Introducing the Intel® Math Kernel Library

The Intel® Math Kernel Library (Intel® MKL) improves performance with math routines for software applications that solve large computational problems. Intel MKL provides BLAS and LAPACK linear algebra routines, fast Fourier transforms, vectorized math functions, random number generation functions, and other functionality.

NOTE

It is your responsibility when using Intel MKL to ensure that input data has the required format and does not contain invalid characters. These can cause unexpected behavior of the library.

The library requires subroutine and function parameters to be valid before being passed. While some Intel MKL routines do limited checking of parameter errors, your application should check for NULL pointers, for example.

Intel MKL is optimized for the latest Intel processors, including processors with multiple cores (see the *Intel MKL Release Notes* for the full list of supported processors). Intel MKL also performs well on non-Intel processors.

For more details about functionality provided by Intel MKL, see the [Function Domains](#) section.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Getting Help and Support

Intel provides a support web site that contains a rich repository of self help information, including getting started tips, known product issues, product errata, license information, user forums, and more. Visit the Intel MKL support website at <http://www.intel.com/software/products/support/>.

What's New

This Developer Reference documents Intel® Math Kernel Library (Intel® MKL) 2017 Update 2 release for the C interface.

NOTE

This publication, the *Intel Math Kernel Library Developer Reference*, was previously known as the *Intel Math Kernel Library Reference Manual*.

The following function domains were updated with new functions, enhancements to the existing functionality, or improvements to the existing documentation:

- Deep Neural Network Functions have been updated to support:
 - Asymmetric border types. For more details, see [dnnConvolutionCreate](#) and [dnnPoolingCreate](#).
 - Selection of the computation method to perform batch normalization. For more details, see the description of the new function [dnnBatchNormalizationCreate_v2](#).
- Support functions have been added to specify and return the number of partitions along the leading dimension of the output matrix for parallel `?gemm` functions. For more details, see [mkl_set_num_stripes](#) and [mkl_get_num_stripes](#).
- Support of ScaLAPACK by the progress routine has been implemented. For more details, see [mkl_progress](#) and [mkl_set_progress](#).

The manual has also been updated to reflect other enhancements to the product, and minor improvements and error corrections have been made.

|----------------------------------|

Notational Conventions

This manual uses the following terms to refer to operating systems:

| | |
|-------------|--|
| Windows* OS | This term refers to information that is valid on all supported Windows* operating systems. |
| Linux* OS | This term refers to information that is valid on all supported Linux* operating systems. |
| macOS* | This term refers to information that is valid on Intel®-based systems running the macOS* operating system. |

This manual uses the following notational conventions:

- Routine name shorthand (for example, `?ungqr` instead of `cungqr/zungqr`).
- Font conventions used for distinction between the text and the code.

Routine Name Shorthand

For shorthand, names that contain a question mark "?" represent groups of routines with similar functionality. Each group typically consists of routines used with four basic data types: single-precision real, double-precision real, single-precision complex, and double-precision complex. The question mark is used to indicate any or all possible varieties of a function; for example:

| | |
|--------------------|--|
| <code>?swap</code> | Refers to all four data types of the vector-vector <code>?swap</code> routine: <code>sswap</code> , <code>dswap</code> , <code>cswap</code> , and <code>zswap</code> . |
|--------------------|--|

Font Conventions

The following font conventions are used:

| | |
|---|---|
| <code>lowercase courier</code> | Code examples: <code>a[k+i][j] = matrix[i][j];</code> data types; for example, <code>const float*</code> |
| <code>lowercase courier mixed with UpperCase courier</code> | Function names; for example, <code>vmlSetMode</code> |
| <code>lowercase courier italic</code> | Variables in arguments and parameters description. For example, <code>incx</code> . |
| <code>*</code> | Used as a multiplication symbol in code examples and equations and where required by the programming language syntax. |

Function Domains

NOTE

It is your responsibility when using Intel MKL to ensure that input data has the required format and does not contain invalid characters. These can cause unexpected behavior of the library.

The library requires subroutine and function parameters to be valid before being passed. While some Intel MKL routines do limited checking of parameter errors, your application should check for NULL pointers, for example.

The Intel® Math Kernel Library includes Fortran routines and functions optimized for Intel® processor-based computers running operating systems that support multiprocessing. In addition to the Fortran interface, Intel MKL includes a C-language interface for the Discrete Fourier transform functions, as well as for the Vector Mathematics and Vector Statistics functions. For hardware and software requirements to use Intel MKL, see *Intel® MKL Release Notes*.

BLAS Routines

The BLAS routines and functions are divided into the following groups according to the operations they perform:

- **BLAS Level 1 Routines** perform operations of both addition and reduction on vectors of data. Typical operations include scaling and dot products.
- **BLAS Level 2 Routines** perform matrix-vector operations, such as matrix-vector multiplication, rank-1 and rank-2 matrix updates, and solution of triangular systems.
- **BLAS Level 3 Routines** perform matrix-matrix operations, such as matrix-matrix multiplication, rank-k update, and solution of triangular systems.

Starting from release 8.0, Intel® MKL also supports the Fortran 95 interface to the BLAS routines.

Starting from release 10.1, a number of **BLAS-like Extensions** are added to enable the user to perform certain data manipulation, including matrix in-place and out-of-place transposition operations combined with simple matrix arithmetic operations.

Sparse BLAS Routines

The **Sparse BLAS Level 1 Routines and Functions** and **Sparse BLAS Level 2 and Level 3 Routines** routines and functions operate on sparse vectors and matrices. These routines perform vector operations similar to the BLAS Level 1, 2, and 3 routines. The Sparse BLAS routines take advantage of vector and matrix sparsity: they allow you to store only non-zero elements of vectors and matrices. Intel MKL also supports Fortran 95 interface to Sparse BLAS routines.

LAPACK Routines

The Intel® Math Kernel Library fully supports the LAPACK 3.6 set of computational, driver, auxiliary and utility routines.

The original versions of LAPACK from which that part of Intel MKL was derived can be obtained from <http://www.netlib.org/lapack/index.html>. The authors of LAPACK are E. Anderson, Z. Bai, C. Bischof, S. Blackford, J. Demmel, J. Dongarra, J. Du Croz, A. Greenbaum, S. Hammarling, A. McKenney, and D. Sorensen.

The **LAPACK routines** can be divided into the following groups according to the operations they perform:

- Routines for solving systems of linear equations, factoring and inverting matrices, and estimating condition numbers (see **LAPACK Routines: Linear Equations**).

- Routines for solving least squares problems, eigenvalue and singular value problems, and Sylvester's equations (see [LAPACK Routines: Least Squares and Eigenvalue Problems](#)).

Starting from release 8.0, Intel MKL also supports the Fortran 95 interface to LAPACK computational and driver routines. This interface provides an opportunity for simplified calls of LAPACK routines with fewer required arguments.

Sparse Solver Routines

Direct sparse solver routines in Intel MKL (see [Chapter 8](#)) solve symmetric and symmetrically-structured sparse matrices with real or complex coefficients. For symmetric matrices, these Intel MKL subroutines can solve both positive-definite and indefinite systems. Intel MKL includes a solver based on the PARDISO* sparse solver, referred to as Intel MKL PARDISO, as well as an alternative set of user callable direct sparse solver routines.

If you use the Intel MKL PARDISO sparse solver, please cite:

O.Schenk and K.Gartner. Solving unsymmetric sparse systems of linear equations with PARDISO. *J. of Future Generation Computer Systems*, 20(3):475-487, 2004.

Intel MKL provides also an iterative sparse solver (see [Chapter 8](#)) that uses Sparse BLAS level 2 and 3 routines and works with different sparse data formats.

Extended Eigensolver Routines

The [Extended Eigensolver RCI Routines](#) is a set of high-performance numerical routines for solving standard ($Ax = \lambda x$) and generalized ($Ax = \lambda Bx$) eigenvalue problems, where A and B are symmetric or Hermitian. It yields all the eigenvalues and eigenvectors within a given search interval. It is based on the Feast algorithm, an innovative fast and stable numerical algorithm presented in [\[Polizzi09\]](#), which deviates fundamentally from the traditional Krylov subspace iteration based techniques (Arnoldi and Lanczos algorithms [\[Bai00\]](#)) or other Davidson-Jacobi techniques [\[Sleijpen96\]](#). The Feast algorithm is inspired by the density-matrix representation and contour integration technique in quantum mechanics.

It is free from orthogonalization procedures. Its main computational tasks consist of solving very few inner independent linear systems with multiple right-hand sides and one reduced eigenvalue problem orders of magnitude smaller than the original one. The Feast algorithm combines simplicity and efficiency and offers many important capabilities for achieving high performance, robustness, accuracy, and scalability on parallel architectures. This algorithm is expected to significantly augment numerical performance in large-scale modern applications.

Some of the characteristics of the Feast algorithm [\[Polizzi09\]](#) are:

- Converges quickly in 2-3 iterations with very high accuracy
- Naturally captures all eigenvalue multiplicities
- No explicit orthogonalization procedure
- Can reuse the basis of pre-computed subspace as suitable initial guess for performing outer-refinement iterations

This capability can also be used for solving a series of eigenvalue problems that are close one another.

- The number of internal iterations is independent of the size of the system and the number of eigenpairs in the search interval
- The inner linear systems can be solved either iteratively (even with modest relative residual error) or directly

VM Functions

The Vector Mathematics functions (see [Chapter 9](#)) include a set of highly optimized implementations of certain computationally expensive core mathematical functions (power, trigonometric, exponential, hyperbolic, etc.) that operate on vectors of real and complex numbers.

Application programs that might significantly improve performance with VM include nonlinear programming software, integrals computation, and many others. VM provides interfaces both for Fortran and C languages.

Statistical Functions

Vector Statistics (VS) contains three sets of functions (see [Chapter 10](#)) providing:

- Pseudorandom, quasi-random, and non-deterministic random number generator subroutines implementing basic continuous and discrete distributions. To provide best performance, the VS subroutines use calls to highly optimized Basic Random Number Generators (BRNGs) and a set of vector mathematical functions.
- A wide variety of convolution and correlation operations.
- Initial statistical analysis of raw single and double precision multi-dimensional datasets.

Fourier Transform Functions

The Intel® MKL multidimensional Fast Fourier Transform (FFT) functions with mixed radix support (see [Chapter 11](#)) provide uniformity of discrete Fourier transform computation and combine functionality with ease of use. Both Fortran and C interface specification are given. There is also a cluster version of FFT functions, which runs on distributed-memory architectures and is provided only for Intel® 64 and Intel® Many Integrated Core architectures.

The FFT functions provide fast computation via the FFT algorithms for arbitrary lengths. See *the Intel® MKL Developer Guide* for the specific radices supported.

Partial Differential Equations Support

Intel® MKL provides tools for solving Partial Differential Equations (PDE) (see [Chapter 13](#)). These tools are Trigonometric Transform interface routines and Poisson Solver.

The Trigonometric Transform routines may be helpful to users who implement their own solvers similar to the Intel MKL Poisson Solver. The users can improve performance of their solvers by using fast sine, cosine, and staggered cosine transforms implemented in the Trigonometric Transform interface.

The Poisson Solver is designed for fast solving of simple Helmholtz, Poisson, and Laplace problems. The Trigonometric Transform interface, which underlies the solver, is based on the Intel MKL FFT interface (refer to [Chapter 11](#)), optimized for Intel® processors.

Support Functions

The Intel® MKL support functions (see [Chapter 15](#)) are used to support the operation of the Intel MKL software and provide basic information on the library and library operation, such as the current library version, timing, setting and measuring of CPU frequency, error handling, and memory allocation.

Starting from release 10.0, the Intel MKL support functions provide additional threading control.

Starting from release 10.1, Intel MKL selectively supports a *Progress Routine* feature to track progress of a lengthy computation and/or interrupt the computation using a callback function mechanism. The user application can define a function called `mkl_progress` that is regularly called from the Intel MKL routine supporting the progress routine feature. See [the Progress Routines](#) section in [Chapter 15](#) for reference. Refer to a specific LAPACK or DSS/PARDISO function description to see whether the function supports this feature or not.

Intel® Math Kernel Library for Deep Neural Networks (Intel® MKL-DNN)

Intel® Math Kernel Library (Intel® MKL) functions for Deep Neural Networks (DNN functions) is a collection of performance primitives for Deep Neural Networks (DNN) applications optimized for Intel® architecture. The implementation of DNN functions includes a limited set of primitives used in the AlexNet topology.

The primitives implement forward and backward passes for several convolution, pooling, normalization, activation, and multi-dimensional transposition operations.

Intel MKL DNN primitives implement a plain C application programming interface (API) that can be used in the existing C/C++ DNN frameworks, as well as in custom DNN applications.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Performance Enhancements

The Intel® Math Kernel Library has been optimized by exploiting both processor and system features and capabilities. Special care has been given to those routines that most profit from cache-management techniques. These especially include matrix-matrix operation routines such as `dgemm()`.

In addition, code optimization techniques have been applied to minimize dependencies of scheduling integer and floating-point units on the results within the processor.

The major optimization techniques used throughout the library include:

- Loop unrolling to minimize loop management costs
- Blocking of data to improve data reuse opportunities
- Copying to reduce chances of data eviction from cache
- Data prefetching to help hide memory latency
- Multiple simultaneous operations (for example, dot products in `dgemm`) to eliminate stalls due to arithmetic unit pipelines
- Use of hardware features such as the SIMD arithmetic units, where appropriate

These are techniques from which the arithmetic code benefits the most.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Parallelism

In addition to the performance enhancements discussed above, Intel® MKL offers performance gains through parallelism provided by the symmetric multiprocessing performance (SMP) feature. You can obtain improvements from SMP in the following ways:

- One way is based on user-managed threads in the program and further distribution of the operations over the threads based on data decomposition, domain decomposition, control decomposition, or some other parallelizing technique. Each thread can use any of the Intel MKL functions (except for the deprecated `?lacon` LAPACK routine) because the library has been designed to be thread-safe.
- Another method is to use the FFT and BLAS level 3 routines. They have been parallelized and require no alterations of your application to gain the performance enhancements of multiprocessing. Performance using multiple processors on the level 3 BLAS shows excellent scaling. Since the threads are called and managed within the library, the application does not need to be recompiled thread-safe.

- Yet another method is to use *tuned LAPACK routines*. Currently these include the single- and double precision flavors of routines for *QR* factorization of general matrices, triangular factorization of general and symmetric positive-definite matrices, solving systems of equations with such matrices, as well as solving symmetric eigenvalue problems.

For instructions on setting the number of available processors for the BLAS level 3 and LAPACK routines, see *Intel® MKL Developer Guide*.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

C Datatypes Specific to Intel MKL

The `mk1_types.h` file defines datatypes specific to Intel MKL.

| C/C++ Type | Fortran Type | LP32 Equivalent (Size in Bytes) | LP64 Equivalent (Size in Bytes) | ILP64 Equivalent (Size in Bytes) |
|---|---------------------------------|---|---|---|
| MKL_INT (MKL integer) | INTEGER (default INTEGER) | C/C++: int Fortran: INTEGER*4 (4 bytes) | C/C++: int Fortran: INTEGER*4 (4 bytes) | C/C++: long long (or define MKL_ILP64 macros Fortran: INTEGER*8 (8 bytes) |
| MKL_UINT (MKL unsigned integer) | N/A | C/C++: unsigned int (4 bytes) | C/C++: unsigned int (4 bytes) | C/C++: unsigned long long (8 bytes) |
| MKL_LONG (MKL long integer) | N/A | C/C++: long (4 bytes) | C/C++: long (Windows: 4 bytes) (Linux, Mac: 8 bytes) | C/C++: long (8 bytes) |
| MKL_Complex8 (Like C99 complex float) | COMPLEX*8 | (8 bytes) | (8 bytes) | (8 bytes) |
| MKL_Complex16 (Like C99 complex double) | COMPLEX*16 | (16 bytes) | (16 bytes) | (16 bytes) |

You can redefine datatypes specific to Intel MKL. One reason to do this is if you have your own types which are binary-compatible with Intel MKL datatypes, with the same representation or memory layout. To redefine a datatype, use one of these methods:

- Insert the `#define` statement redefining the datatype before the `mkl.h` header file `#include` statement. For example,

```
#define MKL_INT size_t
#include "mkl.h"
```

- Use the compiler `-D` option to redefine the datatype. For example,

```
...-DMKL_INT=size_t...
```

NOTE

As the user, if you redefine Intel MKL datatypes you are responsible for making sure that your definition is compatible with that of Intel MKL. If not, it might cause unpredictable results or crash the application.

BLAS and Sparse BLAS Routines

This chapter describes the Intel® Math Kernel Library implementation of the BLAS and Sparse BLAS routines, and BLAS-like extensions. The routine descriptions are arranged in several sections:

- [BLAS Level 1 Routines](#) (vector-vector operations)
- [BLAS Level 2 Routines](#) (matrix-vector operations)
- [BLAS Level 3 Routines](#) (matrix-matrix operations)
- [Sparse BLAS Level 1 Routines](#) (vector-vector operations).
- [Sparse BLAS Level 2 and Level 3 Routines](#) (matrix-vector and matrix-matrix operations)
- [BLAS-like Extensions](#)

Each section presents the routine and function group descriptions in alphabetical order by routine or function group name; for example, the `?asum` group, the `?axpy` group. The question mark in the group name corresponds to different character codes indicating the data type (`s`, `d`, `c`, and `z` or their combination); see [Routine Naming Conventions](#).

When BLAS or Sparse BLAS routines encounter an error, they call the error reporting routine `xerbla`.

In BLAS Level 1 groups `i?amax` and `i?amin`, an "i" is placed before the data-type indicator and corresponds to the index of an element in the vector. These groups are placed in the end of the BLAS Level 1 section.

BLAS Routines

Naming Conventions for BLAS Routines

BLAS routine names have the following structure:

`<character> <name> <mod> ()`

The `<character>` field indicates the data type:

| | |
|----------------|---------------------------|
| <code>s</code> | real, single precision |
| <code>c</code> | complex, single precision |
| <code>d</code> | real, double precision |
| <code>z</code> | complex, double precision |

Some routines and functions can have combined character codes, such as `sc` or `dz`.

For example, the function `scasum` uses a complex input array and returns a real value.

The `<name>` field, in BLAS level 1, indicates the operation type. For example, the BLAS level 1 routines `?dot`, `?rot`, `?swap` compute a vector dot product, vector rotation, and vector swap, respectively.

In BLAS level 2 and 3, `<name>` reflects the matrix argument type:

| | |
|-----------------|---------------------|
| <code>ge</code> | general matrix |
| <code>gb</code> | general band matrix |
| <code>sy</code> | symmetric matrix |

| | |
|----|------------------------------------|
| sp | symmetric matrix (packed storage) |
| sb | symmetric band matrix |
| he | Hermitian matrix |
| hp | Hermitian matrix (packed storage) |
| hb | Hermitian band matrix |
| tr | triangular matrix |
| tp | triangular matrix (packed storage) |
| tb | triangular band matrix. |

The *<mod>* field, if present, provides additional details of the operation. BLAS level 1 names can have the following characters in the *<mod>* field:

| | |
|----|---------------------------------------|
| c | conjugated vector |
| u | unconjugated vector |
| g | Givens rotation construction |
| m | modified Givens rotation |
| mg | modified Givens rotation construction |

BLAS level 2 names can have the following characters in the *<mod>* field:

| | |
|----|---|
| mv | matrix-vector product |
| sv | solving a system of linear equations with a single unknown vector |
| r | rank-1 update of a matrix |
| r2 | rank-2 update of a matrix. |

BLAS level 3 names can have the following characters in the *<mod>* field:

| | |
|-----|--|
| mm | matrix-matrix product |
| sm | solving a system of linear equations with multiple unknown vectors |
| rk | rank- <i>k</i> update of a matrix |
| r2k | rank-2 <i>k</i> update of a matrix. |

The examples below illustrate how to interpret BLAS routine names:

| | |
|--------|---|
| ddot | <i><d></i> <i><dot></i> : double-precision real vector-vector dot product |
| cdotc | <i><c></i> <i><dot></i> <i><c></i> : complex vector-vector dot product, conjugated |
| scasum | <i><sc></i> <i><asum></i> : sum of magnitudes of vector elements, single precision real output and single precision complex input |
| cdotu | <i><c></i> <i><dot></i> <i><u></i> : vector-vector dot product, unconjugated, complex |
| sgemv | <i><s></i> <i><ge></i> <i><mv></i> : matrix-vector product, general matrix, single precision |

`ztrmm` `<z> <tr> <mm>`: matrix-matrix product, triangular matrix, double-precision complex.

Sparse BLAS level 1 naming conventions are similar to those of BLAS level 1. For more information, see [Naming Conventions](#).

C Interface Conventions for BLAS Routines

CBLAS, the C interface to the Basic Linear Algebra Subprograms (BLAS), provides a C language interface to BLAS routines for Intel MKL. While you can call the Fortran implementation of BLAS, for coding in C the CBLAS interface has some advantages such as allowing you to specify column-major or row-major ordering with the `layout` parameter.

For more information about calling Fortran routines from C in general, and specifically about calling BLAS and CBLAS routines, see "Mixed-language Programming with the Intel Math Kernel Library" in the *Intel Math Kernel Library Developer Guide*.

NOTE

This reference contains syntax in C for both the CBLAS interface and the Fortran BLAS routines.

In CBLAS, the Fortran routine names are prefixed with `cblas_` (for example, `dasum` becomes `cblas_dasum`). Names of all CBLAS functions are in lowercase letters.

Complex functions `?dotc` and `?dotu` become CBLAS subroutines (void functions); they return the complex result via a void pointer, added as the last parameter. CBLAS names of these functions are suffixed with `_sub`. For example, the BLAS function `cdotc` corresponds to `cblas_cdotc_sub`.

WARNING

Users of the CBLAS interface should be aware that the CBLAS are just a C interface to the BLAS, which is based on the FORTRAN standard and subject to the FORTRAN standard restrictions. In particular, the output parameters should not be referenced through more than one argument.

NOTE

This interface is not implemented in the Sparse BLAS Level 2 and Level 3 routines.

The arguments of CBLAS functions comply with the following rules:

- Input arguments are declared with the `const` modifier.
- Non-complex scalar input arguments are passed by value.
- Complex scalar input arguments are passed as void pointers.
- Array arguments are passed by address.
- BLAS character arguments are replaced by the appropriate enumerated type.
- Level 2 and Level 3 routines acquire an additional parameter of type `CBLAS_LAYOUT` as their first argument. This parameter specifies whether two-dimensional arrays are row-major (`CblasRowMajor`) or column-major (`CblasColMajor`).

Enumerated Types

The CBLAS interface uses the following enumerated types:

```
enum CBLAS_LAYOUT {
    CblasRowMajor=101, /* row-major arrays */
    CblasColMajor=102}; /* column-major arrays */
enum CBLAS_TRANSPOSE {
    CblasNoTrans=111, /* trans='N' */
    CblasTrans=112, /* trans='T' */
```

```

    CblasConjTrans=113}; /* trans='C' */
enum CBLAS_UPLO {
    CblasUpper=121,      /* uplo ='U' */
    CblasLower=122};   /* uplo ='L' */
enum CBLAS_DIAG {
    CblasNonUnit=131,   /* diag ='N' */
    CblasUnit=132};    /* diag ='U' */
enum CBLAS_SIDE {
    CblasLeft=141,     /* side ='L' */
    CblasRight=142};  /* side ='R' */

```

Matrix Storage Schemes for BLAS Routines

Matrix arguments of BLAS and CBLAS routines can use the following storage schemes:

- *Full storage*: a matrix A is stored in a two-dimensional array a , with the matrix element A_{ij} stored in the array element $a[i + j*lda]$ for column-major layout and $a[j + i*lda]$ for row-major layout, where lda is the leading dimension for the array.
- *Packed storage* scheme allows you to store symmetric, Hermitian, or triangular matrices more compactly. For column-major layout, the upper or lower triangle of the matrix is packed by columns in a one dimensional array. For row-major layout, the upper or lower triangle of the matrix is packed by rows in a one dimensional array.
- *Band storage*: a band matrix is stored compactly in a two-dimensional array. For column-major layout, columns of the matrix are stored in the corresponding columns of the array, and diagonals of the matrix are stored in a specific row of the array. For row-major layout, rows of the matrix are stored in the corresponding rows of the array, and diagonals of the matrix are stored in a specific column of the array.

For more information on matrix storage schemes, see [Matrix Arguments](#) in Appendix B.

Row-Major and Column-Major Layout

The BLAS routines follow the Fortran convention of storing two-dimensional arrays using column-major layout. When calling BLAS routines from C, remember that they require arrays to be in column-major format, not the row-major format that is the convention for C. Unless otherwise specified, the psuedo-code examples for the BLAS routines illustrate matrices stored using column-major layout.

The CBLAS interface allows you to specify either column-major or row-major layout for BLAS Level 2 and Level 3 routines, by setting the `layout` parameter to `CblasColMajor` or `CblasRowMajor`.

BLAS Level 1 Routines and Functions

BLAS Level 1 includes routines and functions, which perform vector-vector operations. [Table “BLAS Level 1 Routine Groups and Their Data Types”](#) lists the BLAS Level 1 routine and function groups and the data types associated with them.

BLAS Level 1 Routine and Function Groups and Their Data Types

| Routine or Function Group | Data Types | Description |
|---------------------------|--------------|---|
| <code>cblas_?asum</code> | s, d, sc, dz | Sum of vector magnitudes (functions) |
| <code>cblas_?axpy</code> | s, d, c, z | Scalar-vector product (routines) |
| <code>cblas_?copy</code> | s, d, c, z | Copy vector (routines) |
| <code>cblas_?dot</code> | s, d | Dot product (functions) |
| <code>cblas_?sdot</code> | sd, d | Dot product with double precision (functions) |

| Routine or Function Group | Data Types | Description |
|---------------------------|--------------------|---|
| <code>cblas_?dotc</code> | c, z | Dot product conjugated (functions) |
| <code>cblas_?dotu</code> | c, z | Dot product unconjugated (functions) |
| <code>cblas_?nrm2</code> | s, d, sc, dz | Vector 2-norm (Euclidean norm) (functions) |
| <code>cblas_?rot</code> | s, d, cs, zd | Plane rotation of points (routines) |
| <code>cblas_?rotg</code> | s, d, c, z | Generate Givens rotation of points (routines) |
| <code>cblas_?rotm</code> | s, d | Modified Givens plane rotation of points (routines) |
| <code>cblas_?rotmg</code> | s, d | Generate modified Givens plane rotation of points (routines) |
| <code>cblas_?scal</code> | s, d, c, z, cs, zd | Vector-scalar product (routines) |
| <code>cblas_?swap</code> | s, d, c, z | Vector-vector swap (routines) |
| <code>cblas_i?amax</code> | s, d, c, z | Index of the maximum absolute value element of a vector (functions) |
| <code>cblas_i?amin</code> | s, d, c, z | Index of the minimum absolute value element of a vector (functions) |
| <code>cblas_?cabs1</code> | s, d | Auxiliary functions, compute the absolute value of a complex number of single or double precision |

cblas_?asum

Computes the sum of magnitudes of the vector elements.

Syntax

```
float cblas_sasum (const MKL_INT n, const float *x, const MKL_INT incx);
float cblas_scasum (const MKL_INT n, const void *x, const MKL_INT incx);
double cblas_dasum (const MKL_INT n, const double *x, const MKL_INT incx);
double cblas_dzasum (const MKL_INT n, const void *x, const MKL_INT incx);
```

Include Files

- `mk1.h`

Description

The `?asum` routine computes the sum of the magnitudes of elements of a real vector, or the sum of magnitudes of the real and imaginary parts of elements of a complex vector:

$$\text{res} = |\text{Re}x_1| + |\text{Im}x_1| + |\text{Re}x_2| + |\text{Im}x_2| + \dots + |\text{Re}x_n| + |\text{Im}x_n|,$$

where x is a vector with n elements.

Input Parameters

n Specifies the number of elements in vector x .

x

Array, size at least $(1 + (n-1) * \text{abs}(incx))$.

incx Specifies the increment for indexing vector *x*.

Return Values

Contains the sum of magnitudes of real and imaginary parts of all elements of the vector.

cblas_?axpy

Computes a vector-scalar product and adds the result to a vector.

Syntax

```
void cblas_saxpy (const MKL_INT n, const float a, const float *x, const MKL_INT incx, float *y, const MKL_INT incy);
```

```
void cblas_daxpy (const MKL_INT n, const double a, const double *x, const MKL_INT incx, double *y, const MKL_INT incy);
```

```
void cblas_caxpy (const MKL_INT n, const void *a, const void *x, const MKL_INT incx, void *y, const MKL_INT incy);
```

```
void cblas_zaxpy (const MKL_INT n, const void *a, const void *x, const MKL_INT incx, void *y, const MKL_INT incy);
```

Include Files

- mkl.h

Description

The ?axpy routines perform a vector-vector operation defined as

```
y := a*x + y
```

where:

a is a scalar

x and *y* are vectors each with a number of elements that equals *n*.

Input Parameters

n Specifies the number of elements in vectors *x* and *y*.

a Specifies the scalar *a*.

x Array, size at least $(1 + (n-1) * \text{abs}(incx))$.

incx Specifies the increment for the elements of *x*.

y Array, size at least $(1 + (n-1) * \text{abs}(incy))$.

incy Specifies the increment for the elements of *y*.

Output Parameters

y Contains the updated vector *y*.

cblas_?copy

Copies vector to another vector.

Syntax

```
void cblas_scopy (const MKL_INT n, const float *x, const MKL_INT incx, float *y, const
MKL_INT incy);
```

```
void cblas_dcopy (const MKL_INT n, const double *x, const MKL_INT incx, double *y,
const MKL_INT incy);
```

```
void cblas_ccopy (const MKL_INT n, const void *x, const MKL_INT incx, void *y, const
MKL_INT incy);
```

```
void cblas_zcopy (const MKL_INT n, const void *x, const MKL_INT incx, void *y, const
MKL_INT incy);
```

Include Files

- mkl.h

Description

The ?copy routines perform a vector-vector operation defined as

```
y = x,
```

where x and y are vectors.

Input Parameters

| | |
|--------|---|
| n | Specifies the number of elements in vectors x and y . |
| x | Array, size at least $(1 + (n-1)*abs(incx))$. |
| $incx$ | Specifies the increment for the elements of x . |
| y | Array, size at least $(1 + (n-1)*abs(incy))$. |
| $incy$ | Specifies the increment for the elements of y . |

Output Parameters

| | |
|-----|--|
| y | Contains a copy of the vector x if n is positive. Otherwise, parameters are unaltered. |
|-----|--|

cblas_?dot

Computes a vector-vector dot product.

Syntax

```
float cblas_sdot (const MKL_INT n, const float *x, const MKL_INT incx, const float *y,
const MKL_INT incy);
```

```
double cblas_ddot (const MKL_INT n, const double *x, const MKL_INT incx, const double
*y, const MKL_INT incy);
```

Include Files

- `mkl.h`

Description

The `?dot` routines perform a vector-vector reduction operation defined as

$$res = \sum_{i=1}^n x_i * y_i,$$

where x_i and y_i are elements of vectors x and y .

Input Parameters

| | |
|-------------------|---|
| <code>n</code> | Specifies the number of elements in vectors x and y . |
| <code>x</code> | Array, size at least $(1+(n-1)*abs(incx))$. |
| <code>incx</code> | Specifies the increment for the elements of x . |
| <code>y</code> | Array, size at least $(1+(n-1)*abs(incy))$. |
| <code>incy</code> | Specifies the increment for the elements of y . |

Return Values

The result of the dot product of x and y , if n is positive. Otherwise, returns 0.

`cblas_?sdot`

Computes a vector-vector dot product with double precision.

Syntax

```
float cblas_sdsdot (const MKL_INT n, const float sb, const float *sx, const MKL_INT incx, const float *sy, const MKL_INT incy);
```

```
double cblas_dsdot (const MKL_INT n, const float *sx, const MKL_INT incx, const float *sy, const MKL_INT incy);
```

Include Files

- `mkl.h`

Description

The `?sdot` routines compute the inner product of two vectors with double precision. Both routines use double precision accumulation of the intermediate results, but the `sdsdot` routine outputs the final result in single precision, whereas the `dsdot` routine outputs the double precision result. The function `sdsdot` also adds scalar value sb to the inner product.

Input Parameters

| | |
|----------------|---|
| <code>n</code> | Specifies the number of elements in the input vectors sx and sy . |
|----------------|---|

| | |
|---------------|---|
| <i>sb</i> | Single precision scalar to be added to inner product (for the function <code>sdsdot</code> only). |
| <i>sx, sy</i> | Arrays, size at least $(1+(n-1)*abs(incx))$ and $(1+(n-1)*abs(incy))$, respectively. Contain the input single precision vectors. |
| <i>incx</i> | Specifies the increment for the elements of <i>sx</i> . |
| <i>incy</i> | Specifies the increment for the elements of <i>sy</i> . |

Return Values

The result of the dot product of *sx* and *sy* (with *sb* added for `sdsdot`), if *n* is positive. Otherwise, returns *sb* for `sdsdot` and 0 for `dsdot`.

cblas_?dotc

Computes a dot product of a conjugated vector with another vector.

Syntax

```
void cblas_cdotc_sub (const MKL_INT n, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *dotc);
```

```
void cblas_zdotc_sub (const MKL_INT n, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *dotc);
```

Include Files

- `mkl.h`

Description

The `?dotc` routines perform a vector-vector operation defined as:

$$res = \sum_{i=1}^n conjg(x_i) * y_i,$$

where x_i and y_i are elements of vectors *x* and *y*.

Input Parameters

| | |
|-------------|---|
| <i>n</i> | Specifies the number of elements in vectors <i>x</i> and <i>y</i> . |
| <i>x</i> | Array, size at least $(1 + (n-1)*abs(incx))$. |
| <i>incx</i> | Specifies the increment for the elements of <i>x</i> . |
| <i>y</i> | Array, size at least $(1 + (n-1)*abs(incy))$. |
| <i>incy</i> | Specifies the increment for the elements of <i>y</i> . |

Output Parameters

| | |
|-------------|--|
| <i>dotc</i> | Contains the result of the dot product of the conjugated <i>x</i> and unconjugated <i>y</i> , if <i>n</i> is positive. Otherwise, it contains 0. |
|-------------|--|

cblas_?dotu

Computes a vector-vector dot product.

Syntax

```
void cblas_cdotu_sub (const MKL_INT n, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *dotu);
```

```
void cblas_zdotu_sub (const MKL_INT n, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *dotu);
```

Include Files

- mkl.h

Description

The ?dotu routines perform a vector-vector reduction operation defined as

$$res = \sum_{i=1}^n x_i * y_i$$

where x_i and y_i are elements of complex vectors x and y .

Input Parameters

| | |
|--------|---|
| n | Specifies the number of elements in vectors x and y . |
| x | Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. |
| $incx$ | Specifies the increment for the elements of x . |
| y | Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. |
| $incy$ | Specifies the increment for the elements of y . |

Output Parameters

| | |
|--------|---|
| $dotu$ | Contains the result of the dot product of x and y , if n is positive. Otherwise, it contains 0. |
|--------|---|

cblas_?nrm2

Computes the Euclidean norm of a vector.

Syntax

```
float cblas_snorm2 (const MKL_INT n, const float *x, const MKL_INT incx);
```

```
double cblas_dnorm2 (const MKL_INT n, const double *x, const MKL_INT incx);
```

```
float cblas_scnrm2 (const MKL_INT n, const void *x, const MKL_INT incx);
```

```
double cblas_dznrm2 (const MKL_INT n, const void *x, const MKL_INT incx);
```

Include Files

- mkl.h

Description

The `?nrm2` routines perform a vector reduction operation defined as

```
res = ||x||,
```

where:

x is a vector,

res is a value containing the Euclidean norm of the elements of x .

Input Parameters

| | |
|--------|---|
| n | Specifies the number of elements in vector x . |
| x | Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. |
| $incx$ | Specifies the increment for the elements of x . |

Return Values

The Euclidean norm of the vector x .

`cblas_?rot`

Performs rotation of points in the plane.

Syntax

```
void cblas_srot (const MKL_INT n, float *x, const MKL_INT incx, float *y, const MKL_INT
incy, const float c, const float s);
```

```
void cblas_drot (const MKL_INT n, double *x, const MKL_INT incx, double *y, const
MKL_INT incy, const double c, const double s);
```

```
void cblas_csrot (const MKL_INT n, void *x, const MKL_INT incx, void *y, const MKL_INT
incy, const float c, const float s);
```

```
void cblas_zdrot (const MKL_INT n, void *x, const MKL_INT incx, void *y, const MKL_INT
incy, const double c, const double s);
```

Include Files

- `mkl.h`

Description

Given two complex vectors x and y , each vector element of these vectors is replaced as follows:

$$x_i = c * x_i + s * y_i$$

$$y_i = c * y_i - s * x_i$$

Input Parameters

| | |
|--------|---|
| n | Specifies the number of elements in vectors x and y . |
| x | Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. |
| $incx$ | Specifies the increment for the elements of x . |

| | |
|-------------|---|
| <i>y</i> | Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. |
| <i>incy</i> | Specifies the increment for the elements of <i>y</i> . |
| <i>c</i> | A scalar. |
| <i>s</i> | A scalar. |

Output Parameters

| | |
|----------|---|
| <i>x</i> | Each element is replaced by $c*x + s*y$. |
| <i>y</i> | Each element is replaced by $c*y - s*x$. |

cblas_?rotg

Computes the parameters for a Givens rotation.

Syntax

```
void cblas_srotg (float *a, float *b, float *c, float *s);  
void cblas_drotg (double *a, double *b, double *c, double *s);  
void cblas_crotg (void *a, const void *b, float *c, void *s);  
void cblas_zrotg (void *a, const void *b, double *c, void *s);
```

Include Files

- mkl.h

Description

Given the Cartesian coordinates (a, b) of a point, these routines return the parameters c , s , r , and z associated with the Givens rotation. The parameters c and s define a unitary matrix such that:

$$\begin{bmatrix} c & s \\ -s & c \end{bmatrix} \begin{bmatrix} a \\ b \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix}$$

The parameter z is defined such that if $|a| > |b|$, z is s ; otherwise if c is not 0 z is $1/c$; otherwise z is 1.

Input Parameters

| | |
|----------|---|
| <i>a</i> | Provides the x-coordinate of the point <i>p</i> . |
| <i>b</i> | Provides the y-coordinate of the point <i>p</i> . |

Output Parameters

| | |
|----------|---|
| <i>a</i> | Contains the parameter r associated with the Givens rotation. |
| <i>b</i> | Contains the parameter z associated with the Givens rotation. |
| <i>c</i> | Contains the parameter c associated with the Givens rotation. |
| <i>s</i> | Contains the parameter s associated with the Givens rotation. |

cblas_?rotm

Performs modified Givens rotation of points in the plane.

Syntax

```
void cblas_srotm (const MKL_INT n, float *x, const MKL_INT incx, float *y, const
MKL_INT incy, const float *param);
```

```
void cblas_drotm (const MKL_INT n, double *x, const MKL_INT incx, double *y, const
MKL_INT incy, const double *param);
```

Include Files

- mkl.h

Description

Given two vectors x and y , each vector element of these vectors is replaced as follows:

$$\begin{bmatrix} x_i \\ y_i \end{bmatrix} = H \begin{bmatrix} x_i \\ y_i \end{bmatrix}$$

for $i=1$ to n , where H is a modified Givens transformation matrix whose values are stored in the `param[1]` through `param[4]` array. See discussion on the `param` argument.

Input Parameters

`n` Specifies the number of elements in vectors x and y .

`x` Array, size at least $(1 + (n - 1) * \text{abs}(incx))$.

`incx` Specifies the increment for the elements of x .

`y` Array, size at least $(1 + (n - 1) * \text{abs}(incy))$.

`incy` Specifies the increment for the elements of y .

`param` Array, size 5.

The elements of the `param` array are:

`param[0]` contains a switch, `flag`. `param[1-4]` contain h_{11} , h_{21} , h_{12} , and h_{22} , respectively, the components of the array H .

Depending on the values of `flag`, the components of H are set as follows:

$$flag = -1.0: H = \begin{bmatrix} h_{11} & h_{12} \\ h_{21} & h_{22} \end{bmatrix}$$

$$flag = 0.0: H = \begin{bmatrix} 1.0 & h_{12} \\ h_{21} & 1.0 \end{bmatrix}$$

$$flag = 1.0: H = \begin{bmatrix} h_{11} & 1.0 \\ -1.0 & h_{22} \end{bmatrix}$$

$$flag = -2.0: H = \begin{bmatrix} 1.0 & 0.0 \\ 0.0 & 1.0 \end{bmatrix}$$

In the last three cases, the matrix entries of 1.0, -1.0, and 0.0 are assumed based on the value of *flag* and are not required to be set in the *param* vector.

Output Parameters

x Each element $x[i]$ is replaced by $h_{11} * x[i] + h_{12} * y[i]$.

y Each element $y[i]$ is replaced by $h_{21} * x[i] + h_{22} * y[i]$.

cblas_?rotmg

Computes the parameters for a modified Givens rotation.

Syntax

```
void cblas_srotmg (float *d1, float *d2, float *x1, const float y1, float *param);
void cblas_drotmg (double *d1, double *d2, double *x1, const double y1, double *param);
```

Include Files

- mkl.h

Description

Given Cartesian coordinates (*x1*, *y1*) of an input vector, these routines compute the components of a modified Givens transformation matrix *H* that zeros the *y*-component of the resulting vector:

$$\begin{bmatrix} x1 \\ 0 \end{bmatrix} = H \begin{bmatrix} x1\sqrt{d1} \\ y1\sqrt{d2} \end{bmatrix}$$

Input Parameters

d1 Provides the scaling factor for the *x*-coordinate of the input vector.

d2 Provides the scaling factor for the *y*-coordinate of the input vector.

x1 Provides the *x*-coordinate of the input vector.

y1 Provides the *y*-coordinate of the input vector.

Output Parameters

d1 Provides the first diagonal element of the updated matrix.

d2 Provides the second diagonal element of the updated matrix.

x1 Provides the *x*-coordinate of the rotated vector before scaling.

param Array, size 5.
The elements of the *param* array are:
param[0] contains a switch, *flag*. the other array elements *param*[1-4] contain the components of the array *H*: h_{11} , h_{21} , h_{12} , and h_{22} , respectively.
Depending on the values of *flag*, the components of *H* are set as follows:

$$flag = -1.0: H = \begin{bmatrix} h_{11} & h_{12} \\ h_{21} & h_{22} \end{bmatrix}$$

$$flag = 0.0: H = \begin{bmatrix} 1.0 & h_{12} \\ h_{21} & 1.0 \end{bmatrix}$$

$$flag = 1.0: H = \begin{bmatrix} h_{11} & 1.0 \\ -1.0 & h_{22} \end{bmatrix}$$

$$flag = -2.0: H = \begin{bmatrix} 1.0 & 0.0 \\ 0.0 & 1.0 \end{bmatrix}$$

In the last three cases, the matrix entries of 1.0, -1.0, and 0.0 are assumed based on the value of *flag* and are not required to be set in the *param* vector.

cblas_?scal

Computes the product of a vector by a scalar.

Syntax

```
void cblas_sscal (const MKL_INT n, const float a, float *x, const MKL_INT incx);
void cblas_dscal (const MKL_INT n, const double a, double *x, const MKL_INT incx);
void cblas_cscal (const MKL_INT n, const void *a, void *x, const MKL_INT incx);
void cblas_zscal (const MKL_INT n, const void *a, void *x, const MKL_INT incx);
void cblas_csscal (const MKL_INT n, const float a, void *x, const MKL_INT incx);
void cblas_zdscal (const MKL_INT n, const double a, void *x, const MKL_INT incx);
```

Include Files

- mkl.h

Description

The ?scal routines perform a vector operation defined as

$$x = a*x$$

where:

a is a scalar, *x* is an *n*-element vector.

Input Parameters

| | |
|-------------|---|
| <i>n</i> | Specifies the number of elements in vector <i>x</i> . |
| <i>a</i> | Specifies the scalar <i>a</i> . |
| <i>x</i> | Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. |
| <i>incx</i> | Specifies the increment for the elements of <i>x</i> . |

Output Parameters

x Updated vector *x*.

cblas_?swap

Swaps a vector with another vector.

Syntax

```
void cblas_sswap (const MKL_INT n, float *x, const MKL_INT incx, float *y, const MKL_INT incy);
```

```
void cblas_dswap (const MKL_INT n, double *x, const MKL_INT incx, double *y, const MKL_INT incy);
```

```
void cblas_cswap (const MKL_INT n, void *x, const MKL_INT incx, void *y, const MKL_INT incy);
```

```
void cblas_zswap (const MKL_INT n, void *x, const MKL_INT incx, void *y, const MKL_INT incy);
```

Include Files

- mkl.h

Description

Given two vectors *x* and *y*, the *?swap* routines return vectors *y* and *x* swapped, each replacing the other.

Input Parameters

n Specifies the number of elements in vectors *x* and *y*.

x Array, size at least $(1 + (n-1)*abs(incx))$.

incx Specifies the increment for the elements of *x*.

y Array, size at least $(1 + (n-1)*abs(incy))$.

incy Specifies the increment for the elements of *y*.

Output Parameters

x Contains the resultant vector *x*, that is, the input vector *y*.

y Contains the resultant vector *y*, that is, the input vector *x*.

cblas_i?amax

Finds the index of the element with maximum absolute value.

Syntax

```
CBLAS_INDEX cblas_isamax (const MKL_INT n, const float *x, const MKL_INT incx);
```

```
CBLAS_INDEX cblas_idamax (const MKL_INT n, const double *x, const MKL_INT incx);
```

```
CBLAS_INDEX cblas_icamax (const MKL_INT n, const void *x, const MKL_INT incx);
```

```
CBLAS_INDEX cblas_izamax (const MKL_INT n, const void *x, const MKL_INT incx);
```

Include Files

- mkl.h

Description

Given a vector x , the $i?amax$ functions return the position of the vector element $x[i]$ that has the largest absolute value for real flavors, or the largest sum $|\operatorname{Re}(x[i])| + |\operatorname{Im}(x[i])|$ for complex flavors.

If n is not positive, 0 is returned.

If more than one vector element is found with the same largest absolute value, the index of the first one encountered is returned.

Input Parameters

| | |
|--------|---|
| n | Specifies the number of elements in vector x . |
| x | Array, size at least $(1+(n-1)*\operatorname{abs}(incx))$. |
| $incx$ | Specifies the increment for the elements of x . |

Return Values

Returns the position of vector element that has the largest absolute value such that $x[index-1]$ has the largest absolute value.

cblas_i?amin

Finds the index of the element with the smallest absolute value.

Syntax

```
CBLAS_INDEX cblas_isamin (const MKL_INT n, const float *x, const MKL_INT incx);
CBLAS_INDEX cblas_idamin (const MKL_INT n, const double *x, const MKL_INT incx);
CBLAS_INDEX cblas_icamin (const MKL_INT n, const void *x, const MKL_INT incx);
CBLAS_INDEX cblas_izamin (const MKL_INT n, const void *x, const MKL_INT incx);
```

Include Files

- mkl.h

Description

Given a vector x , the $i?amin$ functions return the position of the vector element $x[i]$ that has the smallest absolute value for real flavors, or the smallest sum $|\operatorname{Re}(x[i])| + |\operatorname{Im}(x[i])|$ for complex flavors.

If n is not positive, 0 is returned.

If more than one vector element is found with the same smallest absolute value, the index of the first one encountered is returned.

Input Parameters

| | |
|-----|--|
| n | On entry, n specifies the number of elements in vector x . |
| x | Array, size at least $(1+(n-1)*\operatorname{abs}(incx))$. |

incx Specifies the increment for the elements of *x*.

Return Values

Indicates the position of vector element with the smallest absolute value such that $x[index-1]$ has the smallest absolute value.

cblas_?cabs1

Computes absolute value of complex number.

Syntax

```
float cblas_scabs1 (const void *z);
double cblas_dcabs1 (const void *z);
```

Include Files

- mkl.h

Description

The `?cabs1` is an auxiliary routine for a few BLAS Level 1 routines. This routine performs an operation defined as

```
res = |Re(z)| + |Im(z)|,
```

where *z* is a scalar, and *res* is a value containing the absolute value of a complex number *z*.

Input Parameters

z Scalar.

Return Values

The absolute value of a complex number *z*.

BLAS Level 2 Routines

This section describes BLAS Level 2 routines, which perform matrix-vector operations. [Table "BLAS Level 2 Routine Groups and Their Data Types"](#) lists the BLAS Level 2 routine groups and the data types associated with them.

BLAS Level 2 Routine Groups and Their Data Types

| Routine Groups | Data Types | Description |
|--------------------------|------------|---|
| <code>cblas_?gbmv</code> | s, d, c, z | Matrix-vector product using a general band matrix |
| <code>cblas?_gemv</code> | s, d, c, z | Matrix-vector product using a general matrix |
| <code>cblas_?ger</code> | s, d | Rank-1 update of a general matrix |
| <code>cblas_?gerc</code> | c, z | Rank-1 update of a conjugated general matrix |
| <code>cblas_?geru</code> | c, z | Rank-1 update of a general matrix, unconjugated |
| <code>cblas_?hbmV</code> | c, z | Matrix-vector product using a Hermitian band matrix |
| <code>cblas_?hemv</code> | c, z | Matrix-vector product using a Hermitian matrix |

| Routine Groups | Data Types | Description |
|--------------------------|------------|--|
| <code>cblas_?her</code> | c, z | Rank-1 update of a Hermitian matrix |
| <code>cblas_?her2</code> | c, z | Rank-2 update of a Hermitian matrix |
| <code>cblas_?hpmv</code> | c, z | Matrix-vector product using a Hermitian packed matrix |
| <code>cblas_?hpr</code> | c, z | Rank-1 update of a Hermitian packed matrix |
| <code>cblas_?hpr2</code> | c, z | Rank-2 update of a Hermitian packed matrix |
| <code>cblas_?sbmv</code> | s, d | Matrix-vector product using symmetric band matrix |
| <code>cblas_?spmv</code> | s, d | Matrix-vector product using a symmetric packed matrix |
| <code>cblas_?spr</code> | s, d | Rank-1 update of a symmetric packed matrix |
| <code>cblas_?spr2</code> | s, d | Rank-2 update of a symmetric packed matrix |
| <code>cblas_?symv</code> | s, d | Matrix-vector product using a symmetric matrix |
| <code>cblas_?syr</code> | s, d | Rank-1 update of a symmetric matrix |
| <code>cblas_?syr2</code> | s, d | Rank-2 update of a symmetric matrix |
| <code>cblas_?tbmv</code> | s, d, c, z | Matrix-vector product using a triangular band matrix |
| <code>cblas_?tbsv</code> | s, d, c, z | Solution of a linear system of equations with a triangular band matrix |
| <code>cblas_?tpmv</code> | s, d, c, z | Matrix-vector product using a triangular packed matrix |
| <code>cblas_?tpsv</code> | s, d, c, z | Solution of a linear system of equations with a triangular packed matrix |
| <code>cblas_?trmv</code> | s, d, c, z | Matrix-vector product using a triangular matrix |
| <code>cblas_?trsv</code> | s, d, c, z | Solution of a linear system of equations with a triangular matrix |

`cblas_?gbmv`

Computes a matrix-vector product using a general band matrix

Syntax

```
void cblas_sgbmv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const MKL_INT kl, const MKL_INT ku, const float alpha, const float *a, const MKL_INT lda, const float *x, const MKL_INT incx, const float beta, float *y, const MKL_INT incy);
```

```
void cblas_dgbmv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const MKL_INT kl, const MKL_INT ku, const double alpha, const double *a, const MKL_INT lda, const double *x, const MKL_INT incx, const double beta, double *y, const MKL_INT incy);
```

```
void cblas_cgbmv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const MKL_INT kl, const MKL_INT ku, const void *alpha, const void *a, const MKL_INT lda, const void *x, const MKL_INT incx, const void *beta, void *y, const MKL_INT incy);
```

```
void cblas_zgbmv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT
m, const MKL_INT n, const MKL_INT kl, const MKL_INT ku, const void *alpha, const void
*a, const MKL_INT lda, const void *x, const MKL_INT incx, const void *beta, void *y,
const MKL_INT incy);
```

Include Files

- mkl.h

Description

The `?gbmv` routines perform a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y,$$

or

$$y := \alpha * A' * x + \beta * y,$$

or

$$y := \alpha * \text{conjg}(A') * x + \beta * y,$$

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*n* band matrix, with *kl* sub-diagonals and *ku* super-diagonals.

Input Parameters

| | |
|---------------|---|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>trans</i> | Specifies the operation: If <i>trans</i> =CblasNoTrans, then $y := \alpha * A * x + \beta * y$ If <i>trans</i> =CblasTrans, then $y := \alpha * A' * x + \beta * y$ If <i>trans</i> =CblasConjTrans, then $y := \alpha * \text{conjg}(A') * x + \beta * y$ |
| <i>m</i> | Specifies the number of rows of the matrix <i>A</i> . The value of <i>m</i> must be at least zero. |
| <i>n</i> | Specifies the number of columns of the matrix <i>A</i> . The value of <i>n</i> must be at least zero. |
| <i>kl</i> | Specifies the number of sub-diagonals of the matrix <i>A</i> . The value of <i>kl</i> must satisfy $0 \leq kl$. |
| <i>ku</i> | Specifies the number of super-diagonals of the matrix <i>A</i> . The value of <i>ku</i> must satisfy $0 \leq ku$. |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>a</i> | Array, size $lda * n$. |

Layout = CblasColMajor: Before entry, the leading $(kl + ku + 1)$ by n part of the array a must contain the matrix of coefficients. This matrix must be supplied column-by-column, with the leading diagonal of the matrix in row (ku) of the array, the first super-diagonal starting at position 1 in row $(ku - 1)$, the first sub-diagonal starting at position 0 in row $(ku + 1)$, and so on. Elements in the array a that do not correspond to elements in the band matrix (such as the top left ku by ku triangle) are not referenced.

The following program segment transfers a band matrix from conventional full matrix storage ($matrix$, with leading dimension ldm) to band storage (a , with leading dimension lda):

```
for (j = 0; j < n; j++) {
    k = ku - j;
    for (i = max(0, j-ku); i < min(m, j+kl+1); i++) {
        a[(k+i) + j*lda] = matrix[i + j*ldm];
    }
}
```

Layout = CblasRowMajor: Before entry, the leading $(kl + ku + 1)$ by m part of the array a must contain the matrix of coefficients. This matrix must be supplied row-by-row, with the leading diagonal of the matrix in column (kl) of the array, the first super-diagonal starting at position 0 in column $(kl + 1)$, the first sub-diagonal starting at position 1 in row $(kl - 1)$, and so on. Elements in the array a that do not correspond to elements in the band matrix (such as the top left kl by kl triangle) are not referenced.

The following program segment transfers a band matrix from row-major full matrix storage ($matrix$, with leading dimension ldm) to band storage (a , with leading dimension lda):

```
for (i = 0; i < m; i++) {
    k = kl - i;
    for (j = max(0, i-kl); j < min(n, i+ku+1); j++) {
        a[(k+j) + i*lda] = matrix[j + i*ldm];
    }
}
```

| | |
|-------------|--|
| <i>lda</i> | Specifies the leading dimension of a as declared in the calling (sub)program. The value of lda must be at least $(kl + ku + 1)$. |
| x | Array, size at least $(1 + (n - 1) * \text{abs}(incx))$ when $trans=CblasNoTrans$, and at least $(1 + (m - 1) * \text{abs}(incx))$ otherwise. Before entry, the array x must contain the vector x . |
| <i>incx</i> | Specifies the increment for the elements of x . $incx$ must not be zero. |
| <i>beta</i> | Specifies the scalar beta. When $beta$ is equal to zero, then y need not be set on input. |
| y | Array, size at least $(1 + (m - 1) * \text{abs}(incy))$ when $trans=CblasNoTrans$ and at least $(1 + (n - 1) * \text{abs}(incy))$ otherwise. Before entry, the incremented array y must contain the vector y . |
| <i>incy</i> | Specifies the increment for the elements of y . The value of $incy$ must not be zero. |

Output Parameters

y Updated vector *y*.

cblas_?gemv

Computes a matrix-vector product using a general matrix

Syntax

```
void cblas_sgemv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const float alpha, const float *a, const MKL_INT lda, const float *x, const MKL_INT incx, const float beta, float *y, const MKL_INT incy);
```

```
void cblas_dgemv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const double alpha, const double *a, const MKL_INT lda, const double *x, const MKL_INT incx, const double beta, double *y, const MKL_INT incy);
```

```
void cblas_cgemv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, const void *x, const MKL_INT incx, const void *beta, void *y, const MKL_INT incy);
```

```
void cblas_zgemv (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE trans, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, const void *x, const MKL_INT incx, const void *beta, void *y, const MKL_INT incy);
```

Include Files

- mkl.h

Description

The ?gemv routines perform a matrix-vector operation defined as

$$y := \alpha A x + \beta y,$$

or

$$y := \alpha A' x + \beta y,$$

or

$$y := \alpha \text{conjg}(A') x + \beta y,$$

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*n* matrix.

Input Parameters

Layout Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

trans Specifies the operation:
 if *trans*=CblasNoTrans, then $y := \alpha A x + \beta y$;
 if *trans*=CblasTrans, then $y := \alpha A' x + \beta y$;

| | |
|----------|---|
| | if $trans=CblasConjTrans$, then $y := \alpha *conjg(A')*x + \beta*y$. |
| m | Specifies the number of rows of the matrix A . The value of m must be at least zero. |
| n | Specifies the number of columns of the matrix A . The value of n must be at least zero. |
| α | Specifies the scalar α . |
| a | Array, size $lda*k$. For $Layout = CblasColMajor$, k is n . Before entry, the leading m -by- n part of the array a must contain the matrix A . For $Layout = CblasRowMajor$, k is m . Before entry, the leading n -by- m part of the array a must contain the matrix A . |
| lda | Specifies the leading dimension of a as declared in the calling (sub)program. For $Layout = CblasColMajor$, the value of lda must be at least $\max(1, m)$. For $Layout = CblasRowMajor$, the value of lda must be at least $\max(1, n)$. |
| x | Array, size at least $(1+(n-1)*abs(incx))$ when $trans=CblasNoTrans$ and at least $(1+(m-1)*abs(incx))$ otherwise. Before entry, the incremented array x must contain the vector x . |
| $incx$ | Specifies the increment for the elements of x . The value of $incx$ must not be zero. |
| β | Specifies the scalar β . When β is set to zero, then y need not be set on input. |
| y | Array, size at least $(1+(m-1)*abs(incy))$ when $trans=CblasNoTrans$ and at least $(1+(n-1)*abs(incy))$ otherwise. Before entry with non-zero β , the incremented array y must contain the vector y . |
| $incy$ | Specifies the increment for the elements of y . The value of $incy$ must not be zero. |

Output Parameters

| | |
|-----|----------------------|
| y | Updated vector y . |
|-----|----------------------|

cblas_?ger

Performs a rank-1 update of a general matrix.

Syntax

```
void cblas_sger (const CBLAS_LAYOUT Layout, const MKL_INT m, const MKL_INT n, const float alpha, const float *x, const MKL_INT incx, const float *y, const MKL_INT incy, float *a, const MKL_INT lda);
```

```
void cblas_dger (const CBLAS_LAYOUT Layout, const MKL_INT m, const MKL_INT n, const
double alpha, const double *x, const MKL_INT incx, const double *y, const MKL_INT
incy, double *a, const MKL_INT lda);
```

Include Files

- mkl.h

Description

The `?ger` routines perform a matrix-vector operation defined as

```
 $A := \alpha x y^T + A,$ 
```

where:

α is a scalar,

x is an m -element vector,

y is an n -element vector,

A is an m -by- n general matrix.

Input Parameters

| | |
|---------------|---|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>m</i> | Specifies the number of rows of the matrix A . The value of m must be at least zero. |
| <i>n</i> | Specifies the number of columns of the matrix A . The value of n must be at least zero. |
| <i>alpha</i> | Specifies the scalar α . |
| <i>x</i> | Array, size at least $(1 + (m - 1) * \text{abs}(incx))$. Before entry, the incremented array x must contain the m -element vector x . |
| <i>incx</i> | Specifies the increment for the elements of x . The value of $incx$ must not be zero. |
| <i>y</i> | Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array y must contain the n -element vector y . |
| <i>incy</i> | Specifies the increment for the elements of y . The value of $incy$ must not be zero. |
| <i>a</i> | Array, size $lda * k$. For $Layout = \text{CblasColMajor}$, k is n . Before entry, the leading m -by- n part of the array a must contain the matrix A . For $Layout = \text{CblasRowMajor}$, k is m . Before entry, the leading n -by- m part of the array a must contain the matrix A . |
| <i>lda</i> | Specifies the leading dimension of a as declared in the calling (sub)program. |

For $Layout = CblasColMajor$, the value of lda must be at least $\max(1, m)$.

For $Layout = CblasRowMajor$, the value of lda must be at least $\max(1, n)$.

Output Parameters

a Overwritten by the updated matrix.

`cblas_?gerc`

Performs a rank-1 update (conjugated) of a general matrix.

Syntax

```
void cblas_cgerc (const CBLAS_LAYOUT Layout, const MKL_INT m, const MKL_INT n, const
void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy,
void *a, const MKL_INT lda);
```

```
void cblas_zgerc (const CBLAS_LAYOUT Layout, const MKL_INT m, const MKL_INT n, const
void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy,
void *a, const MKL_INT lda);
```

Include Files

- `mkl.h`

Description

The `?gerc` routines perform a matrix-vector operation defined as

$$A := \alpha * x * \text{conj}(y') + A,$$

where:

α is a scalar,

x is an m -element vector,

y is an n -element vector,

A is an m -by- n matrix.

Input Parameters

| | |
|----------|---|
| $Layout$ | Specifies whether two-dimensional array storage is row-major (<code>CblasRowMajor</code>) or column-major (<code>CblasColMajor</code>). |
| m | Specifies the number of rows of the matrix A . The value of m must be at least zero. |
| n | Specifies the number of columns of the matrix A . The value of n must be at least zero. |
| α | Specifies the scalar α . |

| | |
|-------------|---|
| <i>x</i> | Array, size at least $(1 + (m - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>m</i> -element vector <i>x</i> . |
| <i>incx</i> | Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero. |
| <i>y</i> | Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> . |
| <i>incy</i> | Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero. |
| <i>a</i> | Array, size <i>lda</i> * <i>k</i> . For <i>Layout</i> = CblasColMajor, <i>k</i> is <i>n</i> . Before entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>a</i> must contain the matrix <i>A</i> . For <i>Layout</i> = CblasRowMajor, <i>k</i> is <i>m</i> . Before entry, the leading <i>n</i> -by- <i>m</i> part of the array <i>a</i> must contain the matrix <i>A</i> . |
| <i>lda</i> | Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. For <i>Layout</i> = CblasColMajor, the value of <i>lda</i> must be at least $\max(1, m)$. For <i>Layout</i> = CblasRowMajor, the value of <i>lda</i> must be at least $\max(1, n)$. |

Output Parameters

| | |
|----------|------------------------------------|
| <i>a</i> | Overwritten by the updated matrix. |
|----------|------------------------------------|

cblas_?geru

Performs a rank-1 update (unconjugated) of a general matrix.

Syntax

```
void cblas_cgeru (const CBLAS_LAYOUT Layout, const MKL_INT m, const MKL_INT n, const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *a, const MKL_INT lda);
```

```
void cblas_zgeru (const CBLAS_LAYOUT Layout, const MKL_INT m, const MKL_INT n, const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT incy, void *a, const MKL_INT lda);
```

Include Files

- mkl.h

Description

The ?geru routines perform a matrix-vector operation defined as

$$A := \alpha * x * y^T + A,$$

where:

α is a scalar,
 x is an m -element vector,
 y is an n -element vector,
 A is an m -by- n matrix.

Input Parameters

| | |
|---------------|---|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>m</i> | Specifies the number of rows of the matrix A . The value of m must be at least zero. |
| <i>n</i> | Specifies the number of columns of the matrix A . The value of n must be at least zero. |
| <i>alpha</i> | Specifies the scalar α . |
| <i>x</i> | Array, size at least $(1 + (m - 1) * \text{abs}(incx))$. Before entry, the incremented array x must contain the m -element vector x . |
| <i>incx</i> | Specifies the increment for the elements of x . The value of $incx$ must not be zero. |
| <i>y</i> | Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array y must contain the n -element vector y . |
| <i>incy</i> | Specifies the increment for the elements of y . The value of $incy$ must not be zero. |
| <i>a</i> | Array, size $lda * k$. For <i>Layout</i> = CblasColMajor, k is n . Before entry, the leading m -by- n part of the array a must contain the matrix A . For <i>Layout</i> = CblasRowMajor, k is m . Before entry, the leading n -by- m part of the array a must contain the matrix A . |
| <i>lda</i> | Specifies the leading dimension of a as declared in the calling (sub)program. For <i>Layout</i> = CblasColMajor, the value of lda must be at least $\max(1, m)$. For <i>Layout</i> = CblasRowMajor, the value of lda must be at least $\max(1, n)$. |

Output Parameters

a Overwritten by the updated matrix.

cblas_?hbmV

Computes a matrix-vector product using a Hermitian band matrix.

Syntax

```
void cblas_chbmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const MKL_INT k, const void *alpha, const void *a, const MKL_INT lda, const void *x,
const MKL_INT incx, const void *beta, void *y, const MKL_INT incy);
```

```
void cblas_zhbmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const MKL_INT k, const void *alpha, const void *a, const MKL_INT lda, const void *x,
const MKL_INT incx, const void *beta, void *y, const MKL_INT incy);
```

Include Files

- mkl.h

Description

The ?hbmv routines perform a matrix-vector operation defined as $y := \alpha A x + \beta y$,

where:

α and β are scalars,

x and y are n -element vectors,

A is an n -by- n Hermitian band matrix, with k super-diagonals.

Input Parameters

| | |
|---------------|--|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | Specifies whether the upper or lower triangular part of the Hermitian band matrix A is used: If <i>uplo</i> = CblasUpper, then the upper triangular part of the matrix A is used. If <i>uplo</i> = CblasLower, then the low triangular part of the matrix A is used. |
| <i>n</i> | Specifies the order of the matrix A . The value of n must be at least zero. |
| <i>k</i> | For <i>uplo</i> = CblasUpper: Specifies the number of super-diagonals of the matrix A . For <i>uplo</i> = CblasLower: Specifies the number of sub-diagonals of the matrix A . The value of k must satisfy $0 \leq k$. |
| <i>alpha</i> | Specifies the scalar α . |
| <i>a</i> | Array, size $lda * n$. <i>Layout</i> = CblasColMajor: Before entry with <i>uplo</i> = CblasUpper, the leading $(k + 1)$ by n part of the array a must contain the upper triangular band part of the Hermitian matrix. The matrix must be supplied column-by-column, with the leading diagonal of the matrix in row k of the array, the first super-diagonal starting at position 1 in row $(k - 1)$, and so on. The top left k by k triangle of the array a is not referenced. |

The following program segment transfers the upper triangular part of a Hermitian band matrix from conventional full matrix storage (*matrix*, with leading dimension *ldm*) to band storage (*a*, with leading dimension *lda*):

```
for (j = 0; j < n; j++) {
    m = k - j;
    for (i = max(0, j - k); i <= j; i++) {
        a[(m+i) + j*lda] = matrix[i + j*ldm];
    }
}
```

Before entry with *uplo* = *CblasLower*, the leading $(k + 1)$ by n part of the array *a* must contain the lower triangular band part of the Hermitian matrix, supplied column-by-column, with the leading diagonal of the matrix in row 0 of the array, the first sub-diagonal starting at position 0 in row 1, and so on. The bottom right k by k triangle of the array *a* is not referenced.

The following program segment transfers the lower triangular part of a Hermitian band matrix from conventional full matrix storage (*matrix*, with leading dimension *ldm*) to band storage (*a*, with leading dimension *lda*):

```
for (j = 0; j < n; j++) {
    m = -j;
    for (i = j; i < min(n, j + k + 1); i++) {
        a[(m+i) + j*lda] = matrix[i + j*ldm];
    }
}
```

Layout = *CblasRowMajor*:

Before entry with *uplo* = *CblasUpper*, the leading $(k + 1)$ -by- n part of array *a* must contain the upper triangular band part of the Hermitian matrix. The matrix must be supplied row-by-row, with the leading diagonal of the matrix in column 0 of the array, the first super-diagonal starting at position 0 in column 1, and so on. The bottom right k -by- k triangle of array *a* is not referenced.

The following program segment transfers the upper triangular part of a Hermitian band matrix from row-major full matrix storage (*matrix* with leading dimension *ldm*) to row-major band storage (*a*, with leading dimension *lda*):

```
for (i = 0; i < n; i++) {
    m = -i;
    for (j = i; j < MIN(n, i+k+1); j++) {
        a[(m+j) + i*lda] = matrix[j + i*ldm];
    }
}
```

Before entry with *uplo* = *CblasLower*, the leading $(k + 1)$ -by- n part of array *a* must contain the lower triangular band part of the Hermitian matrix, supplied row-by-row, with the leading diagonal of the matrix in column k of the array, the first sub-diagonal starting at position 1 in column $k-1$, and so on. The top left k -by- k triangle of array *a* is not referenced.

The following program segment transfers the lower triangular part of a Hermitian row-major band matrix from row-major full matrix storage (*matrix*, with leading dimension *ldm*) to row-major band storage (*a*, with leading dimension *lda*):

```
for (i = 0; i < n; i++) {
    m = k - i;
    for (j = max(0, i-k); j <= i; j++) {
        a[(m+j) + i*lda] = matrix[j + i*ldm];
    }
}
```

The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

| | |
|-------------|--|
| <i>lda</i> | Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $(k + 1)$. |
| <i>x</i> | Array, size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the vector <i>x</i> . |
| <i>incx</i> | Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero. |
| <i>beta</i> | Specifies the scalar <i>beta</i> . |
| <i>y</i> | Array, size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <i>y</i> must contain the vector <i>y</i> . |
| <i>incy</i> | Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero. |

Output Parameters

| | |
|----------|--|
| <i>y</i> | Overwritten by the updated vector <i>y</i> . |
|----------|--|

cblas_?hemv

Computes a matrix-vector product using a Hermitian matrix.

Syntax

```
void cblas_chemv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const void *alpha, const void *a, const MKL_INT lda, const void *x, const MKL_INT
incx, const void *beta, void *y, const MKL_INT incy);
```

```
void cblas_zhemv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const void *alpha, const void *a, const MKL_INT lda, const void *x, const MKL_INT
incx, const void *beta, void *y, const MKL_INT incy);
```

Include Files

- mkl.h

Description

The `?hemv` routines perform a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y,$$

where:

α and β are scalars,

x and y are n -element vectors,

A is an n -by- n Hermitian matrix.

Input Parameters

| | |
|---------------|--|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (<code>CblasRowMajor</code>) or column-major (<code>CblasColMajor</code>). |
| <i>uplo</i> | Specifies whether the upper or lower triangular part of the array a is used. If $uplo = CblasUpper$, then the upper triangular of the array a is used. If $uplo = CblasLower$, then the low triangular of the array a is used. |
| <i>n</i> | Specifies the order of the matrix A . The value of n must be at least zero. |
| <i>alpha</i> | Specifies the scalar α . |
| <i>a</i> | Array, size $lda * n$. Before entry with $uplo = CblasUpper$, the leading n -by- n upper triangular part of the array a must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of a is not referenced. Before entry with $uplo = CblasLower$, the leading n -by- n lower triangular part of the array a must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of a is not referenced. The imaginary parts of the diagonal elements need not be set and are assumed to be zero. |
| <i>lda</i> | Specifies the leading dimension of a as declared in the calling (sub)program. The value of lda must be at least $\max(1, n)$. |
| <i>x</i> | Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array x must contain the n -element vector x . |
| <i>incx</i> | Specifies the increment for the elements of x . The value of $incx$ must not be zero. |
| <i>beta</i> | Specifies the scalar β . When β is supplied as zero then y need not be set on input. |
| <i>y</i> | Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array y must contain the n -element vector y . |
| <i>incy</i> | Specifies the increment for the elements of y . The value of $incy$ must not be zero. |

Output Parameters

| | |
|----------|---|
| <i>y</i> | Overwritten by the updated vector y . |
|----------|---|

cblas_?her

Performs a rank-1 update of a Hermitian matrix.

Syntax

```
void cblas_cher (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const float alpha, const void *x, const MKL_INT incx, void *a, const MKL_INT lda);
```

```
void cblas_zher (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const double alpha, const void *x, const MKL_INT incx, void *a, const MKL_INT lda);
```

Include Files

- mkl.h

Description

The ?her routines perform a matrix-vector operation defined as

$$A := \alpha x \text{conjg}(x') + A,$$

where:

alpha is a real scalar,

x is an *n*-element vector,

A is an *n*-by-*n* Hermitian matrix.

Input Parameters

| | |
|---------------|---|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | Specifies whether the upper or lower triangular part of the array <i>a</i> is used. If <i>uplo</i> = CblasUpper, then the upper triangular of the array <i>a</i> is used. If <i>uplo</i> = CblasLower, then the low triangular of the array <i>a</i> is used. |
| <i>n</i> | Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero. |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>x</i> | Array, dimension at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> . |
| <i>incx</i> | Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero. |
| <i>a</i> | Array, size <i>lda</i> * <i>n</i> . Before entry with <i>uplo</i> = CblasUpper, the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = CblasLower, the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of <i>a</i> is not referenced. |

The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

lda

Specifies the leading dimension of *a* as declared in the calling (sub)program. The value of *lda* must be at least $\max(1, n)$.

Output Parameters

a

With *uplo* = CblasUpper, the upper triangular part of the array *a* is overwritten by the upper triangular part of the updated matrix.

With *uplo* = CblasLower, the lower triangular part of the array *a* is overwritten by the lower triangular part of the updated matrix.

The imaginary parts of the diagonal elements are set to zero.

cblas_?her2

Performs a rank-2 update of a Hermitian matrix.

Syntax

```
void cblas_cher2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT
incy, void *a, const MKL_INT lda);
```

```
void cblas_zher2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT
incy, void *a, const MKL_INT lda);
```

Include Files

- mkl.h

Description

The ?her2 routines perform a matrix-vector operation defined as

$$A := \alpha * x * \text{conjg}(y') + \text{conjg}(\alpha) * y * \text{conjg}(x') + A,$$

where:

alpha is a scalar,

x and *y* are *n*-element vectors,

A is an *n*-by-*n* Hermitian matrix.

Input Parameters

Layout

Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

uplo

Specifies whether the upper or lower triangular part of the array *a* is used.

If *uplo* = CblasUpper, then the upper triangular of the array *a* is used.

If *uplo* = CblasLower, then the low triangular of the array *a* is used.

n

Specifies the order of the matrix *A*. The value of *n* must be at least zero.

| | |
|--------------|---|
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>x</i> | Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> . |
| <i>incx</i> | Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero. |
| <i>y</i> | Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> . |
| <i>incy</i> | Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero. |
| <i>a</i> | Array, size <i>lda</i> * <i>n</i> . Before entry with <i>uplo</i> = CblasUpper, the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = CblasLower, the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of <i>a</i> is not referenced. The imaginary parts of the diagonal elements need not be set and are assumed to be zero. |
| <i>lda</i> | Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$. |

Output Parameters

| | |
|----------|---|
| <i>a</i> | With <i>uplo</i> = CblasUpper, the upper triangular part of the array <i>a</i> is overwritten by the upper triangular part of the updated matrix. With <i>uplo</i> = CblasLower, the lower triangular part of the array <i>a</i> is overwritten by the lower triangular part of the updated matrix. The imaginary parts of the diagonal elements are set to zero. |
|----------|---|

cblas_?hpmv

Computes a matrix-vector product using a Hermitian packed matrix.

Syntax

```
void cblas_chpmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const void *alpha, const void *ap, const void *x, const MKL_INT incx, const void
*beta, void *y, const MKL_INT incy);
```

```
void cblas_zhpmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const void *alpha, const void *ap, const void *x, const MKL_INT incx, const void
*beta, void *y, const MKL_INT incy);
```

Include Files

- mkl.h

Description

The ?hpmv routines perform a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y,$$

where:

α and β are scalars,

x and y are n -element vectors,

A is an n -by- n Hermitian matrix, supplied in packed form.

Input Parameters

| | |
|---------------|--|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | Specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array ap . If $uplo = CblasUpper$, then the upper triangular part of the matrix A is supplied in the packed array ap . If $uplo = CblasLower$, then the low triangular part of the matrix A is supplied in the packed array ap . |
| <i>n</i> | Specifies the order of the matrix A . The value of n must be at least zero. |
| <i>alpha</i> | Specifies the scalar α . |
| <i>ap</i> | Array, size at least $((n * (n + 1)) / 2)$. For $Layout = CblasColMajor$: Before entry with $uplo = CblasUpper$, the array ap must contain the upper triangular part of the Hermitian matrix packed sequentially, column-by-column, so that $ap[0]$ contains $A_{1,1}$, $ap[1]$ and $ap[2]$ contain $A_{1,2}$ and $A_{2,2}$ respectively, and so on. Before entry with $uplo = CblasLower$, the array ap must contain the lower triangular part of the Hermitian matrix packed sequentially, column-by-column, so that $ap[0]$ contains $A_{1,1}$, $ap[1]$ and $ap[2]$ contain $A_{2,1}$ and $A_{3,1}$ respectively, and so on. For $Layout = CblasRowMajor$: Before entry with $uplo = CblasUpper$, the array ap must contain the upper triangular part of the Hermitian matrix packed sequentially, row-by-row, $ap[0]$ contains $A_{1,1}$, $ap[1]$ and $ap[2]$ contain $A_{1,2}$ and $A_{1,3}$ respectively, and so on. Before entry with $uplo = CblasLower$, the array ap must contain the lower triangular part of the Hermitian matrix packed sequentially, row-by-row, so that $ap[0]$ contains $A_{1,1}$, $ap[1]$ and $ap[2]$ contain $A_{2,1}$ and $A_{2,2}$ respectively, and so on. The imaginary parts of the diagonal elements need not be set and are assumed to be zero. |
| <i>x</i> | Array, size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array x must contain the n -element vector x . |
| <i>incx</i> | Specifies the increment for the elements of x . |

The value of *incx* must not be zero.

beta

Specifies the scalar *beta*.

When *beta* is equal to zero then *y* need not be set on input.

y

Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array *y* must contain the *n*-element vector *y*.

incy

Specifies the increment for the elements of *y*.

The value of *incy* must not be zero.

Output Parameters

y

Overwritten by the updated vector *y*.

cblas_?hpr

Performs a rank-1 update of a Hermitian packed matrix.

Syntax

```
void cblas_chpr (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const float alpha, const void *x, const MKL_INT incx, void *ap);
```

```
void cblas_zhpr (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const double alpha, const void *x, const MKL_INT incx, void *ap);
```

Include Files

- mkl.h

Description

The ?hpr routines perform a matrix-vector operation defined as

$$A := \alpha * x * \text{conjg}(x') + A,$$

where:

alpha is a real scalar,

x is an *n*-element vector,

A is an *n*-by-*n* Hermitian matrix, supplied in packed form.

Input Parameters

Layout

Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

uplo

Specifies whether the upper or lower triangular part of the matrix *A* is supplied in the packed array *ap*.

If *uplo* = CblasUpper, the upper triangular part of the matrix *A* is supplied in the packed array *ap*.

If *uplo* = CblasLower, the low triangular part of the matrix *A* is supplied in the packed array *ap*.

| | |
|--------------|---|
| <i>n</i> | Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero. |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>x</i> | Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> . |
| <i>incx</i> | Specifies the increment for the elements of <i>x</i> . <i>incx</i> must not be zero. |
| <i>ap</i> | <p>Array, size at least $((n * (n + 1)) / 2)$.</p> <p>For <i>Layout</i> = CblasColMajor:</p> <p>Before entry with <i>uplo</i> = CblasUpper, the array <i>ap</i> must contain the upper triangular part of the Hermitian matrix packed sequentially, column-by-column, so that <i>ap</i>[0] contains $A_{1,1}$, <i>ap</i>[1] and <i>ap</i>[2] contain $A_{1,2}$ and $A_{2,2}$ respectively, and so on.</p> <p>Before entry with <i>uplo</i> = CblasLower, the array <i>ap</i> must contain the lower triangular part of the Hermitian matrix packed sequentially, column-by-column, so that <i>ap</i>[0] contains $A_{1,1}$, <i>ap</i>[1] and <i>ap</i>[2] contain $A_{2,1}$ and $A_{3,1}$ respectively, and so on.</p> <p>For <i>Layout</i> = CblasRowMajor:</p> <p>Before entry with <i>uplo</i> = CblasUpper, the array <i>ap</i> must contain the upper triangular part of the Hermitian matrix packed sequentially, row-by-row, <i>ap</i>[0] contains $A_{1,1}$, <i>ap</i>[1] and <i>ap</i>[2] contain $A_{1,2}$ and $A_{1,3}$ respectively, and so on.</p> <p>Before entry with <i>uplo</i> = CblasLower, the array <i>ap</i> must contain the lower triangular part of the Hermitian matrix packed sequentially, row-by-row, so that <i>ap</i>[0] contains $A_{1,1}$, <i>ap</i>[1] and <i>ap</i>[2] contain $A_{2,1}$ and $A_{2,2}$ respectively, and so on.</p> <p>The imaginary parts of the diagonal elements need not be set and are assumed to be zero.</p> |

Output Parameters

| | |
|-----------|--|
| <i>ap</i> | <p>With <i>uplo</i> = CblasUpper, overwritten by the upper triangular part of the updated matrix.</p> <p>With <i>uplo</i> = CblasLower, overwritten by the lower triangular part of the updated matrix.</p> <p>The imaginary parts of the diagonal elements are set to zero.</p> |
|-----------|--|

cblas_?hpr2

Performs a rank-2 update of a Hermitian packed matrix.

Syntax

```
void cblas_chpr2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT
incy, void *ap);
```

```
void cblas_zhpr2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const void *alpha, const void *x, const MKL_INT incx, const void *y, const MKL_INT
incy, void *ap);
```

Include Files

- mkl.h

Description

The ?hpr2 routines perform a matrix-vector operation defined as

$$A := \alpha * x * \text{conjg}(y') + \text{conjg}(\alpha) * y * \text{conjg}(x') + A,$$

where:

alpha is a scalar,

x and *y* are *n*-element vectors,

A is an *n*-by-*n* Hermitian matrix, supplied in packed form.

Input Parameters

| | |
|---------------|---|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | Specifies whether the upper or lower triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = CblasUpper, then the upper triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = CblasLower, then the low triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . |
| <i>n</i> | Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero. |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>x</i> | Array, dimension at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> . |
| <i>incx</i> | Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero. |
| <i>y</i> | Array, size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> . |
| <i>incy</i> | Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero. |
| <i>ap</i> | Array, size at least $((n * (n + 1)) / 2)$. For <i>Layout</i> = CblasColMajor: Before entry with <i>uplo</i> = CblasUpper, the array <i>ap</i> must contain the upper triangular part of the Hermitian matrix packed sequentially, column-by-column, so that <i>ap</i> [0] contains $A_{1,1}$, <i>ap</i> [1] and <i>ap</i> [2] contain $A_{1,2}$ and $A_{2,2}$ respectively, and so on. |

Before entry with `uplo = CblasLower`, the array `ap` must contain the lower triangular part of the Hermitian matrix packed sequentially, column-by-column, so that `ap[0]` contains $A_{1,1}$, `ap[1]` and `ap[2]` contain $A_{2,1}$ and $A_{3,1}$ respectively, and so on.

For `Layout = CblasRowMajor`:

Before entry with `uplo = CblasUpper`, the array `ap` must contain the upper triangular part of the Hermitian matrix packed sequentially, row-by-row, `ap[0]` contains $A_{1,1}$, `ap[1]` and `ap[2]` contain $A_{1,2}$ and $A_{1,3}$ respectively, and so on.

Before entry with `uplo = CblasLower`, the array `ap` must contain the lower triangular part of the Hermitian matrix packed sequentially, row-by-row, so that `ap[0]` contains $A_{1,1}$, `ap[1]` and `ap[2]` contain $A_{2,1}$ and $A_{2,2}$ respectively, and so on.

The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

Output Parameters

`ap`

With `uplo = CblasUpper`, overwritten by the upper triangular part of the updated matrix.

With `uplo = CblasLower`, overwritten by the lower triangular part of the updated matrix.

The imaginary parts of the diagonal elements need are set to zero.

`cblas_?sbmv`

Computes a matrix-vector product using a symmetric band matrix.

Syntax

```
void cblas_ssbmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const MKL_INT k, const float alpha, const float *a, const MKL_INT lda, const float *x,
const MKL_INT incx, const float beta, float *y, const MKL_INT incy);
```

```
void cblas_dsbmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const MKL_INT k, const double alpha, const double *a, const MKL_INT lda, const double
*x, const MKL_INT incx, const double beta, double *y, const MKL_INT incy);
```

Include Files

- `mk1.h`

Description

The `?sbmv` routines perform a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y,$$

where:

α and β are scalars,

x and y are n -element vectors,

A is an n -by- n symmetric band matrix, with k super-diagonals.

Input Parameters

| | |
|---------------|---|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | Specifies whether the upper or lower triangular part of the band matrix <i>A</i> is used: if <i>uplo</i> = CblasUpper - upper triangular part; if <i>uplo</i> = CblasLower - low triangular part. |
| <i>n</i> | Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero. |
| <i>k</i> | Specifies the number of super-diagonals of the matrix <i>A</i> . The value of <i>k</i> must satisfy $0 \leq k$. |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>a</i> | Array, size <i>lda</i> * <i>n</i> . Before entry with <i>uplo</i> = CblasUpper, the leading (<i>k</i> + 1) by <i>n</i> part of the array <i>a</i> must contain the upper triangular band part of the symmetric matrix, supplied column-by-column, with the leading diagonal of the matrix in row <i>k</i> of the array, the first super-diagonal starting at position 1 in row (<i>k</i> - 1), and so on. The top left <i>k</i> by <i>k</i> triangle of the array <i>a</i> is not referenced. |

The following program segment transfers the upper triangular part of a symmetric band matrix from conventional full matrix storage (*matrix*, with leading dimension *ldm*) to band storage (*a*, with leading dimension *lda*):

```
for (j = 0; j < n; j++) {
    m = k - j;
    for (i = max( 0, j - k); i <= j; i++) {
        a[(m+i) + j*lda] = matrix[i + j*ldm];
    }
}
```

Before entry with *uplo* = CblasLower, the leading (*k* + 1) by *n* part of the array *a* must contain the lower triangular band part of the symmetric matrix, supplied column-by-column, with the leading diagonal of the matrix in row 0 of the array, the first sub-diagonal starting at position 0 in row 1, and so on. The bottom right *k* by *k* triangle of the array *a* is not referenced.

The following program segment transfers the lower triangular part of a symmetric band matrix from conventional full matrix storage (*matrix*, with leading dimension *ldm*) to band storage (*a*, with leading dimension *lda*):

```
for (j = 0; j < n; j++) {
    m = -j;
    for (i = j; i < min(n, j + k + 1); i++) {
        a[(m+i) + j*lda] = matrix[i + j*ldm];
    }
}
```

Layout = CblasRowMajor:

Before entry with *uplo* = CblasUpper, the leading (*k* + 1)-by-*n* part of array *a* must contain the upper triangular band part of the symmetric matrix. The matrix must be supplied row-by-row, with the leading diagonal

of the matrix in column 0 of the array, the first super-diagonal starting at position 0 in column 1, and so on. The bottom right k -by- k triangle of array a is not referenced.

The following program segment transfers the upper triangular part of a symmetric band matrix from row-major full matrix storage ($matrix$ with leading dimension ldm) to row-major band storage (a , with leading dimension lda):

```
for (i = 0; i < n; i++) {
    m = -i;
    for (j = i; j < MIN(n, i+k+1); j++) {
        a[(m+j) + i*lda] = matrix[j + i*ldm];
    }
}
```

Before entry with $uplo = CblasLower$, the leading $(k + 1)$ -by- n part of array a must contain the lower triangular band part of the symmetric matrix, supplied row-by-row, with the leading diagonal of the matrix in column k of the array, the first sub-diagonal starting at position 1 in column $k-1$, and so on. The top left k -by- k triangle of array a is not referenced.

The following program segment transfers the lower triangular part of a symmetric row-major band matrix from row-major full matrix storage ($matrix$, with leading dimension ldm) to row-major band storage (a , with leading dimension lda):

```
for (i = 0; i < n; i++) {
    m = k - i;
    for (j = max(0, i-k); j <= i; j++) {
        a[(m+j) + i*lda] = matrix[j + i*ldm];
    }
}
```

| | |
|-------------|--|
| <i>lda</i> | Specifies the leading dimension of a as declared in the calling (sub)program. The value of lda must be at least $(k + 1)$. |
| x | Array, size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array x must contain the vector x . |
| <i>incx</i> | Specifies the increment for the elements of x . The value of <i>incx</i> must not be zero. |
| <i>beta</i> | Specifies the scalar <i>beta</i> . |
| y | Array, size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array y must contain the vector y . |
| <i>incy</i> | Specifies the increment for the elements of y . The value of <i>incy</i> must not be zero. |

Output Parameters

| | |
|-----|---|
| y | Overwritten by the updated vector y . |
|-----|---|

cblas_?spmv

Computes a matrix-vector product using a symmetric packed matrix.

Syntax

```
void cblas_sspmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const float alpha, const float *ap, const float *x, const MKL_INT incx, const float
beta, float *y, const MKL_INT incy);
```

```
void cblas_dspmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const double alpha, const double *ap, const double *x, const MKL_INT incx, const double
beta, double *y, const MKL_INT incy);
```

Include Files

- mkl.h

Description

The ?spmv routines perform a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y,$$

where:

α and β are scalars,

x and y are n -element vectors,

A is an n -by- n symmetric matrix, supplied in packed form.

Input Parameters

| | |
|---------------|---|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | Specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array ap . If $uplo = CblasUpper$, then the upper triangular part of the matrix A is supplied in the packed array ap . If $uplo = CblasLower$, then the low triangular part of the matrix A is supplied in the packed array ap . |
| <i>n</i> | Specifies the order of the matrix A . The value of n must be at least zero. |
| <i>alpha</i> | Specifies the scalar α . |
| <i>ap</i> | Array, size at least $((n * (n + 1)) / 2)$. For $Layout = CblasColMajor$: Before entry with $uplo = CblasUpper$, the array ap must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that $ap[0]$ contains $A_{1,1}$, $ap[1]$ and $ap[2]$ contain $A_{1,2}$ and $A_{2,2}$ respectively, and so on. Before entry with $uplo = CblasLower$, the array ap must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that $ap[0]$ contains $A_{1,1}$, $ap[1]$ and $ap[2]$ contain $A_{2,1}$ and $A_{3,1}$ respectively, and so on. |

For *Layout* = CblasRowMajor:

Before entry with *uplo* = CblasUpper, the array *ap* must contain the upper triangular part of the symmetric matrix packed sequentially, row-by-row, *ap*[0] contains $A_{1,1}$, *ap*[1] and *ap*[2] contain $A_{1,2}$ and $A_{1,3}$ respectively, and so on. Before entry with *uplo* = CblasLower, the array *ap* must contain the lower triangular part of the symmetric matrix packed sequentially, row-by-row, so that *ap*[0] contains $A_{1,1}$, *ap*[1] and *ap*[2] contain $A_{2,1}$ and $A_{2,2}$ respectively, and so on.

| | |
|-------------|---|
| <i>x</i> | Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> . |
| <i>incx</i> | Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero. |
| <i>beta</i> | Specifies the scalar <i>beta</i> . When <i>beta</i> is supplied as zero, then <i>y</i> need not be set on input. |
| <i>y</i> | Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> . |
| <i>incy</i> | Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero. |

Output Parameters

| | |
|----------|--|
| <i>y</i> | Overwritten by the updated vector <i>y</i> . |
|----------|--|

cblas_?spr

Performs a rank-1 update of a symmetric packed matrix.

Syntax

```
void cblas_sspr (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const float alpha, const float *x, const MKL_INT incx, float *ap);
```

```
void cblas_dspr (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const double alpha, const double *x, const MKL_INT incx, double *ap);
```

Include Files

- mkl.h

Description

The ?spr routines perform a matrix-vector operation defined as

$$a := \alpha * x * x' + A,$$

where:

alpha is a real scalar,

x is an *n*-element vector,

A is an *n*-by-*n* symmetric matrix, supplied in packed form.

Input Parameters

| | |
|---------------|---|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | <p>Specifies whether the upper or lower triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i>.</p> <p>If <i>uplo</i> = CblasUpper, then the upper triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i>.</p> <p>If <i>uplo</i> = CblasLower, then the low triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i>.</p> |
| <i>n</i> | Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero. |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>x</i> | Array, size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> . |
| <i>incx</i> | <p>Specifies the increment for the elements of <i>x</i>.</p> <p>The value of <i>incx</i> must not be zero.</p> |
| <i>ap</i> | <p>For <i>Layout</i> = CblasColMajor:</p> <p>Before entry with <i>uplo</i> = CblasUpper, the array <i>ap</i> must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i>[0] contains $A_{1,1}$, <i>ap</i>[1] and <i>ap</i>[2] contain $A_{1,2}$ and $A_{2,2}$ respectively, and so on.</p> <p>Before entry with <i>uplo</i> = CblasLower, the array <i>ap</i> must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i>[0] contains $A_{1,1}$, <i>ap</i>[1] and <i>ap</i>[2] contain $A_{2,1}$ and $A_{3,1}$ respectively, and so on.</p> <p>For <i>Layout</i> = CblasRowMajor:</p> <p>Before entry with <i>uplo</i> = CblasUpper, the array <i>ap</i> must contain the upper triangular part of the symmetric matrix packed sequentially, row-by-row, <i>ap</i>[0] contains $A_{1,1}$, <i>ap</i>[1] and <i>ap</i>[2] contain $A_{1,2}$ and $A_{1,3}$ respectively, and so on.</p> <p>Before entry with <i>uplo</i> = CblasLower, the array <i>ap</i> must contain the lower triangular part of the symmetric matrix packed sequentially, row-by-row, so that <i>ap</i>[0] contains $A_{1,1}$, <i>ap</i>[1] and <i>ap</i>[2] contain $A_{2,1}$ and $A_{2,2}$ respectively, and so on.</p> |

Output Parameters

| | |
|-----------|---|
| <i>ap</i> | <p>With <i>uplo</i> = CblasUpper, overwritten by the upper triangular part of the updated matrix.</p> <p>With <i>uplo</i> = CblasLower, overwritten by the lower triangular part of the updated matrix.</p> |
|-----------|---|

cblas_?spr2

Performs a rank-2 update of a symmetric packed matrix.

Syntax

```
void cblas_sspr2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const float alpha, const float *x, const MKL_INT incx, const float *y, const MKL_INT
incy, float *ap);
```

```
void cblas_dspr2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const double alpha, const double *x, const MKL_INT incx, const double *y, const MKL_INT
incy, double *ap);
```

Include Files

- mkl.h

Description

The ?spr2 routines perform a matrix-vector operation defined as

$$A := \alpha x x^T + \alpha y y^T + A,$$

where:

α is a scalar,

x and y are n -element vectors,

A is an n -by- n symmetric matrix, supplied in packed form.

Input Parameters

| | |
|---------------|---|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | Specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array ap . If $uplo = CblasUpper$, then the upper triangular part of the matrix A is supplied in the packed array ap . If $uplo = CblasLower$, then the low triangular part of the matrix A is supplied in the packed array ap . |
| <i>n</i> | Specifies the order of the matrix A . The value of n must be at least zero. |
| <i>alpha</i> | Specifies the scalar α . |
| <i>x</i> | Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array x must contain the n -element vector x . |
| <i>incx</i> | Specifies the increment for the elements of x . The value of $incx$ must not be zero. |
| <i>y</i> | Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array y must contain the n -element vector y . |

| | |
|-------------|---|
| <i>incy</i> | Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero. |
| <i>ap</i> | <p>For <i>Layout</i> = CblasColMajor:</p> <p>Before entry with <i>uplo</i> = CblasUpper, the array <i>ap</i> must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i>[0] contains $A_{1,1}$, <i>ap</i>[1] and <i>ap</i>[2] contain $A_{1,2}$ and $A_{2,2}$ respectively, and so on.</p> <p>Before entry with <i>uplo</i> = CblasLower, the array <i>ap</i> must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i>[0] contains $A_{1,1}$, <i>ap</i>[1] and <i>ap</i>[2] contain $A_{2,1}$ and $A_{3,1}$ respectively, and so on.</p> <p>For <i>Layout</i> = CblasRowMajor:</p> <p>Before entry with <i>uplo</i> = CblasUpper, the array <i>ap</i> must contain the upper triangular part of the symmetric matrix packed sequentially, row-by-row, <i>ap</i>[0] contains $A_{1,1}$, <i>ap</i>[1] and <i>ap</i>[2] contain $A_{1,2}$ and $A_{1,3}$ respectively, and so on.</p> <p>Before entry with <i>uplo</i> = CblasLower, the array <i>ap</i> must contain the lower triangular part of the symmetric matrix packed sequentially, row-by-row, so that <i>ap</i>[0] contains $A_{1,1}$, <i>ap</i>[1] and <i>ap</i>[2] contain $A_{2,1}$ and $A_{2,2}$ respectively, and so on.</p> |

Output Parameters

| | |
|-----------|---|
| <i>ap</i> | <p>With <i>uplo</i> = CblasUpper, overwritten by the upper triangular part of the updated matrix.</p> <p>With <i>uplo</i> = CblasLower, overwritten by the lower triangular part of the updated matrix.</p> |
|-----------|---|

cblas_?symv

Computes a matrix-vector product for a symmetric matrix.

Syntax

```
void cblas_ssymv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const float alpha, const float *a, const MKL_INT lda, const float *x, const MKL_INT incx,
const float beta, float *y, const MKL_INT incy);
```

```
void cblas_dsymv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const double alpha, const double *a, const MKL_INT lda, const double *x, const MKL_INT incx,
const double beta, double *y, const MKL_INT incy);
```

Include Files

- mkl.h

Description

The ?symv routines perform a matrix-vector operation defined as

$$y := \alpha A x + \beta y,$$

where:

alpha and *beta* are scalars,
x and *y* are *n*-element vectors,
A is an *n*-by-*n* symmetric matrix.

Input Parameters

| | |
|---------------|--|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | Specifies whether the upper or lower triangular part of the array <i>a</i> is used. If <i>uplo</i> = CblasUpper, then the upper triangular part of the array <i>a</i> is used. If <i>uplo</i> = CblasLower, then the low triangular part of the array <i>a</i> is used. |
| <i>n</i> | Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero. |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>a</i> | Array, size <i>lda</i> * <i>n</i> . Before entry with <i>uplo</i> = CblasUpper, the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the symmetric matrix <i>A</i> and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = CblasLower, the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the symmetric matrix <i>A</i> and the strictly upper triangular part of <i>a</i> is not referenced. |
| <i>lda</i> | Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$. |
| <i>x</i> | Array, size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> . |
| <i>incx</i> | Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero. |
| <i>beta</i> | Specifies the scalar <i>beta</i> . When <i>beta</i> is supplied as zero, then <i>y</i> need not be set on input. |
| <i>y</i> | Array, size at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> . |
| <i>incy</i> | Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero. |

Output Parameters

y Overwritten by the updated vector *y*.

cblas_?syr

Performs a rank-1 update of a symmetric matrix.

Syntax

```
void cblas_ssyrr (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const float alpha, const float *x, const MKL_INT incx, float *a, const MKL_INT lda);
```

```
void cblas_dsyrr (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const double alpha, const double *x, const MKL_INT incx, double *a, const MKL_INT lda);
```

Include Files

- mkl.h

Description

The ?syrr routines perform a matrix-vector operation defined as

$$A := \alpha x x^T + A,$$

where:

alpha is a real scalar,

x is an *n*-element vector,

A is an *n*-by-*n* symmetric matrix.

Input Parameters

| | |
|---------------|---|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | Specifies whether the upper or lower triangular part of the array <i>a</i> is used. If <i>uplo</i> = CblasUpper, then the upper triangular part of the array <i>a</i> is used. If <i>uplo</i> = CblasLower, then the low triangular part of the array <i>a</i> is used. |
| <i>n</i> | Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero. |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>x</i> | Array, size at least $(1 + (n-1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> . |
| <i>incx</i> | Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero. |
| <i>a</i> | Array, size <i>lda</i> * <i>n</i> . Before entry with <i>uplo</i> = CblasUpper, the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the symmetric matrix <i>A</i> and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = CblasLower, the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the symmetric matrix <i>A</i> and the strictly upper triangular part of <i>a</i> is not referenced. |
| <i>lda</i> | Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$. |

Output Parameters

a With *uplo* = CblasUpper, the upper triangular part of the array *a* is overwritten by the upper triangular part of the updated matrix.

With *uplo* = CblasLower, the lower triangular part of the array *a* is overwritten by the lower triangular part of the updated matrix.

cblas_?syr2

Performs a rank-2 update of symmetric matrix.

Syntax

```
void cblas_ssy2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const float alpha, const float *x, const MKL_INT incx, const float *y, const MKL_INT
incy, float *a, const MKL_INT lda);
```

```
void cblas_dsy2 (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const MKL_INT n,
const double alpha, const double *x, const MKL_INT incx, const double *y, const MKL_INT
incy, double *a, const MKL_INT lda);
```

Include Files

- mkl.h

Description

The ?syr2 routines perform a matrix-vector operation defined as

$$A := \alpha x x^T + \alpha y y^T + A,$$

where:

alpha is a scalar,

x and *y* are *n*-element vectors,

A is an *n*-by-*n* symmetric matrix.

Input Parameters

| | |
|---------------|---|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | Specifies whether the upper or lower triangular part of the array <i>a</i> is used. If <i>uplo</i> = CblasUpper, then the upper triangular part of the array <i>a</i> is used. If <i>uplo</i> = CblasLower, then the low triangular part of the array <i>a</i> is used. |
| <i>n</i> | Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero. |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>x</i> | Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> . |
| <i>incx</i> | Specifies the increment for the elements of <i>x</i> . |

| | |
|-------------|---|
| | The value of <i>incx</i> must not be zero. |
| <i>y</i> | Array, size at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> . |
| <i>incy</i> | Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero. |
| <i>a</i> | Array, size <i>lda</i> * <i>n</i> . Before entry with <i>uplo</i> = CblasUpper, the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = CblasLower, the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of <i>a</i> is not referenced. |
| <i>lda</i> | Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$. |

Output Parameters

| | |
|----------|--|
| <i>a</i> | With <i>uplo</i> = CblasUpper, the upper triangular part of the array <i>a</i> is overwritten by the upper triangular part of the updated matrix. With <i>uplo</i> = CblasLower, the lower triangular part of the array <i>a</i> is overwritten by the lower triangular part of the updated matrix. |
|----------|--|

cblas_?tbmv

Computes a matrix-vector product using a triangular band matrix.

Syntax

```
void cblas_stbmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const
float *a, const MKL_INT lda, float *x, const MKL_INT incx);
```

```
void cblas_dtbmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const
double *a, const MKL_INT lda, double *x, const MKL_INT incx);
```

```
void cblas_ctbmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const
void *a, const MKL_INT lda, void *x, const MKL_INT incx);
```

```
void cblas_ztbmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const
void *a, const MKL_INT lda, void *x, const MKL_INT incx);
```

Include Files

- mkl.h

Description

The ?tbmv routines perform one of the matrix-vector operations defined as

$x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$,

where:

x is an n -element vector,

A is an n -by- n unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

Input Parameters

| | |
|---------------|--|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | Specifies whether the matrix A is an upper or lower triangular matrix: <i>uplo</i> = CblasUpper if <i>uplo</i> = CblasLower, then the matrix is low triangular. |
| <i>trans</i> | Specifies the operation: if <i>trans</i> =CblasNoTrans, then $x := A*x$; if <i>trans</i> =CblasTrans, then $x := A'*x$; if <i>trans</i> =CblasConjTrans, then $x := \text{conjg}(A')*x$. |
| <i>diag</i> | Specifies whether the matrix A is unit triangular: if <i>diag</i> = CblasUnit then the matrix is unit triangular; if <i>diag</i> = CblasNonUnit, then the matrix is not unit triangular. |
| <i>n</i> | Specifies the order of the matrix A . The value of n must be at least zero. |
| <i>k</i> | On entry with <i>uplo</i> = CblasUpper specifies the number of super-diagonals of the matrix A . On entry with <i>uplo</i> = CblasLower, k specifies the number of sub-diagonals of the matrix a . The value of k must satisfy $0 \leq k$. |
| <i>a</i> | Array, size $lda*n$. <i>Layout</i> = CblasColMajor: Before entry with <i>uplo</i> = CblasUpper, the leading $(k + 1)$ by n part of the array a must contain the upper triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row k of the array, the first super-diagonal starting at position 1 in row $(k - 1)$, and so on. The top left k by k triangle of the array a is not referenced. The following program segment transfers an upper triangular band matrix from conventional full matrix storage (<i>matrix</i> , with leading dimension <i>ldm</i>) to band storage (a , with leading dimension <i>lda</i>): |

```

for (j = 0; j < n; j++) {
    m = k - j;
    for (i = max(0, j - k); i <= j; i++) {
        a[(m+i) + j*lda] = matrix[i + j*ldm];
    }
}

```

Before entry with `uplo = CblasLower`, the leading $(k + 1)$ by n part of the array `a` must contain the lower triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row 0 of the array, the first sub-diagonal starting at position 0 in row 1, and so on. The bottom right k by k triangle of the array `a` is not referenced. The following program segment transfers a lower triangular band matrix from conventional full matrix storage (`matrix`, with leading dimension `ldm`) to band storage (`a`, with leading dimension `lda`):

```
for (j = 0; j < n; j++) {
    m = -j;
    for (i = j; i < min(n, j + k + 1); i++) {
        a[(m+i) + j*lda] = matrix[i + j*ldm];
    }
}
```

Note that when `diag = CblasUnit`, the elements of the array `a` corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity.

Layout = `CblasRowMajor`:

Before entry with `uplo = CblasUpper`, the leading $(k + 1)$ -by- n part of array `a` must contain the upper triangular band part of the matrix of coefficients. The matrix must be supplied row-by-row, with the leading diagonal of the matrix in column 0 of the array, the first super-diagonal starting at position 0 in column 1, and so on. The bottom right k -by- k triangle of array `a` is not referenced.

The following program segment transfers the upper triangular part of a Hermitian band matrix from row-major full matrix storage (`matrix` with leading dimension `ldm`) to row-major band storage (`a`, with leading dimension `lda`):

```
for (i = 0; i < n; i++) {
    m = -i;
    for (j = i; j < MIN(n, i+k+1); j++) {
        a[(m+j) + i*lda] = matrix[j + i*ldm];
    }
}
```

Before entry with `uplo = CblasLower`, the leading $(k + 1)$ -by- n part of array `a` must contain the lower triangular band part of the matrix of coefficients, supplied row-by-row, with the leading diagonal of the matrix in column k of the array, the first sub-diagonal starting at position 1 in column $k-1$, and so on. The top left k -by- k triangle of array `a` is not referenced.

The following program segment transfers the lower triangular part of a Hermitian row-major band matrix from row-major full matrix storage (`matrix`, with leading dimension `ldm`) to row-major band storage (`a`, with leading dimension `lda`):

```
for (i = 0; i < n; i++) {
    m = k - i;
    for (j = max(0, i-k); j <= i; j++) {
        a[(m+j) + i*lda] = matrix[j + i*ldm];
    }
}
```

| | |
|-------------|---|
| <i>lda</i> | Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $(k + 1)$. |
| <i>x</i> | Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> . |
| <i>incx</i> | Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero. |

Output Parameters

| | |
|----------|--|
| <i>x</i> | Overwritten with the transformed vector <i>x</i> . |
|----------|--|

cblas_?tbsv

Solves a system of linear equations whose coefficients are in a triangular band matrix.

Syntax

```
void cblas_stbsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const
float *a, const MKL_INT lda, float *x, const MKL_INT incx);
```

```
void cblas_dtbsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const
double *a, const MKL_INT lda, double *x, const MKL_INT incx);
```

```
void cblas_ctbsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const
void *a, const MKL_INT lda, void *x, const MKL_INT incx);
```

```
void cblas_ztbsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const MKL_INT k, const
void *a, const MKL_INT lda, void *x, const MKL_INT incx);
```

Include Files

- mkl.h

Description

The ?tbsv routines solve one of the following systems of equations:

$A*x = b$, or $A'*x = b$, or $\text{conjg}(A')*x = b$,

where:

b and *x* are *n*-element vectors,

A is an *n*-by-*n* unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

The routine does not test for singularity or near-singularity.

Such tests must be performed before calling this routine.

Input Parameters

| | |
|---------------|---|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
|---------------|---|

| | |
|--------------|---|
| <i>uplo</i> | <p>Specifies whether the matrix <i>A</i> is an upper or lower triangular matrix:</p> <p>if <i>uplo</i> = <code>CblasUpper</code> the matrix is upper triangular;</p> <p>if <i>uplo</i> = <code>CblasLower</code>, the matrix is low triangular.</p> |
| <i>trans</i> | <p>Specifies the system of equations:</p> <p>if <i>trans</i>=<code>CblasNoTrans</code>, then $A*x = b$;</p> <p>if <i>trans</i>=<code>CblasTrans</code>, then $A'*x = b$;</p> <p>if <i>trans</i>=<code>CblasConjTrans</code>, then $\text{conjg}(A')*x = b$.</p> |
| <i>diag</i> | <p>Specifies whether the matrix <i>A</i> is unit triangular:</p> <p>if <i>diag</i> = <code>CblasUnit</code> then the matrix is unit triangular;</p> <p>if <i>diag</i> = <code>CblasNonUnit</code>, then the matrix is not unit triangular.</p> |
| <i>n</i> | Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero. |
| <i>k</i> | <p>On entry with <i>uplo</i> = <code>CblasUpper</code>, <i>k</i> specifies the number of super-diagonals of the matrix <i>A</i>. On entry with <i>uplo</i> = <code>CblasLower</code>, <i>k</i> specifies the number of sub-diagonals of the matrix <i>A</i>.</p> <p>The value of <i>k</i> must satisfy $0 \leq k$.</p> |
| <i>a</i> | <p>Array, size <i>lda</i>*<i>n</i>.</p> <p><i>Layout</i> = <code>CblasColMajor</code>:</p> <p>Before entry with <i>uplo</i> = <code>CblasUpper</code>, the leading (<i>k</i> + 1) by <i>n</i> part of the array <i>a</i> must contain the upper triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row <i>k</i> of the array, the first super-diagonal starting at position 1 in row (<i>k</i> - 1), and so on. The top left <i>k</i> by <i>k</i> triangle of the array <i>a</i> is not referenced.</p> <p>The following program segment transfers an upper triangular band matrix from conventional full matrix storage (<i>matrix</i>, with leading dimension <i>ldm</i>) to band storage (<i>a</i>, with leading dimension <i>lda</i>):</p> <pre>for (j = 0; j < n; j++) { m = k - j; for (i = max(0, j - k); i <= j; i++) { a[(m+i) + j*lda] = matrix[i + j*ldm]; } }</pre> <p>Before entry with <i>uplo</i> = <code>CblasLower</code>, the leading (<i>k</i> + 1) by <i>n</i> part of the array <i>a</i> must contain the lower triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row 0 of the array, the first sub-diagonal starting at position 0 in row 1, and so on. The bottom right <i>k</i> by <i>k</i> triangle of the array <i>a</i> is not referenced.</p> |

The following program segment transfers a lower triangular band matrix from conventional full matrix storage (*matrix*, with leading dimension *ldm*) to band storage (*a*, with leading dimension *lda*):

```
for (j = 0; j < n; j++) {
    m = -j;
    for (i = j; i < min(n, j + k + 1); i++) {
        a[(m+i) + j*lda] = matrix[i + j*ldm];
    }
}
```

When *diag* = *CblasUnit*, the elements of the array *a* corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity.

Layout = *CblasRowMajor*:

Before entry with *uplo* = *CblasUpper*, the leading (*k* + 1)-by-*n* part of array *a* must contain the upper triangular band part of the matrix of coefficients. The matrix must be supplied row-by-row, with the leading diagonal of the matrix in column 0 of the array, the first super-diagonal starting at position 0 in column 1, and so on. The bottom right *k*-by-*k* triangle of array *a* is not referenced.

The following program segment transfers the upper triangular part of a Hermitian band matrix from row-major full matrix storage (*matrix* with leading dimension *ldm*) to row-major band storage (*a*, with leading dimension *lda*):

```
for (i = 0; i < n; i++) {
    m = -i;
    for (j = i; j < MIN(n, i+k+1); j++) {
        a[(m+j) + i*lda] = matrix[j + i*ldm];
    }
}
```

Before entry with *uplo* = *CblasLower*, the leading (*k* + 1)-by-*n* part of array *a* must contain the lower triangular band part of the matrix of coefficients, supplied row-by-row, with the leading diagonal of the matrix in column *k* of the array, the first sub-diagonal starting at position 1 in column *k*-1, and so on. The top left *k*-by-*k* triangle of array *a* is not referenced.

The following program segment transfers the lower triangular part of a Hermitian row-major band matrix from row-major full matrix storage (*matrix*, with leading dimension *ldm*) to row-major band storage (*a*, with leading dimension *lda*):

```
for (i = 0; i < n; i++) {
    m = k - i;
    for (j = max(0, i-k); j <= i; j++) {
        a[(m+j) + i*lda] = matrix[j + i*ldm];
    }
}
```

lda

Specifies the leading dimension of *a* as declared in the calling (sub)program. The value of *lda* must be at least (*k* + 1).

x

Array, size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array *x* must contain the *n*-element right-hand side vector *b*.

incx Specifies the increment for the elements of *x*.
The value of *incx* must not be zero.

Output Parameters

x Overwritten with the solution vector *x*.

cblas_?tpmv

Computes a matrix-vector product using a triangular packed matrix.

Syntax

```
void cblas_stpmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const float *ap, float
*x, const MKL_INT incx);
```

```
void cblas_dtpmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const double *ap, double
*x, const MKL_INT incx);
```

```
void cblas_ctpmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *ap, void
*x, const MKL_INT incx);
```

```
void cblas_ztpmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *ap, void
*x, const MKL_INT incx);
```

Include Files

- mkl.h

Description

The ?tpmv routines perform one of the matrix-vector operations defined as

$x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$,

where:

x is an *n*-element vector,

A is an *n*-by-*n* unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

Input Parameters

Layout Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

uplo Specifies whether the matrix *A* is upper or lower triangular:
uplo = CblasUpper
if *uplo* = CblasLower, then the matrix is low triangular.

trans Specifies the operation:
if *trans*=CblasNoTrans, then $x := A*x$;

| | |
|-------------|---|
| | <p>if $trans=CblasTrans$, then $x := A'*x$;</p> <p>if $trans=CblasConjTrans$, then $x := conjg(A')*x$.</p> |
| <i>diag</i> | <p>Specifies whether the matrix A is unit triangular:</p> <p>if $diag = CblasUnit$ then the matrix is unit triangular;</p> <p>if $diag = CblasNonUnit$, then the matrix is not unit triangular.</p> |
| <i>n</i> | Specifies the order of the matrix A . The value of n must be at least zero. |
| <i>ap</i> | <p>Array, size at least $((n*(n + 1))/2)$.</p> <p>For $Layout = CblasColMajor$:</p> <p>Before entry with $uplo = CblasUpper$, the array ap must contain the upper triangular matrix packed sequentially, column-by-column, so that respectively, and so on. Before entry with $uplo = CblasLower$ $ap[0]$ contains $A_{1,1}$, $ap[1]$ and $ap[2]$ contain $A_{1,2}$ and $A_{2,2}$, the array ap must contain the lower triangular matrix packed sequentially, column-by-column, so that $ap[0]$ contains $A_{1,1}$, $ap[1]$ and $ap[2]$ contain $A_{2,1}$ and $A_{3,1}$ respectively, and so on. When $diag = CblasUnit$, the diagonal elements of a are not referenced, but are assumed to be unity.</p> <p>For $Layout = CblasRowMajor$:</p> <p>Before entry with $uplo = CblasUpper$, the array ap must contain the upper triangular matrix packed sequentially, row-by-row, $ap[0]$ contains $A_{1,1}$, $ap[1]$ and $ap[2]$ contain $A_{1,2}$ and $A_{1,3}$ respectively, and so on.</p> <p>Before entry with $uplo = CblasLower$, the array ap must contain the lower triangular matrix packed sequentially, row-by-row, so that $ap[0]$ contains $A_{1,1}$, $ap[1]$ and $ap[2]$ contain $A_{2,1}$ and $A_{2,2}$ respectively, and so on.</p> |
| <i>x</i> | Array, size at least $(1 + (n - 1)*abs(incx))$. Before entry, the incremented array x must contain the n -element vector x . |
| <i>incx</i> | <p>Specifies the increment for the elements of x.</p> <p>The value of $incx$ must not be zero.</p> |

Output Parameters

| | |
|----------|---|
| <i>x</i> | Overwritten with the transformed vector x . |
|----------|---|

cblas_?tpsv

Solves a system of linear equations whose coefficients are in a triangular packed matrix.

Syntax

```
void cblas_stpsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const float *ap, float
*x, const MKL_INT incx);
```

```
void cblas_dtpsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const double *ap, double
*x, const MKL_INT incx);
```

```
void cblas_ctpsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *ap, void
*x, const MKL_INT incx);
```

```
void cblas_ztpsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *ap, void
*x, const MKL_INT incx);
```

Include Files

- mkl.h

Description

The ?tpsv routines solve one of the following systems of equations

$A*x = b$, or $A'*x = b$, or $\text{conjg}(A')*x = b$,

where:

b and x are n -element vectors,

A is an n -by- n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

This routine does not test for singularity or near-singularity.

Such tests must be performed before calling this routine.

Input Parameters

| | |
|---------------|--|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | Specifies whether the matrix A is upper or lower triangular: <i>uplo</i> = CblasUpper if <i>uplo</i> = CblasLower, then the matrix is low triangular. |
| <i>trans</i> | Specifies the system of equations: if <i>trans</i> =CblasNoTrans, then $A*x = b$; if <i>trans</i> =CblasTrans, then $A'*x = b$; if <i>trans</i> =CblasConjTrans, then $\text{conjg}(A')*x = b$. |
| <i>diag</i> | Specifies whether the matrix A is unit triangular: if <i>diag</i> = CblasUnit then the matrix is unit triangular; if <i>diag</i> = CblasNonUnit , then the matrix is not unit triangular. |
| <i>n</i> | Specifies the order of the matrix A . The value of n must be at least zero. |
| <i>ap</i> | Array, size at least $((n*(n + 1))/2)$. For <i>Layout</i> = CblasColMajor: Before entry with <i>uplo</i> = CblasUpper, the array <i>ap</i> must contain the upper triangular part of the triangular matrix packed sequentially, column-by-column, so that <i>ap</i> [0] contains $A_{1,1}$, <i>ap</i> [1] and <i>ap</i> [2] contain $A_{1,2}$ and $A_{2,2}$ respectively, and so on. |

Before entry with `uplo = CblasLower`, the array `ap` must contain the lower triangular part of the triangular matrix packed sequentially, column-by-column, so that `ap[0]` contains $A_{1,1}$, `ap[1]` and `ap[2]` contain $A_{2,1}$ and $A_{3,1}$ respectively, and so on.

For `Layout = CblasRowMajor`:

Before entry with `uplo = CblasUpper`, the array `ap` must contain the upper triangular part of the triangular matrix packed sequentially, row-by-row, `ap[0]` contains $A_{1,1}$, `ap[1]` and `ap[2]` contain $A_{1,2}$ and $A_{1,3}$ respectively, and so on. Before entry with `uplo = CblasLower`, the array `ap` must contain the lower triangular part of the triangular matrix packed sequentially, row-by-row, so that `ap[0]` contains $A_{1,1}$, `ap[1]` and `ap[2]` contain $A_{2,1}$ and $A_{2,2}$ respectively, and so on.

When `diag = CblasUnit`, the diagonal elements of `a` are not referenced, but are assumed to be unity.

`x` Array, size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array `x` must contain the n -element right-hand side vector `b`.

`incx` Specifies the increment for the elements of `x`.
The value of `incx` must not be zero.

Output Parameters

`x` Overwritten with the solution vector `x`.

`cblas_?trmv`

Computes a matrix-vector product using a triangular matrix.

Syntax

```
void cblas_strmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const float *a, const
MKL_INT lda, float *x, const MKL_INT incx);
```

```
void cblas_dtrmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const double *a, const
MKL_INT lda, double *x, const MKL_INT incx);
```

```
void cblas_ctrmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *a, const
MKL_INT lda, void *x, const MKL_INT incx);
```

```
void cblas_ztrmv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *a, const
MKL_INT lda, void *x, const MKL_INT incx);
```

Include Files

- `mkl.h`

Description

The `?trmv` routines perform one of the following matrix-vector operations defined as

$x := A^*x$, or $x := A'x$, or $x := \text{conjg}(A')x$,

where:

x is an n -element vector,

A is an n -by- n unit, or non-unit, upper or lower triangular matrix.

Input Parameters

| | |
|---------------|---|
| <i>layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | Specifies whether the matrix A is upper or lower triangular: <i>uplo</i> = CblasUpper if <i>uplo</i> = CblasLower, then the matrix is low triangular. |
| <i>trans</i> | Specifies the operation: if <i>trans</i> =CblasNoTrans, then $x := A*x$; if <i>trans</i> =CblasTrans, then $x := A'*x$; if <i>trans</i> =CblasConjTrans, then $x := \text{conjg}(A')*x$. |
| <i>diag</i> | Specifies whether the matrix A is unit triangular: if <i>diag</i> = CblasUnit then the matrix is unit triangular; if <i>diag</i> = CblasNonUnit, then the matrix is not unit triangular. |
| <i>n</i> | Specifies the order of the matrix A . The value of n must be at least zero. |
| <i>a</i> | Array, size $lda*n$. Before entry with <i>uplo</i> = CblasUpper, the leading n -by- n upper triangular part of the array a must contain the upper triangular matrix and the strictly lower triangular part of a is not referenced. Before entry with <i>uplo</i> = CblasLower, the leading n -by- n lower triangular part of the array a must contain the lower triangular matrix and the strictly upper triangular part of a is not referenced. When <i>diag</i> = CblasUnit, the diagonal elements of a are not referenced either, but are assumed to be unity. |
| <i>lda</i> | Specifies the leading dimension of a as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$. |
| <i>x</i> | Array, size at least $(1 + (n - 1)*\text{abs}(\text{incx}))$. Before entry, the incremented array x must contain the n -element vector x . |
| <i>incx</i> | Specifies the increment for the elements of x . The value of <i>incx</i> must not be zero. |

Output Parameters

| | |
|----------|---|
| <i>x</i> | Overwritten with the transformed vector x . |
|----------|---|

cblas_?trsv

Solves a system of linear equations whose coefficients are in a triangular matrix.

