the process number of the underlying machine, that is, it is a `tid` for PVM.

## Output Parameters

*prow*                                        INTEGER. Row coordinates of the *pnum* process in the BLACS grid.

*pcol*                                        INTEGER. Column coordinates of the *pnum* process in the BLACS grid.

## Description

Given the system process number, this function returns the row and column coordinates in the BLACS process grid.

## Miscellaneous Routines

This section describes `blacs_barrier` routine.

### BLACS Informational Routines

| Routine name               | Operation performed                                                                                    |
|----------------------------|--------------------------------------------------------------------------------------------------------|
| <code>blacs_barrier</code> | Holds up execution of all processes within the indicated scope until they have all called the routine. |

## `blacs_barrier`

*Holds up execution of all processes within the indicated scope.*

## Syntax

```
call blacs_barrier(icontxt, scope)
```

## Input Parameters

*icontxt*                                    INTEGER. Integer handle that indicates the context.

*scope*                                        CHARACTER\*1. Parameter that indicates whether a process row (*scope*='R'), column ('C'), or entire grid ('A') will participate in the barrier.

## Description

This routine holds up execution of all processes within the indicated scope until they have all called the routine.

## **Examples of BLACS Routines Usage**

---

# Data Fitting Functions

Data Fitting functions in Intel® MKL provide spline-based interpolation capabilities that you can use to approximate functions, function derivatives or integrals, and perform cell search operations.

The Data Fitting component is task based. The task is a data structure or descriptor that holds the parameters related to a specific Data Fitting operation. You can modify the task parameters using the task editing functionality of the library.

For definition of the implemented operations, see [Mathematical Conventions](#).

Data Fitting routines use the following workflow to process a task:

1. Create a task or multiple tasks.
2. Modify the task parameters.
3. Perform a Data Fitting computation.
4. Destroy the task or tasks.

All Data Fitting functions fall into the following categories:

[Task Creation and Initialization Routines](#) - routines that create a new Data Fitting task descriptor and initialize the most common parameters, such as partition of the interpolation interval, values of the vector-valued function, and the parameters describing their structure.

[Task Configuration Routines](#) - routines that set, modify, or query parameters in an existing Data Fitting task.

[Computational Routines](#) - routines that perform Data Fitting computations, such as construction of a spline, interpolation, computation of derivatives and integrals, and search.

[Task Destructors](#) - routines that delete Data Fitting task descriptors and deallocate resources.

You can access the Data Fitting routines through the Fortran and C89/C99 language interfaces. You can also use the C89 interface with more recent versions of C/C++, or the Fortran 90 interface with programs written in Fortran 95.

The `$(MKL)/include` directory of the Intel® MKL contains the following Data Fitting header files:

- `mkl_df.h`

You can find examples that demonstrate usage of Data Fitting routines in the `$(MKL)/examples/datafittingc` directory .

## Data Fitting Function Naming Conventions

The interface of the Data Fitting functions, types, and constants are case-sensitive and can be in lowercase, uppercase, and mixed case.

The names of all routines have the following structure:

```
df[datatype]<base_name>
```

where

- `df` is a prefix indicating that the routine belongs to the Data Fitting component of Intel MKL.
- `[datatype]` field specifies the type of the input and/or output data and can be `s` (for the single precision real type), `d` (for the double precision real type), or `i` (for the integer type). This field is omitted in the names of the routines that are not data type dependent.
- `<base_name>` field specifies the functionality the routine performs. For example, this field can be `NewTask1D`, `Interpolate1D`, or `DeleteTask`

## Data Fitting Function Data Types

The Data Fitting component provides routines for processing single and double precision real data types. The results of cell search operations are returned as a generic integer data type.

All Data Fitting routines use the following data type:

| Type      | Data Object       |
|-----------|-------------------|
| DFTaskPtr | Pointer to a task |

**NOTE**

The actual size of the generic integer type is platform-dependent. Before compiling your application, you need to set an appropriate byte size for integers. For details, see section *Using the ILP64 Interface vs. LP64 Interface* of the Intel® MKL Developer Guide.

## Mathematical Conventions for Data Fitting Functions

This section explains the notation used for Data Fitting function descriptions. Spline notations are based on the terminology and definitions of [deBoor2001]. The Subbotin quadratic spline definition follows the conventions of [StechSub76]. The quasi-uniform partition definition is based on [Schumaker2007].

### Mathematical Notation in the Data Fitting Component

| Concept                                                                                                                                                                                                                                                        | Mathematical Notation                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Partition of interpolation interval $[a, b]$ , where <ul style="list-style-type: none"> <li><math>x_i</math> denotes breakpoints.</li> <li><math>[x_i, x_{i+1})</math> denotes a sub-interval (cell) of size <math>\Delta_i = x_{i+1} - x_i</math>.</li> </ul> | $\{x_i\}_{i=1, \dots, n}$ , where $a = x_1 < x_2 < \dots < x_n = b$                                                                                                                                                                                                                                                                                                                                                            |
| Quasi-uniform partition of interpolation interval $[a, b]$                                                                                                                                                                                                     | Partition $\{x_i\}_{i=1, \dots, n}$ which meets the constraint with a constant $C$ defined as $1 \leq M / m \leq C,$ where <ul style="list-style-type: none"> <li><math>M = \max_{i=1, \dots, n-1} (\Delta_i)</math></li> <li><math>m = \min_{i=1, \dots, n-1} (\Delta_i)</math></li> <li><math>\Delta_i = x_{i+1} - x_i</math></li> </ul>                                                                                     |
| Vector-valued function of dimension $p$ being fit                                                                                                                                                                                                              | $f(x) = (f_1(x), \dots, f_p(x))$                                                                                                                                                                                                                                                                                                                                                                                               |

## Data Fitting Usage Model

Consider an algorithm that uses the Data Fitting functions. Typically, such algorithms consist of four steps or stages:

1. Create a task. You can call the Data Fitting function several times to create multiple tasks.

```
status = dfdNewTask1D(&task, nx, x, xhint, ny, y, yhint);
```

2. Modify the task parameters.

```
status = dfdEditPPSpline1D(task, s_order, c_type, bc_type, bc, ic_type, ic,
scoeff, scoeffhint);
```

3. Perform Data Fitting spline-based computations. You may reiterate steps 2-3 as needed.

```
status = dfdInterpolate1D(task, estimate, method, nsite, site, sitehint, ndorder,
dorder, datahint, r, rhint, cell);
```

4. Destroy the task or tasks.

```
status = dfDeleteTask(&task);
```

## Data Fitting Usage Examples

The examples below illustrate several operations that you can perform with Data Fitting routines.

You can get source code for similar examples in the `.\examples\datafittingc` subdirectory of the Intel MKL installation directory.

The following example demonstrates the construction of a linear spline using Data Fitting routines. The spline approximates a scalar function defined on non-uniform partition. The coefficients of the spline are returned as a one-dimensional array:

### Example of Linear Spline Construction

```
#include "mkl.h"
#define N 500 /* Size of partition, number of breakpoints */
#define SPLINE_ORDER DF_PP_LINEAR /* Linear spline to construct */

int main()
{
 int status; /* Status of a Data Fitting operation */
 DFTaskPtr task; /* Data Fitting operations are task based */

 /* Parameters describing the partition */
 MKL_INT nx; /* The size of partition x */
 double x[N]; /* Partition x */
 MKL_INT xhint; /* Additional information about the structure of breakpoints */

 /* Parameters describing the function */
 MKL_INT ny; /* Function dimension */
 double y[N]; /* Function values at the breakpoints */
 MKL_INT yhint; /* Additional information about the function */

 /* Parameters describing the spline */
 MKL_INT s_order; /* Spline order */
 MKL_INT s_type; /* Spline type */
 MKL_INT ic_type; /* Type of internal conditions */
 double* ic; /* Array of internal conditions */
 MKL_INT bc_type; /* Type of boundary conditions */
 double* bc; /* Array of boundary conditions */

 double scoeff[(N-1)*SPLINE_ORDER]; /* Array of spline coefficients */
 MKL_INT scoeffhint; /* Additional information about the coefficients */

 /* Initialize the partition */
 nx = N;
 /* Set values of partition x */
 ...
 xhint = DF_NO_HINT; /* No additional information about the function is provided.
 By default, the partition is non-uniform. */
 /* Initialize the function */
 ny = 1; /* The function is scalar. */

 /* Set function values */
 ...
 yhint = DF_NO_HINT; /* No additional information about the function is provided. */

 /* Create a Data Fitting task */
 status = dfdNewTask1D(&task, nx, x, xhint, ny, y, yhint);

 /* Check the Data Fitting operation status */
 ...

 /* Initialize spline parameters */
 s_order = DF_PP_LINEAR; /* Spline is of the second order. */
 s_type = DF_PP_DEFAULT; /* Spline is of the default type. */

 /* Define internal conditions for linear spline construction (none in this example) */
 ic_type = DF_NO_IC;
```

```

ic = NULL;

/* Define boundary conditions for linear spline construction (none in this example) */
bc_type = DF_NO_BC;
bc = NULL;
scoeffhint = DF_NO_HINT; /* No additional information about the spline. */

/* Set spline parameters in the Data Fitting task */
status = dfdEditPPSpline1D(task, s_order, s_type, bc_type, bc, ic_type,
 ic, scoeff, scoeffhint);

/* Check the Data Fitting operation status */
...

/* Use a standard computation method to construct a linear spline: */
/* $P_i(x) = c_{i,0} + c_{i,1}(x - x_i)$, $i=0, \dots, N-2$ */
/* The library packs spline coefficients to array scoeff. */
/* $scoeff[2*i+0]=c_{i,0}$ and $scoeff[2*i+1]=c_{i,1}$, $i=0, \dots, N-2$ */
status = dfdConstruct1D(task, DF_PP_SPLINE, DF_METHOD_STD);

/* Check the Data Fitting operation status */
...

/* Process spline coefficients */
...

/* Deallocate Data Fitting task resources */
status = dfDeleteTask(&task);

/* Check the Data Fitting operation status */
...
return 0 ;
}

```

The following example demonstrates cubic spline-based interpolation using Data Fitting routines. In this example, a scalar function defined on non-uniform partition is approximated by Bessel cubic spline using not-a-knot boundary conditions. Once the spline is constructed, you can use the spline to compute spline values at the given sites. Computation results are packed by the Data Fitting routine in row-major format.

### Example of Cubic Spline-Based Interpolation

```

#include "mkl.h"

#define NX 100 /* Size of partition, number of breakpoints */
#define NSITE 1000 /* Number of interpolation sites */
#define SPLINE_ORDER DF_PP_CUBIC /* A cubic spline to construct */

int main()
{
 int status; /* Status of a Data Fitting operation */
 DFTaskPtr task; /* Data Fitting operations are task based */

 /* Parameters describing the partition */
 MKL_INT nx; /* The size of partition x */
 double x[NX]; /* Partition x */
 MKL_INT xhint; /* Additional information about the structure of breakpoints */

 /* Parameters describing the function */
 MKL_INT ny; /* Function dimension */
 double y[NX]; /* Function values at the breakpoints */
}

```

```

MKL_INT yhint; /* Additional information about the function */

/* Parameters describing the spline */
MKL_INT s_order; /* Spline order */
MKL_INT s_type; /* Spline type */
MKL_INT ic_type; /* Type of internal conditions */
double* ic; /* Array of internal conditions */
MKL_INT bc_type; /* Type of boundary conditions */
double* bc; /* Array of boundary conditions */

double scoeff[(NX-1)* SPLINE_ORDER]; /* Array of spline coefficients */
MKL_INT scoeffhint; /* Additional information about the coefficients */

/* Parameters describing interpolation computations */
MKL_INT nsite; /* Number of interpolation sites */
double site[NSITE]; /* Array of interpolation sites */
MKL_INT sitehint; /* Additional information about the structure of
 interpolation sites */

MKL_INT ndorder, dorder; /* Parameters defining the type of interpolation */

double* datahint; /* Additional information on partition and interpolation sites */

double r[NSITE]; /* Array of interpolation results */
MKL_INT rhint; /* Additional information on the structure of the results */
MKL_INT* cell; /* Array of cell indices */

/* Initialize the partition */
nx = NX;

/* Set values of partition x */
...
xhint = DF_NON_UNIFORM_PARTITION; /* The partition is non-uniform. */

/* Initialize the function */
ny = 1; /* The function is scalar. */

/* Set function values */
...
yhint = DF_NO_HINT; /* No additional information about the function is provided. */

/* Create a Data Fitting task */
status = dfdNewTask1D(&task, nx, x, xhint, ny, y, yhint);

/* Check the Data Fitting operation status */
...

/* Initialize spline parameters */
s_order = DF_PP_CUBIC; /* Spline is of the fourth order (cubic spline). */
s_type = DF_PP_BESSEL; /* Spline is of the Bessel cubic type. */

/* Define internal conditions for cubic spline construction (none in this example) */
ic_type = DF_NO_IC;
ic = NULL;

/* Use not-a-knot boundary conditions. In this case, the is first and the last
interior breakpoints are inactive, no additional values are provided. */
bc_type = DF_BC_NOT_A_KNOT;
bc = NULL;

```

```

scoeffhint = DF_NO_HINT; /* No additional information about the spline. */

/* Set spline parameters in the Data Fitting task */
status = dfdEditPPSpline1D(task, s_order, s_type, bc_type, bc, ic_type,
 ic, scoeff, scoeffhint);

/* Check the Data Fitting operation status */
...

/* Use a standard method to construct a cubic Bessel spline: */
/* $P_i(x) = c_{i,0} + c_{i,1}(x - x_i) + c_{i,2}(x - x_i)^2 + c_{i,3}(x - x_i)^3$, */
/* The library packs spline coefficients to array scoeff: */
/* scoeff[4*i+0] = ci,0, scoef[4*i+1] = ci,1, */
/* scoeff[4*i+2] = ci,2, scoef[4*i+3] = ci,3, */
/* i=0,...,N-2 */
status = dfdConstruct1D(task, DF_PP_SPLINE, DF_METHOD_STD);

/* Check the Data Fitting operation status */
...

/* Initialize interpolation parameters */
nsite = NSITE;

/* Set site values */
...

sitehint = DF_NON_UNIFORM_PARTITION; /* Partition of sites is non-uniform */

/* Request to compute spline values */
ndorder = 1;
dorder = 1;
datahint = DF_NO_APRIORI_INFO; /* No additional information about breakpoints or
 sites is provided. */
rhint = DF_MATRIX_STORAGE_ROWS; /* The library packs interpolation results
 in row-major format. */
cell = NULL; /* Cell indices are not required. */

/* Solve interpolation problem using the default method: compute the spline values
 at the points site(i), i=0,..., nsite-1 and place the results to array r */
status = dfdInterpolate1D(task, DF_INTERP, DF_METHOD_STD, nsite, site,
 sitehint, ndorder, &dorder, datahint, r, rhint, cell);

/* Check Data Fitting operation status */
...

/* De-allocate Data Fitting task resources */
status = dfDeleteTask(&task);
/* Check Data Fitting operation status */
...
return 0;
}

```

The following example demonstrates how to compute indices of cells containing given sites. This example uses uniform partition presented with two boundary points. The sites are in the ascending order.

### Example of Cell Search

```

#include "mkl.h"

#define NX 100 /* Size of partition, number of breakpoints */

```

```

#define NSITE 1000 /* Number of interpolation sites */

int main()
{
 int status; /* Status of a Data Fitting operation */
 DFTaskPtr task; /* Data Fitting operations are task based */

 /* Parameters describing the partition */
 MKL_INT nx; /* The size of partition x */
 float x[2]; /* Partition x is uniform and holds endpoints
 of interpolation interval [a, b] */
 MKL_INT xhint; /* Additional information about the structure of breakpoints */

 /* Parameters describing the function */
 MKL_INT ny; /* Function dimension */
 float *y; /* Function values at the breakpoints */
 MKL_INT yhint; /* Additional information about the function */

 /* Parameters describing cell search */
 MKL_INT nsite; /* Number of interpolation sites */
 float site[NSITE]; /* Array of interpolation sites */
 MKL_INT sitehint; /* Additional information about the structure of sites */

 float* datahint; /* Additional information on partition and interpolation sites */

 MKL_INT cell[NSITE]; /* Array for cell indices */

 /* Initialize a uniform partition */
 nx = NX;
 /* Set values of partition x: for uniform partition, */
 /* provide end-points of the interpolation interval [-1.0,1.0] */
 x[0] = -1.0f; x[1] = 1.0f;
 xhint = DF_UNIFORM_PARTITION; /* Partition is uniform */

 /* Initialize function parameters */
 /* In cell search, function values are not necessary and are set to zero/NULL values */
 ny = 0;
 y = NULL;
 yhint = DF_NO_HINT;

 /* Create a Data Fitting task */
 status = dfsNewTask1D(&task, nx, x, xhint, ny, y, yhint);

 /* Check Data Fitting operation status */
 ...

 /* Initialize interpolation (cell search) parameters */
 nsite = NSITE;

 /* Set sites in the ascending order */
 ...
 sitehint = DF_SORTED_DATA; /* Sites are provided in the ascending order. */
 datahint = DF_NO_APRIORI_INFO; /* No additional information
 about breakpoints/sites is provided.*/

 /* Use a standard method to compute indices of the cells that contain
 interpolation sites. The library places the index of the cell containing
 site(i) to the cell(i), i=0,...,nsite-1 */
 status = dfsSearchCells1D(task, DF_METHOD_STD, nsite, site, sitehint,

```

```

 datahint, cell);
/* Check Data Fitting operation status */
...

/* Process cell indices */
...

/* Deallocate Data Fitting task resources */
status = dfDeleteTask(&task);

/* Check Data Fitting operation status */
...
return 0;
}

```

## Data Fitting Function Task Status and Error Reporting

The Data Fitting routines report a task status through integer values. Negative status values indicate errors, while positive values indicate warnings. An error can be caused by invalid parameter values or a memory allocation failure.

The status codes have symbolic names predefined in the header file as macros via the `#define` statements.

If no error occurred, the function returns the `DF_STATUS_OK` code defined as zero:

```
#define DF_STATUS_OK 0
```

In case of an error, the function returns a non-zero error code that specifies the origin of the failure. Header files define the following status codes:

### Status Codes in the Data Fitting Component

| Status Code                                                                          | Description                                             |
|--------------------------------------------------------------------------------------|---------------------------------------------------------|
| <b>Common Status Codes</b>                                                           |                                                         |
| <code>DF_STATUS_OK</code>                                                            | Operation completed successfully.                       |
| <code>DF_ERROR_NULL_TASK</code>                                                      | Data Fitting task is a <code>NULL</code> pointer.       |
| <code>DF_ERROR_MEM_FAILURE</code>                                                    | Memory allocation failure.                              |
| <code>DF_ERROR_METHOD_NOT_SUPPORTED</code>                                           | Requested method is not supported.                      |
| <code>DF_ERROR_COMP_TYPE_NOT_SUPPORTED</code>                                        | Requested computation type is not supported.            |

| <code>DF_ERROR_BAD_X</code>                                                          | Array of breakpoints is invalid.                        |
| <code>DF_ERROR_BAD_X_HINT</code>                                                     | Invalid hint describing the structure of the partition. |
| <code>DF_ERROR_BAD_NY</code>                                                         | Invalid dimension of vector-valued function $y$ .       |
| <code>DF_ERROR_BAD_Y</code>                                                          | Array of function values is invalid.                    |
| <code>DF_ERROR_BAD_Y_HINT</code>                                                     | Invalid flag describing the structure of function $y$   |

### Data Fitting Task-Specific Editing Operations

| Status Code                                | Description                                                                                                                                                                   |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DF_ERROR_BAD_SPLINE_ORDER                  | Invalid spline order.                                                                                                                                                         |
| DF_ERROR_BAD_SPLINE_TYPE                   | Invalid spline type.                                                                                                                                                          |
| DF_ERROR_BAD_IC_TYPE                       | Type of internal conditions used for spline construction is invalid.                                                                                                          |
| DF_ERROR_BAD_IC                            | Array of internal conditions for spline construction is not defined.                                                                                                          |
| DF_ERROR_BAD_BC_TYPE                       | Type of boundary conditions used in spline construction is invalid.                                                                                                           |
| DF_ERROR_BAD_BC                            | Array of boundary conditions for spline construction is not defined.                                                                                                          |
| DF_ERROR_BAD_PP_COEFF                      | Array of piecewise polynomial spline coefficients is not defined.                                                                                                             |
| DF_ERROR_BAD_PP_COEFF_HINT                 | Invalid flag describing the structure of the piecewise polynomial spline coefficients.                                                                                        |
| DF_ERROR_BAD_PERIODIC_VAL                  | Function values at the endpoints of the interpolation interval are not equal as required in periodic boundary conditions.                                                     |
| DF_ERROR_BAD_DATA_ATTR                     | Invalid attribute of the pointer to be set or modified in Data Fitting task descriptor with the <code>df?</code> <code>EditIdxPtr</code> task editor.                         |
| DF_ERROR_BAD_DATA_IDX                      | Index of the pointer to be set or modified in the Data Fitting task descriptor with the <code>df?</code> <code>EditIdxPtr</code> task editor is out of the pre-defined range. |
| <b>Data Fitting Computation Operations</b> |                                                                                                                                                                               |
| DF_ERROR_BAD_NSITE                         | Invalid number of interpolation sites.                                                                                                                                        |
| DF_ERROR_BAD_SITE                          | Array of interpolation sites is not defined.                                                                                                                                  |
| DF_ERROR_BAD_SITE_HINT                     | Invalid flag describing the structure of interpolation sites.                                                                                                                 |
| DF_ERROR_BAD_NDORDER                       | Invalid size of the array defining derivative orders to be computed at interpolation sites.                                                                                   |
| DF_ERROR_BAD_DORDER                        | Array defining derivative orders to be computed at interpolation sites is not defined.                                                                                        |
| DF_ERROR_BAD_DATA_HINT                     | Invalid flag providing additional information about partition or interpolation sites.                                                                                         |
| DF_ERROR_BAD_INTERP                        | Array of spline-based interpolation results is not defined.                                                                                                                   |
| DF_ERROR_BAD_INTERP_HINT                   | Invalid flag defining the structure of spline-based interpolation results.                                                                                                    |
| DF_ERROR_BAD_CELL_IDX                      | Array of indices of partition cells containing interpolation sites is not defined.                                                                                            |
| DF_ERROR_BAD_NLIM                          | Invalid size of arrays containing integration limits.                                                                                                                         |

| Status Code                     | Description                                                                            |
|---------------------------------|----------------------------------------------------------------------------------------|
| DF_ERROR_BAD_LLIM               | Array of the left-side integration limits is not defined.                              |
| DF_ERROR_BAD_RLIM               | Array of the right-side integration limits is not defined.                             |
| DF_ERROR_BAD_INTEGR             | Array of spline-based integration results is not defined.                              |
| DF_ERROR_BAD_INTEGR_HINT        | Invalid flag providing the structure of the array of spline-based integration results. |
| DF_ERROR_BAD_LOOKUP_INTERP_SITE | Bad site provided for interpolation with look-up interpolator.                         |

**NOTE**

The routine that estimates piecewise polynomial cubic spline coefficients can return internal error codes related to the specifics of the implementation. Such error codes indicate invalid input data or other issues unrelated to Data Fitting routines.

## Data Fitting Task Creation and Initialization Routines

Task creation and initialization routines are functions used to create a new task descriptor and initialize its parameters. The Data Fitting component provides the `df?NewTask1D` routine that creates and initializes a new task descriptor for a one-dimensional Data Fitting task.

**df?NewTask1D**

*Creates and initializes a new task descriptor for a one-dimensional Data Fitting task.*

**Syntax**

```
status = dfsNewTask1D(&task, nx, x, xhint, ny, y, yhint)
```

```
status = dfdNewTask1D(&task, nx, x, xhint, ny, y, yhint)
```

**Include Files**

- `mkl.h`

**Input Parameters**

| Name            | Type                                                                                                                | Description                                                                                                                                                                                                                                                                                                                                         |
|-----------------|---------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>nx</code> | <code>const MKL_INT</code>                                                                                          | Number of breakpoints representing partition of interpolation interval $[a, b]$ .                                                                                                                                                                                                                                                                   |
| <code>x</code>  | <code>const float*</code> for <code>dfsNewTask1D</code><br><code>const double*</code> for <code>dfdNewTask1D</code> | One-dimensional array containing the strictly sorted breakpoints from interpolation interval $[a, b]$ . The structure of the array is defined by parameter <code>xhint</code> : <ul style="list-style-type: none"> <li>• If partition is non-uniform or quasi-uniform, the array should contain <code>nx</code> strictly ordered values.</li> </ul> |

| Name                                                                                                         | Type                                                        | Description                                                                                                                                                                                                                                                                                                                       |

| <b>CAUTION</b>                                                                                               |                                                             |                                                                                                                                                                                                                                                                                                                                   |
| The array must be strictly sorted. If it is unordered, the results of data fitting routines are not correct. |                                                             |                                                                                                                                                                                                                                                                                                                                   |
| <hr/>                                                                                                        |                                                             |                                                                                                                                                                                                                                                                                                                                   |
| <i>xhint</i>                                                                                                 | const MKL_INT                                               | A flag describing the structure of partition <i>x</i> . For the list of possible values of <i>xhint</i> , see table "Hint Values for Partition <i>x</i> ". If you set the flag to the DF_NO_HINT value, the library interprets the partition as non-uniform.                                                                      |
| <i>ny</i>                                                                                                    | const MKL_INT                                               | Dimension of vector-valued function <i>y</i> .                                                                                                                                                                                                                                                                                    |
| <i>y</i>                                                                                                     | const float* for dfsNewTask<br>const double* for dfdNewTask | Vector-valued function <i>y</i> , array of size $n_x \times n_y$ .<br>The storage format of function values in the array is defined by the value of flag <i>yhint</i> .                                                                                                                                                           |
| <i>yhint</i>                                                                                                 | const MKL_INT                                               | A flag describing the structure of array <i>y</i> . Valid hint values are listed in table "Hint Values for Vector-Valued Function <i>y</i> ". If you set the flag to the DF_NO_HINT value, the library assumes that all <i>ny</i> coordinates of the vector-valued function <i>y</i> are provided and stored in row-major format. |

### Output Parameters

| Name          | Type      | Description                                                                                                                                                                                                                                            |
|---------------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>task</i>   | DFTaskPtr | Descriptor of the task.                                                                                                                                                                                                                                |
| <i>status</i> | int       | Status of the routine: <ul style="list-style-type: none"> <li>DF_STATUS_OK if the task is created successfully.</li> <li>Non-zero error code if the task creation failed. See "Task Status and Error Reporting" for error code definitions.</li> </ul> |

### Description

The `df?NewTask1D` routine creates and initializes a new Data Fitting task descriptor with user-specified parameters for a one-dimensional Data Fitting task. The *x* and *nx* parameters representing the partition of interpolation interval  $[a, b]$  are mandatory. If you provide invalid values for these parameters, such as a NULL pointer *x* or the number of breakpoints smaller than two, the routine does not create the Data Fitting task and returns an error code.

If you provide a vector-valued function *y*, make sure that the function dimension *ny* and the array of function values *y* are both valid. If any of these parameters are invalid, the routine does not create the Data Fitting task and returns an error code.

If you store coordinates of the vector-valued function *y* in non-contiguous memory locations, you can set the *yhint* flag to `DF_1ST_COORDINATE`, and pass only the first coordinate of the function into the task creation routine. After successful creation of the Data Fitting task, you can pass the remaining coordinates using the `df?EditIdxPtr` task editor.

If the routine fails to create the task descriptor, it returns a `NULL` task pointer.

The routine supports the following hint values for partition  $x$ :

#### Hint Values for Partition $x$

| Value                                   | Description                                                               |
|-----------------------------------------|---------------------------------------------------------------------------|
| <code>DF_NON_UNIFORM_PARTITION</code>   | Partition is non-uniform.                                                 |
| <code>DF_QUASI_UNIFORM_PARTITION</code> | Partition is quasi-uniform.                                               |
| <code>DF_UNIFORM_PARTITION</code>       | Partition is uniform.                                                     |
| <code>DF_NO_HINT</code>                 | No hint is provided. By default, partition is interpreted as non-uniform. |

The routine supports the following hint values for the vector-valued function:

#### Hint Values for Vector-Valued Function $y$

| Value                               | Description                                                                                                                 |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>DF_MATRIX_STORAGE_ROWS</code> | Data is stored in row-major format according to C conventions.                                                              |
| <code>DF_MATRIX_STORAGE_COLS</code> | Data is stored in column-major format according to Fortran conventions.                                                     |
| <code>DF_1ST_COORDINATE</code>      | The first coordinate of vector-valued data is provided.                                                                     |
| <code>DF_NO_HINT</code>             | No hint is provided. By default, the coordinates of vector-valued function $y$ are provided and stored in row-major format. |

#### NOTE

You must preserve the arrays  $x$  (breakpoints) and  $y$  (vector-valued functions) through the entire workflow of the Data Fitting computations for a task, as the task stores the addresses of the arrays for spline-based computations.

## Task Configuration Routines

In order to configure tasks, you can use task editors and task query routines.

Task editors initialize or change the predefined Data Fitting task parameters. You can use task editors to initialize or modify pointers to arrays or parameter values.

Task editors can be task-specific or generic. Task-specific editors can modify more than one parameter related to a specific task. Generic editors modify a single parameter at a time.

The Data Fitting component of Intel MKL provides the following task editors:

#### Data Fitting Task Editors

| Editor                                          | Description                                            | Type          |
|-------------------------------------------------|--------------------------------------------------------|---------------|
| <code>df?</code><br><code>EditPPSpline1D</code> | Changes parameters of the piecewise polynomial spline. | Task-specific |
| <code>df?EditPtr</code>                         | Changes a pointer in the task descriptor.              | Generic       |
| <code>dfiEditVal</code>                         | Changes a value in the task descriptor.                | Generic       |

| Editor                     | Description                                                                                                         | Type    |
|----------------------------|---------------------------------------------------------------------------------------------------------------------|---------|
| <code>df?EditIdxPtr</code> | Changes a coordinate of data represented in matrix format, such as a vector-valued function or spline coefficients. | Generic |

Task query routines are used to read the predefined Data Fitting task parameters. You can use task query routines to read the values of pointers or parameters.

Task query routines are generic (not task-specific), allowing you to read a single parameter at a time.

The Data Fitting component of the Intel MKL provides the following task query routines:

### Data Fitting Task Query Routines

| Editor                      | Description                                                                                                         | Type    |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------|---------|
| <code>df?QueryPtr</code>    | Queries a pointer in the task descriptor.                                                                           | Generic |
| <code>dfiQueryVal</code>    | Queries a value in the task descriptor.                                                                             | Generic |
| <code>df?QueryIdxPtr</code> | Queries a coordinate of data represented in matrix format, such as a vector-valued function or spline coefficients. | Generic |

### `df?EditPPSpline1D`

*Modifies parameters representing a spline in a Data Fitting task descriptor.*

### Syntax

```
status = dfsEditPPSpline1D(task, s_order, s_type, bc_type, bc, ic_type, ic, scoeff, scoeffhint)
```

```
status = dfdEditPPSpline1D(task, s_order, s_type, bc_type, bc, ic_type, ic, scoeff, scoeffhint)
```

### Include Files

- `mkl.h`

### Input Parameters

| Name                 | Type                       | Description                                                                                                                                                        |
|----------------------|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>task</code>    | <code>DFTaskPtr</code>     | Descriptor of the task.                                                                                                                                            |
| <code>s_order</code> | <code>const MKL_INT</code> | Spline order. The parameter takes one of the values described in table " <a href="#">Spline Orders Supported by Data Fitting Functions</a> ".                      |
| <code>s_type</code>  | <code>const MKL_INT</code> | Spline type. The parameter takes one of the values described in table " <a href="#">Spline Types Supported by Data Fitting Functions</a> ".                        |
| <code>bc_type</code> | <code>const MKL_INT</code> | Type of boundary conditions. The parameter takes one of the values described in table " <a href="#">Boundary Conditions Supported by Data Fitting Functions</a> ". |

The size of the array is defined by the value of parameter <i>bc_type</i> : <ul style="list-style-type: none"> <li>• If you set free-end or not-a-knot boundary conditions, pass the NULL pointer to this parameter.</li> <li>• If you combine boundary conditions at the endpoints of the interpolation interval, pass an array of two elements.</li> <li>• If you set a boundary condition for the default quadratic spline or a periodic condition for Hermite or the default cubic spline, pass an array of one element.</li> </ul>                                                                                                                                                                                                                                  |
| <i>ic_type</i>    | const MKL_INT                                                                       | Type of internal conditions. The parameter takes one of the values described in table " <a href="#">Internal Conditions Supported by Data Fitting Functions</a> ".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>ic</i>         | const float* for<br>dfsEditPPSpline1D<br><br>const double* for<br>dfdEditPPSpline1D | A non-NULL pointer to the array of internal conditions. The size of the array is defined by the value of parameter <i>ic_type</i> : <ul style="list-style-type: none"> <li>• If you set first derivatives or second derivatives internal conditions (<i>ic_type</i>=DF_IC_1ST_DER or <i>ic_type</i>=DF_IC_2ND_DER), pass an array of <i>n-1</i> derivative values at the internal points of the interpolation interval.</li> <li>• If you set the knot values internal condition for Subbotin spline (<i>ic_type</i>=DF_IC_Q_KNOT) and the knot partition is non-uniform, pass an array of <i>n+1</i> elements.</li> <li>• If you set the knot values internal condition for Subbotin spline (<i>ic_type</i>=DF_IC_Q_KNOT) and the knot partition is uniform, pass an array of four elements.</li> </ul> |
| <i>scoeff</i>     | const float* for<br>dfsEditPPSpline1D<br><br>const double* for<br>dfdEditPPSpline1D | Spline coefficients. An array of size <i>ny*s_order*(nx-1)</i> . The storage format of the coefficients in the array is defined by the value of flag <i>scoeffhint</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>scoeffhint</i> | const MKL_INT                                                                       | A flag describing the structure of the array of spline coefficients. For valid hint values, see table " <a href="#">Hint Values for Spline Coefficients</a> ". The library stores the coefficients in row-major format. The default value is DF_NO_HINT.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Output Parameters

| Name          | Type | Description                                                                                                                                                                                                                                                                                |
|---------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>status</i> | int  | Status of the routine: <ul style="list-style-type: none"> <li>• DF_STATUS_OK if the routine execution completed successfully.</li> <li>• Non-zero error code if the routine execution failed. See "<a href="#">Task Status and Error Reporting</a>" for error code definitions.</li> </ul> |

## Description

The editor modifies parameters that describe the order, type, boundary conditions, internal conditions, and coefficients of a spline. The spline order definition is provided in the "[Mathematical Conventions](#)" section. You can set the spline order to any value supported by Data Fitting functions. The table below lists the available values:

### Spline Orders Supported by the Data Fitting Functions

| Order           | Description                                                                            |
|-----------------|----------------------------------------------------------------------------------------|
| DF_PP_STD       | Artificial value. Use this value for look-up and step-wise constant interpolants only. |
| DF_PP_LINEAR    | Piecewise polynomial spline of the second order (linear spline).                       |
| DF_PP_QUADRATIC | Piecewise polynomial spline of the third order (quadratic spline).                     |
| DF_PP_CUBIC     | Piecewise polynomial spline of the fourth order (cubic spline).                        |

To perform computations with a spline not supported by Data Fitting routines, set the parameter defining the spline order and pass the spline coefficients to the library in the supported format. For format description, see figure "[Row-major Coefficient Storage Format](#)".

The table below lists the supported spline types:

### Spline Types Supported by Data Fitting Functions

| Type                             | Description                                                                                     |
|----------------------------------|-------------------------------------------------------------------------------------------------|
| DF_PP_DEFAULT                    | The default spline type. You can use this type with linear, quadratic, or user-defined splines. |
| DF_PP_SUBBOTIN                   | Quadratic splines based on Subbotin algorithm, [ <a href="#">StechSub76</a> ].                  |
| DF_PP_NATURAL                    | Natural cubic spline.                                                                           |
| DF_PP_HERMITE                    | Hermite cubic spline.                                                                           |
| DF_PP_BESSEL                     | Bessel cubic spline.                                                                            |
| DF_PP_HYMAN                      | Co-monotone Hyman cubic spline, [ <a href="#">Hyman83</a> ].                                    |
| DF_PP_AKIMA                      | Akima cubic spline.                                                                             |
| DF_LOOKUP_INTERPOLANT            | Look-up interpolant.                                                                            |
| DF_CR_STEPWISE_CONST_INTERPOLANT | Continuous right step-wise constant interpolant.                                                |
| DF_CL_STEPWISE_CONST_INTERPOLANT | Continuous left step-wise constant interpolant.                                                 |

If you perform computations with look-up or step-wise constant interpolants, set the spline order to the DF\_PP\_STD value.

Construction of specific splines may require boundary or internal conditions. To compute coefficients of such splines, you should pass boundary or internal conditions to the library by specifying the type of the conditions and providing the necessary values. For splines that do not require additional conditions, such as linear splines, set condition types to DF\_NO\_BC and DF\_NO\_IC, and pass NULL pointers to the conditions. The table below defines the supported boundary conditions:

**Boundary Conditions Supported by Data Fitting Functions**

| Boundary Condition  | Description                                  | Spline                                                                       |
|---------------------|----------------------------------------------|------------------------------------------------------------------------------|
| DF_NO_BC            | No boundary conditions provided.             | All                                                                          |
| DF_BC_NOT_A_KNOT    | Not-a-knot boundary conditions.              | Akima, Bessel, co-monotone Hyman, Hermite, natural cubic                     |
| DF_BC_FREE_END      | Free-end boundary conditions.                | Akima, Bessel, co-monotone Hyman, Hermite, natural cubic, quadratic Subbotin |
| DF_BC_1ST_LEFT_DER  | The first derivative at the left endpoint.   | Akima, Bessel, co-monotone Hyman, Hermite, natural cubic, quadratic Subbotin |
| DF_BC_1ST_RIGHT_DER | The first derivative at the right endpoint.  | Akima, Bessel, co-monotone Hyman, Hermite, natural cubic, quadratic Subbotin |
| DF_BC_2ST_LEFT_DER  | The second derivative at the left endpoint.  | Akima, Bessel, co-monotone Hyman, Hermite, natural cubic, quadratic Subbotin |
| DF_BC_2ND_RIGHT_DER | The second derivative at the right endpoint. | Akima, Bessel, co-monotone Hyman, Hermite, natural cubic, quadratic Subbotin |
| DF_BC_PERIODIC      | Periodic boundary conditions.                | Linear, all cubic splines                                                    |
| DF_BC_Q_VAL         | Function value at point $(x_0 + x_1)/2$      | Default quadratic                                                            |

**NOTE**

To construct a natural cubic spline, pass these settings to the editor:

- DF\_PP\_CUBIC as the spline order,
- DF\_PP\_NATURAL as the spline type, and
- DF\_BC\_FREE\_END as the boundary condition.

To construct a cubic spline with other boundary conditions, pass these settings to the editor:

- DF\_PP\_CUBIC as the spline order,
- DF\_PP\_NATURAL as the spline type, and
- the required type of boundary condition.

For a co-monotone Hyman cubic spline, you should set the first derivatives as boundary conditions to zeros, otherwise co-monotonicity can be broken on the leftmost and rightmost sub-intervals of the interpolation interval. You can also use first or second divided difference formulas for the first derivatives as boundary conditions. If the sign of the second divided difference differs from the sign of the respective first divided difference, replace the second divided difference with the first one or set the corresponding derivative to zero as the boundary condition. If the co-monotonicity criteria ([Fritsch80]) is not met, Intel MKL can return unexpected results.

For Akima, Hermite, Bessel, co-monotone Hyman, and default cubic splines use the corresponding type defined in [Table Spline Types Supported by Data Fitting Functions](#).

You can combine the values of boundary conditions with a bitwise OR operation. This permits you to pass combinations of first and second derivatives at the endpoints of the interpolation interval into the library. To pass a first derivative at the left endpoint and a second derivative at the right endpoint, set the boundary conditions to `DF_BC_1ST_LEFT_DER OR DF_BC_2ND_RIGHT_DER`.

You should pass the combined boundary conditions as an array of two elements. The first entry of the array contains the value of the boundary condition for the left endpoint of the interpolation interval, and the second entry - for the right endpoint. Pass other boundary conditions as arrays of one element.

For the conditions defined as a combination of valid values, the library applies the following rules to identify the boundary condition type:

- If not required for spline construction, the value of boundary conditions is ignored.
- Not-a-knot condition has the highest priority. If set, other boundary conditions are ignored.
- Free-end condition has the second priority after the not-a-knot condition. If set, other boundary conditions are ignored.
- Periodic boundary condition has the next priority after the free-end condition.
- The first derivative has higher priority than the second derivative at the right and left endpoints.

If you set the periodic boundary condition, make sure that function values at the endpoints of the interpolation interval are identical. Otherwise, the library returns an error code. The table below specifies the values to be provided for each type of spline if the periodic boundary condition is set.

### Boundary Requirements for Periodic Conditions

| Spline Type             | Periodic Boundary Condition Support | Boundary Value    |
|-------------------------|-------------------------------------|-------------------|
| Linear                  | Yes                                 | Not required      |
| Default quadratic       | No                                  |                   |
| Subbotin quadratic      | No                                  |                   |
| Natural cubic           | Yes                                 | Not required      |
| Bessel                  | Yes                                 | Not required      |
| Co-monotone Hyman cubic | Yes                                 | Not required      |
| Akima                   | Yes                                 | Not required      |
| Hermite cubic           | Yes                                 | First derivative  |
| Default cubic           | Yes                                 | Second derivative |

Internal conditions supported in the Data Fitting domain that you can use for the `ic_type` parameter are the following:

### Internal Conditions Supported by Data Fitting Functions

| Internal Condition         | Description                                                                                                                                                     | Spline        |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| <code>DF_NO_IC</code>      | No internal conditions provided.                                                                                                                                |               |
| <code>DF_IC_1ST_DER</code> | Array of first derivatives of size $n-2$ , where $n$ is the number of breakpoints. Derivatives are applicable to each coordinate of the vector-valued function. | Hermite cubic |

| Internal Condition | Description                                                                                                                                                      | Spline             |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| DF_IC_2ND_DER      | Array of second derivatives of size $n-2$ , where $n$ is the number of breakpoints. Derivatives are applicable to each coordinate of the vector-valued function. | Default cubic      |
| DF_IC_Q_KNOT       | Knot array of size $n+1$ , where $n$ is the number of breakpoints.                                                                                               | Subbotin quadratic |

To construct a Subbotin quadratic spline, you have three options to get the array of knots in the library:

- If you do not provide the knots, the library uses the default values of knots  $t = \{t_i\}$ ,  $i = 0, \dots, n$  according to the rule:

$$t_0 = x_0, t_n = x_{n-1}, t_i = (x_i + x_{i-1})/2, i = 1, \dots, n - 1.$$

- If you provide the knots in an array of size  $n + 1$ , the knots form a non-uniform partition. Make sure that the knot values you provide meet the following conditions:

$$t_0 = x_0, t_n = x_{n-1}, t_i \in (x_{i-1}, x_i), i = 1, \dots, n - 1.$$

- If you provide the knots in an array of size 4, the knots form a uniform partition

$$t_0 = x_0, t_1 = l, t_2 = r, t_3 = x_{n-1}, \text{ where } l \in (x_0, x_1) \text{ and } r \in (x_{n-2}, x_{n-1}).$$

In this case, you need to set the value of the `ic_type` parameter holding the type of internal conditions to `DF_IC_Q_KNOT` OR `DF_UNIFORM_PARTITION`.

#### NOTE

Since the partition is uniform, perform an OR operation with the `DF_UNIFORM_PARTITION` partition hint value described in [Table Hint Values for Partition x](#).

For computations based on look-up and step-wise constant interpolants, you can avoid calling the `df?EditPPSpline1D` editor and directly call one of the routines for spline-based computation of spline values, derivatives, or integrals. For example, you can call the `df?Construct1D` routine to construct the required spline with the given attributes, such as order or type.

The memory location of the spline coefficients is defined by the `scoeff` parameter. Make sure that the size of the array is sufficient to hold  $ny * s\_order * (nx-1)$  values.

The `df?EditPPSpline1D` routine supports the following hint values for spline coefficients:

#### Hint Values for Spline Coefficients

| Order             | Description                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------|
| DF_1ST_COORDINATE | The first coordinate of vector-valued data is provided.                                          |
| DF_NO_HINT        | No hint is provided. By default, all sets of spline coefficients are stored in row-major format. |

The coefficients for all coordinates of the vector-valued function are packed in memory one by one in successive order, from function  $y_1$  to function  $y_{ny}$ .

Within each coordinate, the library stores the coefficients as an array, in row-major format:

$$c_{1,0}, c_{1,1}, \dots, c_{1,k}, c_{2,0}, c_{2,1}, \dots, c_{2,k}, \dots, c_{n-1,0}, c_{n-1,1}, \dots, c_{n-1,k}$$

Mapping of the coefficients to storage in the `scoeff` array is described below, where  $c_{i,j}$  is the  $j$ th coefficient of the function

$$P_i(x) = c_{i,0} + c_{i,1}(x - x_i) + \dots + c_{i,k}(x - x_i)^k$$

See [Mathematical Conventions](#) for more details on nomenclature and interpolants.

### Row-major Coefficient Storage Format

$$\begin{array}{l}
 P_1(x) = \vec{c}_{1,0} + \vec{c}_{1,1}(x - x_1) + \dots + \vec{c}_{1,k}(x - x_1)^k \\
 P_2(x) = \vec{c}_{2,0} + \vec{c}_{2,1}(x - x_2) + \dots + \vec{c}_{2,k}(x - x_2)^k \\
 \vdots \\
 P_{n-1}(x) = \vec{c}_{n-1,0} + \vec{c}_{n-1,1}(x - x_{n-1}) + \dots + \vec{c}_{n-1,k}(x - x_{n-1})^k
 \end{array}$$

If you store splines corresponding to different coordinates of the vector-valued function at non-contiguous memory locations, do the following:

1. Set the *scoeffhint* flag to `DF_1ST_COORDINATE` and provide the spline for the first coordinate.
2. Pass the spline coefficients for the remaining coordinates into the Data Fitting task using the `df?EditIdxPtr` task editor.

Using the `df?EditPPSpline1D` task editor, you can provide to the Data Fitting task an already constructed spline that you want to use in computations. To ensure correct interpretation of the memory content, you should set the following parameters:

- Spline order and type, if appropriate. If the spline is not supported by the library, set the *s\_type* parameter to `DF_PP_DEFAULT`.
- Pointer to the array of spline coefficients in row-major format.
- The *scoeffhint* parameter describing the structure of the array:
  - Set the *scoeffhint* flag to the `DF_1ST_COORDINATE` value to pass spline coefficients stored at different memory locations. In this case, you can set the parameters that describe boundary and internal conditions to zero.
  - Use the default value `DF_NO_HINT` for all other cases.

Before passing an already constructed spline into the library, you should call the `dfiEditVal` task editor to provide the dimension of the spline `DF_NY`. See table "[Parameters Supported by the dfiEditVal Task Editor](#)" for details.

After you provide the spline to the Data Fitting task, you can run computations that use this spline.

**NOTE**

You must preserve the arrays *bc* (boundary conditions), *ic* (internal conditions), and *scoeff* (spline coefficients) through the entire workflow of the Data Fitting computations for a task, as the task stores the addresses of the arrays for spline-based computations.

**df?EditPtr**

Modifies a pointer to an array held in a Data Fitting task descriptor.

---

**Syntax**

```
status = dfsEditPtr(task, ptr_attr, ptr)
```

```
status = dfdEditPtr(task, ptr_attr, ptr)
```

**Include Files**

- mkl.h

**Input Parameters**

| Name            | Type                                                        | Description                                                                                                                                |
|-----------------|-------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <i>task</i>     | DFTaskPtr                                                   | Descriptor of the task.                                                                                                                    |
| <i>ptr_attr</i> | const MKL_INT                                               | The parameter to change. For details, see the <i>Pointer Attribute</i> column in table "Pointers Supported by the df?EditPtr Task Editor". |
| <i>ptr</i>      | const float* for dfsEditPtr<br>const double* for dfdEditPtr | New pointer. For details, see the <i>Purpose</i> column in table "Pointers Supported by the df?EditPtr Task Editor".                       |

**Output Parameters**

| Name          | Type | Description                                                                                                                                                                                                                                          |
|---------------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>status</i> | int  | Status of the routine: <ul style="list-style-type: none"> <li>• DF_STATUS_OK if the routine execution completed successfully.</li> <li>• Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.</li> </ul> |

**Description**

The df?EditPtr editor replaces the pointer of type *ptr\_attr* stored in a Data Fitting task descriptor with a new pointer *ptr*. The table below describes types of pointers supported by the editor:

**Pointers Supported by the df?EditPtr Task Editor**

| Pointer Attribute | Purpose                                                                                                                                                                                                                                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DF_X              | Partition $x$ of the interpolation interval, an array of strictly sorted breakpoints. <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p><b>CAUTION</b><br/>The array must be strictly sorted. If it is unordered, the results of data fitting routines are not correct.</p> </div> |
| DF_Y              | Vector-valued function $y$                                                                                                                                                                                                                                                                                 |

| Pointer Attribute | Purpose                                                                                                                                          |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| DF_IC             | Internal conditions for spline construction. For details, see table " <a href="#">Internal Conditions Supported by Data Fitting Functions</a> ". |
| DF_BC             | Boundary conditions for spline construction. For details, see table " <a href="#">Boundary Conditions Supported by Data Fitting Functions</a> ". |
| DF_PP_SCOEFF      | Spline coefficients                                                                                                                              |

You can use `df?EditPtr` to modify different types of pointers including pointers to the vector-valued function and spline coefficients stored in contiguous memory. Use the `df?EditIdxPtr` editor if you need to modify pointers to coordinates of the vector-valued function or spline coefficients stored at non-contiguous memory locations.

If you modify a partition of the interpolation interval, then you should call the `dfiEditVal` task editor with the corresponding value of `DF_XHINT`, even if the structure of the partition remains the same.

If you pass a `NULL` pointer to the `df?EditPtr` task editor, the task remains unchanged and the routine returns an error code. For the predefined error codes, please see "[Task Status and Error Reporting](#)".

### NOTE

You must preserve the arrays  $x$  (breakpoints),  $y$  (vector-valued functions),  $bc$  (boundary conditions),  $ic$  (internal conditions), and  $scoeff$  (spline coefficients) through the entire workflow of the Data Fitting computations which use those arrays, as the task stores the addresses of the arrays for spline-based computations.

### `dfiEditVal`

Modifies a parameter value in a Data Fitting task descriptor.

### Syntax

```
status = dfiEditVal(task, val_attr, val)
```

### Include Files

- `mkl.h`

### Input Parameters

| Name                  | Type                       | Description                                                                                                |
|-----------------------|----------------------------|------------------------------------------------------------------------------------------------------------|
| <code>task</code>     | <code>DFTaskPtr</code>     | Descriptor of the task.                                                                                    |
| <code>val_attr</code> | <code>const MKL_INT</code> | The parameter to change. See table " <a href="#">Parameters Supported by the dfiEditVal Task Editor</a> ". |
| <code>val</code>      | <code>const MKL_INT</code> | A new parameter value. See table " <a href="#">Parameters Supported by the dfiEditVal Task Editor</a> ".   |

### Output Parameters

| Name                | Type             | Description            |
|---------------------|------------------|------------------------|
| <code>status</code> | <code>int</code> | Status of the routine: |

| Name | Type | Description                                                                                                                                                                                                                               |
|------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|      |      | <ul style="list-style-type: none"> <li>DF_STATUS_OK if the routine execution completed successfully.</li> <li>Non-zero error code otherwise. See <a href="#">"Task Status and Error Reporting"</a> for error code definitions.</li> </ul> |

## Description

The `dfiEditVal` task editor replaces the parameter of type `val_attr` stored in a Data Fitting task descriptor with a new value `val`. The table below describes valid types of parameter `val_attr` supported by the editor:

### Parameters Supported by the `dfiEditVal` Task Editor

| Parameter Attribute | Purpose                                                                                                                                                                        |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DF_NX               | Number of breakpoints                                                                                                                                                          |
| DF_XHINT            | A flag describing the structure of partition. See table <a href="#">"Hint Values for Partition x"</a> for the list of available values.                                        |
| DF_NY               | Dimension of the vector-valued function                                                                                                                                        |
| DF_YHINT            | A flag describing the structure of the vector-valued function. See table <a href="#">"Hint Values for Vector Function y"</a> for the list of available values.                 |
| DF_SPLINE_ORDER     | Spline order. See table <a href="#">"Spline Orders Supported by Data Fitting Functions"</a> for the list of available values.                                                  |
| DF_SPLINE_TYPE      | Spline type. See table <a href="#">"Spline Types Supported by Data Fitting Functions"</a> for the list of available values.                                                    |
| DF_BC_TYPE          | Type of boundary conditions used in spline construction. See table <a href="#">"Boundary Conditions Supported by Data Fitting Functions"</a> for the list of available values. |
| DF_IC_TYPE          | Type of internal conditions used in spline construction. See table <a href="#">"Internal Conditions Supported by Data Fitting Functions"</a> for the list of available values. |
| DF_PP_COEFF_HINT    | A flag describing the structure of spline coefficients. See table <a href="#">"Hint Values for Spline Coefficients"</a> for the list of available values.                      |
| DF_CHECK_FLAG       | A flag which controls checking of Data Fitting parameters. See table <a href="#">"Possible Values for the DF_CHECK_FLAG Parameter"</a> for the list of available values.       |

If you pass a zero value for the parameter describing the size of the arrays that hold coefficients for a partition, a vector-valued function, or a spline, the parameter held in the Data fitting task remains unchanged and the routine returns an error code. For the predefined error codes, see ["Task Status and Error Reporting"](#).

### Possible Values for the `DF_CHECK_FLAG` Parameter

| Value                | Description                                                                                 |
|----------------------|---------------------------------------------------------------------------------------------|
| DF_ENABLE_CHECK_FLAG | Checks the correctness of parameters of Data Fitting computational routines (default mode). |

| Value                 | Description                                                                                |
|-----------------------|--------------------------------------------------------------------------------------------|
| DF_DISABLE_CHECK_FLAG | Disables checking of the correctness of parameters of Data Fitting computational routines. |

Use `DF_CHECK_FLAG` for `val_attr` in order to control validation of parameters of Data Fitting computational routines such as `df?Construct1D`, `df?Interpolate1D/df?InterpolateEx1D`, and `df?SearchCells1D/df?SearchCellsEx1D`, which can perform better with a small number of interpolation sites or integration limits (fewer than one dozen). The default mode, with checking of parameters enabled, should be used as you develop a Data Fitting-based application. After you complete development you can disable parameter checking in order to improve the performance of your application.

If you modify the parameter describing dimensions of the arrays that hold the vector-valued function or spline coefficients in contiguous memory, you should call the `df?EditPtr` task editor with the corresponding pointers to the vector-valued function or spline coefficients even when this pointer remains unchanged. Call the `df?EditIdxPtr` editor if those arrays are stored in non-contiguous memory locations.

You must call the `dfiEditVal` task editor to edit the structure of the partition `DF_XHINT` every time you modify a partition using `df?EditPtr`, even if the structure of the partition remains the same.

### df?EditIdxPtr

*Modifies a pointer to the memory representing a coordinate of the data stored in matrix format.*

### Syntax

```
status = dfsEditIdxPtr(task, ptr_attr, idx, ptr)
```

```
status = dfdEditIdxPtr(task, ptr_attr, idx, ptr)
```

### Include Files

- `mkl.h`

### Input Parameters

| Name                  | Type                                                                                                                  | Description                                                                                                                                                              |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>task</code>     | <code>DFTaskPtr</code>                                                                                                | Descriptor of the task.                                                                                                                                                  |
| <code>ptr_attr</code> | <code>const MKL_INT</code>                                                                                            | Type of the data to be modified. The parameter takes one of the values described in "Data Attributes Supported by the <code>df?EditIdxPtr</code> Task Editor".           |
| <code>idx</code>      | <code>const MKL_INT</code>                                                                                            | Index of the coordinate whose pointer is to be modified.                                                                                                                 |
| <code>ptr</code>      | <code>const float*</code> for <code>dfsEditIdxPtr</code><br><code>const double*</code> for <code>dfdEditIdxPtr</code> | Pointer to the data that holds values of coordinate <code>idx</code> . For details, see table "Data Attributes Supported by the <code>df?EditIdxPtr</code> Task Editor". |

### Output Parameters

| Name                | Type             | Description            |
|---------------------|------------------|------------------------|
| <code>status</code> | <code>int</code> | Status of the routine: |

| Name | Type | Description                                                                                                                                                                                                                                                |
|------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|      |      | <ul style="list-style-type: none"> <li>• <code>DF_STATUS_OK</code> if the routine execution completed successfully.</li> <li>• Non-zero error code otherwise. See "<a href="#">Task Status and Error Reporting</a>" for error code definitions.</li> </ul> |

## Description

The routine modifies a pointer to the array that holds the `idx` coordinate of vector-valued function `y` or the pointer to the array of spline coefficients corresponding to the given coordinate.

You can use the editor if you need to pass into a Data Fitting task or modify the pointer to coordinates of the vector-valued function or spline coefficients held at non-contiguous memory locations. Do not use the editor for coordinates at contiguous memory locations in row-major format.

Before calling this editor, make sure that you have created and initialized the task using a task creation function or a relevant editor such as the generic or specific `df?EditPPSpline1D` editor.

## Data Attributes Supported by the `df?EditIdxPtr` Task Editor

| Data Attribute            | Description                              |
|---------------------------|------------------------------------------|
| <code>DF_Y</code>         | Vector-valued function <code>y</code>    |
| <code>DF_PP_SCOEFF</code> | Piecewise polynomial spline coefficients |

When using `df?EditIdxPtr`, you might receive an error code in the following cases:

- You passed an unsupported parameter value into the editor.
- The value of the index exceeds the predefined value that equals the dimension `ny` of the vector-valued function.
- You pass a `NULL` pointer to the editor. In this case, the task remains unchanged.
- You pass a pointer to the `idx` coordinate of the vector-valued function you provided to contiguous memory in column-major format.

The code example below demonstrates how to use the editor for providing values of a vector-valued function stored in two non-contiguous arrays:

```
#define NX 1000 /* number of break points */
#define NY 2 /* dimension of vector-valued function */
int main()
{
 DFTaskPtr task;
 double x[NX];
 double y1[NX], y2[NX]; /* vector-valued function is stored as two arrays */
 /* Provide first coordinate of two-dimensional function y into creation routine */
 status = dfdNewTask1D(&task, NX, x, DF_NON_UNIFORM_PARTITION, NY, y1,
 DF_1ST_COORDINATE);
 /* Provide second coordiante of two-dimensional function */
 status = dfdEditIdxPtr(task, DF_Y, 1, y2);
 ...
}
```

## `df?QueryPtr`

*Reads a pointer to an array held in a Data Fitting task descriptor.*

## Syntax

```
status = dfsQueryPtr(task, ptr_attr, ptr)
```

```
status = dfdQueryPtr(task, ptr_attr, ptr)
```

## Include Files

- mkl.h

## Input Parameters

| <i>status</i> | int                                                 | Status of the routine: <ul style="list-style-type: none"> <li>• DF_STATUS_OK if the routine execution completed successfully.</li> <li>• Non-zero error code otherwise. See "<a href="#">Task Status and Error Reporting</a>" for error code definitions.</li> </ul> |

## Description

The `df?QueryPtr` routine returns the pointer of type `ptr_attr` stored in a Data Fitting task descriptor as parameter `ptr`. Attributes of the pointers supported by the query function are identical to those supported by the editor `df?EditPtr` editor in the table "[Pointers Supported by the df?EditPtr Task Editor](#)".

You can use `df?QueryPtr` to read different types of pointers including pointers to the vector-valued function and spline coefficients stored in contiguous memory.

## `dfiQueryVal`

*Reads a parameter value in a Data Fitting task descriptor.*

---

## Syntax

```
status = dfiQueryVal(task, val_attr, val)
```

## Include Files

- mkl.h

## Input Parameters

See "Task Status and Error Reporting" for error code definitions.</li> </ul> |

## Description

The routine returns a pointer to the array that holds the `idx` coordinate of vector-valued function `y` or the pointer to the array of spline coefficients corresponding to the given coordinate.

You can use the query routine if you need the pointer to coordinates of the vector-valued function or spline coefficients held at non-contiguous memory locations or at a contiguous memory location in row-major format (the default storage format for spline coefficients).

Before calling this query routine, make sure that you have created and initialized the task using a task creation function or a relevant editor such as the generic or specific `df?EditPPSpline1D` editor.

When using `df?QueryIdxPtr`, you might receive an error code in the following cases:

- You passed an unsupported parameter value into the editor.
- The value of the index exceeds the predefined value that equals the dimension `ny` of the vector-valued function.
- You request the pointer to the `idx` coordinate of the vector-valued function you provided to contiguous memory in column-major format.

## Data Fitting Computational Routines

Data Fitting computational routines are functions used to perform spline-based computations, such as:

- spline construction
- computation of values, derivatives, and integrals of the predefined order
- cell search

Once you create a Data Fitting task and initialize the required parameters, you can call computational routines as many times as necessary.

The table below lists the available computational routines:

### Data Fitting Computational Routines

| Routine                         | Description                                                                   |
|---------------------------------|-------------------------------------------------------------------------------|
| <code>df?Construct1D</code>     | Constructs a spline for a one-dimensional Data Fitting task.                  |
| <code>df?Interpolate1D</code>   | Computes spline values and derivatives.                                       |
| <code>df?InterpolateEx1D</code> | Computes spline values and derivatives by calling user-provided interpolants. |
| <code>df?Integrate1D</code>     | Computes spline-based integrals.                                              |

| Routine                            | Description                                                                                    |
|------------------------------------|------------------------------------------------------------------------------------------------|
| <a href="#">df?IntegrateEx1D</a>   | Computes spline-based integrals by calling user-provided integrators.                          |
| <a href="#">df?SearchCells1D</a>   | Finds indices of cells containing interpolation sites.                                         |
| <a href="#">df?SearchCellsEx1D</a> | Finds indices of cells containing interpolation sites by calling user-provided cell searchers. |

If a Data Fitting computation completes successfully, the computational routines return the `DF_STATUS_OK` code. If an error occurs, the routines return an error code specifying the origin of the failure. Some possible errors are the following:

- The task pointer is `NULL`.
- Memory allocation failed.
- The computation failed for another reason.

For the list of available status codes, see "[Task Status and Error Reporting](#)".

---

#### NOTE

Data Fitting computational routines do not control errors for floating-point conditions, such as overflow, gradual underflow, or operations with Not a Number (NaN) values.

---

## [df?Construct1D](#)

---

### Syntax

Constructs a spline of the given type.

```
status = dfsConstruct1D(task, s_format, method)
```

```
status = dfdConstruct1D(task, s_format, method)
```

### Include Files

- `mkl.h`

### Input Parameters

| Name                  | Type                       | Description                                                              |

|      |      | <ul style="list-style-type: none"> <li>Non-zero error code if the routine execution failed. See <a href="#">"Task Status and Error Reporting"</a> for error code definitions.</li> </ul> |

### Description

Before calling `df?Construct1D`, you need to create and initialize the task, and set the parameters representing the spline. Then you can call the `df?Construct1D` routine to construct the spline. The format of the spline is defined by parameter `s_format`. The method for spline construction is defined by parameter `method`. Upon successful construction, the spline coefficients are available in the user-provided memory location in the format you set through the Data Fitting editor. For the available storage formats, see table ["Hint Values for Spline Coefficients"](#).

### `df?Interpolate1D/df?InterpolateEx1D`

*Runs data fitting computations.*

### Syntax

```
status = dfsInterpolate1D(task, type, method, nsite, site, sitehint, ndorder, dorder, datahint, r, rhint, cell)
```

```
status = dfdInterpolate1D(task, type, method, nsite, site, sitehint, ndorder, dorder, datahint, r, rhint, cell)
```

```
status = dfsInterpolateEx1D(task, type, method, nsite, site, sitehint, ndorder, dorder, datahint, r, rhint, cell, le_cb, le_params, re_cb, re_params, i_cb, i_params, search_cb, search_params)
```

```
status = dfdInterpolateEx1D(task, type, method, nsite, site, sitehint, ndorder, dorder, datahint, r, rhint, cell, le_cb, le_params, re_cb, re_params, i_cb, i_params, search_cb, search_params)
```

### Include Files

|-------------------|------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cell</code> |      | Array of cell indices in partition $x$ that contain the interpolation sites, which is computed if <code>type</code> is <code>DF_CELL</code> . |

## Description

The `df?Interpolate1D/df?InterpolateEx1D` routine performs spline-based computations with user-defined settings. The routine supports two types of computations for interpolation sites provided in array `site`:

### Computation Types Supported by the `df?Interpolate1D/df?InterpolateEx1D` Routines

| Type                             | Description                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>DF_INTERP</code>           | Compute derivatives of predefined order. The derivative of the zero order is the spline value.                                                                                                                                                                                                                                               |
| <code>DF_INTERP_USER_CELL</code> | <p>Compute derivatives of predefined order given user-provided cell indices. The derivative of the zero order is the spline value.</p> <p>For this type of the computations you should provide a valid <code>cell</code> array, which holds the indices of cells in the <code>site</code> array containing relevant interpolation sites.</p> |
| <code>DF_CELL</code>             | Compute indices of cells in partition $x$ that contain the sites.                                                                                                                                                                                                                                                                            |

If the indices of cells which contain interpolation types are available before the call to `df?`

`Interpolate1D/df?InterpolateEx1D`, you can improve performance by using the `DF_INTERP_USER_CELL` computation type.

#### NOTE

If you pass any combination of `DF_INTERP`, `DF_INTERP_USER_CELL`, and `DF_CELL` computation types to the routine, the library uses the `DF_INTERP_USER_CELL` computation mode.

If you specify `DF_INTERP_USER_CELL` computation mode and a user-defined callback function for computing cell indices to `df?InterpolateEx1D`, the library uses the `DF_INTERP_USER_CELL` computation mode, and the call-back function is not called.