Syntax

```
void cblas_strsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const float *a, const
MKL_INT lda, float *x, const MKL_INT incx);
```

```
void cblas_dtrsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const double *a, const
MKL_INT lda, double *x, const MKL_INT incx);
```

```
void cblas_ctrsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *a, const
MKL_INT lda, void *x, const MKL_INT incx);
```

```
void cblas_ztrsv (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const CBLAS_DIAG diag, const MKL_INT n, const void *a, const
MKL_INT lda, void *x, const MKL_INT incx);
```

Include Files

- mkl.h

Description

The `?trsv` routines solve one of the systems of equations:

$$A*x = b, \text{ or } A'*x = b, \text{ or } \text{conjg}(A')*x = b,$$

where:

b and x are n -element vectors,

A is an n -by- n unit, or non-unit, upper or lower triangular matrix.

The routine does not test for singularity or near-singularity.

Such tests must be performed before calling this routine.

Input Parameters

| | |
|---------------|--|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | Specifies whether the matrix A is upper or lower triangular: <i>uplo</i> = CblasUpper if <i>uplo</i> = CblasLower, then the matrix is low triangular. |
| <i>trans</i> | Specifies the systems of equations: if <i>trans</i> =CblasNoTrans, then $A*x = b$; if <i>trans</i> =CblasTrans, then $A'*x = b$; if <i>trans</i> =CblasConjTrans, then $\text{conjg}(A')*x = b$. |
| <i>diag</i> | Specifies whether the matrix A is unit triangular: if <i>diag</i> = CblasUnit then the matrix is unit triangular; if <i>diag</i> = CblasNonUnit, then the matrix is not unit triangular. |
| <i>n</i> | Specifies the order of the matrix A . The value of n must be at least zero. |

| | |
|-------------|---|
| <i>a</i> | Array, size $lda*n$. Before entry with $uplo = CblasUpper$, the leading n -by- n upper triangular part of the array a must contain the upper triangular matrix and the strictly lower triangular part of a is not referenced. Before entry with $uplo = CblasLower$, the leading n -by- n lower triangular part of the array a must contain the lower triangular matrix and the strictly upper triangular part of a is not referenced. When $diag = CblasUnit$, the diagonal elements of a are not referenced either, but are assumed to be unity. |
| <i>lda</i> | Specifies the leading dimension of a as declared in the calling (sub)program. The value of lda must be at least $\max(1, n)$. |
| <i>x</i> | Array, size at least $(1 + (n - 1)*abs(incx))$. Before entry, the incremented array x must contain the n -element right-hand side vector b . |
| <i>incx</i> | Specifies the increment for the elements of x . The value of $incx$ must not be zero. |

Output Parameters

| | |
|----------|--|
| <i>x</i> | Overwritten with the solution vector x . |
|----------|--|

BLAS Level 3 Routines

BLAS Level 3 routines perform matrix-matrix operations. [Table "BLAS Level 3 Routine Groups and Their Data Types"](#) lists the BLAS Level 3 routine groups and the data types associated with them.

BLAS Level 3 Routine Groups and Their Data Types

| Routine Group | Data Types | Description |
|---------------------------|------------|--|
| <code>cblas_?gemm</code> | s, d, c, z | Computes a matrix-matrix product with general matrices. |
| <code>cblas_?hemm</code> | c, z | Computes a matrix-matrix product where one input matrix is Hermitian. |
| <code>cblas_?herk</code> | c, z | Performs a Hermitian rank-k update. |
| <code>cblas_?her2k</code> | c, z | Performs a Hermitian rank-2k update. |
| <code>cblas_?symm</code> | s, d, c, z | Computes a matrix-matrix product where one input matrix is symmetric. |
| <code>cblas_?syrk</code> | s, d, c, z | Performs a symmetric rank-k update. |
| <code>cblas_?syr2k</code> | s, d, c, z | Performs a symmetric rank-2k update. |
| <code>cblas_?trmm</code> | s, d, c, z | Computes a matrix-matrix product where one input matrix is triangular. |
| <code>cblas_?trsm</code> | s, d, c, z | Solves a triangular matrix equation. |

Symmetric Multiprocessing Version of Intel® MKL

Many applications spend considerable time executing BLAS routines. This time can be scaled by the number of processors available on the system through using the symmetric multiprocessing (SMP) feature built into the Intel MKL Library. The performance enhancements based on the parallel use of the processors are available without any programming effort on your part.

To enhance performance, the library uses the following methods:

- The BLAS functions are blocked where possible to restructure the code in a way that increases the localization of data reference, enhances cache memory use, and reduces the dependency on the memory bus.
- The code is distributed across the processors to maximize parallelism.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

cblas_?gemm

Computes a matrix-matrix product with general matrices.

Syntax

```
void cblas_sgemm (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE transa, const
CBLAS_TRANSPOSE transb, const MKL_INT m, const MKL_INT n, const MKL_INT k, const float
alpha, const float *a, const MKL_INT lda, const float *b, const MKL_INT ldb, const
float beta, float *c, const MKL_INT ldc);

void cblas_dgemm (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE transa, const
CBLAS_TRANSPOSE transb, const MKL_INT m, const MKL_INT n, const MKL_INT k, const double
alpha, const double *a, const MKL_INT lda, const double *b, const MKL_INT ldb, const
double beta, double *c, const MKL_INT ldc);

void cblas_cgemm (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE transa, const
CBLAS_TRANSPOSE transb, const MKL_INT m, const MKL_INT n, const MKL_INT k, const void
*alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void
*beta, void *c, const MKL_INT ldc);

void cblas_zgemm (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE transa, const
CBLAS_TRANSPOSE transb, const MKL_INT m, const MKL_INT n, const MKL_INT k, const void
*alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void
*beta, void *c, const MKL_INT ldc);
```

Include Files

- mkl.h

Description

The ?gemm routines compute a scalar-matrix-matrix product and add the result to a scalar-matrix product, with general matrices. The operation is defined as

$$C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C,$$

where:

op(X) is one of op(X) = X, or op(X) = X^T, or op(X) = X^H,

alpha and beta are scalars,

A, B and C are matrices:

$\text{op}(A)$ is an m -by- k matrix,

$\text{op}(B)$ is a k -by- n matrix,

C is an m -by- n matrix.

See also

- `?gemm` for the Fortran language interface to this routine
- `?gemm3m`, BLAS-like extension routines, that use matrix multiplication for similar matrix-matrix operations

Input Parameters

| | |
|---------------|--|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>transa</i> | Specifies the form of $\text{op}(A)$ used in the matrix multiplication: if <i>transa</i> =CblasNoTrans, then $\text{op}(A) = A$; if <i>transa</i> =CblasTrans, then $\text{op}(A) = A^T$; if <i>transa</i> =CblasConjTrans, then $\text{op}(A) = A^H$. |
| <i>transb</i> | Specifies the form of $\text{op}(B)$ used in the matrix multiplication: if <i>transb</i> =CblasNoTrans, then $\text{op}(B) = B$; if <i>transb</i> =CblasTrans, then $\text{op}(B) = B^T$; if <i>transb</i> =CblasConjTrans, then $\text{op}(B) = B^H$. |
| <i>m</i> | Specifies the number of rows of the matrix $\text{op}(A)$ and of the matrix C . The value of <i>m</i> must be at least zero. |
| <i>n</i> | Specifies the number of columns of the matrix $\text{op}(B)$ and the number of columns of the matrix C . The value of <i>n</i> must be at least zero. |
| <i>k</i> | Specifies the number of columns of the matrix $\text{op}(A)$ and the number of rows of the matrix $\text{op}(B)$. The value of <i>k</i> must be at least zero. |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |

| | | |
|----------------------------------|---|---|
| <i>a</i> | <i>transa</i> =CblasNoTrans | <i>transa</i> =CblasTrans or <i>transa</i> =CblasConjTrans |
| <i>Layout</i> = CblasColMajor | Array, size $lda*k$. Before entry, the leading m -by- k part of the array <i>a</i> must contain the matrix <i>A</i> . | Array, size $lda*m$. Before entry, the leading k -by- m part of the array <i>a</i> must contain the matrix <i>A</i> . |
| <i>Layout</i> = CblasRowMajor | Array, size $lda*m$. | Array, size $lda*k$. Before entry, the leading m -by- k part of the array <i>a</i> must contain the matrix <i>A</i> . |

Before entry, the leading k -by- m part of the array a must contain the matrix A .

lda

Specifies the leading dimension of a as declared in the calling (sub)program.

| | | |
|----------------------------------|---|---|
| | <i>transa</i> =CblasNoTrans | <i>transa</i> =CblasTrans or <i>transa</i> =CblasConjTrans |
| <i>Layout</i> = CblasColMajor | <i>lda</i> must be at least $\max(1, m)$. | <i>lda</i> must be at least $\max(1, k)$ |
| <i>Layout</i> = CblasRowMajor | <i>lda</i> must be at least $\max(1, k)$ | <i>lda</i> must be at least $\max(1, m)$. |

b

| | | |
|----------------------------------|---|--|
| | <i>transb</i> =CblasNoTrans | <i>transb</i> =CblasTrans or <i>transb</i> =CblasConjTrans |
| <i>Layout</i> = CblasColMajor | Array, size <i>ldb</i> by n . Before entry, the leading k -by- n part of the array b must contain the matrix B . | Array, size <i>ldb</i> by k . Before entry the leading n -by- k part of the array b must contain the matrix B . |
| <i>Layout</i> = CblasRowMajor | Array, size <i>ldb</i> by k . Before entry the leading n -by- k part of the array b must contain the matrix B . | Array, size <i>ldb</i> by n . Before entry, the leading k -by- n part of the array b must contain the matrix B . |

ldb

Specifies the leading dimension of b as declared in the calling (sub)program.

| | | |
|----------------------------------|---|---|
| | <i>transb</i> =CblasNoTrans | <i>transb</i> =CblasTrans or <i>transb</i> =CblasConjTrans |
| <i>Layout</i> = CblasColMajor | <i>ldb</i> must be at least $\max(1, k)$. | <i>ldb</i> must be at least $\max(1, n)$. |
| <i>Layout</i> = CblasRowMajor | <i>ldb</i> must be at least $\max(1, n)$. | <i>ldb</i> must be at least $\max(1, k)$. |

beta

Specifies the scalar *beta*.

When *beta* is equal to zero, then c need not be set on input.

c

| | |
|--|---|
| <p><i>Layout</i> = CblasColMajor</p> | <p>Array, size <i>ldc</i> by <i>n</i>. Before entry, the leading <i>m</i>-by-<i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i>, except when <i>beta</i> is equal to zero, in which case <i>c</i> need not be set on entry.</p> |
| <p><i>Layout</i> = CblasRowMajor</p> | <p>Array, size <i>ldc</i> by <i>m</i>. Before entry, the leading <i>n</i>-by-<i>m</i> part of the array <i>c</i> must contain the matrix <i>C</i>, except when <i>beta</i> is equal to zero, in which case <i>c</i> need not be set on entry.</p> |

ldc

Specifies the leading dimension of *c* as declared in the calling (sub)program.

| | |
|-------------------------------|--|
| <i>Layout</i> = CblasColMajor | <i>ldc</i> must be at least $\max(1, m)$. |
| <i>Layout</i> = CblasRowMajor | <i>ldc</i> must be at least $\max(1, n)$. |

Output Parameters

c

Overwritten by the *m*-by-*n* matrix $(\alpha * \text{op}(A) * \text{op}(B) + \beta * C)$.

Example

For examples of routine usage, see the code in the Intel MKL installation directory:

- cblas_sgemm: examples\cblas\source\cblas_sgemmx.c
- cblas_dgemm: examples\cblas\source\cblas_dgemmx.c
- cblas_cgemm: examples\cblas\source\cblas_cgemmx.c
- cblas_zgemm: examples\cblas\source\cblas_zgemmx.c

cblas_?hemm

Computes a matrix-matrix product where one input matrix is Hermitian.

Syntax

```
void cblas_chemm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO
uplo, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const
MKL_INT lda, const void *b, const MKL_INT ldb, const void *beta, void *c, const
MKL_INT ldc);
```

```
void cblas_zhemm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO
uplo, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const
MKL_INT lda, const void *b, const MKL_INT ldb, const void *beta, void *c, const
MKL_INT ldc);
```

Include Files

- mkl.h

Description

The `?hemm` routines compute a scalar-matrix-matrix product using a Hermitian matrix A and a general matrix B and add the result to a scalar-matrix product using a general matrix C . The operation is defined as

```
 $C := \alpha * A * B + \beta * C$ 
```

or

```
 $C := \alpha * B * A + \beta * C,$ 
```

where:

α and β are scalars,

A is a Hermitian matrix,

B and C are m -by- n matrices.

Input Parameters

| | |
|---------------|--|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>side</i> | Specifies whether the Hermitian matrix A appears on the left or right in the operation as follows: if $side = \text{CblasLeft}$, then $C := \alpha * A * B + \beta * C$; if $side = \text{CblasRight}$, then $C := \alpha * B * A + \beta * C$. |
| <i>uplo</i> | Specifies whether the upper or lower triangular part of the Hermitian matrix A is used: If $uplo = \text{CblasUpper}$, then the upper triangular part of the Hermitian matrix A is used. If $uplo = \text{CblasLower}$, then the low triangular part of the Hermitian matrix A is used. |
| <i>m</i> | Specifies the number of rows of the matrix C . The value of m must be at least zero. |
| <i>n</i> | Specifies the number of columns of the matrix C . The value of n must be at least zero. |
| <i>alpha</i> | Specifies the scalar α . |
| <i>a</i> | Array, size $lda * ka$, where ka is m when $side = \text{CblasLeft}$ and is n otherwise. Before entry with $side = \text{CblasLeft}$, the m -by- m part of the array a must contain the Hermitian matrix, such that when $uplo = \text{CblasUpper}$, the leading m -by- m upper triangular part of the array a must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of a is not referenced, and when $uplo = \text{CblasLower}$, the leading m -by- m lower triangular part of the array a must contain the lower triangular part of the Hermitian matrix, and the strictly upper triangular part of a is not referenced. Before entry with $side = \text{CblasRight}$, the n -by- n part of the array a must contain the Hermitian matrix, such that when $uplo = \text{CblasUpper}$, the leading n -by- n upper triangular part of the array a must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part |

of a is not referenced, and when $uplo = CblasLower$, the leading n -by- n lower triangular part of the array a must contain the lower triangular part of the Hermitian matrix, and the strictly upper triangular part of a is not referenced. The imaginary parts of the diagonal elements need not be set, they are assumed to be zero.

| | |
|-------------|--|
| <i>lda</i> | Specifies the leading dimension of a as declared in the calling (sub) program. When $side = CblasLeft$ then lda must be at least $\max(1, m)$, otherwise lda must be at least $\max(1, n)$. |
| <i>b</i> | For $Layout = CblasColMajor$: array, size $ldb*n$. The leading m -by- n part of the array b must contain the matrix B . For $Layout = CblasRowMajor$: array, size $ldb*m$. The leading n -by- m part of the array b must contain the matrix B . |
| <i>ldb</i> | Specifies the leading dimension of b as declared in the calling (sub)program. When $Layout = CblasColMajor$, ldb must be at least $\max(1, m)$; otherwise, ldb must be at least $\max(1, n)$. |
| <i>beta</i> | Specifies the scalar $beta$. When $beta$ is supplied as zero, then c need not be set on input. |
| <i>c</i> | For $Layout = CblasColMajor$: array, size $ldc*n$. Before entry, the leading m -by- n part of the array c must contain the matrix C , except when $beta$ is zero, in which case c need not be set on entry. For $Layout = CblasRowMajor$: array, size $ldc*m$. Before entry, the leading n -by- m part of the array c must contain the matrix C , except when $beta$ is zero, in which case c need not be set on entry. |
| <i>ldc</i> | Specifies the leading dimension of c as declared in the calling (sub)program. When $Layout = CblasColMajor$, ldc must be at least $\max(1, m)$; otherwise, ldc must be at least $\max(1, n)$. |

Output Parameters

| | |
|----------|---|
| <i>c</i> | Overwritten by the m -by- n updated matrix. |
|----------|---|

cblas_?herk

Performs a Hermitian rank- k update.

Syntax

```
void cblas_cherk (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const float alpha, const void
*a, const MKL_INT lda, const float beta, void *c, const MKL_INT ldc);

void cblas_zherk (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const double alpha, const void
*a, const MKL_INT lda, const double beta, void *c, const MKL_INT ldc);
```

Include Files

- mkl.h

Description

The `?herk` routines perform a rank- k matrix-matrix operation using a general matrix A and a Hermitian matrix C . The operation is defined as

$$C := \alpha * A * A^H + \beta * C,$$

or

$$C := \alpha * A^H * A + \beta * C,$$

where:

α and β are real scalars,

C is an n -by- n Hermitian matrix,

A is an n -by- k matrix in the first case and a k -by- n matrix in the second case.

Input Parameters

| | |
|---------------|--|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | Specifies whether the upper or lower triangular part of the array c is used. If $uplo = CblasUpper$, then the upper triangular part of the array c is used. If $uplo = CblasLower$, then the low triangular part of the array c is used. |
| <i>trans</i> | Specifies the operation: if $trans=CblasNoTrans$, then $C := \alpha * A * A^H + \beta * C$; if $trans=CblasConjTrans$, then $C := \alpha * A^H * A + \beta * C$. |
| <i>n</i> | Specifies the order of the matrix C . The value of n must be at least zero. |
| <i>k</i> | With $trans=CblasNoTrans$, k specifies the number of columns of the matrix A , and with $trans=CblasConjTrans$, k specifies the number of rows of the matrix A . The value of k must be at least zero. |
| <i>alpha</i> | Specifies the scalar α . |

a

| | $trans=CblasNoTrans$ | $trans=CblasConjTrans$ |
|-------------------------------|---|---|
| <i>Layout = CblasColMajor</i> | Array, size $lda * k$. Before entry, the leading n -by- k part of the array a must contain the matrix A . | Array, size $lda * n$. Before entry, the leading k -by- n part of the array a must contain the matrix A . |
| <i>Layout = CblasRowMajor</i> | Array, size $lda * n$. Before entry, the leading k -by- n part of the array a must contain the matrix A . | Array, size $lda * k$. Before entry, the leading n -by- k part of the array a must contain the matrix A . |

lda

| | <i>trans</i> =CblasNoTrans | <i>trans</i> =CblasConjTrans |
|-------------------------------|--|--|
| <i>Layout</i> = CblasColMajor | <i>lda</i> must be at least $\max(1, n)$. | <i>lda</i> must be at least $\max(1, k)$ |
| <i>Layout</i> = CblasRowMajor | <i>lda</i> must be at least $\max(1, k)$ | <i>lda</i> must be at least $\max(1, n)$. |

beta

Specifies the scalar *beta*.

c

Array, size *ldc* by *n*.

Before entry with *uplo* = CblasUpper, the leading *n*-by-*n* upper triangular part of the array *c* must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of *c* is not referenced.

Before entry with *uplo* = CblasLower, the leading *n*-by-*n* lower triangular part of the array *c* must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of *c* is not referenced.

The imaginary parts of the diagonal elements need not be set, they are assumed to be zero.

ldc

Specifies the leading dimension of *c* as declared in the calling (sub)program. The value of *ldc* must be at least $\max(1, n)$.

Output Parameters

c

With *uplo* = CblasUpper, the upper triangular part of the array *c* is overwritten by the upper triangular part of the updated matrix.

With *uplo* = CblasLower, the lower triangular part of the array *c* is overwritten by the lower triangular part of the updated matrix.

The imaginary parts of the diagonal elements are set to zero.

cblas_?her2k

Performs a Hermitian rank-2k update.

Syntax

```
void cblas_cher2k (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const void *alpha, const void
*a, const MKL_INT lda, const void *b, const MKL_INT ldb, const float beta, void *c,
const MKL_INT ldc);
```

```
void cblas_zher2k (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const void *alpha, const void
*a, const MKL_INT lda, const void *b, const MKL_INT ldb, const double beta, void *c,
const MKL_INT ldc);
```

Include Files

- mkl.h

Description

The `zher2k` routines perform a rank-2k matrix-matrix operation using general matrices A and B and a Hermitian matrix C . The operation is defined as

$$C := \alpha * A * B^H + \text{conjg}(\alpha) * B * A^H + \beta * C,$$

or

$$C := \alpha * A^H * B + \text{conjg}(\alpha) * B^H * A + \beta * C,$$

where:

α is a scalar and β is a real scalar,

C is an n -by- n Hermitian matrix,

A and B are n -by- k matrices in the first case and k -by- n matrices in the second case.

Input Parameters

| | |
|---------------|--|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | Specifies whether the upper or lower triangular part of the array c is used. If $uplo = \text{CblasUpper}$, then the upper triangular of the array c is used. If $uplo = \text{CblasLower}$, then the low triangular of the array c is used. |
| <i>trans</i> | Specifies the operation: if $trans = \text{CblasNoTrans}$, then $C := \alpha * A * B^H + \alpha * B * A^H + \beta * C$; if $trans = \text{CblasConjTrans}$, then $C := \alpha * A^H * B + \alpha * B^H * A + \beta * C$. |
| <i>n</i> | Specifies the order of the matrix C . The value of n must be at least zero. |
| <i>k</i> | With $trans = \text{CblasNoTrans}$ specifies the number of columns of the matrix A , and with $trans = \text{CblasConjTrans}$, k specifies the number of rows of the matrix A . The value of k must be at least equal to zero. |
| <i>alpha</i> | Specifies the scalar α . |

a

| | $trans = \text{CblasNoTrans}$ | $trans = \text{CblasConjTrans}$ |
|---------------------------------|---|---|
| $Layout = \text{CblasColMajor}$ | Array, size $lda * k$. Before entry, the leading n -by- k part of the array a must contain the matrix A . | Array, size $lda * n$. Before entry, the leading k -by- n part of the array a must contain the matrix A . |
| $Layout = \text{CblasRowMajor}$ | Array, size $lda * n$. Before entry, the leading k -by- n part of the array a must contain the matrix A . | Array, size $lda * k$. Before entry, the leading n -by- k part of the array a must contain the matrix A . |

lda

Specifies the leading dimension of *a* as declared in the calling (sub)program.

| | <i>trans</i> =CblasNoTrans | <i>trans</i> =CblasConjTrans |
|-------------------------------|--|--|
| <i>Layout</i> = CblasColMajor | <i>lda</i> must be at least $\max(1, n)$. | <i>lda</i> must be at least $\max(1, k)$ |
| <i>Layout</i> = CblasRowMajor | <i>lda</i> must be at least $\max(1, k)$ | <i>lda</i> must be at least $\max(1, n)$. |

beta

Specifies the scalar *beta*.

b

| | <i>trans</i> =CblasNoTrans | <i>trans</i> =CblasConjTrans |
|-------------------------------|---|---|
| <i>Layout</i> = CblasColMajor | Array, size <i>ldb</i> * <i>k</i> . Before entry, the leading <i>n</i> -by- <i>k</i> part of the array <i>b</i> must contain the matrix <i>B</i> . | Array, size <i>ldb</i> * <i>n</i> . Before entry, the leading <i>k</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> . |
| <i>Layout</i> = CblasRowMajor | Array, size <i>lda</i> * <i>n</i> . Before entry, the leading <i>k</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> . | Array, size <i>lda</i> * <i>k</i> . Before entry, the leading <i>n</i> -by- <i>k</i> part of the array <i>b</i> must contain the matrix <i>B</i> . |

ldb

Specifies the leading dimension of *a* as declared in the calling (sub)program.

| | <i>trans</i> =CblasNoTrans | <i>trans</i> =CblasConjTrans |
|-------------------------------|--|--|
| <i>Layout</i> = CblasColMajor | <i>ldb</i> must be at least $\max(1, n)$. | <i>ldb</i> must be at least $\max(1, k)$ |
| <i>Layout</i> = CblasRowMajor | <i>ldb</i> must be at least $\max(1, k)$ | <i>ldb</i> must be at least $\max(1, n)$. |

c

Array, size *ldc* by *n*.

Before entry with *uplo* = CblasUpper, the leading *n*-by-*n* upper triangular part of the array *c* must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of *c* is not referenced.

Before entry with *uplo* = CblasLower, the leading *n*-by-*n* lower triangular part of the array *c* must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of *c* is not referenced.

The imaginary parts of the diagonal elements need not be set, they are assumed to be zero.

ldc

Specifies the leading dimension of *c* as declared in the calling (sub)program. The value of *ldc* must be at least $\max(1, n)$.

Output Parameters

c With *uplo* = CblasUpper, the upper triangular part of the array *c* is overwritten by the upper triangular part of the updated matrix.

With *uplo* = CblasLower, the lower triangular part of the array *c* is overwritten by the lower triangular part of the updated matrix.

The imaginary parts of the diagonal elements are set to zero.

cblas_?symm

Computes a matrix-matrix product where one input matrix is symmetric.

Syntax

```
void cblas_ssymm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const MKL_INT m, const MKL_INT n, const float alpha, const float *a, const MKL_INT lda, const float *b, const MKL_INT ldb, const float beta, float *c, const MKL_INT ldc);
```

```
void cblas_dsymm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const MKL_INT m, const MKL_INT n, const double alpha, const double *a, const MKL_INT lda, const double *b, const MKL_INT ldb, const double beta, double *c, const MKL_INT ldc);
```

```
void cblas_csymm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void *beta, void *c, const MKL_INT ldc);
```

```
void cblas_zsymm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO uplo, const MKL_INT m, const MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void *beta, void *c, const MKL_INT ldc);
```

Include Files

- mkl.h

Description

The ?symm routines compute a scalar-matrix-matrix product with one symmetric matrix and add the result to a scalar-matrix product. The operation is defined as

$$C := \alpha A * B + \beta A * C,$$

or

$$C := \alpha B * A + \beta B * C,$$

where:

alpha and *beta* are scalars,

A is a symmetric matrix,

B and *C* are *m*-by-*n* matrices.

Input Parameters

| | |
|---------------|--|
| <i>layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>side</i> | Specifies whether the symmetric matrix <i>A</i> appears on the left or right in the operation: if <i>side</i> = CblasLeft, then $C := \alpha * A * B + \beta * C$; if <i>side</i> = CblasRight, then $C := \alpha * B * A + \beta * C$. |
| <i>uplo</i> | Specifies whether the upper or lower triangular part of the symmetric matrix <i>A</i> is used: if <i>uplo</i> = CblasUpper, then the upper triangular part is used; if <i>uplo</i> = CblasLower, then the lower triangular part is used. |
| <i>m</i> | Specifies the number of rows of the matrix <i>C</i> . The value of <i>m</i> must be at least zero. |
| <i>n</i> | Specifies the number of columns of the matrix <i>C</i> . The value of <i>n</i> must be at least zero. |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>a</i> | Array, size <i>lda</i> * <i>ka</i> , where <i>ka</i> is <i>m</i> when <i>side</i> = CblasLeft and is <i>n</i> otherwise. Before entry with <i>side</i> = CblasLeft, the <i>m</i> -by- <i>m</i> part of the array <i>a</i> must contain the symmetric matrix, such that when <i>uplo</i> = CblasUpper, the leading <i>m</i> -by- <i>m</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of <i>a</i> is not referenced, and when <i>side</i> = CblasLeft, the leading <i>m</i> -by- <i>m</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of <i>a</i> is not referenced. Before entry with <i>side</i> = CblasRight, the <i>n</i> -by- <i>n</i> part of the array <i>a</i> must contain the symmetric matrix, such that when <i>uplo</i> = CblasUpper array <i>a</i> must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of <i>a</i> is not referenced, and when <i>side</i> = CblasLeft, the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of <i>a</i> is not referenced. |
| <i>lda</i> | Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. When <i>side</i> = CblasLeft then <i>lda</i> must be at least $\max(1, m)$, otherwise <i>lda</i> must be at least $\max(1, n)$. |
| <i>b</i> | For <i>Layout</i> = CblasColMajor: array, size <i>ldb</i> * <i>n</i> . The leading <i>m</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> . For <i>Layout</i> = CblasRowMajor: array, size <i>ldb</i> * <i>m</i> . The leading <i>n</i> -by- <i>m</i> part of the array <i>b</i> must contain the matrix <i>B</i> |

| | |
|-------------|--|
| <i>ldb</i> | Specifies the leading dimension of <i>b</i> as declared in the calling (sub)program. When <i>Layout</i> = CblasColMajor, <i>ldb</i> must be at least $\max(1, m)$; otherwise, <i>ldb</i> must be at least $\max(1, n)$. |
| <i>beta</i> | Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then <i>c</i> need not be set on input. |
| <i>c</i> | For <i>Layout</i> = CblasColMajor: array, size <i>ldc</i> * <i>n</i> . Before entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i> , except when <i>beta</i> is zero, in which case <i>c</i> need not be set on entry. For <i>Layout</i> = CblasRowMajor: array, size <i>ldc</i> * <i>m</i> . Before entry, the leading <i>n</i> -by- <i>m</i> part of the array <i>c</i> must contain the matrix <i>C</i> , except when <i>beta</i> is zero, in which case <i>c</i> need not be set on entry. |
| <i>ldc</i> | Specifies the leading dimension of <i>c</i> as declared in the calling (sub)program. When <i>Layout</i> = CblasColMajor, <i>ldc</i> must be at least $\max(1, m)$; otherwise, <i>ldc</i> must be at least $\max(1, n)$. |

Output Parameters

| | |
|----------|---|
| <i>c</i> | Overwritten by the <i>m</i> -by- <i>n</i> updated matrix. |
|----------|---|

cblas_?syrk

Performs a symmetric rank-k update.

Syntax

```
void cblas_ssyrc (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const float alpha, const float
*a, const MKL_INT lda, const float beta, float *c, const MKL_INT ldc);

void cblas_dsyrk (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const double alpha, const
double *a, const MKL_INT lda, const double beta, double *c, const MKL_INT ldc);

void cblas_csyrk (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const void *alpha, const void
*a, const MKL_INT lda, const void *beta, void *c, const MKL_INT ldc);

void cblas_zsyrk (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE trans, const MKL_INT n, const MKL_INT k, const void *alpha, const void
*a, const MKL_INT lda, const void *beta, void *c, const MKL_INT ldc);
```

Include Files

- mkl.h

Description

The ?syrk routines perform a rank-k matrix-matrix operation for a symmetric matrix *C* using a general matrix *A*. The operation is defined as

$$C := \alpha * A * A' + \beta * C,$$

or

$$C := \alpha * A' * A + \beta * C,$$

where:

α and β are scalars,

C is an n -by- n symmetric matrix,

A is an n -by- k matrix in the first case and a k -by- n matrix in the second case.

Input Parameters

| | |
|---------------|---|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | Specifies whether the upper or lower triangular part of the array c is used. If $uplo = CblasUpper$, then the upper triangular part of the array c is used. If $uplo = CblasLower$, then the low triangular part of the array c is used. |
| <i>trans</i> | Specifies the operation: if $trans=CblasNoTrans$, then $C := \alpha * A * A' + \beta * C$; if $trans=CblasTrans$, then $C := \alpha * A' * A + \beta * C$; if $trans=CblasConjTrans$, then $C := \alpha * A' * A + \beta * C$. |
| <i>n</i> | Specifies the order of the matrix C . The value of n must be at least zero. |
| <i>k</i> | On entry with $trans=CblasNoTrans$, k specifies the number of columns of the matrix a , and on entry with $trans=CblasTrans$ or $trans=CblasConjTrans$, k specifies the number of rows of the matrix a . The value of k must be at least zero. |
| <i>alpha</i> | Specifies the scalar α . |
| <i>a</i> | Array, size $lda * ka$, where ka is k when $trans=CblasNoTrans$, and is n otherwise. Before entry with $trans=CblasNoTrans$, the leading n -by- k part of the array a must contain the matrix A , otherwise the leading k -by- n part of the array a must contain the matrix A . |

| | | |
|-------------------------------|---|---|
| | $trans=CblasNoTrans$ | $trans=CblasConjTrans$ |
| <i>Layout = CblasColMajor</i> | Array, size $lda * k$. Before entry, the leading n -by- k part of the array a must contain the matrix A . | Array, size $lda * n$. Before entry, the leading k -by- n part of the array a must contain the matrix A . |
| <i>Layout = CblasRowMajor</i> | Array, size $lda * n$. Before entry, the leading k -by- n part of the array a must contain the matrix A . | Array, size $lda * k$. Before entry, the leading n -by- k part of the array a must contain the matrix A . |

| | | |
|------------|----------------------|------------------------|
| <i>lda</i> | $trans=CblasNoTrans$ | $trans=CblasConjTrans$ |
|------------|----------------------|------------------------|

| | | |
|-----------------|-----------------------------|-----------------------------|
| <i>Layout</i> = | <i>lda</i> must be at least | <i>lda</i> must be at least |
| CblasColMajor | max(1, <i>n</i>). | max(1, <i>k</i>) |
| <i>Layout</i> = | <i>lda</i> must be at least | <i>lda</i> must be at least |
| CblasRowMajor | max(1, <i>k</i>) | max(1, <i>n</i>). |

| | |
|-------------|--|
| <i>beta</i> | Specifies the scalar <i>beta</i> . |
| <i>c</i> | Array, size <i>ldc</i> * <i>n</i> . Before entry with <i>uplo</i> = CblasUpper, the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>c</i> must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of <i>c</i> is not referenced. Before entry with <i>uplo</i> = CblasLower, the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>c</i> must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of <i>c</i> is not referenced. |
| <i>ldc</i> | Specifies the leading dimension of <i>c</i> as declared in the calling (sub)program. The value of <i>ldc</i> must be at least max(1, <i>n</i>). |

Output Parameters

| | |
|----------|--|
| <i>c</i> | With <i>uplo</i> = CblasUpper, the upper triangular part of the array <i>c</i> is overwritten by the upper triangular part of the updated matrix. With <i>uplo</i> = CblasLower, the lower triangular part of the array <i>c</i> is overwritten by the lower triangular part of the updated matrix. |
|----------|--|

cblas_?syr2k

Performs a symmetric rank-2k update.

Syntax

```
void cblas_ssy2k (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const

const MKL_INT ldc);
```

Include Files

- mkl.h

Description

The `?syr2k` routines perform a rank-2k matrix-matrix operation for a symmetric matrix C using general matrices A and B . The operation is defined as

$$C := \alpha * A * B' + \alpha * B * A' + \beta * C,$$

or

$$C := \alpha * A' * B + \alpha * B' * A + \beta * C,$$

where:

α and β are scalars,

C is an n -by- n symmetric matrix,

A and B are n -by- k matrices in the first case, and k -by- n matrices in the second case.

Input Parameters

| | |
|---------------|---|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | Specifies whether the upper or lower triangular part of the array c is used. If $uplo = CblasUpper$, then the upper triangular part of the array c is used. If $uplo = CblasLower$, then the low triangular part of the array c is used. |
| <i>trans</i> | Specifies the operation: if $trans=CblasNoTrans$, then $C := \alpha * A * B' + \alpha * B * A' + \beta * C$; if $trans=CblasTrans$, then $C := \alpha * A' * B + \alpha * B' * A + \beta * C$; if $trans=CblasConjTrans$, then $C := \alpha * A' * B + \alpha * B' * A + \beta * C$. |
| <i>n</i> | Specifies the order of the matrix C . The value of n must be at least zero. |
| <i>k</i> | On entry with $trans=CblasNoTrans$, k specifies the number of columns of the matrices A and B , and on entry with $trans=CblasTrans$ or $trans=CblasConjTrans$, k specifies the number of rows of the matrices A and B . The value of k must be at least zero. |
| <i>alpha</i> | Specifies the scalar α . |

a

| | <i>trans=CblasNoTrans</i> | <i>trans=CblasConjTrans</i> |
|-------------------------------|---|---|
| <i>Layout = CblasColMajor</i> | Array, size $lda * k$. Before entry, the leading n -by- k part of the array a must contain the matrix A . | Array, size $lda * n$. Before entry, the leading k -by- n part of the array a must contain the matrix A . |
| <i>Layout = CblasRowMajor</i> | Array, size $lda * n$. | Array, size $lda * k$. |

| | |
|--|--|
| Before entry, the leading k -by- n part of the array a must contain the matrix A . | Before entry, the leading n -by- k part of the array a must contain the matrix A . |
|--|--|

lda

Specifies the leading dimension of a as declared in the calling (sub)program.

| | | |
|----------------------------------|--|--|
| | <i>trans</i> =CblasNoTrans | <i>trans</i> =CblasConjTrans |
| <i>Layout</i> = CblasColMajor | <i>lda</i> must be at least $\max(1, n)$. | <i>lda</i> must be at least $\max(1, k)$ |
| <i>Layout</i> = CblasRowMajor | <i>lda</i> must be at least $\max(1, k)$ | <i>lda</i> must be at least $\max(1, n)$. |

b

| | | |
|----------------------------------|---|---|
| | <i>trans</i> =CblasNoTrans | <i>trans</i> =CblasConjTrans |
| <i>Layout</i> = CblasColMajor | Array, size $ldb*k$. Before entry, the leading n -by- k part of the array b must contain the matrix B . | Array, size $ldb*n$. Before entry, the leading k -by- n part of the array b must contain the matrix B . |
| <i>Layout</i> = CblasRowMajor | Array, size $lda*n$. Before entry, the leading k -by- n part of the array b must contain the matrix B . | Array, size $lda*k$. Before entry, the leading n -by- k part of the array b must contain the matrix B . |

ldb

Specifies the leading dimension of a as declared in the calling (sub)program.

| | | |
|----------------------------------|--|--|
| | <i>trans</i> =CblasNoTrans | <i>trans</i> =CblasConjTrans |
| <i>Layout</i> = CblasColMajor | <i>ldb</i> must be at least $\max(1, n)$. | <i>ldb</i> must be at least $\max(1, k)$ |
| <i>Layout</i> = CblasRowMajor | <i>ldb</i> must be at least $\max(1, k)$ | <i>ldb</i> must be at least $\max(1, n)$. |

beta

Specifies the scalar *beta*.

c

Array, size $ldc* n$. Before entry with *uplo* = CblasUpper, the leading n -by- n upper triangular part of the array c must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of c is not referenced.

Before entry with *uplo* = CblasLower, the leading n -by- n lower triangular part of the array c must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of c is not referenced.

ldc Specifies the leading dimension of *c* as declared in the calling (sub)program. The value of *ldc* must be at least $\max(1, n)$.

Output Parameters

c With *uplo* = CblasUpper, the upper triangular part of the array *c* is overwritten by the upper triangular part of the updated matrix.
 With *uplo* = CblasLower, the lower triangular part of the array *c* is overwritten by the lower triangular part of the updated matrix.

cblas_?trmm

Computes a matrix-matrix product where one input matrix is triangular.

Syntax

```
void cblas_strmm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO
uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const
MKL_INT n, const float alpha, const float *a, const MKL_INT lda, float *b, const
MKL_INT ldb);
```

```
void cblas_dtrmm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO
uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const
MKL_INT n, const double alpha, const double *a, const MKL_INT lda, double *b, const
MKL_INT ldb);
```

```
void cblas_ctrmm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO
uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const
MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, void *b, const MKL_INT
ldb);
```

```
void cblas_ztrmm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO
uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const
MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, void *b, const MKL_INT
ldb);
```

Include Files

- mkl.h

Description

The ?trmm routines compute a scalar-matrix-matrix product with one triangular matrix. The operation is defined as

$$B := \alpha * \text{op}(A) * B$$

or

$$B := \alpha * B * \text{op}(A)$$

where:

alpha is a scalar,

B is an *m*-by-*n* matrix,

A is a unit, or non-unit, upper or lower triangular matrix

op(*A*) is one of op(*A*) = *A*, or op(*A*) = *A'*, or op(*A*) = conjg(*A'*).

Input Parameters

| | |
|---------------|--|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>side</i> | Specifies whether $\text{op}(A)$ appears on the left or right of B in the operation: if $\text{side} = \text{CblasLeft}$, then $B := \alpha * \text{op}(A) * B$; if $\text{side} = \text{CblasRight}$, then $B := \alpha * B * \text{op}(A)$. |
| <i>uplo</i> | Specifies whether the matrix A is upper or lower triangular: $\text{uplo} = \text{CblasUpper}$ if $\text{uplo} = \text{CblasLower}$, then the matrix is low triangular. |
| <i>transa</i> | Specifies the form of $\text{op}(A)$ used in the matrix multiplication: if $\text{transa} = \text{CblasNoTrans}$, then $\text{op}(A) = A$; if $\text{transa} = \text{CblasTrans}$, then $\text{op}(A) = A'$; if $\text{transa} = \text{CblasConjTrans}$, then $\text{op}(A) = \text{conjg}(A')$. |
| <i>diag</i> | Specifies whether the matrix A is unit triangular: if $\text{diag} = \text{CblasUnit}$ then the matrix is unit triangular; if $\text{diag} = \text{CblasNonUnit}$, then the matrix is not unit triangular. |
| <i>m</i> | Specifies the number of rows of B . The value of m must be at least zero. |
| <i>n</i> | Specifies the number of columns of B . The value of n must be at least zero. |
| <i>alpha</i> | Specifies the scalar α . When α is zero, then a is not referenced and b need not be set before entry. |
| <i>a</i> | Array, size lda by k , where k is m when $\text{side} = \text{CblasLeft}$ and is n when $\text{side} = \text{CblasRight}$. Before entry with $\text{uplo} = \text{CblasUpper}$, the leading k by k upper triangular part of the array a must contain the upper triangular matrix and the strictly lower triangular part of a is not referenced. Before entry with $\text{uplo} = \text{CblasLower}$, the leading k by k lower triangular part of the array a must contain the lower triangular matrix and the strictly upper triangular part of a is not referenced. When $\text{diag} = \text{CblasUnit}$, the diagonal elements of a are not referenced either, but are assumed to be unity. |
| <i>lda</i> | Specifies the leading dimension of a as declared in the calling (sub)program. When $\text{side} = \text{CblasLeft}$, then lda must be at least $\max(1, m)$, when $\text{side} = \text{CblasRight}$, then lda must be at least $\max(1, n)$. |
| <i>b</i> | For $\text{Layout} = \text{CblasColMajor}$: array, size $ldb * n$. Before entry, the leading m -by- n part of the array b must contain the matrix B . For $\text{Layout} = \text{CblasRowMajor}$: array, size $ldb * m$. Before entry, the leading n -by- m part of the array b must contain the matrix B . |

ldb Specifies the leading dimension of *b* as declared in the calling (sub)program. When *Layout* = CblasColMajor, *ldb* must be at least $\max(1, m)$; otherwise, *ldb* must be at least $\max(1, n)$.

Output Parameters

b Overwritten by the transformed matrix.

cblas_?trsm

Solves a triangular matrix equation.

Syntax

```
void cblas_strsm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO
uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const
MKL_INT n, const float alpha, const float *a, const MKL_INT lda, float *b, const
MKL_INT ldb);
```

```
void cblas_dtrsm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO
uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const
MKL_INT n, const double alpha, const double *a, const MKL_INT lda, double *b, const
MKL_INT ldb);
```

```
void cblas_ctrsm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO
uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const
MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, void *b, const MKL_INT
ldb);
```

```
void cblas_ztrsm (const CBLAS_LAYOUT Layout, const CBLAS_SIDE side, const CBLAS_UPLO
uplo, const CBLAS_TRANSPOSE transa, const CBLAS_DIAG diag, const MKL_INT m, const
MKL_INT n, const void *alpha, const void *a, const MKL_INT lda, void *b, const MKL_INT
ldb);
```

Include Files

- mkl.h

Description

The ?trsm routines solve one of the following matrix equations:

$$\text{op}(A) * X = \alpha * B,$$

or

$$X * \text{op}(A) = \alpha * B,$$

where:

alpha is a scalar,

X and *B* are *m*-by-*n* matrices,

A is a unit, or non-unit, upper or lower triangular matrix

op(*A*) is one of op(*A*) = *A*, or op(*A*) = *A'*, or op(*A*) = conjg(*A'*).

The matrix *B* is overwritten by the solution matrix *X*.

Input Parameters

| | |
|---------------|--|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>side</i> | Specifies whether $\text{op}(A)$ appears on the left or right of X in the equation: if <i>side</i> = CblasLeft, then $\text{op}(A) * X = \alpha * B$; if <i>side</i> = CblasRight, then $X * \text{op}(A) = \alpha * B$. |
| <i>uplo</i> | Specifies whether the matrix A is upper or lower triangular: <i>uplo</i> = CblasUpper if <i>uplo</i> = CblasLower, then the matrix is low triangular. |
| <i>transa</i> | Specifies the form of $\text{op}(A)$ used in the matrix multiplication: if <i>transa</i> =CblasNoTrans, then $\text{op}(A) = A$; if <i>transa</i> =CblasTrans; if <i>transa</i> =CblasConjTrans, then $\text{op}(A) = \text{conjg}(A')$. |
| <i>diag</i> | Specifies whether the matrix A is unit triangular: if <i>diag</i> = CblasUnit then the matrix is unit triangular; if <i>diag</i> = CblasNonUnit , then the matrix is not unit triangular. |
| <i>m</i> | Specifies the number of rows of B . The value of m must be at least zero. |
| <i>n</i> | Specifies the number of columns of B . The value of n must be at least zero. |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . When <i>alpha</i> is zero, then a is not referenced and b need not be set before entry. |
| <i>a</i> | Array, size $lda * k$, where k is m when <i>side</i> = CblasLeft and is n when <i>side</i> = CblasRight. Before entry with <i>uplo</i> = CblasUpper, the leading k by k upper triangular part of the array a must contain the upper triangular matrix and the strictly lower triangular part of a is not referenced. Before entry with <i>uplo</i> = CblasLower lower triangular part of the array a must contain the lower triangular matrix and the strictly upper triangular part of a is not referenced. When <i>diag</i> = CblasUnit, the diagonal elements of a are not referenced either, but are assumed to be unity. |
| <i>lda</i> | Specifies the leading dimension of a as declared in the calling (sub)program. When <i>side</i> = CblasLeft, then <i>lda</i> must be at least $\max(1, m)$, when <i>side</i> = CblasRight, then <i>lda</i> must be at least $\max(1, n)$. |
| <i>b</i> | For <i>Layout</i> = CblasColMajor: array, size $ldb * n$. Before entry, the leading m -by- n part of the array b must contain the matrix B . For <i>Layout</i> = CblasRowMajor: array, size $ldb * m$. Before entry, the leading n -by- m part of the array b must contain the matrix B . |

ldb Specifies the leading dimension of *b* as declared in the calling (sub)program. When *Layout* = `CblasColMajor`, *ldb* must be at least $\max(1, m)$; otherwise, *ldb* must be at least $\max(1, n)$.

Output Parameters

b Overwritten by the solution matrix *X*.

Sparse BLAS Level 1 Routines

This section describes Sparse BLAS Level 1, an extension of BLAS Level 1 included in the Intel® Math Kernel Library beginning with the Intel MKL release 2.1. Sparse BLAS Level 1 is a group of routines and functions that perform a number of common vector operations on sparse vectors stored in compressed form.

Sparse vectors are those in which the majority of elements are zeros. Sparse BLAS routines and functions are specially implemented to take advantage of vector sparsity. This allows you to achieve large savings in computer time and memory. If *nz* is the number of non-zero vector elements, the computer time taken by Sparse BLAS operations will be $O(nz)$.

Vector Arguments

Compressed sparse vectors. Let *a* be a vector stored in an array, and assume that the only non-zero elements of *a* are the following:

```
a[k1], a[k2], a[k3] . . . a[knz],
```

where *nz* is the total number of non-zero elements in *a*.

In Sparse BLAS, this vector can be represented in compressed form by two arrays, *x* (values) and *indx* (indices). Each array has *nz* elements:

```
x[0]=a[k1], x[1]=a[k2], . . . x[nz-1]= a[knz],
```

```
indx[0]=k1, indx[1]=k2, . . . indx[nz-1]= knz.
```

Thus, a sparse vector is fully determined by the triple (*nz*, *x*, *indx*). If you pass a negative or zero value of *nz* to Sparse BLAS, the subroutines do not modify any arrays or variables.

Full-storage vectors. Sparse BLAS routines can also use a vector argument fully stored in a single array (a full-storage vector). If *y* is a full-storage vector, its elements must be stored contiguously: the first element in *y*[0], the second in *y*[1], and so on. This corresponds to an increment *incy* = 1 in BLAS Level 1. No increment value for full-storage vectors is passed as an argument to Sparse BLAS routines or functions.

Naming Conventions for Sparse BLAS Routines

Similar to BLAS, the names of Sparse BLAS subprograms have prefixes that determine the data type involved: *s* and *d* for single- and double-precision real; *c* and *z* for single- and double-precision complex respectively.

If a Sparse BLAS routine is an extension of a "dense" one, the subprogram name is formed by appending the suffix *i* (standing for *indexed*) to the name of the corresponding "dense" subprogram. For example, the Sparse BLAS routine `saxpyi` corresponds to the BLAS routine `saxpy`, and the Sparse BLAS function `cdotci` corresponds to the BLAS function `cdotc`.

Routines and Data Types

Routines and data types supported in the Intel MKL implementation of Sparse BLAS are listed in [Table "Sparse BLAS Routines and Their Data Types"](#).

Sparse BLAS Routines and Their Data Types

| Routine/ Function | Data Types | Description |
|---------------------------|------------|--|
| <code>cblas_?axpyi</code> | s, d, c, z | Scalar-vector product plus vector (routines) |
| <code>cblas_?doti</code> | s, d | Dot product (functions) |
| <code>cblas_?dotci</code> | c, z | Complex dot product conjugated (functions) |
| <code>cblas_?dotui</code> | c, z | Complex dot product unconjugated (functions) |
| <code>cblas_?gthr</code> | s, d, c, z | Gathering a full-storage sparse vector into compressed form $nz, x, indx$ (routines) |
| <code>cblas_?gthrz</code> | s, d, c, z | Gathering a full-storage sparse vector into compressed form and assigning zeros to gathered elements in the full-storage vector (routines) |
| <code>cblas_?roti</code> | s, d | Givens rotation (routines) |
| <code>cblas_?sctr</code> | s, d, c, z | Scattering a vector from compressed form to full-storage form (routines) |

BLAS Level 1 Routines That Can Work With Sparse Vectors

The following BLAS Level 1 routines will give correct results when you pass to them a compressed-form array x (with the increment $incx=1$):

| | |
|---------------------------|--|
| <code>cblas_?asum</code> | sum of absolute values of vector elements |
| <code>cblas_?copy</code> | copying a vector |
| <code>cblas_?nrm2</code> | Euclidean norm of a vector |
| <code>cblas_?scal</code> | scaling a vector |
| <code>cblas_i?amax</code> | index of the element with the largest absolute value for real flavors, or the largest sum $ \operatorname{Re}(x[i]) + \operatorname{Im}(x[i]) $ for complex flavors. |
| <code>cblas_i?amin</code> | index of the element with the smallest absolute value for real flavors, or the smallest sum $ \operatorname{Re}(x[i]) + \operatorname{Im}(x[i]) $ for complex flavors. |

The result i returned by `i?amax` and `i?amin` should be interpreted as index in the compressed-form array, so that the largest (smallest) value is $x[i-1]$; the corresponding index in full-storage array is $indx[i-1]$.

You can also call `cblas_?rotg` to compute the parameters of Givens rotation and then pass these parameters to the Sparse BLAS routines `cblas_?roti`.

`cblas_?axpyi`

Adds a scalar multiple of compressed sparse vector to a full-storage vector.

Syntax

```
void cblas_saxpyi (const MKL_INT nz, const float a, const float *x, const MKL_INT *indx, float *y);
```

```
void cblas_daxpyi (const MKL_INT nz, const double a, const double *x, const MKL_INT *indx, double *y);
```

```
void cblas_caxpyi (const MKL_INT nz, const void *a, const void *x, const MKL_INT *indx, void *y);
```

```
void cblas_zaxpyi (const MKL_INT nz, const void *a, const void *x, const MKL_INT *indx, void *y);
```

Include Files

- mkl.h

Description

The `?axpyi` routines perform a vector-vector operation defined as

```
 $y := a*x + y$ 
```

where:

a is a scalar,

x is a sparse vector stored in compressed form,

y is a vector in full storage form.

The `?axpyi` routines reference or modify only the elements of y whose indices are listed in the array $indx$.

The values in $indx$ must be distinct.

Input Parameters

| | |
|--------|--|
| nz | The number of elements in x and $indx$. |
| a | Specifies the scalar a . |
| x | Array, size at least nz . |
| $indx$ | Specifies the indices for the elements of x . Array, size at least nz . |
| y | Array, size at least $\max(indx[i])$. |

Output Parameters

| | |
|-----|-----------------------------------|
| y | Contains the updated vector y . |
|-----|-----------------------------------|

cblas_?doti

Computes the dot product of a compressed sparse real vector by a full-storage real vector.

Syntax

```
float cblas_sdoti (const MKL_INT nz, const float *x, const MKL_INT *indx, const float *y);
```

```
double cblas_ddoti (const MKL_INT nz, const double *x, const MKL_INT *indx, const double *y);
```

Include Files

- mkl.h

Description

The `?doti` routines return the dot product of x and y defined as

```
res = x[0]*y[indx[0]] + x[1]*y[indx[1]] +...+ x[nz-1]*y[indx[nz-1]]
```

where the triple $(nz, x, indx)$ defines a sparse real vector stored in compressed form, and y is a real vector in full storage form. The functions reference only the elements of y whose indices are listed in the array $indx$. The values in $indx$ must be distinct.

Input Parameters

| | |
|--------|--|
| nz | The number of elements in x and $indx$. |
| x | Array, size at least nz . |
| $indx$ | Specifies the indices for the elements of x . Array, size at least nz . |
| y | Array, size at least $\max(indx[i])$. |

Output Parameters

| | |
|-------|---|
| res | Contains the dot product of x and y , if nz is positive. Otherwise, res contains 0. |
|-------|---|

`cblas_?dotci`

Computes the conjugated dot product of a compressed sparse complex vector with a full-storage complex vector.

Syntax

```
void cblas_cdotci_sub (const MKL_INT nz, const void *x, const MKL_INT *indx, const void *y, void *dotui);
```

```
void cblas_zdotci_sub (const MKL_INT nz, const void *x, const MKL_INT *indx, const void *y, void *dotui);
```

Include Files

- `mkl.h`

Description

The `?dotci` routines return the dot product of x and y defined as

```
conjg(x[0])*y[indx[0]] + ... + conjg(x[nz-1])*y[indx[nz-1]]
```

where the triple $(nz, x, indx)$ defines a sparse complex vector stored in compressed form, and y is a real vector in full storage form. The functions reference only the elements of y whose indices are listed in the array $indx$. The values in $indx$ must be distinct.

Input Parameters

| | |
|------|--|
| nz | The number of elements in x and $indx$. |
|------|--|

| | |
|-------------|--|
| <i>x</i> | Array, size at least <i>nz</i> . |
| <i>indx</i> | Specifies the indices for the elements of <i>x</i> . Array, size at least <i>nz</i> . |
| <i>y</i> | Array, size at least $\max(\text{indx}[i])$. |

Output Parameters

| | |
|--------------|--|
| <i>dotui</i> | Contains the conjugated dot product of <i>x</i> and <i>y</i> , if <i>nz</i> is positive. Otherwise, it contains 0. |
|--------------|--|

cblas_?dotui

Computes the dot product of a compressed sparse complex vector by a full-storage complex vector.

Syntax

```
void cblas_cdotui_sub (const MKL_INT nz, const void *x, const MKL_INT *indx, const void *y, void *dotui);
```

```
void cblas_zdotui_sub (const MKL_INT nz, const void *x, const MKL_INT *indx, const void *y, void *dotui);
```

Include Files

- `mkl.h`

Description

The `?dotui` routines return the dot product of *x* and *y* defined as

```
res = x[0]*y[indx[0]] + x[1]*y[indx[1]] + ... + x[nz - 1]*y[indx[nz - 1]]
```

where the triple (*nz*, *x*, *indx*) defines a sparse complex vector stored in compressed form, and *y* is a real vector in full storage form. The functions reference only the elements of *y* whose indices are listed in the array *indx*. The values in *indx* must be distinct.

Input Parameters

| | |
|-------------|--|
| <i>nz</i> | The number of elements in <i>x</i> and <i>indx</i> . |
| <i>x</i> | Array, size at least <i>nz</i> . |
| <i>indx</i> | Specifies the indices for the elements of <i>x</i> . Array, size at least <i>nz</i> . |
| <i>y</i> | Array, size at least $\max(\text{indx}[i])$. |

Output Parameters

| | |
|--------------|---|
| <i>dotui</i> | Contains the dot product of <i>x</i> and <i>y</i> , if <i>nz</i> is positive. Otherwise, <i>res</i> contains 0. |
|--------------|---|

cblas_?gthr

Gathers a full-storage sparse vector's elements into compressed form.

Syntax

```
void cblas_sgthr (const MKL_INT nz, const float *y, float *x, const MKL_INT *indx);
void cblas_dgthr (const MKL_INT nz, const double *y, double *x, const MKL_INT *indx);
void cblas_cgthr (const MKL_INT nz, const void *y, void *x, const MKL_INT *indx);
void cblas_zgthr (const MKL_INT nz, const void *y, void *x, const MKL_INT *indx);
```

Include Files

- mkl.h

Description

The `?gthr` routines gather the specified elements of a full-storage sparse vector y into compressed form(nz , x , $indx$). The routines reference only the elements of y whose indices are listed in the array $indx$:

$x[i] = y[indx[i]]$, for $i=0,1,\dots,nz-1$.

Input Parameters

| | |
|--------|--|
| nz | The number of elements of y to be gathered. |
| $indx$ | Specifies indices of elements to be gathered. Array, size at least nz . |
| y | Array, size at least $\max(indx[i])$. |

Output Parameters

| | |
|-----|--|
| x | Array, size at least nz . Contains the vector converted to the compressed form. |
|-----|--|

cblas_?gthrz

Gathers a sparse vector's elements into compressed form, replacing them by zeros.

Syntax

```
void cblas_sgthrz (const MKL_INT nz, float *y, float *x, const MKL_INT *indx);
void cblas_dgthrz (const MKL_INT nz, double *y, double *x, const MKL_INT *indx);
void cblas_cgthrz (const MKL_INT nz, void *y, void *x, const MKL_INT *indx);
void cblas_zgthrz (const MKL_INT nz, void *y, void *x, const MKL_INT *indx);
```

Include Files

- mkl.h

Description

The `?gthrz` routines gather the elements with indices specified by the array `indx` from a full-storage vector `y` into compressed form (`nz`, `x`, `indx`) and overwrite the gathered elements of `y` by zeros. Other elements of `y` are not referenced or modified (see also `?gthr`).

Input Parameters

| | |
|-------------------|---|
| <code>nz</code> | The number of elements of <code>y</code> to be gathered. |
| <code>indx</code> | Specifies indices of elements to be gathered. Array, size at least <code>nz</code> . |
| <code>y</code> | Array, size at least $\max(\text{indx}[i])$. |

Output Parameters

| | |
|----------------|---|
| <code>x</code> | Array, size at least <code>nz</code> . Contains the vector converted to the compressed form. |
| <code>y</code> | The updated vector <code>y</code> . |

`cblas_?roti`

Applies Givens rotation to sparse vectors one of which is in compressed form.

Syntax

```
void cblas_sroti (const MKL_INT nz, float *x, const MKL_INT *indx, float *y, const float c, const float s);
```

```
void cblas_droti (const MKL_INT nz, double *x, const MKL_INT *indx, double *y, const double c, const double s);
```

Include Files

- `mkl.h`

Description

The `?roti` routines apply the Givens rotation to elements of two real vectors, `x` (in compressed form `nz`, `x`, `indx`) and `y` (in full storage form):

```
x[i] = c*x[i] + s*y[indx[i]]
```

```
y[indx[i]] = c*y[indx[i]] - s*x[i]
```

The routines reference only the elements of `y` whose indices are listed in the array `indx`. The values in `indx` must be distinct.

Input Parameters

| | |
|-----------------|--|
| <code>nz</code> | The number of elements in <code>x</code> and <code>indx</code> . |
| <code>x</code> | Array, size at least <code>nz</code> . |

| | |
|-------------|--|
| <i>indx</i> | Specifies the indices for the elements of <i>x</i> . Array, size at least <i>nz</i> . |
| <i>y</i> | Array, size at least $\max(\text{indx}[i])$. |
| <i>c</i> | A scalar. |
| <i>s</i> | A scalar. |

Output Parameters

| | |
|-----------------------|---------------------|
| <i>x</i> and <i>y</i> | The updated arrays. |
|-----------------------|---------------------|

cblas_?sctr

Converts compressed sparse vectors into full storage form.

Syntax

```
void cblas_ssctr (const MKL_INT nz, const float *x, const MKL_INT *indx, float *y);
void cblas_dsctr (const MKL_INT nz, const double *x, const MKL_INT *indx, double *y);
void cblas_csctr (const MKL_INT nz, const void *x, const MKL_INT *indx, void *y);
void cblas_zsctr (const MKL_INT nz, const void *x, const MKL_INT *indx, void *y);
```

Include Files

- mkl.h

Description

The `?sctr` routines scatter the elements of the compressed sparse vector (*nz*, *x*, *indx*) to a full-storage vector *y*. The routines modify only the elements of *y* whose indices are listed in the array *indx*:

$y[\text{indx}[i]] = x[i]$, for $i=0,1,\dots,nz-1$.

Input Parameters

| | |
|-------------|---|
| <i>nz</i> | The number of elements of <i>x</i> to be scattered. |
| <i>indx</i> | Specifies indices of elements to be scattered. Array, size at least <i>nz</i> . |
| <i>x</i> | Array, size at least <i>nz</i> . Contains the vector to be converted to full-storage form. |

Output Parameters

| | |
|----------|--|
| <i>y</i> | Array, size at least $\max(\text{indx}[i])$. Contains the vector <i>y</i> with updated elements. |
|----------|--|

Sparse BLAS Level 2 and Level 3 Routines

This section describes Sparse BLAS Level 2 and Level 3 routines included in the Intel® Math Kernel Library (Intel® MKL). Sparse BLAS Level 2 is a group of routines and functions that perform operations between a sparse matrix and dense vectors. Sparse BLAS Level 3 is a group of routines and functions that perform operations between a sparse matrix and dense matrices.

The terms and concepts required to understand the use of the Intel MKL Sparse BLAS Level 2 and Level 3 routines are discussed in the [Linear Solvers Basics](#) appendix.

The Sparse BLAS routines can be useful to implement iterative methods for solving large sparse systems of equations or eigenvalue problems. For example, these routines can be considered as building blocks for [Iterative Sparse Solvers based on Reverse Communication Interface \(RCI ISS\)](#) described in the Chapter 8 of the manual.

Intel MKL provides Sparse BLAS Level 2 and Level 3 routines with typical (or conventional) interface similar to the interface used in the NIST* Sparse BLAS library [[Rem05](#)].

Some software packages and libraries (the [PARDISO* Solver](#) used in Intel MKL, *Sparskit 2* [[Saad94](#)], the Compaq* Extended Math Library (CXML)[[CXML01](#)]) use different (early) variation of the compressed sparse row (CSR) format and support only Level 2 operations with simplified interfaces. Intel MKL provides an additional set of Sparse BLAS Level 2 routines with similar simplified interfaces. Each of these routines operates only on a matrix of the fixed type.

The routines described in this section support both one-based indexing and zero-based indexing of the input data (see details in the section [One-based and Zero-based Indexing](#)).

Naming Conventions in Sparse BLAS Level 2 and Level 3

Each Sparse BLAS Level 2 and Level 3 routine has a six- or eight-character base name preceded by the prefix `mkl_` or `mkl_cspblas_`.

The routines with typical (conventional) interface have six-character base names in accordance with the template:

```
mkl_<character> <data> <operation>( )
```

The routines with simplified interfaces have eight-character base names in accordance with the templates:

```
mkl_<character> <data> <mtype> <operation>( )
```

for routines with one-based indexing; and

```
mkl_cspblas_<character> <data><mtype><operation>( )
```

for routines with zero-based indexing.

The `<character>` field indicates the data type:

| | |
|---|---------------------------|
| s | real, single precision |
| c | complex, single precision |
| d | real, double precision |
| z | complex, double precision |

The `<data>` field indicates the sparse matrix storage format (see section [Sparse Matrix Storage Formats](#)):

| | |
|-----|--|
| coo | coordinate format |
| csr | compressed sparse row format and its variations |
| csc | compressed sparse column format and its variations |

| | |
|------------------|--|
| <code>dia</code> | diagonal format |
| <code>sky</code> | skyline storage format |
| <code>bsr</code> | block sparse row format and its variations |

The `<operation>` field indicates the type of operation:

| | |
|-----------------|---|
| <code>mv</code> | matrix-vector product (Level 2) |
| <code>mm</code> | matrix-matrix product (Level 3) |
| <code>sv</code> | solving a single triangular system (Level 2) |
| <code>sm</code> | solving triangular systems with multiple right-hand sides (Level 3) |

The field `<mtype>` indicates the matrix type:

| | |
|-----------------|--|
| <code>ge</code> | sparse representation of a general matrix |
| <code>sy</code> | sparse representation of the upper or lower triangle of a symmetric matrix |
| <code>tr</code> | sparse representation of a triangular matrix |

Sparse Matrix Storage Formats for Sparse BLAS Routines

The current version of Intel MKL Sparse BLAS Level 2 and Level 3 routines support the following point entry [Duff86] storage formats for sparse matrices:

- *compressed sparse row* format (CSR) and its variations;
- *compressed sparse column* format (CSC);
- *coordinate* format;
- *diagonal* format;
- *skyline* storage format;

and one block entry storage format:

- *block sparse row* format (BSR) and its variations.

For more information see "Sparse Matrix Storage Formats" in Appendix A.

Intel MKL provides auxiliary routines - [matrix converters](#) - that convert sparse matrix from one storage format to another.

Routines and Supported Operations

This section describes operations supported by the Intel MKL Sparse BLAS Level 2 and Level 3 routines. The following notations are used here:

A is a sparse matrix;
 B and C are dense matrices;
 D is a diagonal scaling matrix;
 x and y are dense vectors;
 α and β are scalars;

$\text{op}(A)$ is one of the possible operations:

$\text{op}(A) = A;$

$\text{op}(A) = A^T$ - transpose of A ;
 $\text{op}(A) = A^H$ - conjugated transpose of A .

$\text{inv}(\text{op}(A))$ denotes the inverse of $\text{op}(A)$.

The Intel MKL Sparse BLAS Level 2 and Level 3 routines support the following operations:

- computing the vector product between a sparse matrix and a dense vector:

```
y := alpha*op(A)*x + beta*y
```

- solving a single triangular system:

```
y := alpha*inv(op(A))*x
```

- computing a product between sparse matrix and dense matrix:

```
C := alpha*op(A)*B + beta*C
```

- solving a sparse triangular system with multiple right-hand sides:

```
C := alpha*inv(op(A))*B
```

Intel MKL provides an additional set of the Sparse BLAS Level 2 routines with *simplified interfaces*. Each of these routines operates on a matrix of the fixed type. The following operations are supported:

- computing the vector product between a sparse matrix and a dense vector (for general and symmetric matrices):

```
y := op(A)*x
```

- solving a single triangular system (for triangular matrices):

```
y := inv(op(A))*x
```

Matrix type is indicated by the field `<mtype>` in the routine name (see section [Naming Conventions in Sparse BLAS Level 2 and Level 3](#)).

NOTE

The routines with simplified interfaces support only four sparse matrix storage formats, specifically:

- CSR format in the 3-array variation accepted in the direct sparse solvers and in the CXML;
- diagonal format accepted in the CXML;
- coordinate format;
- BSR format in the 3-array variation.

Note that routines with both typical (conventional) and simplified interfaces use the same computational kernels that work with certain internal data structures.

The Intel MKL Sparse BLAS Level 2 and Level 3 routines do not support in-place operations.

Complete list of all routines is given in the [“Sparse BLAS Level 2 and Level 3 Routines”](#).

Interface Consideration

One-Based and Zero-Based Indexing

The Intel MKL Sparse BLAS Level 2 and Level 3 routines support one-based and zero-based indexing of data arrays.

Routines with typical interfaces support zero-based indexing for the following sparse data storage formats: CSR, CSC, BSR, and COO. Routines with simplified interfaces support zero based indexing for the following sparse data storage formats: CSR, BSR, and COO. See the complete list of [Sparse BLAS Level 2 and Level 3 Routines](#).

The one-based indexing uses the convention of starting array indices at 1. The zero-based indexing uses the convention of starting array indices at 0. For example, indices of the 5-element array x can be presented in case of one-based indexing as follows:

Element index: 1 2 3 4 5

Element value: 1.0 5.0 7.0 8.0 9.0

and in case of zero-based indexing as follows:

Element index: 0 1 2 3 4

Element value: 1.0 5.0 7.0 8.0 9.0

The detailed descriptions of the one-based and zero-based variants of the sparse data storage formats are given in the "[Sparse Matrix Storage Formats](#)" in Appendix A.

Most parameters of the routines are identical for both one-based and zero-based indexing, but some of them have certain differences. The following table lists all these differences.

| Parameter | One-based Indexing | Zero-based Indexing |
|--------------|--|---|
| <i>val</i> | Array containing non-zero elements of the matrix A , its length is $.pntrb[m] - pntrb[1]$ | Array containing non-zero elements of the matrix A , its length is $.pntrb[m-1] - pntrb[0]$ |
| <i>pntrb</i> | Array of length m . This array contains row indices, such that $pntrb[i] - pntrb[1]+1$ is the first index of row i in the arrays <i>val</i> and <i>indx</i> | Array of length m . This array contains row indices, such that $pntrb[i] - pntrb[0]$ is the first index of row i in the arrays <i>val</i> and <i>indx</i> . |
| <i>pntrb</i> | Array of length m . This array contains row indices, such that $pntrb[i] - pntrb[1]$ is the last index of row i in the arrays <i>val</i> and <i>indx</i> . | Array of length m . This array contains row indices, such that $pntrb[i] - pntrb[0]-1$ is the last index of row i in the arrays <i>val</i> and <i>indx</i> . |
| <i>ia</i> | Array of length $m + 1$, containing indices of elements in the array a , such that $ia[i]$ is the index in the array a of the first non-zero element from the row i . The value of the last element $ia[m + 1]$ is equal to the number of non-zeros plus one. | Array of length $m+1$, containing indices of elements in the array a , such that $ia[i]$ is the index in the array a of the first non-zero element from the row i . The value of the last element $ia[m]$ is equal to the number of non-zeros. |
| <i>ldb</i> | Specifies the leading dimension of b as declared in the calling (sub)program. | Specifies the second dimension of b as declared in the calling (sub)program. |
| <i>ldc</i> | Specifies the leading dimension of c as declared in the calling (sub)program. | Specifies the second dimension of c as declared in the calling (sub)program. |

Differences Between Intel MKL and NIST* Interfaces

The Intel MKL Sparse BLAS Level 3 routines have the following conventional interfaces:

`mkl_xyyyymm(transa, m, n, k, alpha, matdescra, arg(A), b, ldb, beta, c, ldc)`, for matrix-matrix product;

`mkl_xyyyysm(transa, m, n, alpha, matdescra, arg(A), b, ldb, c, ldc)`, for triangular solvers with multiple right-hand sides.

Here x denotes data type, and yyy - sparse matrix data structure (storage format).

The analogous NIST* Sparse BLAS (NSB) library routines have the following interfaces:

`xyyyymm(transa, m, n, k, alpha, descra, arg(A), b, ldb, beta, c, ldc, work, lwork)`, for matrix-matrix product;

`xyyyism(transa, m, n, unitd, dv, alpha, descra, arg(A), b, ldb, beta, c, ldc, work, lwork)`, for triangular solvers with multiple right-hand sides.

Some similar arguments are used in both libraries. The argument *transa* indicates what operation is performed and is slightly different in the NSB library (see Table “Parameter *transa*”). The arguments *m* and *k* are the number of rows and column in the matrix *A*, respectively, *n* is the number of columns in the matrix *C*. The arguments *alpha* and *beta* are scalar *alpha* and *beta* respectively (*beta* is not used in the Intel MKL triangular solvers.) The arguments *b* and *c* are rectangular arrays with the leading dimension *ldb* and *ldc*, respectively. `arg(A)` denotes the list of arguments that describe the sparse representation of *A*.

Parameter *transa*

| | MKL interface | NSB interface | Operation |
|-----------|---------------|---------------|--------------------------------|
| data type | char * | INTEGER | |
| value | N or n | 0 | $op(A) = A$ |
| | T or t | 1 | $op(A) = A^T$ |
| | C or c | 2 | $op(A) = A^T$ or $op(A) = A^H$ |

Parameter *matdescra*

The parameter *matdescra* describes the relevant characteristic of the matrix *A*. This manual describes *matdescra* as an array of six elements in line with the NIST* implementation. However, only the first four elements of the array are used in the current versions of the Intel MKL Sparse BLAS routines. Elements *matdescra*[4] and *matdescra*[5] are reserved for future use. Note that whether *matdescra* is described in your application as an array of length 6 or 4 is of no importance because the array is declared as a pointer in the Intel MKL routines. To learn more about declaration of the *matdescra* array, see the Sparse BLAS examples located in the Intel MKL installation directory: `examples/spblas/` for C. The table below lists elements of the parameter *matdescra*, their Fortran values, and their meanings. The parameter *matdescra* corresponds to the argument *descra* from NSB library.

Possible Values of the Parameter *matdescra* [*descra* - 1]

| | MKL interface | | NSB interface | Matrix characteristics |
|-------------|----------------------|----------------------|-------------------|-------------------------------------|
| | one-based indexing | zero-based indexing | | |
| data type | char * | char * | int * | |
| 1st element | <i>matdescra</i> [1] | <i>matdescra</i> [0] | <i>descra</i> [0] | matrix structure |
| value | G | G | 0 | general |
| | S | S | 1 | symmetric ($A = A^T$) |
| | H | H | 2 | Hermitian ($A = (A^H)$) |
| | T | T | 3 | triangular |
| | A | A | 4 | skew(anti)-symmetric ($A = -A^T$) |
| | D | D | 5 | diagonal |

| | MKL interface | | NSB interface | Matrix characteristics |
|-------------------|----------------------|----------------------|-------------------|----------------------------------|
| 2nd element value | <i>matdescra</i> [2] | <i>matdescra</i> [1] | <i>descra</i> [1] | upper/lower triangular indicator |
| | L | L | 1 | lower |
| | U | U | 2 | upper |
| 3rd element value | <i>matdescra</i> [3] | <i>matdescra</i> [2] | <i>descra</i> [2] | main diagonal type |
| | N | N | 0 | non-unit |
| | U | U | 1 | unit |
| 4th element value | <i>matdescra</i> [4] | <i>matdescra</i> [3] | <i>descra</i> [3] | type of indexing |
| | F | | 1 | one-based indexing |
| | | C | 0 | zero-based indexing |

In some cases possible element values of the parameter *matdescra* depend on the values of other elements. The [Table "Possible Combinations of Element Values of the Parameter *matdescra*"](#) lists all possible combinations of element values for both multiplication routines and triangular solvers.

Possible Combinations of Element Values of the Parameter *matdescra*

| Routines | <i>matdescra</i> [0] | <i>matdescra</i> [1] | <i>matdescra</i> [2] | <i>matdescra</i> [3] |
|--|----------------------|----------------------|----------------------|-------------------------|
| Multiplication Routines | G | ignored | ignored | F (default) or C |
| | S or H | L (default) | N (default) | F (default) or C |
| | S or H | L (default) | U | F (default) or C |
| | S or H | U | N (default) | F (default) or C |
| | S or H | U | U | F (default) or C |
| | A | L (default) | ignored | F (default) or C |
| | A | U | ignored | F (default) or C |
| Multiplication Routines and Triangular Solvers | T | L | U | F (default) or C |
| | T | L | N | F (default) or C |
| | T | U | U | F (default) or C |
| | T | U | N | F (default) or C |
| | D | ignored | N (default) | F (default) or C |
| | D | ignored | U | F (default) or C |

For a matrix in the skyline format with the main diagonal declared to be a unit, diagonal elements must be stored in the sparse representation even if they are zero. In all other formats, diagonal elements can be stored (if needed) in the sparse representation if they are not zero.

Operations with Partial Matrices

One of the distinctive features of the Intel MKL Sparse BLAS routines is a possibility to perform operations only on partial matrices composed of certain parts (triangles and the main diagonal) of the input sparse matrix. It can be done by setting properly first three elements of the parameter *matdescra*.

An arbitrary sparse matrix *A* can be decomposed as

$$A = L + D + U$$

where L is the strict lower triangle of A , U is the strict upper triangle of A , D is the main diagonal.

Table "Output Matrices for Multiplication Routines" shows correspondence between the output matrices and values of the parameter `matdescra` for the sparse matrix A for multiplication routines.

Output Matrices for Multiplication Routines

| <code>matdescra[0]</code> | <code>matdescra[1]</code> | <code>matdescra[2]</code> | Output Matrix |
|---------------------------|---------------------------|---------------------------|--|
| G | ignored | ignored | $\alpha * \text{op}(A) * x + \beta * y$ $\alpha * \text{op}(A) * B + \beta * C$ |
| S or H | L | N | $\alpha * \text{op}(L+D+L') * x + \beta * y$ $\alpha * \text{op}(L+D+L') * B + \beta * C$ |
| S or H | L | U | $\alpha * \text{op}(L+I+L') * x + \beta * y$ $\alpha * \text{op}(L+I+L') * B + \beta * C$ |
| S or H | U | N | $\alpha * \text{op}(U'+D+U) * x + \beta * y$ $\alpha * \text{op}(U'+D+U) * B + \beta * C$ |
| S or H | U | U | $\alpha * \text{op}(U'+I+U) * x + \beta * y$ $\alpha * \text{op}(U'+I+U) * B + \beta * C$ |
| T | L | U | $\alpha * \text{op}(L+I) * x + \beta * y$ $\alpha * \text{op}(L+I) * B + \beta * C$ |
| T | L | N | $\alpha * \text{op}(L+D) * x + \beta * y$ $\alpha * \text{op}(L+D) * B + \beta * C$ |
| T | U | U | $\alpha * \text{op}(U+I) * x + \beta * y$ $\alpha * \text{op}(U+I) * B + \beta * C$ |
| T | U | N | $\alpha * \text{op}(U+D) * x + \beta * y$ $\alpha * \text{op}(U+D) * B + \beta * C$ |
| A | L | ignored | $\alpha * \text{op}(L-L') * x + \beta * y$ $\alpha * \text{op}(L-L') * B + \beta * C$ |
| A | U | ignored | $\alpha * \text{op}(U-U') * x + \beta * y$ $\alpha * \text{op}(U-U') * B + \beta * C$ |
| D | ignored | N | $\alpha * D * x + \beta * y$ $\alpha * D * B + \beta * C$ |
| D | ignored | U | $\alpha * x + \beta * y$ $\alpha * B + \beta * C$ |

Table "Output Matrices for Triangular Solvers" shows correspondence between the output matrices and values of the parameter `matdescra` for the sparse matrix A for triangular solvers.

Output Matrices for Triangular Solvers

| <code>matdescra[0]</code> | <code>matdescra[1]</code> | <code>matdescra[2]</code> | Output Matrix |
|---------------------------|---------------------------|---------------------------|--|
| T | L | N | $\alpha * \text{inv}(\text{op}(L)) * x$ $\alpha * \text{inv}(\text{op}(L)) * B$ |
| T | L | U | $\alpha * \text{inv}(\text{op}(L)) * x$ |

| matdescra[0] | matdescra[1] | matdescra[2] | Output Matrix |
|---------------------|---------------------|---------------------|--|
| | | | $alpha*inv(op(L))*B$ |
| T | U | N | $alpha*inv(op(U))*x$ $alpha*inv(op(U))*B$ |
| T | U | U | $alpha*inv(op(U))*x$ $alpha*inv(op(U))*B$ |
| D | ignored | N | $alpha*inv(D)*x$ $alpha*inv(D)*B$ |
| D | ignored | U | $alpha*x$ $alpha*B$ |

Sparse BLAS Level 2 and Level 3 Routines.

Table "Sparse BLAS Level 2 and Level 3 Routines" lists the sparse BLAS Level 2 and Level 3 routines described in more detail later in this section.

Sparse BLAS Level 2 and Level 3 Routines

| Routine/Function | Description |
|---|---|
| Simplified interface, one-based indexing | |
| <code>mkl_?csrgev</code> | Computes matrix - vector product of a sparse general matrix in the CSR format (3-array variation) |
| <code>mkl_?bsrgev</code> | Computes matrix - vector product of a sparse general matrix in the BSR format (3-array variation). |
| <code>mkl_?coogev</code> | Computes matrix - vector product of a sparse general matrix in the coordinate format. |
| <code>mkl_?diagev</code> | Computes matrix - vector product of a sparse general matrix in the diagonal format. |
| <code>mkl_?csrsv</code> | Computes matrix - vector product of a sparse symmetrical matrix in the CSR format (3-array variation) |
| <code>mkl_?bsrsv</code> | Computes matrix - vector product of a sparse symmetrical matrix in the BSR format (3-array variation). |
| <code>mkl_?coosv</code> | Computes matrix - vector product of a sparse symmetrical matrix in the coordinate format. |
| <code>mkl_?diasv</code> | Computes matrix - vector product of a sparse symmetrical matrix in the diagonal format. |
| <code>mkl_?csrtrsv</code> | Triangular solvers with simplified interface for a sparse matrix in the CSR format (3-array variation). |
| <code>mkl_?bsrtrsv</code> | Triangular solver with simplified interface for a sparse matrix in the BSR format (3-array variation). |
| <code>mkl_?cootrsv</code> | Triangular solvers with simplified interface for a sparse matrix in the coordinate format. |

| Routine/Function | Description |
|--|--|
| <code>mkl_?diatrsv</code> | Triangular solvers with simplified interface for a sparse matrix in the diagonal format. |
| Simplified interface, zero-based indexing | |
| <code>mkl_cspblas_?csrgemv</code> | Computes matrix - vector product of a sparse general matrix in the CSR format (3-array variation) with zero-based indexing. |
| <code>mkl_cspblas_?bsrgemv</code> | Computes matrix - vector product of a sparse general matrix in the BSR format (3-array variation) with zero-based indexing. |
| <code>mkl_cspblas_?coogemv</code> | Computes matrix - vector product of a sparse general matrix in the coordinate format with zero-based indexing. |
| <code>mkl_cspblas_?csrsymv</code> | Computes matrix - vector product of a sparse symmetrical matrix in the CSR format (3-array variation) with zero-based indexing. |
| <code>mkl_cspblas_?bsrsymv</code> | Computes matrix - vector product of a sparse symmetrical matrix in the BSR format (3-array variation) with zero-based indexing. |
| <code>mkl_cspblas_?coosymv</code> | Computes matrix - vector product of a sparse symmetrical matrix in the coordinate format with zero-based indexing. |
| <code>mkl_cspblas_?csrtrsv</code> | Triangular solvers with simplified interface for a sparse matrix in the CSR format (3-array variation) with zero-based indexing. |
| <code>mkl_cspblas_?bsrtrsv</code> | Triangular solver with simplified interface for a sparse matrix in the BSR format (3-array variation) with zero-based indexing. |
| <code>mkl_cspblas_?cootrsv</code> | Triangular solver with simplified interface for a sparse matrix in the coordinate format with zero-based indexing. |

Typical (conventional) interface, one-based and zero-based indexing

| | |
|-------------------------|--|
| <code>mkl_?csrsv</code> | Computes matrix - vector product of a sparse matrix in the CSR format. |
| <code>mkl_?bsrsv</code> | Computes matrix - vector product of a sparse matrix in the BSR format. |
| <code>mkl_?cscmv</code> | Computes matrix - vector product for a sparse matrix in the CSC format. |
| <code>mkl_?coomv</code> | Computes matrix - vector product for a sparse matrix in the coordinate format. |
| <code>mkl_?csrsv</code> | Solves a system of linear equations for a sparse matrix in the CSR format. |
| <code>mkl_?bsrsv</code> | Solves a system of linear equations for a sparse matrix in the BSR format. |
| <code>mkl_?cscsv</code> | Solves a system of linear equations for a sparse matrix in the CSC format. |

| Routine/Function | Description |
|-------------------------|--|
| <code>mkl_?coosv</code> | Solves a system of linear equations for a sparse matrix in the coordinate format. |
| <code>mkl_?csrmm</code> | Computes matrix - matrix product of a sparse matrix in the CSR format |
| <code>mkl_?bsrmm</code> | Computes matrix - matrix product of a sparse matrix in the BSR format. |
| <code>mkl_?cscmm</code> | Computes matrix - matrix product of a sparse matrix in the CSC format |
| <code>mkl_?coomm</code> | Computes matrix - matrix product of a sparse matrix in the coordinate format. |
| <code>mkl_?csrsm</code> | Solves a system of linear matrix equations for a sparse matrix in the CSR format. |
| <code>mkl_?bsrsm</code> | Solves a system of linear matrix equations for a sparse matrix in the BSR format. |
| <code>mkl_?cscsm</code> | Solves a system of linear matrix equations for a sparse matrix in the CSC format. |
| <code>mkl_?coosm</code> | Solves a system of linear matrix equations for a sparse matrix in the coordinate format. |

Typical (conventional) interface, one-based indexing

| | |
|-------------------------|---|
| <code>mkl_?diamv</code> | Computes matrix - vector product of a sparse matrix in the diagonal format. |
| <code>mkl_?skymv</code> | Computes matrix - vector product for a sparse matrix in the skyline storage format. |
| <code>mkl_?diasv</code> | Solves a system of linear equations for a sparse matrix in the diagonal format. |
| <code>mkl_?skysv</code> | Solves a system of linear equations for a sparse matrix in the skyline format. |
| <code>mkl_?diamm</code> | Computes matrix - matrix product of a sparse matrix in the diagonal format. |
| <code>mkl_?skymm</code> | Computes matrix - matrix product of a sparse matrix in the skyline storage format. |
| <code>mkl_?diasm</code> | Solves a system of linear matrix equations for a sparse matrix in the diagonal format. |
| <code>mkl_?skysm</code> | Solves a system of linear matrix equations for a sparse matrix in the skyline storage format. |

Auxiliary routines

Matrix converters

| | |
|--------------------------|---|
| <code>mkl_?dnscsr</code> | Converts a sparse matrix in uncompressed representation to CSR format (3-array variation) and vice versa. |
| <code>mkl_?csrcoo</code> | Converts a sparse matrix in CSR format (3-array variation) to coordinate format and vice versa. |

| Routine/Function | Description |
|-------------------------------|---|
| <code>mkl_?csrbsr</code> | Converts a sparse matrix in CSR format to BSR format (3-array variations) and vice versa. |
| <code>mkl_?csrcsc</code> | Converts a sparse matrix in CSR format to CSC format and vice versa (3-array variations). |
| <code>mkl_?csrdia</code> | Converts a sparse matrix in CSR format (3-array variation) to diagonal format and vice versa. |
| <code>mkl_?csrsky</code> | Converts a sparse matrix in CSR format (3-array variation) to sky line format and vice versa. |
| Operations on sparse matrices | |
| <code>mkl_?csradd</code> | Computes the sum of two sparse matrices stored in the CSR format (3-array variation) with one-based indexing. |
| <code>mkl_?csrmultcsr</code> | Computes the product of two sparse matrices stored in the CSR format (3-array variation) with one-based indexing. |
| <code>mkl_?csrmultd</code> | Computes product of two sparse matrices stored in the CSR format (3-array variation) with one-based indexing. The result is stored in the dense matrix. |

`mkl_?csrgemv`

Computes matrix - vector product of a sparse general matrix stored in the CSR format (3-array variation) with one-based indexing.

Syntax

```
void mkl_scsrgemv (const char *transa , const MKL_INT *m , const float *a , const MKL_INT *ia , const MKL_INT *ja , const float *x , float *y );
```

```
void mkl_dcsrgemv (const char *transa , const MKL_INT *m , const double *a , const MKL_INT *ia , const MKL_INT *ja , const double *x , double *y );
```

```
void mkl_ccsrgemv (const char *transa , const MKL_INT *m , const MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex8 *x , MKL_Complex8 *y );
```

```
void mkl_zcsrgemv (const char *transa , const MKL_INT *m , const MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex16 *x , MKL_Complex16 *y );
```

Include Files

- `mkl.h`

Description

The `mkl_?csrgemv` routine performs a matrix-vector operation defined as

$$y := A * x$$

or

$$y := A^T * x,$$

where:

x and y are vectors,

A is an m -by- m sparse square matrix in the CSR format (3-array variation), A^T is the transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

| | |
|---------------|--|
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then as $y := A*x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := A^T*x$, |
| <i>m</i> | Number of rows of the matrix <i>A</i> . |
| <i>a</i> | Array containing non-zero elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details. |
| <i>ia</i> | Array of length $m + 1$, containing indices of elements in the array <i>a</i> , such that $ia[i] - ia[0]$ is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i> . The value of the last element $ia[m] - ia[0]$ is equal to the number of non-zeros. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details. |
| <i>ja</i> | Array containing the column indices plus one for each non-zero element of the matrix <i>A</i> . Its length is equal to the length of the array <i>a</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details. |
| <i>x</i> | Array, size is <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> . |

Output Parameters

| | |
|----------|---|
| <i>y</i> | Array, size at least <i>m</i> . On exit, the array <i>y</i> must contain the vector <i>y</i> . |
|----------|---|

mkl_?bsrgemv

Computes matrix - vector product of a sparse general matrix stored in the BSR format (3-array variation) with one-based indexing.

Syntax

```
void mkl_sbsrgemv (const char *transa , const MKL_INT *m , const MKL_INT *lb , const
float *a , const MKL_INT *ia , const MKL_INT *ja , const float *x , float *y );
void mkl_dbsrgemv (const char *transa , const MKL_INT *m , const MKL_INT *lb , const
double *a , const MKL_INT *ia , const MKL_INT *ja , const double *x , double *y );
void mkl_cbsrgemv (const char *transa , const MKL_INT *m , const MKL_INT *lb , const
MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex8 *x ,
MKL_Complex8 *y );
```

```
void mkl_zbsrgemv (const char *transa , const MKL_INT *m , const MKL_INT *lb , const
MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex16 *x ,
MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_?bsrgemv` routine performs a matrix-vector operation defined as

```
y := A*x
```

or

```
y := AT*x,
```

where:

x and y are vectors,

A is an m -by- m block sparse square matrix in the BSR format (3-array variation), A^T is the transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

| | |
|---------------|---|
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := A*x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A^T*x$, |
| <i>m</i> | Number of block rows of the matrix A . |
| <i>lb</i> | Size of the block in the matrix A . |
| <i>a</i> | Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by $lb*lb$. Refer to <i>values</i> array description in BSR Format for more details. |
| <i>ia</i> | Array of length $(m + 1)$, containing indices of block in the array a , such that $ia[i] - ia[0]$ is the index in the array a of the first non-zero element from the row i . The value of the last element $ia[m] - ia[0]$ is equal to the number of non-zero blocks. Refer to <i>rowIndex</i> array description in BSR Format for more details. |
| <i>ja</i> | Array containing the column indices plus one for each non-zero block in the matrix A . Its length is equal to the number of non-zero blocks of the matrix A . Refer to <i>columns</i> array description in BSR Format for more details. |
| <i>x</i> | Array, size $(m*lb)$. |

On entry, the array x must contain the vector x .

Output Parameters

y Array, size at least $(m \cdot lb)$.
On exit, the array y must contain the vector y .

mkl_?coogemv

Computes matrix-vector product of a sparse general matrix stored in the coordinate format with one-based indexing.

Syntax

```
void mkl_scoogemv (const char *transa , const MKL_INT *m , const float *val , const
MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const float *x , float
*y );
```

```
void mkl_dcoogemv (const char *transa , const MKL_INT *m , const double *val , const
MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const double *x , double
*y );
```

```
void mkl_ccoogemv (const char *transa , const MKL_INT *m , const MKL_Complex8 *val ,
const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const MKL_Complex8
*x , MKL_Complex8 *y );
```

```
void mkl_zcoogemv (const char *transa , const MKL_INT *m , const MKL_Complex16 *val ,
const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const
MKL_Complex16 *x , MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_?coogemv` routine performs a matrix-vector operation defined as

```
 $y := A * x$ 
```

or

```
 $y := A^T * x,$ 
```

where:

x and y are vectors,

A is an m -by- m sparse square matrix in the coordinate format, A^T is the transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

$transa$ Specifies the operation.

If *transa* = 'N' or 'n', then the matrix-vector product is computed as $y := A*x$

If *transa* = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A^T*x$,

| | |
|---------------|---|
| <i>m</i> | Number of rows of the matrix <i>A</i> . |
| <i>val</i> | Array of length <i>nnz</i> , contains non-zero elements of the matrix <i>A</i> in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details. |
| <i>rowind</i> | Array of length <i>nnz</i> , contains the row indices plus one for each non-zero element of the matrix <i>A</i> . Refer to <i>rows</i> array description in Coordinate Format for more details. |
| <i>colind</i> | Array of length <i>nnz</i> , contains the column indices plus one for each non-zero element of the matrix <i>A</i> . Refer to <i>columns</i> array description in Coordinate Format for more details. |
| <i>nnz</i> | Specifies the number of non-zero element of the matrix <i>A</i> . Refer to <i>nnz</i> description in Coordinate Format for more details. |
| <i>x</i> | Array, size is <i>m</i> . One entry, the array <i>x</i> must contain the vector <i>x</i> . |

Output Parameters

| | |
|----------|---|
| <i>y</i> | Array, size at least <i>m</i> . On exit, the array <i>y</i> must contain the vector <i>y</i> . |
|----------|---|

mkl_?diagemv

Computes matrix - vector product of a sparse general matrix stored in the diagonal format with one-based indexing.

Syntax

```
void mkl_sdiagemv (const char *transa , const MKL_INT *m , const float *val , const
MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const float *x , float
*y );

void mkl_ddiagemv (const char *transa , const MKL_INT *m , const double *val , const
MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const double *x , double
*y );

void mkl_cdiagemv (const char *transa , const MKL_INT *m , const MKL_Complex8 *val ,
const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const MKL_Complex8
*x , MKL_Complex8 *y );

void mkl_zdiagemv (const char *transa , const MKL_INT *m , const MKL_Complex16 *val ,
const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const MKL_Complex16
*x , MKL_Complex16 *y );
```

Include Files

- `mkl.h`

Description

The `mkl_?diagemv` routine performs a matrix-vector operation defined as

```
y := A*x
```

or

```
y := AT*x,
```

where:

x and y are vectors,

A is an m -by- m sparse square matrix in the diagonal storage format, A^T is the transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

| | |
|---------------|--|
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := A*x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := A^T*x$, |
| <i>m</i> | Number of rows of the matrix A . |
| <i>val</i> | Two-dimensional array of size $lval*ndiag$, contains non-zero diagonals of the matrix A . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details. |
| <i>lval</i> | Leading dimension of val , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details. |
| <i>idiag</i> | Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix A . Refer to <i>distance</i> array description in Diagonal Storage Scheme for more details. |
| <i>ndiag</i> | Specifies the number of non-zero diagonals of the matrix A . |
| <i>x</i> | Array, size is m . On entry, the array x must contain the vector x . |

Output Parameters

| | |
|----------|--|
| <i>y</i> | Array, size at least m . On exit, the array y must contain the vector y . |
|----------|--|

mkl_?csrsvmv

Computes matrix - vector product of a sparse symmetrical matrix stored in the CSR format (3-array variation) with one-based indexing.

Syntax

```
void mkl_scsrsvmv (const char *uplo , const MKL_INT *m , const float *a , const MKL_INT *ia , const MKL_INT *ja , const float *x , float *y );
```

```
void mkl_dcsrsvmv (const char *uplo , const MKL_INT *m , const double *a , const MKL_INT *ia , const MKL_INT *ja , const double *x , double *y );
```

```
void mkl_ccsrsvmv (const char *uplo , const MKL_INT *m , const MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex8 *x , MKL_Complex8 *y );
```

```
void mkl_zcsrsvmv (const char *uplo , const MKL_INT *m , const MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex16 *x , MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_?csrsvmv` routine performs a matrix-vector operation defined as

```
y := A*x
```

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the CSR format (3-array variation).

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

| | |
|-------------|---|
| <i>uplo</i> | Specifies whether the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used. |
| <i>m</i> | Number of rows of the matrix A . |
| <i>a</i> | Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details. |
| <i>ia</i> | Array of length $m + 1$, containing indices of elements in the array a , such that $ia[i] - ia[0]$ is the index in the array a of the first non-zero element from the row i . The value of the last element $ia[m] - ia[0]$ is equal to the number of non-zeros. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details. |

| | |
|-----------|---|
| <i>ja</i> | Array containing the column indices plus one for each non-zero element of the matrix <i>A</i> . Its length is equal to the length of the array <i>a</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details. |
| <i>x</i> | Array, size is <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> . |

Output Parameters

| | |
|----------|---|
| <i>y</i> | Array, size at least <i>m</i> . On exit, the array <i>y</i> must contain the vector <i>y</i> . |
|----------|---|

mkl_?bsrsymv

Computes matrix-vector product of a sparse symmetrical matrix stored in the BSR format (3-array variation) with one-based indexing.

Syntax

```
void mkl_sbsrsymv (const char *uplo , const MKL_INT *m , const MKL_INT *lb , const
float *a , const MKL_INT *ia , const MKL_INT *ja , const float *x , float *y );
void mkl_dbsrsymv (const char *uplo , const MKL_INT *m , const MKL_INT *lb , const
double *a , const MKL_INT *ia , const MKL_INT *ja , const double *x , double *y );
void mkl_cbsrsymv (const char *uplo , const MKL_INT *m , const MKL_INT *lb , const
MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex8 *x ,
MKL_Complex8 *y );
void mkl_zbsrsymv (const char *uplo , const MKL_INT *m , const MKL_INT *lb , const
MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex16 *x ,
MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_?bsrsymv` routine performs a matrix-vector operation defined as

```
y := A*x
```

where:

x and *y* are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the BSR format (3-array variation).

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

| | |
|-------------|--|
| <i>uplo</i> | Specifies whether the upper or low triangle of the matrix <i>A</i> is considered. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix <i>A</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix <i>A</i> is used. |
| <i>m</i> | Number of block rows of the matrix <i>A</i> . |
| <i>lb</i> | Size of the block in the matrix <i>A</i> . |
| <i>a</i> | Array containing elements of non-zero blocks of the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> multiplied by <i>lb*lb</i> . Refer to <i>values</i> array description in BSR Format for more details. |
| <i>ia</i> | Array of length $(m + 1)$, containing indices of block in the array <i>a</i> , such that $ia[i] - ia[0]$ is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i> . The value of the last element $ia[m] - ia[0]$ is equal to the number of non-zero blocks. Refer to <i>rowIndex</i> array description in BSR Format for more details. |
| <i>ja</i> | Array containing the column indices plus one for each non-zero block in the matrix <i>A</i> . Its length is equal to the number of non-zero blocks of the matrix <i>A</i> . Refer to <i>columns</i> array description in BSR Format for more details. |
| <i>x</i> | Array, size $(m*lb)$. On entry, the array <i>x</i> must contain the vector <i>x</i> . |

Output Parameters

| | |
|----------|---|
| <i>y</i> | Array, size at least $(m*lb)$. On exit, the array <i>y</i> must contain the vector <i>y</i> . |
|----------|---|

mkl_?coosymv

Computes matrix - vector product of a sparse symmetrical matrix stored in the coordinate format with one-based indexing.

Syntax

```
void mkl_scoosymv (const char *uplo , const MKL_INT *m , const float *val , const
MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const float *x , float
*y );
```

```
void mkl_dcoosymv (const char *uplo , const MKL_INT *m , const double *val , const
MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const double *x , double
*y );
```

```
void mkl_ccoosymv (const char *uplo , const MKL_INT *m , const MKL_Complex8 *val ,
const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const MKL_Complex8
*x , MKL_Complex8 *y );
```

```
void mkl_zcoosymv (const char *uplo , const MKL_INT *m , const MKL_Complex16 *val ,
const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const
MKL_Complex16 *x , MKL_Complex16 *y );
```

Include Files

- `mkl.h`

Description

The `mkl_?coosymv` routine performs a matrix-vector operation defined as

```
y := A*x
```

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the coordinate format.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

| | |
|---------------------|--|
| <code>uplo</code> | Specifies whether the upper or low triangle of the matrix A is used. If <code>uplo = 'U' or 'u'</code> , then the upper triangle of the matrix A is used. If <code>uplo = 'L' or 'l'</code> , then the low triangle of the matrix A is used. |
| <code>m</code> | Number of rows of the matrix A . |
| <code>val</code> | Array of length <code>nnz</code> , contains non-zero elements of the matrix A in the arbitrary order. Refer to <code>values</code> array description in Coordinate Format for more details. |
| <code>rowind</code> | Array of length <code>nnz</code> , contains the row indices plus one for each non-zero element of the matrix A . Refer to <code>rows</code> array description in Coordinate Format for more details. |
| <code>colind</code> | Array of length <code>nnz</code> , contains the column indices plus one for each non-zero element of the matrix A . Refer to <code>columns</code> array description in Coordinate Format for more details. |
| <code>nnz</code> | Specifies the number of non-zero element of the matrix A . Refer to <code>nnz</code> description in Coordinate Format for more details. |
| <code>x</code> | Array, size is m . On entry, the array <code>x</code> must contain the vector x . |

Output Parameters

| | |
|----------------|---|
| <code>y</code> | Array, size at least m . On exit, the array <code>y</code> must contain the vector y . |
|----------------|---|

mkl_?diasymv

Computes matrix - vector product of a sparse symmetrical matrix stored in the diagonal format with one-based indexing.

Syntax

```
void mkl_sdiasymv (const char *uplo , const MKL_INT *m , const float *val , const
MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const float *x , float
*y );
```

```
void mkl_ddiasymv (const char *uplo , const MKL_INT *m , const double *val , const
MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const double *x , double
*y );
```

```
void mkl_cdiasymv (const char *uplo , const MKL_INT *m , const MKL_Complex8 *val ,
const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const MKL_Complex8
*x , MKL_Complex8 *y );
```

```
void mkl_zdiasymv (const char *uplo , const MKL_INT *m , const MKL_Complex16 *val ,
const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const MKL_Complex16
*x , MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_?diasymv` routine performs a matrix-vector operation defined as

```
y := A*x
```

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

| | |
|-------------|--|
| <i>uplo</i> | Specifies whether the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used. |
| <i>m</i> | Number of rows of the matrix A . |
| <i>val</i> | Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix A . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details. |
| <i>lval</i> | Leading dimension of <i>val</i> , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details. |

| | |
|--------------|---|
| <i>idiag</i> | Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix <i>A</i> . Refer to <i>distance</i> array description in Diagonal Storage Scheme for more details. |
| <i>ndiag</i> | Specifies the number of non-zero diagonals of the matrix <i>A</i> . |
| <i>x</i> | Array, size is <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> . |

Output Parameters

| | |
|----------|---|
| <i>y</i> | Array, size at least <i>m</i> . On exit, the array <i>y</i> must contain the vector <i>y</i> . |
|----------|---|

mkl_?csrtrsv

Triangular solvers with simplified interface for a sparse matrix in the CSR format (3-array variation) with one-based indexing.

Syntax

```
void mkl_scsrtrsv (const char *uplo , const char *transa , const char *diag , const
MKL_INT *m , const float *a , const MKL_INT *ia , const MKL_INT *ja , const float *x ,
float *y );
```

```
void mkl_dcsrtrsv (const char *uplo , const char *transa , const char *diag , const
MKL_INT *m , const double *a , const MKL_INT *ia , const MKL_INT *ja , const double
*x , double *y );
```

```
void mkl_ccsrtrsv (const char *uplo , const char *transa , const char *diag , const
MKL_INT *m , const MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const
MKL_Complex8 *x , MKL_Complex8 *y );
```

```
void mkl_zcsrtrsv (const char *uplo , const char *transa , const char *diag , const
MKL_INT *m , const MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const
MKL_Complex16 *x , MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_?csrtrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the CSR format (3 array variation):

$$\bar{A}^*y = x$$

or

$$\bar{A}^T y = x,$$

where:

x and *y* are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A^T is the transpose of *A*.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

uplo Specifies whether the upper or low triangle of the matrix A is used.
 If *uplo* = 'U' or 'u', then the upper triangle of the matrix A is used.
 If *uplo* = 'L' or 'l', then the low triangle of the matrix A is used.

transa Specifies the system of linear equations.
 If *transa* = 'N' or 'n', then $A*y = x$
 If *transa* = 'T' or 't' or 'C' or 'c', then $A^T*y = x$,

diag Specifies whether A is unit triangular.
 If *diag* = 'U' or 'u', then A is a unit triangular.
 If *diag* = 'N' or 'n', then A is not unit triangular.

m Number of rows of the matrix A .

a Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to *values* array description in [Sparse Matrix Storage Formats](#) for more details.

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

ia Array of length $m + 1$, containing indices of elements in the array *a*, such that $ia[i] - ia[0]$ is the index in the array *a* of the first non-zero element from the row i . The value of the last element $ia[m] - ia[0]$ is equal to the number of non-zeros. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

ja Array containing the column indices plus one for each non-zero element of the matrix A .

Its length is equal to the length of the array *a*. Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

NOTE

Column indices must be sorted in increasing order for each row.

x Array, size is m .
 On entry, the array *x* must contain the vector x .

Output Parameters

y Array, size at least m .
Contains the vector y .

`mkl_?bsrtrsv`

Triangular solver with simplified interface for a sparse matrix stored in the BSR format (3-array variation) with one-based indexing.

Syntax

```
void mkl_sbsrtrsv (const char *uplo , const char *transa , const char *diag , const
MKL_INT *m , const MKL_INT *lb , const float *a , const MKL_INT *ia , const MKL_INT
*ja , const float *x , float *y );
```

```
void mkl_dbsrtrsv (const char *uplo , const char *transa , const char *diag , const
MKL_INT *m , const MKL_INT *lb , const double *a , const MKL_INT *ia , const MKL_INT
*ja , const double *x , double *y );
```

```
void mkl_cbsrtrsv (const char *uplo , const char *transa , const char *diag , const
MKL_INT *m , const MKL_INT *lb , const MKL_Complex8 *a , const MKL_INT *ia , const
MKL_INT *ja , const MKL_Complex8 *x , MKL_Complex8 *y );
```

```
void mkl_zbsrtrsv (const char *uplo , const char *transa , const char *diag , const
MKL_INT *m , const MKL_INT *lb , const MKL_Complex16 *a , const MKL_INT *ia , const
MKL_INT *ja , const MKL_Complex16 *x , MKL_Complex16 *y );
```

Include Files

- `mkl.h`

Description

The `mkl_?bsrtrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the BSR format (3-array variation) :

```
 $y := A * x$ 
```

or

```
 $y := A^T * x,$ 
```

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A^T is the transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

$uplo$ Specifies the upper or low triangle of the matrix A is used.
If $uplo = 'U'$ or $'u'$, then the upper triangle of the matrix A is used.

If $uplo = 'L'$ or $'l'$, then the low triangle of the matrix A is used.

$transa$

Specifies the operation.

If $transa = 'N'$ or $'n'$, then the matrix-vector product is computed as $y := A*x$

If $transa = 'T'$ or $'t'$ or $'C'$ or $'c'$, then the matrix-vector product is computed as $y := A^T*x$.

$diag$

Specifies whether A is a unit triangular matrix.

If $diag = 'U'$ or $'u'$, then A is a unit triangular.

If $diag = 'N'$ or $'n'$, then A is not a unit triangular.

m

Number of block rows of the matrix A .

lb

Size of the block in the matrix A .

a

Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by $lb*lb$. Refer to *values* array description in [BSR Format](#) for more details.

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

ia

Array of length $(m + 1)$, containing indices of block in the array a , such that $ia[I] - ia[0]$ is the index in the array a of the first non-zero element from the row I . The value of the last element $ia[m] - ia[0]$ is equal to the number of non-zero blocks. Refer to *rowIndex* array description in [BSR Format](#) for more details.

ja

Array containing the column indices plus one for each non-zero block in the matrix A .

Its length is equal to the number of non-zero blocks of the matrix A . Refer to *columns* array description in [BSR Format](#) for more details.

x

Array, size $(m*lb)$.

On entry, the array x must contain the vector x .

Output Parameters

y

Array, size at least $(m*lb)$.

On exit, the array y must contain the vector y .

mkl_?cootrsv

Triangular solvers with simplified interface for a sparse matrix in the coordinate format with one-based indexing.

Syntax

```
void mkl_scootrsv (const char *uplo , const char *transa , const char *diag , const
MKL_INT *m , const float *val , const MKL_INT *rowind , const MKL_INT *colind , const
MKL_INT *nnz , const float *x , float *y );
```

```
void mkl_dcootrsv (const char *uplo , const char *transa , const char *diag , const
MKL_INT *m , const double *val , const MKL_INT *rowind , const MKL_INT *colind , const
MKL_INT *nnz , const double *x , double *y );
```

```
void mkl_ccootrsv (const char *uplo , const char *transa , const char *diag , const
MKL_INT *m , const MKL_Complex8 *val , const MKL_INT *rowind , const MKL_INT *colind ,
const MKL_INT *nnz , const MKL_Complex8 *x , MKL_Complex8 *y );
```

```
void mkl_zcootrsv (const char *uplo , const char *transa , const char *diag , const
MKL_INT *m , const MKL_Complex16 *val , const MKL_INT *rowind , const MKL_INT *colind ,
const MKL_INT *nnz , const MKL_Complex16 *x , MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_?cootrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the coordinate format:

$$A*y = x$$

or

$$A^T*y = x,$$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A^T is the transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

| | |
|---------------|--|
| <i>uplo</i> | Specifies whether the upper or low triangle of the matrix A is considered. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used. |
| <i>transa</i> | Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $A*y = x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $A^T*y = x$, |

| | |
|---------------|---|
| <i>diag</i> | Specifies whether <i>A</i> is unit triangular. If <i>diag</i> = 'U' or 'u', then <i>A</i> is unit triangular. If <i>diag</i> = 'N' or 'n', then <i>A</i> is not unit triangular. |
| <i>m</i> | Number of rows of the matrix <i>A</i> . |
| <i>val</i> | Array of length <i>nnz</i> , contains non-zero elements of the matrix <i>A</i> in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details. |
| <i>rowind</i> | Array of length <i>nnz</i> , contains the row indices plus one for each non-zero element of the matrix <i>A</i> . Refer to <i>rows</i> array description in Coordinate Format for more details. |
| <i>colind</i> | Array of length <i>nnz</i> , contains the column indices plus one for each non-zero element of the matrix <i>A</i> . Refer to <i>columns</i> array description in Coordinate Format for more details. |
| <i>nnz</i> | Specifies the number of non-zero element of the matrix <i>A</i> . Refer to <i>nnz</i> description in Coordinate Format for more details. |
| <i>x</i> | Array, size is <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> . |

Output Parameters

| | |
|----------|---|
| <i>y</i> | Array, size at least <i>m</i> . Contains the vector <i>y</i> . |
|----------|---|

mkl_?diatrsv

Triangular solvers with simplified interface for a sparse matrix in the diagonal format with one-based indexing.

Syntax

```
void mkl_sdiatrsv (const char *uplo , const char *transa , const char *diag , const
MKL_INT *m , const float *val , const MKL_INT *lval , const MKL_INT *idiag , const
MKL_INT *ndiag , const float *x , float *y );
```

```
void mkl_ddiatrsv (const char *uplo , const char *transa , const char *diag , const
MKL_INT *m , const double *val , const MKL_INT *lval , const MKL_INT *idiag , const
MKL_INT *ndiag , const double *x , double *y );
```

```
void mkl_cdiatrsv (const char *uplo , const char *transa , const char *diag , const
MKL_INT *m , const MKL_Complex8 *val , const MKL_INT *lval , const MKL_INT *idiag ,
const MKL_INT *ndiag , const MKL_Complex8 *x , MKL_Complex8 *y );
```

```
void mkl_zdiatrsv (const char *uplo , const char *transa , const char *diag , const
MKL_INT *m , const MKL_Complex16 *val , const MKL_INT *lval , const MKL_INT *idiag ,
const MKL_INT *ndiag , const MKL_Complex16 *x , MKL_Complex16 *y );
```

Include Files

- `mkl.h`

Description

The `mkl_?diatrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the diagonal format:

$$A^*y = x$$

or

$$A^T*y = x,$$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A^T is the transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

| | |
|---------------|--|
| <i>uplo</i> | Specifies whether the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used. |
| <i>transa</i> | Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $A^*y = x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $A^T*y = x$, |
| <i>diag</i> | Specifies whether A is unit triangular. If <i>diag</i> = 'U' or 'u', then A is unit triangular. If <i>diag</i> = 'N' or 'n', then A is not unit triangular. |
| <i>m</i> | Number of rows of the matrix A . |
| <i>val</i> | Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix A . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details. |
| <i>lval</i> | Leading dimension of <i>val</i> , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details. |
| <i>idiag</i> | Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix A . |

NOTE

All elements of this array must be sorted in increasing order.

Refer to *distance* array description in [Diagonal Storage Scheme](#) for more details.

ndiag Specifies the number of non-zero diagonals of the matrix *A*.

x Array, size is *m*.
On entry, the array *x* must contain the vector *x*.

Output Parameters

y Array, size at least *m*.
Contains the vector *y*.

mkl_cspblas_?csrgermv

Computes matrix - vector product of a sparse general matrix stored in the CSR format (3-array variation) with zero-based indexing.

Syntax

```
void mkl_cspblas_scsrgermv (const char *transa , const MKL_INT *m , const float *a ,
const MKL_INT *ia , const MKL_INT *ja , const float *x , float *y );
void mkl_cspblas_dcsrgermv (const char *transa , const MKL_INT *m , const double *a ,
const MKL_INT *ia , const MKL_INT *ja , const double *x , double *y );
void mkl_cspblas_ccsrgermv (const char *transa , const MKL_INT *m , const MKL_Complex8
*a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex8 *x , MKL_Complex8 *y );
void mkl_cspblas_zcsrgermv (const char *transa , const MKL_INT *m , const MKL_Complex16
*a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex16 *x , MKL_Complex16
*y );
```

Include Files

- mkl.h

Description

The `mkl_cspblas_?csrgermv` routine performs a matrix-vector operation defined as

```
y := A*x
```

or

```
y := AT*x,
```

where:

x and *y* are vectors,

A is an *m*-by-*m* sparse square matrix in the CSR format (3-array variation) with zero-based indexing, *A*^T is the transpose of *A*.

NOTE

This routine supports only zero-based indexing of the input arrays.

Input Parameters

| | |
|---------------|--|
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := A*x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A^T*x$, |
| <i>m</i> | Number of rows of the matrix <i>A</i> . |
| <i>a</i> | Array containing non-zero elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details. |
| <i>ia</i> | Array of length $m + 1$, containing indices of elements in the array <i>a</i> , such that <i>ia</i> [<i>I</i>] is the index in the array <i>a</i> of the first non-zero element from the row <i>I</i> . The value of the last element <i>ia</i> [<i>m</i>] is equal to the number of non-zeros. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details. |
| <i>ja</i> | Array containing the column indices for each non-zero element of the matrix <i>A</i> . Its length is equal to the length of the array <i>a</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details. |
| <i>x</i> | Array, size is <i>m</i> . One entry, the array <i>x</i> must contain the vector <i>x</i> . |

Output Parameters

| | |
|----------|---|
| <i>y</i> | Array, size at least <i>m</i> . On exit, the array <i>y</i> must contain the vector <i>y</i> . |
|----------|---|

mkl_cspblas_?bsrgemv

Computes matrix - vector product of a sparse general matrix stored in the BSR format (3-array variation) with zero-based indexing.

Syntax

```
void mkl_cspblas_sbsrgemv (const char *transa , const MKL_INT *m , const MKL_INT *lb ,
const float *a , const MKL_INT *ia , const MKL_INT *ja , const float *x , float *y );
void mkl_cspblas_dbsrgemv (const char *transa , const MKL_INT *m , const MKL_INT *lb ,
const double *a , const MKL_INT *ia , const MKL_INT *ja , const double *x , double
*y );
void mkl_cspblas_cbsrgemv (const char *transa , const MKL_INT *m , const MKL_INT *lb ,
const MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex8 *x ,
MKL_Complex8 *y );
void mkl_cspblas_zbsrgemv (const char *transa , const MKL_INT *m , const MKL_INT *lb ,
const MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex16
*x , MKL_Complex16 *y );
```

Include Files

- `mkl.h`

Description

The `mkl_cspblas_?bsrgemv` routine performs a matrix-vector operation defined as

$$y := A*x$$

or

$$y := A^T*x,$$

where:

x and y are vectors,

A is an m -by- m block sparse square matrix in the BSR format (3-array variation) with zero-based indexing, A^T is the transpose of A .

NOTE

This routine supports only zero-based indexing of the input arrays.

Input Parameters

| | |
|---------------|---|
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := A*x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A^T*x$, |
| <i>m</i> | Number of block rows of the matrix A . |
| <i>lb</i> | Size of the block in the matrix A . |
| <i>a</i> | Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by $lb*lb$. Refer to <i>values</i> array description in BSR Format for more details. |
| <i>ia</i> | Array of length $(m + 1)$, containing indices of block in the array a , such that $ia[i]$ is the index in the array a of the first non-zero element from the row i . The value of the last element $ia[m]$ is equal to the number of non-zero blocks. Refer to <i>rowIndex</i> array description in BSR Format for more details. |
| <i>ja</i> | Array containing the column indices for each non-zero block in the matrix A . Its length is equal to the number of non-zero blocks of the matrix A . Refer to <i>columns</i> array description in BSR Format for more details. |
| <i>x</i> | Array, size $(m*lb)$. On entry, the array x must contain the vector x . |

Output Parameters

y Array, size at least $(m \cdot lb)$.
On exit, the array *y* must contain the vector *y*.

mkl_cspblas_?coogemv

Computes matrix - vector product of a sparse general matrix stored in the coordinate format with zero-based indexing.

Syntax

```
void mkl_cspblas_scoogemv (const char *transa , const MKL_INT *m , const float *val ,
const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const float *x ,
float *y );
```

void mkl_cspblas_dcoogemv (const char *transa , const MKL_INT *m , const double *val ,
const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const double *x ,
double *y );
```

```
void mkl_cspblas_ccoogemv (const char *transa , const MKL_INT *m , const MKL_Complex8
*val , const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const
MKL_Complex8 *x , MKL_Complex8 *y );
```

```
void mkl_cspblas_zcoogemv (const char *transa , const MKL_INT *m , const MKL_Complex16
*val , const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const
MKL_Complex16 *x , MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_cspblas_dcoogemv` routine performs a matrix-vector operation defined as

```
y := A*x
```

or

```
y := AT*x,
```

where:

x and *y* are vectors,

A is an *m*-by-*m* sparse square matrix in the coordinate format with zero-based indexing, *A*^T is the transpose of *A*.

NOTE

This routine supports only zero-based indexing of the input arrays.

Input Parameters

transa Specifies the operation.
If *transa* = 'N' or 'n', then the matrix-vector product is computed as
y := *A***x*

If *transa* = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A^T * x$.

| | |
|---------------|--|
| <i>m</i> | Number of rows of the matrix <i>A</i> . |

| <i>rowind</i> | Array of length <i>nnz</i> , contains the row indices for each non-zero element of the matrix <i>A</i> . Refer to <i>rows</i> array description in Coordinate Format for more details. |
| <i>colind</i> | Array of length <i>nnz</i> , contains the column indices for each non-zero element of the matrix <i>A</i> . Refer to <i>columns</i> array description in Coordinate Format for more details. |
| <i>nnz</i> | Specifies the number of non-zero element of the matrix <i>A</i> . Refer to <i>nnz</i> description in Coordinate Format for more details. |
| <i>x</i> | Array, size is <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> . |

Output Parameters

| | |
|----------|---|
| <i>y</i> | Array, size at least <i>m</i> . On exit, the array <i>y</i> must contain the vector <i>y</i> . |
|----------|---|

mkl_cspblas_?csrsmv

Computes matrix-vector product of a sparse symmetrical matrix stored in the CSR format (3-array variation) with zero-based indexing.

Syntax

```
void mkl_cspblas_scsrsmv (const char *uplo , const MKL_INT *m , const float *a , const
MKL_INT *ia , const MKL_INT *ja , const float *x , float *y );

void mkl_cspblas_dcsrsmv (const char *uplo , const MKL_INT *m , const double *a ,
const MKL_INT *ia , const MKL_INT *ja , const double *x , double *y );

void mkl_cspblas_ccsrsmv (const char *uplo , const MKL_INT *m , const MKL_Complex8
*a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex8 *x , MKL_Complex8 *y );

void mkl_cspblas_zcsrsmv (const char *uplo , const MKL_INT *m , const MKL_Complex16
*a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex16 *x , MKL_Complex16
*y );
```

Include Files

- mkl.h

Description

The `mkl_cspblas_?csrsvmv` routine performs a matrix-vector operation defined as

```
y := A*x
```

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the CSR format (3-array variation) with zero-based indexing.

NOTE

This routine supports only zero-based indexing of the input arrays.

Input Parameters

| | |
|-------------------|---|
| <code>uplo</code> | Specifies whether the upper or low triangle of the matrix A is used. If <code>uplo = 'U' or 'u'</code> , then the upper triangle of the matrix A is used. If <code>uplo = 'L' or 'l'</code> , then the low triangle of the matrix A is used. |
| <code>m</code> | Number of rows of the matrix A . |
| <code>a</code> | Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to <code>values</code> array description in Sparse Matrix Storage Formats for more details. |
| <code>ia</code> | Array of length $m + 1$, containing indices of elements in the array <code>a</code> , such that <code>ia[i]</code> is the index in the array <code>a</code> of the first non-zero element from the row i . The value of the last element <code>ia[m]</code> is equal to the number of non-zeros. Refer to <code>rowIndex</code> array description in Sparse Matrix Storage Formats for more details. |
| <code>ja</code> | Array containing the column indices for each non-zero element of the matrix A . Its length is equal to the length of the array <code>a</code> . Refer to <code>columns</code> array description in Sparse Matrix Storage Formats for more details. |
| <code>x</code> | Array, size is m . On entry, the array <code>x</code> must contain the vector x . |

Output Parameters

| | |
|----------------|---|
| <code>y</code> | Array, size at least m . On exit, the array <code>y</code> must contain the vector y . |
|----------------|---|

`mkl_cspblas_?bsrsvmv`

Computes matrix-vector product of a sparse symmetrical matrix stored in the BSR format (3-arrays variation) with zero-based indexing.

Syntax

```
void mkl_cspblas_sbsrsymv (const char *uplo , const MKL_INT *m , const MKL_INT *lb ,
const float *a , const MKL_INT *ia , const MKL_INT *ja , const float *x , float *y );
void mkl_cspblas_dbsrsymv (const char *uplo , const MKL_INT *m , const MKL_INT *lb ,
const double *a , const MKL_INT *ia , const MKL_INT *ja , const double *x , double
*y );
void mkl_cspblas_cbsrsymv (const char *uplo , const MKL_INT *m , const MKL_INT *lb ,
const MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex8 *x ,
MKL_Complex8 *y );
void mkl_cspblas_zbsrsymv (const char *uplo , const MKL_INT *m , const MKL_INT *lb ,
const MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_Complex16
*x , MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_cspblas_?bsrsymv` routine performs a matrix-vector operation defined as

```
y := A*x
```

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the BSR format (3-array variation) with zero-based indexing.