If the sites do not belong to interpolation interval  $[a, b]$ , the library uses:

- polynomial  $P_0$  of the spline constructed on interval  $[x_0, x_1]$  for computations at the sites to the left of  $a$ .
- polynomial  $P_{n-2}$  of the spline constructed on interval  $[x_{n-2}, x_{n-1}]$  for computations at the sites to the right of  $b$ .

Interpolation sites support the following hints:

### Hint Values for Interpolation Sites

| Value                                 | Description                                                                               |
|---------------------------------------|-------------------------------------------------------------------------------------------|
| <code>DF_NON_UNIFORM_PARTITION</code> | Partition is non-uniform.                                                                 |
| <code>DF_UNIFORM_PARTITION</code>     | Partition is uniform.                                                                     |
| <code>DF_SORTED_DATA</code>           | Interpolation sites are sorted in the ascending order and define a non-uniform partition. |

| Value      | Description                                                                                                  |
|------------|--------------------------------------------------------------------------------------------------------------|
| DF_NO_HINT | No hint is provided. By default, the partition defined by interpolation sites is interpreted as non-uniform. |

**NOTE**

If you pass a sorted array of interpolation sites to the Intel MKL, set the *sitehint* parameter to the DF\_SORTED\_DATA value. The library uses this information when choosing the search algorithm and ignores any other data hints about the structure of the interpolation sites.

Data Fitting computation routines can use the following hints to speed up the computation:

- DF\_UNIFORM\_PARTITION describes the structure of breakpoints and the interpolation sites.
- DF\_QUASI\_UNIFORM\_PARTITION describes the structure of breakpoints.

Pass the above hints to the library when appropriate.

For spline-based interpolation, you should set the derivatives whose values are required for the computation. You can provide the derivatives by setting the *dorder* array of size *ndorder* as follows:

$$dorder[i] = \begin{cases} 1, & \text{if derivative of the } i\text{-th order is required} \\ 0, & \text{otherwise} \end{cases} \quad i = 0, \dots, ndorder - 1$$

Orders of derivatives  $i_d (d = 0, 1, \dots, nder - 1)$ , corresponding to non-zero derivatives to be calculated, form the array  $\{i_d\}$  of length  $nder \leq ndorder$ .

The storage format for the interpolation results is specified using the *rhint* parameter values. For each storage format, Table [Hint Values for the \*rhint\* Parameter](#) describes how to get the result  $R(j, s, i_d)$  from array *r*, for function index  $j (0 \leq j \leq yn - 1)$ , site number  $s (0 \leq s \leq nsite - 1)$ , and derivative index  $i_d (0 \leq d \leq nder - 1)$ , where *yn* is the number of functions, *nsite* is the number of sites, and *nder* is the total number of non-zero derivatives for interpolation. The array *r* can be either a one-dimensional array of size  $ny * nder * nsite$  or a three-dimensional array with the dimensions described in the table.

**Hint Values for the *rhint* Parameter**

| Value                                                              | Location of $R(j, s, i_d)$ , One-dimensional Array Storage | Location of $R(j, s, i_d)$ , Three-dimensional Array Storage    |
|--------------------------------------------------------------------|------------------------------------------------------------|-----------------------------------------------------------------|
| DF_MATRIX_STORAGE_FU<br>NCS_SITES_DERS<br>(DF_MATRIX_STORAGE_ROWS) | $r[d + nder * (s + nsite * j)]$                            | $r[j][s][d]$<br><br><i>r</i> declared as $r[ny][nsite][nder]$ . |
| DF_MATRIX_STORAGE_FU<br>NCS_DERS_SITES<br>(DF_MATRIX_STORAGE_COLS) | $r[s + nsite * (d + nder * j)]$                            | $r[j][d][s]$<br><br><i>r</i> declared as $r[ny][nder][nsite]$ . |

| ...                   | ...                   | ... | ...                           |

- Storage in  $r$  for  $rhint =$  DF\_MATRIX\_STORAGE\_SITES\_FUNCS\_DERS :

$$\begin{array}{cccc}
 R(0, 0, i_0) & R(0, 0, i_1) & \dots & R(0, 0, i_{nder-1}) \\
 R(1, 0, i_0) & R(1, 0, i_1) & \dots & R(1, 0, i_{nder-1}) \\
 \dots & \dots & \dots & \dots \\
 R(ny-1, 0, i_0) & R(ny-1, 0, i_1) & \dots & R(ny-1, 0, i_{nder-1}) \\
 \\
 R(0, 1, i_0) & R(0, 1, i_1) & \dots & R(0, 1, i_{nder-1}) \\
 R(1, 1, i_0) & R(1, 1, i_1) & \dots & R(1, 1, i_{nder-1}) \\
 \dots & \dots & \dots & \dots \\
 R(ny-1, 1, i_0) & R(ny-1, 1, i_1) & \dots & R(ny-1, 1, i_{nder-1}) \\
 \\
 \dots & \dots & \dots & \dots
 \end{array}$$

- Storage in *r* for *rhint* = DF\_MATRIX\_STORAGE\_SITES\_DERS\_FUNCS:

$$\begin{array}{cccc}
 R(0, 0, i_0) & R(1, 0, i_0) & \dots & R(ny-1, 0, i_0) \\
 R(0, 0, i_1) & R(1, 0, i_1) & \dots & R(ny-1, 0, i_1) \\
 \dots & \dots & \dots & \dots \\
 R(0, 0, i_{nder-1}) & R(1, 0, i_{nder-1}) & \dots & R(ny-1, 0, i_{nder-1}) \\
 \\
 R(0, 1, i_0) & R(1, 1, i_0) & \dots & R(ny-1, 1, i_0) \\
 R(0, 1, i_1) & R(1, 1, i_1) & \dots & R(ny-1, 1, i_1) \\
 \dots & \dots & \dots & \dots \\
 R(0, 1, i_{nder-1}) & R(1, 1, i_{nder-1}) & \dots & R(ny-1, 1, i_{nder-1}) \\
 \\
 \dots & \dots & \dots & \dots
 \end{array}$$

To speed up Data Fitting computations, use the *datahint* parameter that provides additional information about the structure of the partition and interpolation sites. This data represents a floating-point or a double array with the following structure:

**Structure of the *datahint* Array**

| Element Number | Description                    |
|----------------|--------------------------------|
| 0              | Task dimension                 |
| 1              | Type of additional information |
| 2              | Reserved field                 |

| Element Number | Description                                                         |
|----------------|---------------------------------------------------------------------|
| 3              | The total number $q$ of elements containing additional information. |
| 4              | Element (1)                                                         |
| ...            | ...                                                                 |
| $q+3$          | Element ( $q$ )                                                     |

Data Fitting computation functions support the following types of additional information for `datahint[1]`:

### Types of Additional Information

| Type                        | Element Number | Parameter                                                                   |
|-----------------------------|----------------|-----------------------------------------------------------------------------|
| DF_NO_APRIORI_INFO          | 0              | No parameters are provided. Information about the data structure is absent. |
| DF_APRIORI_MOST_LIKELY_CELL | 1              | Index of the cell that is likely to contain interpolation sites.            |

To compute indices of the cells that contain interpolation sites, provide the pointer to the array of size `nsite` for the results. The library supports the following scheme of cell indexing for the given partition  $\{x_i\}$ ,  $i=1, \dots, nx$ :

$$cell[j] = i, \text{ if } site[j] \in [x_i, x_{i+1}), i = 0, \dots, nx - 2,$$

$$cell[j] = nx - 1, \text{ if } site[j] \in [x_{nx-1}, x_{nx}],$$

$$cell[j] = nx, \text{ if } site[j] \in (x_{nx}, x_{nx+1}],$$

where

- $x_0 = -\infty$
- $x_{nx+1} = +\infty$
- $j = 0, \dots, n_{site}-1$

To perform interpolation computations with spline types unsupported in the Data Fitting component, use the extended version of the routine `df?InterpolateEx1D`. With this routine, you can provide user-defined callback functions for computations within, to the left of, or to the right of interpolation interval  $[a, b]$ . The callback functions compute indices of the cells that contain the specified interpolation sites or can serve as an approximation for computing the exact indices of such cells.

If you do not pass any function for computations at the sites outside the interval  $[a, b]$ , the routine uses the default settings.

| <i>r</i>      | float* for dfsIntegrate1D/<br>dfsIntegrateEx1D<br><br>double* for dfdIntegrate1D/<br>dfdIntegrateEx1D | Array of integration results. The size of the array should be sufficient to hold <i>nlim*ny</i> values, where <i>ny</i> is the dimension of the vector-valued function. The integration results are packed according to the settings in <i>rhint</i> .                     |

**Description**

The df?Integrate1D/df?IntegrateEx1D routine computes spline-based integral on user-defined intervals

$$I(i, j) = \int_{r_i}^{r_i} f_j(x) dx$$

where  $r_i = rlim[i]$ ,  $l_i = llim[i]$ , and  $i = 0, \dots, ny - 1$ .

If  $rlim[i] < llim[i]$ , the routine returns

$$I(i, j) = -\int_{r_i}^{l_i} f_j(x) dx$$

The routine supports the following hint values for integration results:

**Hint Values for Integration Results**

| Value                  | Description                                                                                                                      |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| DF_MATRIX_STORAGE_ROWS | Data is stored in row-major format according to C conventions.                                                                   |
| DF_MATRIX_STORAGE_COLS | Data is stored in column-major format according to Fortran conventions.                                                          |
| DF_NO_HINT             | No hint is provided. By default, the coordinates of vector-valued function <i>y</i> are provided and stored in row-major format. |

A common structure of the storage formats for the integration results is as follows:

- Row-major format

---

|                |     |                       |
|----------------|-----|-----------------------|
| $I(0, 0)$      | ... | $I(0, nlim - 1)$      |
| ...            | ... | ...                   |
| $I(ny - 1, 0)$ | ... | $I(ny - 1, nlim - 1)$ |

---

- Column-major format

---

|                  |     |                       |
|------------------|-----|-----------------------|
| $I(0, 0)$        | ... | $I(ny - 1, 0)$        |
| ...              | ... | ...                   |
| $I(0, nlim - 1)$ | ... | $I(ny - 1, nlim - 1)$ |

---

Using the *llimhint* and *rlimhint* parameters, you can provide the following hint values for integration limits:

### Hint Values for Integration Limits

---

| Value                    | Description                                                                                             |
|--------------------------|---------------------------------------------------------------------------------------------------------|
| DF_SORTED_DATA           | Integration limits are sorted in the ascending order and define a non-uniform partition.                |
| DF_NON_UNIFORM_PARTITION | Partition defined by integration limits is non-uniform.                                                 |
| DF_UNIFORM_PARTITION     | Partition defined by integration limits is uniform.                                                     |
| DF_NO_HINT               | No hint is provided. By default, partition defined by integration limits is interpreted as non-uniform. |

---

To compute integration with splines unsupported in the Data Fitting component, use the extended version of the routine `df?IntegrateEx1D`. With this routine, you can provide user-defined callback functions that compute:

- integrals within, to the left of, or to the right of the interpolation interval  $[a, b]$
- indices of cells that contain the provided integration limits or can serve as an approximation for computing the exact indices of such cells

If you do not pass callback functions, the routine uses the default settings.

## Description

The `df?SearchCells1D/df?SearchCellsEx1D` routines return array `cell` of indices of sub-intervals (cells) in the partition that contain interpolation sites available in array `site`. For details on the cell indexing scheme, see the description of the `df?Interpolate1D/df?InterpolateEx1D` computation routines.

Use the `datahint` parameter to provide additional information about the structure of the partition and/or interpolation sites. The definition of the `datahint` parameter is available in the description of the `df?Interpolate1D/df?InterpolateEx1D` computation routines.

For description of the user-defined callback for computation of cell indices, see `df?SearchCellsCallBack`.

## Description

When passed into the `df?InterpolateEx1D` routine, this function performs user-defined interpolation operation.

The `library_params` parameter allows the library to provide extra parameters. Currently no parameters are provided.

### [df?IntegrCallBack](#)

*A callback function that you can pass into `df?IntegrateEx1D` to define integration computations.*

## Syntax

```
status = dfsIntegrCallBack(n, lcell, llim, rcell, rlim, r, user_params, library_params)
```

```
status = dfdIntegrCallBack(n, lcell, llim, rcell, rlim, r, user_params, library_params)
```

## Description

When passed into the `df?IntegrateEx1D` routine, this function defines integration computations. If at least one of the integration limits is outside the interpolation interval  $[a, b]$ , the library decomposes the integration into sub-intervals that belong to the extrapolation range to the left of  $a$ , the extrapolation range to the right of  $b$ , and the interpolation interval  $[a, b]$ , as follows:

- If the left integration limit is to the left of the interpolation interval ( $llim < a$ ), the `df?IntegrateEx1D` routine passes *llim* as the left integration limit and  $\min(rlim, a)$  as the right integration limit to the user-defined callback function.

- If the right integration limit is to the right of the interpolation interval ( $rlim > b$ ), the `df?IntegrateEx1D` routine passes  $\max(llim, b)$  as the left integration limit and  $rlim$  as the right integration limit to the user-defined callback function.
- If the left and the right integration limits belong to the interpolation interval, the `df?IntegrateEx1D` routine passes them to the user-defined callback function unchanged.

The value of the integral is the sum of integral values obtained on the sub-intervals.

The `library_params` parameter allows the library to provide extra parameters. Currently no parameters are provided.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

### df?SearchCellsCallBack

A callback function for user-defined search to be passed into `df?InterpolateEx1D`, `df?IntegrateEx1D`, or `df?SearchCellsEx1D`.

### Syntax

```
status = dfsSearchCellsCallBack(n, site, cell, flag, user_params, library_params)
```

```
status = dfdSearchCellsCallBack(n, site, cell, flag, user_params, library_params)
```

### Include Files

- `mkl.h`

### Input Parameters

## Description

When passed into the `df?InterpolateEx1D`, `df?IntegrateEx1D`, or `df?SearchCellsEx1D` routine, this function performs a user-defined search.

The `library_params` parameter allows the library to provide extra parameters. The `df?InterpolateEx1D`, and `df?SearchCellsEx1D` routines do not provide extra parameters and set `library_params` to `NULL`. The `df?IntegrateEx1D` routines use this parameter to specify which type of integration limits, left or right, are provided for the callback. To do this the library declares the `dfSearchCallBackLibraryParams` structure. It currently contains one field, `limit_type_flag`, of type `int`. The field is set by the library to one of two possible values: `DF_INTEGR_SEARCH_CB_LLIM_FLAG` if the left integration limits are provided, or `DF_INTEGR_SEARCH_CB_RLIM_FLAG` if the right integration limits are provided.

## Data Fitting Task Destructors

---

Task destructors are routines used to delete task descriptors and deallocate the corresponding memory resources. The Data Fitting task destructor `dfDeleteTask` destroys a Data Fitting task and frees the memory.

### `dfDeleteTask`

*Destroys a Data Fitting task object and frees the memory.*

---

### Syntax

```
status = dfDeleteTask(&task)
```

### Include Files

- `mkl.h`

### Input Parameters

| Name              | Type                   | Description                        |
|-------------------|------------------------|------------------------------------|
| <code>task</code> | <code>DFTaskPtr</code> | Descriptor of the task to destroy. |

### Output Parameters

| Name                | Type             | Description                                                                                                                                                                                                                                                                      |
|---------------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>status</code> | <code>int</code> | Status of the routine: <ul style="list-style-type: none"><li>• <code>DF_STATUS_OK</code> if the task is deleted successfully.</li><li>• Non-zero error code if the operation failed. See "<a href="#">Task Status and Error Reporting</a>" for error code definitions.</li></ul> |

### Description

Given a pointer to a task descriptor, this routine deletes the Data Fitting task descriptor and frees the memory allocated for the structure. If the task is deleted successfully, the routine sets the task pointer to `NULL`. Otherwise, the routine returns an error code.

# Deep Neural Network Functions

Intel® Math Kernel Library (Intel® MKL) functions for Deep Neural Networks (DNN functions) is a collection of performance primitives for Deep Neural Networks (DNN) applications optimized for Intel® architecture. The implementation of DNN functions includes a set of primitives necessary to accelerate popular image recognition topologies, such as AlexNet, Visual Geometry Group (VGG), GoogleNet, and Residual Networks (ResNet).

The primitives implement forward and backward passes for the following operations:

- Convolution: direct batched convolution
- Inner product
- Pooling: maximum, minimum, and average
- Normalization: local response normalization across channels (LRN) and batch normalization
- Activation: rectified linear neuron activation (ReLU)
- Data manipulation: multi-dimensional transposition (conversion), split, concat, sum, and scale

Intel MKL DNN primitives implement a plain C application programming interface (API) that can be used in the existing C/C++ DNN frameworks, as well as in custom DNN applications.

In addition to input and output arrays of DNN applications, the DNN primitives work with special opaque data types to represent the following:

- DNN operations.

This data type specifies the operation type (for example: convolution forward propagation, convolution backward filter propagation, and so on) and parameters (for example: the filter size for convolution, alpha and beta for normalization, and so on)

- Layouts of processed data.

This data type specifies relative location of elements of processed arrays in memory.

Input and output arrays of DNN operations are called resources. Each DNN operation requires that the resources have certain data layouts. The application can query DNN operations about the required data layouts and check whether the layouts of the resources are really the required layouts.

An application that calls Intel MKL DNN functions should involve the following stages:

## 1. Setup

Given a DNN topology, the application creates all DNN operations necessary to implement scoring, training, or other application-specific computations. To pass data from one DNN operation to the next one, some applications create intermediate conversions and allocate temporary arrays if the appropriate output and input data layouts do not match.

## 2. Execution

This stage consists of calls to the DNN primitives that apply the DNN operations, including necessary conversions, to the input, output, and temporary arrays.

This chapter describes Intel MKL DNN functions, enumerated types used, as well as array layouts and attributes required to perform DNN operations.

The following table lists Intel MKL DNN functions grouped according to their purpose.

### Intel MKL DNN Functions

| Function Name          | Description |
|------------------------|-------------|
| Handling Array Layouts |             |

| Function Name                                                                 | Description                                                                                        |
|-------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| <code>dnnLayoutCreate</code>                                                  | Creates a plain layout.                                                                            |
| <code>dnnLayoutCreateFromPrimitive</code>                                     | Creates a custom layout.                                                                           |
| <code>dnnLayoutGetMemorySize</code>                                           | Returns the size of the array specified by a layout.                                               |
| <code>dnnLayoutCompare</code>                                                 | Checks whether layouts are equal.                                                                  |
| <code>dnnLayoutDelete</code>                                                  | Deletes a layout.                                                                                  |
| <b>Handling Attributes of DNN Operations</b>                                  |                                                                                                    |
| <code>dnnPrimitiveAttributesCreate</code>                                     | Creates an attribute container.                                                                    |
| <code>dnnPrimitiveAttributesDestroy</code>                                    | Destroys an attribute container.                                                                   |
| <code>dnnPrimitiveGetAttributes</code>                                        | Returns the container with attributes set for an instance of a primitive.                          |
| <b>DNN Operations</b>                                                         |                                                                                                    |
| <code>dnnConvolutionCreate,</code><br><code>dnnGroupsConvolutionCreate</code> | Creates propagation operations for convolution layers.                                             |
| <code>dnnInnerProductCreate</code>                                            | Creates propagation operations for inner product layers.                                           |
| <code>dnnReLUCreate</code>                                                    | Creates propagation operations for rectified linear neuron activation layers.                      |
| <code>dnnLRNCreate</code>                                                     | Creates propagation operations for layers performing local response normalization across channels. |
| <code>dnnPoolingCreate</code>                                                 | Creates propagation operations for pooling layers.                                                 |
| <code>dnnBatchNormalizationCreate</code>                                      | Creates propagation operations for batch normalization layers.                                     |
| <code>dnnBatchNormalizationCreate_v2</code>                                   | Creates propagation operations for batch normalization performed using the specified method.       |
| <code>dnnSplitCreate</code>                                                   | Creates split layers.                                                                              |
| <code>dnnConcatCreate</code>                                                  | Creates concatenation layers.                                                                      |
| <code>dnnSumCreate</code>                                                     | Creates sum layers.                                                                                |
| <code>dnnScaleCreate</code>                                                   | Creates scale layers.                                                                              |
| <code>dnnConversionCreate</code>                                              | Creates conversion operations.                                                                     |
| <code>dnnExecute</code>                                                       | Performs DNN operations.                                                                           |
| <code>dnnConversionExecute</code>                                             | Performs a conversion operation.                                                                   |
| <code>dnnDelete</code>                                                        | Deletes descriptions of DNN operations.                                                            |
| <code>dnnAllocateBuffer</code>                                                | Allocates an array with a given layout.                                                            |
| <code>dnnReleaseBuffer</code>                                                 | Releases an array allocated by <code>dnnAllocateBuffer</code> .                                    |

## Enumerated Types

Intel MKL DNN functions use the following enumerated types:

- `dnnError_t`

- `dnnResourceType_t`
- `dnnAlgorithm_t`
- `dnnBorder_t`
- `dnnBatchNormalizationFlag_t`

### `dnnError_t`

Each DNN function returns a value of type `dnnError_t` that indicates completion status of the function.

| Value                                    | Meaning                                                  |
|------------------------------------------|----------------------------------------------------------|
| <code>E_SUCCESS</code>                   | The operation completed successfully.                    |
| <code>E_INCORRECT_INPUT_PARAMETER</code> | The value of one of input parameters is incorrect.       |
| <code>E_MEMORY_ERROR</code>              | Allocation of some memory failed.                        |
| <code>E_UNSUPPORTED_DIMENSION</code>     | The dimension of input or output array is not supported. |
| <code>E_UNIMPLEMENTED</code>             | The operation is not implemented.                        |

### `dnnResourceType_t`

At the execution stage, DNN operations receive a `resources` array, which contains pointers to the operation resources. The value of type `dnnResourceType_t` specifies the index of the pointer to a specific resource in this array:

| Value                                                                    | Resource pointed by<br><code>resources (Value)</code>                                      |
|--------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| <code>dnnResourceSrc, dnnResourceFrom</code>                             | Input data.                                                                                |
| <code>dnnResourceDst, dnnResourceTo</code>                               | Output data.                                                                               |
| <code>dnnResourceFilter</code>                                           | Filter data.                                                                               |
| <code>dnnResourceScaleShift</code>                                       | Scale and shift data.                                                                      |
| <code>dnnResourceBias</code>                                             | Bias data.                                                                                 |
| <code>dnnResourceDiffSrc</code>                                          | Gradient with respect to input data.                                                       |
| <code>dnnResourceDiffFilter</code>                                       | Gradient with respect to filter data.                                                      |
| <code>dnnResourceScaleShift</code>                                       | Gradient with respect to scale and shift.                                                  |
| <code>dnnResourceDiffBias</code>                                         | Gradient with respect to bias data.                                                        |
| <code>dnnResourceDiffDst</code>                                          | Gradient with respect to output data.                                                      |
| <code>dnnResourceWorkspace</code>                                        | Workspace.                                                                                 |
| <code>dnnResourceMultipleSrc, ... ,<br/>dnnResourceMultipleSrc+ k</code> | For multiple input data, elements of the input, from first to last, where $k \in [0, 8]$ . |
| <code>dnnResourceMultipleDst, ... ,<br/>dnnResourceMultipleDst+ k</code> | For multiple output data, elements of the output, from first to last.                      |
| <code>dnnResourceNumber</code>                                           | The number of elements in the <code>resources</code> array.                                |

## `dnnAlgorithm_t`

At the setup stage, the value of type `dnnAlgorithm_t` species the implementation of convolution and pooling:

| Value                                      | Meaning             |
|--------------------------------------------|---------------------|
| <code>dnnAlgorithmConvolutionDirect</code> | Direct convolution. |
| <code>dnnAlgorithmPoolingMax</code>        | Maximum pooling.    |
| <code>dnnAlgorithmPoolingMin</code>        | Minimum pooling.    |
| <code>dnnAlgorithmPoolingAvg</code>        | Average pooling.    |

## `dnnBorder_t`

At the setup stage, the value of type `dnnBorder_t` specifies the method to pad the input array if padding is necessary:

| Value                               | Meaning                              |
|-------------------------------------|--------------------------------------|
| <code>dnnBorderZeros</code>         | Pad with zeros.                      |
| <code>dnnBorderZerosAsymm</code>    | Asymmetrically pad with zeros.       |
| <code>dnnBorderExtrapolation</code> | Extrapolate based on the input data. |

## `dnnBatchNormalizationFlag_t`

At the setup stage, the value of type `dnnBatchNormalizationFlag_t` specifies the method to perform batch normalization:

| Value                                | Meaning                                                                                                                                                                                                           |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dnnUseInputMeanVariance</code> | If this value is set, use externally calculated mean and variance as input for the forward propagation step. Otherwise, for backward propagation, use mean and variance output from the forward propagation step. |
| <code>dnnUseScaleShift</code>        | Use learnable <i>gamma</i> and <i>beta</i> parameters.                                                                                                                                                            |

## Handling Array Layouts

The type `dnnLayout_t` is a pointer to an opaque structure that describes layouts of arrays in the memory. DNN functions distinguish the following kinds of layouts:

- Plain.  
Different DNN operations can use plain layouts for their resources.
- Custom.  
Specific DNN operations require custom layouts for some of their resources.

To create a plain layout, in your application call a `dnnLayoutCreate_<Data Type>` function and pass to it the dimension, sizes, and strides of the array.

To create a custom layout for a resource of a DNN operation, call a `dnnLayoutCreateFromPrimitive_<Data Type>` function and pass to it the description of the operation and index of the resource.

To destroy a layout, call a `dnnLayoutDelete_<Data Type>` function.

## dnnLayoutCreate

*Creates a plain layout.*

---

### Syntax

```
dnnError_t dnnLayoutCreate_F32(dnnLayout_t *pLayout, size_t dimension, const size_t size[], const size_t strides[]);
```

```
dnnError_t dnnLayoutCreate_F64(dnnLayout_t *pLayout, size_t dimension, const size_t size[], const size_t strides[]);
```

### Include Files

- `mkl.h`

### Input Parameters

|                  |                                                                                            |
|------------------|--------------------------------------------------------------------------------------------|
| <i>dimension</i> | The number of dimensions of the array.                                                     |
| <i>size</i>      | The size along each dimension of the array.                                                |
| <i>strides</i>   | The distance (in elements) between consecutive elements along each dimension of the array. |

### Output Parameters

|                |                                       |
|----------------|---------------------------------------|
| <i>pLayout</i> | Pointer to the to the created layout. |
|----------------|---------------------------------------|

### Description

Each `dnnLayoutCreate` function creates a plain layout. The elements of an array that have the layout `*pLayout` are located at offsets  $(X, strides)$  from the beginning of the array where  $(. , .)$  denotes the scalar product of two vectors and the vector  $X$  is such that  $0 \leq X[i] < size[i]$  for  $i$  from 0 to  $dimension-1$ .

## dnnLayoutCreateFromPrimitive

*Creates a custom layout.*

---

### Syntax

```
dnnError_t dnnLayoutCreateFromPrimitive_F32(dnnLayout_t *pLayout, const dnnPrimitive_t primitive, dnnResourceType_t type);
```

```
dnnError_t dnnLayoutCreateFromPrimitive_F64(dnnLayout_t *pLayout, const dnnPrimitive_t primitive, dnnResourceType_t type);
```

### Include Files

- `mkl.h`

### Input Parameters

|                  |                                                 |
|------------------|-------------------------------------------------|
| <i>primitive</i> | The primitive to query for the required layout. |
| <i>type</i>      | The resource with the required layout queried.  |

## Output Parameters

*pLayout* Pointer to the layout to create.

## Description

Each `dnnLayoutCreateFromPrimitive` function creates a layout that a DNN operation requires for its resource.

## `dnnLayoutGetMemorySize`

Returns the size of the array specified by a layout.

## Syntax

```
size_t dnnLayoutGetMemorySize_F32(const dnnLayout_t Layout);
size_t dnnLayoutGetMemorySize_F64(const dnnLayout_t Layout);
```

## Include Files

- `mkl.h`

## Input Parameters

*Layout* The layout for which to compute the size.

## Output Parameters

None.

## Description

Each `dnnLayoutGetMemorySize` function returns the memory size in bytes sufficient to hold an array of a given layout.

## `dnnLayoutCompare`

Checks whether layouts are equal.

## Syntax

```
int dnnLayoutCompare_F32(const dnnLayout_t L1, const dnnLayout_t L2);
int dnnLayoutCompare_F64(const dnnLayout_t L1, const dnnLayout_t L2);
```

## Include Files

- `mkl.h`

## Input Parameters

*L1* The first layout.

*L2* The second layout.

## Output Parameters

None.

To perform a DNN operation, in your application call available Intel MKL DNN functions to do the following:

1. Create a description of a DNN operation
2. Perform the DNN operation
3. Destroy the description of the operation

To create a description of a DNN operation, call a function:

- `dnnConversionCreate_<Data Type>` for conversions
- `dnn<Operation>Create<Direction>[<Resource Name>]_<Data Type>` for other operations

Here

`<Operation>` is Convolution, Pooling, Normalization, or ReLU,

`<Direction>` is Forward or Backward,

`<Resource Name>`, optional, is Bias, Data, Filter, or an empty string,

`<Data Type>` is F32 or F64.

To perform a DNN operation, call a `dnnExecute_<Data Type>` function and pass to it the description of the operation and an array of pointers to operation resources.

Because the `dnnConversionExecute_<Data Type>` function has a simpler interface than `dnnExecute_<Data Type>`, if a DNN operation is a conversion, you can alternatively call the `dnnExecute_<Data Type>` function and pass to it the description of the conversion and pointers to input and output arrays.

To destroy a description of a DNN operation, call a `dnnDelete_<Data Type>` function.

## Notational Conventions

Descriptions of functions that create DNN operations use the following notational conventions:

|         |                                                                                                                               |
|---------|-------------------------------------------------------------------------------------------------------------------------------|
| $x, dx$ | denote <i>dimension</i> -2 spatial indices, where <i>dimension</i> specifies the number of dimensions in the input and output |
| $ic$    | denotes the index of an input channel                                                                                         |
| $oc$    | denotes the index of an output channel                                                                                        |
| $bc$    | denotes the index of an element in a batch                                                                                    |

## dnnConvolutionCreate, dnnGroupsConvolutionCreate

Creates propagation operations for convolution layers.

### Syntax

```
dnnError_t dnnConvolutionCreateForward_F32 (dnnPrimitive_t *pConvolution,

|                           |                                                                                                                                                                                                                                                                      |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>algorithm</i>          | The algorithm to be used by the created propagation operation.                                                                                                                                                                                                       |
| <i>attributes</i>         | The set of attributes for the primitive.                                                                                                                                                                                                                             |
| <i>groups</i>             | The number of groups in the input and output.                                                                                                                                                                                                                        |
| <i>dimension</i>          | The number of dimensions of the input and output.                                                                                                                                                                                                                    |
| <i>srcSize</i>            | <i>srcSize</i> [ <i>i</i> ] is the size of the input along the dimension <i>i</i> .                                                                                                                                                                                  |
| <i>dstSize</i>            | <i>dstSize</i> [ <i>i</i> ] is the size of the output along the dimension <i>i</i> .                                                                                                                                                                                 |
| <i>filterSize</i>         | <i>filterSize</i> [ <i>i</i> ] is the size of the filter along the dimension <i>i</i> .                                                                                                                                                                              |
| <i>convolutionStrides</i> | Spatial intervals where to apply the filters to the input.                                                                                                                                                                                                           |
| <i>inputOffset</i>        | An array of size: <ul style="list-style-type: none"> <li>• <i>dimension</i> - 2 if <i>borderType</i> equals <code>dnnBorderZeros</code></li> <li>• <math>2 * (\textit{dimension} - 2)</math> if <i>borderType</i> equals <code>dnnBorderZerosAsymm</code></li> </ul> |

Describes the offset for the spatial domain. Values of *inputOffset* must be non-positive and specify the spatial offset to add to the indices when applying the filter to the input:

- If *borderType* equals `dnnBorderZeros`, *inputOffset*[*i*] specifies equal left and right offsets.
- If *borderType* equals `dnnBorderZerosAsymm`, *inputOffset*[*i*] specifies the left (top) offset, while *inputOffset*[*dimension - 2 + i*] specifies the right (bottom) offset.

*borderType* The method to pad the input when a summation runs out of the input array.

## Output Parameters

|                                                       |                                              |
|-------------------------------------------------------|----------------------------------------------|
| <i>pConvolution</i>                                   | Pointer to the primitive to create:          |
| <code>dnnConvolutionCreateForward</code>              | Forward without bias                         |

| <code>dnnConvolutionCreateBackwardData</code>         | Backward with respect to data                |
| <code>dnnConvolutionCreateBackwardFilter</code>       | Backward with respect to filter              |
| <code>dnnConvolutionCreateBackwardBias</code>         | Backward with respect to bias                |
| <code>dnnGroupsConvolutionCreateForward</code>        | Forward without bias, with groups            |
| <code>dnnGroupsConvolutionCreateForwardBias</code>    | Forward with bias, with groups               |
| <code>dnnGroupsConvolutionCreateBackwardData</code>   | Backward with respect to data, with groups   |
| <code>dnnGroupsConvolutionCreateBackwardFilter</code> | Backward with respect to filter, with groups |
| <code>dnnGroupsConvolutionCreateBackwardBias</code>   | Backward with respect to bias, with groups   |

## Description

The `dnnConvolutionCreate` and `dnnGroupsConvolutionCreate` functions create forward and backward propagation operations for batch convolutions.

Dimensions from 0 to *dimension-3* are spatial dimensions.

The dimension *dimension-2* is interpreted as input and output channels.

The dimension *dimension-1* is interpreted as elements of the batch.

Let the input and output arrays have plain layout. The channels are divided into *groups* groups. Assuming *g* is the index of some group from 0 to *groups-1*, the output element *dst*[*x*][*oc*][*b*] is computed as follows:

$$dst[x][oc][b] = \text{sum}(dx, ic; src[x.convolutionStrides+dx+inputOffset][ic][b] * filter[dx][ic][oc][g]) + bias[oc][g],$$

where the summation is restricted to the input channels in the group *g* and '.' denotes the element-wise product of two arrays.

If the number of groups is 1, call `dnnConvolutionCreate`, otherwise, call `dnnGroupsConvolutionCreate`.

Formulas to calculate the sizes of the output spatial domain depend on the value of `borderType` as illustrated for the width:

- If `borderType` equals `dnnBorderZeros`,

$$OW = \text{floor}\left(\frac{IW - KW - 2 \cdot \text{inputOffset}[0]}{S}\right) + 1$$

- If `borderType` equals `dnnBorderZerosAsymm`,

$$OW = \text{floor}\left(\frac{IW - KW - \text{inputOffset}[0] - \text{inputOffset}[\text{dimension} - 2]}{S}\right) + 1$$

In these formulas:

`OW` is the output width (`dstSize[0]`)

`IW` is the input width (`srcSize[0]`)

`KW` is the filter size for width (`filterSize[0]`)

`S` is the convolution stride for width (`convolutionStrides[0]`)

## dnnInnerProductCreate

*Creates propagation operations for inner product layers.*

### Syntax

```
dnnError_t dnnInnerProductCreateForward_F32 (dnnPrimitive_t *pInnerProduct,
dnnPrimitiveAttributes_t attributes, size_t dimentions, const size_t srcSize[], size_t
outputChannels);
```

```
dnnError_t dnnInnerProductCreateForwardBias_F32 (dnnPrimitive_t *pInnerProduct,
dnnPrimitiveAttributes_t attributes, size_t dimentions, const size_t srcSize[], size_t
outputChannels);
```

```
dnnError_t dnnInnerProductCreateBackwardData_F32 (dnnPrimitive_t *pInnerProduct,
dnnPrimitiveAttributes_t attributes, size_t dimentions, const size_t srcSize[], size_t
outputChannels);
```

```
dnnError_t dnnInnerProductCreateBackwardFilter_F32 (dnnPrimitive_t *pInnerProduct,
dnnPrimitiveAttributes_t attributes, size_t dimentions, const size_t srcSize[], size_t
outputChannels);
```

```
dnnError_t dnnInnerProductCreateBackwardBias_F32 (dnnPrimitive_t *pInnerProduct,
dnnPrimitiveAttributes_t attributes, size_t dimentions, const size_t dstSize[]);
```

```
dnnError_t dnnInnerProductCreateForward_F64 (dnnPrimitive_t *pInnerProduct,
dnnPrimitiveAttributes_t attributes, size_t dimentions, const size_t srcSize[], size_t
outputChannels);
```

```
dnnError_t dnnInnerProductCreateForwardBias_F64 (dnnPrimitive_t *pInnerProduct,
dnnPrimitiveAttributes_t attributes, size_t dimentions, const size_t srcSize[], size_t
outputChannels);
```

```
dnnError_t dnnInnerProductCreateBackwardData_F64 (dnnPrimitive_t *pInnerProduct,
dnnPrimitiveAttributes_t attributes, size_t dimentions, const size_t srcSize[], size_t
outputChannels);
```

```
dnnError_t dnnInnerProductCreateBackwardFilter_F64 (dnnPrimitive_t *pInnerProduct,
dnnPrimitiveAttributes_t attributes, size_t dimentions, const size_t srcSize[], size_t

| <i>pInnerProduct</i>                                 | Pointer to the primitive to create: |
| <code>dnnInnerProductCreateForward</code>            | Forward without bias                |
| <code>dnnInnerProductCreateForwardBias</code>        | Forward with bias                   |
| <code>dnnInnerProductCreateBackwardData</code>       | Backward with respect to data       |
| <code>dnnInnerProductCreateBackward</code><br>Filter | Backward with respect to filter     |
| <code>dnnInnerProductCreateBackwardBias</code>       | Backward with respect to bias       |

## Description

Each `dnnInnerProductCreate` function creates a forward or backward propagation operation for the inner product. The inner product operation is defined as:

$$IC = \prod_{i=0}^{dimension-2} srcSize[i],$$

$$dst[n][oc] = \sum_{ic=0}^{IC-1} src[n][ic] * filter[oc][ic] + bias[oc].$$

## dnnReLUCreate

Creates propagation operations for rectified linear neuron activation layers.

---

## Syntax

```
dnnError_t dnnReLUCreateForward_F32 (dnnPrimitive_t *pRelu, dnnPrimitiveAttributes_t
attributes, const dnnLayout_t dataLayout, float negativeSlope);

dnnError_t dnnReLUCreateBackward_F32 (dnnPrimitive_t *pRelu, dnnPrimitiveAttributes_t
attributes, const dnnLayout_t diffLayout, const dnnLayout_t dataLayout, float
negativeSlope);

dnnError_t dnnReLUCreateForward_F64 (dnnPrimitive_t *pRelu, dnnPrimitiveAttributes_t
attributes, const dnnLayout_t dataLayout, double negativeSlope);

dnnError_t dnnReLUCreateBackward_F64 (dnnPrimitive_t *pRelu, dnnPrimitiveAttributes_t
attributes, const dnnLayout_t diffLayout, const dnnLayout_t dataLayout, double
negativeSlope);
```

## Include Files

- mkl.h

## Input Parameters

|                      |                                          |
|----------------------|------------------------------------------|
| <i>attributes</i>    | The set of attributes for the primitive. |
| <i>dataLayout</i>    | The layout of the input.                 |
| <i>diffLayout</i>    | The layout of the destination diff.      |
| <i>negativeSlope</i> | The negative slope.                      |

## Output Parameters

|              |                                     |          |
|--------------|-------------------------------------|----------|
| <i>pRelu</i> | Pointer to the primitive to create: |          |
|              | dnnReLUCreateForward                | Forward  |
|              | dnnReLUCreateBackward               | Backward |

## Description

Each `dnnReLUCreate` function creates a forward or backward propagation operation for batch rectified linear neuron activation (ReLU). The ReLU operation is defined as:

$$dst[x] = \max(src[x], 0) + negativeSlope * \min(src[x], 0).$$

## dnnLRNCreate

*Creates propagation operations for layers performing local response normalization across channels.*

## Syntax

```
dnnError_t dnnLRNCreateForward_F32 (dnnPrimitive_t *pLrn, dnnPrimitiveAttributes_t
attributes, const dnnLayout_t dataLayout, size_t kernelSize, float alpha, float beta,
float k);

dnnError_t dnnLRNCreateBackward_F32 (dnnPrimitive_t *pLrn, dnnPrimitiveAttributes_t
attributes, const dnnLayout_t diffLayout, const dnnLayout_t dataLayout, size_t
kernelSize, float alpha, float beta, float k);
```

```
dnnError_t dnnLRNCreateForward_F64 (dnnPrimitive_t *pLrn, dnnPrimitiveAttributes_t
attributes, const dnnLayout_t dataLayout, size_t kernelSize, double alpha, double
beta, double k);
```

```
dnnError_t dnnLRNCreateBackward_F64 (dnnPrimitive_t *pLrn, dnnPrimitiveAttributes_t
attributes, const dnnLayout_t diffLayout, const dnnLayout_t dataLayout, size_t
kernelSize, double alpha, double beta, double k);
```

|-------------------|---------------------------------------------|
| <i>attributes</i> | The set of attributes for the primitive.    |
| <i>dataLayout</i> | The layout of the input.                    |
| <i>diffLayout</i> | The layout of the destination diff.         |
| <i>kernelSize</i> | The number of channels to normalize across. |
| <i>alpha</i>      | The $\alpha$ parameter.                     |
| <i>beta</i>       | The $\beta$ parameter.                      |
| <i>k</i>          | The $k$ parameter.                          |

## Output Parameters

|                      |                                     |
|----------------------|-------------------------------------|
| <i>pLrn</i>          | Pointer to the primitive to create: |
| dnnLRNCreateForward  | Forward                             |
| dnnLRNCreateBackward | Backward                            |

## Description

Each `dnnLRNCreate` function creates a forward or backward propagation operation for local response normalization (LRN) across channels. The LRN operation is defined as:

$$dst[x][oc][b] = \left( k + \frac{\alpha}{kernelSize} \sum_{dc = -kernelSize/2}^{kernelSize/2} (src[x][oc + dc][b])^2 \right)^{-\beta} src[x][oc][b]$$

## dnnPoolingCreate

Creates propagation operations for pooling layers.

### Syntax

```
dnnError_t dnnPoolingCreateForward_F32 (dnnPrimitive_t *pPooling,
dnnPrimitiveAttributes_t attributes, dnnAlgorithm_t op, const dnnLayout_t srcLayout,
const size_t kernelSize[], const size_t kernelStride[], const int inputOffset[], const
dnnBorder_t borderType);
```

```
dnnError_t dnnPoolingCreateBackward_F32 (dnnPrimitive_t *pPooling,
dnnPrimitiveAttributes_t attributes, dnnAlgorithm_t op, const dnnLayout_t srcLayout,
const size_t kernelSize[], const size_t kernelStride[], const int inputOffset[], const
dnnBorder_t borderType);
```

```
dnnError_t dnnPoolingCreateForward_F64 (dnnPrimitive_t *pPooling,
dnnPrimitiveAttributes_t attributes, dnnAlgorithm_t op, const dnnLayout_t srcLayout,
const size_t kernelSize[], const size_t kernelStride[], const int inputOffset[], const
dnnBorder_t borderType);
```

```
dnnError_t dnnPoolingCreateBackward_F64 (dnnPrimitive_t *pPooling,
dnnPrimitiveAttributes_t attributes, dnnAlgorithm_t op, const dnnLayout_t srcLayout,
const size_t kernelSize[], const size_t kernelStride[], const int inputOffset[], const
dnnBorder_t borderType);
```

## Input Parameters

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>op</i>           | The operation used by pooling: min, max, or average.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>attributes</i>   | The set of attributes for the primitive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>srcLayout</i>    | The layout of the input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>kernelSize</i>   | <i>kernelSize[i]</i> is the size of the filter along the dimension <i>i</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>kernelStride</i> | Spatial intervals by which to shift the pooling region.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>inputOffset</i>  | An array of size: <ul style="list-style-type: none"> <li>• <i>dimension - 2</i> if <i>borderType</i> equals <code>dnnBorderZeros</code></li> <li>• <math>2 * (\textit{dimension} - 2)</math> if <i>borderType</i> equals <code>dnnBorderZerosAsymm</code></li> </ul> Describes the offset for the spatial domain. Values of <i>inputOffset</i> must be non-positive and specify the spatial offset to add to the indices when applying the filter to the input: <ul style="list-style-type: none"> <li>• If <i>borderType</i> equals <code>dnnBorderZeros</code>, <i>inputOffset[i]</i> specifies equal left and right offsets.</li> <li>• If <i>borderType</i> equals <code>dnnBorderZerosAsymm</code>, <i>inputOffset[i]</i> specifies the left (top) offset, while <i>inputOffset[dimension - 2 + i]</i> specifies the right (bottom) offset.</li> </ul> |
| <i>borderType</i>   | The method to pad the input when pooling runs out of the input array.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Output Parameters

|                                       |                                     |
|---------------------------------------|-------------------------------------|
| <i>pPooling</i>                       | Pointer to the primitive to create: |
| <code>dnnPoolingCreateForward</code>  | Forward                             |
| <code>dnnPoolingCreateBackward</code> | Backward                            |

## Description

Each `dnnPoolingCreate` function creates a forward or backward propagation operation for pooling layers. A pooling operation is defined as:

$$op(\{src[x \cdot kernelStride + dx + inputOffset][oc][b] \mid 0 < = dx[I] < kernelSize[i]\}).$$

Formulas to calculate the sizes of the output spatial domain depend on the value of *borderType* as illustrated for the width:

- If *borderType* equals `dnnBorderZeros`,

$$OW = \text{ceil}\left(\frac{IW - KW - 2 \cdot \text{inputOffset}[0]}{S}\right) + 1$$

- If *borderType* equals `dnnBorderZerosAsymm`,

$$OW = \text{floor}\left(\frac{IW - KW - \text{inputOffset}[0] - \text{inputOffset}[\text{dimension} - 2]}{S}\right) + 1$$

In these formulas:

*OW* is the output width

*IW* is the input width

*KW* is the kernel width (`kernelSize[0]`)

*S* is the kernel stride for width (`kernelStride[0]`)

## dnnBatchNormalizationCreate

*Creates propagation operations for batch normalization layers.*

---

### Syntax

```
dnnError_t dnnBatchNormalizationCreateForward_F32 (dnnPrimitive_t *pBatchNormalization,
dnnPrimitiveAttributes_t attributes, const dnnLayout_t dataLayout, float eps);
```

```
dnnError_t dnnBatchNormalizationCreateBackwardScaleShift_F32 (dnnPrimitive_t
*pBatchNormalization, dnnPrimitiveAttributes_t attributes, const dnnLayout_t
dataLayout, float eps);
```

```
dnnError_t dnnBatchNormalizationCreateBackwardData_F32 (dnnPrimitive_t
*pBatchNormalization, dnnPrimitiveAttributes_t attributes, const dnnLayout_t
dataLayout, float eps);
```

```
dnnError_t dnnBatchNormalizationCreateForward_F64 (dnnPrimitive_t *pBatchNormalization,
dnnPrimitiveAttributes_t attributes, const dnnLayout_t dataLayout, double eps);
```

```
dnnError_t dnnBatchNormalizationCreateBackwardScaleShift_F64 (dnnPrimitive_t
*pBatchNormalization, dnnPrimitiveAttributes_t attributes, const dnnLayout_t
dataLayout, double eps);
```

```
dnnError_t dnnBatchNormalizationCreateBackwardData_F64 (dnnPrimitive_t
*pBatchNormalization, dnnPrimitiveAttributes_t attributes, const dnnLayout_t
dataLayout, double eps);
```

### Input Parameters

|                   |                                          |
|-------------------|------------------------------------------|
| <i>dataLayout</i> | The layout of the input.                 |
| <i>attributes</i> | The set of attributes for the primitive. |
| <i>eps</i>        | The <i>eps</i> parameter.                |

## Output Parameters

*pBatchNormalization*

Pointer to the primitive to create:

|                                                   |                                             |
|---------------------------------------------------|---------------------------------------------|
| dnnBatchNormalization<br>CreateForward            | Forward                                     |
| dnnBatchNormalization<br>CreateBackwardData       | Backward with respect to data               |
| dnnBatchNormalization<br>CreateBackwardScaleShift | Backward with respect to scale<br>and shift |

## Description

Each `dnnBatchNormalizationCreate` function creates a forward or backward propagation operation for the batch normalization. Batch normalization is defined as:

$$dst[w][h][k][n] = \gamma[k] \frac{src[w][h][k][n] - M[k]}{\sqrt{S[k] + eps}} + \beta[k],$$

where

$w \in [1, W]$ ,  $h \in [1, H]$ ,  $n \in [1, N]$ ,  $k \in [1, K]$ ,

$\gamma[k]$  is the weight and  $\beta[k]$  is the bias of  $k$ ,

$$M[k] = \frac{1}{WHN} \sum_{whn} src[w][h][k][n],$$

$$S[k] = \frac{1}{WHN} \sum_{whn} (src[w][h][k][n] - M[k])^2,$$

and  $eps$  is the constant to improve numerical stability.

This primitive does the same as the `dnnBatchNormalizationCreate_v2` primitive called with the `dnnUseScaleShift` value of `flags` except that `dnnBatchNormalizationCreate` saves the mean and variance in the workspace buffer instead of output buffers.

## dnnBatchNormalizationCreate\_v2

*Creates propagation operations for batch normalization performed using the specified method.*

### Syntax

```
dnnError_t dnnBatchNormalizationCreate_Forward_v2_F32 (dnnPrimitive_t
*pBatchNormalization, dnnPrimitiveAttributes_t attributes, const dnnLayout_t
dataLayout, float eps, unsigned int flags);
```

```
dnnError_t dnnBatchNormalizationCreate_Backward_v2_F32 (dnnPrimitive_t
*pBatchNormalization, dnnPrimitiveAttributes_t attributes, const dnnLayout_t
dataLayout, float eps, unsigned int flags);
```

```
dnnError_t dnnBatchNormalizationCreate_Forward_v2_F64 (dnnPrimitive_t
*pBatchNormalization, dnnPrimitiveAttributes_t attributes, const dnnLayout_t
dataLayout, double eps, unsigned int flags);
```

```
dnnError_t dnnBatchNormalizationCreate_Backward_v2_F64 (dnnPrimitive_t
*pBatchNormalization, dnnPrimitiveAttributes_t attributes, const dnnLayout_t
dataLayout, double eps, unsigned int flags);
```

## Include Files

- `mkl.h`

## Input Parameters

|                         |                                                                      |
|-------------------------|----------------------------------------------------------------------|
| <code>dataLayout</code> | The layout of the input.                                             |
| <code>attributes</code> | The set of attributes for the primitive.                             |
| <code>eps</code>        | The <code>eps</code> parameter.                                      |
| <code>flags</code>      | The set of flags to define the computation method for the primitive. |

## Output Parameters

|                                  |                                     |          |
|----------------------------------|-------------------------------------|----------|
| <code>pBatchNormalization</code> | Pointer to the primitive to create: |          |
|                                  | <code>dnnBatchNormalization</code>  | Forward  |
|                                  | <code>CreateForward</code>          |          |
|                                  | <code>dnnBatchNormalization</code>  | Backward |
|                                  | <code>CreateBackward</code>         |          |

## Description

Each `dnnBatchNormalizationCreate_v2` function creates a forward or backward propagation operation for batch normalization to be performed using the computation method specified by `flags`.

Batch normalization is defined as:

$$dst[w][h][k][n] = \gamma[k] \frac{src[w][h][k][n] - M[k]}{\sqrt{S[k] + eps}} + \beta[k],$$

where

$$w \in [1, W], h \in [1, H], n \in [1, N], k \in [1, K],$$

$\gamma[k]$  is the weight and  $\beta[k]$  is the bias of  $k$ ,

$$M[k] = \frac{1}{WHN} \sum_{whn} src[w][h][k][n],$$

$$S[k] = \frac{1}{WHN} \sum_{whn} (src[w][h][k][n] - M[k])^2,$$

and `eps` is the constant to improve numerical stability.

`dnnBatchNormalizationCreate_v2` called with the `dnnUseScaleShift` value of `flags` does the same as `dnnBatchNormalizationCreate` except that `dnnBatchNormalizationCreate_v2` saves the mean and variance in separate output buffers instead of the workspace buffer.

## dnnSplitCreate

*Creates split layers.*

### Syntax

```
dnnError_t dnnSplitCreate_F32 (dnnPrimitive_t *pSplit, dnnPrimitiveAttributes_t
attributes, const size_t nDstTensors, dnnLayout_t dataLayout, size_t dstChannelSize[]);

dnnError_t dnnSplitCreate_F64 (dnnPrimitive_t *pSplit, dnnPrimitiveAttributes_t
attributes, const size_t nDstTensors, dnnLayout_t dataLayout, size_t dstChannelSize[]);
```

## Include Files

- `mkl.h`

## Input Parameters

|                             |                                                                                         |
|-----------------------------|-----------------------------------------------------------------------------------------|
| <code>attributes</code>     | The set of attributes for the primitive.                                                |
| <code>nDstTensors</code>    | The number of output tensors.                                                           |
| <code>dataLayout</code>     | The layout of the input tensor.                                                         |
| <code>dstChannelSize</code> | <code>dstChannelSize[i]</code> is the number of channels for the $i$ -th output tensor. |

## Output Parameters

`pSplit` Pointer to the primitive to create.

## Description

Each `dnnSplitCreate` function creates a split primitive. The split of a tensor into  $M$  tensors with  $C_0, C_1, \dots, C_{M-1}$  channels, respectively, and same other sizes is defined as:

$$dst_m[n][c][h][w] = src[n][\sum_{i=0}^{k-1} C_i + c][h][w], c \in [0, C_m - 1],$$

where  $\sum_{i=0}^{M-1} C_i = C$ .

## dnnConcatCreate

*Creates concatenation layers.*

---

## Syntax

```
dnnError_t dnnConcatCreate_F32 (dnnPrimitive_t *pConcat, dnnPrimitiveAttributes_t
attributes, size_t nSrcTensors, const dnnLayout_t *src);
```

```
dnnError_t dnnConcatCreate_F64 (dnnPrimitive_t *pConcat, dnnPrimitiveAttributes_t
attributes, size_t nSrcTensors, const dnnLayout_t *src);
```

## Include Files

- `mkl.h`

## Input Parameters

|                          |                                          |
|--------------------------|------------------------------------------|
| <code>attributes</code>  | The set of attributes for the primitive. |
| <code>nSrcTensors</code> | The number of input tensors.             |
| <code>src</code>         | Pointer to the layout of input tensors.  |

## Output Parameters

`pConcat` Pointer to the primitive to create.

## Description

Each `dnnConcatCreate` function creates a concatenation primitive. The concatenation tensor for  $M$  tensors with  $C_0, C_1, \dots, C_{M-1}$  channels, respectively, and same other sizes is defined as:

$$dst[n][\sum_{i=0}^{m-1} C_i + k][h][w] = src_m[n][k][h][w], k \in [0, C_m - 1],$$

where  $\sum_{i=0}^{M-1} C_i = C$ .

## dnnSumCreate

*Creates sum layers.*

---

### Syntax

```
dnnError_t dnnSumCreate_F32 (dnnPrimitive_t *pSum, dnnPrimitiveAttributes_t attributes,
const size_t nSummands, dnnLayout_t dataLayout, float *coefficients);
```

```
dnnError_t dnnSumCreate_F64 (dnnPrimitive_t *pSum, dnnPrimitiveAttributes_t attributes,
const size_t nSummands, dnnLayout_t dataLayout, float *coefficients);
```

### Include Files

- `mkl.h`

### Input Parameters

|                     |                                                    |
|---------------------|----------------------------------------------------|
| <i>attributes</i>   | The set of attributes for the primitive.           |
| <i>nSummands</i>    | The number of input layouts.                       |
| <i>dataLayout</i>   | Pointer to the layout of the input.                |
| <i>coefficients</i> | Coefficients of input tensors in the weighted sum. |

### Output Parameters

|             |                                     |
|-------------|-------------------------------------|
| <i>pSum</i> | Pointer to the primitive to create. |
|-------------|-------------------------------------|

### Description

Each `dnnSumCreate` function creates a sum primitive. The sum (weighted) of  $N$  tensors of the same sizes is defined as:

$$dst[x] = \sum_{n=0}^{N-1} \alpha_n src_n[x].$$

## dnnScaleCreate

*Creates scale layers.*

---

## Syntax

```
dnnError_t dnnScaleCreate_F32 (dnnPrimitive_t *pScale, dnnPrimitiveAttributes_t
attributes, const dnnLayout_t dataLayout, float alpha);
```

```
dnnError_t dnnScaleCreate_F64 (dnnPrimitive_t *pScale, dnnPrimitiveAttributes_t
attributes, const dnnLayout_t dataLayout, float alpha);
```

## Include Files

- mkl.h

## Input Parameters

|                   |                                          |
|-------------------|------------------------------------------|
| <i>attributes</i> | The set of attributes for the primitive. |
| <i>dataLayout</i> | The layout of the input.                 |
| <i>alpha</i>      | The scaling factor.                      |

## Output Parameters

|               |                                     |
|---------------|-------------------------------------|
| <i>pScale</i> | Pointer to the primitive to create. |
|---------------|-------------------------------------|

## Description

Each `dnnScaleCreate` function creates a scale primitive. A scaling operation is defined as follows:

$$dst[x] = alpha * src[x].$$

The primitive supports the following kinds of scaling:

- In-place: the *src* and *dst* pointers reference the same memory block.
- Out-of-place: the *src* and *dst* pointers reference different non-interleaving memory blocks.

## dnnConversionCreate

*Creates conversion operations.*

---

## Syntax

```
dnnError_t dnnConversionCreate_F32 (dnnPrimitive_t *pConversion, const dnnLayout_t
from, const dnnLayout_t to);
```

```
dnnError_t dnnConversionCreate_F64 (dnnPrimitive_t *pConversion, const dnnLayout_t
from, const dnnLayout_t to);
```

## Include Files

- mkl.h

## Input Parameters

|             |                             |
|-------------|-----------------------------|
| <i>from</i> | The layout to convert from. |
| <i>to</i>   | The layout to convert to.   |

## Output Parameters

*pConversion* Pointer to the primitive to create.

### Description

Each `dnnConversionCreate` function creates a forward or backward propagation operation for conversion layers.

If both layouts are plain, they must have the same number of dimensions and the same size along each dimension. In this case, the following formula is applied:

$$dst[(x, stridesTo)] = src[(x, stridesFrom)],$$

where *stridesFrom* and *stridesTo* are strides in layouts from and to and  $(. , .)$  denotes the scalar product of two vectors.

If one of the layouts is custom, *dst* is the matrix-vector product  $C * src$  for a matrix  $C = C (from, to)$  such that all  $C_{ij}$  are 0 or 1,  $\sum (j; C_{ij}) \leq 1$ , and  $\sum (i; C_{ij}) \geq 1$ .

### dnnExecute

*Performs DNN operations.*

#### Syntax

```
dnnError_t dnnExecute_F32 (dnnPrimitive_t primitive, void *resources[]);
```

```
dnnError_t dnnExecute_F64 (dnnPrimitive_t primitive, void *resources[]);
```

#### Include Files

- `mkl.h`

### Input Parameters

*primitive* The description of a DNN operation to perform.

*resources* An array of pointers to the resources according to the following table:

| DNN Operation                               | Indices of input resources                                                                      |
|---------------------------------------------|-------------------------------------------------------------------------------------------------|
| Convolution forward without bias            | <code>dnnResourceSrc,</code><br><code>dnnResourceFilter</code>                                  |
| Convolution forward with bias               | <code>dnnResourceSrc,</code><br><code>dnnResourceFilter,</code><br><code>dnnResourceBias</code> |
| Convolution backward with respect to data   | <code>dnnResourceDiffDst,</code><br><code>dnnResourceFilter</code>                              |
| Convolution backward with respect to filter | <code>dnnResourceDiffDst,</code><br><code>dnnResourceSrc</code>                                 |
| Convolution backward with respect to bias   | <code>dnnResourceDiffDst</code>                                                                 |
| Inner product forward without bias          | <code>dnnResourceSrc,</code><br><code>dnnResourceFilter</code>                                  |

| <b>DNN Operation</b>                                                                                                                                            | <b>Indices of input resources</b>                                                                                                                                                                                                                  |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Inner product forward with bias                                                                                                                                 | dnnResourceSrc,<br>dnnResourceFilter,<br>dnnResourceBias                                                                                                                                                                                           |
| Inner product backward with respect to data                                                                                                                     | dnnResourceDiffDst,<br>dnnResourceFilter                                                                                                                                                                                                           |
| Inner product backward with respect to filter                                                                                                                   | dnnResourceDiffDst,<br>dnnResourceSrc                                                                                                                                                                                                              |
| Inner product backward with respect to bias                                                                                                                     | dnnResourceDiffDst                                                                                                                                                                                                                                 |
| LRN forward                                                                                                                                                     | dnnResourceSrc,<br>dnnResourceWorkspace                                                                                                                                                                                                            |
| LRN backward                                                                                                                                                    | dnnResourceDiffDst,<br>dnnResourceWorkspace                                                                                                                                                                                                        |
| ReLU forward                                                                                                                                                    | dnnResourceSrc                                                                                                                                                                                                                                     |
| ReLU backward                                                                                                                                                   | dnnResourceDiffDst                                                                                                                                                                                                                                 |

## Description

Each `dnnExecute` function performs a DNN operation on given resources. All the required resources, including the output resources, must point to arrays having a plain layout or to the arrays allocated with a `dnnAllocateBuffer` function. The `dnnExecute` functions do not use the remaining elements of the `resources` array in dereferencing operations.

The following table explains more usage details of `dnnExecute` for specific operations:

| DNN Operation                | Indices of output resources                                                                                                                                                                                                                                                                                                                |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Local response normalization | The resource indexed <code>dnnResourceWorkspace</code> is required on forward and backward propagations. On backward propagation, use the buffer allocated for the workspace on forward propagation.                                                                                                                                       |

| Batch normalization          | Perform backward batch normalization with respect to data before backward batch normalization with respect to scale and shift.<br><br>The resource indexed <code>dnnResourceWorkspace</code> is required on forward and backward propagations. On backward propagation, use the buffer allocated for the workspace on forward propagation. |

## DNN Operation

Batch normalization with specified computation method; created with `dnnBatchNormalizationCreate_v2`

## Indices of output resources

The resources indexed `dnnResourceMean` and `dnnResourceVariance` are required on forward and backward propagations. On backward propagation, use the buffers allocated for the mean and variance on forward propagation.

## dnnConversionExecute

*Performs a conversion operation.*

### Syntax

```
dnnError_t dnnConversionExecute_F32 (dnnPrimitive_t conversion, void *from, void *to);
dnnError_t dnnConversionExecute_F64 (dnnPrimitive_t conversion, void *from, void *to);
```

### Include Files

- `mkl.h`

### Input Parameters

|                   |                                                         |
|-------------------|---------------------------------------------------------|
| <i>conversion</i> | The description of the conversion operation to perform. |
| <i>from</i>       | Pointer to the input.                                   |

### Output Parameters

|           |                        |
|-----------|------------------------|
| <i>to</i> | Pointer to the output. |
|-----------|------------------------|

### Description

Each `dnnConversionExecute` function performs a conversion operation.

## dnnDelete

*Deletes descriptions of DNN operations.*

### Syntax

```
dnnError_t dnnDelete_F32(dnnPrimitive_t primitive);
dnnError_t dnnDelete_F64(dnnPrimitive_t primitive);
```

### Include Files

- `mkl.h`

### Input Parameters

|                  |                          |
|------------------|--------------------------|
| <i>primitive</i> | The primitive to delete. |
|------------------|--------------------------|

### Output Parameters

None.

# Linear Solvers Basics

Many applications in science and engineering require the solution of a system of linear equations. This problem is usually expressed mathematically by the matrix-vector equation,  $Ax = b$ , where  $A$  is an  $m$ -by- $n$  matrix,  $x$  is the  $n$  element column vector and  $b$  is the  $m$  element column vector. The matrix  $A$  is usually referred to as the coefficient matrix, and the vectors  $x$  and  $b$  are referred to as the solution vector and the right-hand side, respectively.

Basic concepts related to solving linear systems with sparse matrices are described in [Sparse Linear Systems](#) and various storage schemes for sparse matrices are described in [Sparse Matrix Storage Formats](#).

## Sparse Linear Systems

In many real-life applications, most of the elements in  $A$  are zero. Such a matrix is referred to as sparse. Conversely, matrices with very few zero elements are called dense. For sparse matrices, computing the solution to the equation  $Ax = b$  can be made much more efficient with respect to both storage and computation time, if the sparsity of the matrix can be exploited. The more an algorithm can exploit the sparsity without sacrificing the correctness, the better the algorithm.

Generally speaking, computer software that finds solutions to systems of linear equations is called a solver. A solver designed to work specifically on sparse systems of equations is called a sparse solver. Solvers are usually classified into two groups - direct and iterative.

**Iterative Solvers** start with an initial approximation to a solution and attempt to estimate the difference between the approximation and the true result. Based on the difference, an iterative solver calculates a new approximation that is closer to the true result than the initial approximation. This process is repeated until the difference between the approximation and the true result is sufficiently small. The main drawback to iterative solvers is that the rate of convergence depends greatly on the values in the matrix  $A$ . Consequently, it is not possible to predict how long it will take for an iterative solver to produce a solution. In fact, for ill-conditioned matrices, the iterative process will not converge to a solution at all. However, for well-conditioned matrices it is possible for iterative solvers to converge to a solution very quickly. Consequently, if an application involves well-conditioned matrices iterative solvers can be very efficient.

**Direct Solvers**, on the other hand, factor the matrix  $A$  into the product of two triangular matrices and then perform a forward and backward triangular solve.

This approach makes the time required to solve a systems of linear equations relatively predictable, based on the size of the matrix. In fact, for sparse matrices, the solution time can be predicted based on the number of non-zero elements in the array  $A$ .