NOTE

This routine supports only zero-based indexing of the input arrays.

Input Parameters

| | |
|-------------------|--|
| <code>uplo</code> | Specifies whether the upper or low triangle of the matrix A is used. If <code>uplo = 'U' or 'u'</code> , then the upper triangle of the matrix A is used. If <code>uplo = 'L' or 'l'</code> , then the low triangle of the matrix A is used. |
| <code>m</code> | Number of block rows of the matrix A . |
| <code>lb</code> | Size of the block in the matrix A . |
| <code>a</code> | Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by $lb*lb$. Refer to <code>values</code> array description in BSR Format for more details. |

| | |
|-----------|--|
| <i>ia</i> | Array of length $(m + 1)$, containing indices of block in the array <i>a</i> , such that <i>ia</i> [<i>i</i>] is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i> . The value of the last element <i>ia</i> [<i>m</i>] is equal to the number of non-zero blocks. Refer to <i>rowIndex</i> array description in BSR Format for more details. |
| <i>ja</i> | Array containing the column indices for each non-zero block in the matrix <i>A</i> . Its length is equal to the number of non-zero blocks of the matrix <i>A</i> . Refer to <i>columns</i> array description in BSR Format for more details. |
| <i>x</i> | Array, size $(m \cdot lb)$. On entry, the array <i>x</i> must contain the vector <i>x</i> . |

Output Parameters

| | |
|----------|---|
| <i>y</i> | Array, size at least $(m \cdot lb)$. On exit, the array <i>y</i> must contain the vector <i>y</i> . |
|----------|---|

mkl_cspblas_?coosymv

Computes matrix - vector product of a sparse symmetrical matrix stored in the coordinate format with zero-based indexing .

Syntax

```
void mkl_cspblas_scoosymv (const char *uplo , const MKL_INT *m , const float *val ,
const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const float *x ,
float *y );
```

```
void mkl_cspblas_dcoosymv (const char *uplo , const MKL_INT *m , const double *val ,
const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const double *x ,
double *y );
```

```
void mkl_cspblas_ccoosymv (const char *uplo , const MKL_INT *m , const MKL_Complex8
*val , const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const
MKL_Complex8 *x , MKL_Complex8 *y );
```

```
void mkl_cspblas_zcoosymv (const char *uplo , const MKL_INT *m , const MKL_Complex16
*val , const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const
MKL_Complex16 *x , MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_cspblas_?coosymv` routine performs a matrix-vector operation defined as

```
y := A*x
```

where:

x and *y* are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the coordinate format with zero-based indexing.

NOTE

This routine supports only zero-based indexing of the input arrays.

Input Parameters

| | |
|---------------|---|
| <i>uplo</i> | Specifies whether the upper or low triangle of the matrix <i>A</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix <i>A</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix <i>A</i> is used. |
| <i>m</i> | Number of rows of the matrix <i>A</i> . |
| <i>val</i> | Array of length <i>nnz</i> , contains non-zero elements of the matrix <i>A</i> in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details. |
| <i>rowind</i> | Array of length <i>nnz</i> , contains the row indices for each non-zero element of the matrix <i>A</i> . Refer to <i>rows</i> array description in Coordinate Format for more details. |
| <i>colind</i> | Array of length <i>nnz</i> , contains the column indices for each non-zero element of the matrix <i>A</i> . Refer to <i>columns</i> array description in Coordinate Format for more details. |
| <i>nnz</i> | Specifies the number of non-zero element of the matrix <i>A</i> . Refer to <i>nnz</i> description in Coordinate Format for more details. |
| <i>x</i> | Array, size is <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> . |

Output Parameters

| | |
|----------|---|
| <i>y</i> | Array, size at least <i>m</i> . On exit, the array <i>y</i> must contain the vector <i>y</i> . |
|----------|---|

mkl_cspblas_?csrtrsv

Triangular solvers with simplified interface for a sparse matrix in the CSR format (3-array variation) with zero-based indexing.

Syntax

```
void mkl_cspblas_scsrtrsv (const char *uplo , const char *transa , const char *diag ,
const MKL_INT *m , const float *a , const MKL_INT *ia , const MKL_INT *ja , const float
*x , float *y );

void mkl_cspblas_dcsrtrsv (const char *uplo , const char *transa , const char *diag ,
const MKL_INT *m , const double *a , const MKL_INT *ia , const MKL_INT *ja , const
double *x , double *y );

void mkl_cspblas_ccsrtrsv (const char *uplo , const char *transa , const char *diag ,
const MKL_INT *m , const MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja ,
const MKL_Complex8 *x , MKL_Complex8 *y );
```

```
void mkl_cspblas_zcsrtrsv (const char *uplo , const char *transa , const char *diag ,
const MKL_INT *m , const MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja ,
const MKL_Complex16 *x , MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_cspblas_?csrtrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the CSR format (3-array variation) with zero-based indexing:

$$A*y = x$$

or

$$A^T*y = x,$$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A^T is the transpose of A .

NOTE

This routine supports only zero-based indexing of the input arrays.

Input Parameters

| | |
|---------------|---|
| <i>uplo</i> | Specifies whether the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used. |
| <i>transa</i> | Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $A*y = x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $A^T*y = x$, |
| <i>diag</i> | Specifies whether matrix A is unit triangular. If <i>diag</i> = 'U' or 'u', then A is unit triangular. If <i>diag</i> = 'N' or 'n', then A is not unit triangular. |
| <i>m</i> | Number of rows of the matrix A . |
| <i>a</i> | Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details. |

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

ia Array of length $m+1$, containing indices of elements in the array *a*, such that *ia*[*i*] is the index in the array *a* of the first non-zero element from the row *i*. The value of the last element *ia*[*m*] is equal to the number of non-zeros. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

ja Array containing the column indices for each non-zero element of the matrix *A*.
Its length is equal to the length of the array *a*. Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

NOTE

Column indices must be sorted in increasing order for each row.

x Array, size is *m*.
On entry, the array *x* must contain the vector *x*.

Output Parameters

y Array, size at least *m*.
Contains the vector *y*.

mkl_cspblas_?bsrtrsv

Triangular solver with simplified interface for a sparse matrix stored in the BSR format (3-array variation) with zero-based indexing.

Syntax

```
void mkl_cspblas_sbsrtrsv (const char *uplo , const char *transa , const char *diag ,
const MKL_INT *m , const MKL_INT *lb , const float *a , const MKL_INT *ia , const
MKL_INT *ja , const float *x , float *y );
```

```
void mkl_cspblas_dbsrtrsv (const char *uplo , const char *transa , const char *diag ,
const MKL_INT *m , const MKL_INT *lb , const double *a , const MKL_INT *ia , const
MKL_INT *ja , const double *x , double *y );
```

```
void mkl_cspblas_cbsrtrsv (const char *uplo , const char *transa , const char *diag ,
const MKL_INT *m , const MKL_INT *lb , const MKL_Complex8 *a , const MKL_INT *ia ,
const MKL_INT *ja , const MKL_Complex8 *x , MKL_Complex8 *y );
```

```
void mkl_cspblas_zbsrtrsv (const char *uplo , const char *transa , const char *diag ,
const MKL_INT *m , const MKL_INT *lb , const MKL_Complex16 *a , const MKL_INT *ia ,
const MKL_INT *ja , const MKL_Complex16 *x , MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mk1_cspblas_?bsrtrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the BSR format (3-array variation) with zero-based indexing:

```
y := A*x
```

or

```
y := AT*x,
```

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A^T is the transpose of A .

NOTE

This routine supports only zero-based indexing of the input arrays.

Input Parameters

| | |
|---------------|--|
| <i>uplo</i> | Specifies the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used. |
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := A*x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A^T*x$. |
| <i>diag</i> | Specifies whether matrix A is unit triangular or not. If <i>diag</i> = 'U' or 'u', A is unit triangular. If <i>diag</i> = 'N' or 'n', A is not unit triangular. |
| <i>m</i> | Number of block rows of the matrix A . |
| <i>lb</i> | Size of the block in the matrix A . |
| <i>a</i> | Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by $lb*lb$. Refer to <i>values</i> array description in BSR Format for more details. |

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

| | |
|-----------|--|
| <i>ia</i> | Array of length $(m + 1)$, containing indices of block in the array <i>a</i> , such that <i>ia</i> [<i>I</i>] is the index in the array <i>a</i> of the first non-zero element from the row <i>I</i> . The value of the last element <i>ia</i> [<i>m</i>] is equal to the number of non-zero blocks. Refer to <i>rowIndex</i> array description in BSR Format for more details. |
| <i>ja</i> | Array containing the column indices for each non-zero block in the matrix <i>A</i> . Its length is equal to the number of non-zero blocks of the matrix <i>A</i> . Refer to <i>columns</i> array description in BSR Format for more details. |
| <i>x</i> | Array, size $(m \cdot lb)$. On entry, the array <i>x</i> must contain the vector <i>x</i> . |

Output Parameters

| | |
|----------|---|
| <i>y</i> | Array, size at least $(m \cdot lb)$. On exit, the array <i>y</i> must contain the vector <i>y</i> . |
|----------|---|

[mkl_cspblas_?cootrsv](#)

Triangular solvers with simplified interface for a sparse matrix in the coordinate format with zero-based indexing .

Syntax

```
void mkl_cspblas_scootrsv (const char *uplo , const char *transa , const char *diag ,
const MKL_INT *m , const float *val , const MKL_INT *rowind , const MKL_INT *colind ,
const MKL_INT *nnz , const float *x , float *y );

void mkl_cspblas_dcootrsv (const char *uplo , const char *transa , const char *diag ,
const MKL_INT *m , const double *val , const MKL_INT *rowind , const MKL_INT *colind ,
const MKL_INT *nnz , const double *x , double *y );

Description

The `mkl_cspblas_?cootrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the coordinate format with zero-based indexing:

$$A \cdot y = x$$

or

$$A^T \cdot y = x,$$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A^T is the transpose of A .

NOTE

This routine supports only zero-based indexing of the input arrays.

Input Parameters

| | |
|---------------|--|
| <i>uplo</i> | Specifies whether the upper or low triangle of the matrix A is considered. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used. |
| <i>transa</i> | Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $A*y = x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $A^T*y = x$, |
| <i>diag</i> | Specifies whether A is unit triangular. If <i>diag</i> = 'U' or 'u', then A is unit triangular. If <i>diag</i> = 'N' or 'n', then A is not unit triangular. |
| <i>m</i> | Number of rows of the matrix A . |
| <i>val</i> | Array of length <i>nnz</i> , contains non-zero elements of the matrix A in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details. |
| <i>rowind</i> | Array of length <i>nnz</i> , contains the row indices for each non-zero element of the matrix A . Refer to <i>rows</i> array description in Coordinate Format for more details. |
| <i>colind</i> | Array of length <i>nnz</i> , contains the column indices for each non-zero element of the matrix A . Refer to <i>columns</i> array description in Coordinate Format for more details. |
| <i>nnz</i> | Specifies the number of non-zero element of the matrix A . Refer to <i>nnz</i> description in Coordinate Format for more details. |
| <i>x</i> | Array, size is <i>m</i> . On entry, the array <i>x</i> must contain the vector x . |

Output Parameters

| | |
|----------|--|
| <i>y</i> | Array, size at least <i>m</i> . Contains the vector y . |
|----------|--|

mkl_?csrvm

Computes matrix - vector product of a sparse matrix stored in the CSR format.

Syntax

```
void mkl_scsrvm (const char *transa , const MKL_INT *m , const MKL_INT *k , const float
*alpha , const char *matdescra , const float *val , const MKL_INT *indx , const MKL_INT
*pntrb , const MKL_INT *pntre , const float *x , const float *beta , float *y );
```

```
void mkl_dcsrvm (const char *transa , const MKL_INT *m , const MKL_INT *k , const
double *alpha , const char *matdescra , const double *val , const MKL_INT *indx , const
MKL_INT *pntrb , const MKL_INT *pntre , const double *x , const double *beta , double
*y );
```

```
void mkl_ccsrvm (const char *transa , const MKL_INT *m , const MKL_INT *k , const
MKL_Complex8 *alpha , const char *matdescra , const MKL_Complex8 *val , const MKL_INT
*indx , const MKL_INT *pntrb , const MKL_INT *pntre , const MKL_Complex8 *x , const
MKL_Complex8 *beta , MKL_Complex8 *y );
```

```
void mkl_zcsrvm (const char *transa , const MKL_INT *m , const MKL_INT *k , const
MKL_Complex16 *alpha , const char *matdescra , const MKL_Complex16 *val , const MKL_INT
*indx , const MKL_INT *pntrb , const MKL_INT *pntre , const MKL_Complex16 *x , const
MKL_Complex16 *beta , MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_?csrvm` routine performs a matrix-vector operation defined as

```
y := alpha*A*x + beta*y
```

or

```
y := alpha*AT*x + beta*y,
```

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*k* sparse matrix in the CSR format, *A^T* is the transpose of *A*.

NOTE

This routine supports a CSR format both with one-based indexing and zero-based indexing.

Input Parameters

| | |
|---------------|--|
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha A x + \beta y$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha A^T x + \beta y$, |
| <i>m</i> | Number of rows of the matrix <i>A</i> . |

| | |
|------------------|--|
| <i>k</i> | Number of columns of the matrix <i>A</i> . |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>matdescra</i> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" . |
| <i>val</i> | Array containing non-zero elements of the matrix <i>A</i> . Its length is $pntrb[m-1] - pntrb[0]$. Refer to <i>values</i> array description in CSR Format for more details. |
| <i>indx</i> | For one-based indexing, array containing the column indices plus one for each non-zero element of the matrix <i>A</i> . For zero-based indexing, array containing the column indices for each non-zero element of the matrix <i>A</i> . Its length is equal to length of the <i>val</i> array. Refer to <i>columns</i> array description in CSR Format for more details. |
| <i>pntrb</i> | Array of length <i>m</i> . This array contains row indices, such that $pntrb[i] - pntrb[0]$ is the first index of row <i>i</i> in the arrays <i>val</i> and <i>indx</i> . Refer to <i>pointerb</i> array description in CSR Format for more details. |
| <i>pntrr</i> | Array of length <i>m</i> . This array contains row indices, such that $pntrr[i] - pntrb[0]-1$ is the last index of row <i>i</i> in the arrays <i>val</i> and <i>indx</i> . Refer to <i>pointerE</i> array description in CSR Format for more details. |
| <i>x</i> | Array, size at least <i>k</i> if <i>transa</i> = 'N' or 'n' and at least <i>m</i> otherwise. On entry, the array <i>x</i> must contain the vector <i>x</i> . |
| <i>beta</i> | Specifies the scalar <i>beta</i> . |
| <i>y</i> | Array, size at least <i>m</i> if <i>transa</i> = 'N' or 'n' and at least <i>k</i> otherwise. On entry, the array <i>y</i> must contain the vector <i>y</i> . |

Output Parameters

| | |
|----------|--|
| <i>y</i> | Overwritten by the updated vector <i>y</i> . |
|----------|--|

mkl_?bsrmv

Computes matrix - vector product of a sparse matrix stored in the BSR format.

Syntax

```
void mkl_sbsrmv (const char *transa , const MKL_INT *m , const MKL_INT *k , const
MKL_INT *lb , const float *alpha , const char *matdescra , const float *val , const
MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntrc , const float *x , const
float *beta , float *y );
```

```
void mkl_dbsrmv (const char *transa , const MKL_INT *m , const MKL_INT *k , const
MKL_INT *lb , const double *alpha , const char *matdescra , const double *val , const
MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntrc , const double *x , const
double *beta , double *y );
```

```
void mkl_cbsrmv (const char *transa , const MKL_INT *m , const MKL_INT *k , const
MKL_INT *lb , const MKL_Complex8 *alpha , const char *matdescra , const MKL_Complex8
*val , const MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntrc , const
MKL_Complex8 *x , const MKL_Complex8 *beta , MKL_Complex8 *y );
```

```
void mkl_zbsrmv (const char *transa , const MKL_INT *m , const MKL_INT *k , const
MKL_INT *lb , const MKL_Complex16 *alpha , const char *matdescra , const MKL_Complex16
*val , const MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntrc , const
MKL_Complex16 *x , const MKL_Complex16 *beta , MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_?bsrmv` routine performs a matrix-vector operation defined as

$$y := \alpha A^*x + \beta y$$

or

$$y := \alpha A^T x + \beta y,$$

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*k* block sparse matrix in the BSR format, A^T is the transpose of *A*.

NOTE

This routine supports a BSR format both with one-based indexing and zero-based indexing.

Input Parameters

| | |
|---------------|---|
| <i>transa</i> | <p>Specifies the operation.</p> <p>If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as</p> $y := \alpha A^*x + \beta y$ <p>If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as</p> $y := \alpha A^T x + \beta y,$ |
| <i>m</i> | Number of block rows of the matrix <i>A</i> . |

| | |
|------------------|--|
| <i>k</i> | Number of block columns of the matrix <i>A</i> . |
| <i>lb</i> | Size of the block in the matrix <i>A</i> . |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>matdescra</i> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" . |
| <i>val</i> | Array containing elements of non-zero blocks of the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> multiplied by $lb*lb$. Refer to <i>values</i> array description in BSR Format for more details. |
| <i>indx</i> | For one-based indexing, array containing the column indices plus one for each non-zero block of the matrix <i>A</i> . For zero-based indexing, array containing the column indices for each non-zero block of the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> . Refer to <i>columns</i> array description in BSR Format for more details. |
| <i>pntrb</i> | Array of length <i>m</i> . This array contains row indices, such that $pntrb[i] - pntrb[0]$ is the first index of block row <i>i</i> in the array <i>indx</i> . Refer to <i>pointerB</i> array description in BSR Format for more details. |
| <i>pntrE</i> | Array of length <i>m</i> . For zero-based indexing this array contains row indices, such that $pntrE[i] - pntrb[0] - 1$ is the last index of block row <i>i</i> in the array <i>indx</i> . Refer to <i>pointerE</i> array description in BSR Format for more details. |
| <i>x</i> | Array, size at least $(k*lb)$ if <i>transa</i> = 'N' or 'n', and at least $(m*lb)$ otherwise. On entry, the array <i>x</i> must contain the vector <i>x</i> . |
| <i>beta</i> | Specifies the scalar <i>beta</i> . |
| <i>y</i> | Array, size at least $(m*lb)$ if <i>transa</i> = 'N' or 'n', and at least $(k*lb)$ otherwise. On entry, the array <i>y</i> must contain the vector <i>y</i> . |

Output Parameters

| | |
|----------|--|
| <i>y</i> | Overwritten by the updated vector <i>y</i> . |
|----------|--|

mkl_?cscmv

Computes matrix-vector product for a sparse matrix in the CSC format.

Syntax

```
void mkl_scscmv (const char *transa , const MKL_INT *m , const MKL_INT *k , const float
*alpha , const char *matdescra , const float *val , const MKL_INT *indx , const MKL_INT
*pntrb , const MKL_INT *pntre , const float *x , const float *beta , float *y );
```

```
void mkl_dcscmv (const char *transa , const MKL_INT *m , const MKL_INT *k , const
double *alpha , const char *matdescra , const double *val , const MKL_INT *indx , const
MKL_INT *pntrb , const MKL_INT *pntre , const double *x , const double *beta , double
*y );
```

```
void mkl_ccscmv (const char *transa , const MKL_INT *m , const MKL_INT *k , const
MKL_Complex8 *alpha , const char *matdescra , const MKL_Complex8 *val , const MKL_INT
*indx , const MKL_INT *pntrb , const MKL_INT *pntre , const MKL_Complex8 *x , const
MKL_Complex8 *beta , MKL_Complex8 *y );
```

```
void mkl_zcscmv (const char *transa , const MKL_INT *m , const MKL_INT *k , const
MKL_Complex16 *alpha , const char *matdescra , const MKL_Complex16 *val , const MKL_INT
*indx , const MKL_INT *pntrb , const MKL_INT *pntre , const MKL_Complex16 *x , const
MKL_Complex16 *beta , MKL_Complex16 *y );
```

Include Files

Description

The `mkl_?cscmv` routine performs a matrix-vector operation defined as

$$y := \alpha A^*x + \beta y$$

or

$$y := \alpha A^T x + \beta y,$$

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*k* sparse matrix in compressed sparse column (CSC) format, A^T is the transpose of *A*.

NOTE

This routine supports CSC format both with one-based indexing and zero-based indexing.

Input Parameters

| | |
|---------------|--|
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha A^*x + \beta y$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha A^T x + \beta y,$ |
| <i>m</i> | Number of rows of the matrix <i>A</i> . |
| <i>k</i> | Number of columns of the matrix <i>A</i> . |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |

| | |
|------------------|---|
| <i>matdescra</i> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" . |
| <i>val</i> | Array containing non-zero elements of the matrix <i>A</i> . Its length is $pntrb[k-1] - pntrb[0]$. Refer to <i>values</i> array description in CSC Format for more details. |
| <i>indx</i> | For one-based indexing, array containing the column indices plus one for each non-zero element of the matrix <i>A</i> . For zero-based indexing, array containing the column indices for each non-zero element of the matrix <i>A</i> . Its length is equal to length of the <i>val</i> array. Refer to <i>rows</i> array description in CSC Format for more details. |
| <i>pntrb</i> | Array of length <i>k</i> . This array contains column indices, such that $pntrb[i] - pntrb[0] + 1$ is the first index of column <i>i</i> in the arrays <i>val</i> and <i>indx</i> . Refer to <i>pointerb</i> array description in CSC Format for more details. |
| <i>pntrb</i> | Array of length <i>k</i> . For one-based indexing this array contains column indices, such that $pntrb[i] - pntrb[1]$ is the last index of column <i>i</i> in the arrays <i>val</i> and <i>indx</i> . For zero-based indexing this array contains column indices, such that $pntrb[i] - pntrb[1] - 1$ is the last index of column <i>i</i> in the arrays <i>val</i> and <i>indx</i> . Refer to <i>pointerE</i> array description in CSC Format for more details. |
| <i>x</i> | Array, size at least <i>k</i> if <i>transa</i> = 'N' or 'n' and at least <i>m</i> otherwise. On entry, the array <i>x</i> must contain the vector <i>x</i> . |
| <i>beta</i> | Specifies the scalar <i>beta</i> . |
| <i>y</i> | Array, size at least <i>m</i> if <i>transa</i> = 'N' or 'n' and at least <i>k</i> otherwise. On entry, the array <i>y</i> must contain the vector <i>y</i> . |

Output Parameters

y Overwritten by the updated vector *y*.

mkl_?coomv

Computes matrix - vector product for a sparse matrix in the coordinate format.

Syntax

```
void mkl_scoomv (const char *transa , const MKL_INT *m , const MKL_INT *k , const float *alpha , const char *matdescra , const float *val , const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const float *x , const float *beta , float *y );
```

```
void mkl_dcoomv (const char *transa , const MKL_INT *m , const MKL_INT *k , const
double *alpha , const char *matdescra , const double *val , const MKL_INT *rowind ,
const MKL_INT *colind , const MKL_INT *nnz , const double *x , const double *beta ,
double *y );
```

```
void mkl_ccoomv (const char *transa , const MKL_INT *m , const MKL_INT *k , const

*rowind , const MKL_INT *colind , const MKL_INT *nnz , const MKL_Complex8 *x , const
MKL_Complex8 *beta , MKL_Complex8 *y );
```

```
void mkl_zcoomv (const char *transa , const MKL_INT *m , const MKL_INT *k , const
MKL_Complex16 *alpha , const char *matdescra , const MKL_Complex16 *val , const MKL_INT
*rowind , const MKL_INT *colind , const MKL_INT *nnz , const MKL_Complex16 *x , const
MKL_Complex16 *beta , MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_?coomv` routine performs a matrix-vector operation defined as

```
 $y := \alpha A x + \beta y$ 
```

or

```
 $y := \alpha A^T x + \beta y,$ 
```

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*k* sparse matrix in compressed coordinate format, A^T is the transpose of *A*.

NOTE

This routine supports a coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

| | |
|------------------|--|
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha A x + \beta y$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha A^T x + \beta y,$ |
| <i>m</i> | Number of rows of the matrix <i>A</i> . |
| <i>k</i> | Number of columns of the matrix <i>A</i> . |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |

|----------|--|
| <i>y</i> | Overwritten by the updated vector <i>y</i> . |
|----------|--|

mkl_?csrsv

Solves a system of linear equations for a sparse matrix in the CSR format.

Syntax

```
void mkl_scsrsv (const char *transa , const MKL_INT *m , const float *alpha , const
char *matdescra , const float *val , const MKL_INT *indx , const MKL_INT *pntrb , const
MKL_INT *pntre , const float *x , float *y );
```

```
void mkl_dcsrsv (const char *transa , const MKL_INT *m , const double *alpha , const
char *matdescra , const double *val , const MKL_INT *indx , const MKL_INT *pntrb ,
const MKL_INT *pntre , const double *x , double *y );
```

```
void mkl_ccsrsv (const char *transa , const MKL_INT *m , const MKL_Complex8 *alpha ,
const char *matdescra , const MKL_Complex8 *val , const MKL_INT *indx , const MKL_INT
*pntrb , const MKL_INT *pntre , const MKL_Complex8 *x , MKL_Complex8 *y );
```

```
void mkl_zcsrsv (const char *transa , const MKL_INT *m , const MKL_Complex16 *alpha ,
const char *matdescra , const MKL_Complex16 *val , const MKL_INT *indx , const MKL_INT
*pntrb , const MKL_INT *pntrc , const MKL_Complex16 *x , MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_?csrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the CSR format:

```
y := alpha*inv(A)*x
```

or

```
y := alpha*inv(AT)*x,
```

where:

alpha is scalar, *x* and *y* are vectors, *A* is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, *A^T* is the transpose of *A*.

NOTE

This routine supports a CSR format both with one-based indexing and zero-based indexing.

Input Parameters

| | |
|------------------|--|
| <i>transa</i> | Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $y := \alpha \cdot \text{inv}(A) \cdot x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha \cdot \text{inv}(A^T) \cdot x$, |
| <i>m</i> | Number of columns of the matrix <i>A</i> . |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>matdescra</i> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" . |
| <i>val</i> | Array containing non-zero elements of the matrix <i>A</i> . Its length is <code>pntrc[m - 1] - pntrb[0]</code> . Refer to <i>values</i> array description in CSR Format for more details. |

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

indx For one-based indexing, array containing the column indices plus one for each non-zero element of the matrix *A*. For zero-based indexing, array containing the column indices for each non-zero element of the matrix *A*. Its length is equal to length of the *val* array.

Refer to *columns* array description in [CSR Format](#) for more details.

NOTE

Column indices must be sorted in increasing order for each row.

pntrb Array of length *m*.
This array contains row indices, such that *pntrb*[*i*] - *pntrb*[0] is the first index of row *i* in the arrays *val* and *indx*.

Refer to *pointerb* array description in [CSR Format](#) for more details.

pntrE Array of length *m*.
This array contains row indices, such that *pntrE*[*i*] - *pntrb*[0] - 1 is the last index of row *i* in the arrays *val* and *indx*.

Refer to *pointerE* array description in [CSR Format](#) for more details.

x Array, size at least *m*.
On entry, the array *x* must contain the vector *x*. The elements are accessed with unit increment.

y Array, size at least *m*.
On entry, the array *y* must contain the vector *y*. The elements are accessed with unit increment.

Output Parameters

y Contains solution vector *x*.

mkl_?bsrsv

Solves a system of linear equations for a sparse matrix in the BSR format.

Syntax

```
void mkl_sbsrsv (const char *transa , const MKL_INT *m , const MKL_INT *lb , const
float *alpha , const char *matdescra , const float *val , const MKL_INT *indx , const
MKL_INT *pntrb , const MKL_INT *pntrE , const float *x , float *y );
```

```
void mkl_dbsrsv (const char *transa , const MKL_INT *m , const MKL_INT *lb , const
double *alpha , const char *matdescra , const double *val , const MKL_INT *indx , const
MKL_INT *pntrb , const MKL_INT *pntrE , const double *x , double *y );
```

```
void mkl_cbsrsv (const char *transa , const MKL_INT *m , const MKL_INT *lb , const
MKL_Complex8 *alpha , const char *matdescra , const MKL_Complex8 *val , const MKL_INT
*indx , const MKL_INT *pntrb , const MKL_INT *pntrE , const MKL_Complex8 *x ,
MKL_Complex8 *y );
```

```
void mkl_zbsrsv (const char *transa , const MKL_INT *m , const MKL_INT *lb , const
MKL_Complex16 *alpha , const char *matdescra , const MKL_Complex16 *val , const MKL_INT
*indx , const MKL_INT *pntrb , const MKL_INT *pntre , const MKL_Complex16 *x ,
MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_?bsrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the BSR format:

```
y := alpha*inv(A)*x
```

or

```
y := alpha*inv(AT)* x,
```

where:

alpha is scalar, *x* and *y* are vectors, *A* is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, *A*^T is the transpose of *A*.

NOTE

This routine supports a BSR format both with one-based indexing and zero-based indexing.

Input Parameters

| | |
|------------------|--|
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha \cdot \text{inv}(A) \cdot x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha \cdot \text{inv}(A^T) \cdot x$, |
| <i>m</i> | Number of block columns of the matrix <i>A</i> . |
| <i>lb</i> | Size of the block in the matrix <i>A</i> . |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>matdescra</i> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" . |
| <i>val</i> | Array containing elements of non-zero blocks of the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> multiplied by $lb \cdot lb$. Refer to the <i>values</i> array description in BSR Format for more details. |

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

| | |
|--------------|---|
| <i>indx</i> | For one-based indexing, array containing the column indices plus one for each non-zero element of the matrix <i>A</i> . For zero-based indexing, array containing the column indices for each non-zero element of the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> . Refer to the <i>columns</i> array description in BSR Format for more details. |
| <i>pntrb</i> | Array of length <i>m</i> . This array contains row indices, such that $pntrb[i] - pntrb[0]$ is the first index of block row <i>i</i> in the array <i>indx</i> . Refer to <i>pointerB</i> array description in BSR Format for more details. |
| <i>pntrc</i> | Array of length <i>m</i> . For one-based indexing this array contains row indices, such that $pntrc[i] - pntrb[1]$ is the last index of block row <i>i</i> in the array <i>indx</i> . For zero-based indexing this array contains row indices, such that $pntrc[i] - pntrb[0] - 1$ is the last index of block row <i>i</i> in the array <i>indx</i> . Refer to <i>pointerE</i> array description in BSR Format for more details. |
| <i>x</i> | Array, size at least $(m \cdot lb)$. On entry, the array <i>x</i> must contain the vector <i>x</i> . The elements are accessed with unit increment. |
| <i>y</i> | Array, size at least $(m \cdot lb)$. On entry, the array <i>y</i> must contain the vector <i>y</i> . The elements are accessed with unit increment. |

Output Parameters

| | |
|----------|-------------------------------------|
| <i>y</i> | Contains solution vector <i>x</i> . |
|----------|-------------------------------------|

mkl_?cscsv

Solves a system of linear equations for a sparse matrix in the CSC format.

Syntax

```
void mkl_scscsv (const char *transa , const MKL_INT *m , const float *alpha , const char *matdescra , const float *val , const MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntrc , const float *x , float *y );
```

```
void mkl_dcscsv (const char *transa , const MKL_INT *m , const double *alpha , const char *matdescra , const double *val , const MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntrc , const double *x , double *y );
```

```
void mkl_ccscsv (const char *transa , const MKL_INT *m , const MKL_Complex8 *alpha ,
const char *matdescra , const MKL_Complex8 *val , const MKL_INT *indx , const MKL_INT
*pntrb , const MKL_INT *pntre , const MKL_Complex8 *x , MKL_Complex8 *y );
```

```
void mkl_zcscsv (const char *transa , const MKL_INT *m , const MKL_Complex16 *alpha ,
const char *matdescra , const MKL_Complex16 *val , const MKL_INT *indx , const MKL_INT
*pntrb , const MKL_INT *pntre , const MKL_Complex16 *x , MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_?cscsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the CSC format:

```
 $y := \alpha \cdot \text{inv}(A) \cdot x$ 
```

or

```
 $y := \alpha \cdot \text{inv}(A^T) \cdot x,$ 
```

where:

α is scalar, x and y are vectors, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A^T is the transpose of A .

NOTE

This routine supports a CSC format both with one-based indexing and zero-based indexing.

Input Parameters

| | |
|------------------|--|
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha \cdot \text{inv}(A) \cdot x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha \cdot \text{inv}(A^T) \cdot x,$ |
| <i>m</i> | Number of columns of the matrix A . |
| <i>alpha</i> | Specifies the scalar α . |
| <i>matdescra</i> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" . |
| <i>val</i> | Array containing non-zero elements of the matrix A . Its length is $\text{pntre}[m-1] - \text{pntrb}[0]$. Refer to <i>values</i> array description in CSC Format for more details. |

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

indx

For one-based indexing, array containing the row indices plus one for each non-zero element of the matrix *A*.

For zero-based indexing, array containing the row indices for each non-zero element of the matrix *A*.

Its length is equal to length of the *val* array.

Refer to *columns* array description in [CSC Format](#) for more details.

NOTE

Row indices must be sorted in increasing order for each column.

pntrb

Array of length *m*.

This array contains column indices, such that $pntrb[i] - pntrb[0]$ is the first index of column *i* in the arrays *val* and *indx*.

Refer to *pointerb* array description in [CSC Format](#) for more details.

pntrE

Array of length *m*.

This array contains column indices, such that $pntrE[i] - pntrb[0] - 1$ is the last index of column *i* in the arrays *val* and *indx*.

Refer to *pointerE* array description in [CSC Format](#) for more details.

x

Array, size at least *m*.

On entry, the array *x* must contain the vector *x*. The elements are accessed with unit increment.

y

Array, size at least *m*.

On entry, the array *y* must contain the vector *y*. The elements are accessed with unit increment.

Output Parameters*y*

Contains the solution vector *x*.

mkl_?coosv

Solves a system of linear equations for a sparse matrix in the coordinate format.

Syntax

```
void mkl_scoosv (const char *transa , const MKL_INT *m , const float *alpha , const
char *matdescra , const float *val , const MKL_INT *rowind , const MKL_INT *colind ,
const MKL_INT *nnz , const float *x , float *y );
```

```
void mkl_dcoosv (const char *transa , const MKL_INT *m , const double *alpha , const
char *matdescra , const double *val , const MKL_INT *rowind , const MKL_INT *colind ,
const MKL_INT *nnz , const double *x , double *y );
```

```
void mkl_ccoosv (const char *transa , const MKL_INT *m , const MKL_Complex8 *alpha ,
const char *matdescra , const MKL_Complex8 *val , const MKL_INT *rowind , const MKL_INT
*colind , const MKL_INT *nnz , const MKL_Complex8 *x , MKL_Complex8 *y );

void mkl_zcoosv (const char *transa , const MKL_INT *m , const MKL_Complex16 *alpha ,
const char *matdescra , const MKL_Complex16 *val , const MKL_INT *rowind , const
MKL_INT *colind , const MKL_INT *nnz , const MKL_Complex16 *x , MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_?coosv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the coordinate format:

```
 $y := \alpha \cdot \text{inv}(A) \cdot x$ 
```

or

```
 $y := \alpha \cdot \text{inv}(A^T) \cdot x,$ 
```

where:

α is scalar, x and y are vectors, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A^T is the transpose of A .

NOTE

This routine supports a coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

| | |
|------------------|--|
| <i>transa</i> | Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $y := \alpha \cdot \text{inv}(A) \cdot x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha \cdot \text{inv}(A^T) \cdot x,$ |
| <i>m</i> | Number of rows of the matrix A . |
| <i>alpha</i> | Specifies the scalar α . |
| <i>matdescra</i> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" . |
| <i>val</i> | Array of length <i>nnz</i> , contains non-zero elements of the matrix A in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details. |
| <i>rowind</i> | Array of length <i>nnz</i> . For one-based indexing, contains the row indices plus one for each non-zero element of the matrix A . |

For zero-based indexing, contains the row indices for each non-zero element of the matrix A .

Refer to `rows` array description in [Coordinate Format](#) for more details.

`colind`

Array of length `nnz`.

For one-based indexing, contains the column indices plus one for each non-zero element of the matrix A .

For zero-based indexing, contains the column indices for each non-zero element of the matrix A .

Refer to `columns` array description in [Coordinate Format](#) for more details.

`nnz`

Specifies the number of non-zero element of the matrix A .

Refer to `nnz` description in [Coordinate Format](#) for more details.

`x`

Array, size at least m .

On entry, the array `x` must contain the vector x . The elements are accessed with unit increment.

`y`

Array, size at least m .

On entry, the array `y` must contain the vector y . The elements are accessed with unit increment.

Output Parameters

`y`

Contains solution vector x .

`mkl_?csrmm`

Computes matrix - matrix product of a sparse matrix stored in the CSR format.

Syntax

```
void mkl_scsrmm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const float *alpha , const char *matdescra , const float *val , const
MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntre , const float *b , const
MKL_INT *ldb , const float *beta , float *c , const MKL_INT *ldc );
```

```
void mkl_dcsrmm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const double *alpha , const char *matdescra , const double *val , const
MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntre , const double *b , const
MKL_INT *ldb , const double *beta , double *c , const MKL_INT *ldc );
```

```
void mkl_ccsrmm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const MKL_Complex8 *alpha , const char *matdescra , const MKL_Complex8
*val , const MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntre , const
MKL_Complex8 *b , const MKL_INT *ldb , const MKL_Complex8 *beta , MKL_Complex8 *c ,
const MKL_INT *ldc );
```

```
void mkl_zcsrmm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const MKL_Complex16 *alpha , const char *matdescra , const MKL_Complex16
*val , const MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntre , const
MKL_Complex16 *b , const MKL_INT *ldb , const MKL_Complex16 *beta , MKL_Complex16 *c ,
const MKL_INT *ldc );
```

Include Files

- `mkl.h`

Description

The `mkl_?csrmm` routine performs a matrix-matrix operation defined as

$$C := \alpha * A * B + \beta * C$$

or

$$C := \alpha * A^T * B + \beta * C$$

or

$$C := \alpha * A^H * B + \beta * C,$$

where:

alpha and *beta* are scalars,

B and *C* are dense matrices, *A* is an *m*-by-*k* sparse matrix in compressed sparse row (CSR) format, A^T is the transpose of *A*, and A^H is the conjugate transpose of *A*.

NOTE

This routine supports a CSR format both with one-based indexing and zero-based indexing.

Input Parameters

| | |
|------------------|--|
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then $C := \alpha * A * B + \beta * C$, If <i>transa</i> = 'T' or 't', then $C := \alpha * A^T * B + \beta * C$, If <i>transa</i> = 'C' or 'c', then $C := \alpha * A^H * B + \beta * C$. |
| <i>m</i> | Number of rows of the matrix <i>A</i> . |
| <i>n</i> | Number of columns of the matrix <i>C</i> . |
| <i>k</i> | Number of columns of the matrix <i>A</i> . |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>matdescra</i> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" . |
| <i>val</i> | Array containing non-zero elements of the matrix <i>A</i> . For zero-based indexing its length is $pntrc[m-1] - pntrb[0]$. Refer to <i>values</i> array description in CSR Format for more details. |
| <i>indx</i> | For one-based indexing, array containing the column indices plus one for each non-zero element of the matrix <i>A</i> . |

For zero-based indexing, array containing the column indices for each non-zero element of the matrix A .

Its length is equal to length of the `val` array.

Refer to `columns` array description in [CSR Format](#) for more details.

`pntrb`

Array of length m .

This array contains row indices, such that `pntrb[I] - pntrb[0]` is the first index of row I in the arrays `val` and `indx`.

Refer to `pointerb` array description in [CSR Format](#) for more details.

`pntrE`

Array of length m .

This array contains row indices, such that `pntrE[I] - pntrb[0] - 1` is the last index of row I in the arrays `val` and `indx`.

Refer to `pointerE` array description in [CSR Format](#) for more details.

`b`

Array, size `ldb` by at least n for non-transposed matrix A and at least m for transposed for one-based indexing, and (at least k for non-transposed matrix A and at least m for transposed, `ldb`) for zero-based indexing.

On entry with `transa='N'` or `'n'`, the leading k -by- n part of the array `b` must contain the matrix B , otherwise the leading m -by- n part of the array `b` must contain the matrix B .

`ldb`

Specifies the leading dimension of `b` for one-based indexing, and the second dimension of `b` for zero-based indexing, as declared in the calling (sub)program.

`beta`

Specifies the scalar `beta`.

`c`

Array, size `ldc` by n for one-based indexing, and (m , `ldc`) for zero-based indexing.

On entry, the leading m -by- n part of the array `c` must contain the matrix C , otherwise the leading k -by- n part of the array `c` must contain the matrix C .

`ldc`

Specifies the leading dimension of `c` for one-based indexing, and the second dimension of `c` for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

`c`

Overwritten by the matrix $(\alpha * A * B + \beta * C)$, $(\alpha * A^T * B + \beta * C)$, or $(\alpha * A^H * B + \beta * C)$.

mkl_?bsrmm

Computes matrix - matrix product of a sparse matrix stored in the BSR format.

Syntax

```
void mkl_sbsrmm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const MKL_INT *lb , const float *alpha , const char *matdescra , const
float *val , const MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntre , const
float *b , const MKL_INT *ldb , const float *beta , float *c , const MKL_INT *ldc );

void mkl_dbsrmm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const MKL_INT *lb , const double *alpha , const char *matdescra , const
double *val , const MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntre , const
double *b , const MKL_INT *ldb , const double *beta , double *c , const MKL_INT *ldc );

void mkl_cbsrmm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const MKL_INT *lb , const MKL_Complex8 *alpha , const char *matdescra ,
const MKL_Complex8 *val , const MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT
*pntre , const MKL_Complex8 *b , const MKL_INT *ldb , const MKL_Complex8 *beta ,
MKL_Complex8 *c , const MKL_INT *ldc );

void mkl_zbsrmm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const MKL_INT *lb , const MKL_Complex16 *alpha , const char *matdescra ,
const MKL_Complex16 *val , const MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT
*pntre , const MKL_Complex16 *b , const MKL_INT *ldb , const MKL_Complex16 *beta ,
MKL_Complex16 *c , const MKL_INT *ldc );
```

Include Files

- mkl.h

Description

The `mkl_?bsrmm` routine performs a matrix-matrix operation defined as

```
 $C := \alpha * A * B + \beta * C$ 
```

or

```
 $C := \alpha * A^T * B + \beta * C$ 
```

or

```
 $C := \alpha * A^H * B + \beta * C,$ 
```

where:

alpha and *beta* are scalars,

B and *C* are dense matrices, *A* is an *m*-by-*k* sparse matrix in block sparse row (BSR) format, A^T is the transpose of *A*, and A^H is the conjugate transpose of *A*.

NOTE

This routine supports a BSR format both with one-based indexing and zero-based indexing.

Input Parameters

| | |
|---------------|---|
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-matrix product is computed as $C := \alpha * A * B + \beta * C$ |
|---------------|---|

If $transa = 'T'$ or $'t'$, then the matrix-vector product is computed as
 $C := \alpha * A^T * B + \beta * C$

If $transa = 'C'$ or $'c'$, then the matrix-vector product is computed as
 $C := \alpha * A^H * B + \beta * C,$

| | |
|-------------|--|
| m | Number of block rows of the matrix A . |
| n | Number of columns of the matrix C . |
| k | Number of block columns of the matrix A . |
| lb | Size of the block in the matrix A . |
| α | Specifies the scalar α . |
| $matdescra$ | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter $matdescra$ ($descra$)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter $matdescra$" . |
| val | Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by $lb * lb$. Refer to the $values$ array description in BSR Format for more details. |
| $indx$ | For one-based indexing, array containing the column indices plus one for each non-zero block in the matrix A . For zero-based indexing, array containing the column indices for each non-zero block in the matrix A . Its length is equal to the number of non-zero blocks in the matrix A . Refer to the $columns$ array description in BSR Format for more details. |
| $pntrb$ | Array of length m . This array contains row indices, such that $pntrb[I] - pntrb[0]$ is the first index of block row I in the array $indx$. Refer to $pointerB$ array description in BSR Format for more details. |
| $pntrb$ | Array of length m . This array contains row indices, such that $pntrb[I] - pntrb[0] - 1$ is the last index of block row I in the array $indx$. Refer to $pointerE$ array description in BSR Format for more details. |
| b | Array, size ldb by at least n for non-transposed matrix A and at least m for transposed for one-based indexing, and (at least k for non-transposed matrix A and at least m for transposed, ldb) for zero-based indexing. On entry with $transa='N'$ or $'n'$, the leading n -by- k block part of the array b must contain the matrix B , otherwise the leading m -by- n block part of the array b must contain the matrix B . |
| ldb | Specifies the leading dimension (in blocks) of b as declared in the calling (sub)program. |

| | |
|-------------|--|
| <i>beta</i> | Specifies the scalar <i>beta</i> . |
| <i>c</i> | Array, size $ldc * n$ for one-based indexing, size $k * ldc$ for zero-based indexing. On entry, the leading <i>m</i> -by- <i>n</i> block part of the array <i>c</i> must contain the matrix <i>C</i> , otherwise the leading <i>n</i> -by- <i>k</i> block part of the array <i>c</i> must contain the matrix <i>C</i> . |
| <i>ldc</i> | Specifies the leading dimension (in blocks) of <i>c</i> as declared in the calling (sub)program. |

Output Parameters

| | |
|----------|--|
| <i>c</i> | Overwritten by the matrix $(\alpha * A * B + \beta * C)$ or $(\alpha * A^T * B + \beta * C)$ or $(\alpha * A^H * B + \beta * C)$. |
|----------|--|

mkl_?cscmm

Computes matrix-matrix product of a sparse matrix stored in the CSC format.

Syntax

```
void mkl_scscmm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const float *alpha , const char *matdescra , const float *val , const
MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntre , const float *b , const
MKL_INT *ldb , const float *beta , float *c , const MKL_INT *ldc );
```

```
void mkl_dcscmm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const double *alpha , const char *matdescra , const double *val , const
MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntre , const double *b , const
MKL_INT *ldb , const double *beta , double *c , const MKL_INT *ldc );
```

```
void mkl_ccscmm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const MKL_Complex8 *alpha , const char *matdescra , const MKL_Complex8
*val , const MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntre , const
MKL_Complex8 *b , const MKL_INT *ldb , const MKL_Complex8 *beta , MKL_Complex8 *c ,
const MKL_INT *ldc );
```

```
void mkl_zcscmm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const MKL_Complex16 *alpha , const char *matdescra , const MKL_Complex16
*val , const MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntre , const
MKL_Complex16 *b , const MKL_INT *ldb , const MKL_Complex16 *beta , MKL_Complex16 *c ,
const MKL_INT *ldc );
```

Include Files

- mkl.h

Description

The `mkl_?cscmm` routine performs a matrix-matrix operation defined as

```
C :=  $\alpha * A * B + \beta * C$ 
```

or

```
C :=  $\alpha * A^T * B + \beta * C$ ,
```

or

$$C := \alpha * A^H * B + \beta * C,$$

where:

α and β are scalars,

B and C are dense matrices, A is an m -by- k sparse matrix in compressed sparse column (CSC) format, A^T is the transpose of A , and A^H is the conjugate transpose of A .

NOTE

This routine supports CSC format both with one-based indexing and zero-based indexing.

Input Parameters

| | |
|------------------|--|
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then $C := \alpha * A * B + \beta * C$ If <i>transa</i> = 'T' or 't', then $C := \alpha * A^T * B + \beta * C$, If <i>transa</i> = 'C' or 'c', then $C := \alpha * A^H * B + \beta * C$ |
| <i>m</i> | Number of rows of the matrix A . |
| <i>n</i> | Number of columns of the matrix C . |
| <i>k</i> | Number of columns of the matrix A . |
| <i>alpha</i> | Specifies the scalar α . |
| <i>matdescra</i> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" . |
| <i>val</i> | Array containing non-zero elements of the matrix A . Its length is $pntrb[k-1] - pntrb[0]$. Refer to <i>values</i> array description in CSC Format for more details. |
| <i>indx</i> | For one-based indexing, array containing the row indices plus one for each non-zero element of the matrix A . For zero-based indexing, array containing the column indices for each non-zero element of the matrix A . Its length is equal to length of the <i>val</i> array. Refer to <i>rows</i> array description in CSC Format for more details. |
| <i>pntrb</i> | Array of length k . This array contains column indices, such that $pntrb[i] - pntrb[0]$ is the first index of column i in the arrays <i>val</i> and <i>indx</i> . Refer to <i>pointerb</i> array description in CSC Format for more details. |
| <i>pntrc</i> | Array of length k . |

This array contains column indices, such that $pntre[i] - pntxb[0] - 1$ is the last index of column i in the arrays val and $indx$.

Refer to *pointerE* array description in [CSC Format](#) for more details.

| | |
|-------------|---|
| <i>b</i> | <p>Array, size ldb by at least n for non-transposed matrix A and at least m for transposed for one-based indexing, and (at least k for non-transposed matrix A and at least m for transposed, ldb) for zero-based indexing.</p> <p>On entry with $transa = 'N'$ or $'n'$, the leading k-by-n part of the array b must contain the matrix B, otherwise the leading m-by-n part of the array b must contain the matrix B.</p> |
| <i>ldb</i> | <p>Specifies the leading dimension of b for one-based indexing, and the second dimension of b for zero-based indexing, as declared in the calling (sub)program.</p> |
| <i>beta</i> | <p>Specifies the scalar $beta$.</p> |
| <i>c</i> | <p>Array, size ldc by n for one-based indexing, and (m, ldc) for zero-based indexing.</p> <p>On entry, the leading m-by-n part of the array c must contain the matrix C, otherwise the leading k-by-n part of the array c must contain the matrix C.</p> |
| <i>ldc</i> | <p>Specifies the leading dimension of c for one-based indexing, and the second dimension of c for zero-based indexing, as declared in the calling (sub)program.</p> |

Output Parameters

| | |
|----------|---|
| <i>c</i> | <p>Overwritten by the matrix $(alpha * A * B + beta * C)$ or $(alpha * A^T * B + beta * C)$ or $(alpha * A^H * B + beta * C)$.</p> |
|----------|---|

mkl_?coomm

Computes matrix-matrix product of a sparse matrix stored in the coordinate format.

Syntax

```
void mkl_scoomm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const float *alpha , const char *matdescra , const float *val , const
MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const float *b , const
MKL_INT *ldb , const float *beta , float *c , const MKL_INT *ldc );

void mkl_dcoomm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const double *alpha , const char *matdescra , const double *val , const
MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const double *b , const
MKL_INT *ldb , const double *beta , double *c , const MKL_INT *ldc );

void mkl_ccoomm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const MKL_Complex8 *alpha , const char *matdescra , const MKL_Complex8
*val , const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const
MKL_Complex8 *b , const MKL_INT *ldb , const MKL_Complex8 *beta , MKL_Complex8 *c ,
const MKL_INT *ldc );
```

```
void mkl_zcoomm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const MKL_Complex16 *alpha , const char *matdescra , const MKL_Complex16
*val , const MKL_INT *rowind , const MKL_INT *colind , const MKL_INT *nnz , const
MKL_Complex16 *b , const MKL_INT *ldb , const MKL_Complex16 *beta , MKL_Complex16 *c ,
const MKL_INT *ldc );
```

Include Files

Description

The `mkl_?coomm` routine performs a matrix-matrix operation defined as

$$C := \alpha * A * B + \beta * C$$

or

$$C := \alpha * A^T * B + \beta * C,$$

or

$$C := \alpha * A^H * B + \beta * C,$$

where:

alpha and *beta* are scalars,

B and *C* are dense matrices, *A* is an *m*-by-*k* sparse matrix in the coordinate format, A^T is the transpose of *A*, and A^H is the conjugate transpose of *A*.

NOTE

This routine supports a coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

| | |
|------------------|--|
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then $C := \alpha * A * B + \beta * C$ If <i>transa</i> = 'T' or 't', then $C := \alpha * A^T * B + \beta * C,$ If <i>transa</i> = 'C' or 'c', then $C := \alpha * A^H * B + \beta * C.$ |
| <i>m</i> | Number of rows of the matrix <i>A</i> . |
| <i>n</i> | Number of columns of the matrix <i>C</i> . |
| <i>k</i> | Number of columns of the matrix <i>A</i> . |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>matdescra</i> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" . |
| <i>val</i> | Array of length <i>nnz</i> , contains non-zero elements of the matrix <i>A</i> in the arbitrary order. |

| | |
|---------------|--|
| | Refer to <i>values</i> array description in Coordinate Format for more details. |
| <i>rowind</i> | <p>Array of length <i>nnz</i>.</p> <p>For one-based indexing, contains the row indices plus one for each non-zero element of the matrix <i>A</i>.</p> <p>For zero-based indexing, contains the row indices for each non-zero element of the matrix <i>A</i>.</p> <p>Refer to <i>rows</i> array description in Coordinate Format for more details.</p> |

MKL_INT *ldb , MKL_Complex16 *c , const MKL_INT *ldc );
```

Include Files

- mkl.h

Description

The `mkl_?csrsm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the CSR format:

$$C := \alpha \operatorname{inv}(A) * B$$

or

$$C := \alpha \operatorname{inv}(A^T) * B,$$

where:

α is scalar, B and C are dense matrices, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A^T is the transpose of A .

NOTE

This routine supports a CSR format both with one-based indexing and zero-based indexing.

Input Parameters

| | |
|---------------|--|
| <i>transa</i> | Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $C := \alpha \operatorname{inv}(A) * B$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha \operatorname{inv}(A^T) * B,$ |
| <i>m</i> | Number of columns of the matrix A . |
| <i>n</i> | Number of columns of the matrix C . |
| <i>alpha</i> | Specifies the scalar α . |

| | |
|------------------|---|
| <i>matdescra</i> | <p>Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>".</p> |
| <i>val</i> | <p>Array containing non-zero elements of the matrix <i>A</i>. For zero-based indexing its length is $pntrb[m-1] - pntrb[0]$. Refer to <i>values</i> array description in CSR Format for more details.</p> <hr/> <p>NOTE The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right). No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.</p> <hr/> |
| <i>indx</i> | <p>For one-based indexing, array containing the column indices plus one for each non-zero element of the matrix <i>A</i>. For zero-based indexing, array containing the column indices for each non-zero element of the matrix <i>A</i>. Its length is equal to length of the <i>val</i> array. Refer to <i>columns</i> array description in CSR Format for more details.</p> <hr/> <p>NOTE Column indices must be sorted in increasing order for each row.</p> <hr/> |
| <i>pntrb</i> | <p>Array of length <i>m</i>. This array contains row indices, such that $pntrb[i] - pntrb[0]$ is the first index of row <i>i</i> in the arrays <i>val</i> and <i>indx</i>. Refer to <i>pointerb</i> array description in CSR Format for more details.</p> |
| <i>pntrE</i> | <p>Array of length <i>m</i>. For zero-based indexing this array contains row indices, such that $pntrE[i] - pntrb[0] - 1$ is the last index of row <i>i</i> in the arrays <i>val</i> and <i>indx</i>. Refer to <i>pointerE</i> array description in CSR Format for more details.</p> |
| <i>b</i> | <p>Array, size $ldb * n$ for one-based indexing, and (m, ldb) for zero-based indexing. On entry the leading <i>m</i>-by-<i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i>.</p> |
| <i>ldb</i> | <p>Specifies the leading dimension of <i>b</i> for one-based indexing, and the second dimension of <i>b</i> for zero-based indexing, as declared in the calling (sub)program.</p> |

ldc Specifies the leading dimension of *c* for one-based indexing, and the second dimension of *c* for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

c Array, size *ldc* by *n* for one-based indexing, and (*m*, *ldc*) for zero-based indexing.
The leading *m*-by-*n* part of the array *c* contains the output matrix *C*.

mkl_?cscsm

Solves a system of linear matrix equations for a sparse matrix in the CSC format.

Syntax

```
void mkl_scscsm (const char *transa , const MKL_INT *m , const MKL_INT *n , const float
*alpha , const char *matdescra , const float *val , const MKL_INT *indx , const MKL_INT
*pntrb , const MKL_INT *pntre , const float *b , const MKL_INT *ldb , float *c , const
MKL_INT *ldc );
```

```
void mkl_dcscsm (const char *transa , const MKL_INT *m , const MKL_INT *n , const

Description

The `mkl_?cscsm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the CSC format:

```
 $C := \alpha \text{inv}(A) * B$ 
```

or

```
 $C := \alpha \text{inv}(A^T) * B,$ 
```

where:

alpha is scalar, *B* and *C* are dense matrices, *A* is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A^T is the transpose of *A*.

NOTE

This routine supports a CSC format both with one-based indexing and zero-based indexing.

Input Parameters

| | |
|------------------|--|
| <i>transa</i> | Specifies the system of equations. If <i>transa</i> = 'N' or 'n', then $C := \alpha * \text{inv}(A) * B$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha * \text{inv}(A^T) * B$, |
| <i>m</i> | Number of columns of the matrix A. |
| <i>n</i> | Number of columns of the matrix C. |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>matdescra</i> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" . |
| <i>val</i> | Array containing non-zero elements of the matrix A. For zero-based indexing its length is $\text{pntrb}[m] - \text{pntrb}[0]$. Refer to <i>values</i> array description in CSC Format for more details. |

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

| | |
|-------------|---|
| <i>indx</i> | For one-based indexing, array containing the row indices plus one for each non-zero element of the matrix A. For zero-based indexing, array containing the row indices for each non-zero element of the matrix A. Refer to <i>rows</i> array description in CSC Format for more details. |
|-------------|---|

NOTE

Row indices must be sorted in increasing order for each column.

| | |
|--------------|--|
| <i>pntrb</i> | Array of length <i>m</i> . This array contains column indices, such that $\text{pntrb}[I] - \text{pntrb}[0]$ is the first index of column <i>I</i> in the arrays <i>val</i> and <i>indx</i> . Refer to <i>pointerb</i> array description in CSC Format for more details. |
| <i>pntrc</i> | Array of length <i>m</i> . This array contains column indices, such that $\text{pntrc}[I] - \text{pntrb}[1] - 1$ is the last index of column <i>I</i> in the arrays <i>val</i> and <i>indx</i> . |

Refer to *pointerE* array description in [CSC Format](#) for more details.

| | |
|------------|--|
| <i>b</i> | Array, size <i>ldb</i> by <i>n</i> for one-based indexing, and (<i>m</i> , <i>ldb</i>) for zero-based indexing. On entry the leading <i>m</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> . |
| <i>ldb</i> | Specifies the leading dimension of <i>b</i> for one-based indexing, and the second dimension of <i>b</i> for zero-based indexing, as declared in the calling (sub)program. |
| <i>ldc</i> | Specifies the leading dimension of <i>c</i> for one-based indexing, and the second dimension of <i>c</i> for zero-based indexing, as declared in the calling (sub)program. |

Output Parameters

| | |
|----------|--|
| <i>c</i> | Array, size <i>ldc</i> by <i>n</i> for one-based indexing, and (<i>m</i> , <i>ldc</i>) for zero-based indexing. The leading <i>m</i> -by- <i>n</i> part of the array <i>c</i> contains the output matrix <i>C</i> . |
|----------|--|

mkl_?coosm

Solves a system of linear matrix equations for a sparse matrix in the coordinate format.

Syntax

```
void mkl_scoosm (const char *transa , const MKL_INT *m , const MKL_INT *n , const float
*alpha , const char *matdescra , const float *val , const MKL_INT *rowind , const
MKL_INT *colind , const MKL_INT *nnz , const float *b , const MKL_INT *ldb , float
*c , const MKL_INT *ldc );
```

```
void mkl_dcoosm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
double *alpha , const char *matdescra , const double *val , const MKL_INT *rowind ,
const MKL_INT *colind , const MKL_INT *nnz , const double *b , const MKL_INT *ldb ,
double *c , const MKL_INT *ldc );
```

```
void mkl_ccoosm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_Complex8 *alpha , const char *matdescra , const MKL_Complex8 *val , const MKL_INT
*rowind , const MKL_INT *colind , const MKL_INT *nnz , const MKL_Complex8 *b , const
MKL_INT *ldb , MKL_Complex8 *c , const MKL_INT *ldc );
```

```
void mkl_zcoosm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_Complex16 *alpha , const char *matdescra , const MKL_Complex16 *val , const MKL_INT
*rowind , const MKL_INT *colind , const MKL_INT *nnz , const MKL_Complex16 *b , const
MKL_INT *ldb , MKL_Complex16 *c , const MKL_INT *ldc );
```

Include Files

Description

The `mkl_?coosm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the coordinate format:

```
C := alpha*inv(A)*B
```

or

```
C := alpha*inv(AT)*B,
```

where:

alpha is scalar, *B* and *C* are dense matrices, *A* is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, *A*^T is the transpose of *A*.

NOTE

This routine supports a coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

| | |
|------------------|---|
| <i>transa</i> | <p>Specifies the system of linear equations.</p> <p>If <i>transa</i> = 'N' or 'n', then the matrix-matrix product is computed as $C := \text{alpha} * \text{inv}(A) * B$</p> <p>If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $C := \text{alpha} * \text{inv}(A^T) * B$,</p> |
| <i>m</i> | Number of rows of the matrix <i>A</i> . |
| <i>n</i> | Number of columns of the matrix <i>C</i> . |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>matdescra</i> | <p>Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)". Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>".</p> |
| <i>val</i> | <p>Array of length <i>nnz</i>, contains non-zero elements of the matrix <i>A</i> in the arbitrary order.</p> <p>Refer to <i>values</i> array description in Coordinate Format for more details.</p> |
| <i>rowind</i> | <p>Array of length <i>nnz</i>.</p> <p>For one-based indexing, contains the row indices plus one for each non-zero element of the matrix <i>A</i>.</p> <p>For zero-based indexing, contains the row indices for each non-zero element of the matrix <i>A</i>.</p> <p>Refer to <i>rows</i> array description in Coordinate Format for more details.</p> |
| <i>colind</i> | <p>Array of length <i>nnz</i>.</p> <p>For one-based indexing, contains the column indices plus one for each non-zero element of the matrix <i>A</i></p> <p>For zero-based indexing, contains the row indices for each non-zero element of the matrix <i>A</i></p> <p>Refer to <i>columns</i> array description in Coordinate Format for more details.</p> |
| <i>nnz</i> | Specifies the number of non-zero element of the matrix <i>A</i> . |

Refer to *nnz* description in [Coordinate Format](#) for more details.

| | |
|------------|---|
| <i>b</i> | <p>Array, size <i>ldb</i> by <i>n</i> for one-based indexing, and (<i>m</i>, <i>ldb</i>) for zero-based indexing.</p> <p>Before entry the leading <i>m</i>-by-<i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i>.</p> |
| <i>ldb</i> | <p>Specifies the leading dimension of <i>b</i> for one-based indexing, and the second dimension of <i>b</i> for zero-based indexing, as declared in the calling (sub)program.</p> |
| <i>ldc</i> | <p>Specifies the leading dimension of <i>c</i> for one-based indexing, and the second dimension of <i>c</i> for zero-based indexing, as declared in the calling (sub)program.</p> |

Output Parameters

| | |
|----------|---|
| <i>c</i> | <p>Array, size <i>ldc</i> by <i>n</i> for one-based indexing, and (<i>m</i>, <i>ldc</i>) for zero-based indexing.</p> <p>The leading <i>m</i>-by-<i>n</i> part of the array <i>c</i> contains the output matrix <i>C</i>.</p> |
|----------|---|

mkl_?bsrsm

Solves a system of linear matrix equations for a sparse matrix in the BSR format.

Syntax

```
void mkl_sbsrsm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *lb , const float *alpha , const char *matdescra , const float *val , const
MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntre , const float *b , const
MKL_INT *ldb , float *c , const MKL_INT *ldc );
```

```
void mkl_dbsrsm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *lb , const double *alpha , const char *matdescra , const double *val , const
MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntre , const double *b , const
MKL_INT *ldb , double *c , const MKL_INT *ldc );
```

```
void mkl_cbsrsm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *lb , const MKL_Complex8 *alpha , const char *matdescra , const MKL_Complex8
*val , const MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntre , const
MKL_Complex8 *b , const MKL_INT *ldb , MKL_Complex8 *c , const MKL_INT *ldc );
```

```
void mkl_zbsrsm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *lb , const MKL_Complex16 *alpha , const char *matdescra , const MKL_Complex16
*val , const MKL_INT *indx , const MKL_INT *pntrb , const MKL_INT *pntre , const
MKL_Complex16 *b , const MKL_INT *ldb , MKL_Complex16 *c , const MKL_INT *ldc );
```

Include Files

- mkl.h

Description

The `mkl_?bsrsm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the BSR format:

$$C := \alpha * \text{inv}(A) * B$$

or

$$C := \alpha * \text{inv}(A^T) * B,$$

where:

α is scalar, B and C are dense matrices, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A^T is the transpose of A .

NOTE

This routine supports a BSR format both with one-based indexing and zero-based indexing.

Input Parameters

| | |
|------------------|--|
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-matrix product is computed as $C := \alpha * \text{inv}(A) * B$. If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $C := \alpha * \text{inv}(A^T) * B$. |
| <i>m</i> | Number of block columns of the matrix A . |
| <i>n</i> | Number of columns of the matrix C . |
| <i>lb</i> | Size of the block in the matrix A . |
| <i>alpha</i> | Specifies the scalar α . |
| <i>matdescra</i> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" . |
| <i>val</i> | Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by $lb * lb$. Refer to the <i>values</i> array description in BSR Format for more details. |

NOTE

The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

| | |
|-------------|---|
| <i>indx</i> | For one-based indexing, array containing the column indices plus one for each non-zero element of the matrix A . For zero-based indexing, array containing the column indices for each non-zero element of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A . |
|-------------|---|

| | |
|--------------|---|
| | Refer to the <i>columns</i> array description in BSR Format for more details. |
| <i>pntrb</i> | <p>Array of length <i>m</i>.</p> <p>This array contains row indices, such that <i>pntrb[i] - pntrb[0]</i> is the first index of block row <i>i</i> in the array <i>indx</i>.</p> <p>Refer to <i>pointerB</i> array description in BSR Format for more details.</p> |
| <i>pntrE</i> | <p>Array of length <i>m</i>.</p> <p>This array contains row indices, such that <i>pntrE[i] - pntrb[0] - 1</i> is the last index of block row <i>i</i> in the arrays <i>val</i> and <i>indx</i>.</p> <p>Refer to <i>pointerE</i> array description in BSR Format for more details.</p> |
| <i>b</i> | <p>Array, size <i>ldb* n</i> for one-based indexing, size <i>m* ldb</i> for zero-based indexing.</p> <p>On entry the leading <i>m-by-n</i> part of the array <i>b</i> must contain the matrix <i>B</i>.</p> |
| <i>ldb</i> | Specifies the leading dimension (in blocks) of <i>b</i> as declared in the calling (sub)program. |
| <i>ldc</i> | Specifies the leading dimension (in blocks) of <i>c</i> as declared in the calling (sub)program. |

Output Parameters

| | |
|----------|---|
| <i>c</i> | <p>Array, size <i>ldc* n</i> for one-based indexing, size <i>m* ldc</i> for zero-based indexing.</p> <p>The leading <i>m-by-n</i> part of the array <i>c</i> contains the output matrix <i>C</i>.</p> |
|----------|---|

mkl_?diamv

Computes matrix - vector product for a sparse matrix in the diagonal format with one-based indexing.

Syntax

```
void mkl_sdiamv (const char *transa , const MKL_INT *m , const MKL_INT *k , const float
*alpha , const char *matdescra , const float *val , const MKL_INT *lval , const MKL_INT
*idiag , const MKL_INT *ndiag , const float *x , const float *beta , float *y );

void mkl_ddiamv (const char *transa , const MKL_INT *m , const MKL_INT *k , const
double *alpha , const char *matdescra , const double *val , const MKL_INT *lval , const
MKL_INT *idiag , const MKL_INT *ndiag , const double *x , const double *beta , double
*y );

void mkl_cdiamv (const char *transa , const MKL_INT *m , const MKL_INT *k , const
MKL_Complex8 *alpha , const char *matdescra , const MKL_Complex8 *val , const MKL_INT
*lval , const MKL_INT *idiag , const MKL_INT *ndiag , const MKL_Complex8 *x , const
MKL_Complex8 *beta , MKL_Complex8 *y );

void mkl_zdiamv (const char *transa , const MKL_INT *m , const MKL_INT *k , const
MKL_Complex16 *alpha , const char *matdescra , const MKL_Complex16 *val , const MKL_INT
*lval , const MKL_INT *idiag , const MKL_INT *ndiag , const MKL_Complex16 *x , const
MKL_Complex16 *beta , MKL_Complex16 *y );
```

Include Files

- `mkl.h`

Description

The `mkl_?diamv` routine performs a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y$$

or

$$y := \alpha * A^T * x + \beta * y,$$

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*k* sparse matrix stored in the diagonal format, A^T is the transpose of *A*.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

| | |
|------------------|--|
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha * A * x + \beta * y$, If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha * A^T * x + \beta * y$. |
| <i>m</i> | Number of rows of the matrix <i>A</i> . |
| <i>k</i> | Number of columns of the matrix <i>A</i> . |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>matdescra</i> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" . |
| <i>val</i> | Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix <i>A</i> . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details. |
| <i>lval</i> | Leading dimension of <i>val</i> , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details. |
| <i>idiag</i> | Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix <i>A</i> . Refer to <i>distance</i> array description in Diagonal Storage Scheme for more details. |
| <i>ndiag</i> | Specifies the number of non-zero diagonals of the matrix <i>A</i> . |

| | |
|--------|---|
| x | Array, size at least k if $transa = 'N'$ or $'n'$, and at least m otherwise. On entry, the array x must contain the vector x . |
| $beta$ | Specifies the scalar $beta$. |
| y | Array, size at least m if $transa = 'N'$ or $'n'$, and at least k otherwise. On entry, the array y must contain the vector y . |

Output Parameters

| | |
|-----|---|
| y | Overwritten by the updated vector y . |
|-----|---|

mkl_?skymv

Computes matrix - vector product for a sparse matrix in the skyline storage format with one-based indexing.

Syntax

```
void mkl_sskymv (const char *transa , const MKL_INT *m , const MKL_INT *k , const float *alpha , const char *matdescra , const float *val , const MKL_INT *pntr , const float *x , const float *beta , float *y );
```

```
void mkl_dskymv (const char *transa , const MKL_INT *m , const MKL_INT *k , const double *alpha , const char *matdescra , const double *val , const MKL_INT *pntr , const double *x , const double *beta , double *y );
```

```
void mkl_cskymv (const char *transa , const MKL_INT *m , const MKL_INT *k , const MKL_Complex8 *alpha , const char *matdescra , const MKL_Complex8 *val , const MKL_INT *pntr , const MKL_Complex8 *x , const MKL_Complex8 *beta , MKL_Complex8 *y );
```

```
void mkl_zskymv (const char *transa , const MKL_INT *m , const MKL_INT *k , const MKL_Complex16 *alpha , const char *matdescra , const MKL_Complex16 *val , const MKL_INT *pntr , const MKL_Complex16 *x , const MKL_Complex16 *beta , MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_?skymv` routine performs a matrix-vector operation defined as

```
 $y := alpha * A * x + beta * y$ 
```

or

```
 $y := alpha * A^T * x + beta * y,$ 
```

where:

$alpha$ and $beta$ are scalars,

x and y are vectors,

A is an m -by- k sparse matrix stored using the skyline storage scheme, A^T is the transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

| | |
|------------------|--|
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha * A * x + \beta * y$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha * A^T * x + \beta * y$, |
| <i>m</i> | Number of rows of the matrix <i>A</i> . |
| <i>k</i> | Number of columns of the matrix <i>A</i> . |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>matdescra</i> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" . |

NOTE

General matrices (*matdescra*[0]='G') is not supported.

| | |
|-------------|--|
| <i>val</i> | Array containing the set of elements of the matrix <i>A</i> in the skyline profile form. If <i>matdescrsa</i> [1]= 'L', then <i>val</i> contains elements from the low triangle of the matrix <i>A</i> . If <i>matdescrsa</i> [1]= 'U', then <i>val</i> contains elements from the upper triangle of the matrix <i>A</i> . Refer to <i>values</i> array description in Skyline Storage Scheme for more details. |
| <i>pntr</i> | Array of length (<i>m</i> + 1) for lower triangle, and (<i>k</i> + 1) for upper triangle. It contains the indices specifying in the <i>val</i> the positions of the first element in each row (column) of the matrix <i>A</i> . Refer to <i>pointers</i> array description in Skyline Storage Scheme for more details. |
| <i>x</i> | Array, size at least <i>k</i> if <i>transa</i> = 'N' or 'n' and at least <i>m</i> otherwise. On entry, the array <i>x</i> must contain the vector <i>x</i> . |
| <i>beta</i> | Specifies the scalar <i>beta</i> . |
| <i>y</i> | Array, size at least <i>m</i> if <i>transa</i> = 'N' or 'n' and at least <i>k</i> otherwise. On entry, the array <i>y</i> must contain the vector <i>y</i> . |

Output Parameters

| | |
|----------|--|
| <i>y</i> | Overwritten by the updated vector <i>y</i> . |
|----------|--|

mkl_?diasv

Solves a system of linear equations for a sparse matrix in the diagonal format with one-based indexing.

Syntax

```
void mkl_sdiasv (const char *transa , const MKL_INT *m , const float *alpha , const
char *matdescra , const float *val , const MKL_INT *lval , const MKL_INT *idiag , const
MKL_INT *ndiag , const float *x , float *y );
```

```
void mkl_ddiasv (const char *transa , const MKL_INT *m , const double *alpha , const
char *matdescra , const double *val , const MKL_INT *lval , const MKL_INT *idiag ,
const MKL_INT *ndiag , const double *x , double *y );
```

```
void mkl_cdiasv (const char *transa , const MKL_INT *m , const MKL_Complex8 *alpha ,
const char *matdescra , const MKL_Complex8 *val , const MKL_INT *lval , const MKL_INT
*idiag , const MKL_INT *ndiag , const MKL_Complex8 *x , MKL_Complex8 *y );
```

```
void mkl_zdiasv (const char *transa , const MKL_INT *m , const MKL_Complex16 *alpha ,
const char *matdescra , const MKL_Complex16 *val , const MKL_INT *lval , const MKL_INT
*idiag , const MKL_INT *ndiag , const MKL_Complex16 *x , MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_?diasv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the diagonal format:

```
 $y := \alpha \text{inv}(A) * x$ 
```

or

```
 $y := \alpha \text{inv}(A^T) * x,$ 
```

where:

α is scalar, x and y are vectors, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A^T is the transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

| | |
|---------------|--|
| <i>transa</i> | Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $y := \alpha \text{inv}(A) * x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha \text{inv}(A^T) * x,$ |
| <i>m</i> | Number of rows of the matrix A . |
| <i>alpha</i> | Specifies the scalar α . |

| | |
|------------------|--|
| <i>matdescra</i> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table “Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)” . Possible combinations of element values of this parameter are given in Table “Possible Combinations of Element Values of the Parameter <i>matdescra</i>” . |
| <i>val</i> | Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix <i>A</i> . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details. |
| <i>lval</i> | Leading dimension of <i>val</i> , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details. |
| <i>idiag</i> | Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix <i>A</i> . |

NOTE

All elements of this array must be sorted in increasing order.

Refer to *distance* array description in [Diagonal Storage Scheme](#) for more details.

| | |
|--------------|---|
| <i>ndiag</i> | Specifies the number of non-zero diagonals of the matrix <i>A</i> . |
| <i>x</i> | Array, size at least <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> . The elements are accessed with unit increment. |
| <i>y</i> | Array, size at least <i>m</i> . On entry, the array <i>y</i> must contain the vector <i>y</i> . The elements are accessed with unit increment. |

Output Parameters

| | |
|----------|-------------------------------------|
| <i>y</i> | Contains solution vector <i>x</i> . |
|----------|-------------------------------------|

mkl_?skysv

Solves a system of linear equations for a sparse matrix in the skyline format with one-based indexing.

Syntax

```
void mkl_sskysv (const char *transa , const MKL_INT *m , const float *alpha , const
char *matdescra , const float *val , const MKL_INT *pntr , const float *x , float *y );
void mkl_dskysv (const char *transa , const MKL_INT *m , const double *alpha , const
char *matdescra , const double *val , const MKL_INT *pntr , const double *x , double
*y );
void mkl_cskysv (const char *transa , const MKL_INT *m , const MKL_Complex8 *alpha ,
const char *matdescra , const MKL_Complex8 *val , const MKL_INT *pntr , const
MKL_Complex8 *x , MKL_Complex8 *y );
```

```
void mkl_zskysv (const char *transa , const MKL_INT *m , const MKL_Complex16 *alpha ,
const char *matdescra , const MKL_Complex16 *val , const MKL_INT *pntr , const
MKL_Complex16 *x , MKL_Complex16 *y );
```

Include Files

- mkl.h

Description

The `mkl_?skysv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the skyline storage format:

```
 $y := \alpha \text{inv}(A) * x$ 
```

or

```
 $y := \alpha \text{inv}(A^T) * x,$ 
```

where:

α is scalar, x and y are vectors, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A^T is the transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

| | |
|------------------|--|
| <i>transa</i> | Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $y := \alpha \text{inv}(A) * x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha \text{inv}(A^T) * x,$ |
| <i>m</i> | Number of rows of the matrix A . |
| <i>alpha</i> | Specifies the scalar α . |
| <i>matdescra</i> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" . |

NOTE

General matrices (*matdescra*[0]='G') is not supported.

| | |
|------------|---|
| <i>val</i> | Array containing the set of elements of the matrix A in the skyline profile form. If <i>matdescra</i> [2]= 'L', then <i>val</i> contains elements from the low triangle of the matrix A . If <i>matdescsa</i> [2]= 'U', then <i>val</i> contains elements from the upper triangle of the matrix A . |
|------------|---|

Refer to *values* array description in [Skyline Storage Scheme](#) for more details.

| | |
|-------------|--|
| <i>pntr</i> | <p>Array of length $(m + 1)$ for lower triangle, and $(k + 1)$ for upper triangle.</p> <p>It contains the indices specifying in the <i>val</i> the positions of the first element in each row (column) of the matrix A. Refer to <i>pointers</i> array description in Skyline Storage Scheme for more details.</p> |
| <i>x</i> | <p>Array, size at least <i>m</i>.</p> <p>On entry, the array <i>x</i> must contain the vector <i>x</i>. The elements are accessed with unit increment.</p> |
| <i>y</i> | <p>Array, size at least <i>m</i>.</p> <p>On entry, the array <i>y</i> must contain the vector <i>y</i>. The elements are accessed with unit increment.</p> |

Output Parameters

| | |
|----------|-------------------------------------|
| <i>y</i> | Contains solution vector <i>x</i> . |
|----------|-------------------------------------|

mkl_?diamm

Computes matrix-matrix product of a sparse matrix stored in the diagonal format with one-based indexing.

Syntax

```
void mkl_sdiamm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const float *alpha , const char *matdescra , const float *val , const
MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const float *b , const
MKL_INT *ldb , const float *beta , float *c , const MKL_INT *ldc );
```

```
void mkl_ddiamm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const double *alpha , const char *matdescra , const double *val , const
MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const double *b , const
MKL_INT *ldb , const double *beta , double *c , const MKL_INT *ldc );
```

```
void mkl_cdiamm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const MKL_Complex8 *alpha , const char *matdescra , const MKL_Complex8
*val , const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const
MKL_Complex8 *b , const MKL_INT *ldb , const MKL_Complex8 *beta , MKL_Complex8 *c ,
const MKL_INT *ldc );
```

```
void mkl_zdiamm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const MKL_Complex16 *alpha , const char *matdescra , const MKL_Complex16
*val , const MKL_INT *lval , const MKL_INT *idiag , const MKL_INT *ndiag , const
MKL_Complex16 *b , const MKL_INT *ldb , const MKL_Complex16 *beta , MKL_Complex16 *c ,
const MKL_INT *ldc );
```

Include Files

Description

The `mkl_?diamm` routine performs a matrix-matrix operation defined as

$$C := \alpha * A * B + \beta * C$$

or

$$C := \alpha * A^T * B + \beta * C,$$

or

$$C := \alpha * A^H * B + \beta * C,$$

where:

α and β are scalars,

B and C are dense matrices, A is an m -by- k sparse matrix in the diagonal format, A^T is the transpose of A , and A^H is the conjugate transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

| | |
|------------------|--|
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then $C := \alpha * A * B + \beta * C$, If <i>transa</i> = 'T' or 't', then $C := \alpha * A^T * B + \beta * C$, If <i>transa</i> = 'C' or 'c', then $C := \alpha * A^H * B + \beta * C$. |
| <i>m</i> | Number of rows of the matrix A . |
| <i>n</i> | Number of columns of the matrix C . |
| <i>k</i> | Number of columns of the matrix A . |
| <i>alpha</i> | Specifies the scalar α . |
| <i>matdescra</i> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" . |
| <i>val</i> | Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix A . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details. |
| <i>lval</i> | Leading dimension of <i>val</i> , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details. |
| <i>idiag</i> | Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix A . Refer to <i>distance</i> array description in Diagonal Storage Scheme for more details. |
| <i>ndiag</i> | Specifies the number of non-zero diagonals of the matrix A . |

| | |
|-------------|--|
| <i>b</i> | Array, size $ldb * n$. On entry with <i>transa</i> = 'N' or 'n', the leading k -by- n part of the array <i>b</i> must contain the matrix <i>B</i> , otherwise the leading m -by- n part of the array <i>b</i> must contain the matrix <i>B</i> . |
| <i>ldb</i> | Specifies the leading dimension of <i>b</i> as declared in the calling (sub)program. |
| <i>beta</i> | Specifies the scalar <i>beta</i> . |
| <i>c</i> | Array, size ldc by n . On entry, the leading m -by- n part of the array <i>c</i> must contain the matrix <i>C</i> , otherwise the leading k -by- n part of the array <i>c</i> must contain the matrix <i>C</i> . |
| <i>ldc</i> | Specifies the leading dimension of <i>c</i> as declared in the calling (sub)program. |

Output Parameters

| | |
|----------|---|
| <i>c</i> | Overwritten by the matrix $(\alpha * A * B + \beta * C)$, $(\alpha * A^T * B + \beta * C)$, or $(\alpha * A^H * B + \beta * C)$. |
|----------|---|

mkl_?skymm

Computes matrix-matrix product of a sparse matrix stored using the skyline storage scheme with one-based indexing.

Syntax

```
void mkl_sskymm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const float *alpha , const char *matdescra , const float *val , const
MKL_INT *pntr , const float *b , const MKL_INT *ldb , const float *beta , float *c ,
const MKL_INT *ldc );
```

```
void mkl_dskymm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const double *alpha , const char *matdescra , const double *val , const
MKL_INT *pntr , const double *b , const MKL_INT *ldb , const double *beta , double
*c , const MKL_INT *ldc );
```

```
void mkl_cskymm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const MKL_Complex8 *alpha , const char *matdescra , const MKL_Complex8
*val , const MKL_INT *pntr , const MKL_Complex8 *b , const MKL_INT *ldb , const
MKL_Complex8 *beta , MKL_Complex8 *c , const MKL_INT *ldc );
```

```
void mkl_zskymm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , const MKL_Complex16 *alpha , const char *matdescra , const MKL_Complex16
*val , const MKL_INT *pntr , const MKL_Complex16 *b , const MKL_INT *ldb , const
MKL_Complex16 *beta , MKL_Complex16 *c , const MKL_INT *ldc );
```

Description

The `mkl_?skymm` routine performs a matrix-matrix operation defined as

$$C := \alpha * A * B + \beta * C$$

or

$$C := \alpha * A^T * B + \beta * C,$$

or

$$C := \alpha * A^H * B + \beta * C,$$

where:

α and β are scalars,

B and C are dense matrices, A is an m -by- k sparse matrix in the skyline storage format, A^T is the transpose of A , and A^H is the conjugate transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

| | |
|------------------|--|
| <i>transa</i> | Specifies the operation. If <i>transa</i> = 'N' or 'n', then $C := \alpha * A * B + \beta * C$, If <i>transa</i> = 'T' or 't', then $C := \alpha * A^T * B + \beta * C$, If <i>transa</i> = 'C' or 'c', then $C := \alpha * A^H * B + \beta * C$. |
| <i>m</i> | Number of rows of the matrix A . |
| <i>n</i> | Number of columns of the matrix C . |
| <i>k</i> | Number of columns of the matrix A . |
| <i>alpha</i> | Specifies the scalar α . |
| <i>matdescra</i> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" . |

NOTE

General matrices (*matdescra* [0]='G') is not supported.

| | |
|------------|---|
| <i>val</i> | Array containing the set of elements of the matrix A in the skyline profile form. If <i>matdescrsa</i> [2]= 'L', then <i>val</i> contains elements from the low triangle of the matrix A . If <i>matdescrsa</i> [2]= 'U', then <i>val</i> contains elements from the upper triangle of the matrix A . |
|------------|---|

Refer to *values* array description in [Skyline Storage Scheme](#) for more details.

pntr Array of length $(m + 1)$ for lower triangle, and $(k + 1)$ for upper triangle. It contains the indices specifying the positions of the first element of the matrix *A* in each row (for the lower triangle) or column (for upper triangle) in the *val* array such that $val[pntr[i] - 1]$ is the first element in row or column $i + 1$. Refer to *pointers* array description in [Skyline Storage Scheme](#) for more details.

b Array, size $ldb * n$.
On entry with *transa* = 'N' or 'n', the leading k -by- n part of the array *b* must contain the matrix *B*, otherwise the leading m -by- n part of the array *b* must contain the matrix *B*.

ldb Specifies the leading dimension of *b* as declared in the calling (sub)program.

beta Specifies the scalar *beta*.

c Array, size ldc by n .
On entry, the leading m -by- n part of the array *c* must contain the matrix *C*, otherwise the leading k -by- n part of the array *c* must contain the matrix *C*.

ldc Specifies the leading dimension of *c* as declared in the calling (sub)program.

Output Parameters

c Overwritten by the matrix $(alpha * A * B + beta * C)$, $(alpha * A^T * B + beta * C)$, or $(alpha * A^H * B + beta * C)$.

mkl_?diasm

Solves a system of linear matrix equations for a sparse matrix in the diagonal format with one-based indexing.

Syntax

```
void mkl_sdiasm (const char *transa , const MKL_INT *m , const MKL_INT *n , const float
*alpha , const char *matdescra , const float *val , const MKL_INT *lval , const MKL_INT
*idiag , const MKL_INT *ndiag , const float *b , const MKL_INT *ldb , float *c , const
MKL_INT *ldc );
```

```
void mkl_ddiasm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
double *alpha , const char *matdescra , const double *val , const MKL_INT *lval , const
MKL_INT *idiag , const MKL_INT *ndiag , const double *b , const MKL_INT *ldb , double
*c , const MKL_INT *ldc );
```

```
void mkl_cdiasm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_Complex8 *alpha , const char *matdescra , const MKL_Complex8 *val , const MKL_INT
*lval , const MKL_INT *idiag , const MKL_INT *ndiag , const MKL_Complex8 *b , const
MKL_INT *ldb , MKL_Complex8 *c , const MKL_INT *ldc );
```

```
void mkl_zdiasm (const char *transa , const MKL_INT *m , const MKL_INT *n , const
MKL_Complex16 *alpha , const char *matdescra , const MKL_Complex16 *val , const MKL_INT
*lval , const MKL_INT *idiag , const MKL_INT *ndiag , const MKL_Complex16 *b , const
MKL_INT *ldb , MKL_Complex16 *c , const MKL_INT *ldc );
```

Description

The `mkl_?diasm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the diagonal format:

$$C := \alpha * \text{inv}(A) * B$$

or

$$C := \alpha * \text{inv}(A^T) * B,$$

where:

α is scalar, B and C are dense matrices, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A^T is the transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

| | |
|------------------|--|
| <i>transa</i> | Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $C := \alpha * \text{inv}(A) * B$, If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha * \text{inv}(A^T) * B$. |
| <i>m</i> | Number of rows of the matrix A . |
| <i>n</i> | Number of columns of the matrix C . |
| <i>alpha</i> | Specifies the scalar α . |
| <i>matdescra</i> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <i>matdescra</i> (<i>descra</i>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <i>matdescra</i>" . |
| <i>val</i> | Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix A . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details. |
| <i>lval</i> | Leading dimension of <i>val</i> , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details. |
| <i>idiag</i> | Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix A . |

NOTE

All elements of this array must be sorted in increasing order.

Refer to *distance* array description in [Diagonal Storage Scheme](#) for more details.

| | |
|--------------|--|
| <i>ndiag</i> | Specifies the number of non-zero diagonals of the matrix <i>A</i> . |
| <i>b</i> | Array, size <i>ldb</i> * <i>n</i> . On entry the leading <i>m</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> . |
| <i>ldb</i> | Specifies the leading dimension of <i>b</i> as declared in the calling (sub)program. |
| <i>ldc</i> | Specifies the leading dimension of <i>c</i> as declared in the calling (sub)program. |

Output Parameters

| | |
|----------|--|
| <i>c</i> | Array, size <i>ldc</i> by <i>n</i> . The leading <i>m</i> -by- <i>n</i> part of the array <i>c</i> contains the matrix <i>C</i> . |
|----------|--|

mkl_?skysm

Solves a system of linear matrix equations for a sparse matrix stored using the skyline storage scheme with one-based indexing.

Syntax

```
void mkl_sskysm (const char *transa , const MKL_INT *m , const MKL_INT *n , const float *alpha , const char *matdescra , const float *val , const MKL_INT *pntr , const float *b , const MKL_INT *ldb , float *c , const MKL_INT *ldc );
```

```
void mkl_dskysm (const char *transa , const MKL_INT *m , const MKL_INT *n , const double *alpha , const char *matdescra , const double *val , const MKL_INT *pntr , const double *b , const MKL_INT *ldb , double *c , const MKL_INT *ldc );
```

```
void mkl_cskysm (const char *transa , const MKL_INT *m , const MKL_INT *n , const MKL_Complex8 *alpha , const char *matdescra , const MKL_Complex8 *val , const MKL_INT *pntr , const MKL_Complex8 *b , const MKL_INT *ldb , MKL_Complex8 *c , const MKL_INT *ldc );
```

```
void mkl_zskysm (const char *transa , const MKL_INT *m , const MKL_INT *n , const MKL_Complex16 *alpha , const char *matdescra , const MKL_Complex16 *val , const MKL_INT *pntr , const MKL_Complex16 *b , const MKL_INT *ldb , MKL_Complex16 *c , const MKL_INT *ldc );
```

Include Files

- mkl.h

Description

The `mkl_?skysm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the skyline storage format:

$$C := \alpha * \text{inv}(A) * B$$

or

$$C := \alpha * \text{inv}(A^T) * B,$$

where:

α is scalar, B and C are dense matrices, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A^T is the transpose of A .

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

| | |
|------------------------|--|
| <code>transa</code> | Specifies the system of linear equations. If <code>transa = 'N' or 'n'</code> , then $C := \alpha * \text{inv}(A) * B$, If <code>transa = 'T' or 't' or 'C' or 'c'</code> , then $C := \alpha * \text{inv}(A^T) * B$, |
| <code>m</code> | Number of rows of the matrix A . |
| <code>n</code> | Number of columns of the matrix C . |
| <code>alpha</code> | Specifies the scalar α . |
| <code>matdescra</code> | Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table "Possible Values of the Parameter <code>matdescra</code> (<code>descra</code>)" . Possible combinations of element values of this parameter are given in Table "Possible Combinations of Element Values of the Parameter <code>matdescra</code>" . |

NOTE

General matrices (`matdescra[0]='G'`) is not supported.

| | |
|-------------------|---|
| <code>val</code> | Array containing the set of elements of the matrix A in the skyline profile form. If <code>matdescrsa[2]= 'L'</code> , then <code>val</code> contains elements from the low triangle of the matrix A . If <code>matdescrsa[2]= 'U'</code> , then <code>val</code> contains elements from the upper triangle of the matrix A . Refer to <code>values</code> array description in Skyline Storage Scheme for more details. |
| <code>pntr</code> | Array of length $(m + 1)$ for lower triangle, and $(n + 1)$ for upper triangle. |

It contains the indices specifying the positions of the first element of the matrix A in each row (for the lower triangle) or column (for upper triangle) in the `val` array such that `val[ptr[i] - 1]` is the first element in row or column $i + 1$. Refer to `pointers` array description in [Skyline Storage Scheme](#) for more details.

`b` Array, size `ldb * n`.
On entry the leading m -by- n part of the array `b` must contain the matrix B .

`ldb` Specifies the leading dimension of `b` as declared in the calling (sub)program.

`ldc` Specifies the leading dimension of `c` as declared in the calling (sub)program.

Output Parameters

`c` Array, size `ldc` by `n`.
The leading m -by- n part of the array `c` contains the matrix C .

mkl_?dnscsr

Convert a sparse matrix in uncompressed representation to the CSR format and vice versa.

Syntax

```
void mkl_ddnscsr (const MKL_INT *job , const MKL_INT *m , const MKL_INT *n , double
*adns , const MKL_INT *lda , double *acsr , MKL_INT *ja , MKL_INT *ia , MKL_INT
*info );

void mkl_sdnscsr (const MKL_INT *job , const MKL_INT *m , const MKL_INT *n , float
*adns , const MKL_INT *lda , float *acsr , MKL_INT *ja , MKL_INT *ia , MKL_INT *info );

void mkl_cdnscsr (const MKL_INT *job , const MKL_INT *m , const MKL_INT *n ,
MKL_Complex8 *adns , const MKL_INT *lda , MKL_Complex8 *acsr , MKL_INT *ja , MKL_INT
*ia , MKL_INT *info );

void mkl_zdnscsr (const MKL_INT *job , const MKL_INT *m , const MKL_INT *n ,
MKL_Complex16 *adns , const MKL_INT *lda , MKL_Complex16 *acsr , MKL_INT *ja , MKL_INT
*ia , MKL_INT *info );
```

Include Files

- `mkl.h`

Description

This routine converts a sparse matrix A between formats: stored as a rectangular array (dense representation) and stored using compressed sparse row (CSR) format (3-array variation).

Input Parameters

`job` Array, contains the following conversion parameters:

- `job[0]`: Conversion type.

- If $job[0]=0$, the rectangular matrix A is converted to the CSR format;
- if $job[0]=1$, the rectangular matrix A is restored from the CSR format.
- $job[1]$: index base for the rectangular matrix A .
 - If $job[1]=0$, zero-based indexing for the rectangular matrix A is used;
 - if $job[1]=1$, one-based indexing for the rectangular matrix A is used.
- $job[2]$: Index base for the matrix in CSR format.
 - If $job[2]=0$, zero-based indexing for the matrix in CSR format is used;
 - if $job[2]=1$, one-based indexing for the matrix in CSR format is used.
- $job[3]$: Portion of matrix.
 - If $job[3]=0$, $adns$ is a lower triangular part of matrix A ;
 - If $job[3]=1$, $adns$ is an upper triangular part of matrix A ;
 - If $job[3]=2$, $adns$ is a whole matrix A .
- $job[4]=nzmax$: maximum number of the non-zero elements allowed if $job[0]=0$.
- $job[5]$: job indicator for conversion to CSR format.
 - If $job[5]=0$, only array ia is generated for the output storage.
 - If $job[5]>0$, arrays $acsr$, ia , ja are generated for the output storage.

m Number of rows of the matrix A .

n Number of columns of the matrix A .

$adns$ (input/output)

If the conversion type is from uncompressed to CSR, on input $adns$ contains an uncompressed (dense) representation of matrix A .

lda Specifies the leading dimension of $adns$ as declared in the calling (sub)program.

For zero-based indexing of A , lda must be at least $\max(1, n)$.

For one-based indexing of A , lda must be at least $\max(1, m)$.

$acsr$ (input/output)

If conversion type is from CSR to uncompressed, on input $acsr$ contains the non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to [values](#) array description in [Sparse Matrix Storage Formats](#) for more details.

ja (input/output). If conversion type is from CSR to uncompressed, on input for zero-based indexing of A ja contains the column indices plus one for each non-zero element of the matrix A . For one-based indexing of A ja contains the column indices for each non-zero element of the matrix A .

Its length is equal to the length of the array *acsr*. Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

ia

(input/output). Array of length $m + 1$.

If conversion type is from CSR to uncompressed, on input for zero-based indexing of *A* *ia* contains indices of elements in the array *acsr*, such that $ia[i] - 1$ is the index in the array *acsr* of the first non-zero element from the row *i*. For one-based indexing of *A* *ia* contains indices of elements in the array *acsr*, such that $ia[i]$ is the index in the array *acsr* of the first non-zero element from the row *i*.

The value of $ia[m] - ia[0]$ is equal to the number of non-zeros. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

Output Parameters

adns

If conversion type is from CSR to uncompressed, on output *adns* contains the uncompressed (dense) representation of matrix *A*.

acsr, ja, ia

If conversion type is from uncompressed to CSR, on output *acsr*, *ja*, and *ia* contain the compressed sparse row (CSR) format (3-array variation) of matrix *A* (see [Sparse Matrix Storage Formats](#) for a description of the storage format).

info

Integer info indicator only for restoring the matrix *A* from the CSR format.

If $info=0$, the execution is successful.

If $info=i$, the routine is interrupted processing the *i*-th row because there is no space in the arrays *acsr* and *ja* according to the value *nzmax*.

mkl_?csrcoo

Converts a sparse matrix in the CSR format to the coordinate format and vice versa.

Syntax

```
void mkl_scsrcoo (const MKL_INT *job , const MKL_INT *n , float *acsr , MKL_INT *ja ,
MKL_INT *ia , MKL_INT *nnz , float *acoo , MKL_INT *rowind , MKL_INT *colind , MKL_INT
*info );
```

```
void mkl_dcsrcoo (const MKL_INT *job , const MKL_INT *n , double *acsr , MKL_INT *ja ,
MKL_INT *ia , MKL_INT *nnz , double *acoo , MKL_INT *rowind , MKL_INT *colind ,
MKL_INT *info );
```

```
void mkl_ccsrcoo (const MKL_INT *job , const MKL_INT *n , MKL_Complex8 *acsr , MKL_INT
*ja , MKL_INT *ia , MKL_INT *nnz , MKL_Complex8 *acoo , MKL_INT *rowind , MKL_INT
*colind , MKL_INT *info );
```

```
void mkl_zcsrcoo (const MKL_INT *job , const MKL_INT *n , MKL_Complex16 *acsr , MKL_INT
*ja , MKL_INT *ia , MKL_INT *nnz , MKL_Complex16 *acoo , MKL_INT *rowind , MKL_INT
*colind , MKL_INT *info );
```

Description

This routine converts a sparse matrix A stored in the compressed sparse row (CSR) format (3-array variation) to coordinate format and vice versa.

Input Parameters

| | |
|------------|---|
| <i>job</i> | <p>Array, contains the following conversion parameters:</p> <p><i>job</i>[0]</p> <p>If <i>job</i>[0]=0, the matrix in the CSR format is converted to the coordinate format;</p> <p>if <i>job</i>[0]=1, the matrix in the coordinate format is converted to the CSR format.</p> <p>if <i>job</i>[0]=2, the matrix in the coordinate format is converted to the CSR format, and the column indices in CSR representation are sorted in the increasing order within each row.</p> <p><i>job</i>[1]</p> <p>If <i>job</i>[1]=0, zero-based indexing for the matrix in CSR format is used;</p> <p>if <i>job</i>[1]=1, one-based indexing for the matrix in CSR format is used.</p> <p><i>job</i>[2]</p> <p>If <i>job</i>[2]=0, zero-based indexing for the matrix in coordinate format is used;</p> <p>if <i>job</i>[2]=1, one-based indexing for the matrix in coordinate format is used.</p> <p><i>job</i>[4]</p> <p><i>job</i>[4]=<i>nzmax</i> - maximum number of the non-zero elements allowed if <i>job</i>[0]=0.</p> <p><i>job</i>[5] - job indicator.</p> <p>For conversion to the coordinate format:</p> <p>If <i>job</i>[5]=1, only array <i>rowind</i> is filled in for the output storage.</p> <p>If <i>job</i>[5]=2, arrays <i>rowind</i>, <i>colind</i> are filled in for the output storage.</p> <p>If <i>job</i>[5]=3, all arrays <i>rowind</i>, <i>colind</i>, <i>acoo</i> are filled in for the output storage.</p> <p>For conversion to the CSR format:</p> <p>If <i>job</i>[5]=0, all arrays <i>acsr</i>, <i>ja</i>, <i>ia</i> are filled in for the output storage.</p> <p>If <i>job</i>[5]=1, only array <i>ia</i> is filled in for the output storage.</p> <p>If <i>job</i>[5]=2, then it is assumed that the routine already has been called with the <i>job</i>[5]=1, and the user allocated the required space for storing the output arrays <i>acsr</i> and <i>ja</i>.</p> |
| <i>n</i> | Dimension of the matrix A . |
| <i>nnz</i> | Specifies the number of non-zero elements of the matrix A for <i>job</i> [0]≠0. Refer to <i>nnz</i> description in Coordinate Format for more details. |

| | |
|---------------------|---|
| <code>acsr</code> | (input/output) Array containing non-zero elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details. |
| <code>ja</code> | (input/output). For <code>job[1] = 1</code> (one-based indexing for the matrix in CSR format), array containing the column indices plus one for each non-zero element of the matrix <i>A</i> . For <code>job[1] = 0</code> (zero-based indexing for the matrix in CSR format), array containing the column indices for each non-zero element of the matrix <i>A</i> . Its length is equal to the length of the array <code>acsr</code> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details. |
| <code>ia</code> | (input/output). Array of length $n + 1$, containing indices of elements in the array <code>acsr</code> , such that <code>ia[i] - ia[0]</code> is the index in the array <code>acsr</code> of the first non-zero element from the row <i>i</i> . The value of the last element <code>ia[n] - ia[0]</code> is equal to the number of non-zeros plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details. |
| <code>acoo</code> | (input/output) Array containing non-zero elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details. |
| <code>rowind</code> | (input/output). Array of length <code>nnz</code> , contains the row indices for each non-zero element of the matrix <i>A</i> . Refer to <i>rows</i> array description in Coordinate Format for more details. |
| <code>colind</code> | (input/output). Array of length <code>nnz</code> , contains the column indices for each non-zero element of the matrix <i>A</i> . Refer to <i>columns</i> array description in Coordinate Format for more details. |

Output Parameters

| | |
|-------------------|---|
| <code>nnz</code> | Returns the number of converted elements of the matrix <i>A</i> for <code>job[0]=0</code> . |
| <code>info</code> | Integer info indicator only for converting the matrix <i>A</i> from the CSR format. If <code>info=0</code> , the execution is successful. If <code>info=1</code> , the routine is interrupted because there is no space in the arrays <code>acoo</code> , <code>rowind</code> , <code>colind</code> according to the value <code>nzmax</code> . |

mkl_?csrbsr

Converts a square sparse matrix in the CSR format to the BSR format and vice versa.

Syntax

```
void mkl_scsrbsr (const MKL_INT *job , const MKL_INT *m , const MKL_INT *mblk , const
MKL_INT *ldabsr , float *acsr , MKL_INT *ja , MKL_INT *ia , float *absr , MKL_INT
*jab , MKL_INT *iab , MKL_INT *info );
```

```

void mkl_dcsrbsr (const MKL_INT *job , const MKL_INT *m , const MKL_INT *mblk , const
MKL_INT *ldabsr , double *acsr , MKL_INT *ja , MKL_INT *ia , double *absr , MKL_INT
*jab , MKL_INT *iab , MKL_INT *info );

void mkl_ccsrbsr (const MKL_INT *job , const MKL_INT *m , const MKL_INT *mblk , const
MKL_INT *ldabsr , MKL_Complex8 *acsr , MKL_INT *ja , MKL_INT *ia , MKL_Complex8
*absr , MKL_INT *jab , MKL_INT *iab , MKL_INT *info );

void mkl_zcsrbsr (const MKL_INT *job , const MKL_INT *m , const MKL_INT *mblk , const
MKL_INT *ldabsr , MKL_Complex16 *acsr , MKL_INT *ja , MKL_INT *ia , MKL_Complex16
*absr , MKL_INT *jab , MKL_INT *iab , MKL_INT *info );

```

Include Files

- mkl.h

Description

This routine converts a square sparse matrix A stored in the compressed sparse row (CSR) format (3-array variation) to the block sparse row (BSR) format and vice versa.

Input Parameters

job

Array, contains the following conversion parameters:

job[0]

If *job*[0]=0, the matrix in the CSR format is converted to the BSR format;
if *job*[0]=1, the matrix in the BSR format is converted to the CSR format.

job[1]

If *job*[1]=0, zero-based indexing for the matrix in CSR format is used;
if *job*[1]=1, one-based indexing for the matrix in CSR format is used.

job[2]

If *job*[2]=0, zero-based indexing for the matrix in the BSR format is used;
if *job*[2]=1, one-based indexing for the matrix in the BSR format is used.

job[3] is only used for conversion to CSR format. By default, the converter saves the blocks without checking whether an element is zero or not. If *job*[3]=1, then the converter only saves non-zero elements in blocks.

job[5] - job indicator.

For conversion to the BSR format:

If *job*[5]=0, only arrays *jab*, *iab* are generated for the output storage.

If *job*[5]>0, all output arrays *absr*, *jab*, and *iab* are filled in for the output storage.

If *job*[5]=-1, *iab*[*m*] - *iab*[0] returns the number of non-zero blocks.

For conversion to the CSR format:

If *job*[5]=0, only arrays *ja*, *ia* are generated for the output storage.

m

Actual row dimension of the matrix A for convert to the BSR format; block row dimension of the matrix A for convert to the CSR format.

| | |
|---------------|---|
| <i>mblk</i> | Size of the block in the matrix <i>A</i> . |
| <i>ldabsr</i> | Leading dimension of the array <i>absr</i> as declared in the calling program. <i>ldabsr</i> must be greater than or equal to <i>mblk*mblk</i> . |
| <i>acsr</i> | (input/output) Array containing non-zero elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details. |
| <i>ja</i> | (input/output). Array containing the column indices for each non-zero element of the matrix <i>A</i> . Its length is equal to the length of the array <i>acsr</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details. |
| <i>ia</i> | (input/output). Array of length $m + 1$, containing indices of elements in the array <i>acsr</i> , such that $ia[I] - iab[0]$ is the index in the array <i>acsr</i> of the first non-zero element from the row <i>I</i> . The value of $ia[m] - iab[0]$ is equal to the number of non-zeros. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details. |
| <i>absr</i> | (input/output) Array containing elements of non-zero blocks of the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> multiplied by <i>mblk*mblk</i> . Refer to <i>values</i> array description in BSR Format for more details. |
| <i>jab</i> | (input/output). Array containing the column indices for each non-zero block of the matrix <i>A</i> . Its length is equal to the number of non-zero blocks of the matrix <i>A</i> . Refer to <i>columns</i> array description in BSR Format for more details. |
| <i>iab</i> | (input/output). Array of length $(m + 1)$, containing indices of blocks in the array <i>absr</i> , such that $iab[i] - iab[0]$ is the index in the array <i>absr</i> of the first non-zero element from the <i>i</i> -th row. The value of $iab[m]$ is equal to the number of non-zero blocks. Refer to <i>rowIndex</i> array description in BSR Format for more details. |

Output Parameters

| | |
|-------------|---|
| <i>info</i> | Integer info indicator only for converting the matrix <i>A</i> from the CSR format. If <i>info</i> =0, the execution is successful. If <i>info</i> =1, it means that <i>mblk</i> is equal to 0. If <i>info</i> =2, it means that <i>ldabsr</i> is less than <i>mblk*mblk</i> and there is no space for all blocks. |
|-------------|---|

mkl_?csrsc

Converts a square sparse matrix in the CSR format to the CSC format and vice versa.

Syntax

```
void mkl_dcsrcsc (const MKL_INT *job , const MKL_INT *n , double *acsr , MKL_INT *ja ,
MKL_INT *ia , double *acsc , MKL_INT *jal , MKL_INT *ial , MKL_INT *info );

void mkl_scsrcsc (const MKL_INT *job , const MKL_INT *n , float *acsr , MKL_INT *ja ,
MKL_INT *ia , float *acsc , MKL_INT *jal , MKL_INT *ial , MKL_INT *info );

void mkl_ccsrcsc (const MKL_INT *job , const MKL_INT *n , MKL_Complex8 *acsr , MKL_INT
*ja , MKL_INT *ia , MKL_Complex8 *acsc , MKL_INT *jal , MKL_INT *ial , MKL_INT *info );

void mkl_zcsrcsc (const MKL_INT *job , const MKL_INT *n , MKL_Complex16 *acsr , MKL_INT
*ja , MKL_INT *ia , MKL_Complex16 *acsc , MKL_INT *jal , MKL_INT *ial , MKL_INT
*info );
```

Include Files

Description

This routine converts a square sparse matrix A stored in the compressed sparse row (CSR) format (3-array variation) to the compressed sparse column (CSC) format and vice versa.

Input Parameters

job

Array, contains the following conversion parameters:

job[0]

If *job*[0]=0, the matrix in the CSR format is converted to the CSC format;
if *job*[0]=1, the matrix in the CSC format is converted to the CSR format.

job[1]

If *job*[1]=0, zero-based indexing for the matrix in CSR format is used;
if *job*[1]=1, one-based indexing for the matrix in CSR format is used.

job[2]

If *job*[2]=0, zero-based indexing for the matrix in the CSC format is used;
if *job*[2]=1, one-based indexing for the matrix in the CSC format is used.

job[5] - job indicator.

For conversion to the CSC format:

If *job*[5]=0, only arrays *jal*, *ial* are filled in for the output storage.

If *job*[5]≠0, all output arrays *acsc*, *jal*, and *ial* are filled in for the output storage.

For conversion to the CSR format:

If *job*[5]=0, only arrays *ja*, *ia* are filled in for the output storage.

If *job*[5]≠0, all output arrays *acsr*, *ja*, and *ia* are filled in for the output storage.

m

Dimension of the square matrix A .

acsr

(input/output)

Array containing non-zero elements of the square matrix *A*. Its length is equal to the number of non-zero elements in the matrix *A*. Refer to *values* array description in [Sparse Matrix Storage Formats](#) for more details.

ja (input/output). Array containing the column indices for each non-zero element of the matrix *A*.

Its length is equal to the length of the array *acsr*. Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

ia (input/output). Array of length $m + 1$, containing indices of elements in the array *acsr*, such that $ia[i] - ia[0]$ is the index in the array *acsr* of the first non-zero element from the row *i*. The value of $ia[m] - ia[0]$ is equal to the number of non-zeros. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

acsc (input/output)

Array containing non-zero elements of the square matrix *A*. Its length is equal to the number of non-zero elements in the matrix *A*. Refer to *values* array description in [Sparse Matrix Storage Formats](#) for more details.

jal (input/output). Array containing the row indices for each non-zero element of the matrix *A*.

Its length is equal to the length of the array *acsc*. Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

ial (input/output). Array of length $m + 1$, containing indices of elements in the array *acsc*, such that $ial[i] - ial[0]$ is the index in the array *acsc* of the first non-zero element from the column *i*. The value of $ial[m] - ial[0]$ is equal to the number of non-zeros. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

Output Parameters

info This parameter is not used now.

mkl_?csrdia

Converts a sparse matrix in the CSR format to the diagonal format and vice versa.

Syntax

```
void mkl_dcsrdia (const MKL_INT *job , const MKL_INT *n , double *acsr , MKL_INT *ja ,
MKL_INT *ia , double *adia , const MKL_INT *ndiag , MKL_INT *distance , MKL_INT
*idiag , double *acsr_rem , MKL_INT *ja_rem , MKL_INT *ia_rem , MKL_INT *info );
```

```
void mkl_scsrdia (const MKL_INT *job , const MKL_INT *n , float *acsr , MKL_INT *ja ,
MKL_INT *ia , float *adia , const MKL_INT *ndiag , MKL_INT *distance , MKL_INT
*idiag , float *acsr_rem , MKL_INT *ja_rem , MKL_INT *ia_rem , MKL_INT *info );
```

```
void mkl_ccsrdia (const MKL_INT *job , const MKL_INT *n , MKL_Complex8 *acsr , MKL_INT
*ja , MKL_INT *ia , MKL_Complex8 *adia , const MKL_INT *ndiag , MKL_INT *distance ,
MKL_INT *idiag , MKL_Complex8 *acsr_rem , MKL_INT *ja_rem , MKL_INT *ia_rem , MKL_INT
*info );
```

```
void mkl_zcsrda (const MKL_INT *job , const MKL_INT *n , MKL_Complex16 *acsr , MKL_INT
*ja , MKL_INT *ia , MKL_Complex16 *adia , const MKL_INT *ndiag , MKL_INT *distance ,
MKL_INT *idiag , MKL_Complex16 *acsr_rem , MKL_INT *ja_rem , MKL_INT *ia_rem , MKL_INT
*info );
```

Include Files

- mkl.h

Description

This routine converts a sparse matrix A stored in the compressed sparse row (CSR) format (3-array variation) to the diagonal format and vice versa.

Input Parameters

job

Array, contains the following conversion parameters:

job[0]

If *job*[0]=0, the matrix in the CSR format is converted to the diagonal format;

if *job*[0]=1, the matrix in the diagonal format is converted to the CSR format.

job[1]

If *job*[1]=0, zero-based indexing for the matrix in CSR format is used;

if *job*[1]=1, one-based indexing for the matrix in CSR format is used.

job[2]

If *job*[2]=0, zero-based indexing for the matrix in the diagonal format is used;

if *job*[2]=1, one-based indexing for the matrix in the diagonal format is used.

job[5] - job indicator.

For conversion to the diagonal format:

If *job*[5]=0, diagonals are not selected internally, and *acsr_rem*, *ja_rem*, *ia_rem* are not filled in for the output storage.

If *job*[5]=1, diagonals are not selected internally, and *acsr_rem*, *ja_rem*, *ia_rem* are filled in for the output storage.

If *job*[5]=10, diagonals are selected internally, and *acsr_rem*, *ja_rem*, *ia_rem* are not filled in for the output storage.

If *job*[5]=11, diagonals are selected internally, and *csr_rem*, *ja_rem*, *ia_rem* are filled in for the output storage.

For conversion to the CSR format:

If *job*[5]=0, each entry in the array *adia* is checked whether it is zero. Zero entries are not included in the array *acsr*.

If *job*[5]≠0, each entry in the array *adia* is not checked whether it is zero.

m

Dimension of the matrix A .

| | |
|---------------------------------|--|
| <i>acsr</i> | (input/output) Array containing non-zero elements of the matrix A. Its length is equal to the number of non-zero elements in the matrix A. Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details. |
| <i>ja</i> | (input/output). Array containing the column indices for each non-zero element of the matrix A. Its length is equal to the length of the array <i>acsr</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details. |
| <i>ia</i> | (input/output). Array of length $m + 1$, containing indices of elements in the array <i>acsr</i> , such that $ia[i] - ia[0]$ is the index in the array <i>acsr</i> of the first non-zero element from the row i . The value of $ia[m] - ia[0]$ is equal to the number of non-zeros. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details. |
| <i>adia</i> | (input/output) Array of size $(ndiag * idiag)$ containing diagonals of the matrix A. The key point of the storage is that each element in the array <i>adia</i> retains the row number of the original matrix. To achieve this diagonals in the lower triangular part of the matrix are padded from the top, and those in the upper triangular part are padded from the bottom. |
| <i>ndiag</i> | Specifies the leading dimension of the array <i>adia</i> as declared in the calling (sub)program, must be at least $\max(1, m)$. |
| <i>distance</i> | Array of length <i>idiag</i> , containing the distances between the main diagonal and each non-zero diagonal to be extracted. The distance is positive if the diagonal is above the main diagonal, and negative if the diagonal is below the main diagonal. The main diagonal has a distance equal to zero. |
| <i>idiag</i> | Number of diagonals to be extracted. For conversion to diagonal format on return this parameter may be modified. |
| <i>acsr_rem, ja_rem, ia_rem</i> | Remainder of the matrix in the CSR format if it is needed for conversion to the diagonal format. |

Output Parameters

info This parameter is not used now.

mkl_?csrsky

Converts a sparse matrix in CSR format to the skyline format and vice versa.

Syntax

```
void mkl_dcsrsky (const MKL_INT *job , const MKL_INT *m , double *acsr , MKL_INT *ja ,
MKL_INT *ia , double *asky , MKL_INT *pointers , MKL_INT *info );
```

```
void mkl_scsrsky (const MKL_INT *job , const MKL_INT *m , float *acsr , MKL_INT *ja ,
MKL_INT *ia , float *asky , MKL_INT *pointers , MKL_INT *info );
```

```
void mkl_ccsrsky (const MKL_INT *job , const MKL_INT *m , MKL_Complex8 *acsr , MKL_INT
*ja , MKL_INT *ia , MKL_Complex8 *asky , MKL_INT *pointers , MKL_INT *info );
void mkl_zcsrsky (const MKL_INT *job , const MKL_INT *m , MKL_Complex16 *acsr , MKL_INT
*ja , MKL_INT *ia , MKL_Complex16 *asky , MKL_INT *pointers , MKL_INT *info );
```

Include Files

- mkl.h

Description

This routine converts a sparse matrix A stored in the compressed sparse row (CSR) format (3-array variation) to the skyline format and vice versa.

Input Parameters

job

Array, contains the following conversion parameters:

job[0]

If *job*[0]=0, the matrix in the CSR format is converted to the skyline format;

if *job*[0]=1, the matrix in the skyline format is converted to the CSR format.

job[1]

If *job*[1]=0, zero-based indexing for the matrix in CSR format is used;

if *job*[1]=1, one-based indexing for the matrix in CSR format is used.

job[2]

If *job*[2]=0, zero-based indexing for the matrix in the skyline format is used;

if *job*[2]=1, one-based indexing for the matrix in the skyline format is used.

job[3]

For conversion to the skyline format:

If *job*[3]=0, the upper part of the matrix A in the CSR format is converted.

If *job*[3]=1, the lower part of the matrix A in the CSR format is converted.

For conversion to the CSR format:

If *job*[3]=0, the matrix is converted to the upper part of the matrix A in the CSR format.

If *job*[3]=1, the matrix is converted to the lower part of the matrix A in the CSR format.

job[4]

job[4]=*nzmax* - maximum number of the non-zero elements of the matrix A if *job*[0]=0.

job[5] - job indicator.

Only for conversion to the skyline format:

If *job*[5]=0, only arrays *pointers* is filled in for the output storage.

If `job[5]=1`, all output arrays `asky` and `pointers` are filled in for the output storage.

| | |
|-----------------------|---|
| <code>m</code> | Dimension of the matrix <i>A</i> . |
| <code>acsr</code> | (input/output) Array containing non-zero elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to <code>values</code> array description in Sparse Matrix Storage Formats for more details. |
| <code>ja</code> | (input/output). Array containing the column indices for each non-zero element of the matrix <i>A</i> . Its length is equal to the length of the array <code>acsr</code> . Refer to <code>columns</code> array description in Sparse Matrix Storage Formats for more details. |
| <code>ia</code> | (input/output). Array of length $m + 1$, containing indices of elements in the array <code>acsr</code> , such that $ia[i] - ia[0]$ is the index in the array <code>acsr</code> of the first non-zero element from the row <i>i</i> . The value of $ia[m] - ia[0]$ is equal to the number of non-zeros. Refer to <code>rowIndex</code> array description in Sparse Matrix Storage Formats for more details. |
| <code>asky</code> | (input/output) Array, for a lower triangular part of <i>A</i> it contains the set of elements from each row starting from the first non-zero element to and including the diagonal element. For an upper triangular matrix it contains the set of elements from each column of the matrix starting with the first non-zero element down to and including the diagonal element. Encountered zero elements are included in the sets. Refer to <code>values</code> array description in Skyline Storage Format for more details. |
| <code>pointers</code> | (input/output). Array with dimension $(m+1)$, where <i>m</i> is number of rows for lower triangle (columns for upper triangle), $pointers[i-1] - pointers[0]$ gives the index of element in the array <code>asky</code> that is first non-zero element in row (column) <i>i</i> . The value of <code>pointers[m]</code> is set to $nnz + pointers[0]$, where <i>nnz</i> is the number of elements in the array <code>asky</code> . Refer to <code>pointers</code> array description in Skyline Storage Format for more details |

Output Parameters

| | |
|-------------------|--|
| <code>info</code> | Integer info indicator only for converting the matrix <i>A</i> from the CSR format. If <code>info=0</code> , the execution is successful. If <code>info=1</code> , the routine is interrupted because there is no space in the array <code>asky</code> according to the value <code>nzmax</code> . |
|-------------------|--|

mkl_?csradd

Computes the sum of two matrices stored in the CSR format (3-array variation) with one-based indexing.

Syntax

```
void mkl_dcsradd (const char *trans , const MKL_INT *request , const MKL_INT *sort ,
const MKL_INT *m , const MKL_INT *n , double *a , MKL_INT *ja , MKL_INT *ia , const
double *beta , double *b , MKL_INT *jb , MKL_INT *ib , double *c , MKL_INT *jc ,
MKL_INT *ic , const MKL_INT *nzmax , MKL_INT *info );
```

```
void mkl_scsradd (const char *trans , const MKL_INT *request , const MKL_INT *sort ,
const MKL_INT *m , const MKL_INT *n , float *a , MKL_INT *ja , MKL_INT *ia , const
float *beta , float *b , MKL_INT *jb , MKL_INT *ib , float *c , MKL_INT *jc , MKL_INT
*ic , const MKL_INT *nzmax , MKL_INT *info );
```

```
void mkl_ccsradd (const char *trans , const MKL_INT *request , const MKL_INT *sort ,
const MKL_INT *m , const MKL_INT *n , MKL_Complex8 *a , MKL_INT *ja , MKL_INT *ia ,
const MKL_Complex8 *beta , MKL_Complex8 *b , MKL_INT *jb , MKL_INT *ib , MKL_Complex8

Description

The `mkl_?csradd` routine performs a matrix-matrix operation defined as

$$C := A + \text{beta} * \text{op}(B)$$

where:

A , B , C are the sparse matrices in the CSR format (3-array variation).