## Matrix Fundamentals

A matrix is a rectangular array of either real or complex numbers. A matrix is denoted by a capital letter; its elements are denoted by the same lower case letter with row/column subscripts. Thus, the value of the element in row  $i$  and column  $j$  in matrix  $A$  is denoted by  $a(i, j)$ . For example, a 3 by 4 matrix  $A$ , is written as follows:

$$A = \begin{bmatrix} a(1, 1) & a(1, 2) & a(1, 3) & a(1, 4) \\ a(2, 1) & a(2, 2) & a(2, 3) & a(2, 4) \\ a(3, 1) & a(3, 2) & a(3, 3) & a(3, 4) \end{bmatrix}$$

Note that with the above notation, we assume the standard Fortran programming language convention of starting array indices at 1 rather than the C programming language convention of starting them at 0.

A matrix in which all of the elements are real numbers is called a real matrix. A matrix that contains at least one complex number is called a complex matrix. A real or complex matrix  $A$  with the property that  $a(i,j) = a(j,i)$ , is called a symmetric matrix. A complex matrix  $A$  with the property that  $a(i,j) = \text{conj}(a(j,i))$ , is called a Hermitian matrix. Note that programs that manipulate symmetric and Hermitian matrices need only store half of the matrix values, since the values of the non-stored elements can be quickly reconstructed from the stored values.

A matrix that has the same number of rows as it has columns is referred to as a square matrix. The elements in a square matrix that have same row index and column index are called the diagonal elements of the matrix, or simply the diagonal of the matrix.

The transpose of a matrix  $A$  is the matrix obtained by “flipping” the elements of the array about its diagonal. That is, we exchange the elements  $a(i,j)$  and  $a(j,i)$ . For a complex matrix, if we both flip the elements about the diagonal and then take the complex conjugate of the element, the resulting matrix is called the Hermitian transpose or conjugate transpose of the original matrix. The transpose and Hermitian transpose of a matrix  $A$  are denoted by  $A^T$  and  $A^H$  respectively.

A column vector, or simply a vector, is a  $n \times 1$  matrix, and a row vector is a  $1 \times n$  matrix. A real or complex matrix  $A$  is said to be positive definite if the vector-matrix product  $x^T Ax$  is greater than zero for all non-zero vectors  $x$ . A matrix that is not positive definite is referred to as indefinite.

An upper (or lower) triangular matrix, is a square matrix in which all elements below (or above) the diagonal are zero. A unit triangular matrix is an upper or lower triangular matrix with all 1's along the diagonal.

A matrix  $P$  is called a permutation matrix if, for any matrix  $A$ , the result of the matrix product  $PA$  is identical to  $A$  except for interchanging the rows of  $A$ . For a square matrix, it can be shown that if  $PA$  is a permutation of the rows of  $A$ , then  $AP^T$  is the same permutation of the columns of  $A$ . Additionally, it can be shown that the inverse of  $P$  is  $P^T$ .

In order to save space, a permutation matrix is usually stored as a linear array, called a permutation vector, rather than as an array. Specifically, if the permutation matrix maps the  $i$ -th row of a matrix to the  $j$ -th row, then the  $i$ -th element of the permutation vector is  $j$ .

A matrix with non-zero elements only on the diagonal is called a diagonal matrix. As is the case with a permutation matrix, it is usually stored as a vector of values, rather than as a matrix.

## Direct Method

For solvers that use the direct method, the basic technique employed in finding the solution of the system  $Ax = b$  is to first factor  $A$  into triangular matrices. That is, find a lower triangular matrix  $L$  and an upper triangular matrix  $U$ , such that  $A = LU$ . Having obtained such a factorization (usually referred to as an  $LU$  decomposition or  $LU$  factorization), the solution to the original  $LU$  problem can be rewritten as follows.

$$\begin{aligned} Ax &= b \\ \Rightarrow LUx &= b \\ \Rightarrow L(Ux) &= b \end{aligned}$$

This leads to the following two-step process for finding the solution to the original system of equations:

1. Solve the systems of equations  $Ly = b$ .
2. Solve the system  $Ux = y$ .

Solving the systems  $Ly = b$  and  $Ux = y$  is referred to as a forward solve and a backward solve, respectively.

If a symmetric matrix  $A$  is also positive definite, it can be shown that  $A$  can be factored as  $LL^T$  where  $L$  is a lower triangular matrix. Similarly, a Hermitian matrix,  $A$ , that is positive definite can be factored as  $A = LL^H$ . For both symmetric and Hermitian matrices, a factorization of this form is called a Cholesky factorization.

In a Cholesky factorization, the matrix  $U$  in an  $LU$  decomposition is either  $L^T$  or  $L^H$ . Consequently, a solver can increase its efficiency by only storing  $L$ , and one-half of  $A$ , and not computing  $U$ . Therefore, users who can express their application as the solution of a system of positive definite equations will gain a significant performance improvement over using a general representation.

For matrices that are symmetric (or Hermitian) but not positive definite, there are still some significant efficiencies to be had. It can be shown that if  $A$  is symmetric but not positive definite, then  $A$  can be factored as  $A = LDL^T$ , where  $D$  is a diagonal matrix and  $L$  is a lower unit triangular matrix. Similarly, if  $A$  is Hermitian, it can be factored as  $A = LDL^H$ . In either case, we again only need to store  $L$ ,  $D$ , and half of  $A$  and we need not compute  $U$ . However, the backward solve phases must be amended to solving  $L^T x = D^{-1} y$  rather than  $L^T x = y$ .

### Fill-In and Reordering of Sparse Matrices

Two important concepts associated with the solution of sparse systems of equations are fill-in and reordering. The following example illustrates these concepts.

Consider the system of linear equation  $Ax = b$ , where  $A$  is a symmetric positive definite sparse matrix, and  $A$  and  $b$  are defined by the following:

$$A = \begin{bmatrix} 9 & \frac{3}{2} & 6 & \frac{3}{4} & 3 \\ \frac{3}{2} & \frac{1}{2} & * & * & * \\ 6 & * & 12 & * & * \\ \frac{3}{4} & * & * & \frac{5}{8} & * \\ 3 & * & * & * & 16 \end{bmatrix}, b = \begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{bmatrix}$$

A star (\*) is used to represent zeros and to emphasize the sparsity of  $A$ . The Cholesky factorization of  $A$  is:  $A = LL^T$ , where  $L$  is the following:

$$L = \begin{bmatrix} 3 & * & * & * & * \\ \frac{1}{2} & \frac{1}{2} & * & * & * \\ 2 & -2 & 2 & * & * \\ \frac{1}{4} & \frac{1}{-4} & \frac{1}{-2} & \frac{1}{2} & * \\ 1 & -1 & -2 & -3 & 1 \end{bmatrix}$$

Notice that even though the matrix  $A$  is relatively sparse, the lower triangular matrix  $L$  has no zeros below the diagonal. If we computed  $L$  and then used it for the forward and backward solve phase, we would do as much computation as if  $A$  had been dense.

The situation of  $L$  having non-zeros in places where  $A$  has zeros is referred to as fill-in. Computationally, it would be more efficient if a solver could exploit the non-zero structure of  $A$  in such a way as to reduce the fill-in when computing  $L$ . By doing this, the solver would only need to compute the non-zero entries in  $L$ . Toward this end, consider permuting the rows and columns of  $A$ . As described in [Matrix Fundamentals](#) section, the permutations of the rows of  $A$  can be represented as a permutation matrix,  $P$ . The result of permuting the rows is the product of  $P$  and  $A$ . Suppose, in the above example, we swap the first and fifth row of  $A$ , then swap the first and fifth columns of  $A$ , and call the resulting matrix  $B$ . Mathematically, we can express the process of permuting the rows and columns of  $A$  to get  $B$  as  $B = PAP^T$ . After permuting the rows and columns of  $A$ , we see that  $B$  is given by the following:

$$B = \begin{bmatrix} 16 & * & * & * & 3 \\ * & \frac{1}{2} & * & * & \frac{3}{2} \\ * & * & 12 & * & 6 \\ * & * & * & \frac{5}{8} & \frac{3}{4} \\ 3 & \frac{3}{2} & 6 & \frac{3}{4} & 9 \end{bmatrix}$$

Since  $B$  is obtained from  $A$  by simply switching rows and columns, the numbers of non-zero entries in  $A$  and  $B$  are the same. However, when we find the Cholesky factorization,  $B = LL^T$ , we see the following:

$$L = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix}$$

The fill-in associated with  $B$  is much smaller than the fill-in associated with  $A$ . Consequently, the storage and computation time needed to factor  $B$  is much smaller than to factor  $A$ . Based on this, we see that an efficient sparse solver needs to find permutation  $P$  of the matrix  $A$ , which minimizes the fill-in for factoring  $B = PAP^T$ , and then use the factorization of  $B$  to solve the original system of equations.

Although the above example is based on a symmetric positive definite matrix and a Cholesky decomposition, the same approach works for a general  $LU$  decomposition. Specifically, let  $P$  be a permutation matrix,  $B = PAP^T$  and suppose that  $B$  can be factored as  $B = LU$ . Then

$$Ax = b$$

$$\Rightarrow PA(P^{-1}P)x = Pb$$

$$\Rightarrow PA(P^T P)x = Pb$$

$$\Rightarrow (PAP^T)(Px) = Pb$$

$$\Rightarrow B(Px) = Pb$$

$$\Rightarrow LU(Px) = Pb$$

It follows that if we obtain an  $LU$  factorization for  $B$ , we can solve the original system of equations by a three step process:

1. Solve  $Ly = Pb$ .
2. Solve  $Uz = y$ .
3. Set  $x = P^Tz$ .

If we apply this three-step process to the current example, we first need to perform the forward solve of the systems of equation  $Ly = Pb$ :

$$Ly = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix} * \begin{bmatrix} y1 \\ y2 \\ y3 \\ y4 \\ y5 \end{bmatrix} = \begin{bmatrix} 5 \\ 2 \\ 3 \\ 4 \\ 1 \end{bmatrix}$$

This gives:  $y^T = \frac{5}{4}, 2\sqrt{2}, \frac{\sqrt{3}}{2}, \frac{16}{\sqrt{10}}, \frac{-979\sqrt{3}}{12\sqrt{5}}$ .

The second step is to perform the backward solve,  $Uz = y$ . Or, in this case, since a Cholesky factorization is used,  $L^Tz = y$ .

$$\begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix}^T * \begin{bmatrix} z1 \\ z2 \\ z3 \\ z4 \\ z5 \end{bmatrix} = \begin{bmatrix} \frac{5}{4} \\ 2(\sqrt{2}) \\ \frac{\sqrt{3}}{2} \\ \frac{16}{\sqrt{10}} \\ \frac{-979\sqrt{3}}{12\sqrt{5}} \end{bmatrix}$$

This gives  $z^T = \frac{123}{2}, 983, \frac{1961}{12}, 398, \frac{-979}{3}$ .

The third and final step is to set  $x = P^Tz$ . This gives  $x^T = \frac{-979}{3}, 983, \frac{1961}{12}, 398, \frac{123}{2}$ .

## Sparse Matrix Storage Formats

As discussed above, it is more efficient to store only the non-zero elements of a sparse matrix. There are a number of common storage formats used for sparse matrices, but most of them employ the same basic technique. That is, store all non-zero elements of the matrix into a linear array and provide auxiliary arrays to describe the locations of the non-zero elements in the original matrix.

### Storage Formats for the Direct Sparse Solvers

Storing the non-zero elements of a sparse matrix into a linear array is done by walking down each column (column-major format) or across each row (row-major format) in order, and writing the non-zero elements to a linear array in the order they appear in the walk.

### DSS Symmetric Matrix Storage

For symmetric matrices, it is necessary to store only the upper triangular half of the matrix (upper triangular format) or the lower triangular half of the matrix (lower triangular format).

The Intel MKL direct sparse solvers use a row-major upper triangular storage format: the matrix is compressed row-by-row and for symmetric matrices only non-zero elements in the upper triangular half of the matrix are stored.

The Intel MKL sparse matrix storage format for direct sparse solvers is specified by three arrays: *values*, *columns*, and *rowIndex*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix.

|                 |                                                                                                                                                                                                                     |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>values</i>   | A real or complex array that contains the non-zero elements of a sparse matrix. The non-zero elements are mapped into the <i>values</i> array using the row-major upper triangular storage mapping described above. |
| <i>columns</i>  | Element <i>i</i> of the integer array <i>columns</i> is the number of the column that contains the <i>i</i> -th element in the <i>values</i> array.                                                                 |
| <i>rowIndex</i> | Element <i>j</i> of the integer array <i>rowIndex</i> gives the index of the element in the <i>values</i> array that is first non-zero element in a row <i>j</i> .                                                  |

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in the matrix.

As the *rowIndex* array gives the location of the first non-zero element within a row, and the non-zero elements are stored consecutively, the number of non-zero elements in the *i*-th row is equal to the difference of *rowIndex*[*i*] and *rowIndex*[*i*+1].

To have this relationship hold for the last row of the matrix, an additional entry (dummy entry) is added to the end of *rowIndex*. Its value is equal to the number of non-zero elements plus one. This makes the total length of the *rowIndex* array one larger than the number of rows in the matrix.

**NOTE**

The Intel MKL sparse storage scheme for the direct sparse solvers supports both one-based indexing and zero-based indexing.

Consider the symmetric matrix *A*:

$$A = \begin{pmatrix} 1 & -1 & * & -3 & * \\ -1 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -3 & * & 6 & 7 & * \\ * & * & 4 & * & -5 \end{pmatrix}$$

Only elements from the upper triangle are stored. The actual arrays for the matrix *A* are as follows:

**Storage Arrays for a Symmetric Matrix****one-based indexing**

|                 |   |    |    |    |   |   |     |   |   |     |
|-----------------|---|----|----|----|---|---|-----|---|---|-----|
| <i>values</i>   | = | (1 | -1 | -3 | 5 | 4 | 6   | 4 | 7 | -5) |
| <i>columns</i>  | = | (1 | 2  | 4  | 2 | 3 | 4   | 5 | 4 | 5)  |
| <i>rowIndex</i> | = | (1 | 4  | 5  | 8 | 9 | 10) |   |   |     |

**zero-based indexing**

|                 |   |    |    |    |   |   |    |   |   |     |
|-----------------|---|----|----|----|---|---|----|---|---|-----|
| <i>values</i>   | = | (1 | -1 | -3 | 5 | 4 | 6  | 4 | 7 | -5) |
| <i>columns</i>  | = | (0 | 1  | 3  | 1 | 2 | 3  | 4 | 3 | 4)  |
| <i>rowIndex</i> | = | (0 | 3  | 4  | 7 | 8 | 9) |   |   |     |

**Storage Format Restrictions**

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
- no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

**DSS Nonsymmetric Matrix Storage**

For a non-symmetric or non-Hermitian matrix, all non-zero elements need to be stored. Consider the non-symmetric matrix *B*:

$$B = \begin{pmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{pmatrix}$$

The matrix *B* has 13 non-zero elements, and all of them are stored as follows:

**Storage Arrays for a Non-Symmetric Matrix****one-based indexing**

|                 |   |    |    |    |    |    |     |   |   |    |   |   |   |     |
|-----------------|---|----|----|----|----|----|-----|---|---|----|---|---|---|-----|
| <i>values</i>   | = | (1 | -1 | -3 | -2 | 5  | 4   | 6 | 4 | -4 | 2 | 7 | 8 | -5) |
| <i>columns</i>  | = | (1 | 2  | 4  | 1  | 2  | 3   | 4 | 5 | 1  | 3 | 4 | 2 | 5)  |
| <i>rowIndex</i> | = | (1 | 4  | 6  | 9  | 12 | 14) |   |   |    |   |   |   |     |

**zero-based indexing**

|                 |   |    |    |    |    |    |     |   |   |    |   |   |   |     |
|-----------------|---|----|----|----|----|----|-----|---|---|----|---|---|---|-----|
| <i>values</i>   | = | (1 | -1 | -3 | -2 | 5  | 4   | 6 | 4 | -4 | 2 | 7 | 8 | -5) |
| <i>columns</i>  | = | (0 | 1  | 3  | 0  | 1  | 2   | 3 | 4 | 0  | 2 | 3 | 1 | 4)  |
| <i>rowIndex</i> | = | (0 | 3  | 5  | 8  | 11 | 13) |   |   |    |   |   |   |     |

**Storage Format Restrictions**

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
- no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

**DSS Structurally Symmetric Matrix Storage**

Direct sparse solvers can also solve symmetrically structured systems of equations. A symmetrically structured system of equations is one where the pattern of non-zero elements is symmetric. That is, a matrix has a symmetric structure if  $a_{j,i}$  is not zero if and only if  $a_{i,j}$  is not zero. From the point of view of the solver software, a "non-zero" element of a matrix is any element stored in the *values* array, even if its value is equal to 0. In that sense, any non-symmetric matrix can be turned into a symmetrically structured matrix by carefully adding zeros to the *values* array. For example, the above matrix *B* can be turned into a symmetrically structured matrix by adding two non-zero entries:

$$B = \begin{pmatrix} 1 & -1 & * & 3 & * \\ -2 & 5 & * & * & 0 \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & 0 & * & -5 \end{pmatrix}$$

The matrix *B* can be considered to be symmetrically structured with 15 non-zero elements and represented as:

**Storage Arrays for a Symmetrically Structured Matrix**

**one-based indexing**

|                 |   |    |    |    |    |    |     |   |   |   |    |   |   |   |   |     |
|-----------------|---|----|----|----|----|----|-----|---|---|---|----|---|---|---|---|-----|
| <i>values</i>   | = | (1 | -1 | -3 | -2 | 5  | 0   | 4 | 6 | 4 | -4 | 2 | 7 | 8 | 0 | -5) |
| <i>columns</i>  | = | (1 | 2  | 4  | 1  | 2  | 5   | 3 | 4 | 5 | 1  | 3 | 4 | 2 | 3 | 5)  |
| <i>rowIndex</i> | = | (1 | 4  | 7  | 10 | 13 | 16) |   |   |   |    |   |   |   |   |     |

**zero-based indexing**

|                 |   |    |    |    |    |    |     |   |   |   |    |   |   |   |   |     |
|-----------------|---|----|----|----|----|----|-----|---|---|---|----|---|---|---|---|-----|
| <i>values</i>   | = | (1 | -1 | -3 | -2 | 5  | 0   | 4 | 6 | 4 | -4 | 2 | 7 | 8 | 0 | -5) |
| <i>columns</i>  | = | (0 | 1  | 3  | 0  | 1  | 4   | 2 | 3 | 4 | 0  | 2 | 3 | 1 | 2 | 4)  |
| <i>rowIndex</i> | = | (0 | 3  | 6  | 9  | 12 | 15) |   |   |   |    |   |   |   |   |     |

**Storage Format Restrictions**

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
- no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

## DSS Distributed Symmetric Matrix Storage

The distributed assembled matrix input format can be used by the Parallel Direct Sparse Solver for Clusters Interface.

In this format, the symmetric input matrix  $A$  is divided into sequential row subsets, or domains. Each domain belongs to an MPI process. Neighboring domains can overlap. For such intersection between two domains, the element values of the full matrix can be obtained by summing the respective elements of both domains.

As in the centralized format, the distributed format uses three arrays to describe the input data, but the *values*, *columns*, and *rowIndex* arrays on each processor only describe the domain belonging to that particular processor and not the entire matrix.

For example, consider a symmetric matrix  $A$ :

$$A = \begin{pmatrix} 6 & -1 & * & -3 & * \\ -1 & 5 & * & * & * \\ * & * & 11 & 5 & 4 \\ -3 & * & 5 & 10 & * \\ * & * & 4 & * & 5 \end{pmatrix}$$

This array could be distributed between two domains corresponding to two MPI processes, with the first containing rows 1 through 3, and the second containing rows 3 through 5.

**NOTE**

For the symmetric input matrix, it is not necessary to store the values from the lower triangle.

$$A_{Domain1} = \begin{pmatrix} 6 & -1 & * & -3 & * \\ -1 & 5 & * & * & * \\ * & * & 3 & * & 2 \end{pmatrix}$$

### Distributed Storage Arrays for a Symmetric Matrix, Domain 1

|                            |   |    |    |    |    |   |    |
|----------------------------|---|----|----|----|----|---|----|
| <b>one-based indexing</b>  |   |    |    |    |    |   |    |
| <i>values</i>              | = | (6 | -1 | -3 | 5  | 3 | 2) |
| <i>columns</i>             | = | (1 | 2  | 4  | 2  | 3 | 5) |
| <i>rowIndex</i>            | = | (1 | 4  | 5  | 7) |   |    |
| <b>zero-based indexing</b> |   |    |    |    |    |   |    |
| <i>values</i>              | = | (6 | -1 | -3 | 5  | 3 | 2) |
| <i>columns</i>             | = | (0 | 1  | 3  | 1  | 2 | 4) |
| <i>rowIndex</i>            | = | (0 | 3  | 4  | 6) |   |    |

$$A_{Domain2} = \begin{pmatrix} * & * & 8 & 5 & 2 \\ -3 & * & 5 & 10 & * \\ * & * & 4 & * & 5 \end{pmatrix}$$

### Distributed Storage Arrays for a Symmetric Matrix, Domain 2

|                            |   |    |   |   |    |    |
|----------------------------|---|----|---|---|----|----|
| <b>one-based indexing</b>  |   |    |   |   |    |    |
| <i>values</i>              | = | (8 | 5 | 2 | 10 | 5) |
| <i>columns</i>             | = | (3 | 4 | 5 | 4  | 5) |
| <i>rowIndex</i>            | = | (1 | 4 | 5 | 6) |    |
| <b>zero-based indexing</b> |   |    |   |   |    |    |
| <i>values</i>              | = | (8 | 5 | 2 | 10 | 5) |
| <i>columns</i>             | = | (2 | 3 | 4 | 3  | 4) |
| <i>rowIndex</i>            | = | (0 | 3 | 4 | 5) |    |

The third row of matrix  $A$  is common between domain 1 and domain 2. The values of row 3 of matrix  $A$  are the sums of the respective elements of row 3 of matrix  $A_{Domain1}$  and row 1 of matrix  $A_{Domain2}$ .

## Storage Format Restrictions

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
- no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

**Sparse BLAS CSR Matrix Storage Format**

The Intel MKL compressed sparse row (CSR) format is specified by four arrays: the *values*, *columns*, *pointerB*, and *pointerE*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

|                 |                                                                                                                                                                                                                                                         |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>values</i>   | A real or complex array that contains the non-zero elements of <i>A</i> . Values of the non-zero elements of <i>A</i> are mapped into the <i>values</i> array using the row-major storage mapping described above.                                      |
| <i>columns</i>  | Element <i>i</i> of the integer array <i>columns</i> is the number of the column in <i>A</i> that contains the <i>i</i> -th value in the <i>values</i> array.                                                                                           |
| <i>pointerB</i> | Element <i>j</i> of this integer array gives the index of the element in the <i>values</i> array that is first non-zero element in a row <i>j</i> of <i>A</i> . Note that this index is equal to <i>pointerB</i> [ <i>j</i> ] - <i>pointerB</i> [0]+1 . |
| <i>pointerE</i> | An integer array that contains row indices, such that <i>pointerE</i> [ <i>j</i> ]- <i>pointerB</i> [0] is the index of the element in the <i>values</i> array that is last non-zero element in a row <i>j</i> of <i>A</i> .                            |

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in *A*. The length of the *pointerB* and *pointerE* arrays is equal to the number of rows in *A*.

**NOTE**

Note that the Intel MKL Sparse BLAS routines support the CSR format both with one-based indexing and zero-based indexing.

The matrix *B*

$$B = \begin{pmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{pmatrix}$$

can be represented in the CSR format as:

### Storage Arrays for a Matrix in CSR Format

#### one-based indexing

```

values = (1 -1 -3 -2 5 4 6 4 -4 2 7 8 -5)
columns = (1 2 4 1 2 3 4 5 1 3 4 2 5)
pointerB = (1 4 6 9 12)
pointerE = (4 6 9 12 14)

```

#### zero-based indexing

```

values = (1 -1 -3 -2 5 4 6 4 -4 2 7 8 -5)
columns = (0 1 3 0 1 2 3 4 0 2 3 1 4)
pointerB = (0 3 5 8 11)
pointerE = (3 5 8 11 13)

```

This storage format is used in the NIST Sparse BLAS library [Rem05].

### Three Array Variation of CSR Format

The storage format accepted for the direct sparse solvers is a variation of the CSR format. It also is used in the Intel MKL Sparse BLAS Level 2 both with one-based indexing and zero-based indexing. The above matrix  $B$  can be represented in this format (referred to as the 3-array variation of the CSR format or CSR3) as:

### Storage Arrays for a Matrix in CSR Format (3-Array Variation)

#### one-based indexing

```

values = (1 -1 -3 -2 5 4 6 4 -4 2 7 8 -5)
columns = (1 2 4 1 2 3 4 5 1 3 4 2 5)
rowIndex = (1 4 6 9 12 14)

```

#### zero-based indexing

```

values = (1 -1 -3 -2 5 4 6 4 -4 2 7 8 -5)
columns = (0 1 3 0 1 2 3 4 0 2 3 1 4)
rowIndex = (0 3 5 8 11 13)

```

The 3-array variation of the CSR format has a restriction: all non-zero elements are stored continuously, that is the set of non-zero elements in the row  $J$  goes just after the set of non-zero elements in the row  $J-1$ .

There are no such restrictions in the general (NIST) CSR format. This may be useful, for example, if there is a need to operate with different submatrices of the matrix at the same time. In this case, it is enough to define the arrays *pointerB* and *pointerE* for each needed submatrix so that all these arrays are pointers to the same array *values*.

By definition, the array *rowIndex* from the Table "Storage Arrays for a Non-Symmetric Example Matrix" is related to the arrays *pointerB* and *pointerE* from the Table "Storage Arrays for an Example Matrix in CSR Format", and you can see that

```

pointerB[i] = rowIndex[i] for i=0, ..4;
pointerE[i] = rowIndex[i+1] for i=0, ..4.

```

This enables calling a routine that has *values*, *columns*, *pointerB* and *pointerE* as input parameters for a sparse matrix stored in the format accepted for the direct sparse solvers. For example, a routine with the interface:

```

void name_routine(... , double *values, MKL_INT *columns, MKL_INT *pointerB, MKL_INT
*pointerE, ...)

```

can be called with parameters *values*, *columns*, *rowIndex* as follows:

```

name_routine(... , values, columns, rowIndex, rowIndex+1, ...).

```

## Sparse BLAS CSC Matrix Storage Format

The compressed sparse column format (CSC) is similar to the CSR format, but the columns are used instead the rows. In other words, the CSC format is identical to the CSR format for the transposed matrix. The CSR format is specified by four arrays: *values*, *columns*, *pointerB*, and *pointerE*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

|                 |                                                                                                                                                                                                                                                           |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>values</i>   | A real or complex array that contains the non-zero elements of <i>A</i> . Values of the non-zero elements of <i>A</i> are mapped into the <i>values</i> array using the column-major storage mapping.                                                     |
| <i>rows</i>     | Element <i>i</i> of the integer array <i>rows</i> is the number of the row in <i>A</i> that contains the <i>i</i> -th value in the <i>values</i> array.                                                                                                   |
| <i>pointerB</i> | Element <i>j</i> of this integer array gives the index of the element in the <i>values</i> array that is first non-zero element in a column <i>j</i> of <i>A</i> . Note that this index is equal to <i>pointerB</i> [ <i>j</i> ] - <i>pointerB</i> [0]+1. |
| <i>pointerE</i> | An integer array that contains column indices, such that <i>pointerE</i> [ <i>j</i> ]- <i>pointerB</i> [0] is the index of the element in the <i>values</i> array that is last non-zero element in a column <i>j</i> of <i>A</i> .                        |

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in *A*. The length of the *pointerB* and *pointerE* arrays is equal to the number of columns in *A*.

---

### NOTE

Note that the Intel MKL Sparse BLAS routines support the CSC format both with one-based indexing and zero-based indexing.

---

For example, consider matrix *B*:

$$B = \begin{pmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{pmatrix}$$

It can be represented in the CSC format as:

### Storage Arrays for a Matrix in CSC Format

---

|                            |   |    |    |    |    |     |   |   |   |    |   |   |   |     |
|----------------------------|---|----|----|----|----|-----|---|---|---|----|---|---|---|-----|
| <b>one-based indexing</b>  |   |    |    |    |    |     |   |   |   |    |   |   |   |     |
| <i>values</i>              | = | (1 | -2 | -4 | -1 | 5   | 8 | 4 | 2 | -3 | 6 | 7 | 4 | -5) |
| <i>rows</i>                | = | (1 | 2  | 4  | 1  | 2   | 5 | 3 | 4 | 1  | 3 | 4 | 3 | 5)  |
| <i>pointerB</i>            | = | (1 | 4  | 7  | 9  | 12) |   |   |   |    |   |   |   |     |
| <i>pointerE</i>            | = | (4 | 7  | 9  | 12 | 14) |   |   |   |    |   |   |   |     |
| <b>zero-based indexing</b> |   |    |    |    |    |     |   |   |   |    |   |   |   |     |
| <i>values</i>              | = | (1 | -2 | -4 | -1 | 5   | 8 | 4 | 2 | -3 | 6 | 7 | 4 | -5) |
| <i>rows</i>                | = | (0 | 1  | 3  | 0  | 1   | 4 | 2 | 3 | 0  | 2 | 3 | 2 | 4)  |
| <i>pointerB</i>            | = | (0 | 3  | 6  | 8  | 11) |   |   |   |    |   |   |   |     |
| <i>pointerE</i>            | = | (3 | 6  | 8  | 11 | 13) |   |   |   |    |   |   |   |     |

---

## Sparse BLAS Coordinate Matrix Storage Format

The coordinate format is the most flexible and simplest format for the sparse matrix representation. Only non-zero elements are stored, and the coordinates of each non-zero element are given explicitly. Many commercial libraries support the matrix-vector multiplication for the sparse matrices in the coordinate format.

The Intel MKL coordinate format is specified by three arrays: *values*, *rows*, and *column*, and a parameter *nnz* which is number of non-zero elements in *A*. All three arrays have dimension *nnz*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

|                |                                                                                                                                                               |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>values</i>  | A real or complex array that contains the non-zero elements of <i>A</i> in any order.                                                                         |
| <i>rows</i>    | Element <i>i</i> of the integer array <i>rows</i> is the number of the row in <i>A</i> that contains the <i>i</i> -th value in the <i>values</i> array.       |
| <i>columns</i> | Element <i>i</i> of the integer array <i>columns</i> is the number of the column in <i>A</i> that contains the <i>i</i> -th value in the <i>values</i> array. |

**NOTE**

Note that the Intel MKL Sparse BLAS routines support the coordinate format both with one-based indexing and zero-based indexing.

For example, the sparse matrix *C*

$$C = \begin{pmatrix} 1 & -1 & -3 & 0 & 0 \\ -2 & 5 & 0 & 0 & 0 \\ 0 & 0 & 4 & 6 & 4 \\ -4 & 0 & 2 & 7 & 0 \\ 0 & 8 & 0 & 0 & -5 \end{pmatrix}$$

can be represented in the coordinate format as follows:

**Storage Arrays for an Example Matrix in case of the coordinate format**

| one-based indexing  |   |    |    |    |    |   |   |   |   |    |   |   |   |     |
|---------------------|---|----|----|----|----|---|---|---|---|----|---|---|---|-----|
| <i>values</i>       | = | (1 | -1 | -3 | -2 | 5 | 4 | 6 | 4 | -4 | 2 | 7 | 8 | -5) |
| <i>rows</i>         | = | (1 | 1  | 1  | 2  | 2 | 3 | 3 | 3 | 4  | 4 | 4 | 5 | 5)  |
| <i>columns</i>      | = | (1 | 2  | 3  | 1  | 2 | 3 | 4 | 5 | 1  | 3 | 4 | 2 | 5)  |
| zero-based indexing |   |    |    |    |    |   |   |   |   |    |   |   |   |     |
| <i>values</i>       | = | (1 | -1 | -3 | -2 | 5 | 4 | 6 | 4 | -4 | 2 | 7 | 8 | -5) |
| <i>rows</i>         | = | (0 | 0  | 0  | 1  | 1 | 2 | 2 | 2 | 3  | 3 | 3 | 4 | 4)  |
| <i>columns</i>      | = | (0 | 1  | 2  | 0  | 1 | 2 | 3 | 4 | 0  | 2 | 3 | 1 | 4)  |

**Sparse BLAS Diagonal Matrix Storage Format**

If the sparse matrix has diagonals containing only zero elements, then the diagonal storage format can be used to reduce the amount of information needed to locate the non-zero elements. This storage format is particularly useful in many applications where the matrix arises from a finite element or finite difference discretization. The Intel MKL diagonal storage format is specified by two arrays: *values* and *distance*, and two parameters: *ndiag*, which is the number of non-empty diagonals, and *lval*, which is the declared leading dimension in the calling (sub)programs. The following table describes the arrays *values* and *distance*:

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>values</i> | A real or complex two-dimensional array is dimensioned as <i>lval</i> by <i>ndiag</i> . Each column of it contains the non-zero elements of certain diagonal of <i>A</i> . The key point of the storage is that each element in <i>values</i> retains the row number of the original matrix. To achieve this diagonals in the lower triangular part of the matrix are padded from the top, and those in the upper triangular part are padded from the bottom. Note that the value of <i>distance</i> [ <i>i</i> ] is the number of elements to be padded for diagonal <i>i</i> . |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

*distance* An integer array with dimension *ndiag*. Element *i* of the array *distance* is the distance between *i*-diagonal and the main diagonal. The distance is positive if the diagonal is above the main diagonal, and negative if the diagonal is below the main diagonal. The main diagonal has a distance equal to zero.