$\text{op}(B)$ is one of $\text{op}(B) = B$, or $\text{op}(B) = B^T$, or $\text{op}(B) = B^H$

beta is a scalar.

The routine works correctly if and only if the column indices in sparse matrix representations of matrices A and B are arranged in the increasing order for each row. If not, use the parameter `sort` (see below) to reorder column indices and the corresponding elements of the input matrices.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

| | |
|----------------|---|
| <i>trans</i> | Specifies the operation. If <i>trans</i> = 'N' or 'n', then $C := A + \text{beta} * B$ If <i>trans</i> = 'T' or 't', then $C := A + \text{beta} * B^T$ If <i>trans</i> = 'C' or 'c', then $C := A + \text{beta} * B^H$. |
| <i>request</i> | If <i>request</i> =0, the routine performs addition. The memory for the output arrays <i>ic</i> , <i>jc</i> , <i>c</i> must be allocated beforehand. |

If $request=1$, the routine only computes the values of the array ic of length $m + 1$. The memory for the ic array must be allocated beforehand. On exit the value $ic[m] - 1$ is the actual number of the elements in the arrays c and jc .

If $request=2$, after the routine is called previously with the parameter $request=1$ and after the output arrays jc and c are allocated in the calling program with length at least $ic[m] - 1$, the routine performs addition.

$sort$

Specifies the type of reordering. If this parameter is not set (default), the routine does not perform reordering.

If $sort=1$, the routine arranges the column indices ja for each row in the increasing order and reorders the corresponding values of the matrix A in the array a .

If $sort=2$, the routine arranges the column indices jb for each row in the increasing order and reorders the corresponding values of the matrix B in the array b .

If $sort=3$, the routine performs reordering for both input matrices A and B .

m

Number of rows of the matrix A .

n

Number of columns of the matrix A .

a

Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to *values* array description in [Sparse Matrix Storage Formats](#) for more details.

ja

Array containing the column indices plus one for each non-zero element of the matrix A . For each row the column indices must be arranged in the increasing order.

The length of this array is equal to the length of the array a . Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

ia

Array of length $m + 1$, containing indices of elements in the array a , such that $ia[i] - ia[0]$ is the index in the array a of the first non-zero element from the row i . The value of the last element $ia[m]$ is equal to the number of non-zero elements of the matrix A plus one. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

$beta$

Specifies the scalar $beta$.

b

Array containing non-zero elements of the matrix B . Its length is equal to the number of non-zero elements in the matrix B . Refer to *values* array description in [Sparse Matrix Storage Formats](#) for more details.

jb

Array containing the column indices plus one for each non-zero element of the matrix B . For each row the column indices must be arranged in the increasing order.

The length of this array is equal to the length of the array b . Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

| | |
|--------------|---|
| <i>ib</i> | <p>Array of length $m + 1$ when <i>trans</i> = 'N' or 'n', or $n + 1$ otherwise.</p> <p>This array contains indices of elements in the array <i>b</i>, such that $ib[i] - ib[0]$ is the index in the array <i>b</i> of the first non-zero element from the row <i>i</i>. The value of the last element $ib[m]$ or $ib[n]$ is equal to the number of non-zero elements of the matrix <i>B</i> plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.</p> |
| <i>nzmax</i> | <p>The length of the arrays <i>c</i> and <i>jc</i>.</p> <p>This parameter is used only if <i>request</i>=0. The routine stops calculation if the number of elements in the result matrix <i>C</i> exceeds the specified value of <i>nzmax</i>.</p> |

Output Parameters

| | |
|-------------|---|
| <i>c</i> | <p>Array containing non-zero elements of the result matrix <i>C</i>. Its length is equal to the number of non-zero elements in the matrix <i>C</i>. Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.</p> |
| <i>jc</i> | <p>Array containing the column indices plus one for each non-zero element of the matrix <i>C</i>.</p> <p>The length of this array is equal to the length of the array <i>c</i>. Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.</p> |
| <i>ic</i> | <p>Array of length $m + 1$, containing indices of elements in the array <i>c</i>, such that $ic[i] - ic[0]$ is the index in the array <i>c</i> of the first non-zero element from the row <i>i</i>. The value of the last element $ic[m]$ is equal to the number of non-zero elements of the matrix <i>C</i> plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.</p> |
| <i>info</i> | <p>If <i>info</i>=0, the execution is successful.</p> <p>If <i>info</i>=<i>I</i>>0, the routine stops calculation in the <i>I</i>-th row of the matrix <i>C</i> because number of elements in <i>C</i> exceeds <i>nzmax</i>.</p> <p>If <i>info</i>=-1, the routine calculates only the size of the arrays <i>c</i> and <i>jc</i> and returns this value plus 1 as the last element of the array <i>ic</i>.</p> |

mkl_?csrmultcsr

Computes product of two sparse matrices stored in the CSR format (3-array variation) with one-based indexing.

Syntax

```
void mkl_dcsrcmultcsr (const char *trans , const MKL_INT *request , const MKL_INT
*sort , const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , double *a , MKL_INT
*ja , MKL_INT *ia , double *b , MKL_INT *jb , MKL_INT *ib , double *c , MKL_INT *jc ,
MKL_INT *ic , const MKL_INT *nzmax , MKL_INT *info );

void mkl_scsrcmultcsr (const char *trans , const MKL_INT *request , const MKL_INT
*sort , const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , float *a , MKL_INT
*ja , MKL_INT *ia , float *b , MKL_INT *jb , MKL_INT *ib , float *c , MKL_INT *jc ,
MKL_INT *ic , const MKL_INT *nzmax , MKL_INT *info );
```

```
void mkl_ccsrmultcsr (const char *trans , const MKL_INT *request , const MKL_INT
*sort , const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , MKL_Complex8 *a ,
MKL_INT *ja , MKL_INT *ia , MKL_Complex8 *b , MKL_INT *jb , MKL_INT *ib , MKL_Complex8
*c , MKL_INT *jc , MKL_INT *ic , const MKL_INT *nzmax , MKL_INT *info );
```

```
void mkl_zcsrmultcsr (const char *trans , const MKL_INT *request , const MKL_INT
*sort , const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , MKL_Complex16 *a ,
MKL_INT *ja , MKL_INT *ia , MKL_Complex16 *b , MKL_INT *jb , MKL_INT *ib ,
MKL_Complex16 *c , MKL_INT *jc , MKL_INT *ic , const MKL_INT *nzmax , MKL_INT *info );
```

Include Files

- mkl.h

Description

The `mkl_?csrmultcsr` routine performs a matrix-matrix operation defined as

$$C := \text{op}(A) * B$$

where:

A, B, C are the sparse matrices in the CSR format (3-array variation);

$\text{op}(A)$ is one of $\text{op}(A) = A$, or $\text{op}(A) = A^T$, or $\text{op}(A) = A^H$.

You can use the parameter `sort` to perform or not perform reordering of non-zero entries in input and output sparse matrices. The purpose of reordering is to rearrange non-zero entries in compressed sparse row matrix so that column indices in compressed sparse representation are sorted in the increasing order for each row.

The following table shows correspondence between the value of the parameter `sort` and the type of reordering performed by this routine for each sparse matrix involved:

| Value of the parameter <i>sort</i> | Reordering of A (arrays <i>a, ja, ia</i>) | Reordering of B (arrays <i>b, jb, ib</i>) | Reordering of C (arrays <i>c, jc, ic</i>) |
|--|---|---|---|
| 1 | yes | no | yes |
| 2 | no | yes | yes |
| 3 | yes | yes | yes |
| 4 | yes | no | no |
| 5 | no | yes | no |
| 6 | yes | yes | no |
| 7 | no | no | no |
| arbitrary value not equal to 1, 2, ..., 7 | no | no | yes |

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

trans

Specifies the operation.

If *trans* = 'N' or 'n', then $C := A * B$

If *trans* = 'T' or 't' or 'C' or 'c', then $C := A^T * B$.

| | |
|----------------|--|
| <i>request</i> | <p>If <i>request</i>=0, the routine performs multiplication, the memory for the output arrays <i>ic</i>, <i>jc</i>, <i>c</i> must be allocated beforehand.</p> <p>If <i>request</i>=1, the routine computes only values of the array <i>ic</i> of length $m + 1$, the memory for this array must be allocated beforehand. On exit the value $ic[m] - 1$ is the actual number of the elements in the arrays <i>c</i> and <i>jc</i>.</p> <p>If <i>request</i>=2, the routine has been called previously with the parameter <i>request</i>=1, the output arrays <i>jc</i> and <i>c</i> are allocated in the calling program and they are of the length $ic[m] - 1$ at least.</p> |
| <i>sort</i> | Specifies whether the routine performs reordering of non-zeros entries in input and/or output sparse matrices (see table above). |
| <i>m</i> | Number of rows of the matrix <i>A</i> . |
| <i>n</i> | Number of columns of the matrix <i>A</i> . |
| <i>k</i> | Number of columns of the matrix <i>B</i> . |
| <i>a</i> | Array containing non-zero elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details. |
| <i>ja</i> | <p>Array containing the column indices plus one for each non-zero element of the matrix <i>A</i>. For each row the column indices must be arranged in the increasing order.</p> <p>The length of this array is equal to the length of the array <i>a</i>. Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.</p> |
| <i>ia</i> | <p>Array of length $m + 1$.</p> <p>This array contains indices of elements in the array <i>a</i>, such that $ia[i] - ia[0]$ is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i>. The value of the last element $ia[m]$ is equal to the number of non-zero elements of the matrix <i>A</i> plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.</p> |
| <i>b</i> | Array containing non-zero elements of the matrix <i>B</i> . Its length is equal to the number of non-zero elements in the matrix <i>B</i> . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details. |
| <i>jb</i> | <p>Array containing the column indices plus one for each non-zero element of the matrix <i>B</i>. For each row the column indices must be arranged in the increasing order.</p> <p>The length of this array is equal to the length of the array <i>b</i>. Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.</p> |
| <i>ib</i> | Array of length $n + 1$ when <i>trans</i> = 'N' or 'n', or $m + 1$ otherwise. |

This array contains indices of elements in the array b , such that $ib[i] - ib[0]$ is the index in the array b of the first non-zero element from the row i . The value of the last element $ib[n]$ or $ib[m]$ is equal to the number of non-zero elements of the matrix B plus one. Refer to `rowIndex` array description in [Sparse Matrix Storage Formats](#) for more details.

`nzmax`

The length of the arrays c and jc .

This parameter is used only if `request=0`. The routine stops calculation if the number of elements in the result matrix C exceeds the specified value of `nzmax`.

Output Parameters

`c`

Array containing non-zero elements of the result matrix C . Its length is equal to the number of non-zero elements in the matrix C . Refer to `values` array description in [Sparse Matrix Storage Formats](#) for more details.

`jc`

Array containing the column indices plus one for each non-zero element of the matrix C .

The length of this array is equal to the length of the array c . Refer to `columns` array description in [Sparse Matrix Storage Formats](#) for more details.

`ic`

Array of length $m + 1$ when `trans = 'N'` or `'n'`, or $n + 1$ otherwise.

This array contains indices of elements in the array c , such that $ic[i] - ic[0]$ is the index in the array c of the first non-zero element from the row i . The value of the last element $ic[m]$ or $ic[n]$ is equal to the number of non-zero elements of the matrix C plus one. Refer to `rowIndex` array description in [Sparse Matrix Storage Formats](#) for more details.

`info`

If `info=0`, the execution is successful.

If `info=I>0`, the routine stops calculation in the I -th row of the matrix C because number of elements in C exceeds `nzmax`.

If `info=-1`, the routine calculates only the size of the arrays c and jc and returns this value plus 1 as the last element of the array ic .

mkl_?csrmultd

Computes product of two sparse matrices stored in the CSR format (3-array variation) with one-based indexing. The result is stored in the dense matrix.

Syntax

```
void mkl_dcsmultd (const char *trans , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , double *a , MKL_INT *ja , MKL_INT *ia , double *b , MKL_INT *jb , MKL_INT
*ib , double *c , MKL_INT *ldc );
```

```
void mkl_scsmultd (const char *trans , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , float *a , MKL_INT *ja , MKL_INT *ia , float *b , MKL_INT *jb , MKL_INT
*ib , float *c , MKL_INT *ldc );
```

```
void mkl_ccsrmultd (const char *trans , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , MKL_Complex8 *a , MKL_INT *ja , MKL_INT *ia , MKL_Complex8 *b , MKL_INT
*jb , MKL_INT *ib , MKL_Complex8 *c , MKL_INT *ldc );
```

```
void mkl_zcsrmultd (const char *trans , const MKL_INT *m , const MKL_INT *n , const
MKL_INT *k , MKL_Complex16 *a , MKL_INT *ja , MKL_INT *ia , MKL_Complex16 *b , MKL_INT
*jb , MKL_INT *ib , MKL_Complex16 *c , MKL_INT *ldc );
```

Include Files

- mkl.h

Description

The `mkl_?csrmultd` routine performs a matrix-matrix operation defined as

$$C := \text{op}(A) * B$$

where:

A , B are the sparse matrices in the CSR format (3-array variation), C is dense matrix;

$\text{op}(A)$ is one of $\text{op}(A) = A$, or $\text{op}(A) = A^T$, or $\text{op}(A) = A^H$.

The routine works correctly if and only if the column indices in sparse matrix representations of matrices A and B are arranged in the increasing order for each row.

NOTE

This routine supports only one-based indexing of the input arrays.

Input Parameters

| | |
|--------------|--|
| <i>trans</i> | Specifies the operation. If <i>trans</i> = 'N' or 'n', then $C := A * B$ If <i>trans</i> = 'T' or 't' or 'C' or 'c', then $C := A^T * B$. |
| <i>m</i> | Number of rows of the matrix A . |
| <i>n</i> | Number of columns of the matrix A . |
| <i>k</i> | Number of columns of the matrix B . |
| <i>a</i> | Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details. |
| <i>ja</i> | Array containing the column indices plus one for each non-zero element of the matrix A . For each row the column indices must be arranged in the increasing order. The length of this array is equal to the length of the array <i>a</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details. |
| <i>ia</i> | Array of length $m + 1$ when <i>trans</i> = 'N' or 'n', or $n + 1$ otherwise. |

This array contains indices of elements in the array a , such that $ia[i] - ia[0]$ is the index in the array a of the first non-zero element from the row i . The value of the last element $ia[m]$ or $ia[n]$ is equal to the number of non-zero elements of the matrix A plus one. Refer to `rowIndex` array description in [Sparse Matrix Storage Formats](#) for more details.

b Array containing non-zero elements of the matrix B . Its length is equal to the number of non-zero elements in the matrix B . Refer to `values` array description in [Sparse Matrix Storage Formats](#) for more details.

jb Array containing the column indices plus one for each non-zero element of the matrix B . For each row the column indices must be arranged in the increasing order.

The length of this array is equal to the length of the array b . Refer to `columns` array description in [Sparse Matrix Storage Formats](#) for more details.

ib Array of length $m + 1$.

This array contains indices of elements in the array b , such that $ib[i] - ib[0]$ is the index in the array b of the first non-zero element from the row i . The value of the last element $ib[m]$ is equal to the number of non-zero elements of the matrix B plus one. Refer to `rowIndex` array description in [Sparse Matrix Storage Formats](#) for more details.

Output Parameters

c Array containing non-zero elements of the result matrix C .

ldc Specifies the leading dimension of the dense matrix C as declared in the calling (sub)program. Must be at least $\max(m, 1)$ when `trans = 'N'` or `'n'`, or $\max(1, n)$ otherwise.

Inspector-executor Sparse BLAS Routines

The inspector-executor API for Sparse BLAS divides operations into two stages: analysis and execution. During the initial analysis stage, the API inspects the matrix sparsity pattern and applies matrix structure changes. In the execution stage, subsequent routine calls reuse this information in order to improve performance.

The inspector-executor API supports key Sparse BLAS operations for iterative sparse solvers:

- Sparse matrix-vector multiplication
- Sparse matrix-matrix multiplication with a sparse or dense result
- Solution of triangular systems
- Sparse matrix addition

Naming conventions in Inspector-executor Sparse BLAS Routines

The Inspector-executor Sparse BLAS API routine names use the following convention:

```
mkl_sparse_[<character>]<operation>[_<format>]
```

The `<character>` field indicates the data type:

| | |
|---|---------------------------|
| s | real, single precision |
| c | complex, single precision |
| d | real, double precision |
| z | complex, double precision |

The data type is included in the name only if the function accepts dense matrix or scalar floating point parameters.

The *<operation>* field indicates the type of operation:

| | |
|------------------------------|--|
| create | create matrix handle |
| copy | create a copy of matrix handle |
| convert | convert matrix between sparse formats |
| export | export matrix from internal representation to CSR or BSR format |
| destroy | frees memory allocated for matrix handle |
| set_ <i><op></i> _hint | provide information about number of upcoming compute operations and operation type for optimization purposes, where <i><op></i> is mv, sv, mm, sm, or memory |
| optimize | analyze the matrix using hints and store optimization information in matrix handle |
| mv | compute sparse matrix-vector product |
| mm | compute sparse matrix by dense matrix product (batch mv) |
| sppmm/sppmmd | compute sparse matrix by sparse matrix product and store the result as a sparse/dense matrix |
| trsv | solve a triangular system |
| trsm | solve a triangular system with multiple right-hand sides |
| add | compute sum of two sparse matrices |

The *<format>* field indicates the sparse matrix storage format:

| | |
|-----|---|
| coo | coordinate format |
| csr | compressed sparse row format plus variations |
| csc | compressed sparse column format plus variations |
| bsr | block sparse row format plus variations |

The format is included in the function name only if the function parameters include an explicit sparse matrix in one of the conventional sparse matrix formats.

Sparse Matrix Storage Formats for Inspector-executor Sparse BLAS Routines

Inspector-executor Sparse BLAS routines support four conventional sparse matrix storage formats:

- compressed sparse row format (CSR) plus variations

- compressed sparse column format (CSC) plus variations
- coordinate format (COO)
- block sparse row format (BSR) plus variations

Computational routines operate on a matrix handle that stores a matrix in CSR or BSR formats. Other formats should be converted to CSR or BSR format before calling any computational routines. For more information see [Sparse Matrix Storage Formats](#).

Supported Inspector-executor Sparse BLAS Operations

The Inspector-executor Sparse BLAS API can perform several operations involving sparse matrices. These notations are used in the description of the operations:

- A , G , V are sparse matrices
- B and C are dense matrices
- x and y are dense vectors
- $alpha$ and $beta$ are scalars

$op(A)$ represents a possible transposition of matrix A

$$\begin{aligned} op(A) &= A \\ op(A) &= A^T - \text{transpose of } A \\ op(A) &= A^H - \text{conjugate transpose of } A \end{aligned}$$

$op(A)^{-1}$ denotes the inverse of $op(A)$.

The Inspector-executor Sparse BLAS routines support the following operations:

- computing the vector product between a sparse matrix and a dense vector:

$$y := alpha * op(A) * x + beta * y$$

- solving a single triangular system:

$$y := alpha * inv(op(A)) * x$$

- computing a product between a sparse matrix and a dense matrix:

$$C := alpha * op(A) * B + beta * C$$

- computing a product between sparse matrices with a sparse result:

$$V := alpha * op(A) * G$$

- computing a product between sparse matrices with a dense result:

$$C := alpha * op(A) * G$$

- computing a sum of sparse matrices with a sparse result:

$$V := alpha * op(A) + G$$

- solving a sparse triangular system with multiple right-hand sides:

$$C := alpha * inv(op(A)) * B$$

Matrix manipulation routines

The [Matrix Manipulation routines](#) table lists the Matrix Manipulation routines and the data types associated with them.

Matrix Manipulation Routines and Their Data Types

| Routine or Function Group | Data Types | Description |
|--------------------------------------|------------|--|
| <code>mkl_sparse_?_create_csr</code> | s, d, c, z | Creates a handle for a CSR format matrix. |
| <code>mkl_sparse_?_create_csc</code> | s, d, c, z | Creates a handle for a CSC format matrix. |
| <code>mkl_sparse_?_create_coo</code> | s, d, c, z | Creates a handle for a matrix in COO format. |
| <code>mkl_sparse_?_create_bsr</code> | s, d, c, z | Creates a handle for a matrix in BSR format. |
| <code>mkl_sparse_copy</code> | NA | Creates a copy of a matrix handle. |
| <code>mkl_sparse_destroy</code> | NA | Frees memory allocated for matrix handle. |
| <code>mkl_sparse_convert_csr</code> | NA | Converts internal matrix representation to CSR format. |
| <code>mkl_sparse_convert_bsr</code> | NA | Converts internal matrix representation to BSR format or changes BSR block size. |
| <code>mkl_sparse_?_export_csr</code> | s, d, c, z | Exports CSR matrix from internal representation. |
| <code>mkl_sparse_?_export_bsr</code> | s, d, c, z | Exports BSR matrix from internal representation. |
| <code>mkl_sparse_?_set_value</code> | s, d, c, z | Changes a single value of matrix in internal representation. |

`mkl_sparse_?_create_csr`

Creates a handle for a CSR format matrix.

Syntax

```
sparse_status_t mkl_sparse_s_create_csr (sparse_matrix_t *A, sparse_index_base_t indexing, MKL_INT rows, MKL_INT cols, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT *col_indx, float *values);
```

```
sparse_status_t mkl_sparse_d_create_csr (sparse_matrix_t *A, sparse_index_base_t indexing, MKL_INT rows, MKL_INT cols, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT *col_indx, double *values);
```

```
sparse_status_t mkl_sparse_c_create_csr (sparse_matrix_t *A, sparse_index_base_t indexing, MKL_INT rows, MKL_INT cols, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT *col_indx, MKL_Complex8 *values);
```

```
sparse_status_t mkl_sparse_z_create_csr (sparse_matrix_t *A, sparse_index_base_t indexing, MKL_INT rows, MKL_INT cols, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT *col_indx, MKL_Complex16 *values);
```

Include Files

- `mkl_spblas.h`

Description

The `mkl_sparse_?_create_csr` routine creates a handle for an m -by- k matrix A in CSR format.

Input Parameters

| | |
|-------------------|--|
| <i>indexing</i> | Indicates how input arrays are indexed. |
| | <p>SPARSE_INDEX_BASE_Z Zero-based (C-style) indexing: indices start at 0.</p> <p>SPARSE_INDEX_BASE_O One-based (Fortran-style) indexing: indices start at 1.</p> |
| <i>rows</i> | Number of rows of matrix <i>A</i> . |
| <i>cols</i> | Number of columns of matrix <i>A</i> . |
| <i>rows_start</i> | <p>Array of length at least <i>m</i>. This array contains row indices, such that $rows_start[i] - rows_start[0]$ is the first index of row <i>i</i> in the arrays <i>values</i> and <i>col_indx</i>.</p> <p>Refer to <i>pointerb</i> array description in CSR Format for more details.</p> |
| <i>rows_end</i> | <p>Array of at least length <i>m</i>. This array contains row indices, such that $rows_end[i] - rows_start[0] - 1$ is the last index of row <i>i</i> in the arrays <i>values</i> and <i>col_indx</i>.</p> <p>Refer to <i>pointerE</i> array description in CSR Format for more details.</p> |
| <i>col_indx</i> | <p>For one-based indexing, array containing the column indices plus one for each non-zero element of the matrix <i>A</i>. For zero-based indexing, array containing the column indices for each non-zero element of the matrix <i>A</i>. Its length is at least $rows_end[rows - 1] - rows_start[0]$.</p> |
| <i>values</i> | <p>Array containing non-zero elements of the matrix <i>A</i>. Its length is equal to length of the <i>col_indx</i> array.</p> <p>Refer to <i>values</i> array description in CSR Format for more details.</p> |

Output Parameters

| | |
|----------|---|
| <i>A</i> | Handle containing internal data for subsequent Inspector-executor Sparse BLAS operations. |
|----------|---|

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

| | |
|------------------------------|--|
| SPARSE_STATUS_SUCCESS | The operation was successful. |
| SPARSE_STATUS_NOT_INITIALIZE | The routine encountered an empty handle or matrix array. |
| D | |
| SPARSE_STATUS_ALLOC_FAILED | Internal memory allocation failed. |
| SPARSE_STATUS_INVALID_VALUE | The input parameters contain an invalid value. |
| SPARSE_STATUS_EXECUTION_FAIL | Execution failed. |
| ED | |
| SPARSE_STATUS_INTERNAL_ERROR | An error in algorithm implementation occurred. |

SPARSE_STATUS_NOT_SUPPORTED The requested operation is not supported.

mkl_sparse_?_create_csc

Creates a handle for a CSC format matrix.

Syntax

```
sparse_status_t mkl_sparse_s_create_csc (sparse_matrix_t *A, sparse_index_base_t
indexing, MKL_INT rows, MKL_INT cols, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT
*col_indx, float *values);
```

```
sparse_status_t mkl_sparse_d_create_csc (sparse_matrix_t *A, sparse_index_base_t
indexing, MKL_INT rows, MKL_INT cols, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT
*col_indx, double *values);
```

```
sparse_status_t mkl_sparse_c_create_csc (sparse_matrix_t *A, sparse_index_base_t
indexing, MKL_INT rows, MKL_INT cols, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT
*col_indx, MKL_Complex8 *values);
```

```
sparse_status_t mkl_sparse_z_create_csc (sparse_matrix_t *A, sparse_index_base_t
indexing, MKL_INT rows, MKL_INT cols, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT
*col_indx, MKL_Complex16 *values);
```

Include Files

- mkl_spblas.h

Description

The `mkl_sparse_?_create_csc` routine creates a handle for an m -by- k matrix A in CSC format.

Input Parameters

| | |
|-------------------|---|
| <i>indexing</i> | Indicates how input arrays are indexed. SPARSE_INDEX_BASE_Z Zero-based (C-style) indexing: indices start at ERO 0. SPARSE_INDEX_BASE_O One-based (Fortran-style) indexing: indices NE start at 1. |
| <i>rows</i> | Number of rows of the matrix A . |
| <i>cols</i> | Number of columns of the matrix A . |
| <i>rows_start</i> | Array of length at least m . This array contains row indices, such that $rows_start[i] - rows_start[0]$ is the first index of row i in the arrays $values$ and col_indx . Refer to <i>pointerb</i> array description in CSC Format for more details. |
| <i>rows_end</i> | Array of at least length m . This array contains row indices, such that $rows_end[i] - rows_start[0] - 1$ is the last index of row i in the arrays $values$ and col_indx . Refer to <i>pointerE</i> array description in CSC Format for more details. |

| | |
|-----------------------|--|
| <code>col_indx</code> | For one-based indexing, array containing the column indices plus one for each non-zero element of the matrix <i>A</i> . For zero-based indexing, array containing the column indices for each non-zero element of the matrix <i>A</i> . Its length is at least <code>rows_end[rows - 1] - rows_start[0]</code> . |
| <code>values</code> | Array containing non-zero elements of the matrix <i>A</i> . Its length is equal to length of the <code>col_indx</code> array. Refer to <code>values</code> array description in CSC Format for more details. |

Output Parameters

| | |
|----------------|----------------------------------|
| <code>A</code> | Handle containing internal data. |
|----------------|----------------------------------|

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

| | |
|---|--|
| <code>SPARSE_STATUS_SUCCESS</code> | The operation was successful. |
| <code>SPARSE_STATUS_NOT_INITIALIZE</code> | The routine encountered an empty handle or matrix array. |
| <code>D</code> | |
| <code>SPARSE_STATUS_ALLOC_FAILED</code> | Internal memory allocation failed. |
| <code>SPARSE_STATUS_INVALID_VALUE</code> | The input parameters contain an invalid value. |
| <code>SPARSE_STATUS_EXECUTION_FAIL</code> | Execution failed. |
| <code>ED</code> | |
| <code>SPARSE_STATUS_INTERNAL_ERROR</code> | An error in algorithm implementation occurred. |
| <code>SPARSE_STATUS_NOT_SUPPORTED</code> | The requested operation is not supported. |

`mkl_sparse_?_create_coo`

Creates a handle for a matrix in COO format.

Syntax

```
sparse_status_t mkl_sparse_s_create_coo (sparse_matrix_t *A, sparse_index_base_t indexing, MKL_INT rows, MKL_INT cols, MKL_INT nnz, MKL_INT *row_indx, MKL_INT *col_indx, float *values);
```

```
sparse_status_t mkl_sparse_d_create_coo (sparse_matrix_t *A, sparse_index_base_t indexing, MKL_INT rows, MKL_INT cols, MKL_INT nnz, MKL_INT *row_indx, MKL_INT *col_indx, double *values);
```

```
sparse_status_t mkl_sparse_c_create_coo (sparse_matrix_t *A, sparse_index_base_t indexing, MKL_INT rows, MKL_INT cols, MKL_INT nnz, MKL_INT *row_indx, MKL_INT *col_indx, MKL_Complex8 *values);
```

```
sparse_status_t mkl_sparse_z_create_coo (sparse_matrix_t *A, sparse_index_base_t indexing, MKL_INT rows, MKL_INT cols, MKL_INT nnz, MKL_INT *row_indx, MKL_INT *col_indx, MKL_Complex16 *values);
```

Include Files

- `mkl_splblas.h`

Description

The `mkl_sparse_?_create_coo` routine creates a handle for an m -by- k matrix A in COO format.

Input Parameters

| | |
|-----------------|--|
| <i>indexing</i> | Indicates how input arrays are indexed. |
| | <p><code>SPARSE_INDEX_BASE_Z</code> Zero-based (C-style) indexing: indices start at 0.</p> <p><code>SPARSE_INDEX_BASE_ONE</code> One-based (Fortran-style) indexing: indices start at 1.</p> |
| <i>rows</i> | Number of rows of matrix A . |
| <i>cols</i> | Number of columns of matrix A . |
| <i>nnz</i> | Specifies the number of non-zero elements of the matrix A . Refer to <i>nnz</i> description in Coordinate Format for more details. |
| <i>row_indx</i> | Array of length <i>nnz</i> , containing the row indices for each non-zero element of matrix A . Refer to <i>rows</i> array description in Coordinate Format for more details. |
| <i>col_indx</i> | Array of length <i>nnz</i> , containing the column indices for each non-zero element of matrix A . Refer to <i>columns</i> array description in Coordinate Format for more details. |
| <i>values</i> | Array of length <i>nnz</i> , containing the non-zero elements of matrix A in arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details. |

Output Parameters

| | |
|----------|----------------------------------|
| <i>A</i> | Handle containing internal data. |
|----------|----------------------------------|

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

| | |
|---|--|
| <code>SPARSE_STATUS_SUCCESS</code> | The operation was successful. |
| <code>SPARSE_STATUS_NOT_INITIALIZE</code> | The routine encountered an empty handle or matrix array. |
| <code>D</code> | |
| <code>SPARSE_STATUS_ALLOC_FAILED</code> | Internal memory allocation failed. |
| <code>SPARSE_STATUS_INVALID_VALUE</code> | The input parameters contain an invalid value. |
| <code>SPARSE_STATUS_EXECUTION_FAIL</code> | Execution failed. |
| <code>ED</code> | |
| <code>SPARSE_STATUS_INTERNAL_ERROR</code> | An error in algorithm implementation occurred. |
| <code>SPARSE_STATUS_NOT_SUPPORTED</code> | The requested operation is not supported. |

mkl_sparse_?_create_bsr

Creates a handle for a matrix in BSR format.

Syntax

```

sparse_status_t mkl_sparse_s_create_bsr (sparse_matrix_t *A, sparse_index_base_t
indexing, sparse_layout_t block_layout, MKL_INT rows, MKL_INT cols, MKL_INT
block_size, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT *col_indx, float *values);

sparse_status_t mkl_sparse_d_create_bsr (sparse_matrix_t *A, sparse_index_base_t
indexing, sparse_layout_t block_layout, MKL_INT rows, MKL_INT cols, MKL_INT
block_size, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT *col_indx, double *values);

sparse_status_t mkl_sparse_c_create_bsr (sparse_matrix_t *A, sparse_index_base_t
indexing, sparse_layout_t block_layout, MKL_INT rows, MKL_INT cols, MKL_INT
block_size, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT *col_indx, MKL_Complex8
*values);

sparse_status_t mkl_sparse_z_create_bsr (sparse_matrix_t *A, sparse_index_base_t
indexing, sparse_layout_t block_layout, MKL_INT rows, MKL_INT cols, MKL_INT
block_size, MKL_INT *rows_start, MKL_INT *rows_end, MKL_INT *col_indx, MKL_Complex16
*values);

```

Include Files

- mkl_spblas.h

Description

The `mkl_sparse_?_create_bsr` routine creates a handle for an m -by- k matrix A in BSR format.

Input Parameters

| | |
|-------------------------------|---|
| <i>indexing</i> | Indicates how input arrays are indexed. |
| SPARSE_INDEX_BASE_Z ERO | Zero-based (C-style) indexing: indices start at 0. |
| SPARSE_INDEX_BASE_O NE | One-based (Fortran-style) indexing: indices start at 1. |
| <i>block_layout</i> | Specifies layout of blocks: |
| SPARSE_LAYOUT_ROW_M AJOR | Storage of elements of blocks uses row major layout. |
| SPARSE_LAYOUT_COLUMN MAJOR | Storage of elements of blocks uses column major layout. |

NOTE

If you specify `SPARSE_INDEX_BASE_ZERO` for *indexing*, you must use `SPARSE_LAYOUT_ROW_MAJOR` for *block_layout*. Similarly, if you specify `SPARSE_INDEX_BASE_ONE` for *indexing*, you must use `SPARSE_LAYOUT_COLUMN_MAJOR` for *block_layout*. Otherwise `mkl_sparse?_create_bsr` returns `SPARSE_STATUS_NOT_SUPPORTED`.

| | |
|-------------------------|---|
| <code>rows</code> | Number of block rows of matrix <i>A</i> . |
| <code>cols</code> | Number of block columns of matrix <i>A</i> . |
| <code>block_size</code> | Size of blocks in matrix <i>A</i> . |
| <code>rows_start</code> | <p>Array of length <i>m</i>. This array contains row indices, such that <code>rows_start[i] - rows_start[0]</code> is the first index of block row <i>i</i> in the arrays <code>values</code> and <code>col_indx</code>.</p> <p>Refer to <code>pointerb</code> array description in CSR Format for more details.</p> |
| <code>rows_end</code> | <p>Array of length <i>m</i>. This array contains row indices, such that <code>rows_end[i] - rows_start[0] - 1</code> is the last index of block row <i>i</i> in the arrays <code>values</code> and <code>col_indx</code>.</p> <p>Refer to <code>pointerE</code> array description in CSR Format for more details.</p> |
| <code>col_indx</code> | <p>For one-based indexing, array containing the column indices plus one for each non-zero block of the matrix <i>A</i>. For zero-based indexing, array containing the column indices for each non-zero block of the matrix <i>A</i>. Its length is <code>rows_end[rows - 1] - rows_start[0]</code>.</p> |
| <code>values</code> | <p>Array containing non-zero elements of the matrix <i>A</i>. Its length is equal to length of the <code>col_indx</code> array multiplied by <code>block_size*block_size</code>.</p> <p>Refer to the <code>values</code> array description in BSR Format for more details.</p> |

Output Parameters

`A` Handle containing internal data.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

| | |
|---|--|
| <code>SPARSE_STATUS_SUCCESS</code> | The operation was successful. |
| <code>SPARSE_STATUS_NOT_INITIALIZE</code> | The routine encountered an empty handle or matrix array. |
| <code>D</code> | |
| <code>SPARSE_STATUS_ALLOC_FAILED</code> | Internal memory allocation failed. |
| <code>SPARSE_STATUS_INVALID_VALUE</code> | The input parameters contain an invalid value. |
| <code>SPARSE_STATUS_EXECUTION_FAIL</code> | Execution failed. |
| <code>ED</code> | |

SPARSE_STATUS_INTERNAL_ERROR An error in algorithm implementation occurred.

SPARSE_STATUS_NOT_SUPPORTED The requested operation is not supported.

mkl_sparse_copy

Creates a copy of a matrix handle.

Syntax

```
sparse_status_t mkl_sparse_copy (const sparse_matrix_t source, struct matrix_descr
descr, sparse_matrix_t *dest);
```

Include Files

- mkl_spblas.h

Description

The `mkl_sparse_copy` routine creates a copy of a matrix handle.

Input Parameters

| | |
|-------------------------------------|--|
| <i>source</i> | Specifies handle containing internal data. |
| <i>descr</i> | Structure specifying sparse matrix properties. |
| | <code>sparse_matrix_type_t type</code> - Specifies the type of a sparse matrix: |
| SPARSE_MATRIX_TYPE_GENERAL | The matrix is processed as is. |
| SPARSE_MATRIX_TYPE_SYMMETRIC | The matrix is symmetric (only the requested triangle is processed). |
| SPARSE_MATRIX_TYPE_HERMITIAN | The matrix is Hermitian (only the requested triangle is processed). |
| SPARSE_MATRIX_TYPE_TRIANGULAR | The matrix is triangular (only the requested triangle is processed). |
| SPARSE_MATRIX_TYPE_DIAGONAL | The matrix is diagonal (only diagonal elements are processed). |
| SPARSE_MATRIX_TYPE_BLOCK_TRIANGULAR | The matrix is block-triangular (only requested triangle is processed). (Applies to BSR format only.) |
| SPARSE_MATRIX_TYPE_BLOCK_DIAGONAL | The matrix is block-diagonal (only diagonal blocks are processed). (Applies to BSR format only.) |
| | <code>sparse_fill_mode_t mode</code> - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices: |
| SPARSE_FILL_MODE_LOWER | The lower triangular matrix part is processed. |

SPARSE_FILL_MODE_UP PER The upper triangular matrix part is processed.

sparse_diag_type_t *diag* - Specifies diagonal type for non-general matrices:

SPARSE_DIAG_NON_UNIT T Diagonal elements might not be equal to one.

SPARSE_DIAG_UNIT Diagonal elements are equal to one.

Output Parameters

dest Handle containing internal data.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

SPARSE_STATUS_SUCCESS The operation was successful.

SPARSE_STATUS_NOT_INITIALIZE D The routine encountered an empty handle or matrix array.

SPARSE_STATUS_ALLOC_FAILED Internal memory allocation failed.

SPARSE_STATUS_INVALID_VALUE The input parameters contain an invalid value.

SPARSE_STATUS_EXECUTION_FAILED ED Execution failed.

SPARSE_STATUS_INTERNAL_ERROR An error in algorithm implementation occurred.

SPARSE_STATUS_NOT_SUPPORTED The requested operation is not supported.

mkl_sparse_destroy

Frees memory allocated for matrix handle.

Syntax

```
sparse_status_t mkl_sparse_destroy (sparse_matrix_t A);
```

Include Files

- `mkl_spblas.h`

Description

The `mkl_sparse_destroy` routine frees memory allocated for matrix handle.

NOTE

You must free memory allocated for matrices after completing use of them. The `mkl_sparse_destroy` provides a utility to do so.

Input Parameters

A Handle containing internal data.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

`SPARSE_STATUS_SUCCESS` The operation was successful.

`SPARSE_STATUS_NOT_INITIALIZE` The routine encountered an empty handle or matrix array.

`D`

`SPARSE_STATUS_ALLOC_FAILED` Internal memory allocation failed.

`SPARSE_STATUS_INVALID_VALUE` The input parameters contain an invalid value.

`SPARSE_STATUS_EXECUTION_FAIL` Execution failed.

`ED`

`SPARSE_STATUS_INTERNAL_ERROR` An error in algorithm implementation occurred.

`SPARSE_STATUS_NOT_SUPPORTED` The requested operation is not supported.

`mkl_sparse_convert_csr`

Converts internal matrix representation to CSR format.

Syntax

```
sparse_status_t mkl_sparse_convert_csr (const sparse_matrix_t source,
sparse_operation_t operation, sparse_matrix_t *dest);
```

Include Files

- `mkl_spblas.h`

Description

The `mkl_sparse_convert_csr` routine converts internal matrix representation to CSR format.

Input Parameters

source Handle containing internal data.

operation Specifies operation `op()` on input matrix.

`SPARSE_OPERATION_NO` Non-transpose, $op(A) = A$.
`N_TRANSPOSE`

`SPARSE_OPERATION_TR` Transpose, $op(A) = A^T$.
`ANSPOSE`

`SPARSE_OPERATION_CO` Conjugate transpose, $op(A) = A^H$.
`NJUGATE_TRANSPOSE`

Output Parameters

dest Handle containing internal data.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

`SPARSE_STATUS_SUCCESS` The operation was successful.

`SPARSE_STATUS_NOT_INITIALIZE` The routine encountered an empty handle or matrix array.
D

`SPARSE_STATUS_ALLOC_FAILED` Internal memory allocation failed.

`SPARSE_STATUS_INVALID_VALUE` The input parameters contain an invalid value.

`SPARSE_STATUS_EXECUTION_FAIL` Execution failed.
ED

`SPARSE_STATUS_INTERNAL_ERROR` An error in algorithm implementation occurred.

`SPARSE_STATUS_NOT_SUPPORTED` The requested operation is not supported.

`mkl_sparse_convert_bsr`

Converts internal matrix representation to BSR format or changes BSR block size.

Syntax

```
sparse_status_t mkl_sparse_convert_bsr (const sparse_matrix_t source, MKL_INT
block_size, sparse_layout_t block_layout, sparse_operation_t operation, sparse_matrix_t
*dest);
```

Include Files

- `mkl_spblas.h`

Description

The `mkl_sparse_convert_bsr` routine converts internal matrix representation to BSR format or changes BSR block size.

Input Parameters

source Handle containing internal data.

block_size Size of the block in the output structure.

block_layout Specifies layout of blocks:

`SPARSE_LAYOUT_ROW_MAJOR` Storage of elements of blocks uses row major layout.

`SPARSE_LAYOUT_COLUMN_MAJOR` Storage of elements of blocks uses column major layout.

operation Specifies operation `op()` on input matrix.

SPARSE_OPERATION_NO **Non-transpose**, $op(A) = A$.
N_TRANSPOSE

SPARSE_OPERATION_TR **Transpose**, $op(A) = A^T$.
ANSPOSE

SPARSE_OPERATION_CO **Conjugate transpose**, $op(A) = A^H$.
NJUGATE_TRANSPOSE

Output Parameters

dest Handle containing internal data.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

SPARSE_STATUS_SUCCESS The operation was successful.

SPARSE_STATUS_NOT_INITIALIZE The routine encountered an empty handle or matrix array.
D

SPARSE_STATUS_ALLOC_FAILED Internal memory allocation failed.

SPARSE_STATUS_INVALID_VALUE The input parameters contain an invalid value.

SPARSE_STATUS_EXECUTION_FAIL Execution failed.
ED

SPARSE_STATUS_INTERNAL_ERROR An error in algorithm implementation occurred.

SPARSE_STATUS_NOT_SUPPORTED The requested operation is not supported.

mkl_sparse_?_export_csr

Exports CSR matrix from internal representation.

Syntax

```
sparse_status_t mkl_sparse_s_export_csr (const sparse_matrix_t *source,
sparse_index_base_t *indexing, MKL_INT *rows, MKL_INT *cols, MKL_INT **rows_start,
MKL_INT **rows_end, MKL_INT **col_indx, float **values);
```

```
sparse_status_t mkl_sparse_d_export_csr (const sparse_matrix_t *source,
sparse_index_base_t *indexing, MKL_INT *rows, MKL_INT *cols, MKL_INT **rows_start,
MKL_INT **rows_end, MKL_INT **col_indx, double **values);
```

```
sparse_status_t mkl_sparse_c_export_csr (const sparse_matrix_t *source,
sparse_index_base_t *indexing, MKL_INT *rows, MKL_INT *cols, MKL_INT **rows_start,
MKL_INT **rows_end, MKL_INT **col_indx, MKL_Complex8 **values);
```

```
sparse_status_t mkl_sparse_z_export_csr (const sparse_matrix_t *source,
sparse_index_base_t *indexing, MKL_INT *rows, MKL_INT *cols, MKL_INT **rows_start,
MKL_INT **rows_end, MKL_INT **col_indx, MKL_Complex16 **values);
```

Include Files

- mkl_splblas.h

Description

If the matrix specified by the *source* handle is in CSR format, the `mkl_sparse_?_export_csr` routine exports an m -by- k matrix A in CSR format matrix from the internal representation. The routine returns pointers to the internal representation and does not allocate additional memory.

NOTE

Since the exported data is a copy of an internally stored structure, any changes made to it have no effect on subsequent Inspector-executor Sparse BLAS operations.

If the matrix is not already in CSR format, the routine returns `SPARSE_STATUS_INVALID_VALUE`.

Input Parameters

source Handle containing internal data.

Output Parameters

indexing Indicates how input arrays are indexed.

`SPARSE_INDEX_BASE_Z` Zero-based (C-style) indexing: indices start at 0.

`SPARSE_INDEX_BASE_ONE` One-based (Fortran-style) indexing: indices start at 1.

rows Number of rows of the matrix *source*.

cols Number of columns of the matrix *source*.

rows_start Pointer to array of length m . This array contains row indices, such that $rows_start[i] - rows_start[0]$ is the first index of row i in the arrays *values* and *col_indx*.

Refer to *pointerb* array description in [CSR Format](#) for more details.

rows_end Pointer to array of length m . This array contains row indices, such that $rows_end[i] - rows_start[0] - 1$ is the last index of row i in the arrays *values* and *col_indx*.

Refer to *pointerE* array description in [CSR Format](#) for more details.

col_indx For one-based indexing, pointer to array containing the column indices plus one for each non-zero element of the matrix *source*. For zero-based indexing, pointer to array containing the column indices for each non-zero element of the matrix *source*. Its length is $rows_end[rows - 1] - rows_start[0]$.

values Pointer to array containing non-zero elements of the matrix A . Its length is equal to length of the *col_indx* array.

Refer to *values* array description in [CSR Format](#) for more details.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

| | |
|------------------------------------|--|
| SPARSE_STATUS_SUCCESS | The operation was successful. |
| SPARSE_STATUS_NOT_INITIALIZE D | The routine encountered an empty handle or matrix array. |
| SPARSE_STATUS_ALLOC_FAILED | Internal memory allocation failed. |
| SPARSE_STATUS_INVALID_VALUE | The input parameters contain an invalid value. |
| SPARSE_STATUS_EXECUTION_FAIL ED | Execution failed. |
| SPARSE_STATUS_INTERNAL_ERROR | An error in algorithm implementation occurred. |
| SPARSE_STATUS_NOT_SUPPORTED | The requested operation is not supported. |

mkl_sparse_?_export_bsr

Exports BSR matrix from internal representation.

Syntax

```
sparse_status_t mkl_sparse_s_export_bsr (const sparse_matrix_t source,  
sparse_index_base_t *indexing, sparse_layout_t *block_layout, MKL_INT *rows, MKL_INT  
*cols, MKL_INT *block_size, MKL_INT **rows_start, MKL_INT **rows_end, MKL_INT  
**col_indx, float **values);
```

```
sparse_status_t mkl_sparse_d_export_bsr (const sparse_matrix_t source,  
sparse_index_base_t *indexing, sparse_layout_t *block_layout, MKL_INT *rows, MKL_INT  
*cols, MKL_INT *block_size, MKL_INT **rows_start, MKL_INT **rows_end, MKL_INT  
**col_indx, double **values);
```

```
sparse_status_t mkl_sparse_c_export_bsr (const sparse_matrix_t source,  
sparse_index_base_t *indexing, sparse_layout_t *block_layout, MKL_INT *rows, MKL_INT  
*cols, MKL_INT *block_size, MKL_INT **rows_start, MKL_INT **rows_end, MKL_INT  
**col_indx, MKL_Complex8 **values);
```

```
sparse_status_t mkl_sparse_z_export_bsr (const sparse_matrix_t source,  
sparse_index_base_t *indexing, sparse_layout_t *block_layout, MKL_INT *rows, MKL_INT  
*cols, MKL_INT *block_size, MKL_INT **rows_start, MKL_INT **rows_end, MKL_INT  
**col_indx, MKL_Complex16 **values);
```

Include Files

- mkl_spblas.h

Description

If the matrix specified by the *source* handle is in BSR format, the `mkl_sparse_?_export_bsr` routine exports an m -by- k matrix A in BSR format from the internal representation. The routine returns pointers to the internal representation and does not allocate additional memory.

NOTE

Since the exported data is a copy of an internally stored structure, any changes made to it have no effect on subsequent Inspector-executor Sparse BLAS operations.

If the matrix is not already in BSR format, the routine returns `SPARSE_STATUS_INVALID_VALUE`.

Input Parameters

source Handle containing internal data.

Output Parameters

indexing Indicates how input arrays are indexed.

SPARSE_INDEX_BASE_Z
ERO Zero-based (C-style) indexing: indices start at 0.

SPARSE_INDEX_BASE_O
NE One-based (Fortran-style) indexing: indices start at 1.

block_layout Specifies layout of blocks:

SPARSE_LAYOUT_ROW_M
AJOR Storage of elements of blocks uses row major layout.

SPARSE_LAYOUT_COLUMN_MAJOR
N_MAJOR Storage of elements of blocks uses column major layout.

rows Number of block rows of the matrix *source*.

cols Number of columns of the matrix *source*. Number of block columns of matrix *source*.

block_size Size of the block in matrix *source*.

rows_start Pointer to array of length *m*. This array contains row indices, such that $rows_start[i] - rows_start[0]$ is the first index of block row *i* in the arrays *values* and *col_indx*.

Refer to *pointerb* array description in [CSR Format](#) for more details.

rows_end Pointer to array of length *m*. This array contains row indices, such that $rows_end[i] - rows_start[0] - 1$ is the last index of block row *i* in the arrays *values* and *col_indx*.

Refer to *pointerE* array description in [CSR Format](#) for more details.

col_indx For one-based indexing, pointer to array containing the column indices plus one for each non-zero blocks of the matrix *source*. For zero-based indexing, pointer to array containing the column indices for each non-zero blocks of the matrix *source*. Its length is $rows_end[m - 1] - rows_start[0]$.

values Pointer to array containing non-zero elements of matrix *source*. Its length is equal to length of the *col_indx* array multiplied by $block_size * block_size$.

Refer to the *values* array description in [BSR Format](#) for more details.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

SPARSE_STATUS_SUCCESS The operation was successful.

`SPARSE_STATUS_NOT_INITIALIZE` The routine encountered an empty handle or matrix array.
D

`SPARSE_STATUS_ALLOC_FAILED` Internal memory allocation failed.

`SPARSE_STATUS_INVALID_VALUE` The input parameters contain an invalid value.

`SPARSE_STATUS_EXECUTION_FAIL` Execution failed.
ED

`SPARSE_STATUS_INTERNAL_ERROR` An error in algorithm implementation occurred.

`SPARSE_STATUS_NOT_SUPPORTED` The requested operation is not supported.

mkl_sparse_?_set_value

Changes a single value of matrix in internal representation.

Syntax

```
sparse_status_t mkl_sparse_s_set_value (sparse_matrix_t A, MKL_INT row, MKL_INT col, float value);  
  
sparse_status_t mkl_sparse_d_set_value (sparse_matrix_t A, MKL_INT row, MKL_INT col, double value);  
  
sparse_status_t mkl_sparse_c_set_value (sparse_matrix_t A, MKL_INT row, MKL_INT col, MKL_Complex8 value);  
  
sparse_status_t mkl_sparse_z_set_value (sparse_matrix_t A, MKL_INT row, MKL_INT col, MKL_Complex16 value);
```

- `mkl_spblas.h`

Description

Use the `mkl_sparse_?_set_value` routine to change a single value of a matrix in internal Inspector-executor Sparse BLAS format.

Input Parameters

| | |
|--------------------|---|
| <code>A</code> | Specifies handle containing internal data. |
| <code>row</code> | Indicates row of matrix in which to set value. |
| <code>col</code> | Indicates column of matrix in which to set value. |
| <code>value</code> | Indicates value |

Output Parameters

| | |
|----------------|---|
| <code>A</code> | Handle containing modified internal data. |
|----------------|---|

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

| | |
|-----------------------------------|--|
| SPARSE_STATUS_SUCCESS | The operation was successful. |
| SPARSE_STATUS_NOT_INITIALIZE D | The routine encountered an empty handle or matrix array. |
| SPARSE_STATUS_INVALID_VALUE | The input parameters contain an invalid value. |
| SPARSE_STATUS_INTERNAL_ERROR | An error in algorithm implementation occurred. |

Inspector-executor Sparse BLAS Analysis Routines

Analysis Routines and Their Data Types

| Routine or Function Group | Description |
|--|---|
| mkl_sparse_set_mv_hint | Provides estimate of number and type of upcoming matrix-vector operations. |
| mkl_sparse_set_sv_hint | Provides estimate of number and type of upcoming triangular system solver operations. |
| mkl_sparse_set_mm_hint | Provides estimate of number and type of upcoming matrix-matrix multiplication operations. |
| mkl_sparse_set_sm_hint | Provides estimate of number and type of upcoming triangular matrix solve with multiple right hand sides operations. |
| mkl_sparse_set_memory_hint | Provides memory requirements for performance optimization purposes. |
| mkl_sparse_optimize | Analyzes matrix structure and performs optimizations using the hints provided in the handle. |

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

[mkl_sparse_set_mv_hint](#)

Provides estimate of number and type of upcoming matrix-vector operations.

Syntax

```
sparse_status_t mkl_sparse_set_mv_hint (sparse_matrix_t A, sparse_operation_t
operation, struct matrix_descr descr, MKL_INT expected_calls);
```

Include Files

- `mkl_spblas.h`

Description

Use the `mkl_sparse_set_mv_hint` routine to provide the Inspector-executor Sparse BLAS API an estimate of the number of upcoming matrix-vector multiplication operations for performance optimization, and specify whether or not to perform an operation on the matrix.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

operation

Specifies operation `op()` on input matrix.

`SPARSE_OPERATION_NO` Non-transpose, $op(A) = A$.
`N_TRANSPOSE`

`SPARSE_OPERATION_TR` Transpose, $op(A) = A^T$.
`ANSPOSE`

`SPARSE_OPERATION_CO` Conjugate transpose, $op(A) = A^H$.
`NJUGATE_TRANSPOSE`

descr

Structure specifying sparse matrix properties.

`sparse_matrix_type_t` *type* - Specifies the type of a sparse matrix:

`SPARSE_MATRIX_TYPE_` The matrix is processed as is.
`GENERAL`

`SPARSE_MATRIX_TYPE_` The matrix is symmetric (only the requested
`SYMMETRIC` triangle is processed).

`SPARSE_MATRIX_TYPE_` The matrix is Hermitian (only the requested
`HERMITIAN` triangle is processed).

`SPARSE_MATRIX_TYPE_` The matrix is triangular (only the requested
`TRIANGULAR` triangle is processed).

`SPARSE_MATRIX_TYPE_` The matrix is diagonal (only diagonal elements
`DIAGONAL` are processed).

`SPARSE_MATRIX_TYPE_` The matrix is block-triangular (only requested
`BLOCK_TRIANGULAR` triangle is processed). (Applies to BSR format only.)

`SPARSE_MATRIX_TYPE_` The matrix is block-diagonal (only diagonal
`BLOCK_DIAGONAL` blocks are processed). (Applies to BSR format only.)

`sparse_fill_mode_t mode` - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:

`SPARSE_FILL_MODE_LO` The lower triangular matrix part is processed.
WER

`SPARSE_FILL_MODE_UP` The upper triangular matrix part is processed.
PER

`sparse_diag_type_t diag` - Specifies diagonal type for non-general matrices:

`SPARSE_DIAG_NON_UNIT` Diagonal elements might not be equal to one.
T

`SPARSE_DIAG_UNIT` Diagonal elements are equal to one.

`expected_calls`

Number of expected calls to execution routine.

Output Parameters

`A` Handle containing internal data.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

`SPARSE_STATUS_SUCCESS` The operation was successful.

`SPARSE_STATUS_NOT_INITIALIZE` The routine encountered an empty handle or matrix array.
D

`SPARSE_STATUS_ALLOC_FAILED` Internal memory allocation failed.

`SPARSE_STATUS_INVALID_VALUE` The input parameters contain an invalid value.

`SPARSE_STATUS_EXECUTION_FAIL` Execution failed.
ED

`SPARSE_STATUS_INTERNAL_ERROR` An error in algorithm implementation occurred.

`SPARSE_STATUS_NOT_SUPPORTED` The requested operation is not supported.

`mkl_sparse_set_sv_hint`

Provides estimate of number and type of upcoming triangular system solver operations.

Syntax

```
sparse_status_t mkl_sparse_set_sv_hint (sparse_matrix_t A, sparse_operation_t
operation, struct matrix_descr descr, MKL_INT expected_calls);
```

Include Files

- `mkl_splblas.h`

Description

The `mkl_sparse_sv_hint` routine provides an estimate of the number of upcoming triangular system solver operations and type of these operations for performance optimization.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

`SPARSE_STATUS_ALLOC_FAILED` Internal memory allocation failed.

`SPARSE_STATUS_INVALID_VALUE` The input parameters contain an invalid value.

`SPARSE_STATUS_EXECUTION_FAIL` Execution failed.
ED

`SPARSE_STATUS_INTERNAL_ERROR` An error in algorithm implementation occurred.

`SPARSE_STATUS_NOT_SUPPORTED` The requested operation is not supported.

`mkl_sparse_set_mm_hint`

Provides estimate of number and type of upcoming matrix-matrix multiplication operations.

Syntax

```
sparse_status_t mkl_sparse_set_mm_hint (sparse_matrix_t A, sparse_operation_t
operation, struct matrix_descr descr, sparse_layout_t layout, MKL_INT
dense_matrix_size, MKL_INT expected_calls);
```

Include Files

- `mkl_spblas.h`

Description

The `mkl_sparse_set_mm_hint` routine provides an estimate of the number of upcoming matrix-matrix multiplication operations and type of these operations for performance optimization purposes.

Optimization Notice

`sparse_diag_type_t diag` - Specifies diagonal type for non-general matrices:

`SPARSE_DIAG_NON_UNI` Diagonal elements might not be equal to one.
T

`SPARSE_DIAG_UNIT` Diagonal elements are equal to one.

`layout`

Specifies layout of elements:

`SPARSE_LAYOUT_COLUMN` Storage of elements uses column major layout.
N_MAJOR

`SPARSE_LAYOUT_ROW_M` Storage of elements uses row major layout.
A_JOR

`dense_matrix_size`

Number of columns in dense matrix.

`expected_calls`

Number of expected calls to execution routine.

Output Parameters

A

Handle containing internal data.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

`SPARSE_STATUS_SUCCESS` The operation was successful.

`SPARSE_STATUS_NOT_INITIALIZE` The routine encountered an empty handle or matrix array.
D

`SPARSE_STATUS_ALLOC_FAILED` Internal memory allocation failed.

`SPARSE_STATUS_INVALID_VALUE` The input parameters contain an invalid value.

`SPARSE_STATUS_EXECUTION_FAIL` Execution failed.
ED

`SPARSE_STATUS_INTERNAL_ERROR` An error in algorithm implementation occurred.

`SPARSE_STATUS_NOT_SUPPORTED` The requested operation is not supported.

`mkl_sparse_set_sm_hint`

Provides estimate of number and type of upcoming triangular matrix solve with multiple right hand sides operations.

Syntax

```
sparse_status_t mkl_sparse_set_sm_hint (sparse_matrix_t A, sparse_operation_t
operation, struct matrix_descr descr, sparse_layout_t layout, MKL_INT
dense_matrix_size, MKL_INT expected_calls);
```

Include Files

- mkl_splblas.h

Description

The `mkl_sparse_set_sm_hint` routine provides an estimate of the number of upcoming triangular matrix solve with multiple right hand sides operations and type of these operations for performance optimization purposes.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. Notice revision #20110804

Input Parameters

operation

Specifies operation `op()` on input matrix.

`SPARSE_OPERATION_NO` Non-transpose, $op(A) = A$.
`N_TRANSPOSE`

`SPARSE_OPERATION_TR` Transpose, $op(A) = A^T$.
`ANSPOSE`

`SPARSE_OPERATION_CO` Conjugate transpose, $op(A) = A^H$.
`NJUGATE_TRANSPOSE`

descr

Structure specifying sparse matrix properties.

`sparse_matrix_type_t type` - Specifies the type of a sparse matrix:

`SPARSE_MATRIX_TYPE_` The matrix is processed as is.
`GENERAL`

`SPARSE_MATRIX_TYPE_` The matrix is symmetric (only the requested
`SYMMETRIC` triangle is processed).

`SPARSE_MATRIX_TYPE_` The matrix is Hermitian (only the requested
`HERMITIAN` triangle is processed).

`SPARSE_MATRIX_TYPE_` The matrix is triangular (only the requested
`TRIANGULAR` triangle is processed).

SPARSE_MATRIX_TYPE_ DIAGONAL The matrix is diagonal (only diagonal elements are processed).

SPARSE_MATRIX_TYPE_ BLOCK_TRIANGULAR The matrix is block-triangular (only requested triangle is processed). (Applies to BSR format only.)

SPARSE_MATRIX_TYPE_ BLOCK_DIAGONAL The matrix is block-diagonal (only diagonal blocks are processed). (Applies to BSR format only.)

`sparse_fill_mode_t mode` - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:

SPARSE_FILL_MODE_LO WER The lower triangular matrix part is processed.

SPARSE_FILL_MODE_UP PER The upper triangular matrix part is processed.

`sparse_diag_type_t diag` - Specifies diagonal type for non-general matrices:

SPARSE_DIAG_NON_UNIT T Diagonal elements might not be equal to one.

SPARSE_DIAG_UNIT Diagonal elements are equal to one.

`layout`

Specifies layout of elements:

SPARSE_LAYOUT_COLUMN_MAJOR N_MAJOR Storage of elements uses column major layout.

SPARSE_LAYOUT_ROW_MAJOR AJOR Storage of elements uses row major layout.

`dense_matrix_size`

Number of right-hand-side.

`expected_calls`

Number of expected calls to execution routine.

Output Parameters

A

Handle containing internal data.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

SPARSE_STATUS_SUCCESS The operation was successful.

SPARSE_STATUS_NOT_INITIALIZE D The routine encountered an empty handle or matrix array.

SPARSE_STATUS_ALLOC_FAILED Internal memory allocation failed.

SPARSE_STATUS_INVALID_VALUE The input parameters contain an invalid value.

`SPARSE_STATUS_EXECUTION_FAIL` Execution failed.
`ED`

`SPARSE_STATUS_INTERNAL_ERROR` An error in algorithm implementation occurred.

`SPARSE_STATUS_NOT_SUPPORTED` The requested operation is not supported.

mkl_sparse_set_memory_hint

Provides memory requirements for performance optimization purposes.

Syntax

```
sparse_status_t mkl_sparse_set_memory_hint (sparse_matrix_t A, sparse_memory_usage_t policy);
```

Include Files

- `mkl_spblas.h`

Description

The `mkl_sparse_set_memory_hint` routine allocates additional memory for further performance optimization purposes.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

| | |
|---------------------------------------|--|
| <code>policy</code> | Specify memory utilization policy for optimization routine using these types: |
| <code>SPARSE_MEMORY_NONE</code> | Routine can allocate memory only for auxiliary structures (such as for workload balancing); the amount of memory is proportional to vector size. |
| <code>SPARSE_MEMORY_AGGRESSIVE</code> | Default. |
| | Routine can allocate memory up to the size of matrix <i>A</i> for converting into the appropriate sparse format. |

Output Parameters

`A` Handle containing internal data.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

| | |
|---|--|
| <code>SPARSE_STATUS_SUCCESS</code> | The operation was successful. |
| <code>SPARSE_STATUS_NOT_INITIALIZE</code> D | The routine encountered an empty handle or matrix array. |
| <code>SPARSE_STATUS_ALLOC_FAILED</code> | Internal memory allocation failed. |
| <code>SPARSE_STATUS_INVALID_VALUE</code> | The input parameters contain an invalid value. |
| <code>SPARSE_STATUS_EXECUTION_FAIL</code> ED | Execution failed. |
| <code>SPARSE_STATUS_INTERNAL_ERROR</code> | An error in algorithm implementation occurred. |
| <code>SPARSE_STATUS_NOT_SUPPORTED</code> | The requested operation is not supported. |

`mkl_sparse_optimize`

Analyzes matrix structure and performs optimizations using the hints provided in the handle.

Syntax

```
sparse_status_t mkl_sparse_optimize (sparse_matrix_t A);
```

Include Files

- `mkl_splblas.h`

Description

The `mkl_sparse_optimize` routine analyzes matrix structure and performs optimizations using the hints provided in the handle. Generally, specifying a higher number of expected operations allows for more aggressive and time consuming optimizations.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Inspector-executor Sparse BLAS Execution Routines

Execution Routines and Their Data Types

| Routine or Function Group | Data Types | Description |
|-----------------------------------|------------|--|
| mkl_sparse_?_mv | s, d, c, z | Computes a sparse matrix-vector product. |
| mkl_sparse_?_trsv | s, d, c, z | Solves a system of linear equations for a square sparse matrix. |
| mkl_sparse_?_mm | s, d, c, z | Computes the product of a sparse matrix and a dense matrix. |
| mkl_sparse_?_trsm | s, d, c, z | Solves a system of linear equations with multiple right hand sides for a square sparse matrix. |
| mkl_sparse_?_add | s, d, c, z | Computes sum of two sparse matrices. |
| mkl_sparse_spmv | s, d, c, z | Computes the product of two sparse matrices and stores the result as a sparse matrix. |
| mkl_sparse_?_spmv | s, d, c, z | Computes the product of two sparse matrices and stores the result as a dense matrix. |

[mkl_sparse_?_mv](#)

Computes a sparse matrix-vector product.

Syntax

```
sparse_status_t mkl_sparse_s_mv (sparse_operation_t operation, float alpha, const
sparse_matrix_t A, struct matrix_descr descr, const float *x, float beta, float *y);
sparse_status_t mkl_sparse_d_mv (sparse_operation_t operation, double alpha, const
sparse_matrix_t A, struct matrix_descr descr, const double *x, double beta, double *y);
sparse_status_t mkl_sparse_c_mv (sparse_operation_t operation, MKL_Complex8 alpha,
const sparse_matrix_t A, struct matrix_descr descr, const MKL_Complex8 *x, MKL_Complex8
beta, MKL_Complex8 *y);
sparse_status_t mkl_sparse_z_mv (sparse_operation_t operation, MKL_Complex16 alpha,
const sparse_matrix_t A, struct matrix_descr descr, const MKL_Complex16 *x,
MKL_Complex16 beta, MKL_Complex16 *y);
```

Include Files

- `mkl_splblas.h`

Description

The `mkl_sparse_?_mv` routine computes a sparse matrix-vector product defined as

$$y := \alpha * \text{op}(A) * x + \beta * y$$

where:

alpha and *beta* are scalars, *x* and *y* are vectors, and *A* is a matrix handle of a matrix with *m* rows and *k* columns.

Input Parameters

| | |
|------------------|---|
| <i>operation</i> | Specifies operation <code>op()</code> on input matrix. |
| | <p><code>SPARSE_OPERATION_NO</code> Non-transpose, $\text{op}(A) = A$.</p> <p><code>N_TRANSPOSE</code></p> <p><code>SPARSE_OPERATION_TR</code> Transpose, $\text{op}(A) = A^T$.</p> <p><code>ANSPOSE</code></p> <p><code>SPARSE_OPERATION_CO</code> Conjugate transpose, $\text{op}(A) = A^H$.</p> <p><code>NJUGATE_TRANSPOSE</code></p> |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>A</i> | Handle containing sparse matrix in internal data structure. |
| <i>descr</i> | Structure specifying sparse matrix properties. |
| | <p><code>sparse_matrix_type_t</code> <i>type</i> - Specifies the type of a sparse matrix:</p> <p><code>SPARSE_MATRIX_TYPE_</code> The matrix is processed as is.</p> <p><code>GENERAL</code></p> <p><code>SPARSE_MATRIX_TYPE_</code> The matrix is symmetric (only the requested triangle is processed).</p> <p><code>SYMMETRIC</code></p> <p><code>SPARSE_MATRIX_TYPE_</code> The matrix is Hermitian (only the requested triangle is processed).</p> <p><code>HERMITIAN</code></p> <p><code>SPARSE_MATRIX_TYPE_</code> The matrix is triangular (only the requested triangle is processed).</p> <p><code>TRIANGULAR</code></p> <p><code>SPARSE_MATRIX_TYPE_</code> The matrix is diagonal (only diagonal elements are processed).</p> <p><code>DIAGONAL</code></p> <p><code>SPARSE_MATRIX_TYPE_</code> The matrix is block-triangular (only requested triangle is processed). (Applies to BSR format only.)</p> <p><code>BLOCK_TRIANGULAR</code></p> <p><code>SPARSE_MATRIX_TYPE_</code> The matrix is block-diagonal (only diagonal blocks are processed). (Applies to BSR format only.)</p> <p><code>BLOCK_DIAGONAL</code></p> <p><code>sparse_fill_mode_t</code> <i>mode</i> - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:</p> |

SPARSE_FILL_MODE_LO The lower triangular matrix part is processed.
WER

SPARSE_FILL_MODE_UP The upper triangular matrix part is processed.
PER

sparse_diag_type_t *diag* - Specifies diagonal type for non-general matrices:

SPARSE_DIAG_NON_UNIT Diagonal elements might not be equal to one.
T

SPARSE_DIAG_UNIT Diagonal elements are equal to one.

x Array with size equal to the number of columns of *A* if *operation* = SPARSE_OPERATION_NON_TRANSPOSE and at least rows of *A* otherwise. On entry, the array *x* must contain the vector *x*.

beta Specifies the scalar *beta*.

y Array with size at least *m* if *operation*=SPARSE_OPERATION_NON_TRANSPOSE and at least *k* otherwise. On entry, the array *y* must contain the vector *y*.

Output Parameters

y Overwritten by the updated vector *y*.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

SPARSE_STATUS_SUCCESS The operation was successful.

SPARSE_STATUS_NOT_INITIALIZE The routine encountered an empty handle or matrix array.
D

SPARSE_STATUS_ALLOC_FAILED Internal memory allocation failed.

SPARSE_STATUS_INVALID_VALUE The input parameters contain an invalid value.

SPARSE_STATUS_EXECUTION_FAILED Execution failed.
ED

SPARSE_STATUS_INTERNAL_ERROR An error in algorithm implementation occurred.

SPARSE_STATUS_NOT_SUPPORTED The requested operation is not supported.

mkl_sparse_?_trsv

Solves a system of linear equations for a triangular sparse matrix.

Syntax

```
sparse_status_t mkl_sparse_s_trsv (sparse_operation_t operation, float alpha, const
sparse_matrix_t A, struct matrix_descr descr, const float *x, float *y);
```

```

sparse_status_t mkl_sparse_d_trsv (sparse_operation_t operation, double alpha, const
sparse_matrix_t A, struct matrix_descr descr, const double *x, double *y);

sparse_status_t mkl_sparse_c_trsv (sparse_operation_t operation, MKL_Complex8 alpha,
const sparse_matrix_t A, struct matrix_descr descr, const MKL_Complex8 *x, MKL_Complex8
*y);

sparse_status_t mkl_sparse_z_trsv (sparse_operation_t operation, MKL_Complex16 alpha,
const sparse_matrix_t A, struct matrix_descr descr, const MKL_Complex16 *x,
MKL_Complex16 *y);

```

Include Files

- mkl_spblas.h

Description

The `mkl_sparse_?_trsv` routine solves a system of linear equations for a matrix:

$$\text{op}(A)*y = \text{alpha} * x$$

where A is a triangular sparse matrix, alpha is a scalar, and x and y are vectors.

Input Parameters

| | |
|------------------|--|
| <i>operation</i> | Specifies operation <code>op()</code> on input matrix. |
| | <p>SPARSE_OPERATION_NO Non-transpose, $\text{op}(A) = A$. N_TRANSPOSE</p> <p>SPARSE_OPERATION_TR Transpose, $\text{op}(A) = A^T$. ANSPOSE</p> <p>SPARSE_OPERATION_CO Conjugate transpose, $\text{op}(A) = A^H$. NJUGATE_TRANSPOSE</p> |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |
| <i>A</i> | Handle containing sparse matrix in internal data structure. |
| <i>descr</i> | Structure specifying sparse matrix properties. |
| | <p><code>sparse_matrix_type_t type</code> - Specifies the type of a sparse matrix:</p> <p>SPARSE_MATRIX_TYPE_ The matrix is processed as is. GENERAL</p> <p>SPARSE_MATRIX_TYPE_ The matrix is symmetric (only the requested SYMMETRIC triangle is processed).</p> <p>SPARSE_MATRIX_TYPE_ The matrix is Hermitian (only the requested HERMITIAN triangle is processed).</p> <p>SPARSE_MATRIX_TYPE_ The matrix is triangular (only the requested TRIANGULAR triangle is processed).</p> <p>SPARSE_MATRIX_TYPE_ The matrix is diagonal (only diagonal elements DIAGONAL are processed).</p> |

SPARSE_MATRIX_TYPE_BLOCK_TRIANGULAR The matrix is block-triangular (only requested triangle is processed). (Applies to BSR format only.)

SPARSE_MATRIX_TYPE_BLOCK_DIAGONAL The matrix is block-diagonal (only diagonal blocks are processed). (Applies to BSR format only.)

`sparse_fill_mode_t mode` - Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:

SPARSE_FILL_MODE_LOWER The lower triangular matrix part is processed.

SPARSE_FILL_MODE_UPPER The upper triangular matrix part is processed.

`sparse_diag_type_t diag` - Specifies diagonal type for non-general matrices:

SPARSE_DIAG_NON_UNIT Diagonal elements might not be equal to one.

SPARSE_DIAG_UNIT Diagonal elements are equal to one.

`x` Array of size at least m , where m is the number of rows of matrix A . On entry, the array `x` must contain the vector x .

Output Parameters

`y` Array of size at least m containing the solution to the system of linear equations.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

SPARSE_STATUS_SUCCESS The operation was successful.

SPARSE_STATUS_NOT_INITIALIZED The routine encountered an empty handle or matrix array.

SPARSE_STATUS_ALLOC_FAILED Internal memory allocation failed.

SPARSE_STATUS_INVALID_VALUE The input parameters contain an invalid value.

SPARSE_STATUS_EXECUTION_FAILED Execution failed.

SPARSE_STATUS_INTERNAL_ERROR An error in algorithm implementation occurred.

SPARSE_STATUS_NOT_SUPPORTED The requested operation is not supported.

`mkl_sparse_?_mm`

Computes the product of a sparse matrix and a dense matrix.

Syntax

```
sparse_status_t mkl_sparse_s_mm (sparse_operation_t operation, float alpha, const
sparse_matrix_t A, struct matrix_descr descr, sparse_layout_t layout, const float *x,
MKL_INT columns, MKL_INT ldx, float beta, float *y, MKL_INT ldy);
```

```
sparse_status_t mkl_sparse_d_mm (sparse_operation_t operation, double alpha, const
sparse_matrix_t A, struct matrix_descr descr, sparse_layout_t layout, const double *x,
MKL_INT columns, MKL_INT ldx, double beta, double *y, MKL_INT ldy);
```

```
sparse_status_t mkl_sparse_c_mm (sparse_operation_t operation, MKL_Complex8 alpha,
const sparse_matrix_t A, struct matrix_descr descr, sparse_layout_t layout, const
MKL_Complex8 *x, MKL_INT columns, MKL_INT ldx, MKL_Complex8 beta, MKL_Complex8 *y,
MKL_INT ldy);
```

```
sparse_status_t mkl_sparse_z_mm (sparse_operation_t operation, MKL_Complex16 alpha,
const sparse_matrix_t A, struct matrix_descr descr, sparse_layout_t layout, const
MKL_Complex16 *x, MKL_INT columns, MKL_INT ldx, MKL_Complex16 beta, MKL_Complex16 *y,
MKL_INT ldy);
```

Include Files

- mkl_spblas.h

Description

The `mkl_sparse_?_mm` routine performs a matrix-matrix operation:

```
 $y := \alpha * \text{op}(A) * x + \beta * y$ 
```

where α and β are scalars, A is a sparse matrix, and x and y are dense matrices.

The `mkl_sparse_?_mm` and `mkl_sparse_?_trsm` routines support these configurations:

| | | |
|--|--|--|
| | Column-major dense matrix: $layout =$ SPARSE_LAYOUT_COLUMN_MAJ OR | Row-major dense matrix: $layout =$ SPARSE_LAYOUT_ROW_MAJOR |
| 0-based sparse matrix: SPARSE_INDEX_BASE_ZERO | CSR BSR: general non-transposed matrix multiplication only | All formats |
| 1-based sparse matrix: SPARSE_INDEX_BASE_ONE | All formats | CSR BSR: general non-transposed matrix multiplication only |

Input Parameters

operation

Specifies operation `op()` on input matrix.

SPARSE_OPERATION_NO Non-transpose, $\text{op}(A) = A$.
N_TRANSPOSE

SPARSE_OPERATION_TR Transpose, $\text{op}(A) = A^T$.
ANSPOSE

SPARSE_OPERATION_CO Conjugate transpose, $\text{op}(A) = A^H$.
NJUGATE_TRANSPOSE

| | |
|---------------|--|
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |

Output Parameters

y Overwritten by the updated matrix *y*.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

- SPARSE_STATUS_SUCCESS The operation was successful.
- SPARSE_STATUS_NOT_INITIALIZE The routine encountered an empty handle or matrix array.
- D
- SPARSE_STATUS_ALLOC_FAILED Internal memory allocation failed.
- SPARSE_STATUS_INVALID_VALUE The input parameters contain an invalid value.
- SPARSE_STATUS_EXECUTION_FAIL Execution failed.
- ED
- SPARSE_STATUS_INTERNAL_ERROR An error in algorithm implementation occurred.
- SPARSE_STATUS_NOT_SUPPORTED The requested operation is not supported.

mkl_sparse_?_trsm

Solves a system of linear equations with multiple right hand sides for a triangular sparse matrix.

Syntax

```
sparse_status_t mkl_sparse_s_trsm (sparse_operation_t operation, float alpha, const
sparse_matrix_t A, struct matrix_descr descr, sparse_layout_t layout, const float *x,
MKL_INT columns, MKL_INT ldx, float *y, MKL_INT ldy);
```

```
sparse_status_t mkl_sparse_d_trsm (sparse_operation_t operation, double alpha, const
sparse_matrix_t A, struct matrix_descr descr, sparse_layout_t layout, const double *x,
MKL_INT columns, MKL_INT ldx, double *y, MKL_INT ldy);
```

```
sparse_status_t mkl_sparse_c_trsm (sparse_operation_t operation, MKL_Complex8 alpha,
const sparse_matrix_t A, struct matrix_descr descr, sparse_layout_t layout, const
MKL_Complex8 *x, MKL_INT columns, MKL_INT ldx, MKL_Complex8 *y, MKL_INT ldy);
```

```
sparse_status_t mkl_sparse_z_trsm (sparse_operation_t operation, MKL_Complex16 alpha,
const sparse_matrix_t A, struct matrix_descr descr, sparse_layout_t layout, const
MKL_Complex16 *x, MKL_INT columns, MKL_INT ldx, MKL_Complex16 *y, MKL_INT ldy);
```

Include Files

- mkl_spblas.h

Description

The `mkl_sparse_?_trsm` routine solves a system of linear equations with multiple right hand sides for a triangular sparse matrix:

$$y := \alpha * \text{inv}(\text{op}(A)) * x$$

where:

alpha is a scalar, *x* and *y* are dense matrices, and *A* is a sparse matrix.

The `mkl_sparse_?_mm` and `mkl_sparse_?_trsm` routines support these configurations:

| | | |
|--|---|--|
| | Column-major dense matrix: <i>layout</i> = SPARSE_LAYOUT_COLUMN_MAJ OR | Row-major dense matrix: <i>layout</i> = SPARSE_LAYOUT_ROW_MAJOR |
| 0-based sparse matrix: SPARSE_INDEX_BASE_ZERO | CSR BSR: general non-transposed matrix multiplication only | All formats |
| 1-based sparse matrix: SPARSE_INDEX_BASE_ONE | All formats | CSR BSR: general non-transposed matrix multiplication only |

Input Parameters

operation Specifies operation `op()` on input matrix.

SPARSE_OPERATION_NO Non-transpose, `op(A) = A`.
N_TRANSPOSE

| | | |
|---------------|-----------------------------------|--|
| | SPARSE_OPERATION_TR | Transpose, $\text{op}(A) = A^T$. |
| | ANSPOSE | |
| | SPARSE_OPERATION_CO | Conjugate transpose, $\text{op}(A) = A^H$. |
| | NJUGATE_TRANSPOSE | |
| <i>alpha</i> | | Specifies the scalar <i>alpha</i> . |
| <i>A</i> | | Handle containing sparse matrix in internal data structure. |
| <i>descr</i> | | Structure specifying sparse matrix properties. |
| | <code>sparse_matrix_type_t</code> | <i>type</i> - Specifies the type of a sparse matrix: |
| | SPARSE_MATRIX_TYPE_ | The matrix is processed as is. |
| | GENERAL | |
| | SPARSE_MATRIX_TYPE_ | The matrix is symmetric (only the requested |
| | SYMMETRIC | triangle is processed). |
| | SPARSE_MATRIX_TYPE_ | The matrix is Hermitian (only the requested |
| | HERMITIAN | triangle is processed). |
| | SPARSE_MATRIX_TYPE_ | The matrix is triangular (only the requested |
| | TRIANGULAR | triangle is processed). |
| | SPARSE_MATRIX_TYPE_ | The matrix is diagonal (only diagonal elements |
| | DIAGONAL | are processed). |
| | SPARSE_MATRIX_TYPE_ | The matrix is block-triangular (only requested |
| | BLOCK_TRIANGULAR | triangle is processed). (Applies to BSR format |
| | | only.) |
| | SPARSE_MATRIX_TYPE_ | The matrix is block-diagonal (only diagonal |
| | BLOCK_DIAGONAL | blocks are processed. (Applies to BSR format |
| | | only.) |
| | <code>sparse_fill_mode_t</code> | <i>mode</i> - Specifies the triangular matrix part for |
| | | symmetric, Hermitian, triangular, and block-triangular matrices: |
| | SPARSE_FILL_MODE_LO | The lower triangular matrix part is processed. |
| | WER | |
| | SPARSE_FILL_MODE_UP | The upper triangular matrix part is processed. |
| | PER | |
| | <code>sparse_diag_type_t</code> | <i>diag</i> - Specifies diagonal type for non-general |
| | | matrices: |
| | SPARSE_DIAG_NON_UNI | Diagonal elements might not be equal to one. |
| | T | |
| | SPARSE_DIAG_UNIT | Diagonal elements are equal to one. |
| <i>layout</i> | | Describes the storage scheme for the dense matrix: |
| | SPARSE_LAYOUT_COLUM | Storage of elements uses column major layout. |
| | N_MAJOR | |

SPARSE_LAYOUT_ROW_M Storage of elements uses row major layout.
AJOR

x Array of size at least *rows*cols*.

| | | |
|--|---|--|
| | <i>layout =</i> SPARSE_LAYOUT_COLUMN_MAJOR | <i>layout =</i> SPARSE_LAYOUT_ROW_MAJOR |
| <i>rows</i> (number of rows in <i>x</i>) | <i>ldx</i> | number of rows in A |
| <i>cols</i> (number of columns in <i>x</i>) | <i>columns</i> | <i>ldx</i> |

On entry, the array *x* must contain the matrix *x*.

columns Number of columns in matrix *y*.

ldx Specifies the leading dimension of matrix *x*.

y Array of size at least *rows*cols*, where

| | | |
|--|---|--|
| | <i>layout =</i> SPARSE_LAYOUT_COLUMN_MAJOR | <i>layout =</i> SPARSE_LAYOUT_ROW_MAJOR |
| <i>rows</i> (number of rows in <i>y</i>) | <i>ldy</i> | number of rows in A |
| <i>cols</i> (number of columns in <i>y</i>) | <i>columns</i> | <i>ldy</i> |

Output Parameters

y Overwritten by the updated matrix *y*.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

| | |
|------------------------------|--|
| SPARSE_STATUS_SUCCESS | The operation was successful. |
| SPARSE_STATUS_NOT_INITIALIZE | The routine encountered an empty handle or matrix array. |
| D | |
| SPARSE_STATUS_ALLOC_FAILED | Internal memory allocation failed. |
| SPARSE_STATUS_INVALID_VALUE | The input parameters contain an invalid value. |
| SPARSE_STATUS_EXECUTION_FAIL | Execution failed. |
| ED | |
| SPARSE_STATUS_INTERNAL_ERROR | An error in algorithm implementation occurred. |
| SPARSE_STATUS_NOT_SUPPORTED | The requested operation is not supported. |

mkl_sparse_?_add

Computes sum of two sparse matrices.

Syntax

```
sparse_status_t mkl_sparse_s_add (sparse_operation_t operation, const sparse_matrix_t
A, float alpha, const sparse_matrix_t B, sparse_matrix_t *C);
```

```
sparse_status_t mkl_sparse_d_add (sparse_operation_t operation, const sparse_matrix_t
A, double alpha, const sparse_matrix_t B, sparse_matrix_t *C);
```

```
sparse_status_t mkl_sparse_c_add (sparse_operation_t operation, const sparse_matrix_t
A, MKL_Complex8 alpha, const sparse_matrix_t B, sparse_matrix_t *C);
```

```
sparse_status_t mkl_sparse_z_add (sparse_operation_t operation, const sparse_matrix_t
A, MKL_Complex16 alpha, const sparse_matrix_t B, sparse_matrix_t *C);
```

Include Files

- mkl_spblas.h

Description

The `mkl_sparse_?_add` routine performs a matrix-matrix operation:

```
 $C := \alpha * \text{op}(A) + B$ 
```

where *alpha* is a scalar and *A*, *B*, and *C* are sparse matrices.

Input Parameters

A Handle containing a sparse matrix in internal data structure.

alpha Specifies the scalar *alpha*.

operation Specifies operation `op()` on input matrix.

SPARSE_OPERATION_NO Non-transpose, $\text{op}(A) = A$.
N_TRANSPOSE

SPARSE_OPERATION_TR Transpose, $\text{op}(A) = A^T$.
ANSPOSE

SPARSE_OPERATION_CO Conjugate transpose, $\text{op}(A) = A^H$.
NJUGATE_TRANSPOSE

B Handle containing a sparse matrix in internal data structure.

Output Parameters

C Handle containing the resulting sparse matrix in internal data structure.

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

SPARSE_STATUS_SUCCESS The operation was successful.

SPARSE_STATUS_NOT_INITIALIZE The routine encountered an empty handle or matrix array.
D

| | |
|--|--|
| <code>SPARSE_STATUS_ALLOC_FAILED</code> | Internal memory allocation failed. |
| <code>SPARSE_STATUS_INVALID_VALUE</code> | The input parameters contain an invalid value. |
| <code>SPARSE_STATUS_EXECUTION_FAIL</code> <code>ED</code> | Execution failed. |
| <code>SPARSE_STATUS_INTERNAL_ERROR</code> | An error in algorithm implementation occurred. |
| <code>SPARSE_STATUS_NOT_SUPPORTED</code> | The requested operation is not supported. |

mkl_sparse_spm

Computes the product of two sparse matrices and stores the result as a sparse matrix.

Syntax

```
sparse_status_t mkl_sparse_spm (sparse_operation_t operation, const sparse_matrix_t A,  
const sparse_matrix_t B, sparse_matrix_t *C);
```

Include Files

- `mkl_splblas.h`

Description

The `mkl_sparse_spm` routine performs a matrix-matrix operation:

```
C := op(A) *B
```

where *A*, *B*, and *C* are sparse matrices.

Input Parameters

| | |
|------------------|---|
| <i>operation</i> | Specifies operation <code>op()</code> on input matrix. <code>SPARSE_OPERATION_NO</code> Non-transpose, $op(A) = A$. <code>N_TRANSPOSE</code> <code>SPARSE_OPERATION_TR</code> Transpose, $op(A) = A^T$. <code>ANSPOSE</code> <code>SPARSE_OPERATION_CO</code> Conjugate transpose, $op(A) = A^H$. <code>NJUGATE_TRANSPOSE</code> |
| <i>A</i> | Handle containing a sparse matrix in internal data structure. |
| <i>B</i> | Handle containing a sparse matrix in internal data structure. |

Output Parameters

| | |
|----------|---|
| <i>C</i> | Handle containing the resulting sparse matrix in internal data structure. |
|----------|---|

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

| | |
|------------------------------------|-------------------------------|
| <code>SPARSE_STATUS_SUCCESS</code> | The operation was successful. |
|------------------------------------|-------------------------------|

SPARSE_STATUS_NOT_INITIALIZE The routine encountered an empty handle or matrix array.
D

SPARSE_STATUS_ALLOC_FAILED Internal memory allocation failed.

SPARSE_STATUS_INVALID_VALUE The input parameters contain an invalid value.

SPARSE_STATUS_EXECUTION_FAIL Execution failed.
ED

SPARSE_STATUS_INTERNAL_ERROR An error in algorithm implementation occurred.

SPARSE_STATUS_NOT_SUPPORTED The requested operation is not supported.

mkl_sparse_?_spmmd

Computes the product of two sparse matrices and stores the result as a dense matrix.

Syntax

```
sparse_status_t mkl_sparse_s_spmmd (sparse_operation_t operation, const sparse_matrix_t
A, const sparse_matrix_t B, sparse_layout_t layout, float *C, MKL_INT ldc);

sparse_status_t mkl_sparse_d_spmmd (sparse_operation_t operation, const sparse_matrix_t
A, const sparse_matrix_t B, sparse_layout_t layout, double *C, MKL_INT ldc);

sparse_status_t mkl_sparse_c_spmmd (sparse_operation_t operation, const sparse_matrix_t
A, const sparse_matrix_t B, sparse_layout_t layout, MKL_Complex8 *C, MKL_INT ldc);

sparse_status_t mkl_sparse_z_spmmd (sparse_operation_t operation, const sparse_matrix_t
A, const sparse_matrix_t B, sparse_layout_t layout, MKL_Complex16 *C, MKL_INT ldc);
```

Include Files

- mkl_spblas.h

Description

The `mkl_sparse_?_spmmd` routine performs a matrix-matrix operation:

```
C := op(A)*B
```

where A and B are sparse matrices and C is a dense matrix.

Input Parameters

| | |
|------------------|--|
| <i>operation</i> | Specifies operation <code>op()</code> on input matrix. SPARSE_OPERATION_NO Non-transpose, $\text{op}(A) = A$. N_TRANSPOSE SPARSE_OPERATION_TR Transpose, $\text{op}(A) = A^T$. ANSPOSE SPARSE_OPERATION_CO Conjugate transpose, $\text{op}(A) = A^H$. NJUGATE_TRANSPOSE |
| <i>A</i> | Handle containing a sparse matrix in internal data structure. |
| <i>B</i> | Handle containing a sparse matrix in internal data structure. |

| | |
|---------------|--|
| <i>layout</i> | Describes the storage scheme for the dense matrix: |
| | SPARSE_LAYOUT_COLUMN_MAJOR Storage of elements uses column major layout. |
| | SPARSE_LAYOUT_ROW_MAJOR Storage of elements uses row major layout. |
| <i>ldC</i> | Leading dimension of matrix C. |

Output Parameters

| | |
|----------|---|
| <i>C</i> | Resulting dense matrix stored in internal data structure. |
|----------|---|

Return Values

The function returns a value indicating whether the operation was successful or not, and why.

| | |
|--------------------------------|--|
| SPARSE_STATUS_SUCCESS | The operation was successful. |
| SPARSE_STATUS_NOT_INITIALIZE | The routine encountered an empty handle or matrix array. |
| D | |
| SPARSE_STATUS_ALLOC_FAILED | Internal memory allocation failed. |
| SPARSE_STATUS_INVALID_VALUE | The input parameters contain an invalid value. |
| SPARSE_STATUS_EXECUTION_FAILED | Execution failed. |
| ED | |
| SPARSE_STATUS_INTERNAL_ERROR | An error in algorithm implementation occurred. |
| SPARSE_STATUS_NOT_SUPPORTED | The requested operation is not supported. |

BLAS-like Extensions

Intel MKL provides C and Fortran routines to extend the functionality of the BLAS routines. These include routines to compute vector products, matrix-vector products, and matrix-matrix products.

Intel MKL also provides routines to perform certain data manipulation, including matrix in-place and out-of-place transposition operations combined with simple matrix arithmetic operations. Transposition operations are Copy As Is, Conjugate transpose, Transpose, and Conjugate. Each routine adds the possibility of scaling during the transposition operation by giving some *alpha* and/or *beta* parameters. Each routine supports both row-major orderings and column-major orderings.

Table “BLAS-like Extensions” lists these routines.

The <?> symbol in the routine short names is a precision prefix that indicates the data type:

| | |
|----------|---------------|
| <i>s</i> | float |
| <i>d</i> | double |
| <i>c</i> | MKL_Complex8 |
| <i>z</i> | MKL_Complex16 |

BLAS-like Extensions

| Routine | Data Types | Description |
|---------------------------------------|-------------------|---|
| <code>cblas_?axpby</code> | s, d, c, z | Scales two vectors, adds them to one another and stores result in the vector (routines). |
| <code>cblas_?gemmt</code> | s, d, c, z | Computes a matrix-matrix product with general matrices but updates only the upper or lower triangular part of the result matrix. |
| <code>cblas_?gemm3m</code> | c, z | Computes a scalar-matrix-matrix product using matrix multiplications and adds the result to a scalar-matrix product. |
| <code>cblas_?gemm_batch</code> | s, d, c, z | Computes scalar-matrix-matrix products and adds the results to scalar matrix products for groups of general matrices. |
| <code>cblas_? gemm3m_batch</code> | c, z | Computes a scalar-matrix-matrix product using matrix multiplications and adds the result to a scalar-matrix product. |
| <code>mkl_?imatcopy</code> | s, d, c, z | Performs scaling and in-place transposition/copying of matrices. |
| <code>mkl_?omatcopy</code> | s, d, c, z | Performs scaling and out-of-place transposition/copying of matrices. |
| <code>mkl_?omatcopy2</code> | s, d, c, z | Performs two-strided scaling and out-of-place transposition/copying of matrices. |
| <code>mkl_?omatadd</code> | s, d, c, z | Performs scaling and sum of two matrices including their out-of-place transposition/copying. |
| <code>cblas_?gemm_alloc</code> | s, d | Allocates storage for a packed matrix. |
| <code>?cblas_gemm_pack</code> | s, d | Performs scaling and packing of the matrix into the previously allocated buffer. |
| <code>cblas_? gemm_compute</code> | s, d | Computes a matrix-matrix product with general matrices where one or both input matrices are stored in a packed data structure and adds the result to a scalar-matrix product. |
| <code>cblas_?gemm_free</code> | s, d | Frees the storage previously allocated for the packed matrix. |

`cblas_?axpby`

Scales two vectors, adds them to one another and stores result in the vector.

Syntax

```
void cblas_saxpby (const MKL_INT n, const float a, const float *x, const MKL_INT incx,
const float b, float *y, const MKL_INT incy);
```

```
void cblas_daxpby (const MKL_INT n, const double a, const double *x, const MKL_INT
incx, const double b, double *y, const MKL_INT incy);
```

```
void cblas_caxpby (const MKL_INT n, const void *a, const void *x, const MKL_INT incx,
const void *b, void *y, const MKL_INT incy);
```

```
void cblas_zaxpby (const MKL_INT n, const void *a, const void *x, const MKL_INT incx,  
const void *b, void *y, const MKL_INT incy);
```

Include Files

- mkl.h

Description

The `?axpby` routines perform a vector-vector operation defined as

```
 $y := a*x + b*y$ 
```

where:

a and b are scalars

x and y are vectors each with n elements.

Input Parameters

| | |
|--------|---|
| n | Specifies the number of elements in vectors x and y . |
| a | Specifies the scalar a . |
| x | Array, size at least $(1 + (n-1)*abs(incx))$. |
| $incx$ | Specifies the increment for the elements of x . |
| b | Specifies the scalar b . |
| y | Array, size at least $(1 + (n-1)*abs(incy))$. |
| $incy$ | Specifies the increment for the elements of y . |

Output Parameters

| | |
|-----|-----------------------------------|
| y | Contains the updated vector y . |
|-----|-----------------------------------|

Example

For examples of routine usage, see the code in the Intel MKL installation directory:

- `cblas_saxpby`: `examples\cblas\source\cblas_saxpbyx.c`
- `cblas_daxpby`: `examples\cblas\source\cblas_daxpbyx.c`
- `cblas_caxpby`: `examples\cblas\source\cblas_caxpbyx.c`
- `cblas_zaxpby`: `examples\cblas\source\cblas_zaxpbyx.c`

`cblas_?gemmt`

Computes a matrix-matrix product with general matrices but updates only the upper or lower triangular part of the result matrix.

Syntax

```
void cblas_sgemmt (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const  
CBLAS_TRANSPOSE transa, const CBLAS_TRANSPOSE transb, const MKL_INT n, const MKL_INT k,  
const float alpha, const float *a, const MKL_INT lda, const float *b, const MKL_INT  
ldb, const float beta, float *c, const MKL_INT ldc);
```

```

void cblas_dgemmt (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE transa, const CBLAS_TRANSPOSE transb, const MKL_INT n, const MKL_INT k,
const double alpha, const double *a, const MKL_INT lda, const double *b, const MKL_INT
ldb, const double beta, double *c, const MKL_INT ldc);

void cblas_cgemmt (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE transa, const CBLAS_TRANSPOSE transb, const MKL_INT n, const MKL_INT k,
const void *alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb,
const void *beta, void *c, const MKL_INT ldc);

void cblas_zgemmt (const CBLAS_LAYOUT Layout, const CBLAS_UPLO uplo, const
CBLAS_TRANSPOSE transa, const CBLAS_TRANSPOSE transb, const MKL_INT n, const MKL_INT k,

```

Include Files

- mkl.h

Description

The `?gemmt` routines compute a scalar-matrix-matrix product with general matrices and add the result to the upper or lower part of a scalar-matrix product. These routines are similar to the `?gemm` routines, but they only access and update a triangular part of the square result matrix (see Application Notes below).

The operation is defined as

$$C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C,$$

where:

$\text{op}(X)$ is one of $\text{op}(X) = X$, or $\text{op}(X) = X^T$, or $\text{op}(X) = X^H$,

α and β are scalars,

A , B and C are matrices:

$\text{op}(A)$ is an n -by- k matrix,

$\text{op}(B)$ is a k -by- n matrix,

C is an n -by- n upper or lower triangular matrix.

Input Parameters

| | |
|---------------|---|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>uplo</i> | Specifies whether the upper or lower triangular part of the array c is used. If $uplo = 'U'$ or $'u'$, then the upper triangular part of the array c is used. If $uplo = 'L'$ or $'l'$, then the lower triangular part of the array c is used. |
| <i>transa</i> | Specifies the form of $\text{op}(A)$ used in the matrix multiplication: if $transa = 'N'$ or $'n'$, then $\text{op}(A) = A$; if $transa = 'T'$ or $'t'$, then $\text{op}(A) = A^T$; if $transa = 'C'$ or $'c'$, then $\text{op}(A) = A^H$. |
| <i>transb</i> | Specifies the form of $\text{op}(B)$ used in the matrix multiplication: if $transb = 'N'$ or $'n'$, then $\text{op}(B) = B$; |

if $transb = 'T'$ or $'t'$, then $op(B) = B^T$;

if $transb = 'C'$ or $'c'$, then $op(B) = B^H$.

| | |
|---------|--|
| n | Specifies the order of the matrix C . The value of n must be at least zero. |
| k | Specifies the number of columns of the matrix $op(A)$ and the number of rows of the matrix $op(B)$. The value of k must be at least zero. |
| $alpha$ | Specifies the scalar $alpha$. |
| a | Array, size lda by ka , where ka is k when $transa = 'N'$ or $'n'$, and is n otherwise. Before entry with $transa = 'N'$ or $'n'$, the leading n -by- k part of the array a must contain the matrix A , otherwise the leading k -by- n part of the array a must contain the matrix A . |
| lda | Specifies the leading dimension of a as declared in the calling (sub)program. When $transa = 'N'$ or $'n'$, then lda must be at least $\max(1, n)$, otherwise lda must be at least $\max(1, k)$. |
| b | Array, size ldb by kb , where kb is n when $transb = 'N'$ or $'n'$, and is k otherwise. Before entry with $transb = 'N'$ or $'n'$, the leading k -by- n part of the array b must contain the matrix B , otherwise the leading n -by- k part of the array b must contain the matrix B . |
| ldb | Specifies the leading dimension of b as declared in the calling (sub)program. When $transb = 'N'$ or $'n'$, then ldb must be at least $\max(1, k)$, otherwise ldb must be at least $\max(1, n)$. |
| $beta$ | Specifies the scalar $beta$. When $beta$ is equal to zero, then c need not be set on input. |
| c | Array, size ldc by n . Before entry with $uplo = 'U'$ or $'u'$, the leading n -by- n upper triangular part of the array c must contain the upper triangular part of the matrix C and the strictly lower triangular part of c is not referenced. Before entry with $uplo = 'L'$ or $'l'$, the leading n -by- n lower triangular part of the array c must contain the lower triangular part of the matrix C and the strictly upper triangular part of c is not referenced. When $beta$ is equal to zero, then c need not be set on input. |
| ldc | Specifies the leading dimension of c as declared in the calling (sub)program. The value of ldc must be at least $\max(1, n)$. |

Output Parameters

| | |
|-----|--|
| c | When $uplo = 'U'$ or $'u'$, the upper triangular part of the array c is overwritten by the upper triangular part of the updated matrix. When $uplo = 'L'$ or $'l'$, the lower triangular part of the array c is overwritten by the lower triangular part of the updated matrix. |
|-----|--|

Application Notes

These routines only access and update the upper or lower triangular part of the result matrix. This can be useful when the result is known to be symmetric; for example, when computing a product of the form $C := \alpha * B * S * B^T + \beta * C$, where S and C are symmetric matrices and B is a general matrix. In this case, first compute $A := B * S$ (which can be done using the corresponding `?symm` routine), then compute $C := \alpha * A * B^T + \beta * C$ using the `?gemmt` routine.

cblas_?gemm3m

Computes a scalar-matrix-matrix product using matrix multiplications and adds the result to a scalar-matrix product.

Syntax

```
void cblas_cgemm3m (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE transa, const
CBLAS_TRANSPOSE transb, const MKL_INT m, const MKL_INT n, const MKL_INT k, const void
*alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void
*beta, void *c, const MKL_INT ldc);
```

```
void cblas_zgemm3m (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE transa, const
CBLAS_TRANSPOSE transb, const MKL_INT m, const MKL_INT n, const MKL_INT k, const void
*alpha, const void *a, const MKL_INT lda, const void *b, const MKL_INT ldb, const void
*beta, void *c, const MKL_INT ldc);
```

Include Files

- mkl.h

Description

The `?gemm3m` routines perform a matrix-matrix operation with general complex matrices. These routines are similar to the `?gemm` routines, but they use fewer matrix multiplication operations (see *Application Notes* below).

The operation is defined as

$$C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C,$$

where:

$\text{op}(x)$ is one of $\text{op}(x) = x$, or $\text{op}(x) = x'$, or $\text{op}(x) = \text{conjg}(x')$,

α and β are scalars,

A , B and C are matrices:

$\text{op}(A)$ is an m -by- k matrix,

$\text{op}(B)$ is a k -by- n matrix,

C is an m -by- n matrix.

Input Parameters

Layout Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

transa Specifies the form of $\text{op}(A)$ used in the matrix multiplication:
if $\text{transa} = \text{CblasNoTrans}$, then $\text{op}(A) = A$;

if *transa*=CblasTrans, then $\text{op}(A) = A'$;
 if *transa*=CblasConjTrans, then $\text{op}(A) = \text{conjg}(A')$.

transb

Specifies the form of $\text{op}(B)$ used in the matrix multiplication:

if *transb*=CblasNoTrans, then $\text{op}(B) = B$;
 if *transb*=CblasTrans, then $\text{op}(B) = B'$;
 if *transb*=CblasConjTrans, then $\text{op}(B) = \text{conjg}(B')$.

m

Specifies the number of rows of the matrix $\text{op}(A)$ and of the matrix *C*. The value of *m* must be at least zero.

n

Specifies the number of columns of the matrix $\text{op}(B)$ and the number of columns of the matrix *C*.

The value of *n* must be at least zero.

k

Specifies the number of columns of the matrix $\text{op}(A)$ and the number of rows of the matrix $\text{op}(B)$.

The value of *k* must be at least zero.

alpha

Specifies the scalar *alpha*.

a

| | <i>transa</i> =CblasNoTrans | <i>transa</i> =CblasTrans or <i>transa</i> =CblasConjTrans |
|----------------------------------|---|---|
| <i>Layout</i> = CblasColMajor | Array, size <i>lda</i> * <i>k</i> . Before entry, the leading <i>m</i> -by- <i>k</i> part of the array <i>a</i> must contain the matrix <i>A</i> . | Array, size <i>lda</i> * <i>m</i> . Before entry, the leading <i>k</i> -by- <i>m</i> part of the array <i>a</i> must contain the matrix <i>A</i> . |
| <i>Layout</i> = CblasRowMajor | Array, size <i>lda</i> * <i>m</i> . Before entry, the leading <i>k</i> -by- <i>m</i> part of the array <i>a</i> must contain the matrix <i>A</i> . | Array, size <i>lda</i> * <i>k</i> . Before entry, the leading <i>m</i> -by- <i>k</i> part of the array <i>a</i> must contain the matrix <i>A</i> . |

lda

Specifies the leading dimension of *a* as declared in the calling (sub)program.

| | <i>transa</i> =CblasNoTrans | <i>transa</i> =CblasTrans or <i>transa</i> =CblasConjTrans |
|----------------------------------|--|---|
| <i>Layout</i> = CblasColMajor | <i>lda</i> must be at least $\max(1, m)$. | <i>lda</i> must be at least $\max(1, k)$ |
| <i>Layout</i> = CblasRowMajor | <i>lda</i> must be at least $\max(1, k)$ | <i>lda</i> must be at least $\max(1, m)$. |

b

| | | |
|----------------------------------|---|--|
| | <i>transb</i> =CblasNoTrans | <i>transb</i> =CblasTrans or <i>transb</i> =CblasConjTrans |
| <i>Layout</i> = CblasColMajor | Array, size <i>ldb</i> by <i>n</i> . Before entry, the leading <i>k</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> . | Array, size <i>ldb</i> by <i>k</i> . Before entry the leading <i>n</i> -by- <i>k</i> part of the array <i>b</i> must contain the matrix <i>B</i> . |
| <i>Layout</i> = CblasRowMajor | Array, size <i>ldb</i> by <i>k</i> . Before entry the leading <i>n</i> -by- <i>k</i> part of the array <i>b</i> must contain the matrix <i>B</i> . | Array, size <i>ldb</i> by <i>n</i> . Before entry, the leading <i>k</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> . |

ldb

Specifies the leading dimension of *b* as declared in the calling (sub)program.

| | | |
|----------------------------------|---|---|
| | <i>transb</i> =CblasNoTrans | <i>transb</i> =CblasTrans or <i>transb</i> =CblasConjTrans |
| <i>Layout</i> = CblasColMajor | <i>ldb</i> must be at least $\max(1, k)$. | <i>ldb</i> must be at least $\max(1, n)$. |
| <i>Layout</i> = CblasRowMajor | <i>ldb</i> must be at least $\max(1, n)$. | <i>ldb</i> must be at least $\max(1, k)$. |

beta

Specifies the scalar *beta*.

When *beta* is equal to zero, then *c* need not be set on input.

c

| | |
|----------------------------------|--|
| <i>Layout</i> = CblasColMajor | Array, size <i>ldc</i> by <i>n</i> . Before entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i> , except when <i>beta</i> is equal to zero, in which case <i>c</i> need not be set on entry. |
| <i>Layout</i> = CblasRowMajor | Array, size <i>ldc</i> by <i>m</i> . Before entry, the leading <i>n</i> -by- <i>m</i> part of the array <i>c</i> must contain the matrix <i>C</i> , except when <i>beta</i> is equal to zero, in which case <i>c</i> need not be set on entry. |

ldc

Specifies the leading dimension of *c* as declared in the calling (sub)program.

| | |
|-------------------------------|--|
| <i>Layout</i> = CblasColMajor | <i>ldc</i> must be at least $\max(1, m)$. |
| <i>Layout</i> = CblasRowMajor | <i>ldc</i> must be at least $\max(1, n)$. |

Output Parameters

c

Overwritten by the *m*-by-*n* matrix $(\alpha * \text{op}(A) * \text{op}(B) + \beta * C)$.

Application Notes

These routines perform a complex matrix multiplication by forming the real and imaginary parts of the input matrices. This uses three real matrix multiplications and five real matrix additions instead of the conventional four real matrix multiplications and two real matrix additions. The use of three real matrix multiplications reduces the time spent in matrix operations by 25%, resulting in significant savings in compute time for large matrices.

If the errors in the floating point calculations satisfy the following conditions:

$$fl(x \text{ op } y) = (x \text{ op } y) (1 + \delta), |\delta| \leq u, \text{ op} = *, /, fl(x \pm y) = x(1 + \alpha) \pm y(1 + \beta), |\alpha|, |\beta| \leq u$$

then for an n -by- n matrix $\hat{C} = fl(C_1 + iC_2) = fl((A_1 + iA_2)(B_1 + iB_2)) = \hat{C}_1 + i\hat{C}_2$, the following bounds are satisfied:

$$\|\hat{C}_1 - C_1\| \leq 2(n+1)u \|A\|_\infty \|B\|_\infty + O(u^2),$$

$$\|\hat{C}_2 - C_2\| \leq 4(n+4)u \|A\|_\infty \|B\|_\infty + O(u^2),$$

where $\|A\|_\infty = \max(\|A_1\|_\infty, \|A_2\|_\infty)$, and $\|B\|_\infty = \max(\|B_1\|_\infty, \|B_2\|_\infty)$.

Thus the corresponding matrix multiplications are stable.

cblas_?gemm_batch

Computes scalar-matrix-matrix products and adds the results to scalar matrix products for groups of general matrices.

Syntax

```
void cblas_sgemm_batch (const CBLAS_LAYOUT Layout, const CBLAS_TRANSPOSE* transa_array,
const CBLAS_TRANSPOSE* transb_array, const MKL_INT* m_array, const MKL_INT* n_array,

Description

The `?gemm_batch` routines perform a series of matrix-matrix operations with general matrices. They are similar to the `?gemm` routine counterparts, but the `?gemm_batch` routines perform matrix-matrix operations with groups of matrices, processing a number of groups at once. The groups contain matrices with the same parameters.

The operation is defined as

```
idx = 0
for i = 0..group_count - 1
  alpha and beta in alpha_array[i] and beta_array[i]
  for j = 0..group_size[i] - 1
    A, B, and C matrix in a_array[idx], b_array[idx], and c_array[idx]
    C := alpha*op(A)*op(B) + beta*C,
    idx = idx + 1
  end for
end for
```

where:

$\text{op}(X)$ is one of $\text{op}(X) = X$, or $\text{op}(X) = X^T$, or $\text{op}(X) = X^H$,

alpha and *beta* are scalar elements of *alpha_array* and *beta_array*,

A, *B* and *C* are matrices such that for *m*, *n*, and *k* which are elements of *m_array*, *n_array*, and *k_array*:

$\text{op}(A)$ is an *m*-by-*k* matrix,

$\text{op}(B)$ is a *k*-by-*n* matrix,

C is an *m*-by-*n* matrix.

A, *B*, and *C* represent matrices stored at addresses pointed to by *a_array*, *b_array*, and *c_array*, respectively. The number of entries in *a_array*, *b_array*, and *c_array* is *total_batch_count* = the sum of all of the *group_size* entries.

See also [gemm](#) for a detailed description of multiplication for general matrices and [?gemm3m_batch](#), BLAS-like extension routines for similar matrix-matrix operations.

NOTE

Error checking is not performed for Intel MKL Windows* single dynamic libraries for the `?gemm_batch` routines.

Input Parameters

| | |
|---------------------|--|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>transa_array</i> | <p>Array of size <i>group_count</i>. NOTE

Error checking is not performed for Intel MKL Windows* single dynamic libraries for the `?gemm3m_batch` routines.

Input Parameters

| | |
|---------------------|--|
| <i>Layout</i> | Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor). |
| <i>transa_array</i> | <p>Array of size <i>group_count</i>. For the group <i>i</i>, $\text{transa}_i = \text{transa_array}[i]$ specifies the form of $\text{op}(A)$ used in the matrix multiplication:</p> <p>if $\text{transa}_i = \text{CblasNoTrans}$, then $\text{op}(A) = A$;</p> <p>if $\text{transa}_i = \text{CblasTrans}$, then $\text{op}(A) = A^T$;</p> <p>if $\text{transa}_i = \text{CblasConjTrans}$, then $\text{op}(A) = A^H$.</p> |
| <i>transb_array</i> | <p>Array of size <i>group_count</i>. For the group <i>i</i>, $\text{transb}_i = \text{transb_array}[i]$ specifies the form of $\text{op}(B_i)$ used in the matrix multiplication:</p> |

if $transb_i = \text{CblasNoTrans}$, then $op(B) = B$;
 if $transb_i = \text{CblasTrans}$, then $op(B) = B^T$;
 if $transb_i = \text{CblasConjTrans}$, then $op(B) = B^H$.

m_array Array of size *group_count*. For the group *i*, $m_i = m_array[i]$ specifies the number of rows of the matrix $op(A)$ and of the matrix *C*.

The value of each element of *m_array* must be at least zero.

n_array Array of size *group_count*. For the group *i*, $n_i = n_array[i]$ specifies the number of columns of the matrix $op(B)$ and the number of columns of the matrix *C*.

The value of each element of *n_array* must be at least zero.

k_array Array of size *group_count*. For the group *i*, $k_i = k_array[i]$ specifies the number of columns of the matrix $op(A)$ and the number of rows of the matrix $op(B)$.

The value of each element of *k_array* must be at least zero.

alpha_array Array of size *group_count*. For the group *i*, *alpha_array*[*i*] specifies the scalar α_i .

a_array Array, size *total_batch_count*, of pointers to arrays used to store *A* matrices.

lda_array Array of size *group_count*. For the group *i*, $lda_i = lda_array[i]$ specifies the leading dimension of the array storing matrix *A* as declared in the calling (sub)program.

| | | |
|-----------------|---|---|
| | $transa_i = \text{CblasNoTrans}$ | $transa_i = \text{CblasTrans}$ or $transa_i = \text{CblasConjTrans}$ |
| <i>Layout</i> = | <i>lda_i</i> must be at least $\max(1, m_i)$. | <i>lda_i</i> must be at least $\max(1, k_i)$ |
| <i>Layout</i> = | <i>lda_i</i> must be at least $\max(1, k_i)$ | <i>lda_i</i> must be at least $\max(1, m_i)$ |

b_array Array, size *total_batch_count*, of pointers to arrays used to store *B* matrices.

ldb_array Array of size *group_count*. For the group *i*, $ldb_i = ldb_array[i]$ specifies the leading dimension of the array storing matrix *B* as declared in the calling (sub)program.

| | | |
|-----------------|---|---|
| | $transb_i = \text{CblasNoTrans}$ | $transb_i = \text{CblasTrans}$ or $transb_i = \text{CblasConjTrans}$ |
| <i>Layout</i> = | <i>ldb_i</i> must be at least $\max(1, k_i)$. | <i>ldb_i</i> must be at least $\max(1, n_i)$. |

| | | |
|-----------------|---|---|
| <i>Layout</i> = | <i>ldb_i</i> must be at least | <i>ldb_i</i> must be at least |
| CblasRowMajor | $\max(1, n_i)$. | $\max(1, k_i)$. |

beta_array For the group *i*, *beta_array*[*i*] specifies the scalar *beta_i*.
When *beta_i* is equal to zero, then *C* matrices in group *i* need not be set on input.

c_array Array, size *total_batch_count*, of pointers to arrays used to store *C* matrices.

ldc_array Array of size *group_count*. For the group *i*, *ldc_i* = *ldc_array*[*i*] specifies the leading dimension of all arrays storing matrix *C* in group *i* as declared in the calling (sub)program.
When *Layout* = CblasColMajor *ldc_i* must be at least $\max(1, m_i)$.
When *Layout* = CblasRowMajor *ldc_i* must be at least $\max(1, n_i)$.

group_count Specifies the number of groups. Must be at least 0.

group_size Array of size *group_count*. The element *group_size*[*i*] specifies the number of matrices in group *i*. Each element in *group_size* must be at least 0.

Output Parameters

c_array Overwritten by the *m_i*-by-*n_i* matrix (*alpha_i**_{op}(*A*)*_{op}(*B*) + *beta_i***C*) for group *i*.

Application Notes

These routines perform a complex matrix multiplication by forming the real and imaginary parts of the input matrices. This uses three real matrix multiplications and five real matrix additions instead of the conventional four real matrix multiplications and two real matrix additions. The use of three real matrix multiplications reduces the time spent in matrix operations by 25%, resulting in significant savings in compute time for large matrices.

If the errors in the floating point calculations satisfy the following conditions:

$$fl(x \text{ op } y) = (x \text{ op } y) (1 + \delta), |\delta| \leq u, \text{ op} = *, /, fl(x \pm y) = x(1 + \alpha) \pm y(1 + \beta), |\alpha|, |\beta| \leq u$$

then for an *n*-by-*n* matrix $\hat{C} = fl(C_1 + iC_2) = fl((A_1 + iA_2)(B_1 + iB_2)) = \hat{C}_1 + i\hat{C}_2$, the following bounds are satisfied:

$$\|\hat{C}_1 - C_1\| \leq 2(n+1)u \|A\|_\infty \|B\|_\infty + O(u^2),$$

$$\|\hat{C}_2 - C_2\| \leq 4(n+4)u \|A\|_\infty \|B\|_\infty + O(u^2),$$

where $\|A\|_\infty = \max(\|A_1\|_\infty, \|A_2\|_\infty)$, and $\|B\|_\infty = \max(\|B_1\|_\infty, \|B_2\|_\infty)$.

Thus the corresponding matrix multiplications are stable.

mkl_?imatcopy

Performs scaling and in-place transposition/copying of matrices.

Syntax

```
void mkl_simatcopy (const char ordering, const char trans, size_t rows, size_t cols,
const float alpha, float * AB, size_t lda, size_t ldb);
```

```
void mkl_dimatcopy (const char ordering, const char trans, size_t rows, size_t cols,
const double alpha, double * AB, size_t lda, size_t ldb);
```

```
void mkl_cimatcopy (const char ordering, const char trans, size_t rows, size_t cols,
const MKL_Complex8 alpha, MKL_Complex8 * AB, size_t lda, size_t ldb);
```

```
void mkl_zimatcopy (const char ordering, const char trans, size_t rows, size_t cols,
const MKL_Complex16 alpha, MKL_Complex16 * AB, size_t lda, size_t ldb);
```

Include Files

- mkl.h

Description

The `mkl_?imatcopy` routine performs scaling and in-place transposition/copying of matrices. A transposition operation can be a normal matrix copy, a transposition, a conjugate transposition, or just a conjugation. The operation is defined as follows:

$$AB := \alpha * \text{op}(AB).$$

NOTE

Different arrays must not overlap.

Input Parameters

| | |
|-----------------|--|
| <i>ordering</i> | Ordering of the matrix storage. If <i>ordering</i> = 'R' or 'r', the ordering is row-major. If <i>ordering</i> = 'C' or 'c', the ordering is column-major. |
| <i>trans</i> | Parameter that specifies the operation type. If <i>trans</i> = 'N' or 'n', $\text{op}(AB) = AB$ and the matrix <i>AB</i> is assumed unchanged on input. If <i>trans</i> = 'T' or 't', it is assumed that <i>AB</i> should be transposed. If <i>trans</i> = 'C' or 'c', it is assumed that <i>AB</i> should be conjugate transposed. If <i>trans</i> = 'R' or 'r', it is assumed that <i>AB</i> should be only conjugated. If the data is real, then <i>trans</i> = 'R' is the same as <i>trans</i> = 'N', and <i>trans</i> = 'C' is the same as <i>trans</i> = 'T'. |
| <i>rows</i> | The number of rows in matrix <i>AB</i> before the transpose operation. |
| <i>cols</i> | The number of columns in matrix <i>AB</i> before the transpose operation. |
| <i>ab</i> | Array. |
| <i>alpha</i> | This parameter scales the input matrix by <i>alpha</i> . |

| | |
|------------|---|
| <i>lda</i> | <p>Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the source matrix; measured in the number of elements.</p> <p>This parameter must be at least <i>rows</i> if <i>ordering</i> = 'C' or 'c', and $\max(1, cols)$ otherwise.</p> |
| <i>ldb</i> | <p>Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the destination matrix; measured in the number of elements.</p> <p>To determine the minimum value of <i>ldb</i> on output, consider the following guideline:</p> <p>If <i>ordering</i> = 'C' or 'c', then</p> <ul style="list-style-type: none">• If <i>trans</i> = 'T' or 't' or 'C' or 'c', this parameter must be at least $\max(1, cols)$• If <i>trans</i> = 'N' or 'n' or 'R' or 'r', this parameter must be at least $\max(1, rows)$ <p>If <i>ordering</i> = 'R' or 'r', then</p> <ul style="list-style-type: none">• If <i>trans</i> = 'T' or 't' or 'C' or 'c', this parameter must be at least $\max(1, rows)$• If <i>trans</i> = 'N' or 'n' or 'R' or 'r', this parameter must be at least $\max(1, cols)$ |

Output Parameters

| | |
|-----------|---|
| <i>ab</i> | <p>Array.</p> <p>Contains the matrix <i>AB</i>.</p> |
|-----------|---|

Interfaces

mkl_?omatcopy

Performs scaling and out-place transposition/copying of matrices.

Syntax

```
void mkl_somatcopy (char ordering, char trans, size_t rows, size_t cols, const float alpha, const float * A, size_t lda, float * B, size_t ldb);  
void mkl_domatcopy (char ordering, char trans, size_t rows, size_t cols, const double alpha, const double * A, size_t lda, double * B, size_t ldb);  
void mkl_comatcopy (char ordering, char trans, size_t rows, size_t cols, const MKL_Complex8 alpha, const MKL_Complex8 * A, size_t lda, MKL_Complex8 * B, size_t ldb);  
void mkl_zomatcopy (char ordering, char trans, size_t rows, size_t cols, const MKL_Complex16 alpha, const MKL_Complex16 * A, size_t lda, MKL_Complex16 * B, size_t ldb);
```

Include Files

| <i>ldb</i> | If <i>ordering</i> = 'R' or 'r', <i>ldb</i> represents the number of elements in array <i>b</i> between adjacent rows of matrix <i>B</i> . <ul style="list-style-type: none"> If <i>trans</i> = 'T' or 't' or 'C' or 'c', <i>ldb</i> must be at least equal to <i>rows</i>. |

- If *trans* = 'N' or 'n' or 'R' or 'r', *ldb* must be at least equal to *cols*.

If *ordering* = 'C' or 'c', *ldb* represents the number of elements in array *b* between adjacent columns of matrix *B*.

- If *trans* = 'T' or 't' or 'C' or 'c', *ldb* must be at least equal to *cols*.
- If *trans* = 'N' or 'n' or 'R' or 'r', *ldb* must be at least equal to *rows*.

Output Parameters

b Array, size at least *m*.
Contains the destination matrix.

Interfaces

mkl_?omatcopy2

Performs two-strided scaling and out-of-place transposition/copying of matrices.

Syntax

```
void mkl_somatcopy2 (char ordering, char trans, size_t rows, size_t cols, const float alpha, const float * A, size_t lda, size_t stridea, float * B, size_t ldb, size_t strideb);
```

```
void mkl_domatcopy2 (char ordering, char trans, size_t rows, size_t cols, const double alpha, const double * A, size_t lda, size_t stridea, double * B, size_t ldb, size_t strideb);
```

```
void mkl_comatcopy2 (char ordering, char trans, size_t rows, size_t cols, const MKL_Complex8 alpha, const MKL_Complex8 * A, size_t lda, size_t stridea, MKL_Complex8 * B, size_t ldb, size_t strideb);
```

```
void mkl_zomatcopy2 (char ordering, char trans, size_t rows, size_t cols, const MKL_Complex16 alpha, const MKL_Complex16 * A, size_t lda, size_t stridea, MKL_Complex16 * B, size_t ldb, size_t strideb);
```

Include Files

- mkl.h

Description

The `mkl_?omatcopy2` routine performs two-strided scaling and out-of-place transposition/copying of matrices. A transposition operation can be a normal matrix copy, a transposition, a conjugate transposition, or just a conjugation. The operation is defined as follows:

$$B := \alpha *_{op}(A)$$

Normally, matrices in the BLAS or LAPACK are specified by a single stride index. For instance, in the column-major order, $A(2,1)$ is stored in memory one element away from $A(1,1)$, but $A(1,2)$ is a leading dimension away. The leading dimension in this case is at least the number of rows of the source matrix. If a matrix has two strides, then both $A(2,1)$ and $A(1,2)$ may be an arbitrary distance from $A(1,1)$.

NOTE

Different arrays must not overlap.

Input Parameters

| | |
|-----------------|---|
| <i>ordering</i> | Ordering of the matrix storage. If <i>ordering</i> = 'R' or 'r', the ordering is row-major. If <i>ordering</i> = 'C' or 'c', the ordering is column-major. |
| <i>trans</i> | Parameter that specifies the operation type. If <i>trans</i> = 'N' or 'n', $op(A) = A$ and the matrix <i>A</i> is assumed unchanged on input. If <i>trans</i> = 'T' or 't', it is assumed that <i>A</i> should be transposed. If <i>trans</i> = 'C' or 'c', it is assumed that <i>A</i> should be conjugate transposed. If <i>trans</i> = 'R' or 'r', it is assumed that <i>A</i> should be only conjugated. If the data is real, then <i>trans</i> = 'R' is the same as <i>trans</i> = 'N', and <i>trans</i> = 'C' is the same as <i>trans</i> = 'T'. |
| <i>rows</i> | The number of rows in matrix <i>B</i> (the destination matrix). |
| <i>cols</i> | The number of columns in matrix <i>B</i> (the destination matrix). |
| <i>alpha</i> | This parameter scales the input matrix by <i>alpha</i> . |
| <i>a</i> | Array. |
| <i>lda</i> | If <i>ordering</i> = 'R' or 'r', <i>lda</i> represents the number of elements in array <i>a</i> between adjacent rows of matrix <i>A</i> ; <i>lda</i> must be at least equal to the number of columns of matrix <i>A</i> . If <i>ordering</i> = 'C' or 'c', <i>lda</i> represents the number of elements in array <i>a</i> between adjacent columns of matrix <i>A</i> ; <i>lda</i> must be at least 1 and not more than the number of columns in matrix <i>A</i> . |
| <i>stridea</i> | If <i>ordering</i> = 'R' or 'r', <i>stridea</i> represents the number of elements in array <i>a</i> between adjacent columns of matrix <i>A</i> . <i>stridea</i> must be at least 1 and not more than the number of columns in matrix <i>A</i> . If <i>ordering</i> = 'C' or 'c', <i>stridea</i> represents the number of elements in array <i>a</i> between adjacent rows of matrix <i>A</i> . <i>stridea</i> must be at least equal to the number of columns in matrix <i>A</i> . |
| <i>b</i> | Array. |
| <i>ldb</i> | If <i>ordering</i> = 'R' or 'r', <i>ldb</i> represents the number of elements in array <i>b</i> between adjacent rows of matrix <i>B</i> . <ul style="list-style-type: none"> If <i>trans</i> = 'T' or 't' or 'C' or 'c', <i>ldb</i> must be at least equal to $rows/strideb$. |

- If *trans* = 'N' or 'n' or 'R' or 'r', *ldb* must be at least equal to *cols/strideb*.

If *ordering* = 'C' or 'c', *ldb* represents the number of elements in array *b* between adjacent columns of matrix *B*.

- If *trans* = 'T' or 't' or 'C' or 'c', *ldb* must be at least 1 and not more than *rows/strideb*.
- If *trans* = 'N' or 'n' or 'R' or 'r', *ldb* must be at least 1 and not more than *cols/strideb*.

strideb

If *ordering* = 'R' or 'r', *strideb* represents the number of elements in array *b* between adjacent columns of matrix *B*.

- If *trans* = 'T' or 't' or 'C' or 'c', *strideb* must be at least 1 and not more than *rows* (the number of rows in matrix *B*).
- If *trans* = 'N' or 'n' or 'R' or 'r', *strideb* must be at least 1 and not more than *cols* (the number of columns in matrix *B*).

If *ordering* = 'C' or 'c', *strideb* represents the number of elements in array *b* between adjacent rows of matrix *B*.

- If *trans* = 'T' or 't' or 'C' or 'c', *strideb* must be at least equal to *rows* (the number of rows in matrix *B*).
- If *trans* = 'N' or 'n' or 'R' or 'r', *strideb* must be at least equal to *cols* (the number of columns in matrix *B*).

Output Parameters

b Array, size at least *m*.
Contains the destination matrix.

Interfaces

mkl_?omatadd

Scales and sums two matrices including in addition to performing out-of-place transposition operations.

Syntax

```
void mkl_somatadd (char ordering, char transa, char transb, size_t m, size_t n, const float alpha, const float * A, size_t lda, const float beta, const float * B, size_t ldb, float * C, size_t ldc);
```

```
void mkl_domatadd (char ordering, char transa, char transb, size_t m, size_t n, const double alpha, const double * A, size_t lda, const double beta, const double * B, size_t ldb, double * C, size_t ldc);
```

```
void mkl_comatadd (char ordering, char transa, char transb, size_t m, size_t n, const MKL_Complex8 alpha, const MKL_Complex8 * A, size_t lda, const MKL_Complex8 beta, const MKL_Complex8 * B, size_t ldb, MKL_Complex8 * C, size_t ldc);
```

```
void mkl_zomatadd (char ordering, char transa, char transb, size_t m, size_t n, const
MKL_Complex16 alpha, const MKL_Complex16 * A, size_t lda, const MKL_Complex16 beta,
const MKL_Complex16 * B, size_t ldb, MKL_Complex16 * C, size_t ldc);
```

Include Files

- mkl.h

Description

The `mkl_?omatadd` routine scales and adds two matrices, as well as performing out-of-place transposition operations. A transposition operation can be no operation, a transposition, a conjugate transposition, or a conjugation (without transposition). The following out-of-place memory movement is done:

$$C := \alpha * \text{op}(A) + \beta * \text{op}(B)$$

where the `op(A)` and `op(B)` operations are transpose, conjugate-transpose, conjugate (no transpose), or no transpose, depending on the values of `transa` and `transb`. If no transposition of the source matrices is required, m is the number of rows and n is the number of columns in the source matrices A and B . In this case, the output matrix C is m -by- n .

NOTE

Note that different arrays must not overlap.

Input Parameters

| | |
|-----------------|---|
| <i>ordering</i> | Ordering of the matrix storage. If <i>ordering</i> = 'R' or 'r', the ordering is row-major. If <i>ordering</i> = 'C' or 'c', the ordering is column-major. |
| <i>transa</i> | Parameter that specifies the operation type on matrix A . If <i>transa</i> = 'N' or 'n', $\text{op}(A)=A$ and the matrix A is assumed unchanged on input. If <i>transa</i> = 'T' or 't', it is assumed that A should be transposed. If <i>transa</i> = 'C' or 'c', it is assumed that A should be conjugate transposed. If <i>transa</i> = 'R' or 'r', it is assumed that A should be conjugated (and not transposed). If the data is real, then <i>transa</i> = 'R' is the same as <i>transa</i> = 'N', and <i>transa</i> = 'C' is the same as <i>transa</i> = 'T'. |
| <i>transb</i> | Parameter that specifies the operation type on matrix B . If <i>transb</i> = 'N' or 'n', $\text{op}(B)=B$ and the matrix B is assumed unchanged on input. If <i>transb</i> = 'T' or 't', it is assumed that B should be transposed. If <i>transb</i> = 'C' or 'c', it is assumed that B should be conjugate transposed. If <i>transb</i> = 'R' or 'r', it is assumed that B should be conjugated (and not transposed). |

If the data is real, then `transb = 'R'` is the same as `transb = 'N'`, and `transb = 'C'` is the same as `transb = 'T'`.

| | |
|--------------------|--|
| <code>m</code> | The number of matrix rows in <code>op(A)</code> , <code>op(B)</code> , and <code>C</code> . |
| <code>n</code> | The number of matrix columns in <code>op(A)</code> , <code>op(B)</code> , and <code>C</code> . |
| <code>alpha</code> | This parameter scales the input matrix by <code>alpha</code> . |
| <code>a</code> | Array. |
| <code>lda</code> | Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the source matrix <code>A</code> ; measured in the number of elements. For <code>ordering = 'C'</code> or <code>'c'</code> : when <code>transa = 'N', 'n', 'R', or 'r'</code> , <code>lda</code> must be at least <code>max(1, m)</code> ; otherwise <code>lda</code> must be <code>max(1, n)</code> . For <code>ordering = 'R'</code> or <code>'r'</code> : when <code>transa = 'N', 'n', 'R', or 'r'</code> , <code>lda</code> must be at least <code>max(1, n)</code> ; otherwise <code>lda</code> must be <code>max(1, m)</code> . |
| <code>beta</code> | This parameter scales the input matrix by <code>beta</code> . |
| <code>b</code> | Array. |
| <code>ldb</code> | Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the source matrix <code>B</code> ; measured in the number of elements. For <code>ordering = 'C'</code> or <code>'c'</code> : when <code>transa = 'N', 'n', 'R', or 'r'</code> , <code>ldb</code> must be at least <code>max(1, m)</code> ; otherwise <code>ldb</code> must be <code>max(1, n)</code> . For <code>ordering = 'R'</code> or <code>'r'</code> : when <code>transa = 'N', 'n', 'R', or 'r'</code> , <code>ldb</code> must be at least <code>max(1, n)</code> ; otherwise <code>ldb</code> must be <code>max(1, m)</code> . |
| <code>ldc</code> | Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the destination matrix <code>C</code> ; measured in the number of elements. If <code>ordering = 'C'</code> or <code>'c'</code> , then <code>ldc</code> must be at least <code>max(1, m)</code> , otherwise <code>ldc</code> must be at least <code>max(1, n)</code> . |

Output Parameters

| | |
|----------------|--------|
| <code>c</code> | Array. |
|----------------|--------|

Interfaces

`cblas_?gemm_alloc`

Allocates storage for a packed matrix.

Syntax

```
float* cblas_sgemm_alloc (const CBLAS_IDENTIFIER identifier, const MKL_INT m, const MKL_INT n, const MKL_INT k);
```

```
double* cblas_dgemm_alloc (const CBLAS_IDENTIFIER identifier, const MKL_INT m, const MKL_INT n, const MKL_INT k);
```

Include Files

- `mkl.h`

Description

The `cblas_?gemm_alloc` routine is one of a set of related routines that enable use of an internal packed storage. Call the `cblas_?gemm_alloc` routine first to allocate storage for a packed matrix structure to be used in subsequent calls, ultimately to compute

$$C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C,$$

where:

$\text{op}(X)$ is one of the operations $\text{op}(X) = X$, $\text{op}(X) = X^T$, or $\text{op}(X) = X^H$,

α and β are scalars,

A , B , and C are matrices:

$\text{op}(A)$ is an m -by- k matrix,

$\text{op}(B)$ is a k -by- n matrix,

C is an m -by- n matrix.

The `cblas_?gemm_alloc` routine is not supported on Windows* OS for the IA-32 architecture with single dynamic library linking.

Input Parameters

| | |
|-------------------|---|
| <i>identifier</i> | Specifies which matrix is to be packed: If <i>identifier</i> = <code>CblasAMatrix</code> , the routine allocates storage to pack matrix A . If <i>identifier</i> = <code>CblasBMatrix</code> , the routine allocates storage to pack matrix B . |
| <i>m</i> | Specifies the number of rows of matrix $\text{op}(A)$ and of the matrix C . The value of m must be at least zero. |
| <i>n</i> | Specifies the number of columns of matrix $\text{op}(B)$ and the number of columns of matrix C . The value of n must be at least zero. |
| <i>k</i> | Specifies the number of columns of matrix $\text{op}(A)$ and the number of rows of matrix $\text{op}(B)$. The value of k must be at least zero. |

Return Values

The function returns the allocated storage.

```

Include Files

- mkl.h

Description

The `cblas_?gemm_pack` routine is one of a set of related routines that enable use of an internal packed storage. Call `cblas_?gemm_pack` after successfully calling `cblas_?gemm_alloc`. The `cblas_?gemm_pack` scales the identified matrix by α and packs it into the buffer allocated previously with `cblas_?gemm_alloc`.

The `cblas_?gemm_pack` routine performs this operation:

$$dest := \alpha * op(src) \text{ as part of the computation } C := \alpha * op(A) * op(B) + \beta * C$$

where:

$op(X)$ is one of the operations $op(X) = X$, $op(X) = X^T$, or $op(X) = X^H$,

α and β are scalars,

src is a matrix,

A , B , and C are matrices

$op(src)$ is an m -by- k matrix if $identifier = CblasAMatrix$,

$op(src)$ is a k -by- n matrix if $identifier = CblasBMatrix$,

$dest$ is an internal packed storage buffer.

NOTE

You must use the same value of the `Layout` parameter for the entire sequence of related `cblas_?gemm_pack` and `cblas_?gemm_compute` calls.

For best performance, use the same number of threads for packing and for computing.

If packing for both A and B matrices, you must use the same number of threads for packing A as for packing B .

Input Parameters

`Layout` Specifies whether two-dimensional array storage is row-major (CblasRowMajor) or column-major (CblasColMajor).

`identifier` Specifies which matrix is to be packed:
If `identifier = CblasAMatrix`, the routine allocates storage to pack matrix A .

If *identifier* = `CblasBMatrix`, the routine allocates storage to pack matrix *B*.

trans

Specifies the form of `op(src)` used in the packing:

If *trans* = `CblasNoTrans` `op(src)` = *src*.

If *trans* = `CblasTrans` `op(src)` = *src*^T.

If *trans* = `CblasConjTrans` `op(src)` = *src*^H.

m

Specifies the number of rows of the matrix `op(A)` and of the matrix *C*. The value of *m* must be at least zero.

n

Specifies the number of columns of the matrix `op(B)` and the number of columns of the matrix *C*. The value of *n* must be at least zero.

k

Specifies the number of columns of the matrix `op(A)` and the number of rows of the matrix `op(B)`. The value of *k* must be at least zero.

alpha

Specifies the scalar *alpha*.

src

Array:

| | <i>identifier</i> = <code>CblasAMatrix</code> | | <i>identifier</i> = <code>CblasBMatrix</code> | |

const MKL_INT ldc);
```

Include Files

- mkl.h

Description

The `cblas_?gemm_compute` routine is one of a set of related routines that enable use of an internal packed storage. After calling `cblas_?gemm_pack` call `cblas_?gemm_compute` to compute

$$C := \text{op}(A) * \text{op}(B) + \text{beta} * C,$$

where:

$\text{op}(X)$ is one of the operations $\text{op}(X) = X$, $\text{op}(X) = X^T$, or $\text{op}(X) = X^H$,

beta is a scalar,

A , B , and C are matrices:

$\text{op}(A)$ is an m -by- k matrix,

$\text{op}(B)$ is a k -by- n matrix,

C is an m -by- n matrix.

NOTE

You must use the same value of the `Layout` parameter for the entire sequence of related `cblas_?gemm_pack` and `cblas_?gemm_compute` calls.

For best performance, use the same number of threads for packing and for computing.

If packing for both A and B matrices, you must use the same number of threads for packing A as for packing B .

Input Parameters

| | |
|---------------------|---|
| <code>Layout</code> | Specifies whether two-dimensional array storage is row-major (<code>CblasRowMajor</code>) or column-major (<code>CblasColMajor</code>). |
| <code>transa</code> | Specifies the form of $\text{op}(A)$ used in the matrix multiplication, one of the <code>CBLAS_TRANSPOSE</code> or <code>CBLAS_STORAGE</code> enumerated types: If <code>transa = CblasNoTrans</code> $\text{op}(A) = A$. |

If $transa = \text{CblasTrans}$ $\text{op}(A) = A^T$.

If $transa = \text{CblasConjTrans}$ $\text{op}(A) = A^H$.

If $transa = \text{CblasPacked}$ the matrix in array a is packed and lda is ignored.

$transb$

Specifies the form of $\text{op}(B)$ used in the matrix multiplication, one of the `CBLAS_TRANSPOSE` or `CBLAS_STORAGE` enumerated types:

If $transb = \text{CblasNoTrans}$ $\text{op}(B) = B$.

If $transb = \text{CblasTrans}$ $\text{op}(B) = B^T$.

If $transb = \text{CblasConjTrans}$ $\text{op}(B) = B^H$.

If $transb = \text{CblasPacked}$ the matrix in array b is packed and ldb is ignored.

m

Specifies the number of rows of the matrix $\text{op}(A)$ and of the matrix C . The value of m must be at least zero.

n

Specifies the number of columns of the matrix $\text{op}(B)$ and the number of columns of the matrix C . The value of n must be at least zero.

k

Specifies the number of columns of the matrix $\text{op}(A)$ and the number of rows of the matrix $\text{op}(B)$. The value of k must be at least zero.

a

Array:

| | | | |
|--|--|--|--|
| | $transa =$ <code>CblasNoTrans</code> | $transa =$ <code>CblasTrans</code> or $transa =$ <code>CblasConjTrans</code> | $transa =$ <code>CblasPacked</code> |
| $Layout =$ <code>CblasColMajor</code> | Size $lda * k$. Before entry, the leading m -by- k part of the array a must contain the matrix A . | Size $lda * m$. Before entry, the leading k -by- m part of the array a must contain the matrix A . | Stored in internal packed format. |
| $Layout =$ <code>CblasRowMajor</code> | Size $lda * m$. Before entry, the leading k -by- m part of the array a must contain the matrix A . | Size $lda * k$. Before entry, the leading m -by- k part of the array a must contain the matrix A . | Stored in internal packed format. |

lda

Specifies the leading dimension of a as declared in the calling (sub)program.

| | | | |
|--|---|---|--|
| | $transa =$ <code>CblasNoTrans</code> | $transa =$ <code>CblasTrans</code> or $transa =$ <code>CblasConjTrans</code> | $transa =$ <code>CblasPacked</code> |
|--|---|---|--|

| | | | |
|----------------------------------|--|--|------------------------|
| <i>Layout</i> = CblasColMajor | <i>lda</i> must be at least $\max(1, m)$. | <i>lda</i> must be at least $\max(1, k)$. | <i>lda</i> is ignored. |
| <i>Layout</i> = CblasRowMajor | <i>lda</i> must be at least $\max(1, k)$. | <i>lda</i> must be at least $\max(1, m)$. | <i>lda</i> is ignored. |

b

Array:

| | | | |
|----------------------------------|--|--|-----------------------------------|
| | <i>transb</i> = CblasNoTrans | <i>transb</i> = CblasTrans or <i>transb</i> = CblasConjTrans | <i>transb</i> = CblasPacked |
| <i>Layout</i> = CblasColMajor | Size $ldb \cdot n$. Before entry, the leading k -by- n part of the array <i>b</i> must contain the matrix <i>B</i> . | Size $ldb \cdot k$. Before entry, the leading n -by- k part of the array <i>b</i> must contain the matrix <i>B</i> . | Stored in internal packed format. |
| <i>Layout</i> = CblasRowMajor | Size $ldb \cdot k$. Before entry, the leading n -by- k part of the array <i>b</i> must contain the matrix <i>B</i> . | Size $ldb \cdot n$. Before entry, the leading k -by- n part of the array <i>b</i> must contain the matrix <i>B</i> . | Stored in internal packed format. |

ldb

Specifies the leading dimension of *b* as declared in the calling (sub)program.

| | | | |
|----------------------------------|--|---|--------------------------------|
| | <i>transb</i> = CblasNoTrans | <i>transb</i> = CblasTrans or <i>transb</i> = CblasConjTrans | <i>transb</i> = CblasPacked |
| <i>Layout</i> = CblasColMajor | <i>ldb</i> must be at least $\max(1, k)$. | <i>ldb</i> must be at least $\max(1, n)$. | <i>ldb</i> is ignored. |
| <i>Layout</i> = CblasRowMajor | <i>ldb</i> must be at least $\max(1, n)$. | <i>ldb</i> must be at least $\max(1, k)$. | <i>ldb</i> is ignored. |

beta

Specifies the scalar *beta*. When *beta* is equal to zero, then *c* need not be set on input.

c

Array:

| | |
|----------------------------------|---|
| <i>Layout</i> = CblasColMajor | Size $ldc*n$. Before entry, the leading m -by- n part of the array c must contain the matrix C , except when $beta$ is equal to zero, in which case c need not be set on entry. |
| <i>Layout</i> = CblasRowMajor | Size $ldc*m$. Before entry, the leading n -by- m part of the array c must contain the matrix C , except when $beta$ is equal to zero, in which case c need not be set on entry. |

ldc

Specifies the leading dimension of c as declared in the calling (sub)program.

| | |
|-------------------------------|--|
| <i>Layout</i> = CblasColMajor | <i>ldc</i> must be at least $\max(1, m)$. |
| <i>Layout</i> = CblasRowMajor | <i>ldc</i> must be at least $\max(1, n)$. |

Output Parameters

c

Overwritten by the m -by- n matrix $op(A) * op(B) + beta * C$.

cblas_?gemm_free

Frees the storage previously allocated for the packed matrix.

Syntax

```
void cblas_sgemm_free (float *dest);
```

```
void cblas_dgemm_free (double *dest);
```

Include Files

- mkl.h

Description

The `cblas_?gemm_free` routine is one of a set of related routines that enable use of an internal packed storage. Call the `cblas_?gemm_free` routine last to release storage for the packed matrix structure allocated with `cblas_?gemm_alloc`.

Input Parameters

dest

Previously allocated storage.

LAPACK Routines

This chapter describes the Intel® Math Kernel Library implementation of routines from the LAPACK package that are used for solving systems of linear equations, linear least squares problems, eigenvalue and singular value problems, and performing a number of related computational tasks. The library includes LAPACK routines for both real and complex data. Routines are supported for systems of equations with the following types of matrices:

- general
- banded
- symmetric or Hermitian positive-definite (full, packed, and rectangular full packed (RFP) storage)
- symmetric or Hermitian positive-definite banded
- symmetric or Hermitian indefinite (both full and packed storage)
- symmetric or Hermitian indefinite banded
- triangular (full, packed, and RFP storage)
- triangular banded
- tridiagonal
- diagonally dominant tridiagonal.

NOTE

Different arrays used as parameters to Intel MKL LAPACK routines must not overlap.

WARNING

LAPACK routines assume that input matrices do not contain IEEE 754 special values such as `INF` or `NaN` values. Using these special values may cause LAPACK to return unexpected results or become unstable.

C Interface Conventions for LAPACK Routines

The C interfaces are implemented for most of the Intel MKL LAPACK driver and computational routines.

Function Prototypes

Intel MKL supports four distinct floating-point precisions. Each corresponding prototype looks similar, usually differing only in the data type. C interface LAPACK function names follow the form `<?><name>`, where `<?>` is:

- `LAPACKE_s` for float
- `LAPACKE_d` for double
- `LAPACKE_c` for `lapack_complex_float`
- `LAPACKE_z` for `lapack_complex_double`

A specific example follows. To solve a system of linear equations with a packed Cholesky-factored Hermitian positive-definite matrix with complex precision, use the following:

```
lapack_int LAPACKE_c pptrs(int matrix_layout, char uplo, lapack_int n, lapack_int nrhs,
const lapack_complex_float * ap, lapack_complex_float * b, lapack_int ldb);
```

Workspace Arrays

In contrast to the Fortran interface, the LAPACK C interface omits workspace parameters because workspace is allocated during runtime and released upon completion of the function operation.

If you prefer to allocate workspace arrays yourself, the LAPACK C interface provides alternate interfaces with *work* parameters. The name of the alternate interface is the same as the LAPACK C interface with *_work* appended. For example, the syntax for the singular value decomposition of a real bidiagonal matrix is:

```
Fortran:          call sbdsdc ( uplo, compq, n, d, e, u, ldu, vt, ldvt, q, iq,
                    work , iwork, info )

C LAPACK interface:  lapack_int LAPACKE_sbdsdc ( int matrix_layout, char uplo, char
                    compq, lapack_int n, float* d, float* e, float* u, lapack_int
                    ldu, float* vt, lapack_int ldvt, float* q, lapack_int* iq );

Alternate C LAPACK  lapack_int LAPACKE_sbdsdc_work( int matrix_layout, char uplo,
interface with work char compq, lapack_int n, float* d, float* e, float* u,
parameters:         lapack_int ldu, float* vt, lapack_int ldvt, float* q, lapack_int*
                    iq, float* work , lapack_int* iwork );
```

See the *install_dir/include/mkl_lapacke.h* file for the full list of alternative C LAPACK interfaces.

The Intel MKL Fortran-specific documentation contains details about workspace arrays.

Mapping Fortran Data Types against C Data Types

Fortran Data Types vs. C Data Types

| FORTRAN | C |
|---------------------------|-----------------------|
| INTEGER | lapack_int |
| LOGICAL | lapack_logical |
| REAL | float |
| DOUBLE PRECISION | double |
| COMPLEX | lapack_complex_float |
| COMPLEX*16/DOUBLE COMPLEX | lapack_complex_double |
| CHARACTER | char |

C Type Definitions

You can find type definitions specific to Intel MKL such as `MKL_INT`, `MKL_Complex8`, and `MKL_Complex16` in *install_dir/mkl_types.h*.

```
C types
#ifdef lapack_int
#define lapack_int MKL_INT
#endif

#ifdef lapack_logical
#define lapack_logical lapack_int
#endif
```

Complex Type Definitions Complex type for single precision:

```
#ifdef lapack_complex_float
#define lapack_complex_float MKL_Complex8
#endif
```

Complex type for double precision:

```
#ifndef lapack_complex_double
#define lapack_complex_double    MKL_Complex16
#endif
```

Matrix Layout Definitions

```
#define LAPACK_ROW_MAJOR    101
#define LAPACK_COL_MAJOR    102
```

See [Matrix Layout for LAPACK Routines](#) for an explanation of row-major order and column-major order storage.

Error Code Definitions

```
#define LAPACK_WORK_MEMORY_ERROR    -1010    /* Failed to allocate
memory
                                           for a working array */
#define LAPACK_TRANSPOSE_MEMORY_ERROR    -1011    /* Failed to allocate
memory
                                           for transposed matrix */
```

Matrix Layout for LAPACK Routines

There are two general methods of storing a two dimensional matrix in linear (one dimensional) memory: column-wise (column major order) or row-wise (row major order). Consider an M -by- N matrix A :

$$A = \begin{bmatrix} a_{1,1} & a_{1,2} & \dots & a_{1,j_0+1} & a_{1,j_0+2} & \dots & a_{1,j_0+L-1} & a_{1,j_0+L} & \dots & a_{1,N} \\ a_{2,1} & a_{2,2} & \dots & a_{2,j_0+1} & a_{2,j_0+2} & \dots & a_{2,j_0+L-1} & a_{2,j_0+L} & \dots & a_{2,N} \\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{i_0+1,1} & a_{i_0+1,2} & \dots & a_{i_0+1,j_0+1} & a_{i_0+1,j_0+2} & \dots & a_{i_0+1,j_0+L-1} & a_{i_0+1,j_0+L} & \dots & a_{i_0+1,N} \\ a_{i_0+2,1} & a_{i_0+2,2} & \dots & a_{i_0+2,j_0+1} & a_{i_0+2,j_0+2} & \dots & a_{i_0+2,j_0+L-1} & a_{i_0+2,j_0+L} & \dots & a_{i_0+2,N} \\ \vdots & \vdots & \dots & \vdots & \vdots & \vdots & \vdots & \vdots & \dots & \vdots \\ a_{i_0+K-1,1} & a_{i_0+K-1,2} & \dots & a_{i_0+K-1,j_0+1} & a_{i_0+K-1,j_0+2} & \dots & a_{i_0+K-1,j_0+L-1} & a_{i_0+K-1,j_0+L} & \dots & a_{i_0+K-1,N} \\ a_{i_0+K,1} & a_{i_0+K,2} & \dots & a_{i_0+K,j_0+1} & a_{i_0+K,j_0+2} & \dots & a_{i_0+K,j_0+L-1} & a_{i_0+K,j_0+L} & \dots & a_{i_0+K,N} \\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{M,1} & a_{M,2} & \dots & a_{M,j_0+1} & a_{M,j_0+2} & \dots & a_{M,j_0+L-1} & a_{M,j_0+L} & \dots & a_{M,N} \end{bmatrix}$$

Column Major Layout

In column major layout the first index, i , of matrix elements $a_{i,j}$ changes faster than the second index when accessing sequential memory locations. In other words, for $1 \leq i < M$, if the element $a_{i,j}$ is stored in a specific location in memory, the element $a_{i+1,j}$ is stored in the next location, and, for $1 \leq j < N$, the element $a_{M,j}$ is stored in the location previous to element $a_{1,j+1}$. So the matrix elements are located in memory according to this sequence:

$$\{a_{1,1}a_{2,1} \dots a_{M,1}a_{1,2}a_{2,2} \dots a_{M,2} \dots \dots a_{1,N}a_{2,N} \dots a_{M,N}\}$$

Row Major Layout

In row major layout the second index, j , of matrix elements $a_{i,j}$ changes faster than the first index when accessing sequential memory locations. In other words, for $1 \leq j < N$, if the element $a_{i,j}$ is stored in a specific location in memory, the element $a_{i,j+1}$ is stored in the next location, and, for $1 \leq i < M$, the element $a_{i,N}$ is stored in the location previous to element $a_{i+1,1}$. So the matrix elements are located in memory according to this sequence:

$$\{a_{1,1}a_{1,2} \dots a_{1,N}a_{2,1}a_{2,2} \dots a_{2,N} \dots \dots a_{N,1}a_{N,2} \dots a_{M,N}\}$$

Leading Dimension Parameter

A leading dimension parameter allows use of LAPACK routines on a submatrix of a larger matrix. For example, the submatrix B can be extracted from the original matrix A defined previously:

$$B = \begin{bmatrix} a_{i_0+1,j_0+1} & a_{i_0+1,j_0+2} & \dots & a_{i_0+1,j_0+L-1} & a_{i_0+1,j_0+L} \\ a_{i_0+2,j_0+1} & a_{i_0+2,j_0+2} & \dots & a_{i_0+2,j_0+L-1} & a_{i_0+2,j_0+L} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ a_{i_0+K-1,j_0+1} & a_{i_0+K-1,j_0+2} & \dots & a_{i_0+K-1,j_0+L-1} & a_{i_0+K-1,j_0+L} \\ a_{i_0+K,j_0+1} & a_{i_0+K,j_0+2} & \dots & a_{i_0+K,j_0+L-1} & a_{i_0+K,j_0+L} \end{bmatrix}$$

B is formed from rows with indices $i_0 + 1$ to $i_0 + K$ and columns $j_0 + 1$ to $j_0 + L$ of matrix A . To specify matrix B , LAPACK routines require four parameters:

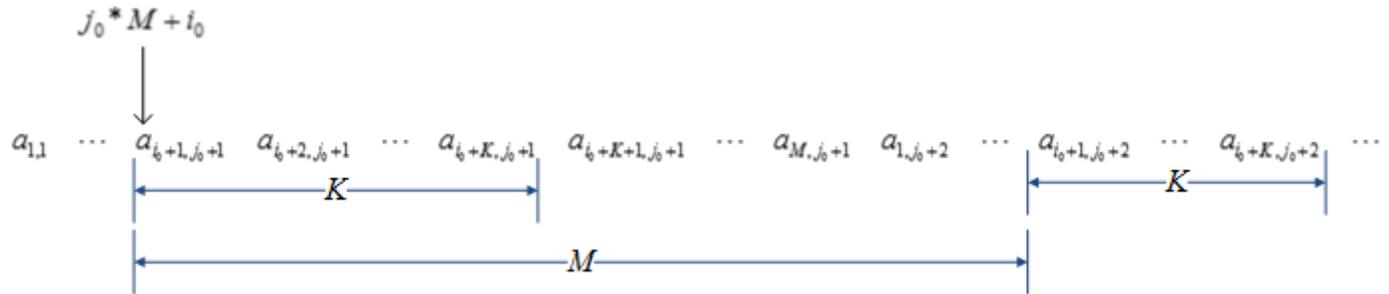

- the number of rows K ;
- the number of columns L ;
- a pointer to the start of the array containing elements of B ;
- the leading dimension of the array containing elements of B .

The leading dimension depends on the layout of the matrix:

- Column major layout

Leading dimension $ldb=M$, the number of rows of matrix A .

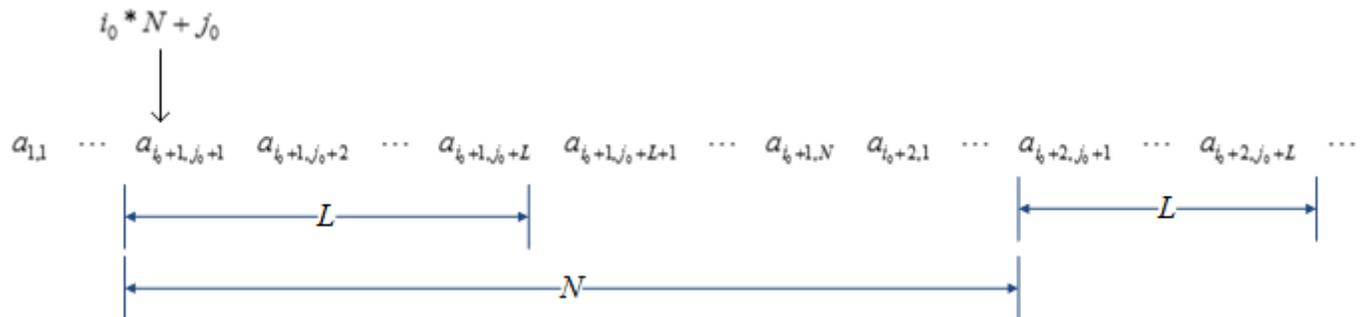

Starting address: offset by $i_0 + j_0 * ldb$ from $a_{1,1}$.

- Row major layout

Leading dimension $ldb=N$, the number of columns of matrix A .

Starting address: offset by $i_0 * ldb + j_0$ from $a_{1,1}$.

Matrix Storage Schemes for LAPACK Routines

LAPACK routines use the following matrix storage schemes:

- Full Storage
- Packed Storage
- Band Storage
- Rectangular Full Packed (RFP) Storage

Full Storage

Consider an m -by- n matrix A :

$$A = \begin{pmatrix} a_{1,1} & a_{1,2} & a_{1,3} & \cdots & a_{1,n} \\ a_{2,1} & a_{2,2} & a_{2,3} & \cdots & a_{2,n} \\ a_{3,1} & a_{3,2} & a_{3,3} & \cdots & a_{3,n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{m,1} & a_{m,2} & a_{m,3} & \cdots & a_{m,n} \end{pmatrix}$$

It is stored in a one-dimensional array a of length at least $lda*n$ for column major layout or $m*lda$ for row major layout. Element $a_{i,j}$ is stored as array element $a[k]$ where the mapping of $k(i, j)$ is defined as

- column major layout: $k(i, j) = i - 1 + (j - 1)*lda$
- row major layout: $k(i, j) = (i - 1)*lda + j - 1$

NOTE

Although LAPACK accepts parameter values of zero for matrix size, in general the size of the array used to store an m -by- n matrix A with leading dimension lda should be greater than or equal to $\max(1, n*lda)$ for column major layout and $\max(1, m*lda)$ for row major layout.

NOTE

Even though the array used to store a matrix is one-dimensional, for simplicity the documentation sometimes refers parts of the array such as rows, columns, upper and lower triangular part, and diagonals. These refer to the parts of the matrix stored within the array. For example, the lower triangle of array a is defined as the subset of elements $a[k(i, j)]$ with $i \geq j$.

Packed Storage

The packed storage format compactly stores matrix elements when only one part of the matrix, the upper or lower triangle, is necessary to determine all of the elements of the matrix. This is the case when the matrix is upper triangular, lower triangular, symmetric, or Hermitian. For an n -by- n matrix of one of these types, a linear array ap of length $n*(n + 1)/2$ is adequate. Two parameters define the storage scheme:

$matrix_layout$, which specifies column major (with the value `LAPACK_COL_MAJOR`) or row major (with the value `LAPACK_ROW_MAJOR`) matrix layout, and $uplo$, which specifies that the upper triangle (with the value 'U') or the lower triangle (with the value 'L') is stored.

Element $a_{i,j}$ is stored as array element $a[k]$ where the mapping of $k(i, j)$ is defined as

| | |
|---|--|
| $matrix_layout = \text{LAPACK_COL_MAJOR}$ | $matrix_layout = \text{LAPACK_ROW_MAJOR}$ |
| $uplo = 'U' \quad 1 \leq i \leq j \leq n \quad k(i, j) = i - 1 + j*(j - 1)/2$ | $k(i, j) = j - 1 + (i - 1)*(2*n - i)/2$ |

$$AB = \begin{pmatrix} & & & & a_{1,1} & a_{1,2} & \cdots & a_{1,k_u+1} \\ & & & & & a_{2,1} & a_{2,2} & a_{2,3} & \cdots & a_{2,k_u+2} \\ & & & & & & a_{3,1} & a_{3,2} & a_{3,3} & a_{3,4} & \cdots & a_{3,k_u+3} \\ & & & & & & & \ddots & \vdots & \vdots & \vdots & \vdots \\ a_{k_l+1,1} & a_{k_l+1,2} & \cdots & \cdots & & & & & & a_{k_l+1,k_l+1} & a_{k_l+1,k_l+2} & \cdots & a_{k_l+1,k_u+k_l+1} \\ a_{k_l+2,2} & a_{k_l+2,3} & \cdots & \cdots & & & & & & a_{k_l+2,k_l+2} & a_{k_l+2,k_l+3} & \cdots & a_{k_l+2,k_u+k_l+2} \\ a_{k_l+3,3} & a_{k_l+3,4} & \cdots & \cdots & & & & & & a_{k_l+3,k_l+3} & a_{k_l+3,k_l+4} & \cdots & a_{k_l+3,k_u+k_l+3} \\ \vdots & \vdots \end{pmatrix}$$

The number of columns of AB is $kl + ku + 1$, and the number of rows of AB is m .

NOTE

For both column major and row major layout, elements of the upper left triangle of AB are not used. Depending on the relationship of the dimensions m , n , kl , and ku , the lower right triangle might not be used.

- Converting the Packed Matrix to a One-Dimensional Array: The packed matrix AB is stored in a linear array ab as described in [Full Storage](#). The size of ab should be greater than or equal to the total number of elements of matrix AB : $ldab*n$ for column major layout or $ldab*m$ for row major layout. The leading dimension of ab , $ldab$, must be greater than or equal to $kl + ku + 1$ (and some routines require it to be even larger).

Element a_{ij} is stored as array element $a[k(i, j)]$ where the mapping of $k(i, j)$ is defined as

- column major layout: $k(i, j) = i + ku - j + (j - 1)*ldab$; $1 \leq j \leq n$, $\max(1, j - ku) \leq j \leq \min(m, j + kl)$
- row major layout: $k(i, j) = (i - j)*ldab + kl + j - 1$; $1 \leq i \leq m$, $\max(1, i - kl) \leq j \leq \min(n, i + ku)$

NOTE

Although LAPACK accepts parameter values of zero for matrix size, in general the size of the array should be greater than or equal to $\max(1, n*ldab)$ for column major layout and $\max(1, m*ldab)$ for row major layout.

Rectangular Full Packed Storage

A combination of full and packed storage, rectangular full packed storage can be used to store the upper or lower triangle of a matrix which is upper triangular, lower triangular, symmetric, or Hermitian. It offers the storage savings of packed storage plus the efficiency of using full storage Level 3 BLAS and LAPACK routines. Three parameters define the storage scheme: *matrix_layout*, which specifies column major (with the value `LAPACK_COL_MAJOR`) or row major (with the value `LAPACK_ROW_MAJOR`) matrix layout; *uplo*, which specifies that the upper triangle (with the value 'U') or the lower triangle (with the value 'L') is stored; and *transr*, which specifies normal (with the value 'N'), transpose (with the value 'T'), or conjugate transpose (with the value 'C') operation on the matrix.

Consider an N -by- N matrix A :

$$A = \begin{pmatrix} a_{0,0} & a_{0,1} & a_{0,2} & \cdots & a_{0,N-1} \\ a_{1,0} & a_{1,1} & a_{1,2} & \cdots & a_{1,N-1} \\ a_{2,0} & a_{2,1} & a_{2,2} & \cdots & a_{2,N-1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{N-1,0} & a_{N-1,1} & a_{N-1,2} & \cdots & a_{N-1,N-1} \end{pmatrix}$$

The upper or lower triangle of A can be stored in the array ap of length $N*(N + 1)/2$.

Additionally, define k as the integer part of $N/2$, such that $N=2*k$ if N is even, and $N=2*k + 1$ if N is odd.

Storing the matrix involves packing the matrix into a rectangular matrix, and then storing the matrix in a one-dimensional array. The size of rectangular matrix AP required for the N -by- N matrix A is $N + 1$ by $N/2$ for even N , and N by $(N + 1)/2$ for odd N .

These examples illustrate the rectangular full packed storage method.

- Upper triangular - $uplo = 'U'$

Consider a matrix A with $N = 6$:

$$A = \begin{pmatrix} a_{0,0} & a_{0,1} & a_{0,2} & a_{0,3} & a_{0,4} & a_{0,5} \\ a_{1,0} & a_{1,1} & a_{1,2} & a_{1,3} & a_{1,4} & a_{1,5} \\ a_{2,0} & a_{2,1} & a_{2,2} & a_{2,3} & a_{2,4} & a_{2,5} \\ a_{3,0} & a_{3,1} & a_{3,2} & a_{3,3} & a_{3,4} & a_{3,5} \\ a_{4,0} & a_{4,1} & a_{4,2} & a_{4,3} & a_{4,4} & a_{4,5} \\ a_{5,0} & a_{5,1} & a_{5,2} & a_{5,3} & a_{5,4} & a_{5,5} \end{pmatrix}$$

- Not transposed - $transr = 'N'$

The elements of the upper triangle of A can be packed in a matrix with the dimensions $(N + 1)$ -by- $(N/2) = 7$ by 3 :

$$AP = \begin{pmatrix} a_{0,3} & a_{0,4} & a_{0,5} \\ a_{1,3} & a_{1,4} & a_{1,5} \\ a_{2,3} & a_{2,4} & a_{2,5} \\ a_{3,3} & a_{3,4} & a_{3,5} \\ a_{0,0} & a_{4,4} & a_{4,5} \\ a_{0,1} & a_{1,1} & a_{5,5} \\ a_{0,2} & a_{1,2} & a_{2,2} \end{pmatrix}$$

- Transposed or conjugate transposed - $transr = 'T'$ or $transr = 'C'$

The elements of the upper triangle of A can be packed in a matrix with the dimensions $(N/2)$ by $(N + 1) = 3$ by 7 :

$$AP = \begin{pmatrix} a_{0,3} & a_{1,3} & a_{2,3} & a_{3,3} & a_{0,0} & a_{0,1} & a_{0,2} \\ a_{0,4} & a_{1,4} & a_{2,4} & a_{3,4} & a_{4,4} & a_{1,1} & a_{1,2} \\ a_{0,5} & a_{1,5} & a_{2,5} & a_{3,5} & a_{4,5} & a_{5,5} & a_{2,2} \end{pmatrix}$$

Consider a matrix A with $N = 5$:

$$A = \begin{pmatrix} a_{0,0} & a_{0,1} & a_{0,2} & a_{0,3} & a_{0,4} \\ a_{1,0} & a_{1,1} & a_{1,2} & a_{1,3} & a_{1,4} \\ a_{2,0} & a_{2,1} & a_{2,2} & a_{2,3} & a_{2,4} \\ a_{3,0} & a_{3,1} & a_{3,2} & a_{3,3} & a_{3,4} \\ a_{4,0} & a_{4,1} & a_{4,2} & a_{4,3} & a_{4,4} \end{pmatrix}$$

- Not transposed - $transr = 'N'$

The elements of the upper triangle of A can be packed in a matrix with the dimensions (N) -by- $((N + 1)/2) = 5$ by 3 :

$$AP = \begin{pmatrix} a_{0,2} & a_{0,3} & a_{0,4} \\ a_{1,2} & a_{1,3} & a_{1,4} \\ a_{2,2} & a_{2,3} & a_{2,4} \\ a_{0,0} & a_{3,3} & a_{3,4} \\ a_{0,1} & a_{1,1} & a_{4,4} \end{pmatrix}$$

- Transposed or conjugate transposed - $transr = 'T'$ or $transr = 'C'$

The elements of the upper triangle of A can be packed in a matrix with the dimensions $((N+1)/2)$ by $(N) = 5$ by 3:

$$AP = \begin{pmatrix} a_{0,2} & a_{1,2} & a_{2,3} & a_{0,0} & a_{0,1} \\ a_{0,3} & a_{1,3} & a_{2,3} & a_{3,3} & a_{1,1} \\ a_{0,4} & a_{1,4} & a_{2,4} & a_{3,4} & a_{4,4} \end{pmatrix}$$

- Lower triangular - $uplo = 'L'$

Consider a matrix A with $N = 6$:

$$A = \begin{pmatrix} a_{0,0} & a_{0,1} & a_{0,2} & a_{0,3} & a_{0,4} & a_{0,5} \\ a_{1,0} & a_{1,1} & a_{1,2} & a_{1,3} & a_{1,4} & a_{1,5} \\ a_{2,0} & a_{2,1} & a_{2,2} & a_{2,3} & a_{2,4} & a_{2,5} \\ a_{3,0} & a_{3,1} & a_{3,2} & a_{3,3} & a_{3,4} & a_{3,5} \\ a_{4,0} & a_{4,1} & a_{4,2} & a_{4,3} & a_{4,4} & a_{4,5} \\ a_{5,0} & a_{5,1} & a_{5,2} & a_{5,3} & a_{5,4} & a_{5,5} \end{pmatrix}$$

- Not transposed - $transr = 'N'$

The elements of the lower triangle of A can be packed in a matrix with the dimensions $(N + 1)$ -by- $(N/2) = 7$ by 3:

$$AP = \begin{pmatrix} a_{3,3} & a_{4,3} & a_{5,3} \\ a_{0,0} & a_{4,4} & a_{5,4} \\ a_{1,0} & a_{1,1} & a_{5,5} \\ a_{2,0} & a_{2,1} & a_{2,2} \\ a_{3,0} & a_{3,1} & a_{3,2} \\ a_{3,0} & a_{4,1} & a_{4,2} \\ a_{5,0} & a_{5,1} & a_{5,2} \end{pmatrix}$$

- Transposed or conjugate transposed - $transr = 'T'$ or $transr = 'C'$

The elements of the lower triangle of A can be packed in a matrix with the dimensions $(N/2)$ by $(N + 1) = 3$ by 7:

$$AP = \begin{pmatrix} a_{3,3} & a_{0,0} & a_{1,0} & a_{2,0} & a_{3,0} & a_{4,0} & a_{5,0} \\ a_{4,3} & a_{4,4} & a_{1,1} & a_{2,1} & a_{3,1} & a_{4,1} & a_{5,1} \\ a_{5,3} & a_{5,4} & a_{5,5} & a_{2,2} & a_{3,2} & a_{4,2} & a_{5,2} \end{pmatrix}$$

Consider a matrix A with $N = 5$:

$$A = \begin{pmatrix} a_{0,0} & a_{0,1} & a_{0,2} & a_{0,3} & a_{0,4} \\ a_{1,0} & a_{1,1} & a_{1,2} & a_{1,3} & a_{1,4} \\ a_{2,0} & a_{2,1} & a_{2,2} & a_{2,3} & a_{2,4} \\ a_{3,0} & a_{3,1} & a_{3,2} & a_{3,3} & a_{3,4} \\ a_{4,0} & a_{4,1} & a_{4,2} & a_{4,3} & a_{4,4} \end{pmatrix}$$

- Not transposed - *transr* = 'N'

The elements of the lower triangle of *A* can be packed in a matrix with the dimensions (N) -by- $((N+1)/2) = 5$ by 3:

$$AP = \begin{pmatrix} a_{0,0} & a_{3,3} & a_{4,3} \\ a_{1,0} & a_{1,1} & a_{4,4} \\ a_{2,0} & a_{2,1} & a_{2,2} \\ a_{3,0} & a_{3,1} & a_{3,2} \\ a_{4,0} & a_{4,1} & a_{4,2} \end{pmatrix}$$

- Transposed or conjugate transposed - *transr* = 'T' or *transr* = 'C'

The elements of the lower triangle of *A* can be packed in a matrix with the dimensions $((N+1)/2)$ by $(N) = 5$ by 3:

$$AP = \begin{pmatrix} a_{0,0} & a_{1,0} & a_{2,0} & a_{3,0} & a_{4,0} \\ a_{3,3} & a_{1,1} & a_{2,1} & a_{3,1} & a_{4,1} \\ a_{4,3} & a_{4,4} & a_{2,2} & a_{3,2} & a_{4,2} \end{pmatrix}$$

The packed matrix *AP* can be stored using column major layout or row major layout.

NOTE

The *matrix_layout* and *transr* parameters can specify the same storage scheme: for example, the storage scheme for *matrix_layout* = LAPACK_COL_MAJOR and *transr* = 'N' is the same as that for *matrix_layout* = LAPACK_ROW_MAJOR and *transr* = 'T'.

Element $a_{i,j}$ is stored as array element $ap[l]$ where the mapping of $l(i, j)$ is defined in the following tables.

- Column major layout: *matrix_layout* = LAPACK_COL_MAJOR a

| <i>transr</i> | <i>uplo</i> | N | l(i, j) = | i | j |
|---------------|-------------|-----------------------|---------------------------|----------------------------|-------------------------|
| 'N' | 'U' | 2*k | $(j - k) * (N + 1) + i$ | $0 \leq i < N$ | $\max(i, k) \leq j < N$ |
| | | | $i * (N + 1) + j + k + 1$ | $0 \leq i < k$ | $i \leq j < k$ |
| | 2*k + 1 | $(j - k) * N + i$ | $0 \leq i < N$ | $\max(i, k) \leq j < N$ | |
| | | $i * N + j + k + 1$ | $0 \leq i < k$ | $i \leq j < k$ | |
| 'L' | 2*k | $j * (N + 1) + i + 1$ | $0 \leq i < N$ | $0 \leq j \leq \min(i, k)$ | |

| <i>trans</i> <i>r</i> | <i>uplo</i> | N | l(i, j) = | i | j |
|--------------------------|-------------|-----------|---------------------------------|--------------------|----------------------------|
| | | | $(i - k) * (N + 1) + j - k$ | $k \leq i < N$ | $k \leq j \leq i$ |
| | | $2*k + 1$ | $j * N + i$ | $0 \leq i < N$ | $0 \leq j \leq \min(i, k)$ |
| | | | $(i - k) * N + j - k - 1$ | $k + 1 \leq i < N$ | $k + 1 \leq j \leq i$ |
| 'T' or 'C' | 'U' | $2*k$ | $i * k + j - k$ | $0 \leq i < N$ | $\max(i, k) \leq j < N$ |
| | | | $(j + k + 1) * k + i$ | $0 \leq i < k$ | $i \leq j < k$ |
| | | $2*k + 1$ | $i * (k + 1) + j - k$ | $0 \leq i < N$ | $\max(i, k) \leq j < N$ |
| | | | $(j + k + 1) * (k + 1) + i$ | $0 \leq i < k$ | $i \leq j < k$ |
| | 'L' | $2*k$ | $(i + 1) * k + j$ | $0 \leq i < N$ | $0 \leq j \leq \min(i, k)$ |
| | | | $(j - k) * k + i - k$ | $k \leq i < N$ | $k \leq j \leq i$ |
| | | $2*k + 1$ | $i * (k + 1) + j$ | $0 \leq i < N$ | $0 \leq j \leq \min(i, k)$ |
| | | | $(j - k - 1) * (k + 1) + i - k$ | $k + 1 \leq i < N$ | $k + 1 \leq j \leq i$ |

- Row major layout: *matrix_layout* = LAPACK_ROW_MAJOR

| <i>trans</i> <i>r</i> | <i>uplo</i> | N | l(i, j) = | i | j |
|--------------------------|-------------|-----------|---------------------------------|--------------------|----------------------------|
| 'N' | 'U' | $2*k$ | $i * k + j - k$ | $0 \leq i < N$ | $\max(i, k) \leq j < N$ |
| | | | $(k + j + 1) * k + i$ | $0 \leq i < k$ | $i \leq j < k$ |
| | | $2*k + 1$ | $i * (k + 1) + j - k$ | $0 \leq i < N$ | $\max(i, k) \leq j < N$ |
| | | | $(k + j + 1) * (k + 1) + i$ | $0 \leq i < k$ | $i \leq j < k$ |
| | 'L' | $2*k$ | $(i + 1) * k + j$ | $0 \leq i < N$ | $0 \leq j \leq \min(i, k)$ |
| | | | $(j - k) * k + i - k$ | $k \leq i < N$ | $k \leq j \leq i$ |
| | | $2*k + 1$ | $i * (k + 1) + j$ | $0 \leq i < N$ | $0 \leq j \leq \min(i, k)$ |
| | | | $(j - k - 1) * (k + 1) + i - k$ | $k + 1 \leq i < N$ | $k + 1 \leq j \leq i$ |
| 'T' or 'C' | 'U' | $2*k$ | $(j - k) * (N + 1) + i$ | $0 \leq i < N$ | $\max(i, k) \leq j < N$ |

| <i>trans</i> <i>r</i> | <i>uplo</i> | N | l(i, j) = | i | j |
|--------------------------|-------------|-----------|---------------------------|---------------------|----------------------------|
| | | | $i*(N + 1) + k + j + 1$ | $0 \leq i < k$ | $i \leq j < k$ |
| | | $2*k + 1$ | $(j - k)*N + i$ | $0 \leq i < N$ | $\max(i, k) \leq j < N$ |
| | | | $i*N + k + j + 1$ | $0 \leq i < k$ | $i \leq j < k$ |
| | | 'L' | $2*k$ | $j*(N + 1) + i + 1$ | $0 \leq i < N$ |
| | | | $(i - k)*(N + 1) + j - k$ | $k \leq i < N$ | $k \leq j \leq i$ |
| | $2*k + 1$ | | $j*N + i$ | $0 \leq i < N$ | $0 \leq j \leq \min(i, k)$ |
| | | | $(i - k)*N + j - k - 1$ | $k + 1 \leq i < N$ | $k + 1 \leq j \leq i$ |

NOTE

Although LAPACK accepts parameter values of zero for matrix size, in general the size of the array should be greater than or equal to $\max(1, N*(N + 1)/2)$.

Mathematical Notation for LAPACK Routines

Descriptions of LAPACK routines use the following notation:

A^H For an M -by- N matrix A , denotes the conjugate transposed N -by- M matrix with elements:

$$a_{i,j}^H = \overline{a_{j,i}}$$

For a real-valued matrix, $A^H = A^T$.

$x \cdot y$ The *dot product* of two vectors, defined as:

$$x \cdot y = \sum_i x_i \overline{y_i}$$

$Ax = b$ A system of linear equations with an n -by- n matrix $A = \{a_{ij}\}$, a right-hand side vector $b = \{b_i\}$, and an unknown vector $x = \{x_i\}$.

$AX = B$ A set of systems with a common matrix A and multiple right-hand sides. The columns of B are individual right-hand sides, and the columns of X are the corresponding solutions.

$|x|$ the vector with elements $|x_i|$ (absolute values of x_i).

$|A|$ the matrix with elements $|a_{ij}|$ (absolute values of a_{ij}).

$\|x\|_\infty = \max_i |x_i|$ The *infinity-norm* of the vector x .

$\|A\|_\infty = \max_i \sum_j |a_{ij}|$ The *infinity-norm* of the matrix A .

| | |
|------------------------------------|--|
| $\ A\ _1 = \max_j \sum_i a_{ij} $ | The <i>one-norm</i> of the matrix A . $\ A\ _1 = \ A^T\ _\infty = \ A^H\ _\infty$ |
| $\ x\ _2$ | The <i>2-norm</i> of the vector x : $\ x\ _2 = (\sum_i x_i ^2)^{1/2} = \ x\ _E$ (see the definition for <i>Euclidean norm</i> in this section). |
| $\ A\ _2$ | The <i>2-norm</i> (or <i>spectral norm</i>) of the matrix A . $\ A\ _2 = \max_i \sigma_i, \ A\ _2^2 = \max_{\ x\ _2=1} (Ax \cdot Ax)$ |
| $\ A\ _E$ | The <i>Euclidean norm</i> of the matrix A : $\ A\ _E^2 = \sum_i \sum_j a_{ij} ^2$. |
| $\kappa(A) = \ A\ \ A^{-1}\ $ | The <i>condition number</i> of the matrix A . |
| λ_j | <i>Eigenvalues</i> of the matrix A (for the definition of eigenvalues, see Eigenvalue Problems). |
| σ_j | <i>Singular values</i> of the matrix A . They are equal to square roots of the eigenvalues of $A^H A$. (For more information, see Singular Value Decomposition). |

Error Analysis

In practice, most computations are performed with rounding errors. Besides, you often need to solve a system $Ax = b$, where the data (the elements of A and b) are not known exactly. Therefore, it is important to understand how the data errors and rounding errors can affect the solution x .

Data perturbations. If x is the exact solution of $Ax = b$, and $x + \delta x$ is the exact solution of a perturbed problem $(A + \delta A)(x + \delta x) = (b + \delta b)$, then this estimate, given up to linear terms of perturbations, holds:

$$\frac{\|\delta x\|}{\|x\|} \leq \kappa(A) \left(\frac{\|\delta A\|}{\|A\|} + \frac{\|\delta b\|}{\|b\|} \right)$$

where $A + \delta A$ is nonsingular and

$$\kappa(A) = \|A\| \|A^{-1}\|.$$

In other words, relative errors in A or b may be amplified in the solution vector x by a factor $\kappa(A) = \|A\| \|A^{-1}\|$ called the *condition number* of A .

Rounding errors have the same effect as relative perturbations $c(n)\varepsilon$ in the original data. Here ε is the *machine precision*, defined as the smallest positive number x such that $1 + x > 1$; and $c(n)$ is a modest function of the matrix order n . The corresponding solution error is

$\|\delta x\| / \|x\| \leq c(n) \kappa(A) \varepsilon$. (The value of $c(n)$ is seldom greater than $10n$.)

NOTE

Machine precision depends on the data type used. For example, it is usually defined in the `float.h` file as `FLT_EPSILON` the `float` datatype and `DBL_EPSILON` for the `double` datatype.

Thus, if your matrix A is *ill-conditioned* (that is, its condition number $\kappa(A)$ is very large), then the error in the solution x can also be large; you might even encounter a complete loss of precision. LAPACK provides routines that allow you to estimate $\kappa(A)$ (see [Routines for Estimating the Condition Number](#)) and also give you a more precise estimate for the actual solution error (see [Refining the Solution and Estimating Its Error](#)).

LAPACK Linear Equation Routines

This section describes routines for performing the following computations:

- factoring the matrix (except for triangular matrices)
- equilibrating the matrix (except for RFP matrices)
- solving a system of linear equations
- estimating the condition number of a matrix (except for RFP matrices)
- refining the solution of linear equations and computing its error bounds (except for RFP matrices)
- inverting the matrix.

To solve a particular problem, you can call two or more [computational routines](#) or call a corresponding [driver routine](#) that combines several tasks in one call. For example, to solve a system of linear equations with a general matrix, call `?getrf` (*LU* factorization) and then `?getrs` (computing the solution). Then, call `?gerfs` to refine the solution and get the error bounds. Alternatively, use the driver routine `?gesvx` that performs all these tasks in one call.

LAPACK Linear Equation Computational Routines

Table "Computational Routines for Systems of Equations with Real Matrices" lists the LAPACK computational routines for factorizing, equilibrating, and inverting *real* matrices, estimating their condition numbers, solving systems of equations with real matrices, refining the solution, and estimating its error. Table "Computational Routines for Systems of Equations with Complex Matrices" lists similar routines for *complex* matrices.

Computational Routines for Systems of Equations with Real Matrices

Matrix Factorization: LAPACK Computational Routines

This section describes the LAPACK routines for matrix factorization. The following factorizations are supported:

- *LU* factorization
- Cholesky factorization of real symmetric positive-definite matrices
- Cholesky factorization of real symmetric positive-definite matrices with pivoting
- Cholesky factorization of Hermitian positive-definite matrices
- Cholesky factorization of Hermitian positive-definite matrices with pivoting
- Bunch-Kaufman factorization of real and complex symmetric matrices
- Bunch-Kaufman factorization of Hermitian matrices.

You can compute:

- the *LU* factorization using full and band storage of matrices
- the Cholesky factorization using full, packed, RFP, and band storage
- the Bunch-Kaufman factorization using full and packed storage.

`?getrf`

Computes the *LU* factorization of a general *m*-by-*n* matrix.

Syntax

```
lapack_int LAPACKE_sgetrf (int matrix_layout , lapack_int m , lapack_int n , float *  
a , lapack_int lda , lapack_int * ipiv );
```

```
lapack_int LAPACKE_dgetrf (int matrix_layout , lapack_int m , lapack_int n , double *  
a , lapack_int lda , lapack_int * ipiv );
```

```
lapack_int LAPACKE_cgetrf (int matrix_layout , lapack_int m , lapack_int n ,  
lapack_complex_float * a , lapack_int lda , lapack_int * ipiv );
```

```
lapack_int LAPACKE_zgetrf (int matrix_layout , lapack_int m , lapack_int n ,  
lapack_complex_double * a , lapack_int lda , lapack_int * ipiv );
```

Include Files

- mkl.h

Description

The routine computes the LU factorization of a general m -by- n matrix A as

$$A = P*LU,$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$). The routine uses partial pivoting, with row interchanges.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>m</i> | The number of rows in the matrix A ($m \geq 0$). |
| <i>n</i> | The number of columns in A ; $n \geq 0$. |
| <i>a</i> | Array, size at least $\max(1, lda*n)$ for column-major layout or $\max(1, lda*m)$ for row-major layout. Contains the matrix A . |
| <i>lda</i> | The leading dimension of array a , which must be at least $\max(1, m)$ for column-major layout or $\max(1, n)$ for row-major layout. |

Output Parameters

| | |
|-------------|--|
| <i>a</i> | Overwritten by L and U . The unit diagonal elements of L are not stored. |
| <i>ipiv</i> | Array, size at least $\max(1, \min(m, n))$. The pivot indices; for $1 \leq i \leq \min(m, n)$, row i was interchanged with row $ipiv(i)$. |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If $info = -i$, parameter i had an illegal value.

If $info = i$, u_{ii} is 0. The factorization has been completed, but U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

Application Notes

The computed L and U are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(\min(m, n)) \varepsilon P |L| |U|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

The approximate number of floating-point operations for real flavors is

$$(2/3)n^3 \quad \text{If } m = n,$$

$$(1/3)n^2(3m-n) \quad \text{If } m > n,$$

$$(1/3)m^2(3n-m) \quad \text{If } m < n.$$

The number of operations for complex flavors is four times greater.

After calling this routine with $m = n$, you can call the following:

`?getrs` to solve $A^*X = B$ or $A^T X = B$ or $A^H X = B$

`?gecon` to estimate the condition number of A

`?getri` to compute the inverse of A .

[Matrix Storage Schemes for LAPACK Routines](#)

mkl_?getrfnpi

Performs LU factorization (complete or incomplete) of a general matrix without pivoting.

Syntax

```
lapack_int LAPACKE_mkl_sgetrfnpi (int matrix_layout, lapack_int m, lapack_int n,
lapack_int nfact, float* a, lapack_int lda);
```

```
lapack_int LAPACKE_mkl_dgetrfnpi (int matrix_layout, lapack_int m, lapack_int n,
lapack_int nfact, double* a, lapack_int lda);
```

```
lapack_int LAPACKE_mkl_cgetrfnpi (int matrix_layout, lapack_int m, lapack_int n,
lapack_int nfact, lapack_complex_float* a, lapack_int lda);
```

```
lapack_int LAPACKE_mkl_zgetrfnpi (int matrix_layout, lapack_int m, lapack_int n,
lapack_int nfact, lapack_complex_double* a, lapack_int lda);
```

Include Files

- `mkl.h`

Description

The routine computes the LU factorization of a general m -by- n matrix A without using pivoting. It supports incomplete factorization. The factorization has the form:

$$A = L^*U,$$

where L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$).

Incomplete factorization has the form:

$$A = L * U + \tilde{A}$$

where L is lower trapezoidal with unit diagonal elements, U is upper trapezoidal, and \tilde{A} is the unfactored part of matrix A . See the application notes section for further details.

NOTE

Use `?getrf` if it is possible that the matrix is not diagonal dominant.

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>m</code> | The number of rows in matrix A ; $m \geq 0$. |
| <code>n</code> | The number of columns in matrix A ; $n \geq 0$. |
| <code>nfact</code> | The number of rows and columns to factor; $0 \leq \text{nfact} \leq \min(m, n)$. Note that if $\text{nfact} < \min(m, n)$, incomplete factorization is performed. |
| <code>a</code> | Array of size at least $\text{lda} * n$ for column major layout and at least $\text{lda} * m$ for row major layout. Contains the matrix A . |
| <code>lda</code> | The leading dimension of array a . $\text{lda} \geq \max(1, m)$ for column major layout and $\text{lda} \geq \max(1, n)$ for row major layout. |

Output Parameters

| | |
|----------------|--|
| <code>a</code> | Overwritten by L and U . The unit diagonal elements of L are not stored. When incomplete factorization is specified by setting $\text{nfact} < \min(m, n)$, a also contains the unfactored submatrix \tilde{A}_{22} . See the application notes section for further details. |
|----------------|--|

Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, u_{ij} is 0. The requested factorization has been completed, but U is exactly singular. Division by 0 will occur if factorization is completed and factor U is used for solving a system of linear equations.

Application Notes

The computed L and U are the exact factors of a perturbed matrix $A + E$, with

$$|E| \leq c(\min(m, n)) \epsilon |L| |U|$$

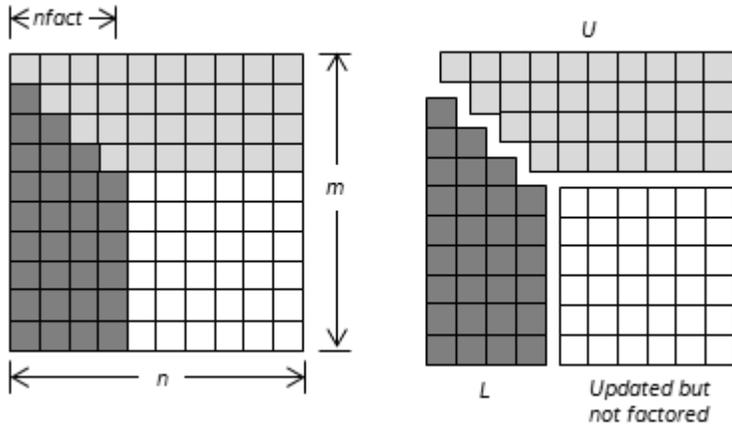

where $c(n)$ is a modest linear function of n , and ε is the machine precision.

The approximate number of floating-point operations for real flavors is

| | |
|---|--------------------------------|
| $(2/3)n^3$ | If $m = n = nfact$ |
| $(1/3)n^2(3m-n)$ | If $m > n = nfact$ |
| $(1/3)m^2(3n-m)$ | If $m = nfact < n$ |
| $(2/3)n^3 - (n-nfact)^3$ | If $m = n, nfact < \min(m, n)$ |
| $(1/3)(n^2(3m-n) - (n-nfact)^2(3m - 2nfact - n))$ | If $m > n > nfact$ |
| $(1/3)(m^2(3n-m) - (m-nfact)^2(3n - 2nfact - m))$ | If $nfact < m < n$ |

The number of operations for complex flavors is four times greater.

When incomplete factorization is specified, the first $nfact$ rows and columns are factored, with the update of the remaining rows and columns of A as follows:

If matrix A is represented as a block 2-by-2 matrix:

$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$$

where

- A_{11} is a square matrix of order $nfact$,
- A_{21} is an $(m - nfact)$ -by- $nfact$ matrix,
- A_{12} is an $nfact$ -by- $(n - nfact)$ matrix, and
- A_{22} is an $(m - nfact)$ -by- $(n - nfact)$ matrix.

The result is

$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} = \begin{bmatrix} L_1 \\ L_2 \end{bmatrix} \cdot [U_1 \ U_2] + \begin{bmatrix} 0 & 0 \\ 0 & \tilde{A}_{22} \end{bmatrix}$$

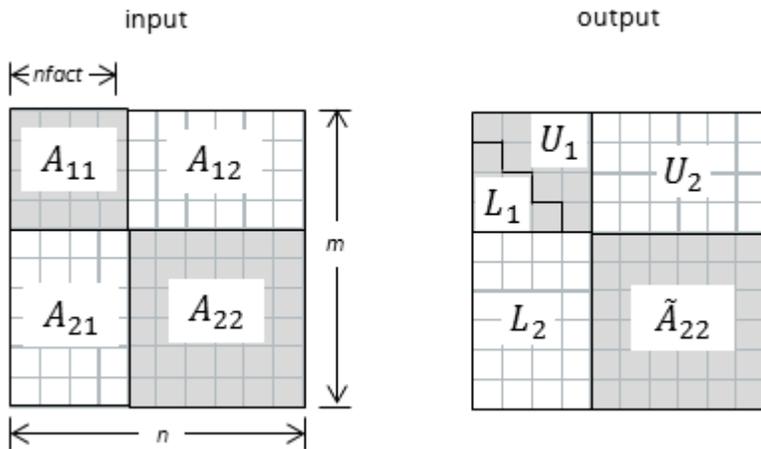

L_1 is a lower triangular square matrix of order $nfact$ with unit diagonal and U_1 is an upper triangular square matrix of order $nfact$. L_1 and U_1 result from LU factorization of matrix A_{11} : $A_{11} = L_1 U_1$.

L_2 is an $(m - nfact)$ -by- $nfact$ matrix and $L_2 = A_{21}U_1^{-1}$. U_2 is an $nfact$ -by- $(n - nfact)$ matrix and $U_2 = L_1^{-1}A_{12}$.

\tilde{A}_{22} is an $(m - nfact)$ -by- $(n - nfact)$ matrix and $\tilde{A}_{22} = A_{22} - L_2U_2$.

On exit, elements of the upper triangle U_1 are stored in place of the upper triangle of block A_{11} in array a ; elements of the lower triangle L_1 are stored in the lower triangle of block A_{11} in array a (unit diagonal

elements are not stored). Elements of L_2 replace elements of A_{21} ; U_2 replaces elements of A_{12} and \tilde{A}_{22} replaces elements of A_{22} .

?getrf2

Computes LU factorization using partial pivoting with row interchanges.

Syntax

```
lapack_int LAPACKE_sgetrf2 (int matrix_layout, lapack_int m, lapack_int n, float * a,
lapack_int lda, lapack_int * ipiv);
```

```
lapack_int LAPACKE_dgetrf2 (int matrix_layout, lapack_int m, lapack_int n, double * a,
lapack_int lda, lapack_int * ipiv);
```

```
lapack_int LAPACKE_cgetrf2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float * a, lapack_int lda, lapack_int * ipiv);
```

```
lapack_int LAPACKE_zgetrf2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double * a, lapack_int lda, lapack_int * ipiv);
```

Include Files

- mkl.h

Description

?getrf2 computes an LU factorization of a general m -by- n matrix A using partial pivoting with row interchanges.

The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

This is the recursive version of the algorithm. It divides the matrix into four submatrices:

$$A = \begin{pmatrix} A11 & A12 \\ A21 & A22 \end{pmatrix}$$

where $A11$ is $n1$ by $n1$ and $A22$ is $n2$ by $n2$ with $n1 = \min(m, n)$, and $n2 = n - n1$.

The subroutine calls itself to factor $\begin{pmatrix} A11 \\ A12 \end{pmatrix}$,

do the swaps on $\begin{pmatrix} A12 \\ A22 \end{pmatrix}$, solve $A12$, update $A22$, then it calls itself to factor $A22$ and do the swaps on $A21$.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>m</i> | The number of rows of the matrix A. $m \geq 0$. |
| <i>n</i> | The number of columns of the matrix A. $n \geq 0$. |
| <i>a</i> | Array, size $lda*n$. On entry, the m -by- n matrix to be factored. |
| <i>lda</i> | The leading dimension of the array <i>a</i> . $lda \geq \max(1, m)$. |

Output Parameters

| | |
|-------------|---|
| <i>a</i> | On exit, the factors L and U from the factorization $A = P * L * U$; the unit diagonal elements of L are not stored. |
| <i>ipiv</i> | Array, size $\min(m, n)$. The pivot indices; for $1 \leq i \leq \min(m, n)$, row i of the matrix was interchanged with row $ipiv[i - 1]$. |

Return Values

This function returns a value *info*.

= 0: successful exit

< 0: if $info = -i$, the i -th argument had an illegal value.

> 0: if $info = i$, $U_{i, i}$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

?gbtrf

Computes the LU factorization of a general m -by- n band matrix.

Syntax

```
lapack_int LAPACKE_sgbtrf (int matrix_layout , lapack_int m , lapack_int n , lapack_int
kl , lapack_int ku , float * ab , lapack_int ldab , lapack_int * ipiv );
```

```
lapack_int LAPACKE_dgbtrf (int matrix_layout , lapack_int m , lapack_int n , lapack_int
kl , lapack_int ku , double * ab , lapack_int ldab , lapack_int * ipiv );
```

```
lapack_int LAPACKE_cgbtrf (int matrix_layout , lapack_int m , lapack_int n , lapack_int
kl , lapack_int ku , lapack_complex_float * ab , lapack_int ldab , lapack_int * ipiv );
lapack_int LAPACKE_zgbtrf (int matrix_layout , lapack_int m , lapack_int n , lapack_int
kl , lapack_int ku , lapack_complex_double * ab , lapack_int ldab , lapack_int *
ipiv );
```

Include Files

- mkl.h

Description

The routine forms the LU factorization of a general m -by- n band matrix A with kl non-zero subdiagonals and ku non-zero superdiagonals, that is,

$$A = P * L * U,$$

where P is a permutation matrix; L is lower triangular with unit diagonal elements and at most kl non-zero elements in each column; U is an upper triangular band matrix with $kl + ku$ superdiagonals. The routine uses partial pivoting, with row interchanges (which creates the additional kl superdiagonals in U).

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>m</i> | The number of rows in matrix A ; $m \geq 0$. |
| <i>n</i> | The number of columns in matrix A ; $n \geq 0$. |
| <i>kl</i> | The number of subdiagonals within the band of A ; $kl \geq 0$. |
| <i>ku</i> | The number of superdiagonals within the band of A ; $ku \geq 0$. |
| <i>ab</i> | Array, size at least $\max(1, ldab * n)$ for column-major layout or $\max(1, ldab * m)$ for row-major layout. The array <i>ab</i> contains the matrix A in band storage as described in Band Storage . |
| <i>ldab</i> | The leading dimension of the array <i>ab</i> . ($ldab \geq 2 * kl + ku + 1$) |

Output Parameters

| | |
|-----------|---|
| <i>ab</i> | Overwritten with elements of L and U . U is stored as an upper triangular band matrix with $kl + ku$ superdiagonals, and L is stored as a lower triangular band matrix with kl subdiagonals (diagonal unit values are not stored). Since the output array has more nonzero elements than the initial matrix A , there are limitations on the value of <i>ldab</i> and the placement of elements of A in array <i>ab</i> . |
|-----------|---|

See Application Notes below for further details.

ipiv Array, size at least $\max(1, \min(m, n))$. The pivot indices; for $1 \leq i \leq \min(m, n)$, row i was interchanged with row $ipiv(i)$.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

If *info* = *i*, u_{ii} is 0. The factorization has been completed, but U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

Application Notes

The computed L and U are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(kl+ku+1) \varepsilon P |L| |U|$$

$c(k)$ is a modest linear function of k , and ε is the machine precision.

The total number of floating-point operations for real flavors varies between approximately $2n(ku+1)kl$ and $2n(kl+ku+1)kl$. The number of operations for complex flavors is four times greater. All these estimates assume that kl and ku are much less than $\min(m, n)$.

As described in [Band Storage](#), storage of a band matrix can be considered in two steps: packing band matrix elements into a matrix AB , then storing the elements in a linear array *ab* using a full storage scheme. The effect of the `?gbtrf` routine on matrix AB is illustrated by this example, for $m = n = 6$, $kl = 2$, $ku = 1$.

- `matrix_layout = LAPACK_COL_MAJOR`

| | |
|--|---|
| <p>On entry:</p> $AB = \begin{bmatrix} * & * & * & + & + & + \\ * & * & + & + & + & + \\ * & a_{1,2} & a_{2,3} & a_{3,4} & a_{4,5} & a_{5,6} \\ a_{1,1} & a_{2,2} & a_{3,3} & a_{4,4} & a_{5,5} & a_{6,6} \\ a_{2,1} & a_{3,2} & a_{4,3} & a_{5,4} & a_{6,5} & * \\ a_{3,1} & a_{4,2} & a_{5,3} & a_{6,4} & * & * \end{bmatrix}$ | <p>On exit:</p> $AB = \begin{bmatrix} * & * & * & u_{1,4} & u_{2,5} & u_{3,6} \\ * & * & u_{1,3} & u_{2,4} & u_{3,5} & u_{4,6} \\ * & u_{1,2} & u_{2,3} & u_{3,4} & u_{4,5} & u_{5,6} \\ u_{1,1} & u_{2,2} & u_{3,3} & u_{4,4} & u_{5,5} & u_{6,6} \\ l_{2,1} & l_{3,2} & l_{4,3} & l_{5,4} & l_{6,5} & * \\ l_{3,1} & l_{4,2} & l_{5,3} & l_{6,4} & * & * \end{bmatrix}$ |
|--|---|

- `matrix_layout = LAPACK_ROW_MAJOR`

| | |
|--|---|
| <p>On entry:</p> $AB = \begin{bmatrix} * & * & a_{1,1} & a_{1,2} & + & + \\ * & a_{2,1} & a_{2,2} & a_{2,3} & + & + \\ a_{3,1} & a_{3,2} & a_{3,3} & a_{3,4} & + & + \\ a_{4,2} & a_{4,3} & a_{4,4} & a_{4,5} & + & * \\ a_{5,3} & a_{5,4} & a_{5,5} & a_{5,6} & * & * \\ a_{6,4} & a_{6,5} & a_{6,6} & * & * & * \end{bmatrix}$ | <p>On exit:</p> $AB = \begin{bmatrix} * & * & u_{1,1} & u_{1,2} & u_{1,3} & u_{1,4} \\ * & l_{2,1} & u_{2,2} & u_{2,3} & u_{2,4} & u_{2,5} \\ l_{3,1} & l_{3,2} & u_{3,3} & u_{3,4} & u_{3,5} & u_{3,6} \\ l_{4,2} & l_{4,3} & u_{4,4} & u_{4,5} & u_{4,6} & * \\ l_{5,3} & l_{5,4} & u_{5,5} & u_{5,6} & * & * \\ l_{6,4} & l_{6,5} & u_{6,6} & * & * & * \end{bmatrix}$ |
|--|---|

Elements marked * are not used; elements marked + need not be set on entry, but are required by the routine to store elements of U because of fill-in resulting from the row interchanges.

After calling this routine with $m = n$, you can call the following routines:

`gbtrs` to solve $A^*X = B$ or $A^T * X = B$ or $A^H * X = B$

`gbcon` to estimate the condition number of A .

Description

The routine computes the LU factorization of a real or complex tridiagonal matrix A using elimination with partial pivoting and row interchanges.

The factorization has the form

$$A = L^*U,$$

where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

Input Parameters

n The order of the matrix A ; $n \geq 0$.

dl, d, du Arrays containing elements of A .

The array dl of dimension $(n - 1)$ contains the subdiagonal elements of A .

The array d of dimension n contains the diagonal elements of A .

The array du of dimension $(n - 1)$ contains the superdiagonal elements of A .

Output Parameters

| | |
|-------------|--|
| <i>dl</i> | Overwritten by the $(n-1)$ multipliers that define the matrix L from the LU factorization of A . |
| <i>d</i> | Overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A . |
| <i>du</i> | Overwritten by the $(n-1)$ elements of the first superdiagonal of U . |
| <i>du2</i> | Array, dimension $(n-2)$. On exit, <i>du2</i> contains $(n-2)$ elements of the second superdiagonal of U . |
| <i>ipiv</i> | Array, dimension (n) . The pivot indices: for $1 \leq i \leq n$, row i was interchanged with row $ipiv[i-1]$. $ipiv[i-1]$ is always i or $i+1$; $ipiv[i-1] = i$ indicates a row interchange was not required. |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

If *info* = *i*, u_{ii} is 0. The factorization has been completed, but U is exactly singular. Division by zero will occur if you use the factor U for solving a system of linear equations.

Application Notes

| | |
|--------|--|
| ?gbtrs | to solve $A * X = B$ or $A^T * X = B$ or $A^H * X = B$ |
| ?gbcon | to estimate the condition number of A . |

?dttfbb

Computes the factorization of a diagonally dominant tridiagonal matrix.

Syntax

```
void sdttrfb (const MKL_INT * n , float * dl , float * d , const float * du , MKL_INT * info );
void ddttrfb (const MKL_INT * n , double * dl , double * d , const double * du , MKL_INT * info );
void cdttrfb (const MKL_INT * n , MKL_Complex8 * dl , MKL_Complex8 * d , const MKL_Complex8 * du , MKL_INT * info );
void zdttrfb_ (const MKL_INT * n , MKL_Complex16 * dl , MKL_Complex16 * d , const MKL_Complex16 * du , MKL_INT * info );
```

Include Files

- mkl.h

Description

The `?dtttrfb` routine computes the factorization of a real or complex tridiagonal matrix A with the BABE (Burning At Both Ends) algorithm without pivoting. The factorization has the form

$$A = L_1 * U * L_2$$

where

- L_1 and L_2 are unit lower bidiagonal with k and $n - k - 1$ subdiagonal elements, respectively, where $k = n/2$, and
- U is an upper bidiagonal matrix with nonzeros in only the main diagonal and first superdiagonal.

Input Parameters

| | |
|-------------|---|
| n | The order of the matrix A ; $n \geq 0$. |
| dl, d, du | Arrays containing elements of A . The array dl of dimension $(n - 1)$ contains the subdiagonal elements of A . The array d of dimension n contains the diagonal elements of A . The array du of dimension $(n - 1)$ contains the superdiagonal elements of A . |

Output Parameters

| | |
|--------|---|
| dl | Overwritten by the $(n - 1)$ multipliers that define the matrix L from the LU factorization of A . |
| d | Overwritten by the n diagonal element reciprocals of the upper triangular matrix U from the factorization of A . |
| du | Overwritten by the $(n-1)$ elements of the superdiagonal of U . |
| $info$ | If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$, u_{ii} is 0. The factorization has been completed, but U is exactly singular. Division by zero will occur if you use the factor U for solving a system of linear equations. |

Application Notes

A diagonally dominant tridiagonal system is defined such that $|d_i| > |dl_{i-1}| + |du_i|$ for any i :

$$1 < i < n, \text{ and } |d_1| > |du_1|, |d_n| > |dl_{n-1}|$$

The underlying BABE algorithm is designed for diagonally dominant systems. Such systems are free from the numerical stability issue unlike the canonical systems that use elimination with partial pivoting (see `?gttrf`). The diagonally dominant systems are much faster than the canonical systems.

NOTE

- The current implementation of BABE has a potential accuracy issue on very small or large data close to the underflow or overflow threshold respectively. Scale the matrix before applying the solver in the case of such input data.
 - Applying the `?dtttrfb` factorization to non-diagonally dominant systems may lead to an accuracy loss, or false singularity detected due to no pivoting.
-

?potrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite matrix.

Syntax

```
lapack_int LAPACKE_spotrf (int matrix_layout , char uplo , lapack_int n , float * a ,
lapack_int lda );

lapack_int LAPACKE_dpotrf (int matrix_layout , char uplo , lapack_int n , double * a ,
lapack_int lda );

lapack_int LAPACKE_cpotrf (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_float * a , lapack_int lda );

lapack_int LAPACKE_zpotrf (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_double * a , lapack_int lda );
```

Include Files

- mkl.h

Description

The routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A :

$$\begin{array}{ll}
 A = U^T * U \text{ for real data, } A = U^H * U \text{ for complex data} & \text{if } uplo = 'U' \\
 A = L * L^T \text{ for real data, } A = L * L^H \text{ for complex data} & \text{if } uplo = 'L'
 \end{array}$$

where L is a lower triangular matrix and U is upper triangular.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored and how A is factored: If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular part of the matrix A , and the strictly lower triangular part of the matrix is not referenced. If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular part of the matrix A , and the strictly upper triangular part of the matrix is not referenced. |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>a</i> | Array, size $\max(1, lda * n)$. The array <i>a</i> contains either the upper or the lower triangular part of the matrix A (see <i>uplo</i>). |

lda The leading dimension of *a*. Must be at least $\max(1, n)$.

Output Parameters

a The upper or lower triangular part of *a* is overwritten by the Cholesky factor *U* or *L*, as specified by *uplo*.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = *-i*, parameter *i* had an illegal value.

If *info* = *i*, the leading minor of order *i* (and therefore the matrix *A* itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix *A*.

Application Notes

If *uplo* = 'U', the computed factor *U* is the exact factor of a perturbed matrix $A + E$, where

$$|E| \leq c(n)\varepsilon |U^H| |U|, |e_{ij}| \leq c(n)\varepsilon \sqrt{a_{ii}a_{jj}}$$

$c(n)$ is a modest linear function of *n*, and ε is the machine precision.

A similar estimate holds for *uplo* = 'L'.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors or $(4/3)n^3$ for complex flavors.

After calling this routine, you can call the following routines:

| | |
|---------------------|--|
| <code>?potrs</code> | to solve $A * X = B$ |
| <code>?pocon</code> | to estimate the condition number of <i>A</i> |
| <code>?potri</code> | to compute the inverse of <i>A</i> . |

?potrf2

Computes Cholesky factorization using a recursive algorithm.

Syntax

```
lapack_int LAPACKE_spotrf2 (int matrix_layout, char uplo, lapack_int n, float * a,
lapack_int lda);
```

```
lapack_int LAPACKE_dpotrf2 (int matrix_layout, char uplo, lapack_int n, double * a,
lapack_int lda);
```

```
lapack_int LAPACKE_cpotrf2 (int matrix_layout, char uplo, lapack_int n,
lapack_complex_float * a, lapack_int lda);
```

```
lapack_int LAPACKE_zpotrf2 (int matrix_layout, char uplo, lapack_int n,
lapack_complex_double * a, lapack_int lda);
```

Include Files

- mkl.h

Description

`zpotrf2` computes the Cholesky factorization of a real or complex symmetric positive definite matrix A using the recursive algorithm.

The factorization has the form

for real flavors:

$$A = U^T * U, \text{ if } uplo = 'U', \text{ or}$$

$$A = L * L^T, \text{ if } uplo = 'L',$$

for complex flavors:

$$A = U^H * U, \text{ if } uplo = 'U',$$

$$\text{or } A = L * L^H, \text{ if } uplo = 'L',$$

where U is an upper triangular matrix and L is lower triangular.

This is the recursive version of the algorithm. It divides the matrix into four submatrices:

$$A = \begin{pmatrix} A11 & A12 \\ A21 & A22 \end{pmatrix}$$

where $A11$ is $n1$ by $n1$ and $A22$ is $n2$ by $n2$, with $n1 = n/2$ and $n2 = n-n1$.

The subroutine calls itself to factor $A11$. Update and scale $A21$ or $A12$, update $A22$ then call itself to factor $A22$.

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>uplo</code> | = 'U': Upper triangle of A is stored; = 'L': Lower triangle of A is stored. |
| <code>n</code> | The order of the matrix A . $n \geq 0$. |
| <code>a</code> | Array, size ($lda*n$). On entry, the symmetric matrix A . If <code>uplo = 'U'</code> , the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced. If <code>uplo = 'L'</code> , the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced. |
| <code>lda</code> | The leading dimension of the array a . $lda \geq \max(1, n)$. |

Output Parameters

a On exit, if *info* = 0, the factor *U* or *L* from the Cholesky factorization.
 For real flavors:
 $A = U^T * U$ or $A = L * L^T$;
 For complex flavors:
 $A = U^H * U$ or $A = L * L^H$.

Return Values

This function returns a value *info*.

= 0: successful exit

< 0: if *info* = -*i*, the *i*-th argument had an illegal value

> 0: if *info* = *i*, the leading minor of order *i* is not positive definite, and the factorization could not be completed.

?pstrf

Computes the Cholesky factorization with complete pivoting of a real symmetric (complex Hermitian) positive semidefinite matrix.

Syntax

```
lapack_int LAPACKE_spstrf( int matrix_layout, char uplo, lapack_int n, float* a,
lapack_int lda, lapack_int* piv, lapack_int* rank, float tol );

lapack_int LAPACKE_dpstrf( int matrix_layout, char uplo, lapack_int n, double* a,
lapack_int lda, lapack_int* piv, lapack_int* rank, double tol );

lapack_int LAPACKE_cpstrf( int matrix_layout, char uplo, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_int* piv, lapack_int* rank, float
tol );

lapack_int LAPACKE_zpstrf( int matrix_layout, char uplo, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_int* piv, lapack_int* rank, double
tol );
```

Include Files

- mkl.h

Description

The routine computes the Cholesky factorization with complete pivoting of a real symmetric (complex Hermitian) positive semidefinite matrix. The form of the factorization is:

$$\begin{aligned}
 P^T * A * P &= U^T * U, \text{ if } uplo = 'U' \text{ for real flavors,} \\
 P^T * A * P &= U^H * U, \text{ if } uplo = 'U' \text{ for complex flavors,} \\
 P^T * A * P &= L * L^T, \text{ if } uplo = 'L' \text{ for real flavors,} \\
 P^T * A * P &= L * L^H, \text{ if } uplo = 'L' \text{ for complex flavors,}
 \end{aligned}$$

where *P* is a permutation matrix stored as vector *piv*, and *U* and *L* are upper and lower triangular matrices, respectively.

This algorithm does not attempt to check that *A* is positive semidefinite. This version of the algorithm calls level 3 BLAS.

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>uplo</code> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If <code>uplo</code> = 'U', the array a stores the upper triangular part of the matrix A , and the strictly lower triangular part of the matrix is not referenced. If <code>uplo</code> = 'L', the array a stores the lower triangular part of the matrix A , and the strictly upper triangular part of the matrix is not referenced. |
| <code>n</code> | The order of matrix A ; $n \geq 0$. |
| <code>a</code> | Array a , size $\max(1, lda * n)$. The array a contains either the upper or the lower triangular part of the matrix A (see <code>uplo</code>). |
| <code>tol</code> | User defined tolerance. If <code>tol</code> < 0, then $n * \epsilon * \max(A_{k,k})$, where ϵ is the machine precision, will be used (see Error Analysis for the definition of machine precision). The algorithm terminates at the $(k-1)$ -st step, if the pivot $\leq tol$. |
| <code>lda</code> | The leading dimension of a ; at least $\max(1, n)$. |

Output Parameters

| | |
|-------------------|--|
| <code>a</code> | If <code>info</code> = 0, the factor U or L from the Cholesky factorization is as described in <i>Description</i> . |
| <code>piv</code> | Array, size at least $\max(1, n)$. The array <code>piv</code> is such that the nonzero entries are $P_{piv[k-1], k}$ ($1 \leq k \leq n$). |
| <code>rank</code> | The rank of a given by the number of steps the algorithm completed. |

Return Values

This function returns a value `info`.

If `info` = 0, the execution is successful.

If `info` = $-k$, the k -th argument had an illegal value.

If `info` > 0, the matrix A is either rank deficient with a computed rank as returned in `rank`, or is not positive semidefinite.

Description

The routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, a Hermitian positive-definite matrix A :

$$\begin{array}{ll}
 A = U^T * U \text{ for real data, } A = U^H * U \text{ for complex data} & \text{if } uplo = 'U' \\
 A = L * L^T \text{ for real data, } A = L * L^H \text{ for complex data} & \text{if } uplo = 'L'
 \end{array}$$

where L is a lower triangular matrix and U is upper triangular.

The matrix A is in the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

This is the block version of the algorithm, calling Level 3 BLAS.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>transr</i> | Must be 'N', 'T' (for real data) or 'C' (for complex data). If <i>transr</i> = 'N', the Normal <i>transr</i> of RFP A is stored. If <i>transr</i> = 'T', the Transpose <i>transr</i> of RFP A is stored. If <i>transr</i> = 'C', the Conjugate-Transpose <i>transr</i> of RFP A is stored. |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If <i>uplo</i> = 'U', the array a stores the upper triangular part of the matrix A . If <i>uplo</i> = 'L', the array a stores the lower triangular part of the matrix A . |
| <i>n</i> | The order of the matrix A ; $n \geq 0$. |
| <i>a</i> | Array, size $(n * (n + 1) / 2)$. The array a contains the matrix A in the RFP format. |

Output Parameters

a *a* is overwritten by the Cholesky factor *U* or *L*, as specified by *uplo* and *trans*.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

If *info* = *i*, the leading minor of order *i* (and therefore the matrix *A* itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix *A*.

lapack_complex_double * ap );
```

Include Files

- mkl.h

Description

The routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite packed matrix *A*:

$$\begin{array}{ll}
 A = U^T * U \text{ for real data, } A = U^H * U \text{ for complex data} & \text{if } uplo = 'U' \\
 A = L * L^T \text{ for real data, } A = L * L^H \text{ for complex data} & \text{if } uplo = 'L'
 \end{array}$$

where *L* is a lower triangular matrix and *U* is upper triangular.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

| | |
|-------------|---|
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is packed in the array ap , and how A is factored: If $uplo = 'U'$, the array ap stores the upper triangular part of the matrix A , and A is factored as U^H*U . If $uplo = 'L'$, the array ap stores the lower triangular part of the matrix A ; A is factored as $L*L^H$. |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>ap</i> | Array, size at least $\max(1, n(n+1)/2)$. The array ap contains either the upper or the lower triangular part of the matrix A (as specified by $uplo$) in packed storage (see Matrix Storage Schemes). |

Output Parameters

| | |
|-----------|--|
| <i>ap</i> | Overwritten by the Cholesky factor U or L , as specified by $uplo$. |
|-----------|--|

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = -i$, parameter i had an illegal value.

If $info = i$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix A .

Application Notes

If $uplo = 'U'$, the computed factor U is the exact factor of a perturbed matrix $A + E$, where

$$|E| \leq c(n)\varepsilon |U^H| |U|, |e_{ij}| \leq c(n)\varepsilon \sqrt{a_{ii}a_{jj}}$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

A similar estimate holds for $uplo = 'L'$.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors and $(4/3)n^3$ for complex flavors.

After calling this routine, you can call the following routines:

| | |
|------------------------|---|
| ?pptrs | to solve $A*X = B$ |
| ?ppcon | to estimate the condition number of A |
| ?pptri | to compute the inverse of A . |

Include Files

- mkl.h

Description

The routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite band matrix A :

$$\begin{aligned}
 A &= U^T * U \text{ for real data, } A = U^H * U \text{ for complex data} && \text{if } uplo = 'U' \\
 A &= L * L^T \text{ for real data, } A = L * L^H \text{ for complex data} && \text{if } uplo = 'L'
 \end{aligned}$$

where L is a lower triangular matrix and U is upper triangular.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored in the array ab , and how A is factored: If $uplo = 'U'$, the upper triangle of A is stored. If $uplo = 'L'$, the lower triangle of A is stored. |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>kd</i> | The number of superdiagonals or subdiagonals in the matrix A ; $kd \geq 0$. |
| <i>ab</i> | Array, size $\max(1, ldab * n)$. The array ab contains either the upper or the lower triangular part of the matrix A (as specified by $uplo$) in band storage (see Matrix Storage Schemes). |
| <i>ldab</i> | The leading dimension of the array ab . ($ldab \geq kd + 1$) |

Output Parameters

ab The upper or lower triangular part of A (in band storage) is overwritten by the Cholesky factor U or L , as specified by *uplo*.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = $-i$, parameter i had an illegal value.

If *info* = i , the leading minor of order i (and therefore the matrix A itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix A .

Application Notes

If *uplo* = 'U', the computed factor U is the exact factor of a perturbed matrix $A + E$, where

$$|E| \leq c(kd + 1)\varepsilon |U^H| |U|, |e_{ij}| \leq c(kd + 1)\varepsilon \sqrt{a_{ii}a_{jj}}$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

A similar estimate holds for *uplo* = 'L'.

The total number of floating-point operations for real flavors is approximately $n(kd+1)^2$. The number of operations for complex flavors is 4 times greater. All these estimates assume that kd is much less than n .

After calling this routine, you can call the following routines:

[?pbtrs](#) to solve $A*X = B$

[?pbcon](#) to estimate the condition number of A .

```

Include Files

- `mkl.h`

Description

The routine forms the factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite tridiagonal matrix A :

$A = L * D * L^T$ for real flavors, or

$A = L * D * L^H$ for complex flavors,

where D is diagonal and L is unit lower bidiagonal. The factorization may also be regarded as having the form $A = U^T * D * U$ for real flavors, or $A = U^H * D * U$ for complex flavors, where U is unit upper bidiagonal.

Input Parameters

| | |
|-----|--|
| n | The order of the matrix A ; $n \geq 0$. |
| d | Array, dimension (n). Contains the diagonal elements of A . |
| e | Array, dimension ($n - 1$). Contains the subdiagonal elements of A . |

Output Parameters

| | |
|-----|---|
| d | Overwritten by the n diagonal elements of the diagonal matrix D from the $L * D * L^T$ (for real flavors) or $L * D * L^H$ (for complex flavors) factorization of A . |
| e | Overwritten by the ($n - 1$) sub-diagonal elements of the unit bidiagonal factor L or U from the factorization of A . |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = - i , parameter i had an illegal value.

If *info* = i , the leading minor of order i (and therefore the matrix A itself) is not positive-definite; if $i < n$, the factorization could not be completed, while if $i = n$, the factorization was completed, but $d[n - 1] \leq 0$.

?sytrf

Include Files

- mkl.h

Description

The routine computes the factorization of a real/complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is:

if $uplo = 'U'$, $A = U * D * U^T$
 if $uplo = 'L'$, $A = L * D * L^T$,

where A is the input matrix, U and L are products of permutation and triangular matrices with unit diagonal (upper triangular for U and lower triangular for L), and D is a symmetric block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .

NOTE

This routine supports the Progress Routine feature. See [Progress Routines](#) section for details.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored and how A is factored: If $uplo = 'U'$, the array a stores the upper triangular part of the matrix A , and A is factored as $U * D * U^T$. If $uplo = 'L'$, the array a stores the lower triangular part of the matrix A , and A is factored as $L * D * L^T$. |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>a</i> | Array, size $\max(1, lda * n)$. The array a contains either the upper or the lower triangular part of the matrix A (see <i>uplo</i>). |
| <i>lda</i> | The leading dimension of a ; at least $\max(1, n)$. |

Output Parameters

| | |
|-------------|---|
| <i>a</i> | The upper or lower triangular part of a is overwritten by details of the block-diagonal matrix D and the multipliers used to obtain the factor U (or L). |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. Contains details of the interchanges and the block structure of D . If $ipiv[i-1] = k > 0$, then d_{ii} is a 1-by-1 block, and the i -th row and column of A was interchanged with the k -th row and column. If $uplo = 'U'$ and $ipiv[i] = ipiv[i-1] = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and i -th row and column of A was interchanged with the m -th row and column. If $uplo = 'L'$ and $ipiv[i] = ipiv[i-1] = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column. |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

If *info* = *i*, D_{ii} is 0. The factorization has been completed, but *D* is exactly singular. Division by 0 will occur if you use *D* for solving a system of linear equations.

Application Notes

The 2-by-2 unit diagonal blocks and the unit diagonal elements of *U* and *L* are not stored. The remaining elements of *U* and *L* are stored in the corresponding columns of the array *a*, but additional row interchanges are required to recover *U* or *L* explicitly (which is seldom necessary).

If *ipiv*[*i*-1] = *i* for all $i = 1 \dots n$, then all off-diagonal elements of *U* (*L*) are stored explicitly in the corresponding elements of the array *a*.

If *uplo* = 'U', the computed factors *U* and *D* are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(n)\epsilon P|U||D||U^T|P^T$$

$c(n)$ is a modest linear function of *n*, and ϵ is the machine precision. A similar estimate holds for the computed *L* and *D* when *uplo* = 'L'.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors or $(4/3)n^3$ for complex flavors.

After calling this routine, you can call the following routines:

| | |
|---------------------|--|
| <code>?sytrs</code> | to solve $A * X = B$ |
| <code>?sycon</code> | to estimate the condition number of <i>A</i> |
| <code>?sytri</code> | to compute the inverse of <i>A</i> . |

If *uplo* = 'U', then $A = U * D * U'$, where

$$U = P(n) * U(n) * \dots * P(k) * U(k) * \dots,$$

that is, *U* is a product of terms $P(k) * U(k)$, where

- *k* decreases from *n* to 1 in steps of 1 and 2.
- *D* is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$.
- $P(k)$ is a permutation matrix as defined by *ipiv*[*k*-1].
- *U*(*k*) is a unit upper triangular matrix, such that if the diagonal block $D(k)$ is of order *s* ($s = 1$ or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 & \\ 0 & I & 0 & \\ 0 & 0 & I & \\ & & & \end{pmatrix} \begin{matrix} k - s \\ s \\ n - k \\ k - s \quad s \quad n - k \end{matrix}$$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and *v* overwrites $A(1:k-1,k)$.

If $s = 2$, the upper triangle of $D(k)$ overwrites $A(k-1,k-1)$, $A(k-1,k)$ and $A(k,k)$, and v overwrites $A(1:k-2,k-1:k)$.

If $uplo = 'L'$, then $A = L * D * L'$, where

```
L = P(1)*L(1)* ... *P(k)*L(k)*...
```

that is, L is a product of terms $P(k)*L(k)$, where

- k increases from 1 to n in steps of 1 and 2.
- D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$.
- $P(k)$ is a permutation matrix as defined by $ipiv(k)$.
- $L(k)$ is a unit lower triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 & & \\ 0 & I & 0 & & \\ 0 & v & I & & \\ & & & \ddots & \\ & & & & I \end{pmatrix} \begin{matrix} k-1 \\ s \\ n-k-s+1 \\ \\ \end{matrix}$$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(k+1:n,k)$.

If $s = 2$, the lower triangle of $D(k)$ overwrites $A(k,k)$, $A(k+1,k)$, and $A(k+1,k+1)$, and v overwrites $A(k+2:n,k:k+1)$.

Description

The routine computes the factorization of a real/complex symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method. The form of the factorization is:

if $uplo = 'U'$, $A = U * D * U^T$
 if $uplo = 'L'$, $A = L * D * L^T$,

where A is the input matrix, U and L are products of permutation and triangular matrices with unit diagonal (upper triangular for U and lower triangular for L), and D is a symmetric block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout for array <i>b</i> is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored and how A is factored: If $uplo = 'U'$, the array <i>a</i> stores the upper triangular part of the matrix A , and A is factored as $U * D * U^T$. If $uplo = 'L'$, the array <i>a</i> stores the lower triangular part of the matrix A , and A is factored as $L * D * L^T$. |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>a</i> | Array, size $lda * n$. The array <i>a</i> contains either the upper or the lower triangular part of the matrix A (see <i>uplo</i>). |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, n)$. |

Output Parameters

| | |
|-------------|--|
| <i>a</i> | The upper or lower triangular part of <i>a</i> is overwritten by details of the block-diagonal matrix D and the multipliers used to obtain the factor U (or L). |
| <i>ipiv</i> | If $ipiv(k) > 0$, then rows and columns k and $ipiv(k)$ were interchanged and $D_{k,k}$ is a 1-by-1 diagonal block. If $uplo = 'U'$ and $ipiv(k) < 0$ and $ipiv(k - 1) < 0$, then rows and columns k and $-ipiv(k)$ were interchanged, rows and columns $k - 1$ and $-ipiv(k - 1)$ were interchanged, and $D_{k-1:k, k-1:k}$ is a 2-by-2 diagonal block. If $uplo = 'L'$ and $ipiv(k) < 0$ and $ipiv(k + 1) < 0$, then rows and columns k and $-ipiv(k)$ were interchanged, rows and columns $k + 1$ and $-ipiv(k + 1)$ were interchanged, and $D_{k:k+1, k:k+1}$ is a 2-by-2 diagonal block. |

Return Values

This function returns a value *info*.

If $info = 0$, the execution is successful.

If $info = -i$, the *i*-th parameter had an illegal value.

If $info = i$, D_{ii} is 0. The factorization has been completed, but D is exactly singular. Division by 0 will occur if you use D for solving a system of linear equations.

Application Notes

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors or $(4/3)n^3$ for complex flavors.

After calling this routine, you can call the following routines:

| | |
|---|---|
| <code>?sytrs_rook</code> | to solve $A*X = B$ |
| <code>?sycon_rook</code> (Fortran only) | to estimate the condition number of A |
| <code>?sytri_rook</code> (Fortran only) | to compute the inverse of A . |

If `uplo = 'U'`, then $A = U*D*U'$, where

$$U = P(n)*U(n)* \dots *P(k)*U(k)*\dots,$$

that is, U is a product of terms $P(k)*U(k)$, where

- k decreases from n to 1 in steps of 1 and 2.
- D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$.
- $P(k)$ is a permutation matrix as defined by `ipiv[k-1]`.
- $U(k)$ is a unit upper triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{pmatrix} \begin{matrix} k-s \\ s \\ n-k \end{matrix}$$

$k-s \quad s \quad n-k$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(1:k-1,k)$.

If $s = 2$, the upper triangle of $D(k)$ overwrites $A(k-1,k-1)$, $A(k-1,k)$ and $A(k,k)$, and v overwrites $A(1:k-2,k-1:k)$.

If `uplo = 'L'`, then $A = L*D*L'$, where

$$L = P(1)*L(1)* \dots *P(k)*L(k)*\dots,$$

that is, L is a product of terms $P(k)*L(k)$, where

- k increases from 1 to n in steps of 1 and 2.
- D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$.
- $P(k)$ is a permutation matrix as defined by `ipiv(k)`.
- $L(k)$ is a unit lower triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & v & I \end{pmatrix} \begin{matrix} k-1 \\ s \\ n-k-s+1 \end{matrix}$$

$k-1 \quad s \quad n-k-s+1$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(k+1:n,k)$.

If $s = 2$, the lower triangle of $D(k)$ overwrites $A(k,k)$, $A(k+1,k)$, and $A(k+1,k+1)$, and v overwrites $A(k+2:n,k:k+1)$.

Description

The routine computes the factorization of a complex Hermitian matrix A using the bounded Bunch-Kaufman diagonal pivoting method:

if $uplo='U'$, $A = U^*D*U^H$
 if $uplo='L'$, $A = L^*D*L^H$,

where A is the input matrix, U (or L) is a product of permutation and unit upper (or lower) triangular matrices, and D is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

Input Parameters

matrix_layout Specifies whether matrix storage layout for array b is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

uplo Must be 'U' or 'L'.
 Indicates whether the upper or lower triangular part of A is stored:
 If $uplo = 'U'$, the array a stores the upper triangular part of the matrix A .
 If $uplo = 'L'$, the array a stores the lower triangular part of the matrix A .

n The order of matrix A ; $n \geq 0$.

a Array a , size $(lda*n)$
 The array a contains the upper or the lower triangular part of the matrix A (see *uplo*).

If $uplo = 'U'$, the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced.

lda

The leading dimension of a ; at least $\max(1, n)$.

Output Parameters

a

The block diagonal matrix D and the multipliers used to obtain the factor U or L (see Application Notes for further details).

$ipiv$

- If $uplo = 'U'$:

If $ipiv(k) > 0$, then rows and columns k and $ipiv(k)$ were interchanged and $D_{k,k}$ is a 1-by-1 diagonal block.

If $ipiv(k) < 0$ and $ipiv(k - 1) < 0$, then rows and columns k and $-ipiv(k)$ were interchanged and rows and columns $k - 1$ and $-ipiv(k - 1)$ were interchanged, $D_{k-1:k,k-1:k}$ is a 2-by-2 diagonal block.

- If $uplo = 'L'$:

If $ipiv(k) > 0$, then rows and columns k and $ipiv(k)$ were interchanged and $D_{k,k}$ is a 1-by-1 diagonal block.

If $ipiv(k) < 0$ and $ipiv(k + 1) < 0$, then rows and columns k and $-ipiv(k)$ were interchanged and rows and columns $k + 1$ and $-ipiv(k + 1)$ were interchanged, $D_{k:k+1,k:k+1}$ is a 2-by-2 diagonal block.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, D_{ii} is exactly 0. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by 0 will occur if you use D for solving a system of linear equations.

Application Notes

If $uplo = 'U'$, then $A = U * D * U^H$, where

$$U = P(n) * U(n) * \dots * P(k) * U(k) * \dots,$$

i.e., U is a product of terms $P(k) * U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$. $P(k)$ is a permutation matrix as defined by $ipiv(k)$, and $U(k)$ is a unit upper triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$U(k) = \begin{matrix} & k-s & s & n-k \\ k-s & \begin{pmatrix} I & v & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{pmatrix} \\ s & \\ n-k & \end{matrix}$$

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is packed in the array ap and how A is factored: If $uplo = 'U'$, the array ap stores the upper triangular part of the matrix A , and A is factored as $U^*D^*U^T$. If $uplo = 'L'$, the array ap stores the lower triangular part of the matrix A , and A is factored as $L^*D^*L^T$. |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>ap</i> | Array, size at least $\max(1, n(n+1)/2)$. The array ap contains the upper or the lower triangular part of the matrix A (as specified by $uplo$) in <i>packed storage</i> (see Matrix Storage Schemes). |

Output Parameters

| | |
|-------------|---|
| <i>ap</i> | The upper or lower triangle of A (as specified by $uplo$) is overwritten by details of the block-diagonal matrix D and the multipliers used to obtain the factor U (or L). |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. Contains details of the interchanges and the block structure of D . If $ipiv[i-1] = k > 0$, then d_{ii} is a 1-by-1 block, and the i -th row and column of A was interchanged with the k -th row and column. If $uplo = 'U'$ and $ipiv[i] = ipiv[i-1] = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and i -th row and column of A was interchanged with the m -th row and column. If $uplo = 'L'$ and $ipiv[i] = ipiv[i-1] = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column. |

Return Values

This function returns a value *info*.

If $info = 0$, the execution is successful.

If $info = -i$, parameter i had an illegal value.

If $info = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular. Division by 0 will occur if you use D for solving a system of linear equations.

Application Notes

The 2-by-2 unit diagonal blocks and the unit diagonal elements of U and L are not stored. The remaining elements of U and L overwrite elements of the corresponding columns of the array ap , but additional row interchanges are required to recover U or L explicitly (which is seldom necessary).

If $ipiv(i) = i$ for all $i = 1 \dots n$, then all off-diagonal elements of U (L) are stored explicitly in packed form.

If $uplo = 'U'$, the computed factors U and D are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(n)\varepsilon P |U| |D| |U^T| P^T$$

$c(n)$ is a modest linear function of n , and ε is the machine precision. A similar estimate holds for the computed L and D when $uplo = 'L'$.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors or $(4/3)n^3$ for complex flavors.

After calling this routine, you can call the following routines:

| | |
|---------------------|---|
| <code>?sptrs</code> | to solve $A * X = B$ |
| <code>?spcon</code> | to estimate the condition number of A |
| <code>?sptri</code> | to compute the inverse of A . |

lapack_complex_float * ap , lapack_int * ipiv );

lapack_int LAPACKE_zhptrf (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_double * ap , lapack_int * ipiv );
```

Include Files

- `mkl.h`

Description

The routine computes the factorization of a complex Hermitian packed matrix A using the Bunch-Kaufman diagonal pivoting method:

```
if uplo='U', A = U * D * UH
if uplo='L', A = L * D * LH,
```

where A is the input matrix, U and L are products of permutation and triangular matrices with unit diagonal (upper triangular for U and lower triangular for L), and D is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is packed and how A is factored: If <i>uplo</i> = 'U', the array <i>ap</i> stores the upper triangular part of the matrix A , and A is factored as $U^*D^*U^H$. If <i>uplo</i> = 'L', the array <i>ap</i> stores the lower triangular part of the matrix A , and A is factored as $L^*D^*L^H$. |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>ap</i> | Array, size at least $\max(1, n(n+1)/2)$. The array <i>ap</i> contains the upper or the lower triangular part of the matrix A (as specified by <i>uplo</i>) in <i>packed storage</i> (see Matrix Storage Schemes). |

Output Parameters

| | |
|-------------|---|
| <i>ap</i> | The upper or lower triangle of A (as specified by <i>uplo</i>) is overwritten by details of the block-diagonal matrix D and the multipliers used to obtain the factor U (or L). |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. Contains details of the interchanges and the block structure of D . If <i>ipiv</i> [$i-1$] = $k > 0$, then d_{ii} is a 1-by-1 block, and the i -th row and column of A was interchanged with the k -th row and column. If <i>uplo</i> = 'U' and <i>ipiv</i> [i] = <i>ipiv</i> [$i-1$] = $-m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and i -th row and column of A was interchanged with the m -th row and column. If <i>uplo</i> = 'L' and <i>ipiv</i> [i] = <i>ipiv</i> [$i-1$] = $-m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column. |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = $-i$, parameter i had an illegal value.

If *info* = i , d_{ii} is 0. The factorization has been completed, but D is exactly singular. Division by 0 will occur if you use D for solving a system of linear equations.

Application Notes

The 2-by-2 unit diagonal blocks and the unit diagonal elements of U and L are not stored. The remaining elements of U and L are stored in the array ap , but additional row interchanges are required to recover U or L explicitly (which is seldom necessary).

If $ipiv[i-1] = i$ for all $i = 1 \dots n$, then all off-diagonal elements of U (L) are stored explicitly in the corresponding elements of the array a .

If $uplo = 'U'$, the computed factors U and D are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(n)\varepsilon P|U||D||U^T|P^T$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

A similar estimate holds for the computed L and D when $uplo = 'L'$.

The total number of floating-point operations is approximately $(4/3)n^3$.

After calling this routine, you can call the following routines:

| | |
|---------------------|---|
| <code>?hptrs</code> | to solve $A * X = B$ |
| <code>?hpcon</code> | to estimate the condition number of A |
| <code>?hptri</code> | to compute the inverse of A . |

```

Include Files

- `mk1.h`

Description

The routine computes the partial factorization $A = LDL^T$, where L is a lower triangular matrix and D is a diagonal matrix.

CAUTION

The routine assumes that the matrix A is factorizable. The routine does not perform pivoting and does not handle diagonal elements which are zero, which cause the routine to produce incorrect results without any indication.

Consider the matrix $A = \begin{pmatrix} a & b^T \\ b & C \end{pmatrix}$, where a is the element in the first row and first column of A , b is a column vector of size $n - 1$ containing the elements from the second through n -th column of A , C is the lower-right square submatrix of A , and I is the identity matrix.

The `mk1_?spffrt2` routine performs $ncolm$ successive factorizations of the form

$$A = \begin{pmatrix} a & b^T \\ b & C \end{pmatrix} = \begin{pmatrix} a & 0 \\ b & I \end{pmatrix} \begin{pmatrix} a^{-1} & 0 \\ 0 & C - ba^{-1}b^T \end{pmatrix} \begin{pmatrix} a & b^T \\ 0 & I \end{pmatrix}.$$

The `mk1_?spffrtx` routine performs $ncolm$ successive factorizations of the form

$$A = \begin{pmatrix} a & b^T \\ b & C \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ ba^{-1} & I \end{pmatrix} \begin{pmatrix} a & 0 \\ 0 & C - ba^{-1}b^T \end{pmatrix} \begin{pmatrix} 1 & (ba^{-1})^T \\ 0 & I \end{pmatrix}.$$

The approximate number of floating point operations performed by real flavors of these routines is $(1/6)*ncolm*(2*ncolm^2 - 6*ncolm*n + 3*ncolm + 6*n^2 - 6*n + 7)$.

The approximate number of floating point operations performed by complex flavors of these routines is $(1/3)*ncolm*(4*ncolm^2 - 12*ncolm*n + 9*ncolm + 12*n^2 - 18*n + 8)$.

Input Parameters

| | |
|--------------------|--|
| <i>ap</i> | Array, size at least $\max(1, n(n+1)/2)$. The array <i>ap</i> contains the lower triangular part of the matrix A in packed storage (see Matrix Storage Schemes for <code>uplo = 'L'</code>). |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>ncolm</i> | The number of columns to factor, $ncolm \leq n$. |
| <i>work, work2</i> | Workspace arrays, size of each at least n . |

Output Parameters

| | |
|-----------|--|
| <i>ap</i> | Overwritten by the factor L . The first $ncolm$ diagonal elements of the input matrix A are replaced with the diagonal elements of D . The subdiagonal elements of the first $ncolm$ columns are replaced with the corresponding elements of L . The rest of the input array is updated as indicated in the Description section. |
|-----------|--|

NOTE

Specifying $n_{colm} = n$ results in complete factorization $A = LDL^T$.

See Also[mkl_progress](#)[Matrix Storage Schemes for LAPACK Routines](#)**Solving Systems of Linear Equations: LAPACK Computational Routines**

This section describes the LAPACK routines for solving systems of linear equations. Before calling most of these routines, you need to factorize the matrix of your system of equations (see [Routines for Matrix Factorization](#) in this chapter). However, the factorization is not necessary if your system of equations has a triangular matrix.

?getrs

Solves a system of linear equations with an LU-factored square coefficient matrix, with multiple right-hand sides.

Syntax

```
lapack_int LAPACKE_sgetrs (int matrix_layout , char trans , lapack_int n , lapack_int
nrhs , const float * a , lapack_int lda , const lapack_int * ipiv , float * b ,
lapack_int ldb );
```

```
lapack_int LAPACKE_dgetrs (int matrix_layout , char trans , lapack_int n , lapack_int
nrhs , const double * a , lapack_int lda , const lapack_int * ipiv , double * b ,
lapack_int ldb );
```

```
lapack_int LAPACKE_cgetrs (int matrix_layout , char trans , lapack_int n , lapack_int
nrhs , const lapack_complex_float * a , lapack_int lda , const lapack_int * ipiv ,
lapack_complex_float * b , lapack_int ldb );
```

```
lapack_int LAPACKE_zgetrs (int matrix_layout , char trans , lapack_int n , lapack_int
nrhs , const lapack_complex_double * a , lapack_int lda , const lapack_int * ipiv ,
lapack_complex_double * b , lapack_int ldb );
```

Include Files

- `mkl.h`

Description

The routine solves for X the following systems of linear equations:

$$A * X = B \quad \text{if } trans = 'N',$$

$$A^T * X = B \quad \text{if } trans = 'T',$$

$$A^H * X = B \quad \text{if } trans = 'C' \text{ (for complex matrices only).}$$

Before calling this routine, you must call [?getrf](#) to compute the LU factorization of A .

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>trans</i> | Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $A^*X = B$ is solved for X . If <i>trans</i> = 'T', then $A^T * X = B$ is solved for X . If <i>trans</i> = 'C', then $A^H * X = B$ is solved for X . |
| <i>n</i> | The order of A ; the number of rows in B ($n \geq 0$). |
| <i>nrhs</i> | The number of right-hand sides; $nrhs \geq 0$. |
| <i>a</i> | Array of size $\max(1, lda * n)$. The array <i>a</i> contains LU factorization of matrix A resulting from the call of <code>?getrf</code> . |
| <i>b</i> | Array of size $\max(1, ldb * nrhs)$ for column major layout, and $\max(1, ldb * n)$ for row major layout. The array <i>b</i> contains the matrix B whose columns are the right-hand sides for the systems of equations. |
| <i>lda</i> | The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. The <i>ipiv</i> array, as returned by <code>?getrf</code> . |

Output Parameters

| | |
|----------|--|
| <i>b</i> | Overwritten by the solution matrix X . |
|----------|--|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n) \varepsilon P |L| |U|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\epsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \|A^{-1}\|_\infty \|A\|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector b is $2n^2$ for real flavors and $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call `?gecon`.

To refine the solution and estimate the error, call `?gerfs`.