The above matrix *C* can be represented in the diagonal storage format as follows:

$$\begin{aligned}
 \text{distance} &= (-3 \ -1 \ 0 \ 1 \ 2) \\
 \text{values} &= \begin{pmatrix} * & * & 1 & -1 & -3 \\ * & -2 & 5 & 0 & 0 \\ * & 0 & 4 & 6 & 4 \\ -4 & 2 & 7 & 0 & * \\ 8 & 0 & -5 & * & * \end{pmatrix}
 \end{aligned}$$

where the asterisks denote padded elements.

When storing symmetric, Hermitian, or skew-symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For the Intel MKL triangular solver routines elements of the array *distance* must be sorted in increasing order. In all other cases the diagonals and distances can be stored in arbitrary order.

### Sparse BLAS Skyline Matrix Storage Format

The skyline storage format is important for the direct sparse solvers, and it is well suited for Cholesky or LU decomposition when no pivoting is required.

The skyline storage format accepted in Intel MKL can store only triangular matrix or triangular part of a matrix. This format is specified by two arrays: *values* and *pointers*. The following table describes these arrays:

*values* A scalar array. For a lower triangular matrix it contains the set of elements from each row of the matrix starting from the first non-zero element to and including the diagonal element. For an upper triangular matrix it contains the set of elements from each column of the matrix starting with the first non-zero element down to and including the diagonal element. Encountered zero elements are included in the sets.

*pointers* An integer array with dimension  $(m+1)$ , where  $m$  is the number of rows for lower triangle (columns for the upper triangle).  $\text{pointers}[i] - \text{pointers}[0]+1$  gives the index of element in *values* that is first non-zero element in row (column)  $i$ . The value of  $\text{pointers}[m]$  is set to  $\text{nnz} + \text{pointers}[0]$ , where  $\text{nnz}$  is the number of elements in the array *values*.

For example, consider the matrix *C*:

$$C = \begin{pmatrix} 1 & -1 & -3 & 0 & 0 \\ -2 & 5 & 0 & 0 & 0 \\ 0 & 0 & 4 & 6 & 4 \\ -4 & 0 & 2 & 7 & 0 \\ 0 & 8 & 0 & 0 & -5 \end{pmatrix}$$

The low triangle of the matrix *C* given above can be stored as follows:

```

values = [1 -2 5 4 -4 0 2 7 8 0 0 -5]
pointers = [0 1 3 4 8 12]

```

and the upper triangle of this matrix *C* can be stored as follows:

```

values = [1 -1 5 -3 0 4 6 7 4 0 -5]
pointers = [0 1 3 6 8 11]

```

This storage format is supported by the NIST Sparse BLAS library [Rem05].

Note that the Intel MKL Sparse BLAS routines operating with the skyline storage format do not support general matrices.

## Sparse BLAS BSR Matrix Storage Format

The Intel MKL block compressed sparse row (BSR) format for sparse matrices is specified by four arrays: *values*, *columns*, *pointerB*, and *pointerE*. The following table describes these arrays.

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>values</i>   | A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block-by-block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of them are equal to zero. Within each non-zero block elements are stored in column-major order in the case of one-based indexing, and in row-major order in the case of the zero-based indexing. |
| <i>columns</i>  | Element <i>i</i> of the integer array <i>columns</i> is the number of the column in the block matrix that contains the <i>i</i> -th non-zero block.                                                                                                                                                                                                                                                                                                                                 |
| <i>pointerB</i> | Element <i>j</i> of this integer array gives the index of the element in the <i>columns</i> array that is first non-zero block in a row <i>j</i> of the block matrix.                                                                                                                                                                                                                                                                                                               |
| <i>pointerE</i> | Element <i>j</i> of this integer array gives the index of the element in the <i>columns</i> array that contains the last non-zero block in a row <i>j</i> of the block matrix plus 1.                                                                                                                                                                                                                                                                                               |

The length of the *values* array is equal to the number of all elements in the non-zero blocks, the length of the *columns* array is equal to the number of non-zero blocks. The length of the *pointerB* and *pointerE* arrays is equal to the number of block rows in the block matrix.

### NOTE

Note that the Intel MKL Sparse BLAS routines support BSR format both with one-based indexing and zero-based indexing.

For example, consider the sparse matrix *D*

$$D = \begin{pmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ * & * & 1 & 4 & * & * \\ * & * & 5 & 1 & * & * \\ * & * & 4 & 3 & 7 & 2 \\ * & * & 0 & 0 & 0 & 0 \end{pmatrix}$$

If the size of the block equals 2, then the sparse matrix *D* can be represented as a 3x3 block matrix *E* with the following structure:

$$E = \begin{pmatrix} L & M & * \\ * & N & * \\ * & P & Q \end{pmatrix}$$

where

$$L = \begin{pmatrix} 1 & 0 \\ 2 & 1 \end{pmatrix}, \quad M = \begin{pmatrix} 6 & 7 \\ 8 & 2 \end{pmatrix}, \quad N = \begin{pmatrix} 1 & 4 \\ 5 & 1 \end{pmatrix}, \quad P = \begin{pmatrix} 4 & 3 \\ 0 & 0 \end{pmatrix}, \quad Q = \begin{pmatrix} 7 & 2 \\ 0 & 0 \end{pmatrix}$$

The matrix *D* can be represented in the BSR format as follows:

one-based indexing

```
values = (1 2 0 1 6 8 7 2 1 5 4 1 4 0 3 0 7 0 2 0)
columns = (1 2 2 2 3)
pointerB = (1 3 4)
pointerE = (3 4 6)
```

zero-based indexing

```
values = [1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0]
columns = [0 1 1 1 2]
pointerB = [0 2 3]
pointerE = [2 3 5]
```

This storage format is supported by the NIST Sparse BLAS library [[Rem05](#)].

**Three Array Variation of BSR Format**

Intel MKL supports the variation of the BSR format that is specified by three arrays: *values*, *columns*, and *rowIndex*. The following table describes these arrays.

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>values</i>   | A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block by block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of them is equal to zero. Within each non-zero block the elements are stored in column major order in the case of the one-based indexing, and in row major order in the case of the zero-based indexing. |
| <i>columns</i>  | Element <i>i</i> of the integer array <i>columns</i> is the number of the column in the block matrix that contains the <i>i</i> -th non-zero block.                                                                                                                                                                                                                                                                                                                                        |
| <i>rowIndex</i> | Element <i>j</i> of this integer array gives the index of the element in the <i>columns</i> array that is first non-zero block in a row <i>j</i> of the block matrix.                                                                                                                                                                                                                                                                                                                      |

The length of the *values* array is equal to the number of all elements in the non-zero blocks, the length of the *columns* array is equal to the number of non-zero blocks.

As the *rowIndex* array gives the location of the first non-zero block within a row, and the non-zero blocks are stored consecutively, the number of non-zero blocks in the *i*-th row is equal to the difference of *rowIndex*[*i*] and *rowIndex*[*i*+1].

To retain this relationship for the last row of the block matrix, an additional entry (dummy entry) is added to the end of *rowIndex* with value equal to the number of non-zero blocks plus one. This makes the total length of the *rowIndex* array one larger than the number of rows of the block matrix.

The above matrix *D* can be represented in this 3-array variation of the BSR format as follows:

one-based indexing

```
values = [1 2 0 1 6 8 7 2 1 5 4 2 4 0 3 0 7 0 2 0]
columns = [1 2 2 2 3]
rowIndex = [1 3 4 6]
```

zero-based indexing

```
values = [1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0]
columns = [0 1 1 1 2]
rowIndex = [0 2 3 5]
```

When storing symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For example, consider the symmetric sparse matrix *F*:

$$F = \begin{pmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ 6 & 8 & 1 & 4 & * & * \\ 7 & 2 & 5 & 2 & * & * \\ * & * & * & * & 7 & 2 \\ * & * & * & * & 0 & 0 \end{pmatrix}$$

If the size of the block equals 2, then the sparse matrix  $F$  can be represented as a 3x3 block matrix  $G$  with the following structure:

$$G = \begin{pmatrix} L & M & * \\ M' & N & * \\ * & * & Q \end{pmatrix}$$

where

$$L = \begin{pmatrix} 1 & 0 \\ 2 & 1 \end{pmatrix}, M = \begin{pmatrix} 6 & 7 \\ 8 & 2 \end{pmatrix}, M' = \begin{pmatrix} 6 & 8 \\ 7 & 2 \end{pmatrix}, N = \begin{pmatrix} 1 & 4 \\ 5 & 2 \end{pmatrix}, \text{ and } Q = \begin{pmatrix} 7 & 2 \\ 0 & 0 \end{pmatrix}$$

The symmetric matrix  $F$  can be represented in this 3-array variation of the BSR format (storing only the upper triangular part) as follows:

one-based indexing

```
values = [1 2 0 1 6 8 7 2 1 5 4 2 7 0 2 0]
columns = [1 2 2 3]
rowIndex = [1 3 4 5]
```

zero-based indexing

```
values = [1 0 2 1 6 7 8 2 1 4 5 2 7 2 0 0]
columns = [0 1 1 2]
rowIndex = [0 2 3 4]
```

### Variable BSR Format

A variation of BSR3 is variable block compressed sparse row format. For a trust level  $t$ ,  $0 \leq t \leq 100$ , rows similar up to  $t$  percent are placed in one supernode.

# Routine and Function Arguments

The major arguments in the BLAS routines are vector and matrix, whereas VM functions work on vector arguments only. The sections that follow discuss each of these arguments and provide examples.

## Vector Arguments in BLAS

Vector arguments are passed in one-dimensional arrays. The array dimension (length) and vector increment are passed as integer variables. The length determines the number of elements in the vector. The increment (also called stride) determines the spacing between vector elements and the order of the elements in the array in which the vector is passed.

A vector of length  $n$  and increment  $incx$  is passed in a one-dimensional array  $x$  whose values are defined as

```
x[0], x[|incx|], ..., x[(n-1)* |incx|]
```

If  $incx$  is positive, then the elements in array  $x$  are stored in increasing order. If  $incx$  is negative, the elements in array  $x$  are stored in decreasing order with the first element defined as  $x[(n-1)* |incx|]$ . If  $incx$  is zero, then all elements of the vector have the same value,  $x[0]$ . The size of the one-dimensional array that stores the vector must always be at least

```
idimx = 1 + (n-1)* |incx|
```

### Example. One-dimensional Real Array

Let  $x[0:6]$  be the one-dimensional real array

```
x = [1.0, 3.0, 5.0, 7.0, 9.0, 11.0, 13.0].
```

If  $incx = 2$  and  $n = 3$ , then the vector argument with elements in order from first to last is  $[1.0, 5.0, 9.0]$ .

If  $incx = -2$  and  $n = 4$ , then the vector elements in order from first to last is  $[13.0, 9.0, 5.0, 1.0]$ .

If  $incx = 0$  and  $n = 4$ , then the vector elements in order from first to last is  $[1.0, 1.0, 1.0, 1.0]$ .

One-dimensional substructures of a matrix, such as the rows, columns, and diagonals, can be passed as vector arguments with the starting address and increment specified.

Storage of the  $m$ -by- $n$  matrix can be based on either column-major ordering where the increment between elements in the same column is 1, the increment between elements in the same row is  $m$ , and the increment between elements on the same diagonal is  $m + 1$ ; or row-major ordering where the increment between elements in the same row is 1, the increment between elements in the same column is  $n$ , and the increment between elements on the same diagonal is  $n + 1$ .

### Example. Two-dimensional Real Matrix

Let  $a$  be a real  $5 \times 4$  matrix declared as .

To scale the third column of  $a$  by 2.0, use the BLAS routine `sscal` with the following calling sequence:

```
cblas_sscal (5, 2.0, a[2], 4)
```

To scale the second row, use the statement:

```
cblas_sscal (4, 2.0, a[4], 1)
```

To scale the main diagonal of  $a$  by 2.0, use the statement:

```
cblas_sscal (4, 2.0, a[0], 5)
```

---

**NOTE**

The default vector argument is assumed to be 1.

---

## Vector Arguments in VM

---

Vector arguments of VM mathematical functions are passed in one-dimensional arrays with unit vector increment. It means that a vector of length  $n$  is passed contiguously in an array  $a$  whose values are defined as

$$a[0], a[1], \dots, a[n-1].$$

To accommodate for arrays with other increments, or more complicated indexing, VM contains auxiliary pack/unpack functions that gather the array elements into a contiguous vector and then scatter them after the computation is complete.

Generally, if the vector elements are stored in a one-dimensional array  $a$  as

$$a[m_0], a[m_1], \dots, a[m_n-1]$$

and need to be regrouped into an array  $y$  as

$$y[k_0], y[k_1], \dots, y[k_n-1],.$$

VM pack/unpack functions can use one of the following indexing methods:

### Positive Increment Indexing

$$k_j = \text{incy} * j, m_j = \text{inca} * j, j = 0, \dots, n-1.$$

Constraint:  $\text{incy} > 0$  and  $\text{inca} > 0$ .

For example, setting  $\text{incy} = 1$  specifies gathering array elements into a contiguous vector.

This method is similar to that used in BLAS, with the exception that negative and zero increments are not permitted.

### Index Vector Indexing

$$k_j = \text{iy}[j], m_j = \text{ia}[j], j = 0, \dots, n-1,.$$

where  $\text{ia}$  and  $\text{iy}$  are arrays of length  $n$  that contain index vectors for the input and output arrays  $a$  and  $y$ , respectively.

### Mask Vector Indexing

Indices  $k_j, m_j$  are such that:

$$m_y[k_j] \neq 0, m_a[m_j] \neq 0, j = 0, \dots, n-1,.$$

where  $m_a$  and  $m_y$  are arrays that contain mask vectors for the input and output arrays  $a$  and  $y$ , respectively.

## Matrix Arguments

---

Matrix arguments of the Intel® Math Kernel Library routines can be stored in arrays, using the following storage schemes:

- [conventional full storage](#)
- [packed storage](#) for Hermitian, symmetric, or triangular matrices
- [band storage](#) for band matrices
- [rectangular full packed storage](#) for symmetric, Hermitian, or triangular matrices as compact as the Packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels.

**Full storage** is the simplest scheme. A matrix  $A$  is stored in a one-dimensional array  $a$ , with the matrix element  $a_{ij}$  stored in the array element  $a[i - 1 + (j - 1)*lda]$ , where  $lda$  is the leading dimension of array  $a$ .

If a matrix is triangular (upper or lower, as specified by the argument  $uplo$ ), only the elements of the relevant triangle are stored; the remaining elements of the array need not be set.

Routines that handle symmetric or Hermitian matrices allow for either the upper or lower triangle of the matrix to be stored in the corresponding elements of the array:

if  $uplo = 'U'$ ,  $a_{ij}$  is stored as described for  $i \leq j$ , other elements of  $a$  need not be set.

if  $uplo = 'L'$ ,  $a_{ij}$  is stored as described for  $j \leq i$ , other elements of  $a$  need not be set.

**Packed storage** allows you to store symmetric, Hermitian, or triangular matrices more compactly: the relevant triangle (again, as specified by the argument  $uplo$ ) is packed by columns in a one-dimensional array  $ap$ :

if  $uplo = 'U'$ ,  $a_{ij}$  is stored in  $ap[i - 1 + j(j - 1)/2]$  for  $i \leq j$

if  $uplo = 'L'$ ,  $a_{ij}$  is stored in  $ap[i - 1 + (2*n - j)*(j - 1)/2]$  for  $j \leq i$ .

In descriptions of LAPACK routines, arrays with packed matrices have names ending in  $p$ .

**Band storage** is as follows: an  $m$ -by- $n$  band matrix with  $kl$  non-zero sub-diagonals and  $ku$  non-zero super-diagonals is stored compactly in an array  $ab$  with  $(kl+ku + 1)*n$  elements. Thus,

$a_{ij}$  is stored in  $ab(ku+1+i-j,j)$  for  $\max(1,j-ku) \leq i \leq \min(n,j+kl)$ .

Use the band storage scheme only when  $kl$  and  $ku$  are much less than the matrix size  $n$ . Although the routines work correctly for all values of  $kl$  and  $ku$ , using the band storage is inefficient if your matrices are not really banded.

The band storage scheme is illustrated by the following example, when

$$m = n = 6, \quad kl = 2, \quad ku = 1$$

Array elements marked \* are not used by the routines:

When a general band matrix is supplied for *LU factorization*, space must be allowed to store  $kl$  additional super-diagonals generated by fill-in as a result of row interchanges. This means that the matrix is stored according to the above scheme, but with  $kl + ku$  super-diagonals. Thus,

$a_{ij}$  is stored in  $ab(kl+ku+1+i-j, j)$  for  $\max(1, j-ku) \leq i \leq \min(n, j+kl)$ .

The band storage scheme for LU factorization is illustrated by the following example, when  $m = n = 6$ ,  $kl = 2$ ,  $ku = 1$ :

| Banded matrix A |          |          |          |          |          | Band storage of A |          |          |          |          |          |

Array elements marked \* are not used by the routines; elements marked + need not be set on entry, but are required by the LU factorization routines to store the results. The input array will be overwritten on exit by the details of the LU factorization as follows:

|          |          |          |          |          |          |
|----------|----------|----------|----------|----------|----------|
| *        | *        | *        | $u_{14}$ | $u_{25}$ | $u_{36}$ |
| *        | *        | $u_{13}$ | $u_{24}$ | $u_{35}$ | $u_{46}$ |
| *        | $u_{12}$ | $u_{23}$ | $u_{34}$ | $u_{45}$ | $u_{56}$ |
| $u_{11}$ | $u_{22}$ | $u_{33}$ | $u_{44}$ | $u_{55}$ | $u_{66}$ |
| $m_{21}$ | $m_{32}$ | $m_{43}$ | $m_{54}$ | $m_{65}$ | *        |
| $m_{31}$ | $m_{42}$ | $m_{53}$ | $m_{64}$ | *        | *        |

where  $u_{ij}$  are the elements of the upper triangular matrix U, and  $m_{ij}$  are the multipliers used during factorization.

Triangular band matrices are stored in the same format, with either  $kl=0$  if upper triangular, or  $ku=0$  if lower triangular. For symmetric or Hermitian band matrices with  $k$  sub-diagonals or super-diagonals, you need to store only the upper or lower triangle, as specified by the argument *uplo*:

if *uplo* = 'U',  $a_{ij}$  is stored in  $ab(k+1+i-j,j)$  for  $\max(1,j-k) \leq i \leq j$

if *uplo* = 'L',  $a_{ij}$  is stored in  $ab(1+i-j,j)$  for  $j \leq i \leq \min(n,j+k)$ .

In descriptions of LAPACK routines, arrays that hold matrices in band storage have names ending in *b*.

In Fortran, column-major ordering of storage is assumed. This means that elements of the same column occupy successive storage locations.

Three quantities are usually associated with a two-dimensional array argument: its leading dimension, which specifies the number of storage locations between elements in the same row, its number of rows, and its number of columns. For a matrix in full storage, the leading dimension of the array must be at least as large as the number of rows in the matrix.

A character transposition parameter is often passed to indicate whether the matrix argument is to be used in normal or transposed form or, for a complex matrix, if the conjugate transpose of the matrix is to be used.

The values of the transposition parameter for these three cases are the following:

'N' or 'n'                      normal (no conjugation, no transposition)

|            |                      |
|------------|----------------------|
| 'T' or 't' | transpose            |
| 'C' or 'c' | conjugate transpose. |

### Example. Two-Dimensional Complex Array

Suppose  $A$  (1:5, 1:4) is the complex two-dimensional array presented by matrix

$$\begin{bmatrix} (1.1, 0.11) & (1.2, 0.12) & (1.3, 0.13) & (1.4, 0.14) \\ (2.1, 0.21) & (2.2, 0.22) & (2.3, 0.23) & (1.4, 0.24) \\ (3.1, 0.31) & (3.2, 0.32) & (3.3, 0.33) & (1.4, 0.34) \\ (4.1, 0.41) & (4.2, 0.42) & (4.3, 0.43) & (1.4, 0.44) \\ (5.1, 0.51) & (5.2, 0.52) & (5.3, 0.53) & (1.4, 0.54) \end{bmatrix}$$

Let  $transa$  be the transposition parameter,  $m$  be the number of rows,  $n$  be the number of columns, and  $lda$  be the leading dimension. Then if

$transa = 'N'$ ,  $m = 4$ ,  $n = 2$ , and  $lda = 5$ , the matrix argument would be

$$\begin{bmatrix} (1.1, 0.11) & (1.2, 0.12) \\ (2.1, 0.21) & (2.2, 0.22) \\ (3.1, 0.31) & (3.2, 0.32) \\ (4.1, 0.41) & (4.2, 0.42) \end{bmatrix}$$

If  $transa = 'T'$ ,  $m = 4$ ,  $n = 2$ , and  $lda = 5$ , the matrix argument would be

$$\begin{bmatrix} (1.1, 0.11) & (2.1, 0.21) & (3.1, 0.31) & (4.1, 0.41) \\ (1.2, 0.12) & (2.2, 0.22) & (3.2, 0.32) & (4.2, 0.42) \end{bmatrix}$$

If  $transa = 'C'$ ,  $m = 4$ ,  $n = 2$ , and  $lda = 5$ , the matrix argument would be

$$\begin{bmatrix} (1.1, -0.11) & (2.1, -0.21) & (3.1, -0.31) & (4.1, -0.41) \\ (1.2, -0.12) & (2.2, -0.22) & (3.2, -0.32) & (4.2, -0.42) \end{bmatrix}$$

Note that care should be taken when using a leading dimension value which is different from the number of rows specified in the declaration of the two-dimensional array. For example, suppose the array  $A$  above is declared as a complex 5-by-4 matrix.

Then if  $transa = 'N'$ ,  $m = 3$ ,  $n = 4$ , and  $lda = 4$ , the matrix argument will be

$$\begin{bmatrix} (1.1, 0.11) & (5.1, 0.51) & (4.2, 0.42) & (3.3, 0.33) \\ (2.1, 0.21) & (1.2, 0.12) & (5.2, 0.52) & (4.3, 0.43) \\ (3.1, 0.31) & (2.2, 0.22) & (1.3, 0.13) & (5.3, 0.53) \end{bmatrix}$$

**Rectangular Full Packed storage** allows you to store symmetric, Hermitian, or triangular matrices as compact as the Packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels. To store an  $n$ -by- $n$  triangle (and suppose for simplicity that  $n$  is even), you partition the triangle into three parts: two  $n/2$ -by- $n/2$  triangles and an  $n/2$ -by- $n/2$  square, then pack this as an  $n$ -by- $n/2$  rectangle (or  $n/2$ -by- $n$  rectangle), by transposing (or transpose-conjugating) one of the triangles and packing it next to the other triangle. Since the two triangles are stored in full storage, you can use existing efficient routines on them.

There are eight cases of RFP storage representation: when  $n$  is even or odd, the packed matrix is transposed or not, the triangular matrix is lower or upper. See below for all the eight storage schemes illustrated:

$n$  is odd,  $A$  is lower triangular

| Full format                                                    | RFP (not transposed)                | RFP (transposed)                                               |

Intel MKL provides a number of routines such as `?hfrk`, `?sfrk` performing BLAS operations working directly on RFP matrices, as well as some conversion routines, for instance, `?tpttf` goes from the standard packed format to RFP and `?trttf` goes from the full format to RFP.

Please refer to the Netlib site for more information.

Note that in the descriptions of LAPACK routines, arrays with RFP matrices have names ending in `fp`.

# FFTW Interface to Intel® Math Kernel Library

Intel® Math Kernel Library (Intel® MKL) offers FFTW2 and FFTW3 interfaces to Intel MKL Fast Fourier Transform and Trigonometric Transform functionality. The purpose of these interfaces is to enable applications using FFTW ([www.fftw.org](http://www.fftw.org)) to gain performance with Intel MKL without changing the program source code.

Both FFTW2 and FFTW3 interfaces are provided in open source as FFTW wrappers to Intel MKL. For ease of use, FFTW3 interface is also integrated in Intel MKL.

## FFTW Notational Conventions

This appendix typically employs path notations for Windows\* OS.

## FFTW2 Interface to Intel® Math Kernel Library

This section describes a collection of C and Fortran wrappers providing FFTW 2.x interface to Intel MKL. The wrappers translate calls to FFTW 2.x functions into the calls of the Intel MKL Fast Fourier Transform interface (FFT interface).

Note that Intel MKL FFT interface operates on both single- and double-precision floating-point data types.

Because of differences between FFTW and Intel MKL FFT functionalities, there are restrictions on using wrappers instead of the FFTW functions. Some FFTW functions have empty wrappers. However, many typical FFTs can be computed using these wrappers.

Refer to [chapter 11 "Fourier Transform Functions"](#), for better understanding the effects from the use of the wrappers.

### Wrappers Reference

The section provides a brief reference for the FFTW 2.x C interface. For details please refer to the original FFTW 2.x documentation available at [www.fftw.org](http://www.fftw.org).

Each FFTW function has its own wrapper. Some of them, which are *not* expressly listed in this section, are empty and do nothing, but they are provided to avoid link errors and satisfy the function calls.

### One-dimensional Complex-to-complex FFTs

The following functions compute a one-dimensional complex-to-complex Fast Fourier transform.

```
fftw_plan fftw_create_plan(int n, fftw_direction dir, int flags);
fftw_plan fftw_create_plan_specific(int n, fftw_direction dir, int flags, fftw_complex
*in, int istride, fftw_complex *out, int ostride);

void fftw(fftw_plan plan, int howmany, fftw_complex *in, int istride, int idist,
fftw_complex *out, int ostride, int odist);

void fftw_one(fftw_plan plan, fftw_complex *in , fftw_complex *out);

void fftw_destroy_plan(fftw_plan plan);
```

## Multi-dimensional Complex-to-complex FFTs

The following functions compute a multi-dimensional complex-to-complex Fast Fourier transform.

```
fftwnd_plan fftwnd_create_plan(int rank, const int *n, fftw_direction dir, int flags);
fftwnd_plan fftw2d_create_plan(int nx, int ny, fftw_direction dir, int flags);
fftwnd_plan fftw3d_create_plan(int nx, int ny, int nz, fftw_direction dir, int flags);
fftwnd_plan fftwnd_create_plan_specific(int rank, const int *n, fftw_direction dir, int flags,
fftw_complex *in, int istride, fftw_complex *out, int ostride);
fftwnd_plan fftw2d_create_plan_specific(int nx, int ny, fftw_direction dir, int flags,
fftw_complex *in, int istride, fftw_complex *out, int ostride);
fftwnd_plan fftw3d_create_plan_specific(int nx, int ny, int nz, fftw_direction dir, int flags,
fftw_complex *in, int istride, fftw_complex *out, int ostride);

void fftwnd(fftwnd_plan plan, int howmany, fftw_complex *in, int istride, int idist,
fftw_complex *out, int ostride, int odist);

void fftwnd_one(fftwnd_plan plan, fftw_complex *in, fftw_complex *out);

void fftwnd_destroy_plan(fftwnd_plan plan);
```

## One-dimensional Real-to-half-complex/Half-complex-to-real FFTs

Half-complex representation of a conjugate-even symmetric vector of size  $N$  in a real array of the same size  $N$  consists of  $N/2+1$  real parts of the elements of the vector followed by non-zero imaginary parts in the reverse order. Because the Intel MKL FFT interface does not currently support this representation, all wrappers of this kind are empty and do nothing.

Nevertheless, you can perform one-dimensional real-to-complex and complex-to-real transforms using `rfftwnd` functions with `rank=1`.

## Multi-dimensional Real-to-complex/Complex-to-real FFTs

The following functions compute multi-dimensional real-to-complex and complex-to-real Fast Fourier transforms.

```
rfftwnd_plan rfftwnd_create_plan(int rank, const int *n, fftw_direction dir, int flags);
rfftwnd_plan rfftw2d_create_plan(int nx, int ny, fftw_direction dir, int flags);
rfftwnd_plan rfftw3d_create_plan(int nx, int ny, int nz, fftw_direction dir, int flags);

rfftwnd_plan rfftwnd_create_plan_specific(int rank, const int *n, fftw_direction dir, int flags,
fftw_real *in, int istride, fftw_real *out, int ostride);
rfftwnd_plan rfftw2d_create_plan_specific(int nx, int ny, fftw_direction dir, int flags,
fftw_real *in, int istride, fftw_real *out, int ostride);
rfftwnd_plan rfftw3d_create_plan_specific(int nx, int ny, int nz, fftw_direction dir, int flags,
fftw_real *in, int istride, fftw_real *out, int ostride);

void rfftwnd_real_to_complex(rfftwnd_plan plan, int howmany, fftw_real *in, int istride, int idist,
fftw_complex *out, int ostride, int odist);

void rfftwnd_complex_to_real(rfftwnd_plan plan, int howmany, fftw_complex *in, int istride, int idist,
fftw_real *out, int ostride, int odist);

void rfftwnd_one_real_to_complex(rfftwnd_plan plan, fftw_real *in, fftw_complex *out);
```

```
void rffftwnd_one_complex_to_real(rffftwnd_plan plan, fftw_complex *in, fftw_real *out);
void rffftwnd_destroy_plan(rffftwnd_plan plan);
```

## Multi-threaded FFTW

This section discusses multi-threaded FFTW wrappers only. MPI FFTW wrappers, available only with Intel MKL for the Linux\* and Windows\* operating systems, are described in [section "MPI FFTW Wrappers"](#).

Unlike the original FFTW interface, every computational function in the FFTW2 interface to Intel MKL provides multithreaded computation by default, with the maximum number of threads permitted in FFT functions (see "Techniques to Set the Number of Threads" in *Intel MKL Developer Guide*). To limit the number of threads, call the threaded FFTW computational functions:

```
void fftw_threads(int nthreads, fftw_plan plan, int howmany, fftw_complex *in, int
istride, int idist, fftw_complex *out, int ostride, int odist);
void fftw_threads_one(int nthreads, rffftwnd_plan plan, fftw_complex *in, fftw_complex
*out);
...
void rffftwnd_threads_real_to_complex(int nthreads, rffftwnd_plan plan, int howmany,
fftw_real *in, int istride, int idist, fftw_complex *out, int ostride, int odist);
```

Compared to its non-threaded counterpart, every threaded computational function has `threads_` as the second part of its name and additional first parameter `nthreads`. Set the `nthreads` parameter to the thread limit to ensure that the computation requires at most that number of threads.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## FFTW Support Functions

The FFTW wrappers provide memory allocation functions to be used with FFTW:

```
void* fftw_malloc(size_t n);
void fftw_free(void* x);
```

The `fftw_malloc` wrapper aligns the memory on a 16-byte boundary.

If `fftw_malloc` fails to allocate memory, it aborts the application. To override this behavior, set a global variable `fftw_malloc_hook` and optionally the complementary variable `fftw_free_hook`:

```
void>(*fftw_malloc_hook)(size_t n);
void(*fftw_free_hook)(void *p);
```

The wrappers use the function `fftw_die` to abort the application in cases when a caller cannot be informed of an error otherwise (for example, in computational functions that return `void`). To override this behavior, set a global variable `fftw_die_hook`:

```
void(*fftw_die_hook)(const char *error_string);
void fftw_die(const char *s);
```

## Limitations of the FFTW2 Interface to Intel MKL

The FFTW2 wrappers implement the functionality of only those FFTW functions that Intel MKL can reasonably support. Other functions are provided as no-operation functions, whose only purpose is to satisfy link-time symbol resolution. Specifically, no-operation functions include:

- Real-to-half-complex and respective backward transforms
- Print plan functions
- Functions for importing/exporting/forgetting wisdom
- Most of the FFTW functions not covered by the original FFTW2 documentation

Because the Intel MKL implementation of FFTW2 wrappers does not use plan and plan node structures declared in `fftw.h`, the behavior of an application that relies on the internals of the plan structures defined in that header file is undefined.

FFTW2 wrappers define plan as a set of attributes, such as strides, used to commit the Intel MKL FFT descriptor structure. If an FFTW2 computational function is called with attributes different from those recorded in the plan, the function attempts to adjust the attributes of the plan and recommit the descriptor. So, repeated calls of a computational function with the same plan but different strides, distances, and other parameters may be performance inefficient.

Plan creation functions disregard most planner flags passed through the `flags` parameter. These functions take into account only the following values of `flags`:

- `FFTW_IN_PLACE`

If this value of `flags` is supplied, the plan is marked so that computational functions using that plan ignore the parameters related to output (`out`, `ostride`, and `odist`). Unlike the original FFTW interface, the wrappers never use the `out` parameter as a scratch space for in-place transforms.

- `FFTW_THREADSAFE`

If this value of `flags` is supplied, the plan is marked read-only. An attempt to change attributes of a read-only plan aborts the application.