```

```
lapack_int LAPACKE_zgbtrs (int matrix_layout , char trans , lapack_int n , lapack_int
kl , lapack_int ku , lapack_int nrhs , const lapack_complex_double * ab , lapack_int
ldab , const lapack_int * ipiv , lapack_complex_double * b , lapack_int ldb );
```

Include Files

- mkl.h

Description

The routine solves for X the following systems of linear equations:

$A * X = B$ if $trans = 'N'$,

$A^T * X = B$ if $trans = 'T'$,

$A^H * X = B$ if $trans = 'C'$ (for complex matrices only).

Here A is an LU -factored general band matrix of order n with kl non-zero subdiagonals and ku nonzero superdiagonals. Before calling this routine, call `?gbtrf` to compute the LU factorization of A .

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>trans</i> | Must be 'N' or 'T' or 'C'. |
| <i>n</i> | The order of <i>A</i> ; the number of rows in <i>B</i> ; $n \geq 0$. |
| <i>kl</i> | The number of subdiagonals within the band of <i>A</i> ; $kl \geq 0$. |
| <i>ku</i> | The number of superdiagonals within the band of <i>A</i> ; $ku \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; $nrhs \geq 0$. |
| <i>ab</i> | Array <i>ab</i> size $\max(1, ldab*n)$ The array <i>ab</i> contains elements of the LU factors of the matrix <i>A</i> as returned by gbtrf . |
| <i>b</i> | Array <i>b</i> size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout. The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. |
| <i>ldab</i> | The leading dimension of the array <i>ab</i> ; $ldab \geq 2*kl + ku + 1$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?gbtrf . |

Output Parameters

b Overwritten by the solution matrix *X*.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

For each right-hand side *b*, the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(kl + ku + 1)\epsilon P|L||U|$$

$c(k)$ is a modest linear function of *k*, and ϵ is the machine precision.

If x_0 is the true solution, the computed solution *x* satisfies this error bound:

$$\frac{\|x - x_0\|_{\infty}}{\|x\|_{\infty}} \leq c(kl + ku + 1) \text{cond}(A, x)\varepsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_{\infty} / \|x\|_{\infty} \leq \|A^{-1}\|_{\infty} \|A\|_{\infty} = \kappa_{\infty}(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_{\infty}(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_{\infty}(A)$.

The approximate number of floating-point operations for one right-hand side vector is $2n(ku + 2kl)$ for real flavors. The number of operations for complex flavors is 4 times greater. All these estimates assume that kl and ku are much less than $\min(m, n)$.

To estimate the condition number $\kappa_{\infty}(A)$, call `?gbcon`.

To refine the solution and estimate the error, call `?gbrfs`.

Description

The [?dtrs](#) routine solves the following systems of linear equations with multiple right hand sides for X :

$A^*X = B$ if *trans* = 'N',
 $A^T * X = B$ if *trans* = 'T',
 $A^H * X = B$ if *trans* = 'C' (for complex matrices only).

Before calling this routine, call `?dtrfb` to compute the factorization of *A*.

Input Parameters

trans Must be 'N' or 'T' or 'C'.
 Indicates the form of the equations solved for *X*:
 If *trans* = 'N', then $A^*X = B$.
 If *trans* = 'T', then $A^T * X = B$.
 If *trans* = 'C', then $A^H * X = B$.

n The order of *A*; $n \geq 0$.

nrhs The number of right-hand sides, that is, the number of columns in *B*; $nrhs \geq 0$.

dl, d, du Arrays: $dl(n-1)$, $d(n)$, $du(n-1)$.
 The array *dl* contains the $(n-1)$ multipliers that define the matrices L_1, L_2 from the factorization of *A*.
 The array *d* contains the n diagonal elements of the upper triangular matrix *U* from the factorization of *A*.
 The array *du* contains the $(n-1)$ elements of the superdiagonal of *U*.

b Array of size $\max(1, ldb * nrhs)$. Contains the matrix *B* whose columns are the right-hand sides for the systems of equations.

ldb The leading dimension of *b*; $ldb \geq \max(1, n)$.

Output Parameters

b Overwritten by the solution matrix *X*.

info If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

?spotrs

Solves a system of linear equations with a Cholesky-factored symmetric (Hermitian) positive-definite coefficient matrix.

Syntax

```

lapack_int LAPACKE_spotrs (int matrix_layout , char uplo , lapack_int n , lapack_int
nrhs , const float * a , lapack_int lda , float * b , lapack_int ldb );

Description

The routine solves for X the system of linear equations $A * X = B$ with a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A , given the Cholesky factorization of A :

$$A = U^T * U \text{ for real data, } A = U^H * U \text{ for complex data} \quad \text{if } uplo = 'U'$$

$$A = L * L^T \text{ for real data, } A = L * L^H \text{ for complex data} \quad \text{if } uplo = 'L'$$

where L is a lower triangular matrix and U is upper triangular. The system is solved with multiple right-hand sides stored in the columns of the matrix B .

Before calling this routine, you must call [potrf](#) to compute the Cholesky factorization of A .

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', U is stored, where $A = U^T * U$ for real data, $A = U^H * U$ for complex data. If <i>uplo</i> = 'L', L is stored, where $A = L * L^T$ for real data, $A = L * L^H$ for complex data |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides ($nrhs \geq 0$). |
| <i>a</i> | Array A of size at least $\max(1, lda * n)$ The array a contains the factor U or L (see <i>uplo</i>) as returned by potrf . |
| <i>b</i> | The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The size of b must be at least $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout. |
| <i>lda</i> | The leading dimension of a ; $lda \geq \max(1, n)$. |
| <i>ldb</i> | The leading dimension of b ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |

Output Parameters

b Overwritten by the solution matrix *X*.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

If *uplo* = 'U', the computed solution for each right-hand side *b* is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon |U^H| |U|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

A similar estimate holds for *uplo* = 'L'. If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \|A^{-1}\|_\infty \|A\|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$. The approximate number of floating-point operations for one right-hand side vector *b* is $2n^2$ for real flavors and $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call `?pocon`.

To refine the solution and estimate the error, call `?porfs`.

Description

The routine solves a system of linear equations $A^*X = B$ with a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A using the Cholesky factorization of A :

$$\begin{aligned}
 A &= U^T * U \text{ for real data, } A = U^H * U \text{ for complex data} && \text{if } uplo = 'U' \\
 A &= L * L^T \text{ for real data, } A = L * L^H \text{ for complex data} && \text{if } uplo = 'L'
 \end{aligned}$$

Before calling `?pfttrs`, you must call `?pftrf` to compute the Cholesky factorization of A . L stands for a lower triangular matrix and U for an upper triangular matrix.

The matrix A is in the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>transr</code> | Must be 'N', 'T' (for real data) or 'C' (for complex data). If <code>transr = 'N'</code> , the untransposed factor of A is stored in RFP format. If <code>transr = 'T'</code> , the transposed factor of A is stored in RFP format. If <code>transr = 'C'</code> , the conjugate-transposed factor of A is stored in RFP format. |
| <code>uplo</code> | Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <code>uplo = 'U'</code> , U is stored, where $A = U^T * U$ for real data, $A = U^H * U$ for complex data. If <code>uplo = 'L'</code> , L is stored, where $A = L * L^T$ for real data, $A = L * L^H$ for complex data |
| <code>n</code> | The order of the matrix A ; $n \geq 0$. |
| <code>nrhs</code> | The number of right-hand sides, that is, the number of columns of the matrix B ; $nrhs \geq 0$. |
| <code>a</code> | Array <code>a</code> of size $\max(1, n * (n + 1) / 2)$. The array <code>a</code> contains, in the RFP format, the factor U or L obtained by factorization of matrix A . |
| <code>b</code> | The array <code>b</code> of size $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout contains the matrix B whose columns are the right-hand sides for the systems of equations. |
| <code>ldb</code> | The leading dimension of <code>b</code> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |

Output Parameters

b The solution matrix X .

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = $-i$, parameter *i* had an illegal value.

Description

The routine solves for X the system of linear equations $A * X = B$ with a packed symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A , given the Cholesky factorization of A :

$$\begin{aligned} A &= U^T * U \text{ for real data, } A = U^H * U \text{ for complex data} && \text{if } uplo = 'U' \\ A &= L * L^T \text{ for real data, } A = L * L^H \text{ for complex data} && \text{if } uplo = 'L' \end{aligned}$$

where L is a lower triangular matrix and U is upper triangular. The system is solved with multiple right-hand sides stored in the columns of the matrix B .

Before calling this routine, you must call `?pptrf` to compute the Cholesky factorization of A .

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

uplo Must be 'U' or 'L'.

Indicates how the input matrix A has been factored:

If *uplo* = 'U', U is stored, where $A = U^T * U$ for real data, $A = U^H * U$ for complex data.

| | |
|---------|---|
| | If $uplo = 'L'$, L is stored, where $A = L*L^T$ for real data, $A = L*L^H$ for complex data |
| n | The order of matrix A ; $n \geq 0$. |
| $nrhs$ | The number of right-hand sides ($nrhs \geq 0$). |
| ap, b | The size of ap must be at least $\max(1, n(n+1)/2)$. The array ap contains the factor U or L , as specified by $uplo$, in <i>packed storage</i> (see Matrix Storage Schemes). |
| b | The array b of size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout contains the matrix B whose columns are the right-hand sides for the systems of equations. |
| ldb | The leading dimension of b ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |

Output Parameters

b Overwritten by the solution matrix X .

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter i had an illegal value.

Application Notes

If $uplo = 'U'$, the computed solution for each right-hand side b is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\epsilon |U^H| |U|$$

$c(n)$ is a modest linear function of n , and ϵ is the machine precision.

A similar estimate holds for $uplo = 'L'$.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\epsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \|A^{-1}\|_\infty \|A\|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector b is $2n^2$ for real flavors and $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?ppcon](#).

To refine the solution and estimate the error, call [?pprfs](#).

Description

The routine solves for real data a system of linear equations $A^*X = B$ with a symmetric positive-definite or, for complex data, Hermitian positive-definite *band* matrix A , given the Cholesky factorization of A :

$$\begin{array}{ll}
 A = U^T * U \text{ for real data, } A = U^H * U \text{ for complex data} & \text{if } uplo = 'U' \\
 A = L * L^T \text{ for real data, } A = L * L^H \text{ for complex data} & \text{if } uplo = 'L'
 \end{array}$$

where L is a lower triangular matrix and U is upper triangular. The system is solved with multiple right-hand sides stored in the columns of the matrix B .

Before calling this routine, you must call [?pbtrf](#) to compute the Cholesky factorization of A in the band storage form.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If $uplo = 'U'$, U is stored in ab , where $A = U^T * U$ for real matrices and $A = U^H * U$ for complex matrices. If $uplo = 'L'$, L is stored in ab , where $A = L * L^T$ for real matrices and $A = L * L^H$ for complex matrices. |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |

| | |
|-------------|--|
| <i>kd</i> | The number of superdiagonals or subdiagonals in the matrix <i>A</i> ; $kd \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; $nrhs \geq 0$. |
| <i>ab</i> | Array <i>ab</i> is of size $\max(1, ldab*n)$. The array <i>ab</i> contains the Cholesky factor, as returned by the factorization routine, in <i>band storage</i> form. The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. |
| <i>b</i> | The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The size of <i>b</i> is at least $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout. |
| <i>ldab</i> | The leading dimension of the array <i>ab</i> ; $ldab \geq kd + 1$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |

Output Parameters

b Overwritten by the solution matrix *X*.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

For each right-hand side *b*, the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(kd + 1)\epsilon P |U^H| |U| \text{ or } |E| \leq c(kd + 1)\epsilon P |L^H| |L|$$

$c(k)$ is a modest linear function of *k*, and ϵ is the machine precision.

If x_0 is the true solution, the computed solution *x* satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(kd + 1) \text{cond}(A, x) \epsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \|A^{-1}\|_\infty \|A\|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector is $4n*kd$ for real flavors and $16n*kd$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?pbcon](#).

To refine the solution and estimate the error, call [?pbrfs](#).

```

```
lapack_int LAPACKE_zpttrs( int matrix_layout, char uplo, lapack_int n, lapack_int nrhs, const double* d, const lapack_complex_double* e, lapack_complex_double* b, lapack_int ldb );
```

Include Files

- mkl.h

Description

The routine solves for X a system of linear equations $A^*X = B$ with a symmetric (Hermitian) positive-definite tridiagonal matrix A . Before calling this routine, call [?pttrf](#) to compute the $L^*D^*L^T$ or $U^T^*D^*U$ for real data and the $L^*D^*L^H$ or $U^H^*D^*U$ factorization of A for complex data.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Used for <i>cpttrs</i> / <i>zpttrs</i> only. Must be 'U' or 'L'. Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and how A is factored: If <i>uplo</i> = 'U', the array <i>e</i> stores the conjugated values of the superdiagonal of U , and A is factored as $U^H^*D^*U$. If <i>uplo</i> = 'L', the array <i>e</i> stores the subdiagonal of L , and A is factored as $L^*D^*L^H$. |
| <i>n</i> | The order of A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides, that is, the number of columns of the matrix B ; $nrhs \geq 0$. |
| <i>d</i> | Array, dimension (n). Contains the diagonal elements of the diagonal matrix D from the factorization computed by ?pttrf . |
| <i>e</i> | Array <i>e</i> is of size ($n - 1$). |

The array e contains the $(n - 1)$ sub-diagonal elements of the unit bidiagonal factor L or the conjugated values of the superdiagonal of U from the factorization computed by `?pttrf` (see `uplo`).

e, b

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

The size of b is at least $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout.

ldb

The leading dimension of b ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

Output Parameters

b

Overwritten by the solution matrix X .

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, parameter i had an illegal value.

lapack_complex_double * b , lapack_int ldb );
```

Include Files

- `mk1.h`

Description

The routine solves for X the system of linear equations $A * X = B$ with a symmetric matrix A , given the Bunch-Kaufman factorization of A :

if `uplo='U'`, $A = U * D * U^T$

if `uplo='L'`, $A = L * D * L^T$,

where U and L are upper and lower triangular matrices with unit diagonal and D is a symmetric block-diagonal matrix. The system is solved with multiple right-hand sides stored in the columns of the matrix B . You must supply to this routine the factor U (or L) and the array `ipiv` returned by the factorization routine [?sytrf](#).

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>uplo</code> | Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <code>uplo = 'U'</code> , the array <code>a</code> stores the upper triangular factor U of the factorization $A = U * D * U^T$. If <code>uplo = 'L'</code> , the array <code>a</code> stores the lower triangular factor L of the factorization $A = L * D * L^T$. |
| <code>n</code> | The order of matrix A ; $n \geq 0$. |
| <code>nrhs</code> | The number of right-hand sides; $nrhs \geq 0$. |
| <code>ipiv</code> | Array, size at least $\max(1, n)$. The <code>ipiv</code> array, as returned by ?sytrf . |
| <code>a</code> | The array <code>a</code> of size $\max(1, lda * n)$ contains the factor U or L (see <code>uplo</code>). |
| <code>b</code> | The array <code>b</code> contains the matrix B whose columns are the right-hand sides for the system of equations. The size of <code>b</code> is at least $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout. |
| <code>lda</code> | The leading dimension of <code>a</code> ; $lda \geq \max(1, n)$. |
| <code>ldb</code> | The leading dimension of <code>b</code> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |

Output Parameters

`b` Overwritten by the solution matrix X .

Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, parameter `i` had an illegal value.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon P|U||D||U^T|P^T \text{ or } |E| \leq c(n)\varepsilon P|L||D||U^T|P^T$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon$$

where $\text{cond}(A, x) = \frac{\|A^{-1}\|_\infty \|A\|_\infty \|x\|_\infty}{\|x\|_\infty} \leq \|A^{-1}\|_\infty \|A\|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The total number of floating-point operations for one right-hand side vector is approximately $2n^2$ for real flavors or $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?sycon](#).

To refine the solution and estimate the error, call [?sytrfs](#).

```

Include Files

- mkl.h

Description

The routine solves for X the system of linear equations $A \cdot X = B$ with a Hermitian matrix A , given the Bunch-Kaufman factorization of A :

if $uplo='U'$, $A = U \cdot D \cdot U^H$

if $uplo='L'$, $A = L \cdot D \cdot L^H$,

where U and L are upper and lower triangular matrices with unit diagonal and D is a symmetric block-diagonal matrix. The system is solved with multiple right-hand sides stored in the columns of the matrix B . You must supply to this routine the factor U (or L) and the array $ipiv$ returned by the factorization routine [?hetrf](#).

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If $uplo = 'U'$, the array a stores the upper triangular factor U of the factorization $A = U \cdot D \cdot U^H$. If $uplo = 'L'$, the array a stores the lower triangular factor L of the factorization $A = L \cdot D \cdot L^H$. |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; $nrhs \geq 0$. |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. The $ipiv$ array, as returned by ?hetrf . |
| <i>a</i> | The array a of size $\max(1, lda \cdot n)$ contains the factor U or L (see <i>uplo</i>). |
| <i>b</i> | The array b contains the matrix B whose columns are the right-hand sides for the system of equations. The size of b is at least $\max(1, ldb \cdot nrhs)$ for column major layout and $\max(1, ldb \cdot n)$ for row major layout. |

| | |
|------------|---|
| <i>lda</i> | The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |

Output Parameters

| | |
|----------|---|
| <i>b</i> | Overwritten by the solution matrix <i>X</i> . |
|----------|---|

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

For each right-hand side *b*, the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon P|U||D||U^H|P^T \text{ or } |E| \leq c(n)\varepsilon P|L||D||L^H|P^T$$

$c(n)$ is a modest linear function of *n*, and ε is the machine precision.

If x_0 is the true solution, the computed solution *x* satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon$$

where $\text{cond}(A, x) = \frac{\|A^{-1}\| \|A\| \|x\|_\infty}{\|x\|_\infty} \leq \|A^{-1}\|_\infty \|A\|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The total number of floating-point operations for one right-hand side vector is approximately $8n^2$.

To estimate the condition number $\kappa_\infty(A)$, call [?hecon](#).

To refine the solution and estimate the error, call [?herfs](#).

Description

The routine solves for a system of linear equations $A^*X = B$ with a complex Hermitian matrix A using the factorization $A = U^*D^*U^H$ or $A = L^*D^*L^H$ computed by [?hetrf_rook](#).

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout for array b is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>uplo</code> | Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <code>uplo = 'U'</code> , the factorization is of the form $A = U^*D^*U^H$. If <code>uplo = 'L'</code> , the factorization is of the form $A = L^*D^*L^H$. |
| <code>n</code> | The order of matrix A ; $n \geq 0$. |
| <code>nrhs</code> | The number of right-hand sides; $nrhs \geq 0$. |
| <code>ipiv</code> | Array, size at least $\max(1, n)$. The <code>ipiv</code> array, as returned by ?hetrf_rook . |
| <code>a, b</code> | Arrays: a ($lda*n$), b ($ldb*nrhs$). The array a contains the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ?hetrf_rook (see <code>uplo</code>). The array b contains the matrix B whose columns are the right-hand sides for the system of equations. |
| <code>lda</code> | The leading dimension of a ; $lda \geq \max(1, n)$. |
| <code>ldb</code> | The leading dimension of b ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |

Output Parameters

`b` Overwritten by the solution matrix X .

Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

Description

The routine solves for X the system of linear equations $A * X = B$ with a symmetric matrix A , given the Bunch-Kaufman factorization of A :

if $uplo='U'$, $A = U * D * U^T$

if $uplo='L'$, $A = L * D * L^T$,

where U and L are upper and lower *packed* triangular matrices with unit diagonal and D is a symmetric block-diagonal matrix. The system is solved with multiple right-hand sides stored in the columns of the matrix B . You must supply the factor U (or L) and the array $ipiv$ returned by the factorization routine [?sptrf](#).

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If $uplo = 'U'$, the array ap stores the packed factor U of the factorization $A = U * D * U^T$. If $uplo = 'L'$, the array ap stores the packed factor L of the factorization $A = L * D * L^T$. |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; $nrhs \geq 0$. |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. The $ipiv$ array, as returned by ?sptrf . |
| <i>ap</i> | The dimension of array ap must be at least $\max(1, n(n+1)/2)$. The array ap contains the factor U or L , as specified by $uplo$, in <i>packed storage</i> (see Matrix Storage Schemes). |
| <i>b</i> | The array b contains the matrix B whose columns are the right-hand sides for the system of equations. The size of b is $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout. |

ldb The leading dimension of *b*; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

Output Parameters

b Overwritten by the solution matrix *X*.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

For each right-hand side *b*, the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon P|U||D||U^T|P^T \text{ or } |E| \leq c(n)\varepsilon P|L||D||L^T|P^T$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon$$

where $\text{cond}(A, x) = \| |A^{-1}||A| |x| \|_\infty / \|x\|_\infty \leq \|A^{-1}\|_\infty \|A\|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The total number of floating-point operations for one right-hand side vector is approximately $2n^2$ for real flavors or $8n^2$ for complex flavors.

lapack_complex_double * b , lapack_int ldb );
```

Include Files

- `mkl.h`

Description

The routine solves for X the following systems of linear equations with a triangular matrix A , with multiple right-hand sides stored in B :

$A * X = B$ if *trans* = 'N',
 $A^T * X = B$ if *trans* = 'T',
 $A^H * X = B$ if *trans* = 'C' (for complex matrices only).

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

uplo Must be 'U' or 'L'.
 Indicates whether *A* is upper or lower triangular:
 If *uplo* = 'U', then *A* is upper triangular.
 If *uplo* = 'L', then *A* is lower triangular.

trans Must be 'N' or 'T' or 'C'.
 If *trans* = 'N', then $A * X = B$ is solved for *X*.
 If *trans* = 'T', then $A^T * X = B$ is solved for *X*.
 If *trans* = 'C', then $A^H * X = B$ is solved for *X*.

diag Must be 'N' or 'U'.
 If *diag* = 'N', then *A* is not a unit triangular matrix.
 If *diag* = 'U', then *A* is unit triangular: diagonal elements of *A* are assumed to be 1 and not referenced in the array *a*.

n The order of *A*; the number of rows in *B*; $n \geq 0$.

nrhs The number of right-hand sides; $nrhs \geq 0$.

a The array *a* contains the matrix *A*.
 The size of *a* is $\max(1, lda * n)$.

b The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations.
 The size of *b* is $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout.

lda The leading dimension of *a*; $lda \geq \max(1, n)$.

ldb The leading dimension of *b*; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

Output Parameters

b Overwritten by the solution matrix *X*.

Return Values

This function returns a value *info*.

If `info=0`, the execution is successful.

If `info = -i`, parameter `i` had an illegal value.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon |A|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision. If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon \text{ provided } c(n) \text{cond}(A, x)\varepsilon < 1$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \|A^{-1}\|_\infty \|A\|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector b is n^2 for real flavors and $4n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call `?trcon`.

To estimate the error in the solution, call `?trrfs`.

Description

The routine solves for X the following systems of linear equations with a packed triangular matrix A , with multiple right-hand sides stored in B :

$$A * X = B \quad \text{if } trans = 'N',$$

$$A^T * X = B \quad \text{if } trans = 'T',$$

$$A^H * X = B \quad \text{if } trans = 'C' \text{ (for complex matrices only).}$$

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <i>uplo</i> = 'U', then A is upper triangular. If <i>uplo</i> = 'L', then A is lower triangular. |
| <i>trans</i> | Must be 'N' or 'T' or 'C'. If <i>trans</i> = 'N', then $A * X = B$ is solved for X . If <i>trans</i> = 'T', then $A^T * X = B$ is solved for X . If <i>trans</i> = 'C', then $A^H * X = B$ is solved for X . |
| <i>diag</i> | Must be 'N' or 'U'. If <i>diag</i> = 'N', then A is not a unit triangular matrix. If <i>diag</i> = 'U', then A is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array <i>ap</i> . |
| <i>n</i> | The order of A ; the number of rows in B ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; $nrhs \geq 0$. |
| <i>ap</i> | The dimension of array <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>ap</i> contains the matrix A in <i>packed storage</i> (see Matrix Storage Schemes). |
| <i>b</i> | The array <i>b</i> contains the matrix B whose columns are the right-hand sides for the system of equations. The size of <i>b</i> is $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |

Output Parameters

| | |
|----------|--|
| <i>b</i> | Overwritten by the solution matrix X . |
|----------|--|

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

For each right-hand side *b*, the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon |A|$$

c(*n*) is a modest linear function of *n*, and ε is the machine precision.

If x_0 is the true solution, the computed solution *x* satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon \text{ provided } c(n) \text{cond}(A, x)\varepsilon < 1$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \|A^{-1}\|_\infty \|A\|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector *b* is n^2 for real flavors and $4n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?tpcon](#).

To estimate the error in the solution, call [?tprfs](#).

Description

The routine solves for X the following systems of linear equations with a band triangular matrix A , with multiple right-hand sides stored in B :

$$\begin{aligned}
 A * X &= B && \text{if } trans = 'N', \\
 A^T * X &= B && \text{if } trans = 'T', \\
 A^H * X &= B && \text{if } trans = 'C' \text{ (for complex matrices only).}
 \end{aligned}$$

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <i>uplo</i> = 'U', then A is upper triangular. If <i>uplo</i> = 'L', then A is lower triangular. |
| <i>trans</i> | Must be 'N' or 'T' or 'C'. If <i>trans</i> = 'N', then $A * X = B$ is solved for X . If <i>trans</i> = 'T', then $A^T * X = B$ is solved for X . If <i>trans</i> = 'C', then $A^H * X = B$ is solved for X . |
| <i>diag</i> | Must be 'N' or 'U'. If <i>diag</i> = 'N', then A is not a unit triangular matrix. If <i>diag</i> = 'U', then A is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array <i>ab</i> . |
| <i>n</i> | The order of A ; the number of rows in B ; $n \geq 0$. |
| <i>kd</i> | The number of superdiagonals or subdiagonals in the matrix A ; $kd \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; $nrhs \geq 0$. |
| <i>ab</i> | The array <i>ab</i> contains the matrix A in <i>band storage form</i> . The size of <i>ab</i> must be $\max(1, ldab * n)$ |
| <i>b</i> | The array <i>b</i> contains the matrix B whose columns are the right-hand sides for the systems of equations. The size of <i>b</i> is $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout. |
| <i>ldab</i> | The leading dimension of <i>ab</i> ; $ldab \geq kd + 1$. |

ldb The leading dimension of *b*; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

Output Parameters

b Overwritten by the solution matrix *X*.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

For each right-hand side *b*, the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon|A|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision. If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon \text{ provided } c(n) \text{cond}(A, x)\varepsilon < 1$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \|A^{-1}\|_\infty \|A\|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector *b* is $2n \cdot kd$ for real flavors and $8n \cdot kd$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?tbcon](#).

To estimate the error in the solution, call [?tbrfs](#).

[Matrix Storage Schemes for LAPACK Routines](#)

Estimating the Condition Number: LAPACK Computational Routines

This section describes the LAPACK routines for estimating the *condition number* of a matrix. The condition number is used for analyzing the errors in the solution of a system of linear equations (see [Error Analysis](#)). Since the condition number may be arbitrarily large when the matrix is nearly singular, the routines actually compute the *reciprocal* condition number.

[?gecon](#)

Estimates the reciprocal of the condition number of a general matrix in the 1-norm or the infinity-norm.

Syntax

```
lapack_int LAPACKE_sgecon( int matrix_layout, char norm, lapack_int n, const float* a,
lapack_int lda, float anorm, float* rcond );
```

```
lapack_int LAPACKE_dgecon( int matrix_layout, char norm, lapack_int n, const double* a,
lapack_int lda, double anorm, double* rcond );
```

```
lapack_int LAPACKE_cgecon( int matrix_layout, char norm, lapack_int n, const
lapack_complex_float* a, lapack_int lda, float anorm, float* rcond );
```

```
lapack_int LAPACKE_zgecon( int matrix_layout, char norm, lapack_int n, const
lapack_complex_double* a, lapack_int lda, double anorm, double* rcond );
```

Include Files

- mkl.h

Description

The routine estimates the reciprocal of the condition number of a general matrix A in the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty = \kappa_1(A^T) = \kappa_1(A^H).$$

An estimate is obtained for $\|A^{-1}\|$, and the reciprocal of the condition number is computed as $rcond = 1 / (\|A\| \|A^{-1}\|)$.

Before calling this routine:

- compute $anorm$ (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call [?getrf](#) to compute the LU factorization of A .

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>norm</i> | Must be '1' or 'O' or 'I'. If <i>norm</i> = '1' or 'O', then the routine estimates the condition number of matrix A in 1-norm. If <i>norm</i> = 'I', then the routine estimates the condition number of matrix A in infinity-norm. |
| <i>n</i> | The order of the matrix A ; $n \geq 0$. |
| <i>a</i> | The array a contains the LU -factored matrix A , as returned by ?getrf . |
| <i>anorm</i> | The norm of the <i>original</i> matrix A (see Description). |
| <i>lda</i> | The leading dimension of a ; $lda \geq \max(1, n)$. |

Output Parameters

| | |
|--------------|--|
| <i>rcond</i> | An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular. |
|--------------|--|

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than 10*r*. A call to this routine involves solving a number of systems of linear equations $A*x = b$ or $A^H*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2*n^2$ floating-point operations for real flavors and $8*n^2$ for complex flavors.

Description

The routine estimates the reciprocal of the condition number of a general band matrix *A* in the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty = \kappa_1(A^T) = \kappa_1(A^H).$$

An estimate is obtained for $\|A^{-1}\|$, and the reciprocal of the condition number is computed as $rcond = 1 / (\|A\| \|A^{-1}\|)$.

Before calling this routine:

- compute *anorm* (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call [?gbtrf](#) to compute the *LU* factorization of *A*.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>norm</i> | Must be '1' or 'O' or 'I'. If <i>norm</i> = '1' or 'O', then the routine estimates the condition number of matrix <i>A</i> in 1-norm. If <i>norm</i> = 'I', then the routine estimates the condition number of matrix <i>A</i> in infinity-norm. |
| <i>n</i> | The order of the matrix <i>A</i> ; $n \geq 0$. |
| <i>kl</i> | The number of subdiagonals within the band of <i>A</i> ; $kl \geq 0$. |
| <i>ku</i> | The number of superdiagonals within the band of <i>A</i> ; $ku \geq 0$. |
| <i>ldab</i> | The leading dimension of the array <i>ab</i> . ($ldab \geq 2*kl + ku + 1$). |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?gbtrf . |
| <i>ab</i> | The array <i>ab</i> of size $\max(1, ldab*n)$ contains the factored band matrix <i>A</i> , as returned by ?gbtrf . |
| <i>anorm</i> | The norm of the <i>original</i> matrix <i>A</i> (see Description). |

Output Parameters

| | |
|--------------|--|
| <i>rcond</i> | An estimate of the reciprocal of the condition number. The routine sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular. |
|--------------|--|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$ or $A^H*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n(ku + 2kl)$ floating-point operations for real flavors and $8n(ku + 2kl)$ for complex flavors.

Description

The routine estimates the reciprocal of the condition number of a real or complex tridiagonal matrix A in the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty$$

An estimate is obtained for $\|A^{-1}\|$, and the reciprocal of the condition number is computed as $rcond = 1 / (\|A\| \|A^{-1}\|)$.

Before calling this routine:

- compute $anorm$ (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call `?gttrf` to compute the LU factorization of A .

Input Parameters

| | |
|--------------------|---|
| <i>norm</i> | Must be '1' or 'O' or 'I'. If <i>norm</i> = '1' or 'O', then the routine estimates the condition number of matrix A in 1-norm. If <i>norm</i> = 'I', then the routine estimates the condition number of matrix A in infinity-norm. |
| <i>n</i> | The order of the matrix A ; $n \geq 0$. |
| <i>dl,d,du,du2</i> | Arrays: $dl(n-1)$, $d(n)$, $du(n-1)$, $du2(n-2)$. The array <i>dl</i> contains the $(n-1)$ multipliers that define the matrix L from the LU factorization of A as computed by <code>?gttrf</code> . The array <i>d</i> contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A . The array <i>du</i> contains the $(n-1)$ elements of the first superdiagonal of U . The array <i>du2</i> contains the $(n-2)$ elements of the second superdiagonal of U . |

ipiv Array, size (*n*). The array of pivot indices, as returned by `?gttrf`.

anorm The norm of the *original* matrix *A*(see *Description*).

Output Parameters

rcond An estimate of the reciprocal of the condition number. The routine sets *rcond*=0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime *rcond* is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than 10*r*. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

?pocon

Estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite matrix.

Syntax

```
lapack_int LAPACKE_spocon( int matrix_layout, char uplo, lapack_int n, const float* a,
lapack_int lda, float anorm, float* rcond );

lapack_int LAPACKE_dpocon( int matrix_layout, char uplo, lapack_int n, const double* a,
lapack_int lda, double anorm, double* rcond );

lapack_int LAPACKE_cpocon( int matrix_layout, char uplo, lapack_int n, const
lapack_complex_float* a, lapack_int lda, float anorm, float* rcond );

lapack_complex_double* a, lapack_int lda, double anorm, double* rcond );
```

Include Files

- mkl.h

Description

The routine estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite matrix *A*:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 \text{ (since } A \text{ is symmetric or Hermitian, } \kappa_\infty(A) = \kappa_1(A)\text{)}.$$

An estimate is obtained for $\|A^{-1}\|_1$, and the reciprocal of the condition number is computed as $rcond = 1 / (\|A\|_1 \|A^{-1}\|_1)$.

Before calling this routine:

- compute $anorm$ (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call `?potrf` to compute the Cholesky factorization of A .

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>uplo</code> | Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <code>uplo</code> = 'U', A is factored as $A = U^T * U$ for real flavors or $A = U^H * U$ for complex flavors, and U is stored. If <code>uplo</code> = 'L', A is factored as $A = L * L^T$ for real flavors or $A = L * L^H$ for complex flavors, and L is stored. |
| <code>n</code> | The order of the matrix A ; $n \geq 0$. |
| <code>a</code> | The array a of size $\max(1, lda * n)$ contains the factored matrix A , as returned by <code>?potrf</code> . |
| <code>lda</code> | The leading dimension of a ; $lda \geq \max(1, n)$. |
| <code>anorm</code> | The norm of the <i>original</i> matrix A (see <i>Description</i>). |

Output Parameters

| | |
|--------------------|--|
| <code>rcond</code> | An estimate of the reciprocal of the condition number. The routine sets <code>rcond</code> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <code>rcond</code> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular. |
|--------------------|--|

Return Values

This function returns a value `info`.

If `info` = 0, the execution is successful.

If `info` = $-i$, parameter i had an illegal value.

Application Notes

The computed `rcond` is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A * x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

Description

The routine estimates the reciprocal of the condition number of a packed symmetric (Hermitian) positive-definite matrix A :

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 \text{ (since } A \text{ is symmetric or Hermitian, } \kappa_\infty(A) = \kappa_1(A)\text{)}.$$

An estimate is obtained for $\|A^{-1}\|_1$, and the reciprocal of the condition number is computed as $rcond = 1 / (\|A\|_1 \|A^{-1}\|_1)$.

Before calling this routine:

- compute $anorm$ (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call `?pptrf` to compute the Cholesky factorization of A .

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If $uplo = 'U'$, A is factored as $A = U^T * U$ for real flavors or $A = U^H * U$ for complex flavors, and U is stored. If $uplo = 'L'$, A is factored as $A = L * L^T$ for real flavors or $A = L * L^H$ for complex flavors, and L is stored. |
| <i>n</i> | The order of the matrix A ; $n \geq 0$. |
| <i>ap</i> | The array ap contains the packed factored matrix A , as returned by <code>?pptrf</code> . The dimension of ap must be at least $\max(1, n(n+1)/2)$. |
| <i>anorm</i> | The norm of the <i>original</i> matrix A (see <i>Description</i>). |

Output Parameters

rcond An estimate of the reciprocal of the condition number. The routine sets *rcond* = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime *rcond* is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than 10*r*. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

Description

The routine estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite band matrix *A*:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 \text{ (since } A \text{ is symmetric or Hermitian, } \kappa_\infty(A) = \kappa_1(A)\text{)}.$$

An estimate is obtained for $\|A^{-1}\|_1$, and the reciprocal of the condition number is computed as $rcond = 1 / (\|A\|_1 \|A^{-1}\|_1)$.

Before calling this routine:

- compute *anorm* (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call [?pbtrf](#) to compute the Cholesky factorization of *A*.

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>uplo</code> | Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <code>uplo = 'U'</code> , A is factored as $A = U^T * U$ for real flavors or $A = U^H * U$ for complex flavors, and U is stored. If <code>uplo = 'L'</code> , A is factored as $A = L * L^T$ for real flavors or $A = L * L^H$ for complex flavors, and L is stored. |
| <code>n</code> | The order of the matrix A ; $n \geq 0$. |
| <code>kd</code> | The number of superdiagonals or subdiagonals in the matrix A ; $kd \geq 0$. |
| <code>ldab</code> | The leading dimension of the array <code>ab</code> . ($ldab \geq kd + 1$). |
| <code>ab</code> | The array <code>ab</code> of size $\max(1, ldab * n)$ contains the factored matrix A in band form, as returned by <code>?pbtrf</code> . |
| <code>anorm</code> | The norm of the <i>original</i> matrix A (see <i>Description</i>). |

Output Parameters

| | |
|--------------------|--|
| <code>rcond</code> | An estimate of the reciprocal of the condition number. The routine sets <code>rcond = 0</code> if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <code>rcond</code> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular. |
|--------------------|--|

Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, parameter i had an illegal value.

Application Notes

The computed `rcond` is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A * x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $4 * n * (kd + 1)$ floating-point operations for real flavors and $16 * n * (kd + 1)$ for complex flavors.

lapack_int LAPACKE_zptcon( lapack_int n, const double* d, const lapack_complex_double*
e, double anorm, double* rcond );
```

Include Files

- mkl.h

Description

The routine computes the reciprocal of the condition number (in the 1-norm) of a real symmetric or complex Hermitian positive-definite tridiagonal matrix using the factorization $A = L^*D^*L^T$ for real flavors and $A = L^*D^*L^H$ for complex flavors or $A = U^T*D^*U$ for real flavors and $A = U^H*D^*U$ for complex flavors computed by [?pttrf](#) :

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 \text{ (since } A \text{ is symmetric or Hermitian, } \kappa_\infty(A) = \kappa_1(A) \text{)}.$$

The norm $\|A^{-1}\|_1$ is computed by a direct method, and the reciprocal of the condition number is computed as $rcond = 1 / (\|A\|_1 \|A^{-1}\|_1)$.

Before calling this routine:

- compute *anorm* as $\|A\|_1 = \max_j \sum_i |a_{ij}|$
- call [?pttrf](#) to compute the factorization of *A*.

Input Parameters

| | |
|--------------|--|
| <i>n</i> | The order of the matrix <i>A</i> ; $n \geq 0$. |
| <i>d</i> | Arrays, dimension (<i>n</i>). The array <i>d</i> contains the <i>n</i> diagonal elements of the diagonal matrix <i>D</i> from the factorization of <i>A</i> , as computed by ?pttrf ; |
| <i>e</i> | Array, size (<i>n</i> - 1). Contains off-diagonal elements of the unit bidiagonal factor <i>U</i> or <i>L</i> from the factorization computed by ?pttrf . |
| <i>anorm</i> | The 1- norm of the <i>original</i> matrix <i>A</i> (see <i>Description</i>). |

Output Parameters

| | |
|--------------|--|
| <i>rcond</i> | An estimate of the reciprocal of the condition number. The routine sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular. |
|--------------|--|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $4*n*(kd + 1)$ floating-point operations for real flavors and $16*n*(kd + 1)$ for complex flavors.

?ssycon

Estimates the reciprocal of the condition number of a symmetric matrix.

Syntax

```
lapack_int LAPACKE_ssycon( int matrix_layout, char uplo, lapack_int n, const float* a,
lapack_int lda, const lapack_int* ipiv, float anorm, float* rcond );

lapack_int LAPACKE_dsycon( int matrix_layout, char uplo, lapack_int n, const double* a,
lapack_int lda, const lapack_int* ipiv, double anorm, double* rcond );

lapack_int LAPACKE_csycon( int matrix_layout, char uplo, lapack_int n, const
lapack_complex_float* a, lapack_int lda, const lapack_int* ipiv, float anorm, float*
rcond );

lapack_int LAPACKE_zsycon( int matrix_layout, char uplo, lapack_int n, const
lapack_complex_double* a, lapack_int lda, const lapack_int* ipiv, double anorm, double*
rcond );
```

Include Files

Description

The routine estimates the reciprocal of the condition number of a symmetric matrix A :

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 \text{ (since } A \text{ is symmetric, } \kappa_\infty(A) = \kappa_1(A)\text{)}.$$

An estimate is obtained for $\|A^{-1}\|_1$, and the reciprocal of the condition number is computed as $rcond = 1 / (\|A\|_1 \|A^{-1}\|_1)$.

Before calling this routine:

- compute $anorm$ (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call [?sytrf](#) to compute the factorization of A .

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If $uplo = 'U'$, the array a stores the upper triangular factor U of the factorization $A = U*D*U^T$. If $uplo = 'L'$, the array a stores the lower triangular factor L of the factorization $A = L*D*L^T$. |

| | |
|--------------|--|
| <i>n</i> | The order of matrix <i>A</i> ; $n \geq 0$. |
| <i>a</i> | The array <i>a</i> of size $\max(1, lda * n)$ contains the factored matrix <i>A</i> , as returned by <code>?sytrf</code> . |
| <i>lda</i> | The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$. |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. The array <i>ipiv</i> , as returned by <code>?sytrf</code> . |
| <i>anorm</i> | The norm of the <i>original</i> matrix <i>A</i> (see <i>Description</i>). |

Output Parameters

| | |
|--------------|--|
| <i>rcond</i> | An estimate of the reciprocal of the condition number. The routine sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular. |
|--------------|--|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than 10*r*. A call to this routine involves solving a number of systems of linear equations $A * x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

Description

The routine estimates the reciprocal of the condition number of a packed triangular matrix *A* in either the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty = \kappa_1(A^T) = \kappa_1(A^H).$$

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

norm Must be '1' or 'O' or 'I'.

If *norm* = '1' or 'O', then the routine estimates the condition number of matrix *A* in 1-norm.

If *norm* = 'I', then the routine estimates the condition number of matrix *A* in infinity-norm.

| | |
|-------------|--|
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether <i>A</i> is upper or lower triangular: If <i>uplo</i> = 'U', the array <i>ap</i> stores the upper triangle of <i>A</i> in packed form. If <i>uplo</i> = 'L', the array <i>ap</i> stores the lower triangle of <i>A</i> in packed form. |
| <i>diag</i> | Must be 'N' or 'U'. If <i>diag</i> = 'N', then <i>A</i> is not a unit triangular matrix. If <i>diag</i> = 'U', then <i>A</i> is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array <i>ap</i> . |
| <i>n</i> | The order of the matrix <i>A</i> ; $n \geq 0$. |
| <i>ap</i> | The array <i>ap</i> contains the packed matrix <i>A</i> . The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. |

Output Parameters

| | |
|--------------|--|
| <i>rcond</i> | An estimate of the reciprocal of the condition number. The routine sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular. |
|--------------|--|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than 10*r*. A call to this routine involves solving a number of systems of linear equations $A \cdot x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately n^2 floating-point operations for real flavors and $4n^2$ operations for complex flavors.

Description

The routine estimates the reciprocal of the condition number of a triangular band matrix A in either the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty = \kappa_1(A^T) = \kappa_1(A^H).$$

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>norm</i> | Must be '1' or 'O' or 'I'. If <i>norm</i> = '1' or 'O', then the routine estimates the condition number of matrix A in 1-norm. If <i>norm</i> = 'I', then the routine estimates the condition number of matrix A in infinity-norm. |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <i>uplo</i> = 'U', the array <i>ap</i> stores the upper triangle of A in packed form. If <i>uplo</i> = 'L', the array <i>ap</i> stores the lower triangle of A in packed form. |
| <i>diag</i> | Must be 'N' or 'U'. If <i>diag</i> = 'N', then A is not a unit triangular matrix. If <i>diag</i> = 'U', then A is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array <i>ab</i> . |
| <i>n</i> | The order of the matrix A ; $n \geq 0$. |
| <i>kd</i> | The number of superdiagonals or subdiagonals in the matrix A ; $kd \geq 0$. |
| <i>ab</i> | The array <i>ab</i> of size $\max(1, ldab * n)$ contains the band matrix A . |
| <i>ldab</i> | The leading dimension of the array <i>ab</i> . ($ldab \geq kd + 1$). |

Output Parameters

| | |
|--------------|--|
| <i>rcond</i> | An estimate of the reciprocal of the condition number. The routine sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular. |
|--------------|--|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than 10*r*. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2*n(kd + 1)$ floating-point operations for real flavors and $8*n(kd + 1)$ operations for complex flavors.

Refining the Solution and Estimating Its Error: LAPACK Computational Routines

This section describes the LAPACK routines for refining the computed solution of a system of linear equations and estimating the solution error. You can call these routines after factorizing the matrix of the system of equations and computing the solution (see [Routines for Matrix Factorization](#) and [Routines for Solving Systems of Linear Equations](#)).

?gerfs

Refines the solution of a system of linear equations with a general coefficient matrix and estimates its error.

Syntax

```
lapack_int LAPACKE_sgerfs( int matrix_layout, char trans, lapack_int n, lapack_int
nrhs, const float* a, lapack_int lda, const float* af, lapack_int ldaf, const
lapack_int* ipiv, const float* b, lapack_int ldb, float* x, lapack_int ldx, float*
ferr, float* berr );
```

```
lapack_int LAPACKE_dgerfs( int matrix_layout, char trans, lapack_int n, lapack_int
nrhs, const double* a, lapack_int lda, const double* af, lapack_int ldaf, const
lapack_int* ipiv, const double* b, lapack_int ldb, double* x, lapack_int ldx, double*
ferr, double* berr );
```

```
lapack_int LAPACKE_cgerfs( int matrix_layout, char trans, lapack_int n, lapack_int
nrhs, const lapack_complex_float* a, lapack_int lda, const lapack_complex_float* af,
lapack_int ldaf, const lapack_int* ipiv, const lapack_complex_float* b, lapack_int ldb,
lapack_complex_float* x, lapack_int ldx, float* ferr, float* berr );
```

```
lapack_int LAPACKE_zgerfs( int matrix_layout, char trans, lapack_int n, lapack_int
nrhs, const lapack_complex_double* a, lapack_int lda, const lapack_complex_double* af,
lapack_int ldaf, const lapack_int* ipiv, const lapack_complex_double* b, lapack_int
ldb, lapack_complex_double* x, lapack_int ldx, double* ferr, double* berr );
```

Include Files

- mkl.h

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A^*X = B$ or $A^T*X = B$ or $A^H*X = B$ with a general matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \quad \text{such that} \quad (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?getrf](#)
- call the solver routine [?getrs](#).

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>trans</code> | Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <code>trans</code> = 'N', the system has the form $A^*X = B$. If <code>trans</code> = 'T', the system has the form $A^T*X = B$. If <code>trans</code> = 'C', the system has the form $A^H*X = B$. |
| <code>n</code> | The order of the matrix A ; $n \geq 0$. |
| <code>nrhs</code> | The number of right-hand sides; $nrhs \geq 0$. |
| <code>a,af,b,x</code> | Arrays: <code>a</code> (size $\max(1, lda*n)$) contains the original matrix A , as supplied to ?getrf . <code>af</code> (size $\max(1, ldaf*n)$) contains the factored matrix A , as returned by ?getrf . <code>b</code> of size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout contains the right-hand side matrix B . <code>x</code> of size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout contains the solution matrix X . |
| <code>lda</code> | The leading dimension of <code>a</code> ; $lda \geq \max(1, n)$. |
| <code>ldaf</code> | The leading dimension of <code>af</code> ; $ldaf \geq \max(1, n)$. |
| <code>ldb</code> | The leading dimension of <code>b</code> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <code>ldx</code> | The leading dimension of <code>x</code> ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |
| <code>ipiv</code> | Array, size at least $\max(1, n)$. The <code>ipiv</code> array, as returned by ?getrf . |

Output Parameters

| | |
|--------------|---|
| x | The refined solution matrix X . |
| $ferr, berr$ | Arrays, size at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector. |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward error involves solving a number of systems of linear equations $A*x = b$ with the same coefficient matrix A and different right hand sides b ; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

Description

The routine improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution. In addition to a normwise error bound, the code provides a maximum componentwise error bound, if possible. See comments for *err_bnds_norm* and *err_bnds_comp* for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described by the parameters *equed*, *r*, and *c* below. In this case, the solution and error bounds returned are for the original unequilibrated system.

Input Parameters

| | |
|---------------------------------|---|
| <i>matrix_layout</i> | Specifies whether two-dimensional array storage is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>trans</i> | Must be 'N', 'T', or 'C'. Specifies the form of the system of equations: If <i>trans</i> = 'N', the system has the form $A^*X = B$ (No transpose). If <i>trans</i> = 'T', the system has the form $A^T X = B$ (Transpose). If <i>trans</i> = 'C', the system has the form $A^H X = B$ (Conjugate transpose for complex flavors, Transpose for real flavors). |
| <i>equed</i> | Must be 'N', 'R', 'C', or 'B'. Specifies the form of equilibration that was done to <i>A</i> before calling this routine. If <i>equed</i> = 'N', no equilibration was done. If <i>equed</i> = 'R', row equilibration was done, that is, <i>A</i> has been premultiplied by <i>diag(r)</i> . If <i>equed</i> = 'C', column equilibration was done, that is, <i>A</i> has been postmultiplied by <i>diag(c)</i> . If <i>equed</i> = 'B', both row and column equilibration was done, that is, <i>A</i> has been replaced by $diag(r) * A * diag(c)$. The right-hand side <i>B</i> has been changed accordingly. |
| <i>n</i> | The number of linear equations; the order of the matrix <i>A</i> ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; the number of columns of the matrices <i>B</i> and <i>X</i> ; $nrhs \geq 0$. |
| <i>a</i> , <i>af</i> , <i>b</i> | Arrays: <i>a</i> (size $\max(1, lda * n)$), <i>af</i> (size $\max(1, ldaf * n)$), <i>b</i> (size $\max(1, ldb * nrhs)$) for column major layout and $\max(1, ldb * n)$ for row major layout). The array <i>a</i> contains the original <i>n</i> -by- <i>n</i> matrix <i>A</i> . |

The array *af* contains the factored form of the matrix *A*, that is, the factors *L* and *U* from the factorization $A = P * L * U$ as computed by `?getrf`.

The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations.

| | |
|-------------------|--|
| <i>lda</i> | The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$. |
| <i>ldaf</i> | The leading dimension of <i>af</i> ; $ldaf \geq \max(1, n)$. |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. Contains the pivot indices as computed by <code>?getrf</code> ; for row $1 \leq i \leq n$, row <i>i</i> of the matrix was interchanged with row <i>ipiv</i> (<i>i</i>). |
| <i>r, c</i> | <p>Arrays: <i>r</i> (size <i>n</i>), <i>c</i> (size <i>n</i>). The array <i>r</i> contains the row scale factors for <i>A</i>, and the array <i>c</i> contains the column scale factors for <i>A</i>.</p> <p><i>equed</i> = 'R' or 'B', <i>A</i> is multiplied on the left by <i>diag</i>(<i>r</i>); if <i>equed</i> = 'N' or 'C', <i>r</i> is not accessed.</p> <p>If <i>equed</i> = 'R' or 'B', each element of <i>r</i> must be positive.</p> <p>If <i>equed</i> = 'C' or 'B', <i>A</i> is multiplied on the right by <i>diag</i>(<i>c</i>); if <i>equed</i> = 'N' or 'R', <i>c</i> is not accessed.</p> <p>If <i>equed</i> = 'C' or 'B', each element of <i>c</i> must be positive.</p> <p>Each element of <i>r</i> or <i>c</i> should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.</p> |
| <i>ldb</i> | The leading dimension of the array <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>x</i> | <p>Array, of size $\max(1, ldx * nrhs)$ for column major layout and $\max(1, ldx * n)$ for row major layout.</p> <p>The solution matrix <i>X</i> as computed by <code>?getrs</code></p> |
| <i>ldx</i> | The leading dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |
| <i>n_err_bnds</i> | Number of error bounds to return for each right hand side and each type (normwise or componentwise). See <i>err_bnds_norm</i> and <i>err_bnds_comp</i> descriptions in <i>Output Arguments</i> section below. |
| <i>nparams</i> | Specifies the number of parameters set in <i>params</i> . If ≤ 0 , the <i>params</i> array is never referenced and default values are used. |
| <i>params</i> | <p>Array, size <i>nparams</i>. Specifies algorithm parameters. If an entry is less than 0.0, that entry is filled with the default value used for that parameter. Only positions up to <i>nparams</i> are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass <i>nparams</i> = 0, which prevents the source code from accessing the <i>params</i> argument.</p> <p><i>params</i>[0] : Whether to perform iterative refinement or not. Default: 1.0</p> |

| | |
|------|--|
| =0.0 | No refinement is performed and no error bounds are computed. |
| =1.0 | Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support double precision. |

(Other values are reserved for future use.)

params[1] : Maximum number of residual computations allowed for refinement.

Default 10.0

Aggressive Set to 100.0 to permit convergence using approximate factorizations or factorizations other than *LU*. If the factorization uses a technique other than Gaussian elimination, the guarantees in *err_bnds_norm* and *err_bnds_comp* may no longer be trustworthy.

params[2] : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

Output Parameters

| | |
|----------------------|--|
| <i>x</i> | The improved solution matrix <i>X</i> . |
| <i>rcond</i> | Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision, in particular, if <i>rcond</i> = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned. |
| <i>berr</i> | Array, size at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector x_j , that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes x_j an exact solution. |
| <i>err_bnds_norm</i> | Array of size $nrhs * n_err_bnds$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows: |

Normwise relative error in the *i*-th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

- `err=1` "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.
- `err=2` "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.
- `err=3` Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix Z are:

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z=s*a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

The information for right-hand side i , where $1 \leq i \leq nrhs$, and type of error `err` is stored in:

- Column major layout: `err_bnds_norm[(err - 1)*nrhs + i - 1]`.
- Row major layout: `err_bnds_norm[err - 1 + (i - 1)*n_err_bnds]`

`err_bnds_comp`

Array of size `nrhs*n_err_bnds`. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (`params[2] = 0.0`), then `err_bnds_comp` is not accessed. If `n_err_bnds < 3`, then at most the first `n_err_bnds` columns of the `err_bnds_comp` array are returned.

| | |
|--------------|--|
| <i>err=1</i> | "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. |
| <i>err=2</i> | "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true. |
| <i>err=3</i> | Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix Z are: |

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

The information for right-hand side i , where $1 \leq i \leq \text{nrhs}$, and type of error *err* is stored in:

- Column major layout: $\text{err_bnds_comp}[(\text{err} - 1) * \text{nrhs} + i - 1]$.
- Row major layout: $\text{err_bnds_comp}[\text{err} - 1 + (i - 1) * n_err_bnds]$

params

Output parameter only if the input contains erroneous values, namely, in $\text{params}[0]$, $\text{params}[1]$, $\text{params}[2]$. In such a case, the corresponding elements of *params* are filled with default values on output.

Return Values

This function returns a value *info*.

If $\text{info} = 0$, the execution is successful. The solution to every right-hand side is guaranteed.

If $\text{info} = -i$, parameter i had an illegal value.

If $0 < \text{info} \leq n$: $U_{\text{info}, \text{info}}$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; $\text{rcond} = 0$ is returned.

If $\text{info} = n+j$: The solution corresponding to the j -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested $\text{params}[2] = 0.0$, then the j -th

right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that for column major layout $err_bnds_norm[j - 1] = 0.0$ or $err_bnds_comp[j - 1] = 0.0$; or for row major layout $err_bnds_norm[(j - 1)*n_err_bnds] = 0.0$ or $err_bnds_comp[(j - 1)*n_err_bnds] = 0.0$). See the definition of err_bnds_norm and err_bnds_comp for $err = 1$. To get information about all of the right-hand sides, check err_bnds_norm or err_bnds_comp .

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A*X = B$ or $A^T*X = B$ or $A^H*X = B$ with a band matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \quad \text{such that} \quad (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?gbtrf](#)
- call the solver routine [?gbtrs](#).

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>trans</i> | Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', the system has the form $A * X = B$. If <i>trans</i> = 'T', the system has the form $A^T * X = B$. If <i>trans</i> = 'C', the system has the form $A^H * X = B$. |
| <i>n</i> | The order of the matrix <i>A</i> ; $n \geq 0$. |
| <i>kl</i> | The number of sub-diagonals within the band of <i>A</i> ; $kl \geq 0$. |
| <i>ku</i> | The number of super-diagonals within the band of <i>A</i> ; $ku \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; $nrhs \geq 0$. |
| <i>ab,afb,b,x</i> | Arrays: <i>ab</i> (size $\max(1, ldab * n)$) contains the original band matrix <i>A</i> , as supplied to <code>?gbtrf</code> , but stored in rows from 1 to $kl + ku + 1$ for column major layout, and columns from 1 to $kl + ku + 1$ for row major layout. <i>afb</i> (size $\max(1, ldafb * n)$) contains the factored band matrix <i>A</i> , as returned by <code>?gbtrf</code> . <i>b</i> of size $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout contains the right-hand side matrix <i>B</i> . <i>x</i> of size $\max(1, ldx * nrhs)$ for column major layout and $\max(1, ldx * n)$ for row major layout contains the solution matrix <i>X</i> . |
| <i>ldab</i> | The leading dimension of <i>ab</i> , $ldab \geq kl + ku + 1$. |
| <i>ldaafb</i> | The leading dimension of <i>afb</i> , $ldaafb \geq 2 * kl + ku + 1$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>ldx</i> | The leading dimension of <i>x</i> ; $ldx \geq \max(1, n)$. |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. The <i>ipiv</i> array, as returned by <code>?gbtrf</code> . |

Output Parameters

| | |
|-------------------|---|
| <i>x</i> | The refined solution matrix <i>X</i> . |
| <i>ferr, berr</i> | Arrays, size at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector. |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n(kl + ku)$ floating-point operations (for real flavors) or $16n(kl + ku)$ operations (for complex flavors). In addition, each step of iterative refinement involves $2n(4kl + 3ku)$ operations (for real flavors) or $8n(4kl + 3ku)$ operations (for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward error involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

Description

The routine improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution. In addition to a normwise error bound, the code provides a maximum componentwise error bound, if possible. See comments for `err_bnds_norm` and `err_bnds_comp` for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described by the parameters `equed`, `r`, and `c` below. In this case, the solution and error bounds returned are for the original unequilibrated system.

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether two-dimensional array storage is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>trans</code> | Must be 'N', 'T', or 'C'. Specifies the form of the system of equations: If <code>trans</code> = 'N', the system has the form $A^*X = B$ (No transpose). If <code>trans</code> = 'T', the system has the form $A^T * X = B$ (Transpose). If <code>trans</code> = 'C', the system has the form $A^H * X = B$ (Conjugate transpose for complex flavors, Transpose for real flavors). |
| <code>equed</code> | Must be 'N', 'R', 'C', or 'B'. Specifies the form of equilibration that was done to A before calling this routine. If <code>equed</code> = 'N', no equilibration was done. If <code>equed</code> = 'R', row equilibration was done, that is, A has been premultiplied by $diag(r)$. If <code>equed</code> = 'C', column equilibration was done, that is, A has been postmultiplied by $diag(c)$. If <code>equed</code> = 'B', both row and column equilibration was done, that is, A has been replaced by $diag(r) * A * diag(c)$. The right-hand side B has been changed accordingly. |
| <code>n</code> | The number of linear equations; the order of the matrix A ; $n \geq 0$. |
| <code>kl</code> | The number of subdiagonals within the band of A ; $kl \geq 0$. |
| <code>ku</code> | The number of superdiagonals within the band of A ; $ku \geq 0$. |
| <code>nrhs</code> | The number of right-hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$. |
| <code>ab,afb,b</code> | The array <code>ab</code> of size $\max(1, ldab * n)$ contains the original matrix A in band storage, in rows from 1 to $kl + ku + 1$ for column major layout, and in columns from 1 to $kl + ku + 1$ for row major layout. |

| | |
|-------------------|---|
| | <p>The array <i>afb</i> of size $\max(1, l_{dafb} * n)$ contains details of the LU factorization of the banded matrix <i>A</i> as computed by <code>?gbtrf</code>.</p> <p>The array <i>b</i> of size $\max(1, l_{db} * nrhs)$ for column major layout and $\max(1, l_{db} * n)$ for row major layout contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations.</p> |
| <i>ldab</i> | The leading dimension of the array <i>ab</i> ; $ldab \geq kl + ku + 1$. |
| <i>ldafb</i> | The leading dimension of the array <i>afb</i> ; $ldafb \geq 2 * kl + ku + 1$. |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. Contains the pivot indices as computed by <code>?gbtrf</code> ; for row $1 \leq i \leq n$, row <i>i</i> of the matrix was interchanged with row <i>ipiv</i> [<i>i</i> -1]. |
| <i>r, c</i> | <p>Arrays: <i>r</i>(<i>n</i>), <i>c</i>(<i>n</i>). The array <i>r</i> contains the row scale factors for <i>A</i>, and the array <i>c</i> contains the column scale factors for <i>A</i>.</p> <p>If <i>equed</i> = 'R' or 'B', <i>A</i> is multiplied on the left by <i>diag</i>(<i>r</i>); if <i>equed</i> = 'N' or 'C', <i>r</i> is not accessed.</p> <p>If <i>equed</i> = 'R' or 'B', each element of <i>r</i> must be positive.</p> <p>If <i>equed</i> = 'C' or 'B', <i>A</i> is multiplied on the right by <i>diag</i>(<i>c</i>); if <i>equed</i> = 'N' or 'R', <i>c</i> is not accessed.</p> <p>If <i>equed</i> = 'C' or 'B', each element of <i>c</i> must be positive.</p> <p>Each element of <i>r</i> or <i>c</i> should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.</p> |
| <i>ldb</i> | The leading dimension of the array <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>x</i> | <p>Array, size $\max(1, l_{dx} * nrhs)$ for column major layout and $\max(1, l_{dx} * n)$ for row major layout.</p> <p>The solution matrix <i>X</i> as computed by <code>sgbtrs/dgbtrs</code> for real flavors or <code>cgbtrs/zgbtrs</code> for complex flavors.</p> |
| <i>ldx</i> | The leading dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |
| <i>n_err_bnds</i> | Number of error bounds to return for each right-hand side and each type (normwise or componentwise). See <i>err_bnds_norm</i> and <i>err_bnds_comp</i> descriptions in <i>Output Arguments</i> section below. |
| <i>nparams</i> | Specifies the number of parameters set in <i>params</i> . If ≤ 0 , the <i>params</i> array is never referenced and default values are used. |
| <i>params</i> | Array, size <i>nparams</i> . Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with the default value used for that parameter. Only positions up to <i>nparams</i> are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass <i>nparams</i> = 0, which prevents the source code from accessing the <i>params</i> argument. |

params[0] : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).

=0.0 No refinement is performed and no error bounds are computed.

=1.0 Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support double precision.

(Other values are reserved for future use.)

params[1] : Maximum number of residual computations allowed for refinement.

Default 10.0

Aggressive Set to 100.0 to permit convergence using approximate factorizations or factorizations other than *LU*. If the factorization uses a technique other than Gaussian elimination, the guarantees in *err_bnds_norm* and *err_bnds_comp* may no longer be trustworthy.

params[2] : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

Output Parameters

x The improved solution matrix *X*.

rcond Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix *A* after equilibration (if done). If *rcond* is less than the machine precision, in particular, if *rcond* = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

berr Array, size at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector x_j , that is, the smallest relative change in any element of *A* or *B* that makes x_j an exact solution.

err_bnds_norm Array of size $nrhs * n_err_bnds$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the *i*-th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.

err=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

err=3 Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix *Z* are

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z = s * a$, where *s* scales each row by a power of the radix so all absolute row sums of *z* are approximately 1.

The information for right-hand side *i*, where $1 \leq i \leq nrhs$, and type of error *err* is stored in:

- Column major layout: *err_bnds_norm*[(*err* - 1) * *nrhs* + *i* - 1].
- Row major layout: *err_bnds_norm*[*err* - 1 + (*i* - 1) * *n_err_bnds*]

err_bnds_comp

Array of size *nrhs* * *n_err_bnds*. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the *i*-th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (*params*[2] = 0.0), then *err_bnds_comp* is not accessed.

| | |
|--------------|---|
| <i>err=1</i> | "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. |
| <i>err=2</i> | "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true. |
| <i>err=3</i> | Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix Z are |

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

The information for right-hand side i , where $1 \leq i \leq \text{nrhs}$, and type of error *err* is stored in:

- Column major layout: $\text{err_bnds_comp}[(\text{err} - 1) * \text{nrhs} + i - 1]$.
- Row major layout: $\text{err_bnds_comp}[\text{err} - 1 + (i - 1) * n_err_bnds]$

params

Output parameter only if the input contains erroneous values, namely, in $\text{params}[0]$, $\text{params}[1]$, and $\text{params}[2]$. In such a case, the corresponding elements of *params* are filled with default values on output.

Return Values

This function returns a value *info*.

If $\text{info} = 0$, the execution is successful. The solution to every right-hand side is guaranteed.

If $\text{info} = -i$, parameter i had an illegal value.

If $0 < \text{info} \leq n$: $U_{\text{info}, \text{info}}$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; $\text{rcond} = 0$ is returned.

If $\text{info} = n+j$: The solution corresponding to the j -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested $\text{params}[2] = 0.0$, then the j -th

right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that for column major layout $err_bnds_norm[j - 1] = 0.0$ or $err_bnds_comp[j - 1] = 0.0$; or for row major layout $err_bnds_norm[(j - 1)*n_err_bnds] = 0.0$ or $err_bnds_comp[(j - 1)*n_err_bnds] = 0.0$). See the definition of err_bnds_norm and err_bnds_comp for $err = 1$. To get information about all of the right-hand sides, check err_bnds_norm or err_bnds_comp .

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A*X = B$ or $A^T*X = B$ or $A^H*X = B$ with a tridiagonal matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}|/|a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i|/|b_i| \leq \beta |b_i| \quad \text{such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?gttrf](#)

- call the solver routine `?gttrs`.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>trans</i> | Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', the system has the form $A * X = B$. If <i>trans</i> = 'T', the system has the form $A^T * X = B$. If <i>trans</i> = 'C', the system has the form $A^H * X = B$. |
| <i>n</i> | The order of the matrix <i>A</i> ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides, that is, the number of columns of the matrix <i>B</i> ; $nrhs \geq 0$. |
| <i>dl</i> | Array <i>dl</i> of size $n - 1$ contains the subdiagonal elements of <i>A</i> . |
| <i>d</i> | Array <i>d</i> of size n contains the diagonal elements of <i>A</i> . |
| <i>du</i> | Array <i>du</i> of size $n - 1$ contains the superdiagonal elements of <i>A</i> . |
| <i>dlf</i> | Array <i>dlf</i> of size $n - 1$ contains the $(n - 1)$ multipliers that define the matrix <i>L</i> from the <i>LU</i> factorization of <i>A</i> as computed by <code>?gttrf</code> . |
| <i>df</i> | Array <i>df</i> of size n contains the n diagonal elements of the upper triangular matrix <i>U</i> from the <i>LU</i> factorization of <i>A</i> . |
| <i>duf</i> | Array <i>duf</i> of size $n - 1$ contains the $(n - 1)$ elements of the first superdiagonal of <i>U</i> . |
| <i>du2</i> | Array <i>du2</i> of size $n - 2$ contains the $(n - 2)$ elements of the second superdiagonal of <i>U</i> . |
| <i>b</i> | Array <i>b</i> (size $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout) contains the right-hand side matrix <i>B</i> . |
| <i>x</i> | Array <i>x</i> (size $\max(1, ldx * nrhs)$ for column major layout and $\max(1, ldx * n)$) contains the solution matrix <i>X</i> , as computed by <code>?gttrs</code> . |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>ldx</i> | The leading dimension of <i>x</i> ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. The <i>ipiv</i> array, as returned by <code>?gttrf</code> . |

Output Parameters

| | |
|----------|--|
| <i>x</i> | The refined solution matrix <i>X</i> . |
|----------|--|

ferr, berr Arrays, size at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A \cdot X = B$ with a symmetric (Hermitian) positive definite matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A) x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?potrf](#)
- call the solver routine [?potrs](#).

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored. If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored. |
| <i>n</i> | The order of the matrix <i>A</i> ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; $nrhs \geq 0$. |
| <i>a</i> | Array <i>a</i> (size $\max(1, lda * n)$) contains the original matrix <i>A</i> , as supplied to <code>?potrf</code> . |
| <i>af</i> | Array <i>af</i> (size $\max(1, ldaf * n)$) contains the factored matrix <i>A</i> , as returned by <code>?potrf</code> . |
| <i>b</i> | Array <i>b</i> of size $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout contains the right-hand side matrix <i>B</i> . The second dimension of <i>b</i> must be at least $\max(1, nrhs)$. |
| <i>x</i> | Array <i>x</i> of size $\max(1, ldx * nrhs)$ for column major layout and $\max(1, ldx * n)$ for row major layout contains the solution matrix <i>X</i> . |
| <i>lda</i> | The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$. |
| <i>ldaf</i> | The leading dimension of <i>af</i> ; $ldaf \geq \max(1, n)$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>ldx</i> | The leading dimension of <i>x</i> ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |

Output Parameters

| | |
|-------------------|---|
| <i>x</i> | The refined solution matrix <i>X</i> . |
| <i>ferr, berr</i> | Arrays, size at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector. |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward error involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

Description

The routine improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution. In addition to a normwise error bound, the code provides a maximum componentwise error bound, if possible. See comments for *err_bnds_norm* and *err_bnds_comp* for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described by the parameters *equed* and *s* below. In this case, the solution and error bounds returned are for the original unequilibrated system.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether two-dimensional array storage is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored. |
| <i>equed</i> | Must be 'N' or 'Y'. Specifies the form of equilibration that was done to A before calling this routine. If <i>equed</i> = 'N', no equilibration was done. If <i>equed</i> = 'Y', both row and column equilibration was done, that is, A has been replaced by $diag(s) * A * diag(s)$. The right-hand side B has been changed accordingly. |
| <i>n</i> | The number of linear equations; the order of the matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$. |
| <i>a</i> | The array <i>a</i> (size $\max(1, lda * n)$) contains the symmetric/Hermitian matrix A as specified by <i>uplo</i> . If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of <i>a</i> contains the upper triangular part of the matrix A and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of <i>a</i> contains the lower triangular part of the matrix A and the strictly upper triangular part of <i>a</i> is not referenced. |
| <i>af</i> | The array <i>af</i> (size $\max(1, ldaf * n)$) contains the triangular factor L or U from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ as computed by spotrf for real flavors or dspotrf for complex flavors. |
| <i>b</i> | The array <i>b</i> (size $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout) contains the matrix B whose columns are the right-hand sides for the systems of equations. |
| <i>lda</i> | The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$. |
| <i>ldaf</i> | The leading dimension of <i>af</i> ; $ldaf \geq \max(1, n)$. |
| <i>s</i> | Array of size n . The array <i>s</i> contains the scale factors for A . If <i>equed</i> = 'N', <i>s</i> is not accessed. If <i>equed</i> = 'Y', each element of <i>s</i> must be positive. Each element of <i>s</i> should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable. |

| | | | | | | | | | |
|-------------------|---|------|--|------|--|---------|------|------------|---|
| <i>ldb</i> | The leading dimension of the array <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. | | | | | | | | |
| <i>x</i> | <p>Array, size $\max(1, ldx * nrhs)$ for column major layout and $\max(1, ldx * n)$ for row major layout.</p> <p>The solution matrix <i>X</i> as computed by <code>?potrs</code></p> | | | | | | | | |
| <i>ldx</i> | The leading dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. | | | | | | | | |
| <i>n_err_bnds</i> | Number of error bounds to return for each right hand side and each type (normwise or componentwise). See <i>err_bnds_norm</i> and <i>err_bnds_comp</i> descriptions in <i>Output Arguments</i> section below. | | | | | | | | |
| <i>nparams</i> | Specifies the number of parameters set in <i>params</i> . If ≤ 0 , the <i>params</i> array is never referenced and default values are used. | | | | | | | | |
| <i>params</i> | <p>Array, size <i>nparams</i>. Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with the default value used for that parameter. Only positions up to <i>nparams</i> are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass <i>nparams</i> = 0, which prevents the source code from accessing the <i>params</i> argument.</p> <p><i>params</i>[0] : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;">=0.0</td> <td>No refinement is performed and no error bounds are computed.</td> </tr> <tr> <td style="padding-right: 20px;">=1.0</td> <td>Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support double precision.</td> </tr> </table> <p>(Other values are reserved for future use.)</p> <p><i>params</i>[1] : Maximum number of residual computations allowed for refinement.</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;">Default</td> <td>10.0</td> </tr> <tr> <td style="padding-right: 20px;">Aggressive</td> <td>Set to 100.0 to permit convergence using approximate factorizations or factorizations other than <i>LU</i>. If the factorization uses a technique other than Gaussian elimination, the guarantees in <i>err_bnds_norm</i> and <i>err_bnds_comp</i> may no longer be trustworthy.</td> </tr> </table> <p><i>params</i>[2] : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).</p> | =0.0 | No refinement is performed and no error bounds are computed. | =1.0 | Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support double precision. | Default | 10.0 | Aggressive | Set to 100.0 to permit convergence using approximate factorizations or factorizations other than <i>LU</i> . If the factorization uses a technique other than Gaussian elimination, the guarantees in <i>err_bnds_norm</i> and <i>err_bnds_comp</i> may no longer be trustworthy. |
| =0.0 | No refinement is performed and no error bounds are computed. | | | | | | | | |
| =1.0 | Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support double precision. | | | | | | | | |
| Default | 10.0 | | | | | | | | |
| Aggressive | Set to 100.0 to permit convergence using approximate factorizations or factorizations other than <i>LU</i> . If the factorization uses a technique other than Gaussian elimination, the guarantees in <i>err_bnds_norm</i> and <i>err_bnds_comp</i> may no longer be trustworthy. | | | | | | | | |

Output Parameters

| | |
|----------------------|--|
| <i>x</i> | The improved solution matrix X . |
| <i>rcond</i> | Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If <i>rcond</i> is less than the machine precision, in particular, if <i>rcond</i> = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned. |
| <i>berr</i> | Array, size at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector x_j , that is, the smallest relative change in any element of A or B that makes x_j an exact solution. |
| <i>err_bnds_norm</i> | <p>Array of size $nrhs * n_err_bnds$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:</p> <p>Normwise relative error in the i-th solution vector</p> $\frac{\max_j X_{true_{ji}} - X_{ji} }{\max_j X_{ji} }$ <p>The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.</p> |
| <i>err=1</i> | "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors. |
| <i>err=2</i> | "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true. |
| <i>err=3</i> | Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix Z are |

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

The information for right-hand side i , where $1 \leq i \leq nrhs$, and type of error err is stored in:

- Column major layout: $err_bnds_norm[(err - 1) * nrhs + i - 1]$.
- Row major layout: $err_bnds_norm[err - 1 + (i - 1) * n_err_bnds]$

`err_bnds_comp`

Array of size $nrhs * n_err_bnds$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($params[2] = 0.0$), then `err_bnds_comp` is not accessed.

- `err=1` "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors.
- `err=2` "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.
- `err=3` Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix Z are

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

The information for right-hand side i , where $1 \leq i \leq nrhs$, and type of error err is stored in:

- Column major layout: `err_bnds_comp[(err - 1)*nrhs + i - 1]`.
- Row major layout: `err_bnds_comp[err - 1 + (i - 1)*n_err_bnds]`

`params`

Output parameter only if the input contains erroneous values, namely in `params[0]`, `params[1]`, or `params[2]`. In such a case, the corresponding elements of `params` are filled with default values on output.

Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful. The solution to every right-hand side is guaranteed.

If `info = -i`, parameter i had an illegal value.

If $0 < info \leq n$: $U_{info,info}$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; `rcond = 0` is returned.

If `info = n+j`: The solution corresponding to the j -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested `params[2] = 0.0`, then the j -th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that for column major layout `err_bnds_norm[j - 1] = 0.0` or `err_bnds_comp[j - 1] = 0.0`; or for row major layout `err_bnds_norm[(j - 1)*n_err_bnds] = 0.0` or `err_bnds_comp[(j - 1)*n_err_bnds] = 0.0`). See the definition of `err_bnds_norm` and `err_bnds_comp` for `err = 1`. To get information about all of the right-hand sides, check `err_bnds_norm` or `err_bnds_comp`.

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A \cdot X = B$ with a symmetric (Hermitian) positive definite matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution

$$\|x - x_e\|_{\infty} / \|x\|_{\infty}$$

where x_e is the exact solution.

Before calling this routine:

- call the factorization routine [?pptrf](#)
- call the solver routine [?pptrs](#).

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored. |
| <i>n</i> | The order of the matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; $nrhs \geq 0$. |
| <i>ap</i> | <i>ap</i> contains the original matrix A in a packed format, as supplied to ?pptrf . The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. |
| <i>afp</i> | <i>afp</i> contains the factored matrix A in a packed format, as returned by ?pptrf . The dimension of <i>afp</i> must be at least $\max(1, n(n+1)/2)$. |
| <i>b</i> | Array <i>b</i> of size $\max(1, ldb \cdot nrhs)$ for column major layout and $\max(1, ldb \cdot n)$ for row major layout contains the right-hand side matrix B . |
| <i>x</i> | Array <i>x</i> of size $\max(1, ldx \cdot nrhs)$ for column major layout and $\max(1, ldx \cdot n)$ for row major layout contains the solution matrix X . |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |

ldx The leading dimension of *x*; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout.

Output Parameters

x The refined solution matrix *X*.

ferr, berr Arrays, size at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations $A^*x = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A * X = B$ with a symmetric (Hermitian) positive definite band matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\| |x - x_e| |_{\infty} / \|x| |_{\infty}$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?pbtrf](#)
- call the solver routine [?pbtrs](#).

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>uplo</code> | Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <code>uplo = 'U'</code> , the upper triangle of A is stored. If <code>uplo = 'L'</code> , the lower triangle of A is stored. |
| <code>n</code> | The order of the matrix A ; $n \geq 0$. |
| <code>kd</code> | The number of superdiagonals or subdiagonals in the matrix A ; $kd \geq 0$. |
| <code>nrhs</code> | The number of right-hand sides; $nrhs \geq 0$. |
| <code>ab</code> | Array <code>ab</code> (size $\max(ldab * n)$) contains the original band matrix A , as supplied to ?pbtrf . |
| <code>afb</code> | Array <code>afb</code> (size $\max(ldafb * n)$) contains the factored band matrix A , as returned by ?pbtrf . |
| <code>b</code> | Array <code>b</code> of size $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout contains the right-hand side matrix B . |
| <code>x</code> | Array <code>x</code> of size $\max(1, ldx * nrhs)$ for column major layout and $\max(1, ldx * n)$ for row major layout contains the solution matrix X . |
| <code>ldab</code> | The leading dimension of <code>ab</code> ; $ldab \geq kd + 1$. |
| <code>ldafb</code> | The leading dimension of <code>afb</code> ; $ldafb \geq kd + 1$. |
| <code>ldb</code> | The leading dimension of <code>b</code> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |

ldx The leading dimension of *x*; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout.

Output Parameters

x The refined solution matrix *X*.

ferr, berr Arrays, size at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $8n*kd$ floating-point operations (for real flavors) or $32n*kd$ operations (for complex flavors). In addition, each step of iterative refinement involves $12n*kd$ operations (for real flavors) or $48n*kd$ operations (for complex flavors); the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $4n*kd$ floating-point operations for real flavors or $16n*kd$ for complex flavors.

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A^*X = B$ with a symmetric (Hermitian) positive definite tridiagonal matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine `?pttrf`
- call the solver routine `?pttrs`.

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>uplo</code> | Used for complex flavors only. Must be 'U' or 'L'. Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and how A is factored: If <code>uplo = 'U'</code> , the array <code>e</code> stores the superdiagonal of A , and A is factored as $U^H * D * U$. If <code>uplo = 'L'</code> , the array <code>e</code> stores the subdiagonal of A , and A is factored as $L * D * L^H$. |
| <code>n</code> | The order of the matrix A ; $n \geq 0$. |
| <code>nrhs</code> | The number of right-hand sides; $nrhs \geq 0$. |
| <code>d</code> | The array <code>d</code> (size n) contains the n diagonal elements of the tridiagonal matrix A . |
| <code>df</code> | The array <code>df</code> (size n) contains the n diagonal elements of the diagonal matrix D from the factorization of A as computed by <code>?pttrf</code> . |
| <code>e, ef, b, x</code> | The array <code>e</code> (size $n - 1$) contains the $(n - 1)$ off-diagonal elements of the tridiagonal matrix A (see <code>uplo</code>). The array <code>ef</code> (size $n - 1$) contains the $(n - 1)$ off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by <code>?pttrf</code> (see <code>uplo</code>). The array <code>b</code> of size $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout contains the matrix B whose columns are the right-hand sides for the systems of equations. |

The array x of size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout contains the solution matrix X as computed by `?pttrs`.

ldb The leading dimension of b ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

ldx The leading dimension of x ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout.

Output Parameters

x The refined solution matrix X .

ferr, berr Arrays, size at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A \cdot X = B$ with a symmetric full-storage matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?sytrf](#)
- call the solver routine [?sytrs](#).

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored. |
| <i>n</i> | The order of the matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; $nrhs \geq 0$. |
| <i>a</i> | Array <i>a</i> (size $\max(1, lda * n)$) contains the original matrix A , as supplied to ?sytrf . |
| <i>af</i> | Array <i>af</i> (size $\max(1, ldaf * n)$) contains the factored matrix A , as returned by ?sytrf . |
| <i>b</i> | Array <i>b</i> of size $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout contains the right-hand side matrix B . |
| <i>x</i> | Array <i>x</i> of size $\max(1, ldx * nrhs)$ for column major layout and $\max(1, ldx * n)$ for row major layout contains the solution matrix X . |
| <i>lda</i> | The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$. |
| <i>ldaf</i> | The leading dimension of <i>af</i> ; $ldaf \geq \max(1, n)$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>ldx</i> | The leading dimension of <i>x</i> ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?sytrf . |

Output Parameters

| | |
|--------------|---|
| x | The refined solution matrix X . |
| $ferr, berr$ | Arrays, size at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector. |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward error involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

Description

The routine improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution. In addition to a normwise error bound, the code provides a maximum componentwise error bound, if possible. See comments for *err_bnds_norm* and *err_bnds_comp* for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described by the parameters *equed* and *s* below. In this case, the solution and error bounds returned are for the original unequilibrated system.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether two-dimensional array storage is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of <i>A</i> is stored: If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored. If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored. |
| <i>equed</i> | Must be 'N' or 'Y'. Specifies the form of equilibration that was done to <i>A</i> before calling this routine. If <i>equed</i> = 'N', no equilibration was done. If <i>equed</i> = 'Y', both row and column equilibration was done, that is, <i>A</i> has been replaced by $diag(s) * A * diag(s)$. The right-hand side <i>B</i> has been changed accordingly. |
| <i>n</i> | The number of linear equations; the order of the matrix <i>A</i> ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; the number of columns of the matrices <i>B</i> and <i>X</i> ; $nrhs \geq 0$. |
| <i>a, af, b</i> | The array <i>a</i> (size $\max(1, lda * n)$) contains the symmetric/Hermitian matrix <i>A</i> as specified by <i>uplo</i> . If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of <i>a</i> contains the upper triangular part of the matrix <i>A</i> and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of <i>a</i> contains the lower triangular part of the matrix <i>A</i> and the strictly upper triangular part of <i>a</i> is not referenced. The array <i>af</i> (size $\max(1, lda * n)$) contains the triangular factor <i>L</i> or <i>U</i> from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ as computed by ssytrf for real flavors or dsytrf for complex flavors. |

| | |
|----------------|---|
| | The array b (size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout) contains the matrix B whose columns are the right-hand sides for the systems of equations. |
| lda | The leading dimension of a ; $lda \geq \max(1, n)$. |
| $ldaf$ | The leading dimension of af ; $ldaf \geq \max(1, n)$. |
| $ipiv$ | Array, size at least $\max(1, n)$. Contains details of the interchanges and the block structure of D as determined by <code>ssytrf</code> for real flavors or <code>dsytrf</code> for complex flavors. |
| s | Array, size (n) . The array s contains the scale factors for A . If $equed = 'N'$, s is not accessed. If $equed = 'Y'$, each element of s must be positive. Each element of s should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable. |
| ldb | The leading dimension of the array b ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| x | Array, of size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout. The solution matrix X as computed by <code>?sytrs</code> |
| ldx | The leading dimension of the output array x ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |
| n_err_bnds | Number of error bounds to return for each right hand side and each type (normwise or componentwise). See <code>err_bnds_norm</code> and <code>err_bnds_comp</code> descriptions in <i>Output Arguments</i> section below. |
| $nparams$ | Specifies the number of parameters set in <code>params</code> . If ≤ 0 , the <code>params</code> array is never referenced and default values are used. |
| $params$ | Array, size $nparams$. Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with the default value used for that parameter. Only positions up to $nparams$ are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass $nparams = 0$, which prevents the source code from accessing the <code>params</code> argument. <code>params[0]</code> : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors). =0.0 No refinement is performed and no error bounds are computed. |

=1.0 Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support double precision.

(Other values are reserved for future use.)

params[1] : Maximum number of residual computations allowed for refinement.

Default 10.0

Aggressive Set to 100.0 to permit convergence using approximate factorizations or factorizations other than *LU*. If the factorization uses a technique other than Gaussian elimination, the guarantees in *err_bnds_norm* and *err_bnds_comp* may no longer be trustworthy.

params[2] : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

Output Parameters

x The improved solution matrix *X*.

rcond Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix *A* after equilibration (if done). If *rcond* is less than the machine precision, in particular, if *rcond* = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

berr Array, size at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector x_j , that is, the smallest relative change in any element of *A* or *B* that makes x_j an exact solution.

err_bnds_norm Array of size $nrhs * n_err_bnds$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the *i*-th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors.

err=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

err=3 Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix *Z* are:

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

The information for right-hand side *i*, where $1 \leq i \leq \text{nrhs}$, and type of error *err* is stored in:

- Column major layout: *err_bnds_norm*[(*err* - 1)**nrhs* + *i* - 1].
- Row major layout: *err_bnds_norm*[*err* - 1 + (*i* - 1)**n_err_bnds*]

err_bnds_comp

Array of size *nrhs***n_err_bnds*. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the *i*-th solution vector:

$$\max_j \frac{|X_{\text{true}_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (*params*[2] = 0.0), then *err_bnds_comp* is not accessed.

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.

err=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and

$\sqrt{n} * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

err=3

Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix Z are:

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

The information for right-hand side i , where $1 \leq i \leq nrhs$, and type of error *err* is stored in:

- Column major layout: $err_bnds_comp[(err - 1) * nrhs + i - 1]$.
- Row major layout: $err_bnds_comp[err - 1 + (i - 1) * n_err_bnds]$

params

Output parameter only if the input contains erroneous values, namely, in $params[0]$, $params[1]$, $params[2]$. In such a case, the corresponding elements of *params* are filled with default values on output.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful. The solution to every right-hand side is guaranteed.

If *info* = -*i*, parameter *i* had an illegal value.

If $0 < info \leq n$: $U_{info,info}$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; $rcond = 0$ is returned.

If *info* = $n + j$: The solution corresponding to the j -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested $params[2] = 0.0$, then the j -th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that for column major layout $err_bnds_norm[j - 1] = 0.0$ or $err_bnds_comp[j - 1] = 0.0$; or for row major layout $err_bnds_norm[(j - 1) * n_err_bnds] = 0.0$ or $err_bnds_comp[(j - 1) * n_err_bnds] = 0.0$). See the definition of *err_bnds_norm* and *err_bnds_comp* for *err* = 1. To get information about all of the right-hand sides, check *err_bnds_norm* or *err_bnds_comp*.

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A \cdot X = B$ with a complex Hermitian full-storage matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \quad \text{such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?hetrf](#)
- call the solver routine [?hetrs](#).

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored. |
| <i>n</i> | The order of the matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; $nrhs \geq 0$. |
| <i>a, af, b, x</i> | Arrays: <i>a</i> (size max(1, $lda \cdot n$)) contains the original matrix A , as supplied to ?hetrf . <i>af</i> (size max(1, $ldaf \cdot n$)) contains the factored matrix A , as returned by ?hetrf . |

b of size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout contains the right-hand side matrix *B*.
x of size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout contains the solution matrix *X*.

| | |
|-------------|---|
| <i>lda</i> | The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$. |
| <i>ldaf</i> | The leading dimension of <i>af</i> ; $ldaf \geq \max(1, n)$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>ldx</i> | The leading dimension of <i>x</i> ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?hetrf . |

Output Parameters

| | |
|-------------------|---|
| <i>x</i> | The refined solution matrix <i>X</i> . |
| <i>ferr, berr</i> | Arrays, size at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector. |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $16n^2$ operations. In addition, each step of iterative refinement involves $24n^2$ operations; the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $8n^2$ floating-point operations.

The real counterpart of this routine is [?ssyrfs/?dsyrfs](#)

Description

The routine improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution. In addition to a normwise error bound, the code provides a maximum componentwise error bound, if possible. See comments for *err_bnds_norm* and *err_bnds_comp* for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described by the parameters *equed* and *s* below. In this case, the solution and error bounds returned are for the original unequilibrated system.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether two-dimensional array storage is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of <i>A</i> is stored: If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored. If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored. |
| <i>equed</i> | Must be 'N' or 'Y'. Specifies the form of equilibration that was done to <i>A</i> before calling this routine. If <i>equed</i> = 'N', no equilibration was done. If <i>equed</i> = 'Y', both row and column equilibration was done, that is, <i>A</i> has been replaced by $diag(s) * A * diag(s)$. The right-hand side <i>B</i> has been changed accordingly. |
| <i>n</i> | The number of linear equations; the order of the matrix <i>A</i> ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; the number of columns of the matrices <i>B</i> and <i>X</i> ; $nrhs \geq 0$. |
| <i>a, af, b</i> | The array <i>a</i> of size $\max(1, lda * n)$ contains the Hermitian matrix <i>A</i> as specified by <i>uplo</i> . If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of <i>a</i> contains the upper triangular part of the matrix <i>A</i> and the strictly lower |

triangular part of a is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A and the strictly upper triangular part of a is not referenced.

The array af of size $\max(1, ldaf*n)$ contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^T$ or $A = L*D*L^T$ as computed by `ssytrf` for `cherfsx` or `dsytrf` for `zherfsx`.

The array b of size $\max(1, ldb*nrhs)$ for row major layout and $\max(1, ldb*n)$ for column major layout contains the matrix B whose columns are the right-hand sides for the systems of equations.

| | |
|-------------------------|--|
| <code>lda</code> | The leading dimension of a ; $lda \geq \max(1, n)$. |
| <code>ldaf</code> | The leading dimension of af ; $ldaf \geq \max(1, n)$. |
| <code>ipiv</code> | Array, size at least $\max(1, n)$. Contains details of the interchanges and the block structure of D as determined by <code>ssytrf</code> for real flavors or <code>dsytrf</code> for complex flavors. |
| <code>s</code> | <p>Array, size (n). The array s contains the scale factors for A.</p> <p>If $equed = 'N'$, s is not accessed.</p> <p>If $equed = 'Y'$, each element of s must be positive.</p> <p>Each element of s should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.</p> |
| <code>ldb</code> | The leading dimension of the array b ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <code>x</code> | <p>Array, size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout.</p> <p>The solution matrix X as computed by <code>?hetrs</code></p> |
| <code>ldx</code> | The leading dimension of the output array x ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |
| <code>n_err_bnds</code> | Number of error bounds to return for each right hand side and each type (normwise or componentwise). See <code>err_bnds_norm</code> and <code>err_bnds_comp</code> descriptions in <i>Output Arguments</i> section below. |
| <code>nparams</code> | Specifies the number of parameters set in <code>params</code> . If ≤ 0 , the <code>params</code> array is never referenced and default values are used. |
| <code>params</code> | Array, size <code>nparams</code> . Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with the default value used for that parameter. Only positions up to <code>nparams</code> are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass <code>nparams = 0</code> , which prevents the source code from accessing the <code>params</code> argument. |

params[0] : Whether to perform iterative refinement or not. Default: 1.0 (for *cherfsx*), 1.0D+0 (for *zherfsx*).

| | |
|------|--|
| =0.0 | No refinement is performed and no error bounds are computed. |
| =1.0 | Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support double precision. |

(Other values are reserved for future use.)

params[1] : Maximum number of residual computations allowed for refinement.

| | |
|------------|---|
| Default | 10 |
| Aggressive | Set to 100 to permit convergence using approximate factorizations or factorizations other than <i>LU</i> . If the factorization uses a technique other than Gaussian elimination, the guarantees in <i>err_bnds_norm</i> and <i>err_bnds_comp</i> may no longer be trustworthy. |

params[2] : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

Output Parameters

| | |
|----------------------|--|
| <i>x</i> | The improved solution matrix <i>X</i> . |
| <i>rcond</i> | Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision, in particular, if <i>rcond</i> = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned. |
| <i>berr</i> | Array, size at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector x_j , that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes x_j an exact solution. |
| <i>err_bnds_norm</i> | <p>Array of size $nrhs * n_err_bnds$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:</p> <p>Normwise relative error in the <i>i</i>-th solution vector</p> $\frac{\max_j X_{true_{ji}} - X_{ji} }{\max_j X_{ji} }$ <p>The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.</p> |

- `err=1` "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for `cherfsx` and $\sqrt{n} * \text{dlamch}(\epsilon)$ for `zherfsx`.
- `err=2` "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for `cherfsx` and $\sqrt{n} * \text{dlamch}(\epsilon)$ for `zherfsx`. This error bound should only be trusted if the previous boolean is true.
- `err=3` Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix Z are:

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z=s*a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

The information for right-hand side i , where $1 \leq i \leq nrhs$, and type of error `err` is stored in:

- Column major layout: `err_bnds_norm[(err - 1)*nrhs + i - 1]`.
- Row major layout: `err_bnds_norm[err - 1 + (i - 1)*n_err_bnds]`

`err_bnds_comp`

Array of size `nrhs*n_err_bnds`. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (`params[2] = 0.0`), then `err_bnds_comp` is not accessed.

- `err=1` "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for `cherfsx` and $\sqrt{n} * \text{dlamch}(\epsilon)$ for `zherfsx`.

err=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for *cherfsx* and $\sqrt{n} * \text{dlamch}(\epsilon)$ for *zherfsx*. This error bound should only be trusted if the previous boolean is true.

err=3 Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix *Z* are:

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z = s * (a * \text{diag}(x))$, where *x* is the solution for the current right-hand side and *s* scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of *z* are approximately 1.

The information for right-hand side *i*, where $1 \leq i \leq \text{nrhs}$, and type of error *err* is stored in:

- Column major layout: *err_bnds_comp*[(*err* - 1) * *nrhs* + *i* - 1].
- Row major layout: *err_bnds_comp*[*err* - 1 + (*i* - 1) * *n_err_bnds*]

params

Output parameter only if the input contains erroneous values, namely, in *params*[0], *params*[1], *params*[2]. In such a case, the corresponding elements of *params* are filled with default values on output.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful. The solution to every right-hand side is guaranteed.

If *info* = -*i*, parameter *i* had an illegal value.

If $0 < \text{info} \leq n$: $U_{\text{info}, \text{info}}$ is exactly zero. The factorization has been completed, but the factor *D* is exactly singular, so the solution and error bounds could not be computed; *rcond* = 0 is returned.

If *info* = *n*+*j*: The solution corresponding to the *j*-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides *k* with *k* > *j* may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested *params*[2] = 0.0, then the *j*-th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest *j* such that for column major layout *err_bnds_norm*[*j* - 1] = 0.0 or *err_bnds_comp*[*j* - 1] = 0.0; or for row major layout *err_bnds_norm*[(*j* - 1) * *n_err_bnds*] = 0.0 or *err_bnds_comp*[(*j* - 1) * *n_err_bnds*] = 0.0). See the definition of *err_bnds_norm* and *err_bnds_comp* for *err* = 1. To get information about all of the right-hand sides, check *err_bnds_norm* or *err_bnds_comp*.

Description

The routine performs an iterative refinement of the solution to a system of linear equations $A \cdot X = B$ with a packed symmetric matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A) x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?sprtrf](#)
- call the solver routine [?sprtrs](#).

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored. |
| <i>n</i> | The order of the matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; $nrhs \geq 0$. |

| | |
|-----------------|--|
| ap, afp, b, x | <p>Arrays:</p> <p>ap of size $\max(1, n(n+1)/2)$ contains the original packed matrix A, as supplied to <code>?sptrf</code>.</p> <p>afp of size $\max(1, n(n+1)/2)$ contains the factored packed matrix A, as returned by <code>?sptrf</code>.</p> <p>b of size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout contains the right-hand side matrix B.</p> <p>x of size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout contains the solution matrix X.</p> |
| ldb | The leading dimension of b ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| ldx | The leading dimension of x ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq \max(1, nrhs)$ for row major layout. |
| $ipiv$ | Array, size at least $\max(1, n)$. The $ipiv$ array, as returned by <code>?sptrf</code> . |

Output Parameters

| | |
|--------------|---|
| x | The refined solution matrix X . |
| $ferr, berr$ | Arrays, size at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector. |

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter i had an illegal value.

Application Notes

The bounds returned in $ferr$ are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations $A*x = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

Description

The routine estimates the errors in the solution to a system of linear equations $A^*X = B$ or $A^T*X = B$ or $A^H*X = B$ with a triangular matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

The routine also estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine, call the solver routine `?trtrs`.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <i>uplo</i> = 'U', then A is upper triangular. If <i>uplo</i> = 'L', then A is lower triangular. |
| <i>trans</i> | Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', the system has the form $A^*X = B$. If <i>trans</i> = 'T', the system has the form $A^T*X = B$. If <i>trans</i> = 'C', the system has the form $A^H*X = B$. |
| <i>diag</i> | Must be 'N' or 'U'. If <i>diag</i> = 'N', then A is not a unit triangular matrix. If <i>diag</i> = 'U', then A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array a . |
| <i>n</i> | The order of the matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; $nrhs \geq 0$. |
| <i>a, b, x</i> | Arrays: a (size $\max(1, lda * n)$) contains the upper or lower triangular matrix A , as specified by <i>uplo</i> . |

b of size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout contains the right-hand side matrix *B*.

x of size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout contains the solution matrix *X*.

| | |
|------------|---|
| <i>lda</i> | The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>ldx</i> | The leading dimension of <i>x</i> ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |

Output Parameters

ferr, berr Arrays, size at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

A call to this routine involves, for each right-hand side, solving a number of systems of linear equations $A*x = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately n^2 floating-point operations for real flavors or $4n^2$ for complex flavors.

Description

The routine estimates the errors in the solution to a system of linear equations $A^*X = B$ or $A^T*X = B$ or $A^H*X = B$ with a triangular band matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

The routine also estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine, call the solver routine `?tbrs`.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <i>uplo</i> = 'U', then A is upper triangular. If <i>uplo</i> = 'L', then A is lower triangular. |
| <i>trans</i> | Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', the system has the form $A^*X = B$. If <i>trans</i> = 'T', the system has the form $A^T*X = B$. If <i>trans</i> = 'C', the system has the form $A^H*X = B$. |
| <i>diag</i> | Must be 'N' or 'U'. If <i>diag</i> = 'N', A is not a unit triangular matrix. If <i>diag</i> = 'U', A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array <i>ab</i> . |
| <i>n</i> | The order of the matrix A ; $n \geq 0$. |
| <i>kd</i> | The number of super-diagonals or sub-diagonals in the matrix A ; $kd \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; $nrhs \geq 0$. |
| <i>ab, b, x</i> | Arrays: |

ab (size $\max(1, ldab*n)$) contains the upper or lower triangular matrix A , as specified by $uplo$, in band storage format.

b of size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout contains the right-hand side matrix B .

x of size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout contains the solution matrix X .

| | |
|--------|--|
| $ldab$ | The leading dimension of the array ab ; $ldab \geq kd + 1$. |
| ldb | The leading dimension of b ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| ldx | The leading dimension of x ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |

Output Parameters

| | |
|--------------|---|
| $ferr, berr$ | Arrays, size at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector. |
|--------------|---|

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter i had an illegal value.

Application Notes

The bounds returned in $ferr$ are not rigorous, but in practice they almost always overestimate the actual error.

A call to this routine involves, for each right-hand side, solving a number of systems of linear equations $A*x = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately $2n*kd$ floating-point operations for real flavors or $8n*kd$ operations for complex flavors.

[Matrix Storage Schemes for LAPACK Routines](#)

Matrix Inversion: LAPACK Computational Routines

It is seldom necessary to compute an explicit inverse of a matrix. In particular, do not attempt to solve a system of equations $Ax = b$ by first computing A^{-1} and then forming the matrix-vector product $x = A^{-1}b$. Call a solver routine instead (see [Routines for Solving Systems of Linear Equations](#)); this is more efficient and more accurate.

However, matrix inversion routines are provided for the rare occasions when an explicit inverse matrix is needed.

?getri

Computes the inverse of an LU-factored general matrix.

Syntax

```
lapack_int LAPACKE_sgetri (int matrix_layout , lapack_int n , float * a , lapack_int lda , const lapack_int * ipiv );
```

```
lapack_int LAPACKE_dgetri (int matrix_layout , lapack_int n , double * a , lapack_int lda , const lapack_int * ipiv );
```

```
lapack_int LAPACKE_cgetri (int matrix_layout , lapack_int n , lapack_complex_float * a , lapack_int lda , const lapack_int * ipiv );
```

```
lapack_int LAPACKE_zgetri (int matrix_layout , lapack_int n , lapack_complex_double * a , lapack_int lda , const lapack_int * ipiv );
```

Include Files

- mkl.h

Description

The routine computes the inverse $\text{inv}(A)$ of a general matrix A . Before calling this routine, call [?getrf](#) to factorize A .

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>n</i> | The order of the matrix A ; $n \geq 0$. |
| <i>a</i> | Array a (size $\max(1, lda * n)$) contains the factorization of the matrix A , as returned by ?getrf : $A = P * L * U$. The second dimension of a must be at least $\max(1, n)$. |
| <i>lda</i> | The leading dimension of a ; $lda \geq \max(1, n)$. |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?getrf . |

Output Parameters

| | |
|----------|--|
| <i>a</i> | Overwritten by the n -by- n matrix $\text{inv}(A)$. |
|----------|--|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

If *info* = *i*, the *i*-th diagonal element of the factor U is zero, U is singular, and the inversion could not be completed.

Application Notes

The computed inverse X satisfies the following error bound:

$$\|XA - I\| \leq c(n) \varepsilon \|X\| \|P\| \|L\| \|U\|,$$

where $c(n)$ is a modest linear function of n ; ε is the machine precision; I denotes the identity matrix; P , L , and U are the factors of the matrix factorization $A = P * L * U$.

The total number of floating-point operations is approximately $(4/3)n^3$ for real flavors and $(16/3)n^3$ for complex flavors.

Matrix Storage Schemes for LAPACK Routines

?potri

Computes the inverse of a symmetric (Hermitian) positive-definite matrix using the Cholesky factorization.

Syntax

```
lapack_int LAPACKE_spotri (int matrix_layout , char uplo , lapack_int n , float * a ,
lapack_int lda );
```

```
lapack_int LAPACKE_dpotri (int matrix_layout , char uplo , lapack_int n , double * a ,
lapack_int lda );
```

```
lapack_int LAPACKE_cpotri (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_float * a , lapack_int lda );
```

```
lapack_int LAPACKE_zpotri (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_double * a , lapack_int lda );
```

Include Files

- mkl.h

Description

The routine computes the inverse $\text{inv}(A)$ of a symmetric positive definite or, for complex flavors, Hermitian positive-definite matrix A . Before calling this routine, call [?potrf](#) to factorize A .

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored. |
| <i>n</i> | The order of the matrix A ; $n \geq 0$. |
| <i>a</i> | Array a (size $\max(1, lda * n)$). Contains the factorization of the matrix A , as returned by ?potrf . |
| <i>lda</i> | The leading dimension of a ; $lda \geq \max(1, n)$. |

Output Parameters

| | |
|----------|--|
| <i>a</i> | Overwritten by the upper or lower triangle of the inverse of A . |
|----------|--|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = $-i$, parameter i had an illegal value.

If $info = i$, the i -th diagonal element of the Cholesky factor (and therefore the factor itself) is zero, and the inversion could not be completed.

Application Notes

The computed inverse X satisfies the following error bounds:

$$\|XA - I\|_2 \leq c(n) \varepsilon \kappa_2(A), \quad \|AX - I\|_2 \leq c(n) \varepsilon \kappa_2(A),$$

where $c(n)$ is a modest linear function of n , and ε is the machine precision; I denotes the identity matrix.

The 2-norm $\|A\|_2$ of a matrix A is defined by $\|A\|_2 = \max_{x \cdot x=1} (Ax \cdot Ax)^{1/2}$, and the condition number $\kappa_2(A)$ is defined by $\kappa_2(A) = \|A\|_2 \|A^{-1}\|_2$.

The total number of floating-point operations is approximately $(2/3)n^3$ for real flavors and $(8/3)n^3$ for complex flavors.

Matrix Storage Schemes for LAPACK Routines

?pftri

Computes the inverse of a symmetric (Hermitian) positive-definite matrix in RFP format using the Cholesky factorization.

Syntax

```
lapack_int LAPACKE_spftri (int matrix_layout , char transr , char uplo , lapack_int n ,
float * a );
```

```
lapack_int LAPACKE_dpfttri (int matrix_layout , char transr , char uplo , lapack_int n ,
double * a );
```

```
lapack_int LAPACKE_cpfttri (int matrix_layout , char transr , char uplo , lapack_int n ,
lapack_complex_float * a );
```

```
lapack_int LAPACKE_zpfttri (int matrix_layout , char transr , char uplo , lapack_int n ,
lapack_complex_double * a );
```

Include Files

- mkl.h

Description

The routine computes the inverse $inv(A)$ of a symmetric positive definite or, for complex data, Hermitian positive-definite matrix A using the Cholesky factorization:

$$\begin{aligned} A &= U^T * U \text{ for real data, } A = U^H * U \text{ for complex data} && \text{if } uplo='U' \\ A &= L * L^T \text{ for real data, } A = L * L^H \text{ for complex data} && \text{if } uplo='L' \end{aligned}$$

Before calling this routine, call [?pfttrf](#) to factorize A .

The matrix A is in the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

transr Must be 'N', 'T' (for real data) or 'C' (for complex data).

If $transr = 'N'$, the Normal $transr$ of RFP U (if $uplo = 'U'$) or L (if $uplo = 'L'$) is stored.

If $transr = 'T'$, the Transpose $transr$ of RFP U (if $uplo = 'U'$) or L (if $uplo = 'L'$) is stored.

If $transr = 'C'$, the Conjugate-Transpose $transr$ of RFP U (if $uplo = 'U'$) or L (if $uplo = 'L'$) is stored.

$uplo$

Must be 'U' or 'L'.

Indicates how the input matrix A has been factored:

If $uplo = 'U'$, $A = U^T * U$ for real data or $A = U^H * U$ for complex data, and U is stored.

If $uplo = 'L'$, $A = L * L^T$ for real data or $A = L * L^H$ for complex data, and L is stored.

n

The order of the matrix A ; $n \geq 0$.

a

Array, size $(n * (n + 1) / 2)$. The array a contains the factor U or L matrix A in the RFP format.

Output Parameters

a

The symmetric/Hermitian inverse of the original matrix in the same storage format.

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, parameter i had an illegal value.

If $info = i$, the (i, i) element of the factor U or L is zero, and the inverse could not be computed.

Description

The routine computes the inverse $\text{inv}(A)$ of a symmetric positive definite or, for complex flavors, Hermitian positive-definite matrix A in *packed* form. Before calling this routine, call `?pptrf` to factorize A .

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>uplo</code> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular factor is stored in <code>ap</code> : If <code>uplo = 'U'</code> , then the upper triangular factor is stored. If <code>uplo = 'L'</code> , then the lower triangular factor is stored. |
| <code>n</code> | The order of the matrix A ; $n \geq 0$. |
| <code>ap</code> | Array, size at least $\max(1, n(n+1)/2)$. Contains the factorization of the packed matrix A , as returned by <code>?pptrf</code> . The dimension <code>ap</code> must be at least $\max(1, n(n+1)/2)$. |

Output Parameters

| | |
|-----------------|---|
| <code>ap</code> | Overwritten by the packed n -by- n matrix $\text{inv}(A)$. |
|-----------------|---|

Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful.

If `info = -i`, parameter i had an illegal value.

If `info = i`, the i -th diagonal element of the Cholesky factor (and therefore the factor itself) is zero, and the inversion could not be completed.

Application Notes

The computed inverse X satisfies the following error bounds:

$$\|XA - I\|_2 \leq c(n) \varepsilon \kappa_2(A), \quad \|AX - I\|_2 \leq c(n) \varepsilon \kappa_2(A),$$

where $c(n)$ is a modest linear function of n , and ε is the machine precision; I denotes the identity matrix.

The 2-norm $\|A\|_2$ of a matrix A is defined by $\|A\|_2 = \max_{x \cdot x = 1} (Ax \cdot Ax)^{1/2}$, and the condition number $\kappa_2(A)$ is defined by $\kappa_2(A) = \|A\|_2 \|A^{-1}\|_2$.

The total number of floating-point operations is approximately $(2/3)n^3$ for real flavors and $(8/3)n^3$ for complex flavors.

Description

The routine computes the inverse $\text{inv}(A)$ of a symmetric matrix A . Before calling this routine, call [?sytrf](#) to factorize A .

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the array a stores the Bunch-Kaufman factorization $A = U^*D^*U^T$. If <i>uplo</i> = 'L', the array a stores the Bunch-Kaufman factorization $A = L^*D^*L^T$. |
| <i>n</i> | The order of the matrix A ; $n \geq 0$. |
| <i>a</i> | $a(\text{size } \max(1, \text{lda} * n))$ contains the factorization of the matrix A , as returned by ?sytrf . |
| <i>lda</i> | The leading dimension of a ; $\text{lda} \geq \max(1, n)$. |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?sytrf . |

Output Parameters

| | |
|----------|--|
| <i>a</i> | Overwritten by the n -by- n matrix $\text{inv}(A)$. |
|----------|--|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If $info = -i$, parameter i had an illegal value.

If $info = i$, the i -th diagonal element of D is zero, D is singular, and the inversion could not be completed.

Application Notes

The computed inverse X satisfies the following error bounds:

$$|D^*U^T*P^T*X*P*U - I| \leq c(n)\epsilon(|D||U^T|P^T|X|P|U| + |D||D^{-1}|)$$

for $uplo = 'U'$, and

$$|D^*L^T*P^T*X*P*L - I| \leq c(n)\epsilon(|D||L^T|P^T|X|P|L| + |D||D^{-1}|)$$

for $uplo = 'L'$. Here $c(n)$ is a modest linear function of n , and ϵ is the machine precision; I denotes the identity matrix.

The total number of floating-point operations is approximately $(2/3)n^3$ for real flavors and $(8/3)n^3$ for complex flavors.

Description

The routine computes the inverse $\text{inv}(A)$ of a symmetric indefinite matrix A using the factorization $A = U^*D^*U^T$ or $A = L^*D^*L^T$ computed by `?sytrf`.

The `?sytri2` routine allocates a temporary buffer before calling `?sytri2x` that actually computes the inverse.

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>uplo</code> | Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <code>uplo = 'U'</code> , the array a stores the factorization $A = U^*D^*U^T$. If <code>uplo = 'L'</code> , the array a stores the factorization $A = L^*D^*L^T$. |
| <code>n</code> | The order of the matrix A ; $n \geq 0$. |
| <code>a</code> | Array a (size $\max(1, lda * n)$) contains the block diagonal matrix D and the multipliers used to obtain the factor U or L as returned by <code>?sytrf</code> . |
| <code>lda</code> | The leading dimension of a ; $lda \geq \max(1, n)$. |
| <code>ipiv</code> | Array, size at least $\max(1, n)$. Details of the interchanges and the block structure of D as returned by <code>?sytrf</code> . |

Output Parameters

| | |
|----------------|--|
| <code>a</code> | If <code>info = 0</code> , the symmetric inverse of the original matrix. If <code>uplo = 'U'</code> , the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced. If <code>uplo = 'L'</code> , the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced. |
|----------------|--|

Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, $D(i,i) = 0$; D is singular and its inversion could not be computed.

Description

Computes the inverse of a triangular matrix A stored in the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

This is the block version of the algorithm, calling Level 3 BLAS.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>transr</i> | Must be 'N', 'T' (for real data) or 'C' (for complex data). If <i>transr</i> = 'N', the Normal <i>transr</i> of RFP A is stored. If <i>transr</i> = 'T', the Transpose <i>transr</i> of RFP A is stored. If <i>transr</i> = 'C', the Conjugate-Transpose <i>transr</i> of RFP A is stored. |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of RFP A is stored: If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular part of the matrix A . If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular part of the matrix A . |
| <i>diag</i> | Must be 'N' or 'U'. If <i>diag</i> = 'N', then A is not a unit triangular matrix. If <i>diag</i> = 'U', A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array <i>a</i> . |
| <i>n</i> | The order of the matrix A ; $n \geq 0$. |
| <i>a</i> | Array, size $\max(1, n*(n+1)/2)$. The array <i>a</i> contains the matrix A in the RFP format. |

Output Parameters

| | |
|----------|---|
| <i>a</i> | The (triangular) inverse of the original matrix in the same storage format. |
|----------|---|

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

If *info* = *i*, $A_{i,i}$ is exactly zero. The triangular matrix is singular and its inverse cannot be computed.

?tptri

Computes the inverse of a triangular matrix using packed storage.

Syntax

```
lapack_int LAPACKE_stptri (int matrix_layout , char uplo , char diag , lapack_int n ,
float * ap );
```

```
lapack_int LAPACKE_dtptri (int matrix_layout , char uplo , char diag , lapack_int n ,
double * ap );
```

```
lapack_int LAPACKE_ctptri (int matrix_layout , char uplo , char diag , lapack_int n ,
lapack_complex_float * ap );
```

```
lapack_int LAPACKE_ztptri (int matrix_layout , char uplo , char diag , lapack_int n ,
lapack_complex_double * ap );
```

Include Files

- mkl.h

Description

The routine computes the inverse $\text{inv}(A)$ of a packed triangular matrix *A*.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether <i>A</i> is upper or lower triangular: If <i>uplo</i> = 'U', then <i>A</i> is upper triangular. If <i>uplo</i> = 'L', then <i>A</i> is lower triangular. |
| <i>diag</i> | Must be 'N' or 'U'. If <i>diag</i> = 'N', then <i>A</i> is not a unit triangular matrix. If <i>diag</i> = 'U', <i>A</i> is unit triangular: diagonal elements of <i>A</i> are assumed to be 1 and not referenced in the array <i>ap</i> . |
| <i>n</i> | The order of the matrix <i>A</i> ; $n \geq 0$. |
| <i>ap</i> | Array, size at least $\max(1, n(n+1)/2)$. |

Contains the packed triangular matrix A .

Output Parameters

ap Overwritten by the packed n -by- n matrix $\text{inv}(A)$.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter i had an illegal value.

If $info = i$, the i -th diagonal element of A is zero, A is singular, and the inversion could not be completed.

Application Notes

The computed inverse X satisfies the following error bounds:

$$|XA - I| \leq c(n)\epsilon |X| |A|$$

$$|X - A^{-1}| \leq c(n)\epsilon |A^{-1}| |A| |X|,$$

where $c(n)$ is a modest linear function of n ; ϵ is the machine precision; I denotes the identity matrix.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors and $(4/3)n^3$ for complex flavors.

Matrix Equilibration: LAPACK Computational Routines

Routines described in this section are used to compute scaling factors needed to equilibrate a matrix. Note that these routines do not actually scale the matrices.

?gseequ

Computes row and column scaling factors intended to equilibrate a general matrix and reduce its condition number.

Syntax

```
lapack_int LAPACKE_sgeequ( int matrix_layout, lapack_int m, lapack_int n, const float*
a, lapack_int lda, float* r, float* c, float* rowcnd, float* colcnd, float* amax );
```

```
lapack_int LAPACKE_dgeequ( int matrix_layout, lapack_int m, lapack_int n, const double*
a, lapack_int lda, double* r, double* c, double* rowcnd, double* colcnd, double*
amax );
```

```
lapack_int LAPACKE_cgeequ( int matrix_layout, lapack_int m, lapack_int n, const
lapack_complex_float* a, lapack_int lda, float* r, float* c, float* rowcnd, float*
colcnd, float* amax );
```

```
lapack_int LAPACKE_zgeequ( int matrix_layout, lapack_int m, lapack_int n, const
lapack_complex_double* a, lapack_int lda, double* r, double* c, double* rowcnd,
double* colcnd, double* amax );
```

Include Files

- `mkl.h`

Description

The routine computes row and column scalings intended to equilibrate an m -by- n matrix A and reduce its condition number. The output array r returns the row scale factors and the array c the column scale factors. These factors are chosen to try to make the largest element in each row and column of the matrix B with elements $b_{ij}=r[i-1]*a_{ij}*c[j-1]$ have absolute value 1.

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>m</code> | The number of rows of the matrix A ; $m \geq 0$. |
| <code>n</code> | The number of columns of the matrix A ; $n \geq 0$. |
| <code>a</code> | Array: size $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout. Contains the m -by- n matrix A whose equilibration factors are to be computed. |
| <code>lda</code> | The leading dimension of a ; $lda \geq \max(1, m)$. |

Output Parameters

| | |
|---------------------|--|
| <code>r, c</code> | Arrays: r (size m), c (size n). If $info = 0$, or $info > m$, the array r contains the row scale factors of the matrix A . If $info = 0$, the array c contains the column scale factors of the matrix A . |
| <code>rowcnd</code> | If $info = 0$ or $info > m$, <code>rowcnd</code> contains the ratio of the smallest $r[i]$ to the largest $r[i]$. |
| <code>colcnd</code> | If $info = 0$, <code>colcnd</code> contains the ratio of the smallest $c[i]$ to the largest $c[i]$. |
| <code>amax</code> | Absolute value of the largest element of the matrix A . |

Return Values

This function returns a value `info`.

If $info = 0$, the execution is successful.

If $info = -i$, parameter i had an illegal value.

If $info = i$, $i > 0$, and

$i \leq m$, the i -th row of A is exactly zero;

$i > m$, the $(i-m)$ th column of A is exactly zero.

Application Notes

All the components of r and c are restricted to be between `SMLNUM` = smallest safe number and `BIGNUM`= largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

`SMLNUM` and `BIGNUM` are parameters representing machine precision. You can use the `?lamch` routines to compute them. For example, compute single precision values of `SMLNUM` and `BIGNUM` as follows:

```
SMLNUM = slamch ('s')
BIGNUM = 1 / SMLNUM
```

If `rowcnd` \geq 0.1 and `amax` is neither too large nor too small, it is not worth scaling by r .

If `colcnd` \geq 0.1, it is not worth scaling by c .

If `amax` is very close to `SMLNUM` or very close to `BIGNUM`, the matrix A should be scaled.

?geequb

Computes row and column scaling factors restricted to a power of radix to equilibrate a general matrix and reduce its condition number.

Syntax

```
lapack_int LAPACKE_sgeequb( int matrix_layout, lapack_int m, lapack_int n, const float*
a, lapack_int lda, float* r, float* c, float* rowcnd, float* colcnd, float* amax );
```

```
lapack_int LAPACKE_dgeequb( int matrix_layout, lapack_int m, lapack_int n, const
double* a, lapack_int lda, double* r, double* c, double* rowcnd, double* colcnd,
double* amax );
```

```
lapack_int LAPACKE_cgeequb( int matrix_layout, lapack_int m, lapack_int n, const
lapack_complex_float* a, lapack_int lda, float* r, float* c, float* rowcnd, float*
colcnd, float* amax );
```

```
lapack_int LAPACKE_zgeequb( int matrix_layout, lapack_int m, lapack_int n, const
lapack_complex_double* a, lapack_int lda, double* r, double* c, double* rowcnd,
double* colcnd, double* amax );
```

Include Files

- mkl.h

Description

The routine computes row and column scalings intended to equilibrate an m -by- n general matrix A and reduce its condition number. The output array r returns the row scale factors and the array c - the column scale factors. These factors are chosen to try to make the largest element in each row and column of the matrix B with elements $b_{i,j} = r[i-1]*a_{i,j}*c[j-1]$ have an absolute value of at most the radix.

$r[i-1]$ and $c[j-1]$ are restricted to be a power of the radix between `SMLNUM` = smallest safe number and `BIGNUM` = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of a but works well in practice.