FFTW wrappers are generally not thread safe. Therefore, do not use the same plan in parallel user threads simultaneously.

## Installing FFTW2 Interface Wrappers

Wrappers are delivered as source code, which you must compile to build the wrapper library. Then you can substitute the wrapper and Intel MKL libraries for the FFTW library. The source code for the wrappers, makefiles, and files with lists of wrappers are located in the `.\interfaces\fftw2xc` subdirectory in the Intel MKL directory.

## Creating the Wrapper Library

Two header files are used to compile the C wrapper library: `fftw2_mkl.h` and `fftw.h`. The `fftw2_mkl.h` file is located in the `.\interfaces\fftw2xc\wrappers` subdirectory in the Intel MKL directory.

The file `fftw.h`, used to compile libraries and located in the `.\include\fftw` subdirectory in the Intel MKL directory, slightly differs from the original FFTW ([www.fftw.org](http://www.fftw.org)) header file `fftw.h`.

The source code for the wrappers, makefiles, and files with lists of functions are located in the `.\interfaces\fftw2xc` subdirectory in the Intel MKL directory.

A wrapper library contains wrappers for complex and real transforms in a serial and multi-threaded mode for double- or single-precision floating-point data types. A makefile parameter manages the data type.

Parameters of a makefile also specify the platform (required), compiler, and data precision. The makefile comment heading provides the exact description of these parameters.

To build the library, run the `make` command on Linux\* OS and macOS\* or the `nmake` command on Windows\* OS with appropriate parameters.

For example, on Linux OS the command

```
make libintel64
```

builds a double-precision wrapper library for Intel® 64 architecture based applications using the Intel® C++ Compiler or the Intel® Fortran Compiler (Compilers and data precision are chosen by default.)

Each makefile creates the library in the directory with Intel MKL libraries corresponding to the platform used. For example, `./lib/ia32` (on Linux OS and macOS) or `.\lib\ia32` (on Windows\* OS).

In the names of a wrapper library, the suffix corresponds to the compiler used and the letter preceding the underscore is "c" for the C programming language.

For example,

```
fftw2xc_intel.lib (on Windows OS); libfftw2xc_intel.a (on Linux OS and macOS);
```

```
fftw2xc_ms.lib (on Windows OS); libfftw2xc_gnu.a (on Linux OS and macOS).
```

## Application Assembling

Use the necessary original FFTW ([www.fftw.org](http://www.fftw.org)) header files without any modifications. Use the created wrapper library and the Intel MKL library instead of the FFTW library.

## Running FFTW2 Interface Wrapper Examples

Intel MKL provides examples to demonstrate how to use the MPI FFTW wrapper library. The source code for the examples, makefiles used to run them, and files with lists of examples are located in the `.\examples\fftw2xc` subdirectory in the Intel MKL directory. To build examples, several additional files are needed: `fftw.h`, `fftw_threads.h`, `rfftw.h`, and `rfftw_threads.h`. These files are distributed with permission from FFTW and are available in `.\include\fftw`. The original files can also be found in FFTW 2.1.5 at <http://www.fftw.org/download.html>.

An example makefile uses the `function` parameter in addition to the parameters of the corresponding wrapper library makefile (see [Creating a Wrapper Library](#)). The makefile comment heading provides the exact description of these parameters.

An example makefile normally invokes `examples`. However, if the appropriate wrapper library is not yet created, the makefile first builds the library the same way as the wrapper library makefile does and then proceeds to `examples`.

If the parameter `function=<example_name>` is defined, only the specified example runs. Otherwise, all examples from the appropriate subdirectory run. The subdirectory `.\_results` is created, and the results are stored there in the `<example_name>.res` files.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## MPI FFTW2 Wrappers

MPI FFTW wrappers for FFTW 2 are available only with Intel® MKL for the Linux\* and Windows\* operating systems.

## MPI FFTW Wrappers Reference

The section provides a reference for MPI FFTW C interface.

### Complex MPI FFTW

#### Complex One-dimensional MPI FFTW Transforms

```
fftw_mpi_plan fftw_mpi_create_plan(MPI_Comm comm, int n, fftw_direction dir, int
flags);

void fftw_mpi(fftw_mpi_plan p, int n_fields, fftw_complex *local_data, fftw_complex
*work);

void fftw_mpi_local_sizes(fftw_mpi_plan p, int *local_n, int *local_start, int
*local_n_after_transform, int *local_start_after_transform, int *total_local_size);

void fftw_mpi_destroy_plan(fftw_mpi_plan plan);
```

*Argument restrictions:*

- Supported values of *flags* are FFTW\_ESTIMATE, FFTW\_MEASURE, FFTW\_SCRAMBLED\_INPUT and FFTW\_SCRAMBLED\_OUTPUT. The same algorithm corresponds to all these values of the flags parameter. If any other *flags* value is supplied, the wrapper library reports an error '*CDFT error in wrapper: unknown flags*'.
- The only supported value of *n\_fields* is 1.

#### Complex Multi-dimensional MPI FFTW Transforms

```
fftwnd_mpi_plan fftw2d_mpi_create_plan(MPI_Comm comm, int nx, int ny, fftw_direction
dir, int flags);

fftwnd_mpi_plan fftw3d_mpi_create_plan(MPI_Comm comm, int nx, int ny, int nz,
fftw_direction dir, int flags);

fftwnd_mpi_plan fftwnd_mpi_create_plan(MPI_Comm comm, int dim, int *n, fftw_direction
dir, int flags);

void fftwnd_mpi(fftwnd_mpi_plan p, int n_fields, fftw_complex *local_data, fftw_complex
*work, fftwnd_mpi_output_order output_order);

void fftwnd_mpi_local_sizes(fftwnd_mpi_plan p, int *local_nx, int *local_x_start, int
*local_ny_after_transpose, int *local_y_start_after_transpose, int *total_local_size);

void fftwnd_mpi_destroy_plan(fftwnd_mpi_plan plan);
```

*Argument restrictions:*

- Supported values of *flags* are FFTW\_ESTIMATE and FFTW\_MEASURE. If any other value of *flags* is supplied, the wrapper library reports an error '*CDFT error in wrapper: unknown flags*'.
- The only supported value of *n\_fields* is 1.

### Real MPI FFTW

#### Real-to-Complex MPI FFTW Transforms

```
rfftwnd_mpi_plan rfftw2d_mpi_create_plan(MPI_Comm comm, int nx, int ny, fftw_direction
dir, int flags);

rfftwnd_mpi_plan rfftw3d_mpi_create_plan(MPI_Comm comm, int nx, int ny, int nz,
fftw_direction dir, int flags);
```

```

rfftwnd_mpi_plan rfftwnd_mpi_create_plan(MPI_Comm comm, int dim, int *n, fftw_direction
dir, int flags);

void rfftwnd_mpi(rfftwnd_mpi_plan p, int n_fields, fftw_real *local_data, fftw_real
*work, fftwnd_mpi_output_order output_order);

void rfftwnd_mpi_local_sizes(rfftwnd_mpi_plan p, int *local_nx, int *local_x_start, int
*local_ny_after_transpose, int *local_y_start_after_transpose, int *total_local_size);

void rfftwnd_mpi_destroy_plan(rfftwnd_mpi_plan plan);

```

#### Argument restrictions:

- Supported values of *flags* are FFTW\_ESTIMATE and FFTW\_MEASURE. If any other value of *flags* is supplied, the wrapper library reports an error 'CDFT error in wrapper: unknown flags'.
- The only supported value of *n\_fields* is 1.

- 
- Function *rfftwnd\_mpi\_create\_plan* can be used for both one-dimensional and multi-dimensional transforms.
  - Both values of the *output\_order* parameter are supported: FFTW\_NORMAL\_ORDER and FFTW\_TRANSPOSED\_ORDER.
- 

## Creating MPI FFTW2 Wrapper Library

The source code for the wrappers, makefiles, and files with lists of wrappers are located in the `.\interfaces\fftw2x_cdft` subdirectory in the Intel MKL directory.

A wrapper library contains C wrappers for Complex One-dimensional MPI FFTW Transforms and Complex Multi-dimensional MPI FFTW Transforms. The library also contains empty C wrappers for Real Multi-dimensional MPI FFTW Transforms. For details, see [MPI FFTW Wrappers Reference](#).

Parameters of a makefile specify the platform (required), compiler, and data precision. Specifying the platform is required. The makefile comment heading provides the exact description of these parameters.

To build the library, run the `make` command on Linux\* OS and macOS\* or the `nmake` command on Windows\* OS with appropriate parameters.

For example, on Linux OS the command

```
make libintel64
```

builds a double-precision wrapper library for Intel® 64 architecture based applications using Intel MPI and the Intel® C++ Compiler (compilers and data precision are chosen by default.).

A makefile creates the wrapper library in the directory with the Intel MKL libraries corresponding to the used platform. For example, `./lib/ia32` (on Linux OS) or `.\lib\ia32` (on Windows\* OS).

In the wrapper library names, the suffix corresponds to the used data precision. For example,

```
fftw2x_cdft_SINGLE.lib on Windows OS;
```

```
libfftw2x_cdft_DOUBLE.a on Linux OS.
```

## Application Assembling with MPI FFTW Wrapper Library

Use the necessary original FFTW ([www.fftw.org](http://www.fftw.org)) header files without any modifications. Use the created MPI FFTW wrapper library and the Intel MKL library instead of the FFTW library.

## Running MPI FFTW2 Wrapper Examples

There are some examples that demonstrate how to use the MPI FFTW wrapper library for FFTW2. The source C code for the examples, makefiles used to run them, and files with lists of examples are located in the `.\examples\fftw2x_cdft` subdirectory in the Intel MKL directory. To build examples, one additional file `fftw_mpi.h` is needed. This file is distributed with permission from FFTW and is available in `.\include\fftw`. The original file can also be found in FFTW 2.1.5 at <http://www.fftw.org/download.html>.

Parameters for the example makefiles are described in the makefile comment headings and are similar to the parameters of the wrapper library makefiles (see [Creating MPI FFTW Wrapper Library](#)).

The table below lists examples available in the `.\examples\fftw2x_cdft\source` subdirectory.

### Examples of MPI FFTW Wrappers

| Source file for the example | Description                                                                                         |
|-----------------------------|-----------------------------------------------------------------------------------------------------|
| <code>wrappers_c1d.c</code> | One-dimensional Complex MPI FFTW transform, using <code>plan = fftw_mpi_create_plan(...)</code>     |
| <code>wrappers_c2d.c</code> | Two-dimensional Complex MPI FFTW transform, using <code>plan = fftw2d_mpi_create_plan(...)</code>   |
| <code>wrappers_c3d.c</code> | Three-dimensional Complex MPI FFTW transform, using <code>plan = fftw3d_mpi_create_plan(...)</code> |
| <code>wrappers_c4d.c</code> | Four-dimensional Complex MPI FFTW transform, using <code>plan = fftwnd_mpi_create_plan(...)</code>  |
| <code>wrappers_r1d.c</code> | One-dimensional Real MPI FFTW transform, using <code>plan = rfftw_mpi_create_plan(...)</code>       |
| <code>wrappers_r2d.c</code> | Two-dimensional Real MPI FFTW transform, using <code>plan = rfftw2d_mpi_create_plan(...)</code>     |
| <code>wrappers_r3d.c</code> | Three-dimensional Real MPI FFTW transform, using <code>plan = rfftw3d_mpi_create_plan(...)</code>   |
| <code>wrappers_r4d.c</code> | Four-dimensional Real MPI FFTW transform, using <code>plan = rffwnd_mpi_create_plan(...)</code>     |

## FFTW3 Interface to Intel® Math Kernel Library

This section describes a collection of FFTW3 wrappers to Intel MKL. The wrappers translate calls of FFTW3 functions to the calls of the Intel MKL Fourier transform (FFT) or Trigonometric Transform (TT) functions. The purpose of FFTW3 wrappers is to enable developers whose programs currently use the FFTW3 library to gain performance with the Intel MKL Fourier transforms without changing the program source code.

The FFTW3 wrappers provide a limited functionality compared to the original FFTW 3.x library, because of differences between FFTW and Intel MKL FFT and TT functionality. This section describes limitations of the FFTW3 wrappers and hints for their usage. Nevertheless, many typical FFT tasks can be performed using the FFTW3 wrappers to Intel MKL.

The FFTW3 wrappers are integrated in Intel MKL. The only change required to use Intel MKL through the FFTW3 wrappers is to link your application using FFTW3 against Intel MKL.

A reference implementation of the FFTW3 wrappers is also provided in open source. You can find it in the `interfaces` directory of the Intel MKL distribution. You can use the reference implementation to create your own wrapper library (see [Building Your Own Wrapper Library](#))

See also these resources:

Intel MKL Release Notes [for the version of the FFTW3 library supported by the wrappers.](#)

## Using FFTW3 Wrappers

The FFTW3 wrappers are a set of functions and data structures depending on one another. The wrappers are not designed to provide the interface on a function-per-function basis. Some FFTW3 wrapper functions are empty and do nothing, but they are present to avoid link errors and satisfy function calls.

This document does not list the declarations of the functions that the FFTW3 wrappers provide (you can find the declarations in the `fftw3.h` header file). Instead, this section comments particular limitations of the wrappers and provides usage hints:

- The FFTW3 wrappers do not support long double precision because Intel MKL FFT functions operate only on single- and double-precision floating-point data types (`float` and `double`, respectively). Therefore the functions with prefix `fftwl_`, supporting the long double data type, are not provided.
- The wrappers provide equivalent implementation for double- and single-precision functions (those with prefixes `fftw_` and `fftwf_`, respectively). So, all these comments equally apply to the double- and single-precision functions and will refer to functions with prefix `fftw_`, that is, double-precision functions, for brevity.
- The FFTW3 interface that the wrappers provide is defined in the `fftw3.h` header file. This file is borrowed from the FFTW3.x package and distributed within Intel MKL with permission. Additionally, the `fftw3_mkl.h` header file defines supporting structures and supplementary constants and macros.
- Actual functionality of the plan creation wrappers is implemented in `guru64` set of functions. Basic interface, advanced interface, and `guru` interface plan creation functions call the `guru64` interface functions. So, all types of the FFTW3 plan creation interface in the wrappers are functional.
- Plan creation functions may return a `NULL` plan, indicating that the functionality is not supported. So, please carefully check the result returned by plan creation functions in your application. In particular, the following problems return a `NULL` plan:
  - `c2r` and `r2c` problems with a split storage of complex data.
  - `r2r` problems with `kind` values `FFTW_R2HC`, `FFTW_HC2R`, and `FFTW_DHT`. The only supported `r2r` kinds are even/odd DFTs (sine/cosine transforms).
  - Multidimensional `r2r` transforms.
  - Transforms of multidimensional vectors. That is, the only supported values for parameter `howmany_rank` in `guru` and `guru64` plan creation functions are 0 and 1.
  - Multidimensional transforms with `rank > MKL_MAXRANK`.
- The `MKL_RODFT00` value of the `kind` parameter is introduced by the FFTW3 wrappers. For better performance, you are strongly encouraged to use this value rather than `FFTW_RODFT00`. To use this `kind` value, provide an extra first element equal to 0.0 for the input/output vectors. Consider the following example:

```
plan1 = fftw_plan_r2r_1d(n, in1, out1, FFTW_RODFT00, FFTW_ESTIMATE);
plan2 = fftw_plan_r2r_1d(n, in2, out2, MKL_RODFT00, FFTW_ESTIMATE);
```

Both plans perform the same transform, except that the `in2/out2` arrays have one extra zero element at location 0. For example, if `n=3`, `in1={x,y,z}` and `out1={u,v,w}`, then `in2={0,x,y,z}` and `out2={0,u,v,w}`.

- The `flags` parameter in plan creation functions is always ignored. The same algorithm is used regardless of the value of this parameter. In particular, `flags` values `FFTW_ESTIMATE`, `FFTW_MEASURE`, etc. have no effect.
- For multithreaded plans, use normal sequence of calls to the `fftw_init_threads()` and `fftw_plan_with_nthreads()` functions (refer to FFTW documentation).
- Memory allocation function `fftw_malloc` returns memory aligned at a 16-byte boundary. You must free the memory with `fftw_free`.

- The FFTW3 wrappers to Intel MKL use the 32-bit `int` type in both LP64 and ILP64 interfaces of Intel MKL. Use `guru64` FFTW3 interfaces for 64-bit sizes.
- The wrappers typically indicate a problem by returning a `NULL` plan. In a few cases, the wrappers may report a descriptive message of the problem detected. By default the reporting is turned off. To turn it on, set variable `fftw3_mkl.verbose` to a non-zero value, for example:

```
#include "fftw3.h"
#include "fftw3_mkl.h"
fftw3_mkl.verbose = 0;
plan = fftw_plan_r2r(...);
```

- The following functions are empty:
  - For saving, loading, and printing plans
  - For saving and loading wisdom
  - For estimating arithmetic cost of the transforms.
- Do not use macro `FFTW_DLL` with the FFTW3 wrappers to Intel MKL.
- Do not use negative stride values. Though FFTW3 wrappers support negative strides in the part of advanced and guru FFTW interface, the underlying implementation does not.

## Building Your Own FFTW3 Interface Wrapper Library

The FFTW3 wrappers to Intel MKL are delivered both integrated in Intel MKL and as source code, which can be compiled to build a standalone wrapper library with exactly the same functionality. Normally you do not need to build the wrappers yourself.

The source code for the wrappers, makefiles, and files with lists of functions are located in the `.\interfaces\fftw3xc` subdirectory in the Intel MKL directory.

To build the wrappers,

1. Change the current directory to the wrapper directory
2. Run the `make` command on Linux\* OS and macOS\* or the `nmake` command on Windows\* OS with a required target and optionally several parameters.

The target `libia32` or `libintel64` defines the platform architecture, and the other parameters specify the compiler, size of the default integer type, and placement of the resulting wrapper library. You can find a detailed and up-to-date description of the parameters in the makefile.

In the following example, the `make` command is used to build the FFTW3 C wrappers to Intel MKL for use from the GNU `gcc`\* compiler on Linux OS based on Intel® 64 architecture:

```
cd interfaces/fftw3xc
make libintel64 compiler=gnu INSTALL_DIR=/my/path
```

This command builds the wrapper library and places the result, named `libfftw3xc_gnu.a`, into the `/my/path` directory. The name of the resulting library is composed of the name of the compiler used and may be changed by an optional parameter `INSTALL_LIBNAME`.

## Building an Application With FFTW3 Interface Wrappers

Normally, the only change needed to build your application with FFTW3 wrappers replacing original FFTW library is to add Intel MKL at the link stage (see section "*Linking Your Application with Intel® Math Kernel Library*" in the *Intel MKL Developer Guide*).

If you recompile your application, add subdirectory `include\fftw` to the search path for header files to avoid FFTW3 version conflicts.

Sometimes, you may have to modify your application according to the following recommendations:

- The application requires
 

```
#include "fftw3.h" ,
```

 which it probably already includes.
- The application does not require
 

```
#include "mkl_dfti.h" .
```
- The application does not require
 

```
#include "fftw3_mkl.h" .
```

 It is required only in case you want to use the `MKL_RODFT00` constant.
- If the application does not check whether a `NULL` plan is returned by plan creation functions, this check must be added, because the FFTW3 to Intel MKL wrappers do not provide 100% of FFTW3 functionality.

## Running FFTW3 Interface Wrapper Examples

There are some examples that demonstrate how to use the wrapper library. The source code for the examples, makefiles used to run them, and files with lists of examples are located in the `.\examples\fftw3xc` subdirectory in the Intel MKL directory.

Parameters of the example makefiles are similar to the parameters of the wrapper library makefiles. Example makefiles normally build and invoke the examples. If the parameter `function=<example_name>` is defined, then only the specified example will run. Otherwise, all examples will be executed. Results of running the examples are saved in subdirectory `.\_results` in files with extension `.res`.

For detailed information about options for the example makefile, refer to the makefile.

## MPI FFTW3 Wrappers

This section describes a collection of MPI FFTW wrappers to Intel® MKL.

MPI FFTW wrappers are available only with Intel MKL for the Linux\* and Windows\* operating systems.

These wrappers translate calls of MPI FFTW functions to the calls of the Intel MKL cluster Fourier transform (CFFT) functions. The purpose of the wrappers is to enable users of MPI FFTW functions improve performance of the applications without changing the program source code.

Although the MPI FFTW wrappers provide less functionality than the original FFTW3 because of differences between MPI FFTW and Intel MKL CFFT, the wrappers cover many typical CFFT use cases.

The MPI FFTW wrappers are provided as source code. To use the wrappers, you need to build your own wrapper library (see [Building Your Own Wrapper Library](#)).

See also these resources:

Intel MKL Release Notes                      for the version of the FFTW3 library supported by the wrappers.

[www.fftw.org](http://www.fftw.org)                                      for a description of the MPI FFTW interface.

[Cluster FFT Functions](#)                      for a description of the Intel MKL CFFT interface.

## Building Your Own Wrapper Library

The MPI FFTW wrappers for FFTW3 are delivered as source code, which can be compiled to build a wrapper library.

The source code for the wrappers, makefiles, and files with lists of functions are located in subdirectory `.\interfaces\fftw3x_cdft` in the Intel MKL directory.

To build the wrappers,

1. Change the current directory to the wrapper directory

2. Run the `make` command on Linux\* OS or the `nmake` command on Windows\* OS with a required target and optionally several parameters.

The target `libia32` or `libintel64` defines the platform architecture, and the other parameters specify the compiler, size of the default `INTEGER` type, as well as the name and placement of the resulting wrapper library. You can find a detailed and up-to-date description of the parameters in the makefile.

In the following example, the `make` command is used to build the MPI FFTW wrappers to Intel MKL for use from the GNU C compiler on Linux OS based on Intel® 64 architecture:

```
cd interfaces/fftw3x_cdft
make libintel64 compiler=gnu mpi=openmpi INSTALL_DIR=/my/path
```

This command builds the wrapper library using the GNU `gcc` compiler so that the final executable can use Open MPI, and places the result, named `libfftw3x_cdft_DOUBLE.a`, into directory `/my/path`.

## Building an Application

Normally, the only change needed to build your application with MPI FFTW wrappers replacing original FFTW3 library is to add Intel MKL and the wrapper library at the link stage (see section "*Linking Your Application with Intel® Math Kernel Library*" in the *Intel MKL Developer Guide*).

When you are recompiling your application, add subdirectory `include\fftw` to the search path for header files to avoid FFTW3 version conflicts.

## Running Examples

There are some examples that demonstrate how to use the MPI FFTW wrapper library for FFTW3. The source code for the examples, makefiles used to run them, and files with lists of examples are located in the `.\examples\fftw3x_cdft` subdirectory in the Intel MKL directory.

Parameters of the example makefiles are similar to the parameters of the wrapper library makefiles. Example makefiles normally build and invoke the examples. Results of running the examples are saved in subdirectory `.\_results` in files with extension `.res`.

For detailed information about options for the example makefile, refer to the makefile.

# Code Examples

---

This appendix presents code examples of using some Intel MKL routines and functions.

Please refer to respective chapters in the document for detailed descriptions of function parameters and operation.

## BLAS Code Examples

---

### Example. Using BLAS Level 1 Function

---

The following example illustrates a call to the BLAS Level 1 function `sdot`. This function performs a vector-vector operation of computing a scalar product of two single-precision real vectors `x` and `y`.

#### Parameters

|                   |                                                                                 |
|-------------------|---------------------------------------------------------------------------------|
| <code>n</code>    | Specifies the number of elements in vectors <code>x</code> and <code>y</code> . |
| <code>incx</code> | Specifies the increment for the elements of <code>x</code> .                    |
| <code>incy</code> | Specifies the increment for the elements of <code>y</code> .                    |

```
#include <stdio.h>
#include <stdlib.h>

#include "mkl_example.h"

int main()
{
 MKL_INT n, incx, incy, i;
 float *x, *y;
 float res;
 MKL_INT len_x, len_y;

 n = 5;
 incx = 2;
 incy = 1;

 len_x = 1+(n-1)*abs(incx);
 len_y = 1+(n-1)*abs(incy);
 x = (float *)calloc(len_x, sizeof(float));
 y = (float *)calloc(len_y, sizeof(float));
 if(x == NULL || y == NULL) {
 printf("\n Can't allocate memory for arrays\n");
 return 1;
 }

 for (i = 0; i < n; i++) {
 x[i*abs(incx)] = 2.0;
 y[i*abs(incy)] = 1.0;
 }

 res = cblas_sdot(n, x, incx, y, incy);
```

```

 printf("\n SDOT = %7.3f", res);

 free(x);
 free(y);

 return 0;
}

```

As a result of this program execution, the following line is printed:

SDOT = 10.000

### Example. Using BLAS Level 1 Routine

The following example illustrates a call to the BLAS Level 1 routine `scopy`. This routine performs a vector-vector operation of copying a single-precision real vector `x` to a vector `y`.

#### Parameters

|                   |                                                                                 |
|-------------------|---------------------------------------------------------------------------------|
| <code>n</code>    | Specifies the number of elements in vectors <code>x</code> and <code>y</code> . |
| <code>incx</code> | Specifies the increment for the elements of <code>x</code> .                    |
| <code>incy</code> | Specifies the increment for the elements of <code>y</code> .                    |

```

#include <stdio.h>
#include <stdlib.h>

#include "mkl_example.h"

int main()
{
 MKL_INT n, incx, incy, i;
 float *x, *y;
 MKL_INT len_x, len_y;
 n = 3;
 incx = 3;
 incy = 1;

 len_x = 10;
 len_y = 10;
 x = (float *)calloc(len_x, sizeof(float));
 y = (float *)calloc(len_y, sizeof(float));
 if(x == NULL || y == NULL) {
 printf("\n Can't allocate memory for arrays\n");
 return 1;
 }
 for (i = 0; i < 10; i++) {
 x[i] = i + 1;
 }

 cblas_scopy(n, x, incx, y, incy);

/* Print output data */

 printf("\n\n OUTPUT DATA");
 PrintVectorS(FULLPRINT, n, y, incy, "Y");

 free(x);
}

```

```

 free(y);
 return 0;
}

```

As a result of this program execution, the following line is printed:

Y = 1.00000 4.00000 7.00000

### Example. Using BLAS Level 2 Routine

The following example illustrates a call to the BLAS Level 2 routine `sger`. This routine performs a matrix-vector operation

```
a := alpha*x*y' + a.
```

#### Parameters

|              |                                   |
|--------------|-----------------------------------|
| <i>alpha</i> | Specifies a scalar <i>alpha</i> . |
| <i>x</i>     | <i>m</i> -element vector.         |
| <i>y</i>     | <i>n</i> -element vector.         |
| <i>a</i>     | <i>m</i> -by- <i>n</i> matrix.    |

```

#include <stdio.h>
#include <stdlib.h>

#include "mkl_example.h"

int main()
{
 MKL_INT m, n, lda, incx, incy, i, j;
 MKL_INT rmaxa, cmaxa;
 float alpha;
 float *a, *x, *y;
 CBLAS_LAYOUT layout;
 MKL_INT len_x, len_y;

 m = 2;
 n = 3;
 lda = 5;
 incx = 2;
 incy = 1;
 alpha = 0.5;

 layout = CblasRowMajor;

 len_x = 10;
 len_y = 10;
 rmaxa = m + 1;
 cmaxa = n;
 a = (float *)calloc(rmaxa*cmaxa, sizeof(float));
 x = (float *)calloc(len_x, sizeof(float));
 y = (float *)calloc(len_y, sizeof(float));
 if(a == NULL || x == NULL || y == NULL) {
 printf("\n Can't allocate memory for arrays\n");
 return 1;
 }
 if(layout == CblasRowMajor)
 lda=cmaxa;
 else

```

```

 lda=rmaxa;

 for (i = 0; i < 10; i++) {
 x[i] = 1.0;
 y[i] = 1.0;
 }

 for (i = 0; i < m; i++) {
 for (j = 0; j < n; j++) {
 a[i + j*lda] = j + 1;
 }
 }

 cblas_sger(layout, m, n, alpha, x, incx, y, incy, a, lda);

 PrintArrayS(&layout, FULLPRINT, GENERAL_MATRIX, &m, &n, a, &lda, "A");

 free(a);
 free(x);
 free(y);

 return 0;
}

```

As a result of this program execution, matrix *a* is printed as follows:

Matrix A:

```

1.50000 2.50000 3.50000
1.50000 2.50000 3.50000

```

### Example. Using BLAS Level 3 Routine

The following example illustrates a call to the BLAS Level 3 routine `ssymm`. This routine performs a matrix-matrix operation

```
c := alpha*a*b' + beta*c.
```

#### Parameters

|              |                                   |
|--------------|-----------------------------------|
| <i>alpha</i> | Specifies a scalar <i>alpha</i> . |
| <i>beta</i>  | Specifies a scalar <i>beta</i> .  |
| <i>a</i>     | Symmetric matrix                  |
| <i>b</i>     | <i>m</i> -by- <i>n</i> matrix     |
| <i>c</i>     | <i>m</i> -by- <i>n</i> matrix     |

```

#include <stdio.h>
#include <stdlib.h>

#include "mkl_example.h"

int main(int argc, char *argv[])
{
 MKL_INT m, n, i, j;
 MKL_INT lda, ldb, ldc;
 MKL_INT rmaxa, cmaxa, rmaxb, cmaxb, rmaxc, cmaxc;
 float alpha, beta;

```

```

float *a, *b, *c;
CBLAS_LAYOUT layout;
CBLAS_SIDE side;
CBLAS_UPLO upto;
MKL_INT ma, na, typeA;
upto = 'u';
side = 'l';
layout = CblasRowMajor;
m = 3;
n = 2;
lda = 3;
ldb = 3;
ldc = 3;
alpha = 0.5;
beta = 2.0;

if(side == CblasLeft) {
 rmaxa = m + 1;
 cmaxa = m;
 ma = m;
 na = m;
} else {
 rmaxa = n + 1;
 cmaxa = n;
 ma = n;
 na = n;
}
rmaxb = m + 1;
cmaxb = n;
rmaxc = m + 1;
cmaxc = n;
a = (float *)calloc(rmaxa*cmaxa, sizeof(float));
b = (float *)calloc(rmaxb*cmaxb, sizeof(float));
c = (float *)calloc(rmaxc*cmaxc, sizeof(float));
if (a == NULL || b == NULL || c == NULL) {
 printf("\n Can't allocate memory arrays");
 return 1;
}
if(layout == CblasRowMajor) {
 lda=cmaxa;
 ldb=cmaxb;
 ldc=cmaxc;
} else {
 lda=rmaxa;
 ldb=rmaxb;
 ldc=rmaxc;
}
if (upto == CblasUpper) typeA = UPPER_MATRIX;
else typeA = LOWER_MATRIX;
for (i = 0; i < m; i++) {
 for (j = 0; j < m; j++) {
 a[i + j*lda] = 1.0;
 }
}
for (i = 0; i < m; i++) {
 for (j = 0; j < n; j++) {
 c[i + j*ldc] = 1.0;
 b[i + j*ldb] = 2.0;
 }
}

```

```

}

cblas_ssymm(layout, side, uplo, m, n, alpha, a, lda,
 b, ldb, beta, c, ldc);

printf("\n\n OUTPUT DATA");
PrintArrayS(&layout, FULLPRINT, GENERAL_MATRIX, &m, &n, c, &ldc, "C");

free(a);
free(b);
free(c);

return 0;
}

```

As a result of this program execution, matrix *c* is printed as follows:

Matrix C:

5.00000 5.00000

5.00000 5.00000

5.00000 5.00000

The following example illustrates a call from a C program to the Fortran version of the complex BLAS Level 1 function `zdotc()`. This function computes the dot product of two double-precision complex vectors.

### Example. Calling a Complex BLAS Level 1 Function from C

In this example, the complex dot product is returned in the structure *c*.

```

#include <stdio>
#include "mkl_blas.h"
#define N 5
void main()
{
 int n, inca = 1, incb = 1, i;
 MKL_Complex16 a[N], b[N], c;
 void zdotc();
 n = N;
 for(i = 0; i < n; i++){
 a[i].real = (double)i; a[i].imag = (double)i * 2.0;
 b[i].real = (double)(n - i); b[i].imag = (double)i * 2.0;
 }
 zdotc(&c, &n, a, &inca, b, &incb);
 printf("The complex dot product is: (%6.2f, %6.2f)\n", c.real, c.imag);
}

```

#### NOTE

Instead of calling BLAS directly from C programs, you might wish to use the C interface to the Basic Linear Algebra Subprograms (CBLAS) implemented in Intel® MKL. See [C Interface Conventions](#) for more information.

## Fourier Transform Functions Code Examples

This section presents code examples for functions described in the “[FFT Functions](#)” and “[Cluster FFT Functions](#)” sections in the “Fourier Transform Functions” chapter. The examples are grouped in subsections

- [Examples for FFT Functions](#), including [Examples of Using Multi-Threading for FFT Computation](#)
- [Examples for Cluster FFT Functions](#)
- [Auxiliary data transformations](#).

## FFT Code Examples

This section presents examples of using the FFT interface functions described in “[Fourier Transform Functions](#)” chapter.

Here are the examples of two one-dimensional computations. These examples use the default settings for all of the configuration parameters, which are specified in “[Configuration Settings](#)”.