SMLNUM and *BIGNUM* are parameters representing machine precision. You can use the `?lamch` routines to compute them. For example, compute single precision values of *SMLNUM* and *BIGNUM* as follows:

```
SMLNUM = slamch ('s')
BIGNUM = 1 / SMLNUM
```

This routine differs from `?geequ` by restricting the scaling factors to a power of the radix. Except for over- and underflow, scaling by these factors introduces no additional rounding errors. However, the scaled entries' magnitudes are no longer equal to approximately 1 but lie between $\sqrt{\text{radix}}$ and $1/\sqrt{\text{radix}}$.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>m</i> | The number of rows of the matrix <i>A</i> ; $m \geq 0$. |
| <i>n</i> | The number of columns of the matrix <i>A</i> ; $n \geq 0$. |
| <i>a</i> | Array: size $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout. Contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> whose equilibration factors are to be computed. |
| <i>lda</i> | The leading dimension of <i>a</i> ; $lda \geq \max(1, m)$. |

Output Parameters

| | |
|---------------|---|
| <i>r, c</i> | Arrays: $r(m), c(n)$. If <i>info</i> = 0, or <i>info</i> > <i>m</i> , the array <i>r</i> contains the row scale factors for the matrix <i>A</i> . If <i>info</i> = 0, the array <i>c</i> contains the column scale factors for the matrix <i>A</i> . |
| <i>rowcnd</i> | If <i>info</i> = 0 or <i>info</i> > <i>m</i> , <i>rowcnd</i> contains the ratio of the smallest $r[i]$ to the largest $r[i]$. If <i>rowcnd</i> ≥ 0.1 , and <i>amax</i> is neither too large nor too small, it is not worth scaling by <i>r</i> . |
| <i>colcnd</i> | If <i>info</i> = 0, <i>colcnd</i> contains the ratio of the smallest $c[i]$ to the largest $c[i]$. If <i>colcnd</i> ≥ 0.1 , it is not worth scaling by <i>c</i> . |
| <i>amax</i> | Absolute value of the largest element of the matrix <i>A</i> . If <i>amax</i> is very close to <i>SMLNUM</i> or very close to <i>BIGNUM</i> , the matrix should be scaled. |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

If *info* = *i*, $i > 0$, and

$i \leq m$, the *i*-th row of *A* is exactly zero;

$i > m$, the (*i*-*m*)-th column of *A* is exactly zero.

Description

The routine computes row and column scalings intended to equilibrate a symmetric (Hermitian) positive-definite matrix A and reduce its condition number (with respect to the two-norm). The output array s returns scale factors such that contains

$$\frac{1}{\sqrt{a_{i,i}}}$$

These factors are chosen so that the scaled matrix B with elements $B_{i,j}=s[i-1]*A_{i,j}*s[j-1]$ has diagonal elements equal to 1.

This choice of s puts the condition number of B within a factor n of the smallest possible condition number over all possible diagonal scalings.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>n</i> | The order of the matrix A ; $n \geq 0$. |
| <i>a</i> | Array: size $\max(1, lda*n)$. Contains the n -by- n symmetric or Hermitian positive definite matrix A whose scaling factors are to be computed. Only the diagonal elements of A are referenced. |
| <i>lda</i> | The leading dimension of a ; $lda \geq \max(1, n)$. |

Output Parameters

| | |
|--------------|--|
| <i>s</i> | Array, size n . If <i>info</i> = 0, the array s contains the scale factors for A . |
| <i>scond</i> | If <i>info</i> = 0, <i>scond</i> contains the ratio of the smallest $s[i]$ to the largest $s[i]$. |
| <i>amax</i> | Absolute value of the largest element of the matrix A . |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = $-i$, parameter i had an illegal value.

If *info* = i , the i -th diagonal element of A is nonpositive.

Application Notes

If $scond \geq 0.1$ and *amax* is neither too large nor too small, it is not worth scaling by s .

If *amax* is very close to SMLNUM or very close to BIGNUM, the matrix A should be scaled.

Description

The routine computes row and column scalings intended to equilibrate a symmetric (Hermitian) positive definite matrix *A* in packed storage and reduce its condition number (with respect to the two-norm). The output array *s* returns scale factors such that contains

$$s(i) = \frac{1}{\sqrt{a_{i,i}}}$$

These factors are chosen so that the scaled matrix *B* with elements $b_{ij}=s[i-1]*a_{ij}*s[j-1]$ has diagonal elements equal to 1.

This choice of *s* puts the condition number of *B* within a factor *n* of the smallest possible condition number over all possible diagonal scalings.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of <i>A</i> is packed in the array <i>ap</i> : If <i>uplo</i> = 'U', the array <i>ap</i> stores the upper triangular part of the matrix <i>A</i> . If <i>uplo</i> = 'L', the array <i>ap</i> stores the lower triangular part of the matrix <i>A</i> . |
| <i>n</i> | The order of matrix <i>A</i> ; $n \geq 0$. |
| <i>ap</i> | Array, size at least $\max(1, n(n+1)/2)$. The array <i>ap</i> contains the upper or the lower triangular part of the matrix <i>A</i> (as specified by <i>uplo</i>) in <i>packed storage</i> (see Matrix Storage Schemes). |

Output Parameters

| | |
|--------------|---|
| <i>s</i> | Array, size (<i>n</i>). If <i>info</i> = 0, the array <i>s</i> contains the scale factors for <i>A</i> . |
| <i>scond</i> | If <i>info</i> = 0, <i>scond</i> contains the ratio of the smallest <i>s</i> [<i>i</i>] to the largest <i>s</i> [<i>i</i>]. |
| <i>amax</i> | Absolute value of the largest element of the matrix <i>A</i> . |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

If *info* = *i*, the *i*-th diagonal element of *A* is nonpositive.

Application Notes

If $scond \geq 0.1$ and *amax* is neither too large nor too small, it is not worth scaling by *s*.

If *amax* is very close to SMLNUM or very close to BIGNUM, the matrix *A* should be scaled.

Description

The routine solves for X the system of linear equations $A*X = B$, where A is an n -by- n matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The LU decomposition with partial pivoting and row interchanges is used to factor A as $A = P*L*U$, where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. The factored form of A is then used to solve the system of equations $A*X = B$.

The `dsgesv` and `zcgesv` are mixed precision iterative refinement subroutines for exploiting fast single precision hardware. They first attempt to factorize the matrix in single precision (`dsgesv`) or single complex precision (`zcgesv`) and use this factorization within an iterative refinement procedure to produce a solution with double precision (`dsgesv`) / double complex precision (`zcgesv`) normwise backward error quality (see below). If the approach fails, the method switches to a double precision or double complex precision factorization respectively and computes the solution.

The iterative refinement is not going to be a winning strategy if the ratio single precision performance over double precision performance is too small. A reasonable strategy should take the number of right-hand sides and the size of the matrix into account. This might be done with a call to `ilaenv` in the future. At present, iterative refinement is implemented.

The iterative refinement process is stopped if

```
iter > itermax
```

or for all the right-hand sides:

```
rnmr < sqrt(n)*xnrm*anrm*eps*bwdmax
```

where

- *iter* is the number of the current iteration in the iterative refinement process
- *rnmr* is the infinity-norm of the residual
- *xnrm* is the infinity-norm of the solution
- *anrm* is the infinity-operator-norm of the matrix *A*
- *eps* is the machine epsilon returned by `dlamch` ('Epsilon').

The values *itermax* and *bwdmax* are fixed to 30 and 1.0d+00 respectively.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>n</i> | The number of linear equations, that is, the order of the matrix <i>A</i> ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides, that is, the number of columns of the matrix <i>B</i> ; $nrhs \geq 0$. |
| <i>a</i> | The array <i>a</i> (size $\max(1, lda * n)$) contains the <i>n</i> -by- <i>n</i> coefficient matrix <i>A</i> . |
| <i>b</i> | The array <i>b</i> of size $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout contains the <i>n</i> -by- <i>nrhs</i> matrix of right hand side matrix <i>B</i> . |
| <i>lda</i> | The leading dimension of the array <i>a</i> ; $lda \geq \max(1, n)$. |
| <i>ldb</i> | The leading dimension of the array <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>ldx</i> | The leading dimension of the array <i>x</i> ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |

Output Parameters

| | |
|----------|--|
| <i>a</i> | Overwritten by the factors <i>L</i> and <i>U</i> from the factorization of $A = P * L * U$; the unit diagonal elements of <i>L</i> are not stored. If iterative refinement has been successfully used (<i>info</i> = 0 and <i>iter</i> \geq 0), then <i>A</i> is unchanged. If double precision factorization has been used (<i>info</i> = 0 and <i>iter</i> < 0), then the array <i>A</i> contains the factors <i>L</i> and <i>U</i> from the factorization $A = P * L * U$; the unit diagonal elements of <i>L</i> are not stored. |
| <i>b</i> | Overwritten by the solution matrix <i>X</i> for <code>dgesv</code> , <code>sgesv</code> , <code>zgesv</code> , <code>zgesv</code> . Unchanged for <code>dsgesv</code> and <code>zcgsv</code> . |

| | |
|-------------|---|
| <i>ipiv</i> | Array, size at least $\max(1, n)$. The pivot indices that define the permutation matrix P ; row i of the matrix was interchanged with row $ipiv[i-1]$. Corresponds to the single precision factorization (if $info=0$ and $iter \geq 0$) or the double precision factorization (if $info=0$ and $iter < 0$). |
| <i>x</i> | Array, size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout. If $info = 0$, contains the n -by- $nrhs$ solution matrix X . |
| <i>iter</i> | <p>If $iter < 0$: iterative refinement has failed, double precision factorization has been performed</p> <ul style="list-style-type: none"> • If $iter = -1$: the routine fell back to full precision for implementation- or machine-specific reason • If $iter = -2$: narrowing the precision induced an overflow, the routine fell back to full precision • If $iter = -3$: failure of <code>sgetrf</code> for <code>dsgesv</code>, or <code>cgetrf</code> for <code>zcgsv</code> • If $iter = -31$: stop the iterative refinement after the 30th iteration. <p>If $iter > 0$: iterative refinement has been successfully used. Returns the number of iterations.</p> |

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = -i$, parameter i had an illegal value.

If $info = i$, $U_{i, i}$ (computed in double precision for mixed precision subroutines) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

Description

The routine uses the *LU* factorization to compute the solution to a real or complex system of linear equations $A \cdot X = B$, where A is an n -by- n matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine `?gesvx` performs the following steps:

1. If `fact = 'E'`, real scaling factors r and c are computed to equilibrate the system:

$$\text{trans} = \text{'N'}: \text{diag}(r) * A * \text{diag}(c) * \text{inv}(\text{diag}(c)) * X = \text{diag}(r) * B$$

$$\text{trans} = \text{'T'}: (\text{diag}(r) * A * \text{diag}(c))^T * \text{inv}(\text{diag}(r)) * X = \text{diag}(c) * B$$

$$\text{trans} = \text{'C'}: (\text{diag}(r) * A * \text{diag}(c))^H * \text{inv}(\text{diag}(r)) * X = \text{diag}(c) * B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(r) * A * \text{diag}(c)$ and B by $\text{diag}(r) * B$ (if `trans='N'`) or $\text{diag}(c) * B$ (if `trans = 'T' or 'C'`).

2. If `fact = 'N' or 'E'`, the *LU* decomposition is used to factor the matrix A (after equilibration if `fact = 'E'`) as $A = P * L * U$, where P is a permutation matrix, L is a unit lower triangular matrix, and U is upper triangular.
3. If some $U_{i,i} = 0$, so that U is exactly singular, then the routine returns with `info = i`. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, `info = n + 1` is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(c)$ (if `trans = 'N'`) or $\text{diag}(r)$ (if `trans = 'T' or 'C'`) so that it solves the original system before equilibration.

Input Parameters

`matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

`fact` Must be 'F', 'N', or 'E'.

| | |
|--------------|--|
| | <p>Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.</p> <p>If $fact = 'F'$: on entry, af and $ipiv$ contain the factored form of A. If $equed$ is not $'N'$, the matrix A has been equilibrated with scaling factors given by r and c. a, af, and $ipiv$ are not modified.</p> <p>If $fact = 'N'$, the matrix A will be copied to af and factored.</p> <p>If $fact = 'E'$, the matrix A will be equilibrated if necessary, then copied to af and factored.</p> |
| <i>trans</i> | <p>Must be $'N'$, $'T'$, or $'C'$.</p> <p>Specifies the form of the system of equations:</p> <p>If $trans = 'N'$, the system has the form $A * X = B$ (No transpose). If $trans = 'T'$, the system has the form $A^T * X = B$ (Transpose). If $trans = 'C'$, the system has the form $A^H * X = B$ (Transpose for real flavors, conjugate transpose for complex flavors).</p> |
| <i>n</i> | The number of linear equations; the order of the matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$. |
| <i>a</i> | The array a (size $\max(1, lda * n)$) contains the matrix A . If $fact = 'F'$ and $equed$ is not $'N'$, then A must have been equilibrated by the scaling factors in r and/or c . |
| <i>af</i> | The array af (size $\max(1, ldaf * n)$) is an input argument if $fact = 'F'$. It contains the factored form of the matrix A , that is, the factors L and U from the factorization $A = P * L * U$ as computed by <code>?getrf</code> . If $equed$ is not $'N'$, then af is the factored form of the equilibrated matrix A . |
| <i>b</i> | The array b of size $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout contains the matrix B whose columns are the right-hand sides for the systems of equations. |
| <i>lda</i> | The leading dimension of a ; $lda \geq \max(1, n)$. |
| <i>ldaf</i> | The leading dimension of af ; $ldaf \geq \max(1, n)$. |
| <i>ldb</i> | The leading dimension of b ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. The array $ipiv$ is an input argument if $fact = 'F'$. It contains the pivot indices from the factorization $A = P * L * U$ as computed by <code>?getrf</code> ; row i of the matrix was interchanged with row $ipiv[i-1]$. |
| <i>equed</i> | Must be $'N'$, $'R'$, $'C'$, or $'B'$. |

equed is an input argument if *fact* = 'F'. It specifies the form of equilibration that was done:

If *equed* = 'N', no equilibration was done (always true if *fact* = 'N').

If *equed* = 'R', row equilibration was done, that is, *A* has been premultiplied by *diag(r)*.

If *equed* = 'C', column equilibration was done, that is, *A* has been postmultiplied by *diag(c)*.

If *equed* = 'B', both row and column equilibration was done, that is, *A* has been replaced by *diag(r)*A*diag(c)*.

r, c

Arrays: *r* (size *n*), *c* (size *n*). The array *r* contains the row scale factors for *A*, and the array *c* contains the column scale factors for *A*. These arrays are input arguments if *fact* = 'F' only; otherwise they are output arguments.

If *equed* = 'R' or 'B', *A* is multiplied on the left by *diag(r)*; if *equed* = 'N' or 'C', *r* is not accessed.

If *fact* = 'F' and *equed* = 'R' or 'B', each element of *r* must be positive.

If *equed* = 'C' or 'B', *A* is multiplied on the right by *diag(c)*; if *equed* = 'N' or 'R', *c* is not accessed.

If *fact* = 'F' and *equed* = 'C' or 'B', each element of *c* must be positive.

ldx

The leading dimension of the output array *x*; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout.

Output Parameters

x

Array, size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout.

If *info* = 0 or *info* = *n*+1, the array *x* contains the solution matrix *X* to the *original* system of equations. Note that *A* and *B* are modified on exit if *equed* ≠ 'N', and the solution to the *equilibrated* system is:

$diag(C)^{-1} * X$, if *trans* = 'N' and *equed* = 'C' or 'B';
 $diag(R)^{-1} * X$, if *trans* = 'T' or 'C' and *equed* = 'R' or 'B'. The second dimension of *x* must be at least $\max(1, nrhs)$.

a

Array *a* is not modified on exit if *fact* = 'F' or 'N', or if *fact* = 'E' and *equed* = 'N'. If *equed* ≠ 'N', *A* is scaled on exit as follows:

equed = 'R': $A = diag(R) * A$

equed = 'C': $A = A * diag(c)$

equed = 'B': $A = diag(R) * A * diag(c)$.

| | |
|---------------|--|
| <i>af</i> | If <i>fact</i> = 'N' or 'E', then <i>af</i> is an output argument and on exit returns the factors <i>L</i> and <i>U</i> from the factorization $A = PLU$ of the original matrix <i>A</i> (if <i>fact</i> = 'N') or of the equilibrated matrix <i>A</i> (if <i>fact</i> = 'E'). See the description of <i>a</i> for the form of the equilibrated matrix. |
| <i>b</i> | Overwritten by $diag(r)*B$ if <i>trans</i> = 'N' and <i>equed</i> = 'R' or 'B'; overwritten by $diag(c)*B$ if <i>trans</i> = 'T' or 'C' and <i>equed</i> = 'C' or 'B'; not changed if <i>equed</i> = 'N'. |
| <i>r, c</i> | These arrays are output arguments if <i>fact</i> ≠ 'F'. See the description of <i>r, c</i> in <i>Input Arguments</i> section. |
| <i>rcond</i> | An estimate of the reciprocal condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision, in particular, if <i>rcond</i> = 0, the matrix is singular to working precision. This condition is indicated by a return code of <i>info</i> > 0. |
| <i>ferr</i> | Array, size at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector x_j (the <i>j</i> -th column of the solution matrix <i>X</i>). If <i>xtrue</i> is the true solution corresponding to x_j , <i>ferr</i> [<i>j</i> -1] is an estimated upper bound for the magnitude of the largest element in $(x_j - xtrue)$ divided by the magnitude of the largest element in x_j . The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error. |
| <i>berr</i> | Array, size at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector x_j , that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes x_j an exact solution. |
| <i>ipiv</i> | If <i>fact</i> = 'N' or 'E', then <i>ipiv</i> is an output argument and on exit contains the pivot indices from the factorization $A = P*L*U$ of the original matrix <i>A</i> (if <i>fact</i> = 'N') or of the equilibrated matrix <i>A</i> (if <i>fact</i> = 'E'). |
| <i>equed</i> | If <i>fact</i> ≠ 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section). |
| <i>rpivot</i> | On exit, <i>rpivot</i> contains the reciprocal pivot growth factor: $\ A\ /\ U\ $ <p>If <i>rpivot</i> is much less than 1, then the stability of the <i>LU</i> factorization of the (equilibrated) matrix <i>A</i> could be poor. This also means that the solution <i>x</i>, condition estimator <i>rcond</i>, and forward error bound <i>ferr</i> could be unreliable. If factorization fails with $0 < info \leq n$, then <i>rpivot</i> contains the reciprocal pivot growth factor for the leading <i>info</i> columns of <i>A</i>.</p> |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

If *info* = *i*, and $i \leq n$, then $U(i, i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; $rcond = 0$ is returned.

If *info* = $n + 1$, then U is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Description

The routine uses the *LU* factorization to compute the solution to a real or complex system of linear equations $A*X = B$, where A is an n -by- n matrix, the columns of the matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Both normwise and maximum componentwise error bounds are also provided on request. The routine returns a solution with a small guaranteed error ($O(\text{eps})$, where eps is the working machine precision) unless the matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also calculated and returned.

The routine accepts user-provided factorizations and equilibration factors; see definitions of the *fact* and *equed* options. Solving with refinement and using a factorization from a previous call of the routine also produces a solution with $O(\text{eps})$ errors or warnings but that may not be true for general user-provided factorizations and equilibration factors if they differ from what the routine would itself produce.

The routine `?gesvxx` performs the following steps:

1. If *fact* = 'E', scaling factors r and c are computed to equilibrate the system:

$$\text{trans} = \text{'N'}: \text{diag}(r) * A * \text{diag}(c) * \text{inv}(\text{diag}(c)) * X = \text{diag}(r) * B$$

$$\text{trans} = \text{'T'}: (\text{diag}(r) * A * \text{diag}(c))^T * \text{inv}(\text{diag}(r)) * X = \text{diag}(c) * B$$

$$\text{trans} = \text{'C'}: (\text{diag}(r) * A * \text{diag}(c))^H * \text{inv}(\text{diag}(r)) * X = \text{diag}(c) * B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(r) * A * \text{diag}(c)$ and B by $\text{diag}(r) * B$ (if *trans*='N') or $\text{diag}(c) * B$ (if *trans* = 'T' or 'C').

2. If *fact* = 'N' or 'E', the *LU* decomposition is used to factor the matrix A (after equilibration if *fact* = 'E') as $A = P * L * U$, where P is a permutation matrix, L is a unit lower triangular matrix, and U is upper triangular.
3. If some $U_{i,i} = 0$, so that U is exactly singular, then the routine returns with *info* = i . Otherwise, the factored form of A is used to estimate the condition number of the matrix A (see the *rcond* parameter). If the reciprocal of the condition number is less than machine precision, the routine still goes on to solve for X and compute error bounds.
4. The system of equations is solved for X using the factored form of A .
5. By default, unless is set to zero, the routine applies iterative refinement to improve the computed solution matrix and calculate error bounds. Refinement calculates the residual to at least twice the working precision.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(c)$ (if *trans* = 'N') or $\text{diag}(r)$ (if *trans* = 'T' or 'C') so that it solves the original system before equilibration.

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

fact Must be 'F', 'N', or 'E'.

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

If *fact* = 'F', on entry, *af* and *ipiv* contain the factored form of A . If *equed* is not 'N', the matrix A has been equilibrated with scaling factors given by r and c . Parameters a , *af*, and *ipiv* are not modified.

If *fact* = 'N', the matrix A will be copied to *af* and factored.

If *fact* = 'E', the matrix A will be equilibrated, if necessary, copied to *af* and factored.

| | |
|-----------------|---|
| <i>trans</i> | <p>Must be 'N', 'T', or 'C'.</p> <p>Specifies the form of the system of equations:</p> <p>If <i>trans</i> = 'N', the system has the form $A^*X = B$ (No transpose).</p> <p>If <i>trans</i> = 'T', the system has the form $A^T X = B$ (Transpose).</p> <p>If <i>trans</i> = 'C', the system has the form $A^H X = B$ (Conjugate Transpose = Transpose for real flavors, Conjugate Transpose for complex flavors).</p> |
| <i>n</i> | The number of linear equations; the order of the matrix <i>A</i> ; $n \geq 0$. |
| <i>nrhs</i> | The number of right hand sides; the number of columns of the matrices <i>B</i> and <i>X</i> ; $nrhs \geq 0$. |
| <i>a, af, b</i> | <p>Arrays: <i>a</i>(size $\max(lda*n)$), <i>af</i>(size $\max(ldaf*n)$), <i>b</i>(size $\max(1, ldb*nrhs)$) for column major layout and $\max(1, ldb*n)$ for row major layout).</p> <p>The array <i>a</i> contains the matrix <i>A</i>. If <i>fact</i> = 'F' and <i>equed</i> is not 'N', then <i>A</i> must have been equilibrated by the scaling factors in <i>r</i> and/or <i>c</i>.</p> <p>The array <i>af</i> is an input argument if <i>fact</i> = 'F'. It contains the factored form of the matrix <i>A</i>, that is, the factors <i>L</i> and <i>U</i> from the factorization $A = P*L*U$ as computed by <code>?getrf</code>. If <i>equed</i> is not 'N', then <i>af</i> is the factored form of the equilibrated matrix <i>A</i>.</p> <p>The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations.</p> |
| <i>lda</i> | The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$. |
| <i>ldaf</i> | The leading dimension of <i>af</i> ; $ldaf \geq \max(1, n)$. |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F'. It contains the pivot indices from the factorization $A = P*L*U$ as computed by <code>?getrf</code> ; row <i>i</i> of the matrix was interchanged with row <i>ipiv</i> [<i>i</i> -1]. |
| <i>equed</i> | <p>Must be 'N', 'R', 'C', or 'B'.</p> <p><i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done:</p> <p>If <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N').</p> <p>If <i>equed</i> = 'R', row equilibration was done, that is, <i>A</i> has been premultiplied by <i>diag</i>(<i>r</i>).</p> <p>If <i>equed</i> = 'C', column equilibration was done, that is, <i>A</i> has been postmultiplied by <i>diag</i>(<i>c</i>).</p> <p>If <i>equed</i> = 'B', both row and column equilibration was done, that is, <i>A</i> has been replaced by <i>diag</i>(<i>r</i>)*<i>A</i>*<i>diag</i>(<i>c</i>).</p> |
| <i>r, c</i> | Arrays: <i>r</i> (size <i>n</i>), <i>c</i> (size <i>n</i>). The array <i>r</i> contains the row scale factors for <i>A</i> , and the array <i>c</i> contains the column scale factors for <i>A</i> . These arrays are input arguments if <i>fact</i> = 'F' only; otherwise they are output arguments. |

If *equed* = 'R' or 'B', *A* is multiplied on the left by *diag(r)*; if *equed* = 'N' or 'C', *r* is not accessed.

If *fact* = 'F' and *equed* = 'R' or 'B', each element of *r* must be positive.

If *equed* = 'C' or 'B', *A* is multiplied on the right by *diag(c)*; if *equed* = 'N' or 'R', *c* is not accessed.

If *fact* = 'F' and *equed* = 'C' or 'B', each element of *c* must be positive.

Each element of *r* or *c* should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

ldb The leading dimension of the array *b*; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

ldx The leading dimension of the output array *x*; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout.

n_err_bnds Number of error bounds to return for each right hand side and each type (normwise or componentwise). See *err_bnds_norm* and *err_bnds_comp* descriptions in *Output Arguments* section below.

nparams Specifies the number of parameters set in *params*. If ≤ 0 , the *params* array is never referenced and default values are used.

params Array, size $\max(1, nparams)$. Specifies algorithm parameters. If an entry is less than 0.0, that entry is filled with the default value used for that parameter. Only positions up to *nparams* are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass *nparams* = 0, which prevents the source code from accessing the *params* argument.

params[0] : Whether to perform iterative refinement or not. Default: 1.0

=0.0 No refinement is performed and no error bounds are computed.

=1.0 Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support double precision.

(Other values are reserved for future use.)

params[1] : Maximum number of residual computations allowed for refinement.

Default 10.0

Aggressive Set to 100.0 to permit convergence using approximate factorizations or factorizations other than *LU*. If the factorization uses a

technique other than Gaussian elimination, the guarantees in *err_bnds_norm* and *err_bnds_comp* may no longer be trustworthy.

params[2] : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

Output Parameters

- x* Array, size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout.
 If *info* = 0, the array *x* contains the solution *n*-by-*nrhs* matrix *X* to the *original* system of equations. Note that *A* and *B* are modified on exit if *equed* ≠ 'N', and the solution to the *equilibrated* system is:

$$\text{inv}(\text{diag}(c)) * X, \text{ if } \text{trans} = \text{'N'} \text{ and } \text{equed} = \text{'C'} \text{ or } \text{'B'}; \text{ or}$$

$$\text{inv}(\text{diag}(r)) * X, \text{ if } \text{trans} = \text{'T'} \text{ or } \text{'C'} \text{ and } \text{equed} = \text{'R'} \text{ or } \text{'B'}.$$
- a* Array *a* is not modified on exit if *fact* = 'F' or 'N', or if *fact* = 'E' and *equed* = 'N'.
 If *equed* ≠ 'N', *A* is scaled on exit as follows:

$$\text{equed} = \text{'R'}: A = \text{diag}(r) * A$$

$$\text{equed} = \text{'C'}: A = A * \text{diag}(c)$$

$$\text{equed} = \text{'B'}: A = \text{diag}(r) * A * \text{diag}(c).$$
- af* If *fact* = 'N' or 'E', then *af* is an output argument and on exit returns the factors *L* and *U* from the factorization $A = PLU$ of the original matrix *A* (if *fact* = 'N') or of the equilibrated matrix *A* (if *fact* = 'E'). See the description of *a* for the form of the equilibrated matrix.
- b* Overwritten by $\text{diag}(r) * B$ if *trans* = 'N' and *equed* = 'R' or 'B';
 overwritten by *trans* = 'T' or 'C' and *equed* = 'C' or 'B';
 not changed if *equed* = 'N'.
- r, c* These arrays are output arguments if *fact* ≠ 'F'. Each element of these arrays is a power of the radix. See the description of *r, c* in *Input Arguments* section.
- rcond* Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix *A* after equilibration (if done). If *rcond* is less than the machine precision, in particular, if *rcond* = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.
- rpvgrw* Contains the reciprocal pivot growth factor:

$$\|A\|/\|U\|$$

If this is much less than 1, the stability of the *LU* factorization of the (equilibrated) matrix *A* could be poor. This also means that the solution *X*, estimated condition numbers, and error bounds could be unreliable. If factorization fails with $0 < info \leq n$, this parameter contains the reciprocal pivot growth factor for the leading *info* columns of *A*. In *?gesvx*, this quantity is returned in *rpivot*.

berr Array, size at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector x_j , that is, the smallest relative change in any element of *A* or *B* that makes x_j an exact solution.

err_bnds_norm Array of size $nrhs * n_err_bnds$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the *i*-th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors.

err=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

err=3 Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix *Z* are:

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z = s * a$, where *s* scales each row by a power of the radix so all absolute row sums of *z* are approximately 1.

The information for right-hand side i , where $1 \leq i \leq nrhs$, and type of error err is stored in $err_bnds_norm[(err-1)*nrhs + i - 1]$.

err_bnds_comp

Array of size $nrhs*n_err_bnds$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($params[2] = 0.0$), then *err_bnds_comp* is not accessed.

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors.

err=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

err=3 Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix Z are:

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

The information for right-hand side i , where $1 \leq i \leq nrhs$, and type of error err is stored in $err_bnds_comp[(err-1)*nrhs + i - 1]$.

| | |
|---------------|---|
| <i>ipiv</i> | If <i>fact</i> = 'N' or 'E', then <i>ipiv</i> is an output argument and on exit contains the pivot indices from the factorization $A = P*L*U$ of the original matrix <i>A</i> (if <i>fact</i> = 'N') or of the equilibrated matrix <i>A</i> (if <i>fact</i> = 'E'). |
| <i>equed</i> | If <i>fact</i> ≠ 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section). |
| <i>params</i> | If an entry is less than 0.0, that entry is filled with the default value used for that parameter, otherwise the entry is not modified |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful. The solution to every right-hand side is guaranteed.

If *info* = -*i*, parameter *i* had an illegal value.

If $0 < info \leq n$: $U_{info,info}$ is exactly zero. The factorization has been completed, but the factor *U* is exactly singular, so the solution and error bounds could not be computed; *rcond* = 0 is returned.

If *info* = *n*+*j*: The solution corresponding to the *j*-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides *k* with *k* > *j* may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested *params*[2] = 0.0, then the *j*-th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest *j* such that for column major layout $err_bnds_norm[j - 1] = 0.0$ or $err_bnds_comp[j - 1] = 0.0$; or for row major layout $err_bnds_norm[(j - 1)*n_err_bnds] = 0.0$ or $err_bnds_comp[(j - 1)*n_err_bnds] = 0.0$). See the definition of *err_bnds_norm* and *err_bnds_comp* for *err* = 1. To get information about all of the right-hand sides, check *err_bnds_norm* or *err_bnds_comp*.

Description

The routine solves for X the real or complex system of linear equations $A^*X = B$, where A is an n -by- n band matrix with kl subdiagonals and ku superdiagonals, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The LU decomposition with partial pivoting and row interchanges is used to factor A as $A = L^*U$, where L is a product of permutation and unit lower triangular matrices with kl subdiagonals, and U is upper triangular with $kl+ku$ superdiagonals. The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>n</i> | The order of A . The number of rows in B ; $n \geq 0$. |
| <i>kl</i> | The number of subdiagonals within the band of A ; $kl \geq 0$. |
| <i>ku</i> | The number of superdiagonals within the band of A ; $ku \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides. The number of columns in B ; $nrhs \geq 0$. |
| <i>ab, b</i> | Arrays: <i>ab</i> (size $\max(1, ldab*n)$), <i>bof</i> size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout. The array <i>ab</i> contains the matrix A in band storage (see Matrix Storage Schemes). The array <i>b</i> contains the matrix B whose columns are the right-hand sides for the systems of equations. |
| <i>ldab</i> | The leading dimension of the array <i>ab</i> . ($ldab \geq 2kl + ku + 1$) |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |

Output Parameters

| | |
|-------------|--|
| <i>ab</i> | Overwritten by L and U . U is stored as an upper triangular band matrix with $kl + ku$ superdiagonals and L is stored as a lower triangular band matrix with kl subdiagonals. See Matrix Storage Schemes . |
| <i>b</i> | Overwritten by the solution matrix X . |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. The pivot indices: row i was interchanged with row $ipiv[i-1]$. |

Return Values

This function returns a value *info*.

If $info = 0$, the execution is successful.

If $info = -i$, parameter i had an illegal value.

If $info = i$, $U_{i,i}$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

Description

The routine uses the LU factorization to compute the solution to a real or complex system of linear equations $A * X = B$, $A^T * X = B$, or $A^H * X = B$, where A is a band matrix of order n with kl subdiagonals and ku superdiagonals, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?gbsvx performs the following steps:

1. If $fact = 'E'$, real scaling factors r and c are computed to equilibrate the system:

$$trans = 'N': \text{diag}(r) * A * \text{diag}(c) * \text{inv}(\text{diag}(c)) * X = \text{diag}(r) * B$$

$$trans = 'T': (\text{diag}(r) * A * \text{diag}(c))^T * \text{inv}(\text{diag}(r)) * X = \text{diag}(c) * B$$

$$trans = 'C': (\text{diag}(r) * A * \text{diag}(c))^H * \text{inv}(\text{diag}(r)) * X = \text{diag}(c) * B$$

Whether the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(r)*A*\text{diag}(c)$ and B by $\text{diag}(r)*B$ (if $\text{trans} = 'N'$) or $\text{diag}(c)*B$ (if $\text{trans} = 'T'$ or $'C'$).

2. If $\text{fact} = 'N'$ or $'E'$, the LU decomposition is used to factor the matrix A (after equilibration if $\text{fact} = 'E'$) as $A = L*U$, where L is a product of permutation and unit lower triangular matrices with kl subdiagonals, and U is upper triangular with $kl+ku$ superdiagonals.
3. If some $U_{i,i} = 0$, so that U is exactly singular, then the routine returns with $\text{info} = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $\text{info} = n + 1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(c)$ (if $\text{trans} = 'N'$) or $\text{diag}(r)$ (if $\text{trans} = 'T'$ or $'C'$) so that it solves the original system before equilibration.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>fact</i> | <p>Must be 'F', 'N', or 'E'.</p> <p>Specifies whether the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.</p> <p>If $\text{fact} = 'F'$: on entry, afb and ipiv contain the factored form of A. If equed is not 'N', the matrix A is equilibrated with scaling factors given by r and c. ab, afb, and ipiv are not modified.</p> <p>If $\text{fact} = 'N'$, the matrix A will be copied to afb and factored.</p> <p>If $\text{fact} = 'E'$, the matrix A will be equilibrated if necessary, then copied to afb and factored.</p> |
| <i>trans</i> | <p>Must be 'N', 'T', or 'C'.</p> <p>Specifies the form of the system of equations:</p> <p>If $\text{trans} = 'N'$, the system has the form $A*X = B$ (No transpose).</p> <p>If $\text{trans} = 'T'$, the system has the form $A^T*X = B$ (Transpose).</p> <p>If $\text{trans} = 'C'$, the system has the form $A^H*X = B$ (Transpose for real flavors, conjugate transpose for complex flavors).</p> |
| <i>n</i> | The number of linear equations, the order of the matrix A ; $n \geq 0$. |
| <i>kl</i> | The number of subdiagonals within the band of A ; $kl \geq 0$. |
| <i>ku</i> | The number of superdiagonals within the band of A ; $ku \geq 0$. |
| <i>nrhs</i> | The number of right hand sides, the number of columns of the matrices B and X ; $\text{nrhs} \geq 0$. |

| | |
|-------------------|---|
| <i>ab, afb, b</i> | <p>Arrays: <i>ab</i> ($\max(\text{ldab} * n)$), <i>afb</i> ($\max(\text{ldafb} * n)$), <i>b</i> ($\max(1, \text{ldb} * \text{nrhs})$) for column major layout and $\max(1, \text{ldb} * n)$ for row major layout).</p> <p>The array <i>ab</i> contains the matrix <i>A</i> in band storage (see Matrix Storage Schemes). If <i>fact</i> = 'F' and <i>equed</i> is not 'N', then <i>A</i> must have been equilibrated by the scaling factors in <i>r</i> and/or <i>c</i>.</p> <p>The array <i>afb</i> is an input argument if <i>fact</i> = 'F'. It contains the factored form of the matrix <i>A</i>, that is, the factors <i>L</i> and <i>U</i> from the factorization $A = P * L * U$ as computed by <code>?gbtrf</code>. <i>U</i> is stored as an upper triangular band matrix with <i>kl</i> + <i>ku</i> superdiagonals. <i>L</i> is stored as lower triangular band matrix with <i>kl</i> subdiagonals. If <i>equed</i> is not 'N', then <i>afb</i> is the factored form of the equilibrated matrix <i>A</i>.</p> <p>The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations.</p> |
| <i>ldab</i> | The leading dimension of <i>ab</i> ; $\text{ldab} \geq \text{kl} + \text{ku} + 1$. |
| <i>ldafb</i> | The leading dimension of <i>afb</i> ; $\text{ldafb} \geq 2 * \text{kl} + \text{ku} + 1$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $\text{ldb} \geq \max(1, n)$ for column major layout and $\text{ldb} \geq \text{nrhs}$ for row major layout. |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F'. It contains the pivot indices from the factorization $A = P * L * U$ as computed by <code>?gbtrf</code> ; row <i>i</i> of the matrix was interchanged with row <i>ipiv</i> [<i>i</i> -1]. |
| <i>equed</i> | <p>Must be 'N', 'R', 'C', or 'B'.</p> <p><i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done:</p> <p>If <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N').</p> <p>If <i>equed</i> = 'R', row equilibration was done, that is, <i>A</i> has been premultiplied by <i>diag</i>(<i>r</i>).</p> <p>If <i>equed</i> = 'C', column equilibration was done, that is, <i>A</i> has been postmultiplied by <i>diag</i>(<i>c</i>).</p> <p>If <i>equed</i> = 'B', both row and column equilibration was done, that is, <i>A</i> has been replaced by <i>diag</i>(<i>r</i>) * <i>A</i> * <i>diag</i>(<i>c</i>).</p> |
| <i>r, c</i> | <p>Arrays: <i>r</i> (size <i>n</i>), <i>c</i> (size <i>n</i>).</p> <p>The array <i>r</i> contains the row scale factors for <i>A</i>, and the array <i>c</i> contains the column scale factors for <i>A</i>. These arrays are input arguments if <i>fact</i> = 'F' only; otherwise they are output arguments.</p> <p>If <i>equed</i> = 'R' or 'B', <i>A</i> is multiplied on the left by <i>diag</i>(<i>r</i>); if <i>equed</i> = 'N' or 'C', <i>r</i> is not accessed.</p> <p>If <i>fact</i> = 'F' and <i>equed</i> = 'R' or 'B', each element of <i>r</i> must be positive.</p> <p>If <i>equed</i> = 'C' or 'B', <i>A</i> is multiplied on the right by <i>diag</i>(<i>c</i>); if <i>equed</i> = 'N' or 'R', <i>c</i> is not accessed.</p> |

If $fact = 'F'$ and $equed = 'C'$ or $'B'$, each element of c must be positive.

ldx

The leading dimension of the output array x ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout.

Output Parameters

x

Array, size $\max(1, ldx * nrhs)$ for column major layout and $\max(1, ldx * n)$ for row major layout.

If $info = 0$ or $info = n+1$, the array x contains the solution matrix X to the *original* system of equations. Note that A and B are modified on exit if $equed \neq 'N'$, and the solution to the *equilibrated* system is: $inv(diag(c)) * X$, if $trans = 'N'$ and $equed = 'C'$ or $'B'$; $inv(diag(r)) * X$, if $trans = 'T'$ or $'C'$ and $equed = 'R'$ or $'B'$.

ab

Array ab is not modified on exit if $fact = 'F'$ or $'N'$, or if $fact = 'E'$ and $equed = 'N'$.

If $equed \neq 'N'$, A is scaled on exit as follows:

$equed = 'R'$: $A = diag(r) * A$

$equed = 'C'$: $A = A * diag(c)$

$equed = 'B'$: $A = diag(r) * A * diag(c)$.

afb

If $fact = 'N'$ or $'E'$, then afb is an output argument and on exit returns details of the *LU* factorization of the original matrix A (if $fact = 'N'$) or of the equilibrated matrix A (if $fact = 'E'$). See the description of ab for the form of the equilibrated matrix.

b

Overwritten by $diag(r) * b$ if $trans = 'N'$ and $equed = 'R'$ or $'B'$; overwritten by $diag(c) * b$ if $trans = 'T'$ or $'C'$ and $equed = 'C'$ or $'B'$; not changed if $equed = 'N'$.

r, c

These arrays are output arguments if $fact \neq 'F'$. See the description of r, c in *Input Arguments* section.

$rcond$

An estimate of the reciprocal condition number of the matrix A after equilibration (if done).

If $rcond$ is less than the machine precision (in particular, if $rcond = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$.

$ferr$

Array, size at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector x_j (the j -th column of the solution matrix X). If $xtrue$ is the true solution corresponding to x_j , $ferr[j-1]$ is an estimated upper bound for the magnitude of the largest element in $(x_j - xtrue)$ divided by the magnitude of the largest element in x_j . The estimate is as reliable as the estimate for $rcond$, and is almost always a slight overestimate of the true error.

| | |
|---------------|---|
| <i>berr</i> | Array, size at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector x_j , that is, the smallest relative change in any element of A or B that makes x_j an exact solution. |
| <i>ipiv</i> | If <i>fact</i> = 'N' or 'E', then <i>ipiv</i> is an output argument and on exit contains the pivot indices from the factorization $A = L*U$ of the original matrix A (if <i>fact</i> = 'N') or of the equilibrated matrix A (if <i>fact</i> = 'E'). |
| <i>equed</i> | If <i>fact</i> ≠ 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section). |
| <i>rpivot</i> | On exit, <i>rpivot</i> contains the reciprocal pivot growth factor: <div style="text-align: center;"> $\ A\ /\ U\$ </div> <p>If <i>rpivot</i> is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution x, condition estimator <i>rcond</i>, and forward error bound <i>ferr</i> could be unreliable. If factorization fails with $0 < info \leq n$, then <i>rpivot</i> contains the reciprocal pivot growth factor for the leading <i>info</i> columns of A.</p> |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

If *info* = *i*, and $i \leq n$, then $U_{i,i}$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; *rcond* = 0 is returned. If *info* = *i*, and $i = n+1$, then U is nonsingular, but *rcond* is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of *rcond* would suggest.

Description

The routine uses the *LU* factorization to compute the solution to a real or complex system of linear equations $A*X = B$, $A^T*X = B$, or $A^H*X = B$, where A is an n -by- n banded matrix, the columns of the matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Both normwise and maximum componentwise error bounds are also provided on request. The routine returns a solution with a small guaranteed error ($O(\text{eps})$, where eps is the working machine precision) unless the matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also calculated and returned.

The routine accepts user-provided factorizations and equilibration factors; see definitions of the *fact* and *equed* options. Solving with refinement and using a factorization from a previous call of the routine also produces a solution with $O(\text{eps})$ errors or warnings but that may not be true for general user-provided factorizations and equilibration factors if they differ from what the routine would itself produce.

The routine `?gbsvxx` performs the following steps:

1. If *fact* = 'E', scaling factors r and c are computed to equilibrate the system:

$$\text{trans} = \text{'N'}: \text{diag}(r) * A * \text{diag}(c) * \text{inv}(\text{diag}(c)) * X = \text{diag}(r) * B$$

$$\text{trans} = \text{'T'}: (\text{diag}(r) * A * \text{diag}(c))^T * \text{inv}(\text{diag}(r)) * X = \text{diag}(c) * B$$

$$\text{trans} = \text{'C'}: (\text{diag}(r) * A * \text{diag}(c))^H * \text{inv}(\text{diag}(r)) * X = \text{diag}(c) * B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(r) * A * \text{diag}(c)$ and B by $\text{diag}(r) * B$ (if *trans*='N') or $\text{diag}(c) * B$ (if *trans* = 'T' or 'C').

2. If *fact* = 'N' or 'E', the *LU* decomposition is used to factor the matrix A (after equilibration if *fact* = 'E') as $A = P * L * U$, where P is a permutation matrix, L is a unit lower triangular matrix, and U is upper triangular.

3. If some $U_{i,i} = 0$, so that U is exactly singular, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A (see the `rcond` parameter). If the reciprocal of the condition number is less than machine precision, the routine still goes on to solve for X and compute error bounds.
4. The system of equations is solved for X using the factored form of A .
5. By default, unless `params[0]` is set to zero, the routine applies iterative refinement to improve the computed solution matrix and calculate error bounds. Refinement calculates the residual to at least twice the working precision.
6. If equilibration was used, the matrix X is premultiplied by $diag(c)$ (if `trans = 'N'`) or $diag(r)$ (if `trans = 'T'` or `'C'`) so that it solves the original system before equilibration.

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether two-dimensional array storage is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>fact</code> | <p>Must be 'F', 'N', or 'E'.</p> <p>Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.</p> <p>If <code>fact = 'F'</code>, on entry, <code>afb</code> and <code>ipiv</code> contain the factored form of A. If <code>equed</code> is not 'N', the matrix A has been equilibrated with scaling factors given by <code>r</code> and <code>c</code>. Parameters <code>ab</code>, <code>afb</code>, and <code>ipiv</code> are not modified.</p> <p>If <code>fact = 'N'</code>, the matrix A will be copied to <code>afb</code> and factored.</p> <p>If <code>fact = 'E'</code>, the matrix A will be equilibrated, if necessary, copied to <code>afb</code> and factored.</p> |
| <code>trans</code> | <p>Must be 'N', 'T', or 'C'.</p> <p>Specifies the form of the system of equations:</p> <p>If <code>trans = 'N'</code>, the system has the form $A * X = B$ (No transpose).</p> <p>If <code>trans = 'T'</code>, the system has the form $A^T * X = B$ (Transpose).</p> <p>If <code>trans = 'C'</code>, the system has the form $A^H * X = B$ (Conjugate Transpose = Transpose for real flavors, Conjugate Transpose for complex flavors).</p> |
| <code>n</code> | The number of linear equations; the order of the matrix A ; $n \geq 0$. |
| <code>kl</code> | The number of subdiagonals within the band of A ; $kl \geq 0$. |
| <code>ku</code> | The number of superdiagonals within the band of A ; $ku \geq 0$. |
| <code>nrhs</code> | The number of right-hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$. |
| <code>ab, afb, b</code> | <p>Arrays: <code>ab</code> ($\max(ldab * n)$), <code>afb</code> ($\max(ldafb * n)$), <code>b</code> ($\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout).</p> <p>The array <code>ab</code> contains the matrix A in band storage.</p> <p>If <code>fact = 'F'</code> and <code>equed</code> is not 'N', then AB must have been equilibrated by the scaling factors in <code>r</code> and/or <code>c</code>.</p> |

The array *afb* is an input argument if *fact* = 'F'. It contains the factored form of the banded matrix *A*, that is, the factors *L* and *U* from the factorization $A = P * L * U$ as computed by `?gbtrf`. *U* is stored as an upper triangular banded matrix with *kl* + *ku* superdiagonals. *L* is stored as lower triangular band matrix with *kl* subdiagonals. If *equed* is not 'N', then *afb* is the factored form of the equilibrated matrix *A*.

The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations.

| | |
|---------------------|---|
| <i>ldab</i> | The leading dimension of the array <i>ab</i> ; $ldab \geq kl + ku + 1$. |
| <i>ldafb</i> | The leading dimension of the array <i>afb</i> ; $ldafb \geq 2 * kl + ku + 1$. |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F'. It contains the pivot indices from the factorization $A = P * L * U$ as computed by <code>?gbtrf</code> ; row <i>i</i> of the matrix was interchanged with row <i>ipiv</i> [<i>i</i> -1]. |
| <i>equed</i> | Must be 'N', 'R', 'C', or 'B'. <i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done: If <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N'). If <i>equed</i> = 'R', row equilibration was done, that is, <i>A</i> has been premultiplied by <i>diag</i> (<i>r</i>). If <i>equed</i> = 'C', column equilibration was done, that is, <i>A</i> has been postmultiplied by <i>diag</i> (<i>c</i>). If <i>equed</i> = 'B', both row and column equilibration was done, that is, <i>A</i> has been replaced by <i>diag</i> (<i>r</i>) * <i>A</i> * <i>diag</i> (<i>c</i>). |
| <i>r, c</i> | Arrays: <i>r</i> (size <i>n</i>), <i>c</i> (size <i>n</i>). The array <i>r</i> contains the row scale factors for <i>A</i> , and the array <i>c</i> contains the column scale factors for <i>A</i> . These arrays are input arguments if <i>fact</i> = 'F' only; otherwise they are output arguments. If <i>equed</i> = 'R' or 'B', <i>A</i> is multiplied on the left by <i>diag</i> (<i>r</i>); if <i>equed</i> = 'N' or 'C', <i>r</i> is not accessed. If <i>fact</i> = 'F' and <i>equed</i> = 'R' or 'B', each element of <i>r</i> must be positive. If <i>equed</i> = 'C' or 'B', <i>A</i> is multiplied on the right by <i>diag</i> (<i>c</i>); if <i>equed</i> = 'N' or 'R', <i>c</i> is not accessed. If <i>fact</i> = 'F' and <i>equed</i> = 'C' or 'B', each element of <i>c</i> must be positive. Each element of <i>r</i> or <i>c</i> should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable. |
| <i>ldb</i> | The leading dimension of the array <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |

| | | | | | |
|-------------------|--|---------|------|------------|---|
| <i>ldx</i> | The leading dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. | | | | |
| <i>n_err_bnds</i> | Number of error bounds to return for each right hand side and each type (normwise or componentwise). See <i>err_bnds_norm</i> and <i>err_bnds_comp</i> descriptions in <i>Output Arguments</i> section below. | | | | |
| <i>nparams</i> | Specifies the number of parameters set in <i>params</i> . If ≤ 0 , the <i>params</i> array is never referenced and default values are used. | | | | |
| <i>params</i> | <p>Array, size $\max(1, nparams)$. Specifies algorithm parameters. If an entry is less than 0.0, that entry is filled with the default value used for that parameter. Only positions up to <i>nparams</i> are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass <i>nparams</i> = 0, which prevents the source code from accessing the <i>params</i> argument.</p> <p><i>params</i>[0] : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).</p> <p>=0.0 No refinement is performed and no error bounds are computed.</p> <p>=1.0 Use the extra-precise refinement algorithm.</p> <p>(Other values are reserved for future use.)</p> <p><i>params</i>[1] : Maximum number of residual computations allowed for refinement.</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;">Default</td> <td>10.0</td> </tr> <tr> <td>Aggressive</td> <td>Set to 100.0 to permit convergence using approximate factorizations or factorizations other than <i>LU</i>. If the factorization uses a technique other than Gaussian elimination, the guarantees in <i>err_bnds_norm</i> and <i>err_bnds_comp</i> may no longer be trustworthy.</td> </tr> </table> <p><i>params</i>[2] : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).</p> | Default | 10.0 | Aggressive | Set to 100.0 to permit convergence using approximate factorizations or factorizations other than <i>LU</i> . If the factorization uses a technique other than Gaussian elimination, the guarantees in <i>err_bnds_norm</i> and <i>err_bnds_comp</i> may no longer be trustworthy. |
| Default | 10.0 | | | | |
| Aggressive | Set to 100.0 to permit convergence using approximate factorizations or factorizations other than <i>LU</i> . If the factorization uses a technique other than Gaussian elimination, the guarantees in <i>err_bnds_norm</i> and <i>err_bnds_comp</i> may no longer be trustworthy. | | | | |

Output Parameters

| | |
|----------|--|
| <i>x</i> | <p>Array, size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout.</p> <p>If <i>info</i> = 0, the array <i>x</i> contains the solution <i>n</i>-by-<i>nrhs</i> matrix <i>X</i> to the <i>original</i> system of equations. Note that <i>A</i> and <i>B</i> are modified on exit if <i>equed</i> ≠ 'N', and the solution to the <i>equilibrated</i> system is:</p> <p>$inv(diag(c)) * X$, if <i>trans</i> = 'N' and <i>equed</i> = 'C' or 'B'; or</p> <p>$inv(diag(r)) * X$, if <i>trans</i> = 'T' or 'C' and <i>equed</i> = 'R' or 'B'.</p> |
|----------|--|

- ab* Array *ab* is not modified on exit if *fact* = 'F' or 'N', or if *fact* = 'E' and *equed* = 'N'.
If *equed* ≠ 'N', *A* is scaled on exit as follows:
equed = 'R': $A = \text{diag}(r) * A$
equed = 'C': $A = A * \text{diag}(c)$
equed = 'B': $A = \text{diag}(r) * A * \text{diag}(c)$.
- afb* If *fact* = 'N' or 'E', then *afb* is an output argument and on exit returns the factors *L* and *U* from the factorization $A = PLU$ of the original matrix *A* (if *fact* = 'N') or of the equilibrated matrix *A* (if *fact* = 'E').
- b* Overwritten by $\text{diag}(r) * B$ if *trans* = 'N' and *equed* = 'R' or 'B';
overwritten by *trans* = 'T' or 'C' and *equed* = 'C' or 'B';
not changed if *equed* = 'N'.
- r, c* These arrays are output arguments if *fact* ≠ 'F'. Each element of these arrays is a power of the radix. See the description of *r, c* in *Input Arguments* section.
- rcond* Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix *A* after equilibration (if done). If *rcond* is less than the machine precision, in particular, if *rcond* = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.
- rpvgrw* Contains the reciprocal pivot growth factor:
$$\|A\| / \|U\|$$

If this is much less than 1, the stability of the *LU* factorization of the (equilibrated) matrix *A* could be poor. This also means that the solution *X*, estimated condition numbers, and error bounds could be unreliable. If factorization fails with $0 < \text{info} \leq n$, this parameter contains the reciprocal pivot growth factor for the leading *info* columns of *A*. In ?gbsvx, this quantity is returned in *rpivot*.
- berr* Array, size at least $\max(1, \text{nrhs})$. Contains the componentwise relative backward error for each solution vector x_j , that is, the smallest relative change in any element of *A* or *B* that makes x_j an exact solution.
- err_bnds_norm* Array of size *nrhs***n_err_bnds*. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:
Normwise relative error in the *i*-th solution vector
$$\frac{\max_j |X_{\text{true}_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.

err=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

err=3 Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix *Z* are:

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z = s * a$, where *s* scales each row by a power of the radix so all absolute row sums of *z* are approximately 1.

The information for right-hand side *i*, where $1 \leq i \leq nrhs$, and type of error *err* is stored in *err_bnds_norm*[(*err*-1)**nrhs* + *i* - 1].

err_bnds_comp

Array of size *nrhs***n_err_bnds*. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the *i*-th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (*params*[2] = 0.0), then *err_bnds_comp* is not accessed.

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.

err=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

err=3 Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix Z are:

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

The information for right-hand side i , where $1 \leq i \leq \text{nrhs}$, and type of error *err* is stored in `err_bnds_comp[(err-1)*nrhs + i - 1]`.

ipiv If *fact* = 'N' or 'E', then *ipiv* is an output argument and on exit contains the pivot indices from the factorization $A = P * L * U$ of the original matrix A (if *fact* = 'N') or of the equilibrated matrix A (if *fact* = 'E').

equed If *fact* ≠ 'F', then *equed* is an output argument. It specifies the form of equilibration that was done (see the description of *equed* in *Input Arguments* section).

params If an entry is less than 0.0, that entry is filled with the default value used for that parameter, otherwise the entry is not modified.

info If *info* = 0, the execution is successful. The solution to every right-hand side is guaranteed.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If $0 < \text{info} \leq n$: $U_{\text{info}, \text{info}}$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; *rcond* = 0 is returned.

If *info* = $n + j$: The solution corresponding to the *j*-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested `params[2] = 0.0`, then the *j*-th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest *j* such that `err_bnds_norm[j - 1] =`

0.0 or `err_bnds_comp[j - 1] = 0.0`. See the definition of `err_bnds_norm` and `err_bnds_comp` for `err = 1`. To get information about all of the right-hand sides, check `err_bnds_norm` or `err_bnds_comp`.

Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful. The solution to every right-hand side is guaranteed.

If `info = -i`, parameter `i` had an illegal value.

If $0 < info \leq n$: $U_{info,info}$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; `rcond = 0` is returned.

If `info = n+j`: The solution corresponding to the j -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested `params[2] = 0.0`, then the j -th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that for column major layout `err_bnds_norm[j - 1] = 0.0` or `err_bnds_comp[j - 1] = 0.0`; or for row major layout `err_bnds_norm[(j - 1)*n_err_bnds] = 0.0` or `err_bnds_comp[(j - 1)*n_err_bnds] = 0.0`). See the definition of `err_bnds_norm` and `err_bnds_comp` for `err = 1`. To get information about all of the right-hand sides, check `err_bnds_norm` or `err_bnds_comp`.

Description

The routine solves for X the system of linear equations $A * X = B$, where A is an n -by- n tridiagonal matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions. The routine uses Gaussian elimination with partial pivoting.

Note that the equation $A^T * X = B$ may be solved by interchanging the order of the arguments `du` and `dl`.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>n</i> | The order of <i>A</i> , the number of rows in <i>B</i> ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides, the number of columns in <i>B</i> ; $nrhs \geq 0$. |
| <i>dl</i> | The array <i>dl</i> (size $n - 1$) contains the $(n - 1)$ subdiagonal elements of <i>A</i> . |
| <i>d</i> | The array <i>d</i> (size n) contains the diagonal elements of <i>A</i> . |
| <i>du</i> | The array <i>du</i> (size $n - 1$) contains the $(n - 1)$ superdiagonal elements of <i>A</i> . |
| <i>b</i> | The array <i>b</i> of size $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |

Output Parameters

| | |
|-----------|--|
| <i>dl</i> | Overwritten by the $(n-2)$ elements of the second superdiagonal of the upper triangular matrix <i>U</i> from the <i>LU</i> factorization of <i>A</i> . These elements are stored in <i>dl</i> [0], ..., <i>dl</i> [$n - 3$]. |
| <i>d</i> | Overwritten by the n diagonal elements of <i>U</i> . |
| <i>du</i> | Overwritten by the $(n-1)$ elements of the first superdiagonal of <i>U</i> . |
| <i>b</i> | Overwritten by the solution matrix <i>X</i> . |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

If *info* = *i*, $U_{i,i}$ is exactly zero, and the solution has not been computed. The factorization has not been completed unless $i = n$.

Description

The routine uses the *LU* factorization to compute the solution to a real or complex system of linear equations $A \cdot X = B$, $A^T \cdot X = B$, or $A^H \cdot X = B$, where A is a tridiagonal matrix of order n , the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine `?gtsvx` performs the following steps:

1. If `fact = 'N'`, the *LU* decomposition is used to factor the matrix A as $A = L \cdot U$, where L is a product of permutation and unit lower bidiagonal matrices and U is an upper triangular matrix with nonzeros in only the main diagonal and first two superdiagonals.
2. If some $U_{i,i} = 0$, so that U is exactly singular, then the routine returns with `info = i`. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, `info = n + 1` is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
3. The system of equations is solved for X using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>fact</code> | Must be 'F' or 'N'. |

| | |
|----------------------------|--|
| | Specifies whether or not the factored form of the matrix A has been supplied on entry. |
| | If $fact = 'F'$: on entry, dif , df , duf , $du2$, and $ipiv$ contain the factored form of A ; arrays dl , d , du , dif , df , duf , $du2$, and $ipiv$ will not be modified. |
| | If $fact = 'N'$, the matrix A will be copied to dif , df , and duf and factored. |
| $trans$ | Must be 'N', 'T', or 'C'. |
| | Specifies the form of the system of equations: |
| | If $trans = 'N'$, the system has the form $A^*X = B$ (No transpose). |
| | If $trans = 'T'$, the system has the form $A^T*X = B$ (Transpose). |
| | If $trans = 'C'$, the system has the form $A^H*X = B$ (Conjugate transpose). |
| n | The number of linear equations, the order of the matrix A ; $n \geq 0$. |
| $nrhs$ | The number of right hand sides, the number of columns of the matrices B and X ; $nrhs \geq 0$. |
| $dl,d,du,dif,df,duf,du2,b$ | Arrays: dl , size $(n - 1)$, contains the subdiagonal elements of A . d , size (n) , contains the diagonal elements of A . du , size $(n - 1)$, contains the superdiagonal elements of A . dif , size $(n - 1)$. If $fact = 'F'$, then dif is an input argument and on entry contains the $(n - 1)$ multipliers that define the matrix L from the LU factorization of A as computed by <code>?gttrf</code> . df , size (n) . If $fact = 'F'$, then df is an input argument and on entry contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A . duf , size $(n - 1)$. If $fact = 'F'$, then duf is an input argument and on entry contains the $(n - 1)$ elements of the first superdiagonal of U . $du2$, size $(n - 2)$. If $fact = 'F'$, then $du2$ is an input argument and on entry contains the $(n - 2)$ elements of the second superdiagonal of U . b , size $\max(ldb*nrhs)$ for column major layout and $\max(ldb*n)$ for row major layout, contains the right-hand side matrix B . |
| ldb | The leading dimension of b ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| ldx | The leading dimension of x ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |
| $ipiv$ | Array, size at least $\max(1, n)$. If $fact = 'F'$, then $ipiv$ is an input argument and on entry contains the pivot indices, as returned by <code>?gttrf</code> . |

Output Parameters

| | |
|--------------|--|
| <i>x</i> | <p>Array, size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout.</p> <p>If <i>info</i> = 0 or <i>info</i> = <i>n</i>+1, the array <i>x</i> contains the solution matrix <i>X</i>.</p> |
| <i>dlf</i> | <p>If <i>fact</i> = 'N', then <i>dlf</i> is an output argument and on exit contains the (<i>n</i>-1) multipliers that define the matrix <i>L</i> from the <i>LU</i> factorization of <i>A</i>.</p> |
| <i>df</i> | <p>If <i>fact</i> = 'N', then <i>df</i> is an output argument and on exit contains the <i>n</i> diagonal elements of the upper triangular matrix <i>U</i> from the <i>LU</i> factorization of <i>A</i>.</p> |
| <i>duf</i> | <p>If <i>fact</i> = 'N', then <i>duf</i> is an output argument and on exit contains the (<i>n</i>-1) elements of the first superdiagonal of <i>U</i>.</p> |
| <i>du2</i> | <p>If <i>fact</i> = 'N', then <i>du2</i> is an output argument and on exit contains the (<i>n</i>-2) elements of the second superdiagonal of <i>U</i>.</p> |
| <i>ipiv</i> | <p>The array <i>ipiv</i> is an output argument if <i>fact</i> = 'N' and, on exit, contains the pivot indices from the factorization $A = L*U$; row <i>i</i> of the matrix was interchanged with row <i>ipiv</i>[<i>i</i>-1]. The value of <i>ipiv</i>[<i>i</i>-1] will always be <i>i</i> or <i>i</i>+1; <i>ipiv</i>[<i>i</i>-1]=<i>i</i> indicates a row interchange was not required.</p> |
| <i>rcond</i> | <p>An estimate of the reciprocal condition number of the matrix <i>A</i>. If <i>rcond</i> is less than the machine precision (in particular, if <i>rcond</i> = 0), the matrix is singular to working precision. This condition is indicated by a return code of <i>info</i>>0.</p> |
| <i>ferr</i> | <p>Array, size at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector x_j (the <i>j</i>-th column of the solution matrix <i>X</i>). If <i>xtrue</i> is the true solution corresponding to x_j, <i>ferr</i>[<i>j</i>-1] is an estimated upper bound for the magnitude of the largest element in $x_j - xtrue$ divided by the magnitude of the largest element in x_j. The estimate is as reliable as the estimate for <i>rcond</i>, and is almost always a slight overestimate of the true error.</p> |
| <i>berr</i> | <p>Array, size at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector x_j, that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes x_j an exact solution.</p> |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

If *info* = *i*, and $i \leq n$, then $U_{i,i}$ is exactly zero. The factorization has not been completed unless $i = n$, but the factor *U* is exactly singular, so the solution and error bounds could not be computed; *rcond* = 0 is returned. If *info* = *i*, and $i = n + 1$, then *U* is nonsingular, but *rcond* is less than machine precision,

meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of *rcond* would suggest.

d, const MKL_Complex8 * du, MKL_Complex8 * b, const MKL_INT * ldb, MKL_INT * info );

void zdtsvb (const MKL_INT * n, const MKL_INT * nrhs, MKL_Complex16 * dl, MKL_Complex16
* d, const MKL_Complex16 * du, MKL_Complex16 * b, const MKL_INT * ldb, MKL_INT *
info );
```

Include Files

- `mkl.h`

Description

The ?dtsvb routine solves a system of linear equations $A^*X = B$ for X , where A is an n -by- n diagonally dominant tridiagonal matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions. The routine uses the BABE (Burning At Both Ends) algorithm.

Note that the equation $A^T X = B$ may be solved by interchanging the order of the arguments *du* and *dl*.

Input Parameters

| | |
|---------------------|---|
| <i>n</i> | The order of A , the number of rows in B ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$. |
| <i>dl, d, du, b</i> | Arrays: <i>dl</i> (size $n - 1$), <i>d</i> (size n), <i>du</i> (size $n - 1$), <i>b</i> ($\max(ldb*nrhs)$ for column major layout and $\max(ldb*n)$ for row major layout). The array <i>dl</i> contains the $(n - 1)$ subdiagonal elements of A . The array <i>d</i> contains the diagonal elements of A . The array <i>du</i> contains the $(n - 1)$ superdiagonal elements of A . The array <i>b</i> contains the matrix B whose columns are the right-hand sides for the systems of equations. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$. |

Output Parameters

| | |
|-------------|--|
| <i>dl</i> | Overwritten by the $(n-1)$ elements of the subdiagonal of the lower triangular matrices L_1, L_2 from the factorization of A (see dttrfb). |
| <i>d</i> | Overwritten by the n diagonal element reciprocals of U . |
| <i>b</i> | Overwritten by the solution matrix X . |
| <i>info</i> | <p>If $info = 0$, the execution is successful.</p> <p>If $info = -i$, the i-th parameter had an illegal value.</p> <p>If $info = i$, $u_{i,i}$ is exactly zero, and the solution has not been computed. The factorization has not been completed unless $i = n$.</p> |

Application Notes

A diagonally dominant tridiagonal system is defined such that $|d_i| > |dl_{i-1}| + |du_i|$ for any i :

$1 < i < n$, and $|d_1| > |du_1|$, $|d_n| > |dl_{n-1}|$

The underlying BABE algorithm is designed for diagonally dominant systems. Such systems have no numerical stability issue unlike the canonical systems that use elimination with partial pivoting (see [?gtsv](#)). The diagonally dominant systems are much faster than the canonical systems.

NOTE

- The current implementation of BABE has a potential accuracy issue on very small or large data close to the underflow or overflow threshold respectively. Scale the matrix before applying the solver in the case of such input data.
 - Applying the [?dtsvb](#) factorization to non-diagonally dominant systems may lead to an accuracy loss, or false singularity detected due to no pivoting.
-

?posv

Computes the solution to the system of linear equations with a symmetric or Hermitian positive-definite coefficient matrix A and multiple right-hand sides.

Syntax

```
lapack_int LAPACKE_sposv (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs,
float * a, lapack_int lda, float * b, lapack_int ldb);

lapack_int LAPACKE_dposv (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs,
double * a, lapack_int lda, double * b, lapack_int ldb);

lapack_int LAPACKE_cposv (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs,
lapack_complex_float * a, lapack_int lda, lapack_complex_float * b, lapack_int ldb);

lapack_int LAPACKE_zposv (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs,
lapack_complex_double * a, lapack_int lda, lapack_complex_double * b, lapack_int ldb);

lapack_int LAPACKE_dsposv (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs,
double * a, lapack_int lda, double * b, lapack_int ldb, double * x, lapack_int ldx,
lapack_int * iter);
```

```
lapack_int LAPACKE_zcposv (int matrix_layout, char uplo, lapack_int n, lapack_int nrhs,

Description

The routine solves for X the real or complex system of linear equations $A^*X = B$, where A is an n -by- n symmetric/Hermitian positive-definite matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The Cholesky decomposition is used to factor A as

$A = U^T * U$ (real flavors) and $A = U^H * U$ (complex flavors), if $uplo = 'U'$

or $A = L * L^T$ (real flavors) and $A = L * L^H$ (complex flavors), if $uplo = 'L'$,

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A^*X = B$.

The `dsposv` and `zcposv` are mixed precision iterative refinement subroutines for exploiting fast single precision hardware. They first attempt to factorize the matrix in single precision (`dsposv`) or single complex precision (`zcposv`) and use this factorization within an iterative refinement procedure to produce a solution with double precision (`dsposv`) / double complex precision (`zcposv`) normwise backward error quality (see below). If the approach fails, the method switches to a double precision or double complex precision factorization respectively and computes the solution.

The iterative refinement is not going to be a winning strategy if the ratio single precision/complex performance over double precision/double complex performance is too small. A reasonable strategy should take the number of right-hand sides and the size of the matrix into account. This might be done with a call to `llaenv` in the future. At present, iterative refinement is implemented.

The iterative refinement process is stopped if

`iter > itermax`

or for all the right-hand sides:

`rnmr < sqrt(n) * xnmr * anrm * eps * bwdmax`,

where

- `iter` is the number of the current iteration in the iterative refinement process
- `rnmr` is the infinity-norm of the residual
- `xnmr` is the infinity-norm of the solution
- `anrm` is the infinity-operator-norm of the matrix A
- `eps` is the machine epsilon returned by `dlamch` ('Epsilon').

The values `itermax` and `bwdmax` are fixed to 30 and 1.0d+00 respectively.

Input Parameters

`matrix_layout` Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

`uplo` Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of A is stored:

If `uplo = 'U'`, the upper triangle of A is stored.

If `uplo = 'L'`, the lower triangle of A is stored.

| | |
|-------------|---|
| <i>n</i> | The order of matrix <i>A</i> ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides, the number of columns in <i>B</i> ; $nrhs \geq 0$. |
| <i>a, b</i> | Arrays: <i>a</i> (size $\max(1, lda)$), <i>b</i> , size $\max(ldb*nrhs)$ for column major layout and $\max(ldb*n)$ for row major layout,. The array <i>a</i> contains the upper or the lower triangular part of the matrix <i>A</i> (see <i>uplo</i>). Note that in the case of <i>zcposv</i> the imaginary parts of the diagonal elements need not be set and are assumed to be zero. The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. |
| <i>lda</i> | The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>ldx</i> | The leading dimension of the array <i>x</i> ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |

Output Parameters

| | |
|-------------|--|
| <i>a</i> | If <i>info</i> = 0, the upper or lower triangular part of <i>a</i> is overwritten by the Cholesky factor <i>U</i> or <i>L</i> , as specified by <i>uplo</i> . If iterative refinement has been successfully used (<i>info</i> = 0 and <i>iter</i> \geq 0), then <i>A</i> is unchanged. If double precision factorization has been used (<i>info</i> = 0 and <i>iter</i> < 0), then the array <i>A</i> contains the factors <i>L</i> or <i>U</i> from the Cholesky factorization. |
| <i>b</i> | Overwritten by the solution matrix <i>X</i> . |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. The pivot indices that define the permutation matrix <i>P</i> ; row <i>i</i> of the matrix was interchanged with row <i>ipiv</i> (<i>i</i>). Corresponds to the single precision factorization (if <i>info</i> = 0 and <i>iter</i> \geq 0) or the double precision factorization (if <i>info</i> = 0 and <i>iter</i> < 0). |
| <i>x</i> | Array, size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout. If <i>info</i> = 0, contains the <i>n</i> -by- <i>nrhs</i> solution matrix <i>X</i> . |
| <i>iter</i> | If <i>iter</i> < 0: iterative refinement has failed, double precision factorization has been performed <ul style="list-style-type: none"> • If <i>iter</i> = -1: the routine fell back to full precision for implementation- or machine-specific reason • If <i>iter</i> = -2: narrowing the precision induced an overflow, the routine fell back to full precision • If <i>iter</i> = -3: failure of <i>spotrf</i> for <i>dsposv</i>, or <i>cpotrf</i> for <i>zcposv</i> |

- If $iter = -31$: stop the iterative refinement after the 30th iteration.

If $iter > 0$: iterative refinement has been successfully used. Returns the number of iterations.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter i had an illegal value.

If $info = i$, the leading minor of order i (and therefore the matrix A itself) is not positive definite, so the factorization could not be completed, and the solution has not been computed.

Description

The routine uses the *Cholesky* factorization $A=U^T*U$ (real flavors) / $A=U^H*U$ (complex flavors) or $A=L*L^T$ (real flavors) / $A=L*L^H$ (complex flavors) to compute the solution to a real or complex system of linear equations $A*X = B$, where A is a n -by- n real symmetric/Hermitian positive definite matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine `?posvx` performs the following steps:

1. If `fact = 'E'`, real scaling factors s are computed to equilibrate the system:

$$\text{diag}(s) * A * \text{diag}(s) * \text{inv}(\text{diag}(s)) * X = \text{diag}(s) * B.$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(s) * A * \text{diag}(s)$ and B by $\text{diag}(s) * B$.

2. If `fact = 'N'` or `'E'`, the Cholesky decomposition is used to factor the matrix A (after equilibration if `fact = 'E'`) as

$$A = U^T * U \text{ (real)}, A = U^H * U \text{ (complex)}, \text{ if } \text{uplo} = \text{'U'},$$

$$\text{or } A = L * L^T \text{ (real)}, A = L * L^H \text{ (complex)}, \text{ if } \text{uplo} = \text{'L'},$$

where U is an upper triangular matrix and L is a lower triangular matrix.

3. If the leading i -by- i principal minor is not positive-definite, then the routine returns with `info = i`. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, `info = n + 1` is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(s)$ so that it solves the original system before equilibration.

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>fact</code> | <p>Must be 'F', 'N', or 'E'.</p> <p>Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.</p> <p>If <code>fact = 'F'</code>: on entry, <code>af</code> contains the factored form of A. If <code>equed = 'Y'</code>, the matrix A has been equilibrated with scaling factors given by s. <code>a</code> and <code>af</code> will not be modified.</p> <p>If <code>fact = 'N'</code>, the matrix A will be copied to <code>af</code> and factored.</p> <p>If <code>fact = 'E'</code>, the matrix A will be equilibrated if necessary, then copied to <code>af</code> and factored.</p> |
| <code>uplo</code> | <p>Must be 'U' or 'L'.</p> <p>Indicates whether the upper or lower triangular part of A is stored:</p> <p>If <code>uplo = 'U'</code>, the upper triangle of A is stored.</p> <p>If <code>uplo = 'L'</code>, the lower triangle of A is stored.</p> |
| <code>n</code> | The order of matrix A ; $n \geq 0$. |
| <code>nrhs</code> | The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$. |

| | |
|-----------------|---|
| <i>a, af, b</i> | <p>Arrays: <i>a</i>(size $\max(1, lda*n)$), <i>af</i>(size $\max(1, ldaf*n)$), <i>b</i>, size $\max(ldb*nrhs)$ for column major layout and $\max(ldb*n)$ for row major layout, .</p> <p>The array <i>a</i> contains the matrix <i>A</i> as specified by <i>uplo</i>. If <i>fact</i> = 'F' and <i>equed</i> = 'Y', then <i>A</i> must have been equilibrated by the scaling factors in <i>s</i>, and <i>a</i> must contain the equilibrated matrix $diag(s)*A*diag(s)$.</p> <p>The array <i>af</i> is an input argument if <i>fact</i> = 'F'. It contains the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization of <i>A</i> in the same storage format as <i>A</i>. If <i>equed</i> is not 'N', then <i>af</i> is the factored form of the equilibrated matrix $diag(s)*A*diag(s)$.</p> <p>The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations.</p> |
| <i>lda</i> | The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$. |
| <i>ldaf</i> | The leading dimension of <i>af</i> ; $ldaf \geq \max(1, n)$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>equed</i> | <p>Must be 'N' or 'Y'.</p> <p><i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done:</p> <p>if <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N');</p> <p>if <i>equed</i> = 'Y', equilibration was done, that is, <i>A</i> has been replaced by $diag(s)*A*diag(s)$.</p> |
| <i>s</i> | <p>Array, size (<i>n</i>). The array <i>s</i> contains the scale factors for <i>A</i>. This array is an input argument if <i>fact</i> = 'F' only; otherwise it is an output argument.</p> <p>If <i>equed</i> = 'N', <i>s</i> is not accessed.</p> <p>If <i>fact</i> = 'F' and <i>equed</i> = 'Y', each element of <i>s</i> must be positive.</p> |
| <i>ldx</i> | The leading dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |

Output Parameters

| | |
|----------|--|
| <i>x</i> | <p>Array, size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout.</p> <p>If <i>info</i> = 0 or <i>info</i> = <i>n</i>+1, the array <i>x</i> contains the solution matrix <i>X</i> to the <i>original</i> system of equations. Note that if <i>equed</i> = 'Y', <i>A</i> and <i>B</i> are modified on exit, and the solution to the equilibrated system is $inv(diag(s))*X$.</p> |
| <i>a</i> | Array <i>a</i> is not modified on exit if <i>fact</i> = 'F' or 'N', or if <i>fact</i> = 'E' and <i>equed</i> = 'N'. |

| | |
|---------|--|
| | If $fact = 'E'$ and $equed = 'Y'$, A is overwritten by $diag(s) * A * diag(s)$. |
| af | If $fact = 'N'$ or $'E'$, then af is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ (real routines), $A = U^H * U$ or $A = L * L^H$ (complex routines) of the original matrix A (if $fact = 'N'$), or of the equilibrated matrix A (if $fact = 'E'$). See the description of a for the form of the equilibrated matrix. |
| b | Overwritten by $diag(s) * B$, if $equed = 'Y'$; not changed if $equed = 'N'$. |
| s | This array is an output argument if $fact \neq 'F'$. See the description of s in <i>Input Arguments</i> section. |
| $rcond$ | An estimate of the reciprocal condition number of the matrix A after equilibration (if done). If $rcond$ is less than the machine precision (in particular, if $rcond = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$. |
| $ferr$ | Array, size at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector x_j (the j -th column of the solution matrix X). If $xtrue$ is the true solution corresponding to x_j , $ferr[j-1]$ is an estimated upper bound for the magnitude of the largest element in $(x_j - xtrue)$ divided by the magnitude of the largest element in x_j . The estimate is as reliable as the estimate for $rcond$, and is almost always a slight overestimate of the true error. |
| $berr$ | Array, size at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector x_j , that is, the smallest relative change in any element of A or B that makes x_j an exact solution. |
| $equed$ | If $fact \neq 'F'$, then $equed$ is an output argument. It specifies the form of equilibration that was done (see the description of $equed$ in <i>Input Arguments</i> section). |

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter i had an illegal value.

If $info = i$, and $i \leq n$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, so the factorization could not be completed, and the solution and error bounds could not be computed; $rcond = 0$ is returned.

If $info = i$, and $i = n + 1$, then U is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Description

The routine uses the *Cholesky* factorization $A=U^T*U$ (real flavors) / $A=U^H*U$ (complex flavors) or $A=L*L^T$ (real flavors) / $A=L*L^H$ (complex flavors) to compute the solution to a real or complex system of linear equations $A*X = B$, where A is an n -by- n real symmetric/Hermitian positive definite matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Both normwise and maximum componentwise error bounds are also provided on request. The routine returns a solution with a small guaranteed error ($O(\text{eps})$, where eps is the working machine precision) unless the matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also calculated and returned.

The routine accepts user-provided factorizations and equilibration factors; see definitions of the *fact* and *equed* options. Solving with refinement and using a factorization from a previous call of the routine also produces a solution with $O(\text{eps})$ errors or warnings but that may not be true for general user-provided factorizations and equilibration factors if they differ from what the routine would itself produce.

The routine ?posvxx performs the following steps:

1. If *fact* = 'E', scaling factors are computed to equilibrate the system:

$$\text{diag}(s)*A*\text{diag}(s) * \text{inv}(\text{diag}(s))*X = \text{diag}(s)*B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $diag(s)*A*diag(s)$ and B by $diag(s)*B$.

2. If $fact = 'N'$ or $'E'$, the Cholesky decomposition is used to factor the matrix A (after equilibration if $fact = 'E'$) as

$A = U^T*U$ (real), $A = U^H*U$ (complex), if $uplo = 'U'$,

or $A = L*L^T$ (real), $A = L*L^H$ (complex), if $uplo = 'L'$,

where U is an upper triangular matrix and L is a lower triangular matrix.

3. If the leading i -by- i principal minor is not positive-definite, the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A (see the $rcond$ parameter). If the reciprocal of the condition number is less than machine precision, the routine still goes on to solve for X and compute error bounds.
4. The system of equations is solved for X using the factored form of A .
5. By default, unless $params[0]$ is set to zero, the routine applies iterative refinement to get a small error and error bounds. Refinement calculates the residual to at least twice the working precision.
6. If equilibration was used, the matrix X is premultiplied by $diag(s)$ so that it solves the original system before equilibration.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>fact</i> | <p>Must be 'F', 'N', or 'E'.</p> <p>Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.</p> <p>If $fact = 'F'$, on entry, af contains the factored form of A. If $equed$ is not 'N', the matrix A has been equilibrated with scaling factors given by s. Parameters a and af are not modified.</p> <p>If $fact = 'N'$, the matrix A will be copied to af and factored.</p> <p>If $fact = 'E'$, the matrix A will be equilibrated, if necessary, copied to af and factored.</p> |
| <i>uplo</i> | <p>Must be 'U' or 'L'.</p> <p>Indicates whether the upper or lower triangular part of A is stored:</p> <p>If $uplo = 'U'$, the upper triangle of A is stored.</p> <p>If $uplo = 'L'$, the lower triangle of A is stored.</p> |
| <i>n</i> | The number of linear equations; the order of the matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$. |
| <i>a, af, b</i> | <p>Arrays: a(size $\max(lda*n)$), af(size $\max(ldaf*n)$), b(size $\max(1, ldb*nrhs)$) for column major layout and $\max(1, ldb*n)$ for row major layout).</p> <p>The array a contains the matrix A as specified by $uplo$. If $fact = 'F'$ and $equed = 'Y'$, then A must have been equilibrated by the scaling factors in s, and a must contain the equilibrated matrix $diag(s)*A*diag(s)$.</p> |

The array *af* is an input argument if *fact* = 'F'. It contains the triangular factor *U* or *L* from the Cholesky factorization of *A* in the same storage format as *A*. If *equed* is not 'N', then *af* is the factored form of the equilibrated matrix $diag(s) * A * diag(s)$.

The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations.

| | |
|-------------------|---|
| <i>lda</i> | The leading dimension of the array <i>a</i> ; $lda \geq \max(1, n)$. |
| <i>ldaf</i> | The leading dimension of the array <i>af</i> ; $ldaf \geq \max(1, n)$. |
| <i>equed</i> | Must be 'N' or 'Y'. <i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done: If <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N'). if <i>equed</i> = 'Y', both row and column equilibration was done, that is, <i>A</i> has been replaced by $diag(s) * A * diag(s)$. |
| <i>s</i> | Array, size (<i>n</i>). The array <i>s</i> contains the scale factors for <i>A</i> . This array is an input argument if <i>fact</i> = 'F' only; otherwise it is an output argument. If <i>equed</i> = 'N', <i>s</i> is not accessed. If <i>fact</i> = 'F' and <i>equed</i> = 'Y', each element of <i>s</i> must be positive. Each element of <i>s</i> should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable. |
| <i>ldb</i> | The leading dimension of the array <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>ldx</i> | The leading dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |
| <i>n_err_bnds</i> | Number of error bounds to return for each right hand side and each type (normwise or componentwise). See <i>err_bnds_norm</i> and <i>err_bnds_comp</i> descriptions in the <i>Output Arguments</i> section below. |
| <i>nparams</i> | Specifies the number of parameters set in <i>params</i> . If ≤ 0 , the <i>params</i> array is never referenced and default values are used. |
| <i>params</i> | Array, size $\max(1, nparams)$. Specifies algorithm parameters. If an entry is less than 0.0, that entry is filled with the default value used for that parameter. Only positions up to <i>nparams</i> are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass <i>nparams</i> = 0, which prevents the source code from accessing the <i>params</i> argument. <i>params</i> [0] : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors). |

=0.0 No refinement is performed and no error bounds are computed.

=1.0 Use the extra-precise refinement algorithm.

(Other values are reserved for future use.)

params[1] : Maximum number of residual computations allowed for refinement.

Default 10.0

Aggressive Set to 100.0 to permit convergence using approximate factorizations or factorizations other than *LU*. If the factorization uses a technique other than Gaussian elimination, the guarantees in *err_bnds_norm* and *err_bnds_comp* may no longer be trustworthy.

params[2] : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

Output Parameters

x Array, size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout.

If *info* = 0, the array *x* contains the solution *n*-by-*nrhs* matrix *X* to the original system of equations. Note that *A* and *B* are modified on exit if *equed* ≠ 'N', and the solution to the equilibrated system is:

$$\text{inv}(\text{diag}(s)) * X.$$

a Array *a* is not modified on exit if *fact* = 'F' or 'N', or if *fact* = 'E' and *equed* = 'N'.

If *fact* = 'E' and *equed* = 'Y', *A* is overwritten by $\text{diag}(s) * A * \text{diag}(s)$.

af If *fact* = 'N' or 'E', then *af* is an output argument and on exit returns the triangular factor *U* or *L* from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ (real routines), $A = U^H * U$ or $A = L * L^H$ (complex routines) of the original matrix *A* (if *fact* = 'N'), or of the equilibrated matrix *A* (if *fact* = 'E'). See the description of *a* for the form of the equilibrated matrix.

b If *equed* = 'N', *B* is not modified.

If *equed* = 'Y', *B* is overwritten by $\text{diag}(s) * B$.

s This array is an output argument if *fact* ≠ 'F'. Each element of this array is a power of the radix. See the description of *s* in *Input Arguments* section.

rcond Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If *rcond* is less than the machine precision, in particular, if *rcond* = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

rpvgrw Contains the reciprocal pivot growth factor:

$$\|A\|/\|U\|$$

If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X , estimated condition numbers, and error bounds could be unreliable. If factorization fails with $0 < info \leq n$, this parameter contains the reciprocal pivot growth factor for the leading *info* columns of A .

berr Array, size at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector x_j , that is, the smallest relative change in any element of A or B that makes x_j an exact solution.

err_bnds_norm Array of size $nrhs * n_err_bnds$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the i -th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors.

err=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

err=3 Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors to determine if the error estimate is

"guaranteed". These reciprocal condition numbers for some appropriately scaled matrix Z are:

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

The information for right-hand side i , where $1 \leq i \leq nrhs$, and type of error err is stored in `err_bnds_norm[(err-1)*nrhs + i - 1]`.

`err_bnds_comp`

Array of size `nrhs*n_err_bnds`. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (`params[2] = 0.0`), then `err_bnds_comp` is not accessed.

- `err=1` "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold `sqrt(n)*slamch(ε)` for single precision flavors and `sqrt(n)*dlamch(ε)` for double precision flavors.
- `err=2` "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold `sqrt(n)*slamch(ε)` for single precision flavors and `sqrt(n)*dlamch(ε)` for double precision flavors. This error bound should only be trusted if the previous boolean is true.
- `err=3` Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold `sqrt(n)*slamch(ε)` for single precision flavors and `sqrt(n)*dlamch(ε)` for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix Z are:

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

The information for right-hand side i , where $1 \leq i \leq nrhs$, and type of error err is stored in `err_bnds_comp[(err-1)*nrhs + i - 1]`.

`equed`

If `fact` is 'F', then `equed` is an output argument. It specifies the form of equilibration that was done (see the description of `equed` in *Input Arguments* section).

`params`

If an entry is less than 0.0, that entry is filled with the default value used for that parameter, otherwise the entry is not modified.

Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful. The solution to every right-hand side is guaranteed.

If `info = -i`, parameter i had an illegal value.

If $0 < info \leq n$: $U_{info,info}$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; `rcond = 0` is returned.

If `info = n+j`: The solution corresponding to the j -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested `params[2] = 0.0`, then the j -th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that for column major layout `err_bnds_norm[j - 1] = 0.0` or `err_bnds_comp[j - 1] = 0.0`; or for row major layout `err_bnds_norm[(j - 1)*n_err_bnds] = 0.0` or `err_bnds_comp[(j - 1)*n_err_bnds] = 0.0`). See the definition of `err_bnds_norm` and `err_bnds_comp` for `err = 1`. To get information about all of the right-hand sides, check `err_bnds_norm` or `err_bnds_comp`.

- `mkl.h`

Description

The routine solves for X the real or complex system of linear equations $A^*X = B$, where A is an n -by- n real symmetric/Hermitian positive-definite matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The Cholesky decomposition is used to factor A as

$A = U^T * U$ (real flavors) and $A = U^H * U$ (complex flavors), if $uplo = 'U'$

or $A = L * L^T$ (real flavors) and $A = L * L^H$ (complex flavors), if $uplo = 'L'$,

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>uplo</code> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If $uplo = 'U'$, the upper triangle of A is stored. If $uplo = 'L'$, the lower triangle of A is stored. |
| <code>n</code> | The order of matrix A ; $n \geq 0$. |
| <code>nrhs</code> | The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$. |
| <code>ap, b</code> | Arrays: ap (size $\max(1, n * (n + 1) / 2)$), b , size $\max(ldb * nrhs)$ for column major layout and $\max(ldb * n)$ for row major layout,. The array ap contains the upper or the lower triangular part of the matrix A (as specified by $uplo$) in <i>packed storage</i> (see Matrix Storage Schemes). The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. |
| <code>ldb</code> | The leading dimension of b ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |

Output Parameters

| | |
|-----------------|---|
| <code>ap</code> | If $info = 0$, the upper or lower triangular part of A in packed storage is overwritten by the Cholesky factor U or L , as specified by $uplo$. |
| <code>b</code> | Overwritten by the solution matrix X . |

Return Values

This function returns a value `info`.

If $info = 0$, the execution is successful.

If $info = -i$, parameter i had an illegal value.

If $info = i$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, so the factorization could not be completed, and the solution has not been computed.

Description

The routine uses the Cholesky factorization $A=U^T*U$ (real flavors) / $A=U^H*U$ (complex flavors) or $A=L*L^T$ (real flavors) / $A=L*L^H$ (complex flavors) to compute the solution to a real or complex system of linear equations $A*X = B$, where A is a n -by- n symmetric or Hermitian positive-definite matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?ppsvx performs the following steps:

1. If $fact = 'E'$, real scaling factors s are computed to equilibrate the system:

$$diag(s)*A*diag(s)*inv(diag(s))*X = diag(s)*B.$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $diag(s)*A*diag(s)$ and B by $diag(s)*B$.

2. If $fact = 'N'$ or $'E'$, the Cholesky decomposition is used to factor the matrix A (after equilibration if $fact = 'E'$) as

$$A = U^T*U \text{ (real)}, A = U^H*U \text{ (complex)}, \text{ if } uplo = 'U',$$

$$\text{or } A = L*L^T \text{ (real)}, A = L*L^H \text{ (complex)}, \text{ if } uplo = 'L',$$

where U is an upper triangular matrix and L is a lower triangular matrix.

3. If the leading i -by- i principal minor is not positive-definite, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $diag(s)$ so that it solves the original system before equilibration.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>fact</i> | <p>Must be 'F', 'N', or 'E'.</p> <p>Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.</p> <p>If <i>fact</i> = 'F': on entry, <i>afp</i> contains the factored form of A. If <i>equed</i> = 'Y', the matrix A has been equilibrated with scaling factors given by s. <i>ap</i> and <i>afp</i> will not be modified.</p> <p>If <i>fact</i> = 'N', the matrix A will be copied to <i>afp</i> and factored.</p> <p>If <i>fact</i> = 'E', the matrix A will be equilibrated if necessary, then copied to <i>afp</i> and factored.</p> |
| <i>uplo</i> | <p>Must be 'U' or 'L'.</p> <p>Indicates whether the upper or lower triangular part of A is stored:</p> <p>If <i>uplo</i> = 'U', the upper triangle of A is stored.</p> <p>If <i>uplo</i> = 'L', the lower triangle of A is stored.</p> |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; the number of columns in B ; $nrhs \geq 0$. |
| <i>ap, afp, b</i> | <p>Arrays: (size $\max(1, n*(n+1)/2)$, <i>afp</i> (size $\max(1, n*(n+1)/2)$, <i>bof</i> size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout.</p> <p>The array <i>ap</i> contains the upper or lower triangle of the original symmetric/Hermitian matrix A in <i>packed storage</i> (see Matrix Storage Schemes). In case when <i>fact</i> = 'F' and <i>equed</i> = 'Y', <i>ap</i> must contain the equilibrated matrix $diag(s)*A*diag(s)$.</p> <p>The array <i>afp</i> is an input argument if <i>fact</i> = 'F' and contains the triangular factor U or L from the Cholesky factorization of A in the same storage format as A. If <i>equed</i> is not 'N', then <i>afp</i> is the factored form of the equilibrated matrix A.</p> |

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

ldb The leading dimension of b ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

$equed$ Must be 'N' or 'Y'.

$equed$ is an input argument if $fact = 'F'$. It specifies the form of equilibration that was done:

if $equed = 'N'$, no equilibration was done (always true if $fact = 'N'$);

if $equed = 'Y'$, equilibration was done, that is, A has been replaced by $diag(s)A*diag(s)$.

s Array, size (n) . The array s contains the scale factors for A . This array is an input argument if $fact = 'F'$ only; otherwise it is an output argument.

If $equed = 'N'$, s is not accessed.

If $fact = 'F'$ and $equed = 'Y'$, each element of s must be positive.

ldx The leading dimension of the output array x ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout.

Output Parameters

x Array, size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout.

If $info = 0$ or $info = n+1$, the array x contains the solution matrix X to the *original* system of equations. Note that if $equed = 'Y'$, A and B are modified on exit, and the solution to the equilibrated system is $inv(diag(s))*X$.

ap Array ap is not modified on exit if $fact = 'F'$ or 'N', or if $fact = 'E'$ and $equed = 'N'$.

If $fact = 'E'$ and $equed = 'Y'$, ap is overwritten by $diag(s)*A*diag(s)$.

afp If $fact = 'N'$ or 'E', then afp is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A=U^T*U$ or $A=L*L^T$ (real routines), $A=U^H*U$ or $A=L*L^H$ (complex routines) of the original matrix A (if $fact = 'N'$), or of the equilibrated matrix A (if $fact = 'E'$). See the description of ap for the form of the equilibrated matrix.

b Overwritten by $diag(s)*B$, if $equed = 'Y'$; not changed if $equed = 'N'$.

s This array is an output argument if $fact \neq 'F'$. See the description of s in *Input Arguments* section.

| | |
|--------------|---|
| <i>rcond</i> | An estimate of the reciprocal condition number of the matrix A after equilibration (if done). If <i>rcond</i> is less than the machine precision (in particular, if <i>rcond</i> = 0), the matrix is singular to working precision. This condition is indicated by a return code of <i>info</i> > 0. |
| <i>ferr</i> | Array, size at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector x_j (the j -th column of the solution matrix X). If <i>xtrue</i> is the true solution corresponding to x_j , <i>ferr</i> [$j-1$] is an estimated upper bound for the magnitude of the largest element in $(x_j - x_{true})$ divided by the magnitude of the largest element in x_j . The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error. |
| <i>berr</i> | Array, size at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector x_j , that is, the smallest relative change in any element of A or B that makes x_j an exact solution. |
| <i>equed</i> | If <i>fact</i> ≠ 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section). |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

If *info* = *i*, and $i \leq n$, the leading minor of order *i* (and therefore the matrix A itself) is not positive-definite, so the factorization could not be completed, and the solution and error bounds could not be computed; *rcond* = 0 is returned.

If *info* = *i*, and $i = n + 1$, then U is nonsingular, but *rcond* is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of *rcond* would suggest.

Description

The routine solves for X the real or complex system of linear equations $A^*X = B$, where A is an n -by- n symmetric/Hermitian positive definite band matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The Cholesky decomposition is used to factor A as

$A = U^T * U$ (real flavors) and $A = U^H * U$ (complex flavors), if $uplo = 'U'$

or $A = L * L^T$ (real flavors) and $A = L * L^H$ (complex flavors), if $uplo = 'L'$,

where U is an upper triangular band matrix and L is a lower triangular band matrix, with the same number of superdiagonals or subdiagonals as A . The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If $uplo = 'U'$, the upper triangle of A is stored. If $uplo = 'L'$, the lower triangle of A is stored. |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>kd</i> | The number of superdiagonals of the matrix A if $uplo = 'U'$, or the number of subdiagonals if $uplo = 'L'$; $kd \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$. |
| <i>ab, b</i> | Arrays: ab (size $\max(1, ldab * n)$), b of size $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * n)$ for row major layout. The array ab contains the upper or the lower triangular part of the matrix A (as specified by $uplo$) in <i>band storage</i> (see Matrix Storage Schemes). The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. |
| <i>ldab</i> | The leading dimension of the array ab ; $ldab \geq kd + 1$. |
| <i>ldb</i> | The leading dimension of b ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |

Output Parameters

| | |
|-----------|--|
| <i>ab</i> | The upper or lower triangular part of <i>A</i> (in band storage) is overwritten by the Cholesky factor <i>U</i> or <i>L</i> , as specified by <i>uplo</i> , in the same storage format as <i>A</i> . |
| <i>b</i> | Overwritten by the solution matrix <i>X</i> . |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

If *info* = *i*, the leading minor of order *i* (and therefore the matrix *A* itself) is not positive-definite, so the factorization could not be completed, and the solution has not been computed.

Description

The routine uses the Cholesky factorization $A=U^T*U$ (real flavors) / $A=U^H*U$ (complex flavors) or $A=L*L^T$ (real flavors) / $A=L*L^H$ (complex flavors) to compute the solution to a real or complex system of linear equations $A*X = B$, where A is a n -by- n symmetric or Hermitian positive definite band matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine `?pbsvx` performs the following steps:

1. If `fact = 'E'`, real scaling factors s are computed to equilibrate the system:

$$\text{diag}(s)*A*\text{diag}(s)*\text{inv}(\text{diag}(s))*X = \text{diag}(s)*B.$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(s)*A*\text{diag}(s)$ and B by $\text{diag}(s)*B$.

2. If `fact = 'N'` or `'E'`, the Cholesky decomposition is used to factor the matrix A (after equilibration if `fact = 'E'`) as

$$A = U^T*U \text{ (real)}, A = U^H*U \text{ (complex)}, \text{ if } \text{uplo} = 'U',$$

$$\text{or } A = L*L^T \text{ (real)}, A = L*L^H \text{ (complex)}, \text{ if } \text{uplo} = 'L',$$

where U is an upper triangular band matrix and L is a lower triangular band matrix.

3. If the leading i -by- i principal minor is not positive definite, then the routine returns with `info = i`. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, `info = n+1` is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(s)$ so that it solves the original system before equilibration.

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>fact</code> | <p>Must be 'F', 'N', or 'E'.</p> <p>Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.</p> <p>If <code>fact = 'F'</code>: on entry, <code>afb</code> contains the factored form of A. If <code>equed = 'Y'</code>, the matrix A has been equilibrated with scaling factors given by s. <code>ab</code> and <code>afb</code> will not be modified.</p> <p>If <code>fact = 'N'</code>, the matrix A will be copied to <code>afb</code> and factored.</p> <p>If <code>fact = 'E'</code>, the matrix A will be equilibrated if necessary, then copied to <code>afb</code> and factored.</p> |
| <code>uplo</code> | <p>Must be 'U' or 'L'.</p> <p>Indicates whether the upper or lower triangular part of A is stored:</p> <p>If <code>uplo = 'U'</code>, the upper triangle of A is stored.</p> <p>If <code>uplo = 'L'</code>, the lower triangle of A is stored.</p> |

| | |
|-------------------|---|
| <i>n</i> | The order of matrix <i>A</i> ; $n \geq 0$. |
| <i>kd</i> | The number of superdiagonals or subdiagonals in the matrix <i>A</i> ; $kd \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides, the number of columns in <i>B</i> ; $nrhs \geq 0$. |
| <i>ab, afb, b</i> | <p>Arrays: <i>ab</i>(size $\max(1, ldab*n)$), <i>afb</i>(size $\max(1, ldafb*n)$), <i>b</i> of size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout.</p> <p>The array <i>ab</i> contains the upper or lower triangle of the matrix <i>A</i> in <i>band storage</i> (see Matrix Storage Schemes).</p> <p>If <i>fact</i> = 'F' and <i>equed</i> = 'Y', then <i>ab</i> must contain the equilibrated matrix $diag(s) * A * diag(s)$.</p> <p>The array <i>afb</i> is an input argument if <i>fact</i> = 'F'. It contains the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization of the band matrix <i>A</i> in the same storage format as <i>A</i>. If <i>equed</i> = 'Y', then <i>afb</i> is the factored form of the equilibrated matrix <i>A</i>.</p> <p>The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations.</p> |
| <i>ldab</i> | The leading dimension of <i>ab</i> ; $ldab \geq kd + 1$. |
| <i>ldaafb</i> | The leading dimension of <i>afb</i> ; $ldaafb \geq kd + 1$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>equed</i> | <p>Must be 'N' or 'Y'.</p> <p><i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done:</p> <p>if <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N')</p> <p>if <i>equed</i> = 'Y', equilibration was done, that is, <i>A</i> has been replaced by $diag(s) * A * diag(s)$.</p> |
| <i>s</i> | <p>Array, size (<i>n</i>). The array <i>s</i> contains the scale factors for <i>A</i>. This array is an input argument if <i>fact</i> = 'F' only; otherwise it is an output argument.</p> <p>If <i>equed</i> = 'N', <i>s</i> is not accessed.</p> <p>If <i>fact</i> = 'F' and <i>equed</i> = 'Y', each element of <i>s</i> must be positive.</p> |
| <i>ldx</i> | The leading dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |

Output Parameters

| | |
|----------|--|
| <i>x</i> | Array, size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout. |
|----------|--|

If $info = 0$ or $info = n+1$, the array x contains the solution matrix X to the *original* system of equations. Note that if $equed = 'Y'$, A and B are modified on exit, and the solution to the equilibrated system is $inv(diag(s)) * X$.

| | |
|--------------|---|
| <i>ab</i> | On exit, if $fact = 'E'$ and $equed = 'Y'$, A is overwritten by $diag(s) * A * diag(s)$. |
| <i>afb</i> | If $fact = 'N'$ or $'E'$, then <i>afb</i> is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ (real routines), $A = U^H * U$ or $A = L * L^H$ (complex routines) of the original matrix A (if $fact = 'N'$), or of the equilibrated matrix A (if $fact = 'E'$). See the description of <i>ab</i> for the form of the equilibrated matrix. |
| <i>b</i> | Overwritten by $diag(s) * B$, if $equed = 'Y'$; not changed if $equed = 'N'$. |
| <i>s</i> | This array is an output argument if $fact \neq 'F'$. See the description of s in <i>Input Arguments</i> section. |
| <i>rcond</i> | An estimate of the reciprocal condition number of the matrix A after equilibration (if done). If <i>rcond</i> is less than the machine precision (in particular, if $rcond = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$. |
| <i>ferr</i> | Array, size at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector x_j (the j -th column of the solution matrix X). If x_{true} is the true solution corresponding to x_j , $ferr[j-1]$ is an estimated upper bound for the magnitude of the largest element in $(x_j - x_{true})$ divided by the magnitude of the largest element in x_j . The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error. |
| <i>berr</i> | Array, size at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector x_j , that is, the smallest relative change in any element of A or B that makes x_j an exact solution. |
| <i>equed</i> | If $fact \neq 'F'$, then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section). |

Return Values

This function returns a value *info*.

If $info = 0$, the execution is successful.

If $info = -i$, parameter i had an illegal value.

If $info = i$, and $i \leq n$, the leading minor of order i (and therefore the matrix A itself) is not positive definite, so the factorization could not be completed, and the solution and error bounds could not be computed; $rcond = 0$ is returned. If $info = i$, and $i = n + 1$, then U is nonsingular, but *rcond* is less than machine precision,

meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of *rcond* would suggest.

Description

The routine solves for X the real or complex system of linear equations $A \cdot X = B$, where A is an n -by- n symmetric/Hermitian positive-definite tridiagonal matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

A is factored as $A = L \cdot D \cdot L^T$ (real flavors) or $A = L \cdot D \cdot L^H$ (complex flavors), and the factored form of A is then used to solve the system of equations $A \cdot X = B$.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$. |
| <i>d</i> | Array, dimension at least $\max(1, n)$. Contains the diagonal elements of the tridiagonal matrix A . |
| <i>e, b</i> | Arrays: <i>e</i> (size $n - 1$), <i>b</i> of size $\max(1, ldb \cdot nrhs)$ for column major layout and $\max(1, ldb \cdot n)$ for row major layout. The array <i>e</i> contains the $(n - 1)$ subdiagonal elements of A . The array <i>b</i> contains the matrix B whose columns are the right-hand sides for the systems of equations. |

ldb The leading dimension of *b*; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

Output Parameters

d Overwritten by the *n* diagonal elements of the diagonal matrix *D* from the $L^*D^*L^T$ (real)/ $L^*D^*L^H$ (complex) factorization of *A*.

e Overwritten by the (*n* - 1) subdiagonal elements of the unit bidiagonal factor *L* from the factorization of *A*.

b Overwritten by the solution matrix *X*.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

If *info* = *i*, the leading minor of order *i* (and therefore the matrix *A* itself) is not positive-definite, and the solution has not been computed. The factorization has not been completed unless *i* = *n*.

Description

The routine uses the Cholesky factorization $A = L^*D^*L^T$ (real)/ $A = L^*D^*L^H$ (complex) to compute the solution to a real or complex system of linear equations $A^*X = B$, where A is a n -by- n symmetric or Hermitian positive definite tridiagonal matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine `?ptsvx` performs the following steps:

1. If `fact = 'N'`, the matrix A is factored as $A = L^*D^*L^T$ (real flavors)/ $A = L^*D^*L^H$ (complex flavors), where L is a unit lower bidiagonal matrix and D is diagonal. The factorization can also be regarded as having the form $A = U^T^*D^*U$ (real flavors)/ $A = U^H^*D^*U$ (complex flavors).
2. If the leading i -by- i principal minor is not positive-definite, then the routine returns with `info = i`. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, `info = n+1` is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
3. The system of equations is solved for X using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>fact</code> | Must be 'F' or 'N'. Specifies whether or not the factored form of the matrix A is supplied on entry. If <code>fact = 'F'</code> : on entry, <code>df</code> and <code>ef</code> contain the factored form of A . Arrays <code>d</code> , <code>e</code> , <code>df</code> , and <code>ef</code> will not be modified. If <code>fact = 'N'</code> , the matrix A will be copied to <code>df</code> and <code>ef</code> , and factored. |
| <code>n</code> | The order of matrix A ; $n \geq 0$. |
| <code>nrhs</code> | The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$. |
| <code>d, df</code> | Arrays: <code>d</code> (size n), <code>df</code> (size n). The array <code>d</code> contains the n diagonal elements of the tridiagonal matrix A . The array <code>df</code> is an input argument if <code>fact = 'F'</code> and on entry contains the n diagonal elements of the diagonal matrix D from the $L^*D^*L^T$ (real)/ $L^*D^*L^H$ (complex) factorization of A . |
| <code>e,ef,b</code> | Arrays: <code>e</code> (size $n - 1$), <code>ef</code> (size $n - 1$), <code>b</code> , size $\max(ldb*nrhs)$ for column major layout and $\max(ldb*n)$ for row major layout. The array <code>e</code> contains the $(n - 1)$ subdiagonal elements of the tridiagonal matrix A . The array <code>ef</code> is an input argument if <code>fact = 'F'</code> and on entry contains the $(n - 1)$ subdiagonal elements of the unit bidiagonal factor L from the $L^*D^*L^T$ (real)/ $L^*D^*L^H$ (complex) factorization of A . The array <code>b</code> contains the matrix B whose columns are the right-hand sides for the systems of equations. |

| | |
|------------|---|
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>ldx</i> | The leading dimension of <i>x</i> ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |

Output Parameters

| | |
|---------------|---|
| <i>x</i> | Array, size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout. If $info = 0$ or $info = n+1$, the array <i>x</i> contains the solution matrix <i>X</i> to the system of equations. |
| <i>df, ef</i> | These arrays are output arguments if $fact = 'N'$. See the description of <i>df, ef</i> in <i>Input Arguments</i> section. |
| <i>rcond</i> | An estimate of the reciprocal condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision (in particular, if $rcond = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$. |
| <i>ferr</i> | Array, size at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector x_j (the <i>j</i> -th column of the solution matrix <i>X</i>). If <i>xtrue</i> is the true solution corresponding to x_j , $ferr_j$ is an estimated upper bound for the magnitude of the largest element in $(x_j - xtrue)$ divided by the magnitude of the largest element in x_j . The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error. |
| <i>berr</i> | Array, size at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector x_j , that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes x_j an exact solution. |

Return Values

This function returns a value *info*.

If $info = 0$, the execution is successful.

If $info = -i$, parameter *i* had an illegal value.

If $info = i$, and $i \leq n$, the leading minor of order *i* (and therefore the matrix *A* itself) is not positive-definite, so the factorization could not be completed, and the solution and error bounds could not be computed; $rcond = 0$ is returned.

If $info = i$, and $i = n + 1$, then *U* is nonsingular, but *rcond* is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of *rcond* would suggest.

Description

The routine solves for X the real or complex system of linear equations $A*X = B$, where A is an n -by- n symmetric matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The diagonal pivoting method is used to factor A as $A = U*D*U^T$ or $A = L*D*L^T$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of A is then used to solve the system of equations $A*X = B$.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored. |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; the number of columns in B ; $nrhs \geq 0$. |
| <i>a, b</i> | Arrays: a (size $\max(1, lda*n)$), b of size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout. The array a contains the upper or the lower triangular part of the symmetric matrix A (see <i>uplo</i>). |

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

lda The leading dimension of a ; $lda \geq \max(1, n)$.

ldb The leading dimension of b ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

Output Parameters

a If $info = 0$, a is overwritten by the block-diagonal matrix D and the multipliers used to obtain the factor U (or L) from the factorization of A as computed by `?sytrf`.

b If $info = 0$, b is overwritten by the solution matrix X .

$ipiv$ Array, size at least $\max(1, n)$. Contains details of the interchanges and the block structure of D , as determined by `?sytrf`.

If $ipiv[i-1] = k > 0$, then d_{ii} is a 1-by-1 diagonal block, and the i -th row and column of A was interchanged with the k -th row and column.

If $uplo = 'U'$ and $ipiv[i] = ipiv[i-1] = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and (i)-th row and column of A was interchanged with the m -th row and column.

If $uplo = 'L'$ and $ipiv[i] = ipiv[i-1] = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and ($i+1$)-th row and column of A was interchanged with the m -th row and column.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, parameter i had an illegal value.

If $info = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular, so the solution could not be computed.

Description

The routine solves for X the real or complex system of linear equations $A^*X = B$, where A is an n -by- n symmetric matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The diagonal pivoting method is used to factor A as $A = U^*D^*U^T$ or $A = L^*D^*L^T$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The `?sysv_rook` routine is called to compute the factorization of a complex symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal pivoting method.

The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored. |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; the number of columns in B ; $nrhs \geq 0$. |
| <i>a, b</i> | Arrays: a (size $\max(1, lda*n)$), b of size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout. The array a contains the upper or the lower triangular part of the symmetric matrix A (see <i>uplo</i>). The second dimension of a must be at least $\max(1, n)$. The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$. |
| <i>lda</i> | The leading dimension of a ; $lda \geq \max(1, n)$. |
| <i>ldb</i> | The leading dimension of b ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |

Output Parameters

| | |
|-------------|--|
| <i>a</i> | If <i>info</i> = 0, <i>a</i> is overwritten by the block-diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> (or <i>L</i>) from the factorization of <i>A</i> . |
| <i>b</i> | If <i>info</i> = 0, <i>b</i> is overwritten by the solution matrix <i>X</i> . |
| <i>ipiv</i> | <p>Array, size at least $\max(1, n)$. Contains details of the interchanges and the block structure of <i>D</i>.</p> <p>If <i>ipiv</i>[<i>k</i> - 1] > 0, then rows and columns <i>k</i> and <i>ipiv</i>[<i>k</i> - 1] were interchanged and $D_{k,k}$ is a 1-by-1 diagonal block.</p> <p>If <i>uplo</i> = 'U' and <i>ipiv</i>[<i>k</i> - 1] < 0 and <i>ipiv</i>[<i>k</i> - 2] < 0, then rows and columns <i>k</i> and -<i>ipiv</i>[<i>k</i> - 1] were interchanged, rows and columns <i>k</i> - 1 and -<i>ipiv</i>[<i>k</i> - 2] were interchanged, and $D_{k-1:k, k-1:k}$ is a 2-by-2 diagonal block.</p> <p>If <i>uplo</i> = 'L' and <i>ipiv</i>[<i>k</i> - 1] < 0 and <i>ipiv</i>[<i>k</i>] < 0, then rows and columns <i>k</i> and -<i>ipiv</i>[<i>k</i> - 1] were interchanged, rows and columns <i>k</i> + 1 and -<i>ipiv</i>[<i>k</i>] were interchanged, and $D_{k:k+1, k:k+1}$ is a 2-by-2 diagonal block.</p> |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, d_{ii} is 0. The factorization has been completed, but *D* is exactly singular, so the solution could not be computed.

Description

The routine uses the diagonal pivoting factorization to compute the solution to a real or complex system of linear equations $A^*X = B$, where A is a n -by- n symmetric matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine `?sysvx` performs the following steps:

1. If $fact = 'N'$, the diagonal pivoting method is used to factor the matrix A . The form of the factorization is $A = U^*D^*U^T$ or $A = L^*D^*L^T$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.
2. If some $d_{i,i} = 0$, so that D is exactly singular, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
3. The system of equations is solved for X using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>fact</i> | Must be 'F' or 'N'. Specifies whether or not the factored form of the matrix A has been supplied on entry. If $fact = 'F'$: on entry, af and $ipiv$ contain the factored form of A . Arrays a , af , and $ipiv$ will not be modified. If $fact = 'N'$, the matrix A will be copied to af and factored. |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If $uplo = 'U'$, the upper triangle of A is stored. If $uplo = 'L'$, the lower triangle of A is stored. |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$. |

| | |
|-----------------|--|
| <i>a, af, b</i> | <p>Arrays: <i>a</i>(size $\max(1, lda*n)$), <i>af</i>(size $\max(1, ldaf*n)$), <i>b</i> of size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout .</p> <p>The array <i>a</i> contains the upper or the lower triangular part of the symmetric matrix <i>A</i> (see <i>uplo</i>).</p> <p>The array <i>af</i> is an input argument if <i>fact</i> = 'F'. It contains the block diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> or <i>L</i> from the factorization $A = U*D*U^T$ or $A = L*D*L^T$ as computed by ?sytrf.</p> <p>The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations.</p> |
| <i>lda</i> | The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$. |
| <i>ldaf</i> | The leading dimension of <i>af</i> ; $ldaf \geq \max(1, n)$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>ipiv</i> | <p>Array, size at least $\max(1, n)$. The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F'. It contains details of the interchanges and the block structure of <i>D</i>, as determined by ?sytrf.</p> <p>If $ipiv[i-1] = k > 0$, then d_{ii} is a 1-by-1 diagonal block, and the <i>i</i>-th row and column of <i>A</i> was interchanged with the <i>k</i>-th row and column.</p> <p>If <i>uplo</i> = 'U' and $ipiv[i] = ipiv[i-1] = -m < 0$, then <i>D</i> has a 2-by-2 block in rows/columns <i>i</i> and <i>i+1</i>, and (<i>i</i>)-th row and column of <i>A</i> was interchanged with the <i>m</i>-th row and column.</p> <p>If <i>uplo</i> = 'L' and $ipiv[i] = ipiv[i-1] = -m < 0$, then <i>D</i> has a 2-by-2 block in rows/columns <i>i</i> and <i>i+1</i>, and (<i>i+1</i>)-th row and column of <i>A</i> was interchanged with the <i>m</i>-th row and column.</p> |
| <i>ldx</i> | The leading dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |

Output Parameters

| | |
|-----------------|--|
| <i>x</i> | <p>Array, size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout.</p> <p>If <i>info</i> = 0 or <i>info</i> = <i>n</i>+1, the array <i>x</i> contains the solution matrix <i>X</i> to the system of equations.</p> |
| <i>af, ipiv</i> | <p>These arrays are output arguments if <i>fact</i> = 'N'.</p> <p>See the description of <i>af, ipiv</i> in <i>Input Arguments</i> section.</p> |
| <i>rcond</i> | An estimate of the reciprocal condition number of the matrix <i>A</i> . If <i>rcond</i> is less than the machine precision (in particular, if <i>rcond</i> = 0), the matrix is singular to working precision. This condition is indicated by a return code of <i>info</i> > 0. |

| | |
|-------------|---|
| <i>ferr</i> | Array, size at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector x_j (the j -th column of the solution matrix X). If x_{true} is the true solution corresponding to x_j , $ferr[j-1]$ is an estimated upper bound for the magnitude of the largest element in $(x_j - x_{true})$ divided by the magnitude of the largest element in x_j . The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error. |
| <i>berr</i> | Array, size at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector x_j , that is, the smallest relative change in any element of A or B that makes x_j an exact solution. |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

If *info* = *i*, and $i \leq n$, then d_{ii} is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution and error bounds could not be computed; *rcond* = 0 is returned.

If *info* = *i*, and $i = n + 1$, then D is nonsingular, but *rcond* is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of *rcond* would suggest.

Description

The routine uses the *diagonal pivoting* factorization to compute the solution to a real or complex system of linear equations $A^*X = B$, where A is an n -by- n real symmetric/Hermitian matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Both normwise and maximum componentwise error bounds are also provided on request. The routine returns a solution with a small guaranteed error ($O(\text{eps})$, where eps is the working machine precision) unless the matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also calculated and returned.

The routine accepts user-provided factorizations and equilibration factors; see definitions of the *fact* and *equed* options. Solving with refinement and using a factorization from a previous call of the routine also produces a solution with $O(\text{eps})$ errors or warnings but that may not be true for general user-provided factorizations and equilibration factors if they differ from what the routine would itself produce.

The routine `?sysvxx` performs the following steps:

1. If *fact* = 'E', scaling factors are computed to equilibrate the system:

$$\text{diag}(s) * A * \text{diag}(s) * \text{inv}(\text{diag}(s)) * X = \text{diag}(s) * B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(s) * A * \text{diag}(s)$ and B by $\text{diag}(s) * B$.

2. If *fact* = 'N' or 'E', the LU decomposition is used to factor the matrix A (after equilibration if *fact* = 'E') as

$$A = U * D * U^T, \text{ if } \text{uplo} = \text{'U'},$$

$$\text{or } A = L * D * L^T, \text{ if } \text{uplo} = \text{'L'},$$

where U or L is a product of permutation and unit upper (lower) triangular matrices, and D is a symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

3. If some $D(i, i) = 0$, so that D is exactly singular, the routine returns with *info* = i . Otherwise, the factored form of A is used to estimate the condition number of the matrix A (see the *rcond* parameter). If the reciprocal of the condition number is less than machine precision, the routine still goes on to solve for X and compute error bounds.
4. The system of equations is solved for X using the factored form of A .
5. By default, unless `params[0]` is set to zero, the routine applies iterative refinement to get a small error and error bounds. Refinement calculates the residual to at least twice the working precision.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(r)$ so that it solves the original system before equilibration.

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

| | |
|-----------------|---|
| <i>fact</i> | <p>Must be 'F', 'N', or 'E'.</p> <p>Specifies whether or not the factored form of the matrix <i>A</i> is supplied on entry, and if not, whether the matrix <i>A</i> should be equilibrated before it is factored.</p> <p>If <i>fact</i> = 'F', on entry, <i>af</i> and <i>ipiv</i> contain the factored form of <i>A</i>. If <i>equed</i> is not 'N', the matrix <i>A</i> has been equilibrated with scaling factors given by <i>s</i>. Parameters <i>a</i>, <i>af</i>, and <i>ipiv</i> are not modified.</p> <p>If <i>fact</i> = 'N', the matrix <i>A</i> will be copied to <i>af</i> and factored.</p> <p>If <i>fact</i> = 'E', the matrix <i>A</i> will be equilibrated, if necessary, copied to <i>af</i> and factored.</p> |
| <i>uplo</i> | <p>Must be 'U' or 'L'.</p> <p>Indicates whether the upper or lower triangular part of <i>A</i> is stored:</p> <p>If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored.</p> <p>If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.</p> |
| <i>n</i> | The number of linear equations; the order of the matrix <i>A</i> ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; the number of columns of the matrices <i>B</i> and <i>X</i> ; $nrhs \geq 0$. |
| <i>a, af, b</i> | <p>Arrays: <i>a</i>(size $\max(1, lda * n)$), <i>af</i>(size $\max(1, ldaf * n)$), <i>b</i>, size $\max(ldb * nrhs)$ for column major layout and $\max(ldb * n)$ for row major layout,.</p> <p>The array <i>a</i> contains the symmetric matrix <i>A</i> as specified by <i>uplo</i>. If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of <i>a</i> contains the upper triangular part of the matrix <i>A</i> and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of <i>a</i> contains the lower triangular part of the matrix <i>A</i> and the strictly upper triangular part of <i>a</i> is not referenced.</p> <p>The array <i>af</i> is an input argument if <i>fact</i> = 'F'. It contains the block diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> and <i>L</i> from the factorization $A = U * D * U^T$ or $A = L * D * L^T$ as computed by ?sytrf.</p> <p>The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations.</p> |
| <i>lda</i> | The leading dimension of the array <i>a</i> ; $lda \geq \max(1, n)$. |
| <i>ldaf</i> | The leading dimension of the array <i>af</i> ; $ldaf \geq \max(1, n)$. |
| <i>ipiv</i> | <p>Array, size at least $\max(1, n)$. The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F'. It contains details of the interchanges and the block structure of <i>D</i> as determined by ?sytrf. If <i>ipiv</i>[<i>k</i>-1] > 0, rows and columns <i>k</i> and <i>ipiv</i>[<i>k</i>-1] were interchanged and <i>D</i>(<i>k</i>,<i>k</i>) is a 1-by-1 diagonal block.</p> <p>If <i>uplo</i> = 'U' and <i>ipiv</i>[<i>i</i>] = <i>ipiv</i>[<i>i</i> - 1] = <i>m</i> < 0, <i>D</i> has a 2-by-2 diagonal block in rows and columns <i>i</i> and <i>i</i> + 1, and the <i>i</i>-th row and column of <i>A</i> were interchanged with the <i>m</i>-th row and column.</p> |

If $uplo = 'L'$ and $ipiv[i] = ipiv[i - 1] = m < 0$, D has a 2-by-2 diagonal block in rows and columns i and $i + 1$, and the $(i + 1)$ -st row and column of A were interchanged with the m -th row and column.

eques

Must be 'N' or 'Y'.

eques is an input argument if $fact = 'F'$. It specifies the form of equilibration that was done:

If $eques = 'N'$, no equilibration was done (always true if $fact = 'N'$).

if $eques = 'Y'$, both row and column equilibration was done, that is, A has been replaced by $diag(s) * A * diag(s)$.

s

Array, size (n) . The array s contains the scale factors for A . If $eques = 'Y'$, A is multiplied on the left and right by $diag(s)$.

This array is an input argument if $fact = 'F'$ only; otherwise it is an output argument.

If $fact = 'F'$ and $eques = 'Y'$, each element of s must be positive.

Each element of s should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

ldb

The leading dimension of the array b ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

ldx

The leading dimension of the output array x ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout.

n_err_bnds

Number of error bounds to return for each right hand side and each type (normwise or componentwise). See *err_bnds_norm* and *err_bnds_comp* descriptions in the *Output Arguments* section below.

nparams

Specifies the number of parameters set in *params*. If ≤ 0 , the *params* array is never referenced and default values are used.

params

Array, size $\max(1, nparams)$. Specifies algorithm parameters. If an entry is less than 0.0, that entry is filled with the default value used for that parameter. Only positions up to *nparams* are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass $nparams = 0$, which prevents the source code from accessing the *params* argument.

params[0] : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).

=0.0 No refinement is performed and no error bounds are computed.

=1.0 Use the extra-precise refinement algorithm.

(Other values are reserved for future use.)

params[1] : Maximum number of residual computations allowed for refinement.

Default 10.0

Aggressive Set to 100.0 to permit convergence using approximate factorizations or factorizations other than *LU*. If the factorization uses a technique other than Gaussian elimination, the guarantees in *err_bnds_norm* and *err_bnds_comp* may no longer be trustworthy.

params[2] : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

Output Parameters

x Array, size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout).

If *info* = 0, the array *x* contains the solution *n*-by-*nrhs* matrix *X* to the original system of equations. Note that *A* and *B* are modified on exit if *equed* ≠ 'N', and the solution to the equilibrated system is:

$$\text{inv}(\text{diag}(s)) * X.$$

a If *fact* = 'E' and *equed* = 'Y', overwritten by $\text{diag}(s) * A * \text{diag}(s)$.

af If *fact* = 'N', *af* is an output argument and on exit returns the block diagonal matrix *D* and the multipliers used to obtain the factor *U* or *L* from the factorization $A = U * D * U^T$ or $A = L * D * L^T$.

b If *equed* = 'N', *B* is not modified.

If *equed* = 'Y', *B* is overwritten by $\text{diag}(s) * B$.

s This array is an output argument if *fact* ≠ 'F'. Each element of this array is a power of the radix. See the description of *s* in *Input Arguments* section.

rcond Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix *A* after equilibration (if done). If *rcond* is less than the machine precision, in particular, if *rcond* = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

rpvgrw Contains the reciprocal pivot growth factor:

$$\|A\| / \|U\|$$

If this is much less than 1, the stability of the *LU* factorization of the (equilibrated) matrix *A* could be poor. This also means that the solution *X*, estimated condition numbers, and error bounds could be unreliable. If factorization fails with $0 < info \leq n$, this parameter contains the reciprocal pivot growth factor for the leading *info* columns of *A*.

berr Array, size at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector x_j , that is, the smallest relative change in any element of A or B that makes x_j an exact solution.

err_bnds_norm Array of size $nrhs * n_err_bnds$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the i -th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. Up to three pieces of information are returned.

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors.

err=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

err=3 Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix Z are:

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

The information for right-hand side i , where $1 \leq i \leq nrhs$, and type of error *err* is stored in $err_bnds_norm[(err-1)*nrhs + i - 1]$.

err_bnds_comp Array of size $nrhs * n_err_bnds$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($params[2] = 0.0$), then `err_bnds_comp` is not accessed.

`err=1` "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors.

`err=2` "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

`err=3` Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix Z are:

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

The information for right-hand side i , where $1 \leq i \leq nrhs$, and type of error `err` is stored in `err_bnds_comp[(err-1)*nrhs + i - 1]`.

`ipiv` If `fact = 'N'`, `ipiv` is an output argument and on exit contains details of the interchanges and the block structure D , as determined by `ssytrf` for single precision flavors and `dsytrf` for double precision flavors.

`equed` If `fact != 'F'`, then `equed` is an output argument. It specifies the form of equilibration that was done (see the description of `equed` in *Input Arguments* section).

params If an entry is less than 0.0, that entry is filled with the default value used for that parameter, otherwise the entry is not modified.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful. The solution to every right-hand side is guaranteed.

If *info* = -*i*, parameter *i* had an illegal value.

If $0 < \text{info} \leq n$: $U_{\text{info}, \text{info}}$ is exactly zero. The factorization has been completed, but the factor *U* is exactly singular, so the solution and error bounds could not be computed; *rcond* = 0 is returned.

If *info* = *n*+*j*: The solution corresponding to the *j*-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides *k* with *k* > *j* may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested *params*[2] = 0.0, then the *j*-th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest *j* such that for column major layout $\text{err_bnds_norm}[j - 1] = 0.0$ or $\text{err_bnds_comp}[j - 1] = 0.0$; or for row major layout $\text{err_bnds_norm}[(j - 1)*n_err_bnds] = 0.0$ or $\text{err_bnds_comp}[(j - 1)*n_err_bnds] = 0.0$). See the definition of *err_bnds_norm* and *err_bnds_comp* for *err* = 1. To get information about all of the right-hand sides, check *err_bnds_norm* or *err_bnds_comp*.

Description

The routine solves for *X* the complex system of linear equations $A^*X = B$, where *A* is an *n*-by-*n* symmetric matrix, the columns of matrix *B* are individual right-hand sides, and the columns of *X* are the corresponding solutions.

The diagonal pivoting method is used to factor *A* as $A = U^*D^*U^H$ or $A = L^*D^*L^H$, where *U* (or *L*) is a product of permutation and unit upper (lower) triangular matrices, and *D* is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of *A* is then used to solve the system of equations $A^*X = B$.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | <p>Must be 'U' or 'L'.</p> <p>Indicates whether the upper or lower triangular part of A is stored and how A is factored:</p> <p>If $uplo = 'U'$, the array a stores the upper triangular part of the matrix A, and A is factored as U^*D*U^H.</p> <p>If $uplo = 'L'$, the array a stores the lower triangular part of the matrix A, and A is factored as L^*D*L^H.</p> |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$. |
| <i>a, b</i> | <p>Arrays: a(size $\max(1, lda*n)$), b of size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout. The array a contains the upper or the lower triangular part of the Hermitian matrix A (see <i>uplo</i>).</p> <p>The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.</p> |
| <i>lda</i> | The leading dimension of a ; $lda \geq \max(1, n)$. |
| <i>ldb</i> | The leading dimension of b ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |

Output Parameters

| | |
|-------------|--|
| <i>a</i> | If <i>info</i> = 0, a is overwritten by the block-diagonal matrix D and the multipliers used to obtain the factor U (or L) from the factorization of A as computed by ?hetrf . |
| <i>b</i> | If <i>info</i> = 0, b is overwritten by the solution matrix X . |
| <i>ipiv</i> | <p>Array, size at least $\max(1, n)$. Contains details of the interchanges and the block structure of D, as determined by ?hetrf.</p> <p>If $ipiv[i-1] = k > 0$, then d_{ii} is a 1-by-1 diagonal block, and the i-th row and column of A was interchanged with the k-th row and column.</p> <p>If $uplo = 'U'$ and $ipiv[i] = ipiv[i-1] = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and (i)-th row and column of A was interchanged with the m-th row and column.</p> <p>If $uplo = 'L'$ and $ipiv[i] = ipiv[i-1] = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$-th row and column of A was interchanged with the m-th row and column.</p> |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

If *info* = *i*, d_{ii} is 0. The factorization has been completed, but *D* is exactly singular, so the solution could not be computed.

Description

The routine uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A \cdot X = B$, where *A* is an *n*-by-*n* Hermitian matrix, the columns of matrix *B* are individual right-hand sides, and the columns of *X* are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?hesvx performs the following steps:

1. If *fact* = 'N', the diagonal pivoting method is used to factor the matrix *A*. The form of the factorization is $A = U \cdot D \cdot U^H$ or $A = L \cdot D \cdot L^H$, where *U* (or *L*) is a product of permutation and unit upper (lower) triangular matrices, and *D* is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.
2. If some $d_{i,i} = 0$, so that *D* is exactly singular, then the routine returns with *info* = *i*. Otherwise, the factored form of *A* is used to estimate the condition number of the matrix *A*. If the reciprocal of the condition number is less than machine precision, *info* = *n*+1 is returned as a warning, but the routine still goes on to solve for *X* and compute error bounds as described below.
3. The system of equations is solved for *X* using the factored form of *A*.
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>fact</i> | <p>Must be 'F' or 'N'.</p> <p>Specifies whether or not the factored form of the matrix <i>A</i> has been supplied on entry.</p> <p>If <i>fact</i> = 'F': on entry, <i>af</i> and <i>ipiv</i> contain the factored form of <i>A</i>. Arrays <i>a</i>, <i>af</i>, and <i>ipiv</i> are not modified.</p> <p>If <i>fact</i> = 'N', the matrix <i>A</i> is copied to <i>af</i> and factored.</p> |
| <i>uplo</i> | <p>Must be 'U' or 'L'.</p> <p>Indicates whether the upper or lower triangular part of <i>A</i> is stored and how <i>A</i> is factored:</p> <p>If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular part of the Hermitian matrix <i>A</i>, and <i>A</i> is factored as $U^*D^*U^H$.</p> <p>If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular part of the Hermitian matrix <i>A</i>; <i>A</i> is factored as $L^*D^*L^H$.</p> |
| <i>n</i> | The order of matrix <i>A</i> ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides, the number of columns in <i>B</i> ; $nrhs \geq 0$. |
| <i>a, af, b</i> | <p>Arrays: <i>a</i>(size $\max(1, lda*n)$), <i>af</i>(size $\max(1, ldaf*n)$), <i>b</i> of size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout.</p> <p>The array <i>a</i> contains the upper or the lower triangular part of the Hermitian matrix <i>A</i> (see <i>uplo</i>).</p> <p>The array <i>af</i> is an input argument if <i>fact</i> = 'F'. It contains the block diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> or <i>L</i> from the factorization $A = U^*D^*U^H$ or $A = L^*D^*L^H$ as computed by ?hetrf.</p> <p>The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations.</p> |
| <i>lda</i> | The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$. |
| <i>ldaf</i> | The leading dimension of <i>af</i> ; $ldaf \geq \max(1, n)$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>ipiv</i> | <p>Array, size at least $\max(1, n)$. The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F'. It contains details of the interchanges and the block structure of <i>D</i>, as determined by ?hetrf.</p> <p>If <i>ipiv</i>[<i>i</i>-1] = <i>k</i> > 0, then d_{ii} is a 1-by-1 diagonal block, and the <i>i</i>-th row and column of <i>A</i> was interchanged with the <i>k</i>-th row and column.</p> |

If $uplo = 'U'$ and $ipiv[i] = ipiv[i-1] = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and (i) -th row and column of A was interchanged with the m -th row and column.

If $uplo = 'L'$ and $ipiv[i] = ipiv[i-1] = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column.

ldx

The leading dimension of the output array x ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout.

Output Parameters

x

Array, size $\max(1, ldx * nrhs)$ for column major layout and $\max(1, ldx * n)$ for row major layout.

If $info = 0$ or $info = n+1$, the array x contains the solution matrix X to the system of equations.

af, ipiv

These arrays are output arguments if $fact = 'N'$. See the description of *af, ipiv* in *Input Arguments* section.

rcond

An estimate of the reciprocal condition number of the matrix A . If *rcond* is less than the machine precision (in particular, if $rcond = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$.

ferr

Array, size at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector x_j (the j -th column of the solution matrix X). If x_{true} is the true solution corresponding to x_j , $ferr[j-1]$ is an estimated upper bound for the magnitude of the largest element in $(x_j) - x_{true}$ divided by the magnitude of the largest element in x_j . The estimate is as reliable as the estimate for *rcond*, and is almost always a slight overestimate of the true error.

berr

Array, size at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector x_j , that is, the smallest relative change in any element of A or B that makes x_j an exact solution.

Return Values

This function returns a value *info*.

If $info = 0$, the execution is successful.

If $info = -i$, parameter i had an illegal value.

If $info = i$, and $i \leq n$, then d_{ii} is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution and error bounds could not be computed; $rcond = 0$ is returned.

If $info = i$, and $i = n + 1$, then D is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of *rcond* would suggest.

Description

The routine uses the *diagonal pivoting* factorization to compute the solution to a complex/double complex system of linear equations $A \cdot X = B$, where A is an n -by- n Hermitian matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Both normwise and maximum componentwise error bounds are also provided on request. The routine returns a solution with a small guaranteed error ($O(\text{eps})$, where eps is the working machine precision) unless the matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also calculated and returned.

The routine accepts user-provided factorizations and equilibration factors; see definitions of the *fact* and *equed* options. Solving with refinement and using a factorization from a previous call of the routine also produces a solution with $O(\text{eps})$ errors or warnings but that may not be true for general user-provided factorizations and equilibration factors if they differ from what the routine would itself produce.

The routine ?hesvxx performs the following steps:

1. If *fact* = 'E', scaling factors are computed to equilibrate the system:

$$\text{diag}(s) * A * \text{diag}(s) * \text{inv}(\text{diag}(s)) * X = \text{diag}(s) * B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(s) * A * \text{diag}(s)$ and B by $\text{diag}(s) * B$.

2. If *fact* = 'N' or 'E', the LU decomposition is used to factor the matrix A (after equilibration if *fact* = 'E') as

$$A = U * D * U^T, \text{ if } \text{uplo} = \text{'U'},$$

$$\text{or } A = L * D * L^T, \text{ if } \text{uplo} = \text{'L'},$$

where U or L is a product of permutation and unit upper (lower) triangular matrices, and D is a symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

3. If some $D(i, i) = 0$, so that D is exactly singular, the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A (see the *rcond* parameter). If the reciprocal of the condition number is less than machine precision, the routine still goes on to solve for X and compute error bounds.
4. The system of equations is solved for X using the factored form of A .
5. By default, unless `params[0]` is set to zero, the routine applies iterative refinement to get a small error and error bounds. Refinement calculates the residual to at least twice the working precision.
6. If equilibration was used, the matrix X is premultiplied by $diag(r)$ so that it solves the original system before equilibration.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>fact</i> | <p>Must be 'F', 'N', or 'E'.</p> <p>Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.</p> <p>If <i>fact</i> = 'F', on entry, <i>af</i> and <i>ipiv</i> contain the factored form of A. If <i>equed</i> is not 'N', the matrix A has been equilibrated with scaling factors given by <i>s</i>. Parameters <i>a</i>, <i>af</i>, and <i>ipiv</i> are not modified.</p> <p>If <i>fact</i> = 'N', the matrix A will be copied to <i>af</i> and factored.</p> <p>If <i>fact</i> = 'E', the matrix A will be equilibrated, if necessary, copied to <i>af</i> and factored.</p> |
| <i>uplo</i> | <p>Must be 'U' or 'L'.</p> <p>Indicates whether the upper or lower triangular part of A is stored:</p> <p>If <i>uplo</i> = 'U', the upper triangle of A is stored.</p> <p>If <i>uplo</i> = 'L', the lower triangle of A is stored.</p> |
| <i>n</i> | The number of linear equations; the order of the matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$. |
| <i>a, af, b</i> | <p>Arrays: <i>a</i>(size $\max(lda*n)$), <i>af</i>(size $\max(ldaf*n)$), <i>b</i>, (size $\max(l db*nrhs)$ for column major layout and $\max(l db*n)$ for row major layout),.</p> <p>The array <i>a</i> contains the Hermitian matrix A as specified by <i>uplo</i>. If <i>uplo</i> = 'U', the leading n-by-n upper triangular part of <i>a</i> contains the upper triangular part of the matrix A and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading n-by-n lower triangular part of <i>a</i> contains the lower triangular part of the matrix A and the strictly upper triangular part of <i>a</i> is not referenced.</p> <p>The array <i>af</i> is an input argument if <i>fact</i> = 'F'. It contains the block diagonal matrix D and the multipliers used to obtain the factor U and L from the factorization $A = U*D*U^T$ or $A = L*D*L^T$ as computed by <code>?hetrf</code>.</p> <p>The array <i>b</i> contains the matrix B whose columns are the right-hand sides for the systems of equations.</p> |

| | |
|-------------------|---|
| <i>lda</i> | The leading dimension of the array <i>a</i> ; $lda \geq \max(1, n)$. |
| <i>ldaf</i> | The leading dimension of the array <i>af</i> ; $ldaf \geq \max(1, n)$. |
| <i>ipiv</i> | <p>Array, size at least $\max(1, n)$. The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F'. It contains details of the interchanges and the block structure of <i>D</i> as determined by ?sytrf.</p> <p>If $ipiv[k-1] > 0$, rows and columns <i>k</i> and $ipiv[k-1]$ were interchanged and $D_{k,k}$ is a 1-by-1 diagonal block.</p> <p>If <i>uplo</i> = 'U' and $ipiv[i] = ipiv[i - 1] = m < 0$, <i>D</i> has a 2-by-2 diagonal block in rows and columns <i>i</i> and <i>i + 1</i>, and the <i>i</i>-th row and column of <i>A</i> were interchanged with the <i>m</i>-th row and column.</p> <p>If <i>uplo</i> = 'L' and $ipiv[i] = ipiv[i - 1] = m < 0$, <i>D</i> has a 2-by-2 diagonal block in rows and columns <i>i</i> and <i>i + 1</i>, and the (<i>i + 1</i>)-st row and column of <i>A</i> were interchanged with the <i>m</i>-th row and column.</p> |
| <i>equed</i> | <p>Must be 'N' or 'Y'.</p> <p><i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done:</p> <p>If <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N').</p> <p>if <i>equed</i> = 'Y', both row and column equilibration was done, that is, <i>A</i> has been replaced by $diag(s) * A * diag(s)$.</p> |
| <i>s</i> | <p>Array, size (<i>n</i>). The array <i>s</i> contains the scale factors for <i>A</i>. If <i>equed</i> = 'Y', <i>A</i> is multiplied on the left and right by $diag(s)$.</p> <p>This array is an input argument if <i>fact</i> = 'F' only; otherwise it is an output argument.</p> <p>If <i>fact</i> = 'F' and <i>equed</i> = 'Y', each element of <i>s</i> must be positive.</p> <p>Each element of <i>s</i> should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.</p> |
| <i>ldb</i> | The leading dimension of the array <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>ldx</i> | The leading dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |
| <i>n_err_bnds</i> | Number of error bounds to return for each right hand side and each type (normwise or componentwise). See err_bnds_norm and err_bnds_comp descriptions in the <i>Output Arguments</i> section below. |
| <i>nparams</i> | Specifies the number of parameters set in <i>params</i> . If ≤ 0 , the <i>params</i> array is never referenced and default values are used. |
| <i>params</i> | Array, size $\max(1, nparams)$. Specifies algorithm parameters. If an entry is less than 0.0, that entry is filled with the default value used for that parameter. Only positions up to <i>nparams</i> are accessed; defaults are used |

for higher-numbered parameters. If defaults are acceptable, you can pass $nparams = 0$, which prevents the source code from accessing the $params$ argument.

$params[0]$: Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).

=0.0 No refinement is performed and no error bounds are computed.

=1.0 Use the extra-precise refinement algorithm.

(Other values are reserved for future use.)

$params[1]$: Maximum number of residual computations allowed for refinement.

Default 10

Aggressive Set to 100 to permit convergence using approximate factorizations or factorizations other than LU . If the factorization uses a technique other than Gaussian elimination, the guarantees in err_bnds_norm and err_bnds_comp may no longer be trustworthy.

$params[2]$: Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

Output Parameters

- x Array, size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout.
If $info = 0$, the array x contains the solution n -by- $nrhs$ matrix X to the original system of equations. Note that A and B are modified on exit if $equed \neq 'N'$, and the solution to the equilibrated system is:
$$\text{inv}(\text{diag}(s)) * X.$$
- a If $fact = 'E'$ and $equed = 'Y'$, overwritten by $\text{diag}(s) * A * \text{diag}(s)$.
- af If $fact = 'N'$, af is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^T$ or $A = L * D * L^T$.
- b If $equed = 'N'$, B is not modified.
If $equed = 'Y'$, B is overwritten by $\text{diag}(s) * B$.
- s This array is an output argument if $fact \neq 'F'$. Each element of this array is a power of the radix. See the description of s in *Input Arguments* section.

| | | | | | | | |
|----------------------|--|---------------|---|---------------|--|---------------|--|
| <i>rcond</i> | <p>Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision, in particular, if <i>rcond</i> = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.</p> | | | | | | |
| <i>rpvgrw</i> | <p>Contains the reciprocal pivot growth factor:</p> $\ A\ /\ U\ $ <p>If this is much less than 1, the stability of the <i>LU</i> factorization of the (equilibrated) matrix <i>A</i> could be poor. This also means that the solution <i>X</i>, estimated condition numbers, and error bounds could be unreliable. If factorization fails with $0 < info \leq n$, this parameter contains the reciprocal pivot growth factor for the leading <i>info</i> columns of <i>A</i>.</p> | | | | | | |
| <i>berr</i> | <p>Array, size at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector x_j, that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes x_j an exact solution.</p> | | | | | | |
| <i>err_bnds_norm</i> | <p>Array of size $nrhs * n_err_bnds$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:</p> <p>Normwise relative error in the <i>i</i>-th solution vector</p> $\frac{\max_j X_{true_{ji}} - X_{ji} }{\max_j X_{ji} }$ <p>The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top;"><i>err</i>=1</td> <td>"Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for <i>chesvxx</i> and $\sqrt{n} * dlamch(\epsilon)$ for <i>zhesvxx</i>.</td> </tr> <tr> <td style="vertical-align: top;"><i>err</i>=2</td> <td>"Guaranteed" error bound. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for <i>chesvxx</i> and $\sqrt{n} * dlamch(\epsilon)$ for <i>zhesvxx</i> to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix <i>Z</i> are: | | | | | | |

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

The information for right-hand side i , where $1 \leq i \leq nrhs$, and type of error err is stored in $err_bnds_norm[(err-1)*nrhs + i - 1]$.

err_bnds_comp

Array of size $nrhs * n_err_bnds$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($params[2] = 0.0$), then *err_bnds_comp* is not accessed.

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for *chesvxx* and $\sqrt{n} * dlamch(\epsilon)$ for *zhesvxx*.

err=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * slamch(\epsilon)$ for *chesvxx* and $\sqrt{n} * dlamch(\epsilon)$ for *zhesvxx*. This error bound should only be trusted if the previous boolean is true.

err=3 Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for *chesvxx* and $\sqrt{n} * dlamch(\epsilon)$ for *zhesvxx* to determine if the error estimate is "guaranteed". These reciprocal condition numbers for some appropriately scaled matrix Z are:

$$\|Z\|_{\infty} \cdot \|Z^{-1}\|_{\infty}$$

Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

The information for right-hand side i , where $1 \leq i \leq nrhs$, and type of error err is stored in `err_bnds_comp[(err-1)*nrhs + i - 1]`.

`ipiv` If `fact = 'N'`, `ipiv` is an output argument and on exit contains details of the interchanges and the block structure D , as determined by `ssytrf` for single precision flavors and `dsytrf` for double precision flavors.

`equed` If `fact ≠ 'F'`, then `equed` is an output argument. It specifies the form of equilibration that was done (see the description of `equed` in *Input Arguments* section).

`params` If an entry is less than 0.0, that entry is filled with the default value used for that parameter, otherwise the entry is not modified.

Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful. The solution to every right-hand side is guaranteed.

If `info = -i`, the i -th parameter had an illegal value.

If $0 < info \leq n$: $U_{info,info}$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; `rcond = 0` is returned.

If `info = n+j`: The solution corresponding to the j -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested `params[2] = 0.0`, then the j -th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that for column major layout `err_bnds_norm[j - 1] = 0.0` or `err_bnds_comp[j - 1] = 0.0`; or for row major layout `err_bnds_norm[(j - 1)*n_err_bnds] = 0.0` or `err_bnds_comp[(j - 1)*n_err_bnds] = 0.0`). See the definition of `err_bnds_norm` and `err_bnds_comp` for `err = 1`. To get information about all of the right-hand sides, check `err_bnds_norm` or `err_bnds_comp`.

Description

The routine solves for X the real or complex system of linear equations $A^*X = B$, where A is an n -by- n symmetric matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The diagonal pivoting method is used to factor A as $A = U^*D^*U^T$ or $A = L^*D^*L^T$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored. |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$. |
| <i>ap, b</i> | Arrays: <i>ap</i> (size $\max(1, n*(n+1)/2)$, <i>bof</i> size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout. The array <i>ap</i> contains the factor U or L , as specified by <i>uplo</i> , in <i>packed storage</i> (see Matrix Storage Schemes). The array <i>b</i> contains the matrix B whose columns are the right-hand sides for the systems of equations. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |

Output Parameters

| | |
|-------------|---|
| <i>ap</i> | The block-diagonal matrix D and the multipliers used to obtain the factor U (or L) from the factorization of A as computed by <code>?spturf</code> , stored as a packed triangular matrix in the same storage format as A . |
| <i>b</i> | If <i>info</i> = 0, <i>b</i> is overwritten by the solution matrix X . |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. Contains details of the interchanges and the block structure of D , as determined by <code>?spturf</code> . If <i>ipiv</i> [<i>i</i> -1] = $k > 0$, then d_{ij} is a 1-by-1 block, and the i -th row and column of A was interchanged with the k -th row and column. |

If `uplo = 'U'` and `ipiv[i]=ipiv[i-1] = -m < 0`, then D has a 2-by-2 block in rows/columns i and $i+1$, and i -th row and column of A was interchanged with the m -th row and column.

If `uplo = 'L'` and `ipiv[i-1]=ipiv[i] = -m < 0`, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column.

Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful.

If `info = -i`, parameter i had an illegal value.

If `info = i`, `dii` is 0. The factorization has been completed, but D is exactly singular, so the solution could not be computed.

Description

The routine uses the diagonal pivoting factorization to compute the solution to a real or complex system of linear equations $A \cdot X = B$, where A is a n -by- n symmetric matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine `?spsvx` performs the following steps:

1. If $fact = 'N'$, the diagonal pivoting method is used to factor the matrix A . The form of the factorization is $A = U^*D^*U^T$ or $A = L^*D^*L^T$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.
2. If some $d_{i,i} = 0$, so that D is exactly singular, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
3. The system of equations is solved for X using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>fact</i> | <p>Must be 'F' or 'N'.</p> <p>Specifies whether or not the factored form of the matrix A has been supplied on entry.</p> <p>If $fact = 'F'$: on entry, <i>ap</i> and <i>ipiv</i> contain the factored form of A. Arrays <i>ap</i>, <i>afp</i>, and <i>ipiv</i> are not modified.</p> <p>If $fact = 'N'$, the matrix A is copied to <i>afp</i> and factored.</p> |
| <i>uplo</i> | <p>Must be 'U' or 'L'.</p> <p>Indicates whether the upper or lower triangular part of A is stored and how A is factored:</p> <p>If $uplo = 'U'$, the array <i>ap</i> stores the upper triangular part of the symmetric matrix A, and A is factored as $U^*D^*U^T$.</p> <p>If $uplo = 'L'$, the array <i>ap</i> stores the lower triangular part of the symmetric matrix A; A is factored as $L^*D^*L^T$.</p> |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$. |
| <i>ap, afp, b</i> | <p>Arrays: <i>ap</i> (size $\max(1, n*(n+1)/2)$), <i>afp</i> (size $\max(1, n*(n+1)/2)$), <i>b</i> of size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout.</p> <p>The array <i>ap</i> contains the upper or lower triangle of the symmetric matrix A in <i>packed storage</i> (see Matrix Storage Schemes).</p> <p>The array <i>afp</i> is an input argument if $fact = 'F'$. It contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D^*U^T$ or $A = L^*D^*L^T$ as computed by <code>?sptrf</code>, in the same storage format as A.</p> <p>The array <i>b</i> contains the matrix B whose columns are the right-hand sides for the systems of equations.</p> |

| | |
|-------------|--|
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |
| <i>ipiv</i> | <p>Array, size at least $\max(1, n)$. The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F'. It contains details of the interchanges and the block structure of <i>D</i>, as determined by <code>?sptrf</code>.</p> <p>If $ipiv[i-1] = k > 0$, then d_{ij} is a 1-by-1 block, and the <i>i</i>-th row and column of <i>A</i> was interchanged with the <i>k</i>-th row and column.</p> <p>If $uplo = 'U'$ and $ipiv[i]=ipiv[i-1] = -m < 0$, then <i>D</i> has a 2-by-2 block in rows/columns <i>i</i> and <i>i+1</i>, and <i>i</i>-th row and column of <i>A</i> was interchanged with the <i>m</i>-th row and column.</p> <p>If $uplo = 'L'$ and $ipiv[i-1] = ipiv[i] = -m < 0$, then <i>D</i> has a 2-by-2 block in rows/columns <i>i</i> and <i>i+1</i>, and (<i>i+1</i>)-th row and column of <i>A</i> was interchanged with the <i>m</i>-th row and column.</p> |
| <i>ldx</i> | The leading dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout. |

Output Parameters

| | |
|-------------------|--|
| <i>x</i> | <p>Array, size $\max(1, ldx*nrhs)$ for column major layout and $\max(1, ldx*n)$ for row major layout.</p> <p>If <i>info</i> = 0 or <i>info</i> = <i>n</i>+1, the array <i>x</i> contains the solution matrix <i>X</i> to the system of equations.</p> |
| <i>afp, ipiv</i> | These arrays are output arguments if <i>fact</i> = 'N'. See the description of <i>afp, ipiv</i> in <i>Input Arguments</i> section. |
| <i>rcond</i> | An estimate of the reciprocal condition number of the matrix <i>A</i> . If <i>rcond</i> is less than the machine precision (in particular, if <i>rcond</i> = 0), the matrix is singular to working precision. This condition is indicated by a return code of <i>info</i> > 0. |
| <i>ferr, berr</i> | Arrays, size at least $\max(1, nrhs)$. Contain the component-wise forward and relative backward errors, respectively, for each solution vector. |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

If *info* = *i*, and $i \leq n$, then d_{ii} is exactly zero. The factorization has been completed, but the block diagonal matrix *D* is exactly singular, so the solution and error bounds could not be computed; *rcond* = 0 is returned.

If *info* = *i*, and $i = n + 1$, then *D* is nonsingular, but *rcond* is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of *rcond* would suggest.

Description

The routine solves for X the system of linear equations $A^*X = B$, where A is an n -by- n Hermitian matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The diagonal pivoting method is used to factor A as $A = U^*D^*U^H$ or $A = L^*D^*L^H$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored. |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; the number of columns in B ; $nrhs \geq 0$. |
| <i>ap</i> , <i>b</i> | Arrays: <i>ap</i> (size $\max(1, n*(n+1)/2)$, <i>bof</i> size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout. The array <i>ap</i> contains the factor U or L , as specified by <i>uplo</i> , in packed storage (see Matrix Storage Schemes). The array <i>b</i> contains the matrix B whose columns are the right-hand sides for the systems of equations. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout. |

Output Parameters

| | |
|-------------|--|
| <i>ap</i> | The block-diagonal matrix D and the multipliers used to obtain the factor U (or L) from the factorization of A as computed by <code>?hptrf</code> , stored as a packed triangular matrix in the same storage format as A . |
| <i>b</i> | If $info = 0$, b is overwritten by the solution matrix X . |
| <i>ipiv</i> | <p>Array, size at least $\max(1, n)$. Contains details of the interchanges and the block structure of D, as determined by <code>?hptrf</code>.</p> <p>If $ipiv[i-1] = k > 0$, then d_{ij} is a 1-by-1 block, and the i-th row and column of A was interchanged with the k-th row and column.</p> <p>If $uplo = 'U'$ and $ipiv[i]=ipiv[i-1] = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and i-th row and column of A was interchanged with the m-th row and column.</p> <p>If $uplo = 'L'$ and $ipiv[i-1]=ipiv[i] = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$-th row and column of A was interchanged with the m-th row and column.</p> |

Return Values

This function returns a value *info*.

If $info = 0$, the execution is successful.

If $info = -i$, parameter i had an illegal value.

If $info = i, d_{ii}$ is 0. The factorization has been completed, but D is exactly singular, so the solution could not be computed.

?hpsvx

Uses the diagonal pivoting factorization to compute the solution to the system of linear equations with a Hermitian coefficient matrix A stored in packed format, and provides error bounds on the solution.

Syntax

```
lapack_int LAPACKE_chpsvx( int matrix_layout, char fact, char uplo, lapack_int n,
lapack_int nrhs, const lapack_complex_float* ap, lapack_complex_float* afp, lapack_int*
ipiv, const lapack_complex_float* b, lapack_int ldb, lapack_complex_float* x,
lapack_int ldx, float* rcond, float* ferr, float* berr );
```

```
lapack_int LAPACKE_zhpsvx( int matrix_layout, char fact, char uplo, lapack_int n,
lapack_int nrhs, const lapack_complex_double* ap, lapack_complex_double* afp,
lapack_int* ipiv, const lapack_complex_double* b, lapack_int ldb,
lapack_complex_double* x, lapack_int ldx, double* rcond, double* ferr, double* berr );
```

Include Files

- `mkl.h`

Description

The routine uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A*X = B$, where A is a n -by- n Hermitian matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine `?hpsvx` performs the following steps:

1. If `fact = 'N'`, the diagonal pivoting method is used to factor the matrix A . The form of the factorization is $A = U*D*U^H$ or $A = L*D*L^H$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is a Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.
2. If some $d_{i,i} = 0$, so that D is exactly singular, then the routine returns with `info = i`. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, `info = n+1` is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
3. The system of equations is solved for X using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>fact</code> | Must be 'F' or 'N'. Specifies whether or not the factored form of the matrix A has been supplied on entry. If <code>fact = 'F'</code> : on entry, <code>afp</code> and <code>ipiv</code> contain the factored form of A . Arrays <code>ap</code> , <code>afp</code> , and <code>ipiv</code> are not modified. If <code>fact = 'N'</code> , the matrix A is copied to <code>afp</code> and factored. |
| <code>uplo</code> | Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored and how A is factored: If <code>uplo = 'U'</code> , the array <code>ap</code> stores the upper triangular part of the Hermitian matrix A , and A is factored as $U*D*U^H$. If <code>uplo = 'L'</code> , the array <code>ap</code> stores the lower triangular part of the Hermitian matrix A , and A is factored as $L*D*L^H$. |
| <code>n</code> | The order of matrix A ; $n \geq 0$. |
| <code>nrhs</code> | The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$. |
| <code>ap, afp, b</code> | Arrays: <code>ap</code> (size $\max(1, n*(n+1)/2)$), <code>afp</code> (size $\max(1, n*(n+1)/2)$), <code>bof</code> size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*n)$ for row major layout. The array <code>ap</code> contains the upper or lower triangle of the Hermitian matrix A in <i>packed storage</i> (see Matrix Storage Schemes). |

The array *afp* is an input argument if *fact* = 'F'. It contains the block diagonal matrix *D* and the multipliers used to obtain the factor *U* or *L* from the factorization $A = U * D * U^H$ or $A = L * D * L^H$ as computed by `?hptrfs`, in the same storage format as *A*.

The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations.

ldb The leading dimension of *b*; $ldb \geq \max(1, n)$ for column major layout and $ldb \geq nrhs$ for row major layout.

ipiv Array, size at least $\max(1, n)$. The array *ipiv* is an input argument if *fact* = 'F'. It contains details of the interchanges and the block structure of *D*, as determined by `?hptrfs`.

If $ipiv[i-1] = k > 0$, then d_{ii} is a 1-by-1 block, and the *i*-th row and column of *A* was interchanged with the *k*-th row and column.

If $uplo = 'U'$ and $ipiv[i]=ipiv[i-1] = -m < 0$, then *D* has a 2-by-2 block in rows/columns *i* and *i+1*, and *i*-th row and column of *A* was interchanged with the *m*-th row and column.

If $uplo = 'L'$ and $ipiv[i-1]=ipiv[i] = -m < 0$, then *D* has a 2-by-2 block in rows/columns *i* and *i+1*, and (*i+1*)-th row and column of *A* was interchanged with the *m*-th row and column.

ldx The leading dimension of the output array *x*; $ldx \geq \max(1, n)$ for column major layout and $ldx \geq nrhs$ for row major layout.

Output Parameters

x Array, size $\max(1, ldx * nrhs)$ for column major layout and $\max(1, ldx * n)$ for row major layout.

If *info* = 0 or *info* = *n*+1, the array *x* contains the solution matrix *X* to the system of equations.

afp, ipiv These arrays are output arguments if *fact* = 'N'. See the description of *afp, ipiv* in *Input Arguments* section.

rcond An estimate of the reciprocal condition number of the matrix *A*. If *rcond* is less than the machine precision (in particular, if *rcond* = 0), the matrix is singular to working precision. This condition is indicated by a return code of *info* > 0.

ferr Array, size at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector x_j (the *j*-th column of the solution matrix *X*). If *xtrue* is the true solution corresponding to x_j , $ferr[j-1]$ is an estimated upper bound for the magnitude of the largest element in $(x_j - xtrue)$ divided by the magnitude of the largest element in x_j . The estimate is as reliable as the estimate for *rcond*, and is almost always a slight overestimate of the true error.

berr Array, size at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector x_j , that is, the smallest relative change in any element of *A* or *B* that makes x_j an exact solution.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, parameter *i* had an illegal value.

If *info* = *i*, and $i \leq n$, then d_{ii} is exactly zero. The factorization has been completed, but the block diagonal matrix *D* is exactly singular, so the solution and error bounds could not be computed; *rcond* = 0 is returned.

If *info* = *i*, and $i = n + 1$, then *D* is nonsingular, but *rcond* is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of *rcond* would suggest.

LAPACK Least Squares and Eigenvalue Problem Routines

This section includes descriptions of LAPACK [computational routines](#) and [driver routines](#) for solving linear least squares problems, eigenvalue and singular value problems, and performing a number of related computational tasks. For a full reference on LAPACK routines and related information see [LUG].

Least Squares Problems. A typical *least squares problem* is as follows: given a matrix *A* and a vector *b*, find the vector *x* that minimizes the sum of squares $\sum_i ((Ax)_i - b_i)^2$ or, equivalently, find the vector *x* that minimizes the 2-norm $\|Ax - b\|_2$.

In the most usual case, *A* is an *m*-by-*n* matrix with $m \geq n$ and $\text{rank}(A) = n$. This problem is also referred to as finding the *least squares solution* to an *overdetermined* system of linear equations (here we have more equations than unknowns). To solve this problem, you can use the *QR* factorization of the matrix *A* (see [QR Factorization](#)).

If $m < n$ and $\text{rank}(A) = m$, there exist an infinite number of solutions *x* which exactly satisfy $Ax = b$, and thus minimize the norm $\|Ax - b\|_2$. In this case it is often useful to find the unique solution that minimizes $\|x\|_2$. This problem is referred to as finding the *minimum-norm solution* to an *underdetermined* system of linear equations (here we have more unknowns than equations). To solve this problem, you can use the *LQ* factorization of the matrix *A* (see [LQ Factorization](#)).

In the general case you may have a *rank-deficient least squares problem*, with $\text{rank}(A) < \min(m, n)$: find the *minimum-norm least squares solution* that minimizes both $\|x\|_2$ and $\|Ax - b\|_2^2$. In this case (or when the rank of *A* is in doubt) you can use the *QR* factorization with pivoting or *singular value decomposition* (see [Singular Value Decomposition](#)).

Eigenvalue Problems. The eigenvalue problems (from German *eigen* "own") are stated as follows: given a matrix *A*, find the *eigenvalues* λ and the corresponding *eigenvectors* *z* that satisfy the equation

$$Az = \lambda z \text{ (right eigenvectors } z)$$

or the equation

$$z^H A = \lambda z^H \text{ (left eigenvectors } z).$$

If *A* is a real symmetric or complex Hermitian matrix, the above two equations are equivalent, and the problem is called a *symmetric* eigenvalue problem. Routines for solving this type of problems are described in the section [Symmetric Eigenvalue Problems](#).

Routines for solving eigenvalue problems with nonsymmetric or non-Hermitian matrices are described in the section [Nonsymmetric Eigenvalue Problems](#).

The library also includes routines that handle *generalized symmetric-definite eigenvalue problems*: find the eigenvalues λ and the corresponding eigenvectors *x* that satisfy one of the following equations:

$$Az = \lambda Bz, \quad ABz = \lambda z, \quad \text{or} \quad BAz = \lambda z,$$

where A is symmetric or Hermitian, and B is symmetric positive-definite or Hermitian positive-definite. Routines for reducing these problems to standard symmetric eigenvalue problems are described in the section [Generalized Symmetric-Definite Eigenvalue Problems](#).

To solve a particular problem, you usually call several computational routines. Sometimes you need to combine the routines of this chapter with other LAPACK routines described in "LAPACK Routines: Linear Equations" as well as with BLAS routines described in "BLAS and Sparse BLAS Routines".

For example, to solve a set of least squares problems minimizing $\|Ax - b\|^2$ for all columns b of a given matrix B (where A and B are real matrices), you can call `?geqrf` to form the factorization $A = QR$, then call `?ormqr` to compute $C = Q^H B$ and finally call the BLAS routine `?trsm` to solve for X the system of equations $RX = C$.

Another way is to call an appropriate driver routine that performs several tasks in one call. For example, to solve the least squares problem the driver routine `?gels` can be used.

LAPACK Least Squares and Eigenvalue Problem Computational Routines

In the sections that follow, the descriptions of LAPACK computational routines are given. These routines perform distinct computational tasks that can be used for:

[Orthogonal Factorizations](#)

[Singular Value Decomposition](#)

[Symmetric Eigenvalue Problems](#)

[Generalized Symmetric-Definite Eigenvalue Problems](#)

[Nonsymmetric Eigenvalue Problems](#)

[Generalized Nonsymmetric Eigenvalue Problems](#)

[Generalized Singular Value Decomposition](#)

See also the respective [driver routines](#).

Orthogonal Factorizations: LAPACK Computational Routines

This section describes the LAPACK routines for the QR (RQ) and LQ (QL) factorization of matrices. Routines for the RZ factorization as well as for generalized QR and RQ factorizations are also included.

QR Factorization. Assume that A is an m -by- n matrix to be factored.

If $m \geq n$, the QR factorization is given by

$$A = Q \begin{pmatrix} R \\ 0 \end{pmatrix} = (Q_1, Q_2) \begin{pmatrix} R \\ 0 \end{pmatrix}$$

where R is an n -by- n upper triangular matrix with real diagonal elements, and Q is an m -by- m orthogonal (or unitary) matrix.

You can use the QR factorization for solving the following least squares problem: minimize $\|Ax - b\|^2$ where A is a full-rank m -by- n matrix ($m \geq n$). After factoring the matrix, compute the solution x by solving $Rx = (Q_1)^T b$.

If $m < n$, the QR factorization is given by

$$A = QR = Q(R_1 R_2)$$

where R is trapezoidal, R_1 is upper triangular and R_2 is rectangular.

Q is represented as a product of $\min(m, n)$ *elementary reflectors*. Routines are provided to work with Q in this representation.

LQ Factorization LQ factorization of an m -by- n matrix A is as follows. If $m \leq n$,

$$A = (L, 0) Q = (L, 0) \begin{pmatrix} Q_1 \\ Q_2 \end{pmatrix} = (LQ_1)$$

where L is an m -by- m lower triangular matrix with real diagonal elements, and Q is an n -by- n orthogonal (or unitary) matrix.

If $m > n$, the LQ factorization is

$$A = \begin{pmatrix} L_1 \\ L_2 \end{pmatrix} Q$$

where L_1 is an n -by- n lower triangular matrix, L_2 is rectangular, and Q is an n -by- n orthogonal (or unitary) matrix.

You can use the LQ factorization to find the minimum-norm solution of an underdetermined system of linear equations $Ax = b$ where A is an m -by- n matrix of rank m ($m < n$). After factoring the matrix, compute the solution vector x as follows: solve $L_1 y = b$ for y , and then compute $x = (Q_1)^H y$.

Table "Computational Routines for Orthogonal Factorization" lists LAPACK routines that perform orthogonal factorization of matrices.

Computational Routines for Orthogonal Factorization

?sgeqrf

Computes the QR factorization of a general m -by- n matrix.

Syntax

```
lapack_int LAPACKE_sgeqrf (int matrix_layout, lapack_int m, lapack_int n, float* a,
lapack_int lda, float* tau);
```

```
lapack_int LAPACKE_dgeqrf (int matrix_layout, lapack_int m, lapack_int n, double* a,
lapack_int lda, double* tau);
```

```
lapack_int LAPACKE_cgeqrf (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* tau);
```

```
lapack_int LAPACKE_zgeqrf (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_complex_double* tau);
```

Include Files

- mkl.h

Description

The routine forms the QR factorization of a general m -by- n matrix A (see [Orthogonal Factorizations](#)). No pivoting is performed.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors. Routines are provided to work with Q in this representation.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>m</i> | The number of rows in the matrix A ($m \geq 0$). |
| <i>n</i> | The number of columns in A ($n \geq 0$). |
| <i>a</i> | Array a of size $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout contains the matrix A . |
| <i>lda</i> | The leading dimension of a ; at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout. |

Output Parameters

| | |
|----------|---|
| <i>a</i> | Overwritten by the factorization data as follows: The elements on and above the diagonal of the array contain the $\min(m, n)$ -by- n upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array tau , present the orthogonal matrix Q as a product of $\min(m, n)$ elementary reflectors (see Orthogonal Factorizations). |
|----------|---|

tau Array, size at least $\max(1, \min(m, n))$. Contains scalars that define elementary reflectors for the matrix Q in its decomposition in a product of elementary reflectors (see [Orthogonal Factorizations](#)).

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The computed factorization is the exact factorization of a matrix $A + E$, where

$$\|E\|_2 = O(\epsilon) \|A\|_2.$$

The approximate number of floating-point operations for real flavors is

$$(4/3)n^3 \quad \text{if } m = n,$$

$$(2/3)n^2(3m-n) \quad \text{if } m > n,$$

$$(2/3)m^2(3n-m) \quad \text{if } m < n.$$

The number of operations for complex flavors is 4 times greater.

To solve a set of least squares problems minimizing $\|A^*x - b\|_2$ for all columns b of a given matrix B , you can call the following:

| | |
|------------------------------------|--|
| <code>?geqrf</code> (this routine) | to factorize $A = QR$; |
| <code>ormqr</code> | to compute $C = Q^T B$ (for real matrices); |
| <code>unmqr</code> | to compute $C = Q^H B$ (for complex matrices); |
| <code>trsm</code> (a BLAS routine) | to solve $R^*X = C$. |

(The columns of the computed X are the least squares solution vectors x .)

To compute the elements of Q explicitly, call

`orgqr` (for real matrices)

`ungqr` (for complex matrices).

Description

The strictly lower triangular matrix V contains the elementary reflectors $H(i)$ in the i th column below the diagonal. For example, if $m=5$ and $n=3$, the matrix V is

$$V = \begin{bmatrix} 1 & & & & \\ v_1 & 1 & & & \\ v_1 & v_2 & 1 & & \\ v_1 & v_2 & v_3 & & \\ v_1 & v_2 & v_3 & & \end{bmatrix}$$

where v_i represents one of the vectors that define $H(i)$. The vectors are returned in the lower triangular part of array a .

NOTE

The 1s along the diagonal of V are not stored in a .

Let $k = \min(m, n)$. The number of blocks is $b = \text{ceiling}(k/nb)$, where each block is of order nb except for the last block, which is of order $ib = k - (b-1)*nb$. For each of the b blocks, a upper triangular block reflector factor is computed: $t1, t2, \dots, tb$. The nb -by- nb (and ib -by- ib for the last block) ts are stored in the nb -by- n array t as

$$t = (t1t2 \dots tb).$$

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>m</code> | The number of rows in the matrix A ($m \geq 0$). |
| <code>n</code> | The number of columns in A ($n \geq 0$). |
| <code>nb</code> | The block size to be used in the blocked QR ($\min(m, n) \geq nb \geq 1$). |
| <code>a</code> | Array a of size $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout contains the m -by- n matrix A . |
| <code>lda</code> | The leading dimension of a ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |
| <code>ldt</code> | The leading dimension of t ; at least nb for column major layout and $\max(1, \min(m, n))$ for row major layout. |

Output Parameters

| | |
|----------|---|
| <i>a</i> | Overwritten by the factorization data as follows: The elements on and above the diagonal of the array contain the $\min(m,n)$ -by- n upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array t , present the orthogonal matrix Q as a product of $\min(m,n)$ elementary reflectors (see Orthogonal Factorizations). |
| <i>t</i> | Array, size $\max(1, ldt * \min(m, n))$ for column major layout and $\max(1, ldt * nb)$ for row major layout. The upper triangular block reflector's factors stored as a sequence of upper triangular blocks. |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* < 0 and *info* = -*i*, the *i*-th parameter had an illegal value.

?gemqrt

Multiplies a general matrix by the orthogonal/unitary matrix Q of the QR factorization formed by ?geqrt.

Syntax

```
lapack_int LAPACKE_sgemqrt (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, lapack_int nb, const float* v, lapack_int ldv, const
float* t, lapack_int ldt, float* c, lapack_int ldc);
```

```
lapack_int LAPACKE_dgemqrt (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, lapack_int nb, const double* v, lapack_int ldv, const
double* t, lapack_int ldt, double* c, lapack_int ldc);
```

```
lapack_int LAPACKE_cgemqrt (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, lapack_int nb, const lapack_complex_float* v, lapack_int
ldv, const lapack_complex_float* t, lapack_int ldt, lapack_complex_float* c, lapack_int
ldc);
```

```
lapack_int LAPACKE_zgemqrt (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, lapack_int nb, const lapack_complex_double* v, lapack_int
ldv, const lapack_complex_double* t, lapack_int ldt, lapack_complex_double* c,
lapack_int ldc);
```

Include Files

- mkl.h

Description

The ?gemqrt routine overwrites the general real or complex m -by- n matrix C with

| | | |
|---------------------|-------------------|-------------------|
| | <i>side</i> = 'L' | <i>side</i> = 'R' |
| <i>trans</i> = 'N': | $Q * C$ | $C * Q$ |
| <i>trans</i> = 'T': | $Q^T * C$ | $C * Q^T$ |
| <i>trans</i> = 'C': | $Q^H * C$ | $C * Q^H$ |

where Q is a real orthogonal (complex unitary) matrix defined as the product of k elementary reflectors

$Q = H(1) H(2) \dots H(k) = I - V^* T^* V^T$ for real flavors, and

$Q = H(1) H(2) \dots H(k) = I - V^* T^* V^H$ for complex flavors,

generated using the compact WY representation as returned by [geqrt](#). Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>side</i> | ='L': apply Q , Q^T , or Q^H from the left. ='R': apply Q , Q^T , or Q^H from the right. |
| <i>trans</i> | ='N', no transpose, apply Q . ='T', transpose, apply Q^T . ='C', transpose, apply Q^H . |
| <i>m</i> | The number of rows in the matrix C , ($m \geq 0$). |
| <i>n</i> | The number of columns in the matrix C , ($n \geq 0$). |
| <i>k</i> | The number of elementary reflectors whose product defines the matrix Q . Constraints: If $side = 'L'$, $m \geq k \geq 0$ If $side = 'R'$, $n \geq k \geq 0$. |
| <i>nb</i> | The block size used for the storage of t , $k \geq nb \geq 1$. This must be the same value of nb used to generate t in geqrt . |
| <i>v</i> | Array of size $\max(1, ldv * k)$ for column major layout, $\max(1, ldv * m)$ for row major layout and $side = 'L'$, and $\max(1, ldv * n)$ for row major layout and $side = 'R'$. The i th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by geqrt in the first k columns of its array argument a . |
| <i>ldv</i> | The leading dimension of the array v . if $side = 'L'$, ldv must be at least $\max(1, m)$ for column major layout and $\max(1, k)$ for row major layout; if $side = 'R'$, ldv must be at least $\max(1, n)$ for column major layout and $\max(1, k)$ for row major layout. |
| <i>t</i> | Array, size $\max(1, ldt * \min(m, n))$ for column major layout and $\max(1, ldt * nb)$ for row major layout. The upper triangular factors of the block reflectors as returned by geqrt . |
| <i>ldt</i> | The leading dimension of the array t . ldt must be at least nb for column major layout and $\max(1, k)$ for row major layout. |
| <i>c</i> | The m -by- n matrix C . |

ldc The leading dimension of the array *c*. *ldc* must be at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

Output Parameters

c Overwritten by the product Q^*C , C^*Q , Q^T*C , C^*Q^T , Q^H*C , or C^*Q^H as specified by *side* and *trans*.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = *-i*, the *i*-th parameter had an illegal value.

?geqpf

Computes the QR factorization of a general *m*-by-*n* matrix with pivoting.

Syntax

```
lapack_int LAPACKE_sgeqpf (int matrix_layout, lapack_int m, lapack_int n, float* a,
lapack_int lda, lapack_int* jpvt, float* tau);
```

```
lapack_int LAPACKE_dgeqpf (int matrix_layout, lapack_int m, lapack_int n, double* a,
lapack_int lda, lapack_int* jpvt, double* tau);
```

```
lapack_int LAPACKE_cgeqpf (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_int* jpvt, lapack_complex_float* tau);
```

```
lapack_int LAPACKE_zgeqpf (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_int* jpvt, lapack_complex_double*
tau);
```

Include Files

- mkl.h

Description

The routine is deprecated and has been replaced by routine [geqp3](#).

The routine `?geqpf` forms the QR factorization of a general *m*-by-*n* matrix *A* with column pivoting: $A^*P = Q^*R$ (see [Orthogonal Factorizations](#)). Here *P* denotes an *n*-by-*n* permutation matrix.

The routine does not form the matrix *Q* explicitly. Instead, *Q* is represented as a product of $\min(m, n)$ elementary reflectors. Routines are provided to work with *Q* in this representation.

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

m The number of rows in the matrix *A* ($m \geq 0$).

n The number of columns in *A* ($n \geq 0$).

| | |
|-------------|---|
| <i>a</i> | Array <i>a</i> of size $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout contains the matrix <i>A</i> . |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |
| <i>jpvt</i> | Array, size at least $\max(1, n)$. On entry, if $jpvt[i - 1] > 0$, the <i>i</i> -th column of <i>A</i> is moved to the beginning of <i>A*P</i> before the computation, and fixed in place during the computation. If $jpvt[i - 1] = 0$, the <i>i</i> th column of <i>A</i> is a free column (that is, it may be interchanged during the computation with any other free column). |

Output Parameters

| | |
|-------------|--|
| <i>a</i> | Overwritten by the factorization data as follows: The elements on and above the diagonal of the array contain the $\min(m,n)$ -by- <i>n</i> upper trapezoidal matrix <i>R</i> (<i>R</i> is upper triangular if $m \geq n$); the elements below the diagonal, with the array <i>tau</i> , present the orthogonal matrix <i>Q</i> as a product of $\min(m,n)$ elementary reflectors (see Orthogonal Factorizations). |
| <i>tau</i> | Array, size at least $\max(1, \min(m, n))$. Contains additional information on the matrix <i>Q</i> . |
| <i>jpvt</i> | Overwritten by details of the permutation matrix <i>P</i> in the factorization $A*P = Q*R$. More precisely, the columns of <i>A*P</i> are the columns of <i>A</i> in the following order: $jpvt[0], jpvt[1], \dots, jpvt[n - 1]$. |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The computed factorization is the exact factorization of a matrix $A + E$, where

$$\|E\|_2 = O(\epsilon) \|A\|_2.$$

The approximate number of floating-point operations for real flavors is

$$(4/3)n^3 \quad \text{if } m = n,$$

$$(2/3)n^2(3m-n) \quad \text{if } m > n,$$

$$(2/3)m^2(3n-m) \quad \text{if } m < n.$$

The number of operations for complex flavors is 4 times greater.

To solve a set of least squares problems minimizing $\|A*x - b\|_2$ for all columns *b* of a given matrix *B*, you can call the following:

`?geqpf` (this routine) to factorize $A*P = Q*R$;

| | |
|------------------------------------|--|
| <code>ormqr</code> | to compute $C = Q^T * B$ (for real matrices); |
| <code>unmqr</code> | to compute $C = Q^H * B$ (for complex matrices); |
| <code>trsm</code> (a BLAS routine) | to solve $R * X = C$. |

(The columns of the computed X are the permuted least squares solution vectors x ; the output array $jpvt$ specifies the permutation order.)

To compute the elements of Q explicitly, call

| | |
|--------------------|-------------------------|
| <code>orgqr</code> | (for real matrices) |
| <code>ungqr</code> | (for complex matrices). |

?geqp3

Computes the QR factorization of a general m -by- n matrix with column pivoting using level 3 BLAS.

Syntax

```
lapack_int LAPACKE_sgeqp3 (int matrix_layout, lapack_int m, lapack_int n, float* a,
lapack_int lda, lapack_int* jpvt, float* tau);

lapack_int LAPACKE_dgeqp3 (int matrix_layout, lapack_int m, lapack_int n, double* a,
lapack_int lda, lapack_int* jpvt, double* tau);

lapack_int LAPACKE_cgeqp3 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_int* jpvt, lapack_complex_float* tau);

lapack_int LAPACKE_zgeqp3 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_int* jpvt, lapack_complex_double*
tau);
```

Include Files

- `mk1.h`

Description

The routine forms the QR factorization of a general m -by- n matrix A with column pivoting: $A * P = Q * R$ (see [Orthogonal Factorizations](#)) using Level 3 BLAS. Here P denotes an n -by- n permutation matrix. Use this routine instead of `geqpf` for better performance.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors*. Routines are provided to work with Q in this representation.

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>m</code> | The number of rows in the matrix A ($m \geq 0$). |
| <code>n</code> | The number of columns in A ($n \geq 0$). |
| <code>a</code> | Array a of size $\max(1, lda * n)$ for column major layout and $\max(1, lda * m)$ for row major layout contains the matrix A . |

| | |
|-------------|---|
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |
| <i>jpvt</i> | <p>Array, size at least $\max(1, n)$.</p> <p>On entry, if $jpvt[i - 1] \neq 0$, the <i>i</i>-th column of <i>A</i> is moved to the beginning of <i>AP</i> before the computation, and fixed in place during the computation.</p> <p>If $jpvt[i - 1] = 0$, the <i>i</i>-th column of <i>A</i> is a free column (that is, it may be interchanged during the computation with any other free column).</p> |

Output Parameters

| | |
|-------------|--|
| <i>a</i> | <p>Overwritten by the factorization data as follows:</p> <p>The elements on and above the diagonal of the array contain the $\min(m, n)$-by-<i>n</i> upper trapezoidal matrix <i>R</i> (<i>R</i> is upper triangular if $m \geq n$); the elements below the diagonal, with the array <i>tau</i>, present the orthogonal matrix <i>Q</i> as a product of $\min(m, n)$ elementary reflectors (see Orthogonal Factorizations).</p> |
| <i>tau</i> | Array, size at least $\max(1, \min(m, n))$. Contains scalar factors of the elementary reflectors for the matrix <i>Q</i> . |
| <i>jpvt</i> | <p>Overwritten by details of the permutation matrix <i>P</i> in the factorization $A^*P = Q^*R$. More precisely, the columns of <i>AP</i> are the columns of <i>A</i> in the following order:</p> <p>$jpvt[0], jpvt[1], \dots, jpvt[n - 1]$.</p> |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

To solve a set of least squares problems minimizing $\|A^*x - b\|_2$ for all columns *b* of a given matrix *B*, you can call the following:

| | |
|------------------------------------|--|
| <code>?geqp3</code> (this routine) | to factorize $A^*P = Q^*R$; |
| <code>ormqr</code> | to compute $C = Q^T * B$ (for real matrices); |
| <code>unmqr</code> | to compute $C = Q^H * B$ (for complex matrices); |
| <code>trsm</code> (a BLAS routine) | to solve $R^*X = C$. |

(The columns of the computed *X* are the permuted least squares solution vectors *x*; the output array *jpvt* specifies the permutation order.)

To compute the elements of *Q* explicitly, call

| | |
|--------------------|-------------------------|
| <code>orgqr</code> | (for real matrices) |
| <code>ungqr</code> | (for complex matrices). |

?orgqr

Generates the real orthogonal matrix Q of the QR factorization formed by ?geqrf.

Syntax

```
lapack_int LAPACKE_sorgqr (int matrix_layout, lapack_int m, lapack_int n, lapack_int k,
float* a, lapack_int lda, const float* tau);
```

```
lapack_int LAPACKE_dorgqr (int matrix_layout, lapack_int m, lapack_int n, lapack_int k,
double* a, lapack_int lda, const double* tau);
```

Include Files

- mkl.h

Description

The routine generates the whole or part of m -by- m orthogonal matrix Q of the QR factorization formed by the routines [geqrf](#) or [geqpf](#). Use this routine after a call to [sgeqrf/dgeqrf](#) or [sgeqpf/dgeqpf](#).

Usually Q is determined from the QR factorization of an m by p matrix A with $m \geq p$. To compute the whole matrix Q , use:

```
LAPACKE_?orgqr(matrix_layout, m, m, p, a, lda, tau)
```

To compute the leading p columns of Q (which form an orthonormal basis in the space spanned by the columns of A):

```
LAPACKE_?orgqr(matrix_layout, m, p, p, a, lda)
```

To compute the matrix Q^k of the QR factorization of leading k columns of the matrix A :

```
LAPACKE_?orgqr(matrix_layout, m, m, k, a, lda, tau)
```

To compute the leading k columns of Q^k (which form an orthonormal basis in the space spanned by leading k columns of the matrix A):

```
LAPACKE_?orgqr(matrix_layout, m, k, k, a, lda, tau)
```

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>m</i> | The order of the orthogonal matrix Q ($m \geq 0$). |
| <i>n</i> | The number of columns of Q to be computed ($0 \leq n \leq m$). |
| <i>k</i> | The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$). |
| <i>a, tau</i> | Arrays: <i>a</i> and <i>tau</i> are the arrays returned by sgeqrf / dgeqrf or sgeqpf / dgeqpf . The size of <i>a</i> is $\max(1, lda * n)$ for column major layout and $\max(1, lda * m)$ for row major layout . The size of <i>tau</i> must be at least $\max(1, k)$. |

lda The leading dimension of *a*; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

Output Parameters

a Overwritten by *n* leading columns of the *m*-by-*m* orthogonal matrix *Q*.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = *-i*, the *i*-th parameter had an illegal value.

Application Notes

The computed *Q* differs from an exactly orthogonal matrix by a matrix *E* such that

$\|E\|_2 = O(\varepsilon) \|A\|_2$ where ε is the machine precision.

The total number of floating-point operations is approximately $4*m*n*k - 2*(m + n)*k^2 + (4/3)*k^3$.

If $n = k$, the number is approximately $(2/3)*n^2*(3m - n)$.

The complex counterpart of this routine is [ungqr](#).

?ormqr

Multiplies a real matrix by the orthogonal matrix Q of the QR factorization formed by ?geqrf or ?geqpf.

Syntax

```
lapack_int LAPACKE_sormqr (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const float* a, lapack_int lda, const float* tau, float*
c, lapack_int ldc);
```

```
lapack_int LAPACKE_dormqr (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const double* a, lapack_int lda, const double* tau,
double* c, lapack_int ldc);
```

Include Files

- mkl.h

Description

The routine multiplies a real matrix *C* by *Q* or Q^T , where *Q* is the orthogonal matrix *Q* of the *QR* factorization formed by the routines [geqrf](#) or [geqpf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products $Q*C$, Q^T*C , $C*Q$, or $C*Q^T$ (overwriting the result on *C*).

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

side Must be either 'L' or 'R'.

If *side*='L', *Q* or Q^T is applied to *C* from the left.

| | |
|------------------|---|
| | If $side='R'$, Q or Q^T is applied to C from the right. |
| <i>trans</i> | Must be either 'N' or 'T'. If $trans='N'$, the routine multiplies C by Q . If $trans='T'$, the routine multiplies C by Q^T . |
| <i>m</i> | The number of rows in the matrix C ($m \geq 0$). |
| <i>n</i> | The number of columns in C ($n \geq 0$). |
| <i>k</i> | The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$ if $side='L'$; $0 \leq k \leq n$ if $side='R'$. |
| <i>a, tau, c</i> | Arrays: <i>a</i> and <i>tau</i> are the arrays returned by <i>sgeqrf</i> / <i>dgeqrf</i> or <i>sgeqpf</i> / <i>dgeqpf</i> . The size of <i>a</i> is $\max(1, lda*k)$ for column major layout, $\max(1, lda*m)$ for row major layout and $side = 'L'$, and $\max(1, lda*n)$ for row major layout and $side = 'R'$. The size of <i>tau</i> must be at least $\max(1, k)$. Array <i>c</i> of size $\max(1, ldc*n)$ for column major layout and $\max(1, ldc*m)$ for row major layout contains the m -by- n matrix C . |
| <i>lda</i> | The leading dimension of <i>a</i> . Constraints: if $side = 'L'$, $lda \geq \max(1, m)$ for column major layout and $\max(1, k)$ for row major layout ; if $side = 'R'$, $lda \geq \max(1, n)$ for column major layout and $\max(1, k)$ for row major layout. |
| <i>ldc</i> | The leading dimension of <i>c</i> . Constraint: $ldc \geq \max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |

Output Parameters

| | |
|----------|---|
| <i>c</i> | Overwritten by the product Q^*C , Q^T*C , $C*Q$, or $C*Q^T$ (as specified by <i>side</i> and <i>trans</i>). |
|----------|---|

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The complex counterpart of this routine is *unmqr*.

?ungqr

Generates the complex unitary matrix Q of the QR factorization formed by ?geqrf.

Syntax

```
lapack_int LAPACKE_cungqr (int matrix_layout, lapack_int m, lapack_int n, lapack_int k,
lapack_complex_float* a, lapack_int lda, const lapack_complex_float* tau);
```

```
lapack_int LAPACKE_zungqr (int matrix_layout, lapack_int m, lapack_int n, lapack_int k,
lapack_complex_double* a, lapack_int lda, const lapack_complex_double* tau);
```

Include Files

- mkl.h

Description

The routine generates the whole or part of m -by- m unitary matrix Q of the QR factorization formed by the routines `geqrf` or `geqpf`. Use this routine after a call to `cgeqrf/zgeqrf` or `cgeqpf/zgeqpf`.

Usually Q is determined from the QR factorization of an m by p matrix A with $m \geq p$. To compute the whole matrix Q , use:

```
LAPACKE_?ungqr(matrix_layout, m, m, p, a, lda, tau)
```

To compute the leading p columns of Q (which form an orthonormal basis in the space spanned by the columns of A):

```
LAPACKE_?ungqr(matrix_layout, m, p, p, a, lda, tau)
```

To compute the matrix Q^k of the QR factorization of the leading k columns of the matrix A :

```
LAPACKE_?ungqr(matrix_layout, m, m, k, a, lda, tau)
```

To compute the leading k columns of Q^k (which form an orthonormal basis in the space spanned by the leading k columns of the matrix A):

```
LAPACKE_?ungqr(matrix_layout, m, k, k, a, lda, tau)
```

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>m</i> | The order of the unitary matrix Q ($m \geq 0$). |
| <i>n</i> | The number of columns of Q to be computed ($0 \leq n \leq m$). |
| <i>k</i> | The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$). |
| <i>a, tau</i> | Arrays: <i>a</i> and <i>tau</i> are the arrays returned by <code>cgeqrf/zgeqrf</code> or <code>cgeqpf/zgeqpf</code> . The size of <i>a</i> is $\max(1, lda * n)$ for column major layout and $\max(1, lda * m)$ for row major layout . The size of <i>tau</i> must be at least $\max(1, k)$. |

lda The leading dimension of *a*; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

Output Parameters

a Overwritten by *n* leading columns of the *m*-by-*m* unitary matrix *Q*.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = *-i*, the *i*-th parameter had an illegal value.

Application Notes

The computed *Q* differs from an exactly unitary matrix by a matrix *E* such that $\|E\|_2 = O(\varepsilon) * \|A\|_2$, where ε is the machine precision.

The total number of floating-point operations is approximately $16*m*n*k - 8*(m+n)*k^2 + (16/3)*k^3$.

If *n* = *k*, the number is approximately $(8/3)*n^2*(3m - n)$.

The real counterpart of this routine is [orgqr](#).

?unmqr

Multiplies a complex matrix by the unitary matrix Q of the QR factorization formed by ?geqrf.

Syntax

```
lapack_int LAPACKE_cunmqr (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const lapack_complex_float* a, lapack_int lda, const
lapack_complex_float* tau, lapack_complex_float* c, lapack_int ldc);
```

```
lapack_int LAPACKE_zunmqr (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const lapack_complex_double* a, lapack_int lda, const
lapack_complex_double* tau, lapack_complex_double* c, lapack_int ldc);
```

Include Files

- mkl.h

Description

The routine multiplies a rectangular complex matrix *C* by *Q* or *Q*^H, where *Q* is the unitary matrix *Q* of the *QR* factorization formed by the routines [geqrf](#) or [geqpf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products *Q***C*, *Q*^H**C*, *C***Q*, or *C***Q*^H (overwriting the result on *C*).

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

side Must be either 'L' or 'R'.

If *side* = 'L', *Q* or *Q*^H is applied to *C* from the left.

| | |
|------------------|---|
| | If <i>side</i> = 'R', Q or Q^H is applied to C from the right. |
| <i>trans</i> | Must be either 'N' or 'C'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'C', the routine multiplies C by Q^H . |
| <i>m</i> | The number of rows in the matrix C ($m \geq 0$). |
| <i>n</i> | The number of columns in C ($n \geq 0$). |
| <i>k</i> | The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$ if <i>side</i> = 'L'; $0 \leq k \leq n$ if <i>side</i> = 'R'. |
| <i>a, c, tau</i> | Arrays: <i>a</i> size $\max(1, lda * k)$ for column major layout, $\max(1, lda * m)$ for row major layout when <i>side</i> = 'L', and $\max(1, lda * n)$ for row major layout when <i>side</i> = 'R' and <i>tau</i> are the arrays returned by <i>cgeqrf</i> / <i>zgeqrf</i> or <i>cgeqpf</i> / <i>zgeqpf</i> . The size of <i>tau</i> must be at least $\max(1, k)$. <i>c</i> (size $\max(1, ldc * n)$ for column major layout and $\max(1, ldc * m)$ for row major layout) contains the m -by- n matrix C . |
| <i>lda</i> | The leading dimension of <i>a</i> . Constraints: $lda \geq \max(1, m)$ for column major layout and $lda \geq \max(1, k)$ for row major layout if <i>side</i> = 'L'; $lda \geq \max(1, n)$ for column major layout and $lda \geq \max(1, k)$ for row major layout if <i>side</i> = 'R'. |
| <i>ldc</i> | The leading dimension of <i>c</i> . Constraint: $ldc \geq \max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |

Output Parameters

| | |
|----------|--|
| <i>c</i> | Overwritten by the product $Q * C$, $Q^H * C$, $C * Q$, or $C * Q^H$ (as specified by <i>side</i> and <i>trans</i>). |
|----------|--|

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = $-i$, the i -th parameter had an illegal value.

Application Notes

The real counterpart of this routine is [ormqr](#).

?gelqf

Computes the LQ factorization of a general m -by- n matrix.

Syntax

```
lapack_int LAPACKE_sgelqf (int matrix_layout, lapack_int m, lapack_int n, float* a,
lapack_int lda, float* tau);

lapack_int LAPACKE_dgelqf (int matrix_layout, lapack_int m, lapack_int n, double* a,
lapack_int lda, double* tau);

lapack_int LAPACKE_cgelqf (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* tau);

lapack_int LAPACKE_zgelqf (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_complex_double* tau);
```

Include Files

- mkl.h

Description

The routine forms the LQ factorization of a general m -by- n matrix A (see [Orthogonal Factorizations](#)). No pivoting is performed.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors. Routines are provided to work with Q in this representation.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>m</i> | The number of rows in the matrix A ($m \geq 0$). |
| <i>n</i> | The number of columns in A ($n \geq 0$). |
| <i>a</i> | Array a of size $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout contains the matrix A . |
| <i>lda</i> | The leading dimension of a ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |

Output Parameters

| | |
|------------|--|
| <i>a</i> | Overwritten by the factorization data as follows: The elements on and below the diagonal of the array contain the m -by- $\min(m, n)$ lower trapezoidal matrix R (R is lower triangular if $m \leq n$); the elements above the diagonal, with the array τ , represent the orthogonal matrix Q as a product of elementary reflectors. |
| <i>tau</i> | Array, size at least $\max(1, \min(m, n))$. |

Contains scalars that define elementary reflectors for the matrix Q (see [Orthogonal Factorizations](#)).

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The computed factorization is the exact factorization of a matrix $A + E$, where

$$\|E\|_2 = O(\epsilon) \|A\|_2.$$

The approximate number of floating-point operations for real flavors is

$$(4/3)n^3 \quad \text{if } m = n,$$

$$(2/3)n^2(3m-n) \quad \text{if } m > n,$$

$$(2/3)m^2(3n-m) \quad \text{if } m < n.$$

The number of operations for complex flavors is 4 times greater.

To find the minimum-norm solution of an underdetermined least squares problem minimizing $\|A^*x - b\|_2$ for all columns b of a given matrix B , you can call the following:

| | |
|------------------------------------|--|
| <code>?gelqf</code> (this routine) | to factorize $A = L^*Q$; |
| <code>trsm</code> (a BLAS routine) | to solve $L^*Y = B$ for Y ; |
| <code>ormlq</code> | to compute $X = (Q_1)^T * Y$ (for real matrices); |
| <code>unmlq</code> | to compute $X = (Q_1)^H * Y$ (for complex matrices). |

(The columns of the computed X are the minimum-norm solution vectors x . Here A is an m -by- n matrix with $m < n$; Q_1 denotes the first m columns of Q).

To compute the elements of Q explicitly, call

| | |
|--------------------|-------------------------|
| <code>orglq</code> | (for real matrices) |
| <code>unglq</code> | (for complex matrices). |

See Also

[mkl_progress](#)

[Matrix Storage Schemes for LAPACK Routines](#)

?orglq

Generates the real orthogonal matrix Q of the LQ factorization formed by `?gelqf`.

Syntax

```
lapack_int LAPACKE_sorglq (int matrix_layout, lapack_int m, lapack_int n, lapack_int k,
float* a, lapack_int lda, const float* tau);
```

```
lapack_int LAPACKE_dorglq (int matrix_layout, lapack_int m, lapack_int n, lapack_int k,
double* a, lapack_int lda, const double* tau);
```

Include Files

- `mkl.h`

Description

The routine generates the whole or part of n -by- n orthogonal matrix Q of the LQ factorization formed by the routines `gelqf`. Use this routine after a call to `sgelqf/dgelqf`.

Usually Q is determined from the LQ factorization of an p -by- n matrix A with $n \geq p$. To compute the whole matrix Q , use:

```
info = LAPACKE_?orglq(matrix_layout, n, n, p, a, lda, tau)
```

To compute the leading p rows of Q , which form an orthonormal basis in the space spanned by the rows of A , use:

```
info = LAPACKE_?orglq(matrix_layout, p, n, p, a, lda, tau)
```

To compute the matrix Q^k of the LQ factorization of the leading k rows of A , use:

```
info = LAPACKE_?orglq(matrix_layout, n, n, k, a, lda, tau)
```

To compute the leading k rows of Q^k , which form an orthonormal basis in the space spanned by the leading k rows of A , use:

```
info = LAPACKE_?orgqr(matrix_layout, k, n, k, a, lda, tau)
```

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>m</code> | The number of rows of Q to be computed ($0 \leq m \leq n$). |
| <code>n</code> | The order of the orthogonal matrix Q ($n \geq m$). |
| <code>k</code> | The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq m$). |
| <code>a, tau</code> | Arrays: a (size $\max(1, lda * n)$ for column major layout and $\max(1, lda * m)$ for row major layout) and tau are the arrays returned by <code>sgelqf/dgelqf</code> . The size of tau must be at least $\max(1, k)$. |
| <code>lda</code> | The leading dimension of a ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |

Output Parameters

`a` Overwritten by m leading rows of the n -by- n orthogonal matrix Q .

Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

Application Notes

The computed Q differs from an exactly orthogonal matrix by a matrix E such that $\|E\|_2 = O(\epsilon) \|A\|_2$, where ϵ is the machine precision.

The total number of floating-point operations is approximately $4*m*n*k - 2*(m+n)*k^2 + (4/3)*k^3$.

If $m = k$, the number is approximately $(2/3)*m^2*(3n - m)$.

The complex counterpart of this routine is [unglq](#).

?ormlq

Multiplies a real matrix by the orthogonal matrix Q of the LQ factorization formed by [?gelqf](#).

Syntax

```
lapack_int LAPACKE_sormlq (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const float* a, lapack_int lda, const float* tau, float*
c, lapack_int ldc);
```

```
lapack_int LAPACKE_dormlq (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const double* a, lapack_int lda, const double* tau,
double* c, lapack_int ldc);
```

Include Files

- mkl.h

Description

The routine multiplies a real m -by- n matrix C by Q or Q^T , where Q is the orthogonal matrix Q of the LQ factorization formed by the routine [gelqf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products $Q*C$, Q^T*C , $C*Q$, or $C*Q^T$ (overwriting the result on C).

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>side</i> | Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^T is applied to C from the left. If <i>side</i> = 'R', Q or Q^T is applied to C from the right. |
| <i>trans</i> | Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'T', the routine multiplies C by Q^T . |
| <i>m</i> | The number of rows in the matrix C ($m \geq 0$). |
| <i>n</i> | The number of columns in C ($n \geq 0$). |
| <i>k</i> | The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$ if <i>side</i> = 'L'; |

$0 \leq k \leq n$ if *side* = 'R'.

a, *c*, *tau*

Arrays:

a and *tau* are arrays returned by `?gelqf`.

The size of *a* must be:

For *side* = 'L' and column major layout, $\max(1, lda * m)$.

For *side* = 'R' and column major layout, $\max(1, lda * n)$.

For row major layout regardless of *side*, $\max(1, lda * k)$.

The dimension of *tau* must be at least $\max(1, k)$.

c (size $\max(1, ldc * n)$ for column major layout and $\max(1, ldc * m)$ for row major layout) contains the *m*-by-*n* matrix *C*.

lda

The leading dimension of *a*. For column major layout, $lda \geq \max(1, k)$. For row major layout, if *side* = 'L', $lda \geq \max(1, m)$, or, if *side* = 'R', $lda \geq \max(1, n)$.

ldc

The leading dimension of *c*; $ldc \geq \max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

Output Parameters

c

Overwritten by the product $Q * C$, $Q^T * C$, $C * Q$, or $C * Q^T$ (as specified by *side* and *trans*).

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = *-i*, the *i*-th parameter had an illegal value.

Application Notes

The complex counterpart of this routine is `unmlq`.

?unglq

Generates the complex unitary matrix *Q* of the LQ factorization formed by `?gelqf`.

Syntax

```
lapack_int LAPACKE_cunglq (int matrix_layout, lapack_int m, lapack_int n, lapack_int k,
lapack_complex_float* a, lapack_int lda, const lapack_complex_float* tau);
```

```
lapack_int LAPACKE_zunglq (int matrix_layout, lapack_int m, lapack_int n, lapack_int k,
lapack_complex_double* a, lapack_int lda, const lapack_complex_double* tau);
```

Include Files

- `mk1.h`

Description

The routine generates the whole or part of *n*-by-*n* unitary matrix *Q* of the LQ factorization formed by the routines `gelqf`. Use this routine after a call to `cgelqf/zgelqf`.

Usually Q is determined from the LQ factorization of an p -by- n matrix A with $n < p$. To compute the whole matrix Q , use:

```
info = LAPACKE_?unglq(matrix_layout, n, n, p, a, lda, tau)
```

To compute the leading p rows of Q , which form an orthonormal basis in the space spanned by the rows of A , use:

```
info = LAPACKE_?unglq(matrix_layout, p, n, p, a, lda, tau)
```

To compute the matrix Q^k of the LQ factorization of the leading k rows of A , use:

```
info = LAPACKE_?unglq(matrix_layout, n, n, k, a, lda, tau)
```

To compute the leading k rows of Q^k , which form an orthonormal basis in the space spanned by the leading k rows of A , use:

```
info = LAPACKE_?ungqr(matrix_layout, k, n, k, a, lda, tau)
```

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>m</i> | The number of rows of Q to be computed ($0 \leq m \leq n$). |
| <i>n</i> | The order of the unitary matrix Q ($n \geq m$). |
| <i>k</i> | The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq m$). |
| <i>a, tau</i> | Arrays: <i>a</i> (size $\max(1, lda * n)$ for column major layout and $\max(1, lda * m)$ for row major layout) and <i>tau</i> are the arrays returned by <i>cgelqf/zgelqf</i> . The dimension of <i>tau</i> must be at least $\max(1, k)$. |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |

Output Parameters

| | |
|----------|--|
| <i>a</i> | Overwritten by m leading rows of the n -by- n unitary matrix Q . |
|----------|--|

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = $-i$, the i -th parameter had an illegal value.

Application Notes

The computed Q differs from an exactly unitary matrix by a matrix E such that $\|E\|_2 = O(\varepsilon) * \|A\|_2$, where ε is the machine precision.

The total number of floating-point operations is approximately $16 * m * n * k - 8 * (m + n) * k^2 + (16/3) * k^3$.

If $m = k$, the number is approximately $(8/3) * m^2 * (3n - m)$.

The real counterpart of this routine is [orglq](#).

?unmlq

Multiplies a complex matrix by the unitary matrix Q of the LQ factorization formed by ?gelqf.

Syntax

```
lapack_int LAPACKE_cunmlq (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const lapack_complex_float* a, lapack_int lda, const
lapack_complex_float* tau, lapack_complex_float* c, lapack_int ldc);
```

```
lapack_int LAPACKE_zunmlq (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const lapack_complex_double* a, lapack_int lda, const
lapack_complex_double* tau, lapack_complex_double* c, lapack_int ldc);
```

Include Files

| <i>m</i> | The number of rows in the matrix C ($m \geq 0$). |
| <i>n</i> | The number of columns in C ($n \geq 0$). |
| <i>k</i> | The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$ if <i>side</i> = 'L'; $0 \leq k \leq n$ if <i>side</i> = 'R'. |
| <i>a, c, tau</i> | Arrays: <i>a</i> and <i>tau</i> are arrays returned by ?gelqf. The size of <i>a</i> must be: For <i>side</i> = 'L' and column major layout, $\max(1, lda*m)$. For <i>side</i> = 'R' and column major layout, $\max(1, lda*n)$. |

For row major layout regardless of *side*, $\max(1, lda*k)$.

The size of *tau* must be at least $\max(1, k)$.

c(size $\max(1, ldc*n)$ for column major layout and $\max(1, ldc*m$ for row major layout) contains the *m*-by-*n* matrix *C*.

lda The leading dimension of *a*. For column major layout, $lda \geq \max(1, k)$. For row major layout, if *side* = 'L', $lda \geq \max(1, m)$, or, if *side* = 'R', $lda \geq \max(1, n)$.

ldc The leading dimension of *c*; $ldc \geq \max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

Output Parameters

c Overwritten by the product $Q*C$, Q^H*C , $C*Q$, or $C*Q^H$ (as specified by *side* and *trans*).

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The real counterpart of this routine is [ormlq](#).

?geqlf

Computes the QL factorization of a general *m*-by-*n* matrix.

Syntax

```
lapack_int LAPACKE_sgeqlf (int matrix_layout, lapack_int m, lapack_int n, float* a,
lapack_int lda, float* tau);
```

```
lapack_int LAPACKE_dgeqlf (int matrix_layout, lapack_int m, lapack_int n, double* a,
lapack_int lda, double* tau);
```

```
lapack_int LAPACKE_cgeqlf (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* tau);
```

```
lapack_int LAPACKE_zgeqlf (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_complex_double* tau);
```

Include Files

Description

The routine forms the QL factorization of a general *m*-by-*n* matrix *A* (see [Orthogonal Factorizations](#)). No pivoting is performed.

The routine does not form the matrix *Q* explicitly. Instead, *Q* is represented as a product of $\min(m, n)$ elementary reflectors. Routines are provided to work with *Q* in this representation.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <i>m</i> | The number of rows in the matrix A ($m \geq 0$). |
| <i>n</i> | The number of columns in A ($n \geq 0$). |
| <i>a</i> | Array a of size $\max(1, lda * n)$ for column major layout and $\max(1, lda * m)$ for row major layout contains the matrix A . |
| <i>lda</i> | The leading dimension of a ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |

Output Parameters

| | |
|------------|---|
| <i>a</i> | Overwritten on exit by the factorization data as follows: if $m \geq n$, the lower triangle of the subarray $a(m-n+1:m, 1:n)$ contains the n -by- n lower triangular matrix L ; if $m \leq n$, the elements on and below the $(n-m)$ -th superdiagonal contain the m -by- n lower trapezoidal matrix L ; in both cases, the remaining elements, with the array τ , represent the orthogonal/unitary matrix Q as a product of elementary reflectors. |
| <i>tau</i> | Array, size at least $\max(1, \min(m, n))$. Contains scalar factors of the elementary reflectors for the matrix Q (see Orthogonal Factorizations). |

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |

Output Parameters

a Overwritten by the last n columns of the m -by- m unitary matrix Q .

Return Values

This function returns a value *info*.

If `info=0`, the execution is successful.

If `info = -i`, the *i*-th parameter had an illegal value.

Application Notes

The real counterpart of this routine is [orgql](#).

?ormql

Multiplies a real matrix by the orthogonal matrix Q of the QL factorization formed by ?geqlf.

Syntax

```
lapack_int LAPACKE_sormql (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const float* a, lapack_int lda, const float* tau, float*
c, lapack_int ldc);
```

```
lapack_int LAPACKE_dormql (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const double* a, lapack_int lda, const double* tau,
double* c, lapack_int ldc);
```

Include Files

- `mkl.h`

Description

The routine multiplies a real *m*-by-*n* matrix *C* by *Q* or Q^T , where *Q* is the orthogonal matrix *Q* of the *QL* factorization formed by the routine [geqlf](#).

Depending on the parameters *side* and *trans*, the routine [ormql](#) can form one of the matrix products $Q^T C$, $C^T Q$, or $C^* Q^T$ (overwriting the result over *C*).

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <i>side</i> | Must be either 'L' or 'R'. If <i>side</i> = 'L', <i>Q</i> or Q^T is applied to <i>C</i> from the left. If <i>side</i> = 'R', <i>Q</i> or Q^T is applied to <i>C</i> from the right. |
| <i>trans</i> | Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies <i>C</i> by <i>Q</i> . If <i>trans</i> = 'T', the routine multiplies <i>C</i> by Q^T . |
| <i>m</i> | The number of rows in the matrix <i>C</i> ($m \geq 0$). |
| <i>n</i> | The number of columns in <i>C</i> ($n \geq 0$). |
| <i>k</i> | The number of elementary reflectors whose product defines the matrix <i>Q</i> . Constraints: $0 \leq k \leq m$ if <i>side</i> = 'L'; $0 \leq k \leq n$ if <i>side</i> = 'R'. |

| | |
|----------------------------------|--|
| <i>a</i> , <i>tau</i> , <i>c</i> | <p>Arrays: <i>a</i>, <i>tau</i>, <i>c</i>.</p> <p>The size of <i>a</i> must be:</p> <p>For column major layout regardless of <i>side</i>, $\max(1, lda*k)$.</p> <p>For <i>side</i> = 'L' and row major layout, $\max(1, lda*m)$.</p> <p>For <i>side</i> = 'R' and row major layout, $\max(1, lda*n)$.</p> <p>On entry, the <i>i</i>th column of <i>a</i> must contain the vector which defines the elementary reflector H_i, for $i = 1, 2, \dots, k$, as returned by <i>sgeqlf/dgeqlf</i> in the last <i>k</i> columns of its array argument <i>a</i>.</p> <p><i>tau</i>[<i>i</i> - 1] must contain the scalar factor of the elementary reflector H_i, as returned by <i>sgeqlf/dgeqlf</i>.</p> <p>The size of <i>tau</i> must be at least $\max(1, k)$.</p> <p><i>c</i>(size $\max(1, ldc*n)$ for column major layout and $\max(1, ldc*m)$ for row major layout) contains the <i>m</i>-by-<i>n</i> matrix <i>C</i>.</p> |
| <i>lda</i> | <p>The leading dimension of <i>a</i>;</p> <p>if <i>side</i> = 'L', $lda \geq \max(1, m)$ for column major layout and $\max(1, k)$ for row major layout ;</p> <p>if <i>side</i> = 'R', $lda \geq \max(1, n)$ for column major layout and $\max(1, k)$ for row major layout.</p> |
| <i>ldc</i> | <p>The leading dimension of <i>c</i>; $ldc \geq \max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.</p> |

Output Parameters

| | |
|----------|--|
| <i>c</i> | Overwritten by the product $Q^T C$, $Q^T * C$, $C * Q$, or $C * Q^T$ (as specified by <i>side</i> and <i>trans</i>). |
|----------|--|

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The complex counterpart of this routine is [unmql](#).

?unmql

Multiplies a complex matrix by the unitary matrix Q of the QL factorization formed by ?geqlf.

Syntax

```
lapack_int LAPACKE_cunmql (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const lapack_complex_float* a, lapack_int lda, const
lapack_complex_float* tau, lapack_complex_float* c, lapack_int ldc);
```

```
lapack_int LAPACKE_zunmql (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const lapack_complex_double* a, lapack_int lda, const
lapack_complex_double* tau, lapack_complex_double* c, lapack_int ldc);
```

Include Files

- `mkl.h`

Description

The routine multiplies a complex m -by- n matrix C by Q or Q^H , where Q is the unitary matrix Q of the QL factorization formed by the routine `geqlf`.

Depending on the parameters *side* and *trans*, the routine `unmql` can form one of the matrix products Q^*C , Q^H*C , $C*Q$, or $C*Q^H$ (overwriting the result over C).

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <i>side</i> | Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^H is applied to C from the left. If <i>side</i> = 'R', Q or Q^H is applied to C from the right. |
| <i>trans</i> | Must be either 'N' or 'C'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'C', the routine multiplies C by Q^H . |
| <i>m</i> | The number of rows in the matrix C ($m \geq 0$). |
| <i>n</i> | The number of columns in C ($n \geq 0$). |
| <i>k</i> | The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$ if <i>side</i> = 'L'; $0 \leq k \leq n$ if <i>side</i> = 'R'. |
| <i>a, tau, c</i> | Arrays: <i>a</i> , <i>tau</i> , <i>c</i> . The size of <i>a</i> must be: For column major layout regardless of <i>side</i> , $\max(1, lda*k)$. For <i>side</i> = 'L' and row major layout, $\max(1, lda*m)$. For <i>side</i> = 'R' and row major layout, $\max(1, lda*n)$. On entry, the i -th column of <i>a</i> must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by <code>cgeqlf/zgeqlf</code> in the last k columns of its array argument <i>a</i> . <i>tau</i> [$i - 1$] must contain the scalar factor of the elementary reflector $H(i)$, as returned by <code>cgeqlf/zgeqlf</code> . The size of <i>tau</i> must be at least $\max(1, k)$. <i>c</i> (size $\max(1, ldc*n)$ for column major layout and $\max(1, ldc*m)$ for row major layout) contains the m -by- n matrix C . |
| <i>lda</i> | The leading dimension of <i>a</i> . |

If $side = 'L'$, $lda \geq \max(1, m)$ for column major layout and $\max(1, k)$ for row major layout.

If $side = 'R'$, $lda \geq \max(1, n)$ for column major layout and $\max(1, k)$ for row major layout.

ldc The leading dimension of c ; $ldc \geq \max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

Output Parameters

c Overwritten by the product Q^*C , Q^H*C , $C*Q$, or $C*Q^H$ (as specified by $side$ and $trans$).

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

The real counterpart of this routine is [ormql](#).

?gerqf

Computes the RQ factorization of a general m -by- n matrix.

Syntax

```
lapack_int LAPACKE_sgerqf (int matrix_layout, lapack_int m, lapack_int n, float* a,
lapack_int lda, float* tau);
```

```
lapack_int LAPACKE_dgerqf (int matrix_layout, lapack_int m, lapack_int n, double* a,
lapack_int lda, double* tau);
```

```
lapack_int LAPACKE_cgerqf (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* tau);
```

```
lapack_int LAPACKE_zgerqf (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_complex_double* tau);
```

Include Files

- `mkl.h`

Description

The routine forms the RQ factorization of a general m -by- n matrix A (see [Orthogonal Factorizations](#)). No pivoting is performed.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors. Routines are provided to work with Q in this representation.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <i>m</i> | The number of rows in the matrix <i>A</i> ($m \geq 0$). |
| <i>n</i> | The number of columns in <i>A</i> ($n \geq 0$). |
| <i>a</i> | Array <i>a</i> of size $\max(1, lda * n)$ for column major layout and $\max(1, lda * m)$ for row major layout contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> . |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |

Output Parameters

| | |
|------------|--|
| <i>a</i> | Overwritten on exit by the factorization data as follows: if $m \leq n$, the upper triangle of the subarray $a(1:m, n-m+1:n)$ contains the <i>m</i> -by- <i>m</i> upper triangular matrix <i>R</i> ; if $m \geq n$, the elements on and above the (<i>m</i> - <i>n</i>)th subdiagonal contain the <i>m</i> -by- <i>n</i> upper trapezoidal matrix <i>R</i> ; in both cases, the remaining elements, with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of $\min(m, n)$ elementary reflectors. |
| <i>tau</i> | Array, size at least $\max(1, \min(m, n))$. (See Orthogonal Factorizations .) Contains scalar factors of the elementary reflectors for the matrix <i>Q</i> . |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

Related routines include:

double* c, lapack_int ldc);
```

Include Files

- mkl.h

Description

The routine multiplies a real m -by- n matrix C by Q or Q^T , where Q is the real orthogonal matrix defined as a product of k elementary reflectors H_i : $Q = H_1 H_2 \dots H_k$ as returned by the RQ factorization routine [gerqf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products Q^*C , $Q^{T*}C$, C^*Q , or C^*Q^T (overwriting the result over C).

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>side</i> | Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^T is applied to C from the left. If <i>side</i> = 'R', Q or Q^T is applied to C from the right. |
| <i>trans</i> | Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'T', the routine multiplies C by Q^T . |
| <i>m</i> | The number of rows in the matrix C ($m \geq 0$). |
| <i>n</i> | The number of columns in C ($n \geq 0$). |
| <i>k</i> | The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$, if <i>side</i> = 'L'; $0 \leq k \leq n$, if <i>side</i> = 'R'. |

a, *tau*, *c*

Arrays: *a*(size for *side* = 'L': $\max(1, lda*m)$ for column major layout and $\max(1, lda*k)$ for row major layout; for *side* = 'R': $\max(1, lda*n)$ for column major layout and $\max(1, lda*k)$ for row major layout), *tau*, *c* (size $\max(1, ldc*n)$ for column major layout and $\max(1, ldc*m)$ for row major layout).

On entry, the *i*th row of *a* must contain the vector which defines the elementary reflector H_i , for $i = 1, 2, \dots, k$, as returned by *sgerqf*/*dgerqf* in the last *k* rows of its array argument *a*.

tau[*i* - 1] must contain the scalar factor of the elementary reflector H_i , as returned by *sgerqf*/*dgerqf*.

The size of *tau* must be at least $\max(1, k)$.

c contains the *m*-by-*n* matrix *C*.

lda

The leading dimension of *a*; $lda \geq \max(1, k)$ for column major layout. For row major layout, $lda \geq \max(1, m)$ if *side* = 'L', and $lda \geq \max(1, n)$ if *side* = 'R'.

ldc

The leading dimension of *c*; $ldc \geq \max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

Output Parameters

c

Overwritten by the product Q^*C , $Q^T C$, C^*Q , or C^*Q^T (as specified by *side* and *trans*).

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The complex counterpart of this routine is [unmrq](#).

?unmrq

Multiplies a complex matrix by the unitary matrix Q of the RQ factorization formed by ?gerqf.

Syntax

```
lapack_int LAPACKE_cunmrq (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const lapack_complex_float* a, lapack_int lda, const
lapack_complex_float* tau, lapack_complex_float* c, lapack_int ldc);
```

```
lapack_int LAPACKE_zunmrq (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, const lapack_complex_double* a, lapack_int lda, const
lapack_complex_double* tau, lapack_complex_double* c, lapack_int ldc);
```

Include Files

- mkl.h

Description

The routine multiplies a complex m -by- n matrix C by Q or Q^H , where Q is the complex unitary matrix defined as a product of k elementary reflectors $H(i)$ of order n : $Q = H(1)^{H*} H(2)^{H*} \dots H(k)^{H*}$ as returned by the RQ factorization routine [gerqf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products Q^*C , Q^H*C , $C*Q$, or $C*Q^H$ (overwriting the result over C).

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>side</i> | Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^H is applied to C from the left. If <i>side</i> = 'R', Q or Q^H is applied to C from the right. |
| <i>trans</i> | Must be either 'N' or 'C'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'C', the routine multiplies C by Q^H . |
| <i>m</i> | The number of rows in the matrix C ($m \geq 0$). |
| <i>n</i> | The number of columns in C ($n \geq 0$). |
| <i>k</i> | The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$, if <i>side</i> = 'L'; $0 \leq k \leq n$, if <i>side</i> = 'R'. |
| <i>a, tau, c</i> | Arrays: <i>a</i> (size for <i>side</i> = 'L': $\max(1, lda*m)$ for column major layout and $\max(1, lda*k)$ for row major layout; for <i>side</i> = 'R': $\max(1, lda*n)$ for column major layout and $\max(1, lda*k)$ for row major layout), <i>tau</i> , <i>c</i> (size $\max(1, ldc*n)$ for column major layout and $\max(1, ldc*m)$ for row major layout). On entry, the i th row of <i>a</i> must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by cgerqf/zgerqf in the last k rows of its array argument <i>a</i> . <i>tau</i> [$i - 1$] must contain the scalar factor of the elementary reflector $H(i)$, as returned by cgerqf/zgerqf . The size of <i>tau</i> must be at least $\max(1, k)$. <i>c</i> (size $\max(1, ldc*n)$ for column major layout and $\max(1, ldc*m)$ for row major layout) contains the m -by- n matrix C . |
| <i>lda</i> | The leading dimension of <i>a</i> ; $lda \geq \max(1, k)$ for column major layout. For row major layout, $lda \geq \max(1, m)$ if <i>side</i> = 'L', and $lda \geq \max(1, n)$ if <i>side</i> = 'R'. |
| <i>ldc</i> | The leading dimension of <i>c</i> ; $ldc \geq \max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |

Output Parameters

c Overwritten by the product Q^*C , Q^H*C , $C*Q$, or $C*Q^H$ (as specified by *side* and *trans*).

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The real counterpart of this routine is [ormrq](#).

?tzrzf

Reduces the upper trapezoidal matrix A to upper triangular form.

Syntax

```
lapack_int LAPACKE_stzrzf (int matrix_layout, lapack_int m, lapack_int n, float* a,
lapack_int lda, float* tau);
```

```
lapack_int LAPACKE_dtzrzf (int matrix_layout, lapack_int m, lapack_int n, double* a,
lapack_int lda, double* tau);
```

```
lapack_int LAPACKE_ctzrzf (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* tau);
```

```
lapack_int LAPACKE_ztzrzf (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_complex_double* tau);
```

Include Files

- mkl.h

Description

The routine reduces the *m*-by-*n* ($m \leq n$) real/complex upper trapezoidal matrix *A* to upper triangular form by means of orthogonal/unitary transformations. The upper trapezoidal matrix $A = [A1 \ A2] = [A_{1:m, 1:m}, A_{1:m, m+1:n}]$ is factored as

$$A = [R \ 0] * Z,$$

where *Z* is an *n*-by-*n* orthogonal/unitary matrix, *R* is an *m*-by-*m* upper triangular matrix, and *O* is the *m*-by- $(n-m)$ zero matrix.

The ?tzrzf routine replaces the deprecated ?tzrqf routine.

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

m The number of rows in the matrix *A* ($m \geq 0$).

n The number of columns in *A* ($n \geq m$).

| | |
|------------|---|
| <i>a</i> | Array <i>a</i> is of size $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout. The leading <i>m</i> -by- <i>n</i> upper trapezoidal part of the array <i>a</i> contains the matrix <i>A</i> to be factorized. |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |

Output Parameters

| | |
|------------|---|
| <i>a</i> | Overwritten on exit by the factorization data as follows: the leading <i>m</i> -by- <i>m</i> upper triangular part of <i>a</i> contains the upper triangular matrix <i>R</i> , and elements <i>m</i> + 1 to <i>n</i> of the first <i>m</i> rows of <i>a</i> , with the array <i>tau</i> , represent the orthogonal matrix <i>Z</i> as a product of <i>m</i> elementary reflectors. |
| <i>tau</i> | Array, size at least $\max(1, m)$. Contains scalar factors of the elementary reflectors for the matrix <i>Z</i> . |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The factorization is obtained by Householder's method. The *k*-th transformation matrix, *Z*(*k*), which is used to introduce zeros into the (*m* - *k* + 1)-th row of *A*, is given in the form

$$Z(k) = \begin{bmatrix} I & 0 \\ 0 & T(k) \end{bmatrix}$$

where for real flavors

$$T(k) = I - \tau u^* u^T, \quad u(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}$$

and for complex flavors

$$T(k) = I - \tau u^* u^H, \quad u(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}$$

τ is a scalar and $z(k)$ is an l -element vector. τ and $z(k)$ are chosen to annihilate the elements of the k -th row of $A2$.

The scalar τ is returned in the k -th element of τ and the vector $u(k)$ in the k -th row of A , such that the elements of $z(k)$ are stored in the last $m - n$ elements of the k -th row of array a .

The elements of R are returned in the upper triangular part of A .

The matrix Z is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

Related routines include:

Description

The [?ormrz](#) routine multiplies a real m -by- n matrix C by Q or Q^T , where Q is the real orthogonal matrix defined as a product of k elementary reflectors $H(i)$ of order n : $Q = H(1) * H(2) * \dots * H(k)$ as returned by the factorization routine [tzrf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products $Q * C$, $Q^T * C$, $C * Q$, or $C * Q^T$ (overwriting the result over C).

The matrix Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

The [?ormrz](#) routine replaces the deprecated [?latzm](#) routine.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>side</i> | Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^T is applied to C from the left. If <i>side</i> = 'R', Q or Q^T is applied to C from the right. |
| <i>trans</i> | Must be either 'N' or 'T'. |

| | |
|----------------------------------|---|
| | If <i>trans</i> = 'N', the routine multiplies <i>C</i> by <i>Q</i> . If <i>trans</i> = 'T', the routine multiplies <i>C</i> by Q^T . |
| <i>m</i> | The number of rows in the matrix <i>C</i> ($m \geq 0$). |
| <i>n</i> | The number of columns in <i>C</i> ($n \geq 0$). |
| <i>k</i> | The number of elementary reflectors whose product defines the matrix <i>Q</i> . Constraints: $0 \leq k \leq m$, if <i>side</i> = 'L'; $0 \leq k \leq n$, if <i>side</i> = 'R'. |
| <i>l</i> | The number of columns of the matrix <i>A</i> containing the meaningful part of the Householder reflectors. Constraints: $0 \leq l \leq m$, if <i>side</i> = 'L'; $0 \leq l \leq n$, if <i>side</i> = 'R'. |
| <i>a</i> , <i>tau</i> , <i>c</i> | Arrays: <i>a</i> (size for <i>side</i> = 'L': $\max(1, lda * m)$ for column major layout and $\max(1, lda * k)$ for row major layout; for <i>side</i> = 'R': $\max(1, lda * b)$ for column major layout and $\max(1, lda * k)$ for row major layout), <i>tau</i> , <i>c</i> (size $\max(1, ldc * n)$ for column major layout and $\max(1, ldc * m)$ for row major layout). On entry, the <i>i</i> th row of <i>a</i> must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by <i>stzrzf/dtzrzf</i> in the last <i>k</i> rows of its array argument <i>a</i> . <i>tau</i> [<i>i</i> - 1] must contain the scalar factor of the elementary reflector $H(i)$, as returned by <i>stzrzf/dtzrzf</i> . The size of <i>tau</i> must be at least $\max(1, k)$. <i>c</i> contains the <i>m</i> -by- <i>n</i> matrix <i>C</i> . |
| <i>lda</i> | The leading dimension of <i>a</i> ; $lda \geq \max(1, k)$ for column major layout. For row major layout, $lda \geq \max(1, m)$ if <i>side</i> = 'L', and $lda \geq \max(1, n)$ if <i>side</i> = 'R'. |
| <i>ldc</i> | The leading dimension of <i>c</i> ; $ldc \geq \max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |

Output Parameters

| | |
|----------|--|
| <i>c</i> | Overwritten by the product $Q * C$, $Q^T * C$, $C * Q$, or $C * Q^T$ (as specified by <i>side</i> and <i>trans</i>). |
|----------|--|

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The complex counterpart of this routine is [unmrz](#).

?unmrz

Multiplies a complex matrix by the unitary matrix defined from the factorization formed by ?tzrzf.

Syntax

```
lapack_int LAPACKE_cunmrz (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, lapack_int l, const lapack_complex_float* a, lapack_int

```

Include Files

- mkl.h

Description

The routine forms the generalized *QR* factorization of an *n*-by-*m* matrix *A* and an *n*-by-*p* matrix *B* as $A = Q^*R$, $B = Q^*T^*Z$, where *Q* is an *n*-by-*n* orthogonal/unitary matrix, *Z* is a *p*-by-*p* orthogonal/unitary matrix, and *R* and *T* assume one of the forms:

$$R = \begin{matrix} & & m \\ & m & \begin{pmatrix} R_{11} \\ 0 \end{pmatrix} \\ n - m & & \end{matrix}, \quad \text{if } n \geq m$$

or

$$R = \begin{matrix} & n & m - n \\ & \begin{pmatrix} R_{11} & R_{12} \end{pmatrix} \\ n & & \end{matrix}, \quad \text{if } n < m$$

where R_{11} is upper triangular, and

$$T = \begin{matrix} & p - n & n \\ n & \begin{pmatrix} 0 & T_{12} \end{pmatrix} \\ & & \end{matrix}, \quad \text{if } n \leq p,$$

$$T = \begin{matrix} & & p \\ n - p & \begin{pmatrix} T_{11} \\ T_{21} \end{pmatrix} \\ p & & \end{matrix}, \quad \text{if } n > p,$$

where T_{12} or T_{21} is a *p*-by-*p* upper triangular matrix.

In particular, if *B* is square and nonsingular, the *GQR* factorization of *A* and *B* implicitly gives the *QR* factorization of $B^{-1}A$ as:

$B^{-1}A = Z^*T^*(T^{-1}R)$ (for real flavors) or $B^{-1}A = Z^{H*}(T^{-1}R)$ (for complex flavors).

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>n</i> | The number of rows of the matrices <i>A</i> and <i>B</i> ($n \geq 0$). |
| <i>m</i> | The number of columns in <i>A</i> ($m \geq 0$). |
| <i>p</i> | The number of columns in <i>B</i> ($p \geq 0$). |
| <i>a, b</i> | Array <i>a</i> of size $\max(1, lda*m)$ for column major layout and $\max(1, lda*n)$ for row major layout contains the matrix <i>A</i> . Array <i>b</i> of size $\max(1, ldb*p)$ for column major layout and $\max(1, ldb*n)$ for row major layout contains the matrix <i>B</i> . |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, n)$ for column major layout and at least $\max(1, m)$ for row major layout. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; at least $\max(1, n)$ for column major layout and at least $\max(1, p)$ for row major layout. |

Output Parameters

| | |
|-------------------|---|
| <i>a, b</i> | Overwritten by the factorization data as follows: on exit, the elements on and above the diagonal of the array <i>a</i> contain the $\min(n,m)$ -by- <i>m</i> upper trapezoidal matrix <i>R</i> (<i>R</i> is upper triangular if $n \geq m$); the elements below the diagonal, with the array <i>taua</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of $\min(n,m)$ elementary reflectors ; if $n \leq p$, the upper triangle of the subarray <i>b</i> (1: <i>n</i> , <i>p</i> - <i>n</i> +1: <i>p</i>) contains the <i>n</i> -by- <i>n</i> upper triangular matrix <i>T</i> ; if $n > p$, the elements on and above the (<i>n</i> - <i>p</i>)th subdiagonal contain the <i>n</i> -by- <i>p</i> upper trapezoidal matrix <i>T</i> ; the remaining elements, with the array <i>taub</i> , represent the orthogonal/unitary matrix <i>Z</i> as a product of elementary reflectors. |
| <i>taua, taub</i> | Arrays, size at least $\max(1, \min(n, m))$ for <i>taua</i> and at least $\max(1, \min(n, p))$ for <i>taub</i> . The array <i>taua</i> contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix <i>Q</i> . The array <i>taub</i> contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix <i>Z</i> . |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The matrix *Q* is represented as a product of elementary reflectors

$Q = H(1)H(2) \dots H(k)$, where $k = \min(n, m)$.

Each $H(i)$ has the form

$H(i) = I - \tau_a * v * v^T$ for real flavors, or

$H(i) = I - \tau_a * v * v^H$ for complex flavors,

where τ_a is a real/complex scalar, and v is a real/complex vector with $v_j = 0$ for $1 \leq j \leq i - 1$, $v_i = 1$.

On exit, for $i + 1 \leq j \leq n$, v_j is stored in $a[(j - 1) + (i - 1) * lda]$ for column major layout and in $a[(j - 1) * lda + (i - 1)]$ for row major layout and τ_a is stored in $taua[i - 1]$

The matrix Z is represented as a product of elementary reflectors

$Z = H(1)H(2) \dots H(k)$, where $k = \min(n, p)$.

Each $H(i)$ has the form

$H(i) = I - \tau_b * v * v^T$ for real flavors, or

$H(i) = I - \tau_b * v * v^H$ for complex flavors,

where τ_b is a real/complex scalar, and v is a real/complex vector with $v_{p - k + 1} = 1$, $v_j = 0$ for $p - k + 1 \leq j \leq p - 1$.

On exit, for $1 \leq j \leq p - k + i - 1$, v_j is stored in $b[(n - k + i - 1) + (j - 1) * ldb]$ for column major layout and in $b[(n - k + i - 1) * ldb + (j - 1)]$ for row major layout and τ_b is stored in $taub[i - 1]$.

?ggrqf

Computes the generalized RQ factorization of two matrices.

Syntax

```
lapack_int LAPACKE_sggrqf (int matrix_layout, lapack_int m, lapack_int p, lapack_int n,
float* a, lapack_int lda, float* taua, float* b, lapack_int ldb, float* taub);
```

```
lapack_int LAPACKE_dggrqf (int matrix_layout, lapack_int m, lapack_int p, lapack_int n,
double* a, lapack_int lda, double* taua, double* b, lapack_int ldb, double* taub);
```

```
lapack_int LAPACKE_cggrqf (int matrix_layout, lapack_int m, lapack_int p, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* taua,
lapack_complex_float* b, lapack_int ldb, lapack_complex_float* taub);
```

```
lapack_int LAPACKE_zggrqf (int matrix_layout, lapack_int m, lapack_int p, lapack_int n,

Description

The routine forms the generalized RQ factorization of an m -by- n matrix A and an p -by- n matrix B as $A = R * Q$, $B = Z * T * Q$, where Q is an n -by- n orthogonal/unitary matrix, Z is a p -by- p orthogonal/unitary matrix, and R and T assume one of the forms:

$$R = \begin{matrix} n - m & m \\ m & (0 & R_{12}) \end{matrix}, \quad \text{if } m \leq n,$$

or

$$R = \begin{matrix} m - n & & n \\ & & \\ & & \end{matrix} \begin{pmatrix} R_{11} \\ R_{21} \end{pmatrix}, \text{ if } m > n,$$

where R_{11} or R_{21} is upper triangular, and

$$T = \begin{matrix} & & n \\ & n & \\ p - n & & \end{matrix} \begin{pmatrix} T_{11} \\ 0 \end{pmatrix}, \text{ if } p \geq n,$$

or

$$T = \begin{matrix} & p & n - p \\ p & (T_{11} & T_{12}) \end{matrix}, \text{ if } p < n,$$

where T_{11} is upper triangular.

In particular, if B is square and nonsingular, the GRQ factorization of A and B implicitly gives the RQ factorization of $A*B^{-1}$ as:

$$A*B^{-1} = (R*T^{-1}) * Z^T \text{ (for real flavors) or } A*B^{-1} = (R*T^{-1}) * Z^H \text{ (for complex flavors).}$$

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>m</i> | The number of rows of the matrix A ($m \geq 0$). |
| <i>p</i> | The number of rows in B ($p \geq 0$). |
| <i>n</i> | The number of columns of the matrices A and B ($n \geq 0$). |
| <i>a, b</i> | Arrays: <i>a</i> (size $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout) contains the m -by- n matrix A . <i>b</i> (size $\max(1, ldb*n)$ for column major layout and $\max(1, ldb*p)$ for row major layout) contains the p -by- n matrix B . |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; at least $\max(1, p)$ for column major layout and $\max(1, n)$ for row major layout. |

Output Parameters

a, b

Overwritten by the factorization data as follows:

on exit, if $m \leq n$, element R_{ij} ($1 \leq i \leq j \leq m$) of upper triangular matrix R is stored in $a[(i - 1) + (n - m + j - 1) * lda]$ for column major layout and in $a[(i - 1) * lda + (n - m + j - 1)]$ for row major layout.

if $m > n$, the elements on and above the $(m-n)$ th subdiagonal contain the m -by- n upper trapezoidal matrix R ;

the remaining elements, with the array *taua*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors.

The elements on and above the diagonal of the array *b* contain the $\min(p, n)$ -by- n upper trapezoidal matrix T (T is upper triangular if $p \geq n$); the elements below the diagonal, with the array *taub*, represent the orthogonal/unitary matrix Z as a product of elementary reflectors.

taua, taub

Arrays, size at least $\max(1, \min(m, n))$ for *taua* and at least $\max(1, \min(p, n))$ for *taub*.

The array *taua* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Q .

The array *taub* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Z .

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = $-i$, the i -th parameter had an illegal value.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1)H(2) \dots H(k), \text{ where } k = \min(m, n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau_a v v^T \text{ for real flavors, or}$$

$$H(i) = I - \tau_a v v^H \text{ for complex flavors,}$$

where τ_a is a real/complex scalar, and v is a real/complex vector with $v_{n-k+i} = 1, v_{n-k+i+1:n} = 0$.

On exit, $v_{1:n-k+i-1}$ is stored in $a(m-k+i, 1:n-k+i-1)$ and τ_a is stored in $\tau_a[i - 1]$.

The matrix Z is represented as a product of elementary reflectors

$$Z = H(1)H(2) \dots H(k), \text{ where } k = \min(p, n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau_b v v^T \text{ for real flavors, or}$$

$$H(i) = I - \tau_b v v^H \text{ for complex flavors,}$$

where τ_b is a real/complex scalar, and v is a real/complex vector with $v_{1:i-1} = 0, v_i = 1$.

On exit, $v_{i+1:p}$ is stored in $b(i+1:p, i)$ and τ_b is stored in $\tau_b[i - 1]$.

?tpqrt

Computes a blocked QR factorization of a real or complex "triangular-pentagonal" matrix, which is composed of a triangular block and a pentagonal block, using the compact WY representation for Q.

Syntax

```
lapack_int LAPACKE_stpqrt (int matrix_layout, lapack_int m, lapack_int n, lapack_int l,
lapack_int nb, float* a, lapack_int lda, float* b, lapack_int ldb, float* t,
lapack_int ldt);
```

```
lapack_int LAPACKE_dtpqrt (int matrix_layout, lapack_int m, lapack_int n, lapack_int l,
lapack_int nb, double* a, lapack_int lda, double* b, lapack_int ldb, double* t,
lapack_int ldt);
```

```
lapack_int LAPACKE_ctpqrt (int matrix_layout, lapack_int m, lapack_int n, lapack_int l,
lapack_int nb, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b,
lapack_int ldb, lapack_complex_float* t, lapack_int ldt);
```

```
lapack_int LAPACKE_ztpqrt (int matrix_layout, lapack_int m, lapack_int n, lapack_int l,
lapack_int nb, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b,
lapack_int ldb, lapack_complex_double* t, lapack_int ldt);
```

Include Files

- mkl.h

Description

The input matrix C is an $(n+m)$ -by- n matrix

$$C = \begin{bmatrix} A \\ B \end{bmatrix} \leftarrow \begin{array}{l} n \times n \text{ upper triangular} \\ m \times n \text{ pentagonal} \end{array}$$

where A is an n -by- n upper triangular matrix, and B is an m -by- n pentagonal matrix consisting of an $(m-1)$ -by- n rectangular matrix $B1$ on top of an l -by- n upper trapezoidal matrix $B2$:

$$B = \begin{bmatrix} B1 \\ B2 \end{bmatrix} \leftarrow \begin{array}{l} (m-1) \times n \text{ rectangular} \\ l \times n \text{ upper trapezoidal} \end{array}$$

The upper trapezoidal matrix $B2$ consists of the first l rows of an n -by- n upper triangular matrix, where $0 \leq l \leq \min(m, n)$. If $l=0$, B is an m -by- n rectangular matrix. If $m=1=n$, B is upper triangular. The elementary reflectors $H(i)$ are stored in the i th column below the diagonal in the $(n+m)$ -by- n input matrix C . The structure of vectors defining the elementary reflectors is illustrated by:

$$\begin{bmatrix} I \\ V \end{bmatrix} \leftarrow \begin{array}{l} n \times n \text{ identity} \\ m \times n \text{ pentagonal} \end{array}$$

The elements of the unit matrix I are not stored. Thus, V contains all of the necessary information, and is returned in array b .

NOTE

Note that V has the same form as B :

$$V = \begin{bmatrix} V1 \\ V2 \end{bmatrix} \leftarrow \begin{matrix} (m-l) \times n \text{ rectangular} \\ l \times n \text{ upper trapezoidal} \end{matrix}$$

The columns of V represent the vectors which define the $H(i)$ s.

The number of blocks is $k = \text{ceiling}(n/nb)$, where each block is of order nb except for the last block, which is of order $ib = n - (k-1)*nb$. For each of the k blocks, an upper triangular block reflector factor is computed: $T1, T2, \dots, Tk$. The nb -by- nb (ib -by- ib for the last block) T is are stored in the nb -by- n array t as

$$t = [T1T2 \dots Tk] .$$

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>m</i> | The total number of rows in the matrix B ($m \geq 0$). |
| <i>n</i> | The number of columns in B and the order of the triangular matrix A ($n \geq 0$). |
| <i>l</i> | The number of rows of the upper trapezoidal part of B ($\min(m, n) \geq l \geq 0$). |
| <i>nb</i> | The block size to use in the blocked QR factorization ($n \geq nb \geq 1$). |
| <i>a, b</i> | Arrays: <i>a</i> size $lda*n$ contains the n -by- n upper triangular matrix A . <i>b</i> size $\max(1, ldb*n)$ for column major layout and $\max(1, ldb*m)$ for row major layout, the pentagonal m -by- n matrix B . The first $(m-1)$ rows contain the rectangular $B1$ matrix, and the next l rows contain the upper trapezoidal $B2$ matrix. |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, n)$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout. |
| <i>ldt</i> | The leading dimension of <i>t</i> ; at least nb for column major layout and at least $\max(1, n)$ for row major layout. |

Output Parameters

| | |
|----------|---|
| <i>a</i> | The elements on and above the diagonal of the array contain the upper triangular matrix R . |
| <i>b</i> | The pentagonal matrix V . |
| <i>t</i> | Array, size $ldt*n$ for column major layout and $ldt*nb$ for row major layout. |

The upper triangular block reflectors stored in compact form as a sequence of upper triangular blocks.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

?tpmqrt

Applies a real or complex orthogonal matrix obtained from a "triangular-pentagonal" complex block reflector to a general real or complex matrix, which consists of two blocks.

Syntax

```
lapack_int LAPACKE_stpmqrt (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, lapack_int l, lapack_int nb, const float* v, lapack_int
ldv, const float* t, lapack_int ldt, float* a, lapack_int lda, float* b, lapack_int
ldb);
```

```
lapack_int LAPACKE_dtpmqrt (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, lapack_int l, lapack_int nb, const double* v, lapack_int
ldv, const double* t, lapack_int ldt, double* a, lapack_int lda, double* b, lapack_int
ldb);
```

```
lapack_int LAPACKE_ctpmqrt (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, lapack_int l, lapack_int nb, const lapack_complex_float*
v, lapack_int ldv, const lapack_complex_float* t, lapack_int ldt, lapack_complex_float*
a, lapack_int lda, lapack_complex_float* b, lapack_int ldb);
```

```
lapack_int LAPACKE_ztpmqrt (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int k, lapack_int l, lapack_int nb, const lapack_complex_double*
v, lapack_int ldv, const lapack_complex_double* t, lapack_int ldt,
lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb);
```

Include Files

- mkl.h

Description

The columns of the pentagonal matrix *V* contain the elementary reflectors $H(1), H(2), \dots, H(k)$; *V* is composed of a rectangular block *V1* and a trapezoidal block *V2*:

$$V = \begin{bmatrix} V1 \\ V2 \end{bmatrix}$$

The size of the trapezoidal block *V2* is determined by the parameter *l*, where $0 \leq l \leq k$. *V2* is upper trapezoidal, consisting of the first *l* rows of a *k*-by-*k* upper triangular matrix.

If $l=k$, *V2* is upper triangular;

If $l=0$, there is no trapezoidal block, so $V = V1$ is rectangular.

If $side = 'L'$:

$$C = \begin{bmatrix} A \\