### One-dimensional In-place FFT

```
/* C example, float _Complex is defined in C9X */
#include "mkl_dfti.h"
float _Complex x[32];
float y[34];
DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle;
MKL_LONG status;
//...put input data into x[0],...,x[31]; y[0],...,y[31]
status = DftiCreateDescriptor(&my_desc1_handle, DFTI_SINGLE,
 DFTI_COMPLEX, 1, 32);
status = DftiCommitDescriptor(my_desc1_handle);
status = DftiComputeForward(my_desc1_handle, x);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is x[0], ..., x[31]*/
status = DftiCreateDescriptor(&my_desc2_handle, DFTI_SINGLE,
 DFTI_REAL, 1, 32);
status = DftiCommitDescriptor(my_desc2_handle);
status = DftiComputeForward(my_desc2_handle, y);
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is given in CCS format*/
```

### One-dimensional Out-of-place FFT

```
/* C example, float _Complex is defined in C9X */
#include "mkl_dfti.h"
float _Complex x_in[32];
float _Complex x_out[32];
float y_in[32];
float y_out[34];

DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle;
MKL_LONG status;
//...put input data into x_in[0],...,x_in[31]; y_in[0],...,y_in[31]
status = DftiCreateDescriptor(&my_desc1_handle, DFTI_SINGLE,
 DFTI_COMPLEX, 1, 32);
status = DftiSetValue(my_desc1_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor(my_desc1_handle);
status = DftiComputeForward(my_desc1_handle, x_in, x_out);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is x_out[0], ..., x_out[31]*/
status = DftiCreateDescriptor(&my_desc2_handle, DFTI_SINGLE,
 DFTI_REAL, 1, 32);
Status = DftiSetValue(My_Desc2_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
```

```
status = DftiCommitDescriptor(my_desc2_handle);
status = DftiComputeForward(my_desc2_handle, y_in, y_out);
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is given by y_out in CCS format*/
```

## Two-dimensional FFT

---

```
/* C99 example */
#include "mkl_dfti.h"
float _Complex x[32][100];
float y[34][102];
DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle;
MKL_LONG status, l[2];
//...put input data into x[j][k] 0<=j<=31, 0<=k<=99
//...put input data into y[j][k] 0<=j<=31, 0<=k<=99
l[0] = 32; l[1] = 100;
status = DftiCreateDescriptor(&my_desc1_handle, DFTI_SINGLE,
 DFTI_COMPLEX, 2, l);
status = DftiCommitDescriptor(my_desc1_handle);
status = DftiComputeForward(my_desc1_handle, x);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is the complex value x[j][k], 0<=j<=31, 0<=k<=99 */
status = DftiCreateDescriptor(&my_desc2_handle, DFTI_SINGLE,
 DFTI_REAL, 2, l);
status = DftiCommitDescriptor(my_desc2_handle);
status = DftiComputeForward(my_desc2_handle, y);
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is the complex value z(j,k) 0<=j<=31; 0<=k<=99
/* and is stored in CCS format*/
```

The following example demonstrates how you can change the default configuration settings by using the `DftiSetValue` function.

For instance, to preserve the input data after the FFT computation, the configuration of `DFTI_PLACEMENT` should be changed to "not in place" from the default choice of "in place."

The code below illustrates how this can be done:

## Changing Default Settings

---

```
/* C99 example */
#include "mkl_dfti.h"
float _Complex x_in[32], x_out[32];
DFTI_DESCRIPTOR_HANDLE my_desc_handle;
MKL_LONG status;
//...put input data into x_in[j], 0 <= j < 32
status = DftiCreateDescriptor(&my_desc_handle, DFTI_SINGLE,
 DFTI_COMPLEX, 1, 32);
status = DftiSetValue(my_desc_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor(my_desc_handle);
status = DftiComputeForward(my_desc_handle, x_in, x_out);
status = DftiFreeDescriptor(&my_desc_handle);
/* result is x_out[0], x_out[1], ..., x_out[31] */
```

## Using Status Checking Functions

This example illustrates the use of status checking functions described in [Chapter 11](#).

```

/* C */
DFTI_DESCRIPTOR_HANDLE desc;
MKL_LONG status;
// . . . descriptor creation and other code
status = DftiCommitDescriptor(desc);
if (status && !DftiErrorClass(status,DFTI_NO_ERROR))
{
 printf ('Error: %s\n', DftiErrorMessage(status));
}

```

## Computing 2D FFT by One-Dimensional Transforms

Below is an example where a 20-by-40 two-dimensional FFT is computed explicitly using one-dimensional transforms.

```

/* C */
#include "mkl_dfti.h"
float _Complex x[20][40];
MKL_LONG stride[2];
MKL_LONG status;
DFTI_DESCRIPTOR_HANDLE desc_handle_dim1;
DFTI_DESCRIPTOR_HANDLE desc_handle_dim2;
//...
status = DftiCreateDescriptor(&desc_handle_dim1, DFTI_SINGLE,
 DFTI_COMPLEX, 1, 20);
status = DftiCreateDescriptor(&desc_handle_dim2, DFTI_SINGLE,
 DFTI_COMPLEX, 1, 40);

/* perform 40 one-dimensional transforms along 1st dimension */
/* note that the 1st dimension data are not unit-stride */
stride[0] = 0; stride[1] = 40;
status = DftiSetValue(desc_handle_dim1, DFTI_NUMBER_OF_TRANSFORMS, 40);
status = DftiSetValue(desc_handle_dim1, DFTI_INPUT_DISTANCE, 1);
status = DftiSetValue(desc_handle_dim1, DFTI_OUTPUT_DISTANCE, 1);
status = DftiSetValue(desc_handle_dim1, DFTI_INPUT_STRIDES, stride);
status = DftiSetValue(desc_handle_dim1, DFTI_OUTPUT_STRIDES, stride);
status = DftiCommitDescriptor(desc_handle_dim1);
status = DftiComputeForward(desc_handle_dim1, x);
/* perform 20 one-dimensional transforms along 2nd dimension */
/* note that the 2nd dimension is unit stride */
status = DftiSetValue(desc_handle_dim2, DFTI_NUMBER_OF_TRANSFORMS, 20);
status = DftiSetValue(desc_handle_dim2,
 DFTI_INPUT_DISTANCE, 40);
status = DftiSetValue(desc_handle_dim2,
 DFTI_OUTPUT_DISTANCE, 40);
status = DftiCommitDescriptor(desc_handle_dim2);
status = DftiComputeForward(desc_handle_dim2, x);
status = DftiFreeDescriptor(&desc_handle_dim1);
status = DftiFreeDescriptor(&desc_handle_dim2);

```

The following code illustrates real multi-dimensional transforms with CCE format storage of conjugate-even complex matrix. [Example "Three-Dimensional REAL FFT \(C Interface\)"](#) is three-dimensional out-of-place transform in C interface.

### Three-Dimensional REAL FFT

```

/* C99 example */
#include "mkl_dfti.h"
float x[32][100][19];
float _Complex y[32][100][10]; /* 10 = 19/2 + 1 */
DFTI_DESCRIPTOR_HANDLE my_desc_handle;
MKL_LONG status, l[3];
MKL_LONG strides_out[4];

//...put input data into x[j][k][s] 0<=j<=31, 0<=k<=99, 0<=s<=18
l[0] = 32; l[1] = 100; l[2] = 19;

strides_out[0] = 0; strides_out[1] = 1000;
strides_out[2] = 10; strides_out[3] = 1;

status = DftiCreateDescriptor(&my_desc_handle, DFTI_SINGLE,
DFTI_REAL, 3, l);
status = DftiSetValue(my_desc_handle,
DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX);
status = DftiSetValue(my_desc_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiSetValue(my_desc_handle,
DFTI_OUTPUT_STRIDES, strides_out);

status = DftiCommitDescriptor(my_desc_handle);
status = DftiComputeForward(my_desc_handle, x, y);
status = DftiFreeDescriptor(&my_desc_handle);
/* result is the complex value z(j,k,s) 0<=j<=31; 0<=k<=99, 0<=s<=9
and is stored in complex matrix y in CCE format. */

```

### Examples of Using OpenMP\* Threading for FFT Computation

The following sample program shows how to employ internal OpenMP\* threading in Intel MKL for FFT computation.

To specify the number of threads inside Intel MKL, use the following settings:

set MKL\_NUM\_THREADS = 1 for one-threaded mode;

set MKL\_NUM\_THREADS = 4 for multi-threaded mode.

### Using Intel MKL Internal Threading Mode (C Example)

```

#include "mkl_dfti.h"

int main ()
{
 float x[200][100];
 DFTI_DESCRIPTOR_HANDLE fft;
 MKL_LONG len[2] = {200, 100};
 // initialize x
 DftiCreateDescriptor (&fft, DFTI_SINGLE, DFTI_REAL, 2, len);
 DftiCommitDescriptor (fft);
 DftiComputeForward (fft, x);
 DftiFreeDescriptor (&fft);
}

```

```

return 0;
}

```

The following [Example "Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region"](#) and [Example "Using Parallel Mode with Multiple Descriptors Initialized in One Thread"](#) illustrate a parallel customer program with each descriptor instance used only in a single thread.

Specify the number of OpenMP threads for [Example "Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region"](#) like this:

set MKL\_NUM\_THREADS = 1 for Intel MKL to work in the single-threaded mode (recommended);

set OMP\_NUM\_THREADS = 4 for the customer program to work in the multi-threaded mode.

### Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region

Note that in this example, the program can be transformed to become single-threaded at the customer level but using parallel mode within Intel MKL. To achieve this, you need to set the parameter DFTI\_NUMBER\_OF\_TRANSFORMS = 4 and to set the corresponding parameter DFTI\_INPUT\_DISTANCE = 5000.

```

#include "mkl_dfti.h"
#include <omp.h>
#define ARRAY_LEN(a) sizeof(a)/sizeof(a[0])
int main ()
{
 // 4 OMP threads, each does 2D FFT 50x100 points
 MKL_Complex8 x[4][50][100];
 int nth = ARRAY_LEN(x);
 MKL_LONG len[2] = {ARRAY_LEN(x[0]), ARRAY_LEN(x[0][0])};
 int th;
 // assume x is initialized and do 2D FFTs
#pragma omp parallel for shared(len, x)
 for (th = 0; th < nth; th++)
 {
 DFTI_DESCRIPTOR_HANDLE myFFT;

 DftiCreateDescriptor (&myFFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len);
 DftiCommitDescriptor (myFFT);
 DftiComputeForward (myFFT, x[th]);
 DftiFreeDescriptor (&myFFT);
 }
 return 0;
}

```

Specify the number of OpenMP threads for [Example "Using Parallel Mode with Multiple Descriptors Initialized in One Thread"](#) like this:

set MKL\_NUM\_THREADS = 1 for Intel MKL to work in the single-threaded mode (obligatory);

set OMP\_NUM\_THREADS = 4 for the customer program to work in the multi-threaded mode.

### Using Parallel Mode with Multiple Descriptors Initialized in One Thread

```

#include "mkl_dfti.h"
#include <omp.h>
#define ARRAY_LEN(a) sizeof(a)/sizeof(a[0])
int main ()
{
 // 4 OMP threads, each does 2D FFT 50x100 points
 MKL_Complex8 x[4][50][100];
 int nth = ARRAY_LEN(x);
 MKL_LONG len[2] = {ARRAY_LEN(x[0]), ARRAY_LEN(x[0][0])};

```

```

DFTI_DESCRIPTOR_HANDLE FFT[ARRAY_LEN(x)];
int th;

for (th = 0; th < nth; th++)
 DftiCreateDescriptor (&FFT[th], DFTI_SINGLE, DFTI_COMPLEX, 2, len);
for (th = 0; th < nth; th++)
 DftiCommitDescriptor (FFT[th]);
// assume x is initialized and do 2D FFTs
#pragma omp parallel for shared(FFT, x)
for (th = 0; th < nth; th++)
 DftiComputeForward (FFT[th], x[th]);
for (th = 0; th < nth; th++)
 DftiFreeDescriptor (&FFT[th]);
return 0;
}

```

The following [Example “Using Parallel Mode with a Common Descriptor”](#) illustrates a parallel customer program with a common descriptor used in several threads.

## Using Parallel Mode with a Common Descriptor

```

#include "mkl_dfti.h"
#include <omp.h>
#define ARRAY_LEN(a) sizeof(a)/sizeof(a[0])
int main ()
{
 // 4 OMP threads, each does 2D FFT 50x100 points
 MKL_Complex8 x[4][50][100];
 int nth = ARRAY_LEN(x);
 MKL_LONG len[2] = {ARRAY_LEN(x[0]), ARRAY_LEN(x[0][0])};
 DFTI_DESCRIPTOR_HANDLE FFT;
 int th;

 DftiCreateDescriptor (&FFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len);
 DftiCommitDescriptor (FFT);
 // assume x is initialized and do 2D FFTs
#pragma omp parallel for shared(FFT, x)
for (th = 0; th < nth; th++)
 DftiComputeForward (FFT, x[th]);
 DftiFreeDescriptor (&FFT);
 return 0;
}

```

## Examples for Cluster FFT Functions

The following C example computes a 2-dimensional out-of-place FFT using the cluster FFT interface:

### 2D Out-of-place Cluster FFT Computation

```

DFTI_DESCRIPTOR_DM_HANDLE desc;
MKL_LONG len[2], v, i, j, n, s;
Complex *in, *out;

MPI_Init(...);

// Create descriptor for 2D FFT
len[0]=nx;
len[1]=ny;
DftiCreateDescriptorDM(MPI_COMM_WORLD, &desc, DFTI_DOUBLE, DFTI_COMPLEX, 2, len);
// Ask necessary length of in and out arrays and allocate memory

```

```

DftiGetValueDM(desc,CDFT_LOCAL_SIZE,&v);
in=(Complex*)malloc(v*sizeof(Complex));
out=(Complex*)malloc(v*sizeof(Complex));
// Fill local array with initial data. Current process performs n rows,
// 0 row of in corresponds to s row of virtual global array
DftiGetValueDM(desc,CDFT_LOCAL_NX,&n);
DftiGetValueDM(desc,CDFT_LOCAL_X_START,&s);
// Virtual global array globalIN is defined by function f as
// globalIN[i*ny+j]=f(i,j)
for(i=0;i<n;i++)
 for(j=0;j<ny;j++) in[i*ny+j]=f(i+s,j);
// Set that we want out-of-place transform (default is DFTI_INPLACE)
DftiSetValueDM(desc,DFTI_PLACEMENT,DFTI_NOT_INPLACE);
// Commit descriptor, calculate FFT, free descriptor
DftiCommitDescriptorDM(desc);
DftiComputeForwardDM(desc,in,out);
// Virtual global array globalOUT is defined by function g as
// globalOUT[i*ny+j]=g(i,j)
// Now out contains result of FFT. out[i*ny+j]=g(i+s,j)
DftiFreeDescriptorDM(&desc);
free(in);
free(out);
MPI_Finalize();

```

## 1D In-place Cluster FFT Computations

The C example below illustrates one-dimensional in-place cluster FFT computations effected with a user-defined workspace:

```

DFTI_DESCRIPTOR_DM_HANDLE desc;
MKL_LONG len,v,i,n_out,s_out;
Complex *in,*work;

MPI_Init(...);
// Create descriptor for 1D FFT
DftiCreateDescriptorDM(MPI_COMM_WORLD,&desc,DFTI_DOUBLE,DFTI_COMPLEX,1,len);
// Ask necessary length of array and workspace and allocate memory
DftiGetValueDM(desc,CDFT_LOCAL_SIZE,&v);
in=(Complex*)malloc(v*sizeof(Complex));
work=(Complex*)malloc(v*sizeof(Complex));
// Fill local array with initial data. Local array has n elements,
// 0 element of in corresponds to s element of virtual global array
DftiGetValueDM(desc,CDFT_LOCAL_NX,&n);
DftiGetValueDM(desc,CDFT_LOCAL_X_START,&s);
// Set work array as a workspace
DftiSetValueDM(desc,CDFT_WORKSPACE,work);
// Virtual global array globalIN is defined by function f as globalIN[i]=f(i)
for(i=0;i<n;i++) in[i]=f(i+s);
// Commit descriptor, calculate FFT, free descriptor
DftiCommitDescriptorDM(desc);
DftiComputeForwardDM(desc,in);
DftiGetValueDM(desc,CDFT_LOCAL_OUT_NX,&n_out);
DftiGetValueDM(desc,CDFT_LOCAL_OUT_X_START,&s_out);
// Virtual global array globalOUT is defined by function g as globalOUT[i]=g(i)
// Now in contains result of FFT. Local array has n_out elements,
// 0 element of in corresponds to s_out element of virtual global array.
// in[i]==g(i+s_out)
DftiFreeDescriptorDM(&desc);
free(in);

```

```
free(work);
MPI_Finalize();
```

## Auxiliary Data Transformations

This section presents C examples for conversion from the Cartesian to polar representation of complex data and vice versa.

### Conversion from Cartesian to polar representation of complex data

---

```
// Cartesian->polar conversion of complex data
// Cartesian representation: z = re + I*im
// Polar representation: z = r * exp(I*phi)
#include <mkl_vml.h>

void
variant1_Cartesian2Polar(int n,const double *re,const double *im,
 double *r,double *phi)
{
 vdHypot(n,re,im,r); // compute radii r[]
 vdAtan2(n,im,re,phi); // compute phases phi[]
}

void
variant2_Cartesian2Polar(int n,const MKL_Complex16 *z,double *r,double *phi,
 double *temp_re,double *temp_im)
{
 vzAbs(n,z,r); // compute radii r[]
 vdPackI(n, (double*)z + 0, 2, temp_re);
 vdPackI(n, (double*)z + 1, 2, temp_im);
 vdAtan2(n,temp_im,temp_re,phi); // compute phases phi[]
}
```

### Conversion from polar to Cartesian representation of complex data

---

```
// Polar->Cartesian conversion of complex data.
// Polar representation: z = r * exp(I*phi)
// Cartesian representation: z = re + I*im
#include <mkl_vml.h>

void
variant1_Polar2Cartesian(int n,const double *r,const double *phi,
 double *re,double *im)
{
 vdSinCos(n,phi,im,re); // compute direction, i.e. z[]/abs(z[])
 vdMul(n,r,re,re); // scale real part
 vdMul(n,r,im,im); // scale imaginary part
}

void
variant2_Polar2Cartesian(int n,const double *r,const double *phi,
 MKL_Complex16 *z,
 double *temp_re,double *temp_im)
{
 vdSinCos(n,phi,temp_im,temp_re); // compute direction, i.e. z[]/abs(z[])
 vdMul(n,r,temp_im,temp_im); // scale imaginary part
}
```

```
vdMul(n,r,temp_re,temp_re); // scale real part
vdUnpackI(n,temp_re,(double*)z + 0, 2); // fill in result.re
vdUnpackI(n,temp_im,(double*)z + 1, 2); // fill in result.im
}
```

# Bibliography

| $A^H$                       | Denotes the conjugate transpose of a general matrix $A$ . See also conjugate matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| $A^T$                       | Denotes the transpose of a general matrix $A$ . See also transpose.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| band matrix                 | A general $m$ -by- $n$ matrix $A$ such that $a_{ij} = 0$ for $ i - j  > l$ , where $1 < l < \min(m, n)$ . For example, any tridiagonal matrix is a band matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| band storage                | A special storage scheme for band matrices. A matrix is stored in a two-dimensional array: columns of the matrix are stored in the corresponding columns of the array, and <i>diagonals</i> of the matrix are stored in rows of the array.                                                                                                                                                                                                                                                                                                                                                                                       |
| BLAS                        | Abbreviation for Basic Linear Algebra Subprograms. These subprograms implement vector, matrix-vector, and matrix-matrix operations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| BRNG                        | Abbreviation for Basic Random Number Generator. Basic random number generators are pseudorandom number generators imitating i.i.d. random number sequences of uniform distribution. Distributions other than uniform are generated by applying different transformation techniques to the sequences of random numbers of uniform distribution.                                                                                                                                                                                                                                                                                   |
| BRNG registration           | Standardized mechanism that allows a user to include a user-designed BRNG into the VSL and use it along with the predefined VSL basic generators.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Bunch-Kaufman factorization | Representation of a real symmetric or complex Hermitian matrix $A$ in the form $A = PUDU^H P^T$ (or $A = PLDL^H P^T$ ) where $P$ is a permutation matrix, $U$ and $L$ are upper and lower triangular matrices with unit diagonal, and $D$ is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. $U$ and $L$ have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of $D$ .                                                                                                                                                                                                                  |
| c                           | When found as the first letter of routine names, $c$ indicates the usage of single-precision complex data type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| CBLAS                       | C interface to the BLAS. See BLAS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| CDF                         | Cumulative Distribution Function. The function that determines probability distribution for univariate or multivariate random variable $X$ . For univariate distribution the cumulative distribution function is the function of real argument $x$ , which for every $x$ takes a value equal to probability of the event $A: X \leq x$ . For multivariate distribution the cumulative distribution function is the function of a real vector $x = (x_1, x_2, \dots, x_n)$ , which, for every $x$ , takes a value equal to probability of the event $A = (X_1 \leq x_1 \ \& \ X_2 \leq x_2, \ \& \ \dots, \ \& \ X_n \leq x_n)$ . |

|                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cholesky factorization                   | Representation of a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix $A$ in the form $A = U^H U$ or $A = L L^H$ , where $L$ is a lower triangular matrix and $U$ is an upper triangular matrix.                                                                                                                                                                                                                                                                 |
| condition number                         | The number $\kappa(A)$ defined for a given square matrix $A$ as follows: $\kappa(A) = \ A\  \ A^{-1}\ $ .                                                                                                                                                                                                                                                                                                                                                                                           |
| conjugate matrix                         | The matrix $A^H$ defined for a given general matrix $A$ as follows: $(A^H)_{ij} = (a_{ji})^*$ .                                                                                                                                                                                                                                                                                                                                                                                                     |
| conjugate number                         | The conjugate of a complex number $z = a + bi$ is $z^* = a - bi$ .                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| d                                        | When found as the first letter of routine names, d indicates the usage of double-precision real data type.                                                                                                                                                                                                                                                                                                                                                                                          |
| dot product                              | The number denoted $x \cdot y$ and defined for given vectors $x$ and $y$ as follows: $x \cdot y = \sum_i x_i y_i$ .<br>Here $x_i$ and $y_i$ stand for the $i$ -th elements of $x$ and $y$ , respectively.                                                                                                                                                                                                                                                                                           |
| double precision                         | A floating-point data type. On Intel® processors, this data type allows you to store real numbers $x$ such that $2.23 \times 10^{-308} <  x  < 1.79 \times 10^{308}$ . For this data type, the machine precision $\epsilon$ is approximately $10^{-15}$ , which means that double-precision numbers usually contain no more than 15 significant decimal digits. For more information, refer to <i>Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture</i> . |
| eigenvalue                               | See eigenvalue problem.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| eigenvalue problem                       | A problem of finding non-zero vectors $x$ and numbers $\lambda$ (for a given square matrix $A$ ) such that $Ax = \lambda x$ . Here the numbers $\lambda$ are called the eigenvalues of the matrix $A$ and the vectors $x$ are called the eigenvectors of the matrix $A$ .                                                                                                                                                                                                                           |
| eigenvector                              | See eigenvalue problem.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| elementary reflector(Householder matrix) | Matrix of a general form $H = I - \tau v v^T$ , where $v$ is a column vector and $\tau$ is a scalar. In LAPACK elementary reflectors are used, for example, to represent the matrix $Q$ in the $QR$ factorization (the matrix $Q$ is represented as a product of elementary reflectors).                                                                                                                                                                                                            |
| factorization                            | Representation of a matrix as a product of matrices. See also Bunch-Kaufman factorization, Cholesky factorization, $LU$ factorization, $LQ$ factorization, $QR$ factorization, Schur factorization.                                                                                                                                                                                                                                                                                                 |
| FFTs                                     | Abbreviation for Fast Fourier Transforms. See Chapter 11 of this book.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| full storage                             | A storage scheme allowing you to store matrices of any kind. A matrix $A$ is stored in a two-dimensional array $a$ , with the matrix element $a_{ij}$ stored in the array element $a(i, j)$ .                                                                                                                                                                                                                                                                                                       |
| Hermitian matrix                         | A square matrix $A$ that is equal to its conjugate matrix $A^H$ . The conjugate $A^H$ is defined as follows: $(A^H)_{ij} = (a_{ji})^*$ .                                                                                                                                                                                                                                                                                                                                                            |
| I                                        | See identity matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| identity matrix                          | A square matrix $I$ whose diagonal elements are 1, and off-diagonal elements are 0. For any matrix $A$ , $AI = A$ and $IA = A$ .                                                                                                                                                                                                                                                                                                                                                                    |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| i.i.d.             | Independent Identically Distributed.                                                                                                                                                                                                                                                                                                                                                                                                 |
| in-place           | Qualifier of an operation. A function that performs its operation in-place takes its input from an array and returns its output to the same array.                                                                                                                                                                                                                                                                                   |
| Intel MKL          | Abbreviation for Intel® Math Kernel Library.                                                                                                                                                                                                                                                                                                                                                                                         |
| inverse matrix     | The matrix denoted as $A^{-1}$ and defined for a given square matrix $A$ as follows: $AA^{-1} = A^{-1}A = I$ . $A^{-1}$ does not exist for singular matrices $A$ .                                                                                                                                                                                                                                                                   |
| $LQ$ factorization | Representation of an $m$ -by- $n$ matrix $A$ as $A = LQ$ or $A = (L \ 0)Q$ . Here $Q$ is an $n$ -by- $n$ orthogonal (unitary) matrix. For $m \leq n$ , $L$ is an $m$ -by- $m$ lower triangular matrix with real diagonal elements; for $m > n$ ,                                                                                                                                                                                     |
|                    | $L = \begin{bmatrix} L_1 \\ L_2 \end{bmatrix}$                                                                                                                                                                                                                                                                                                                                                                                       |
|                    | where $L_1$ is an $n$ -by- $n$ lower triangular matrix, and $L_2$ is a rectangular matrix.                                                                                                                                                                                                                                                                                                                                           |
| $LU$ factorization | Representation of a general $m$ -by- $n$ matrix $A$ as $A = PLU$ , where $P$ is a permutation matrix, $L$ is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$ ) and $U$ is upper triangular (upper trapezoidal if $m < n$ ).                                                                                                                                                                               |
| machine precision  | The number $\varepsilon$ determining the precision of the machine representation of real numbers. For Intel® architecture, the machine precision is approximately $10^{-7}$ for single-precision data, and approximately $10^{-15}$ for double-precision data. The precision also determines the number of significant decimal digits in the machine representation of real numbers. See also double precision and single precision. |
| MPI                | Message Passing Interface. This standard defines the user interface and functionality for a wide range of message-passing capabilities in parallel computing.                                                                                                                                                                                                                                                                        |
| MPICH              | A freely available, portable implementation of MPI standard for message-passing libraries.                                                                                                                                                                                                                                                                                                                                           |
| orthogonal matrix  | A real square matrix $A$ whose transpose and inverse are equal, that is, $A^T = A^{-1}$ , and therefore $AA^T = A^T A = I$ . All eigenvalues of an orthogonal matrix have the absolute value 1.                                                                                                                                                                                                                                      |
| packed storage     | A storage scheme allowing you to store symmetric, Hermitian, or triangular matrices more compactly. The upper or lower triangle of a matrix is packed by columns in a one-dimensional array.                                                                                                                                                                                                                                         |
| PDF                | Probability Density Function. The function that determines probability distribution for univariate or multivariate continuous random variable $X$ . The probability density function $f(x)$ is closely related with the cumulative distribution function $F(x)$ .<br>For univariate distribution the relation is                                                                                                                     |

$$F(x) = \int_{-\infty}^x f(t)dt .$$

For multivariate distribution the relation is

$$F(x_1, x_2, \dots, x_n) = \int_{-\infty}^{x_1} \int_{-\infty}^{x_2} \dots \int_{-\infty}^{x_n} f(t_1, t_2, \dots, t_n) dt_1 dt_2 \dots dt_n$$

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| positive-definite matrix              | A square matrix $A$ such that $Ax \cdot x > 0$ for any non-zero vector $x$ . Here $\cdot$ denotes the dot product.                                                                                                                                                                                                                                                                                                                                                                                |
| pseudorandom number generator         | A completely deterministic algorithm that imitates truly random sequences.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| QR factorization                      | Representation of an $m$ -by- $n$ matrix $A$ as $A = QR$ , where $Q$ is an $m$ -by- $m$ orthogonal (unitary) matrix, and $R$ is $n$ -by- $n$ upper triangular with real diagonal elements (if $m \geq n$ ) or trapezoidal (if $m < n$ ) matrix.                                                                                                                                                                                                                                                   |
| random stream                         | An abstract source of independent identically distributed random numbers of uniform distribution. In this manual a random stream points to a structure that uniquely defines a random number sequence generated by a basic generator associated with a given random stream.                                                                                                                                                                                                                       |
| RNG                                   | Abbreviation for Random Number Generator. In this manual the term "random number generators" stands for pseudorandom number generators, that is, generators based on completely deterministic algorithms imitating truly random sequences.                                                                                                                                                                                                                                                        |
| Rectangular Full Packed (RFP) storage | A storage scheme combining the full and packed storage schemes for the upper or lower triangle of the matrix. This combination enables using half of the full storage as packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels as the full storage.                                                                                                                                                                                                                    |
| s                                     | When found as the first letter of routine names, $s$ indicates the usage of single-precision real data type.                                                                                                                                                                                                                                                                                                                                                                                      |
| ScaLAPACK                             | Stands for Scalable Linear Algebra PACKage.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Schur factorization                   | Representation of a square matrix $A$ in the form $A = ZTZ^H$ . Here $T$ is an upper quasi-triangular matrix (for complex $A$ , triangular matrix) called the Schur form of $A$ ; the matrix $Z$ is orthogonal (for complex $A$ , unitary). Columns of $Z$ are called Schur vectors.                                                                                                                                                                                                              |
| single precision                      | A floating-point data type. On Intel® processors, this data type allows you to store real numbers $x$ such that $1.18 \cdot 10^{-38} <  x  < 3.40 \cdot 10^{38}$ . For this data type, the machine precision ( $\epsilon$ ) is approximately $10^{-7}$ , which means that single-precision numbers usually contain no more than 7 significant decimal digits. For more information, refer to <i>Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture</i> . |
| singular matrix                       | A matrix whose determinant is zero. If $A$ is a singular matrix, the inverse $A^{-1}$ does not exist, and the system of equations $Ax = b$ does not have a unique solution (that is, there exist no solutions or an infinite number of solutions).                                                                                                                                                                                                                                                |
| singular value                        | The numbers defined for a given general matrix $A$ as the eigenvalues of the matrix $AA^H$ . See also SVD.                                                                                                                                                                                                                                                                                                                                                                                        |

---

|                    |                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SMP                | Abbreviation for Symmetric MultiProcessing. The MKL offers performance gains through parallelism provided by the SMP feature.                                                                                                                            |
| sparse BLAS        | Routines performing basic vector operations on sparse vectors. Sparse BLAS routines take advantage of vectors' sparsity: they allow you to store only non-zero elements of vectors. See BLAS.                                                            |
| sparse vectors     | Vectors in which most of the components are zeros.                                                                                                                                                                                                       |
| storage scheme     | The way of storing matrices. See full storage, packed storage, and band storage.                                                                                                                                                                         |
| SVD                | Abbreviation for Singular Value Decomposition. See <i>also</i> Singular value decomposition section in Chapter 5.                                                                                                                                        |
| symmetric matrix   | A square matrix $A$ such that $a_{ij} = a_{ji}$ .                                                                                                                                                                                                        |
| transpose          | The transpose of a given matrix $A$ is a matrix $A^T$ such that $(A^T)_{ij} = a_{ji}$ (rows of $A$ become columns of $A^T$ , and columns of $A$ become rows of $A^T$ ).                                                                                  |
| trapezoidal matrix | A matrix $A$ such that $A = (A_1 A_2)$ , where $A_1$ is an upper triangular matrix, $A_2$ is a rectangular matrix.                                                                                                                                       |
| triangular matrix  | A matrix $A$ is called an upper (lower) triangular matrix if all its subdiagonal elements (superdiagonal elements) are zeros. Thus, for an upper triangular matrix $a_{ij} = 0$ when $i > j$ ; for a lower triangular matrix $a_{ij} = 0$ when $i < j$ . |
| tridiagonal matrix | A matrix whose non-zero elements are in three diagonals only: the leading diagonal, the first subdiagonal, and the first super-diagonal.                                                                                                                 |
| unitary matrix     | A complex square matrix $A$ whose conjugate and inverse are equal, that is, that is, $A^H = A^{-1}$ , and therefore $AA^H = A^H A = I$ . All eigenvalues of a unitary matrix have the absolute value 1.                                                  |
| VML                | Abbreviation for Vector Mathematical Library. See Chapter 9 of this book.                                                                                                                                                                                |
| VSL                | Abbreviation for Vector Statistical Library. See Chapter 10 of this book.                                                                                                                                                                                |
| $z$                | When found as the first letter of routine names, $z$ indicates the usage of double-precision complex data type.                                                                                                                                          |
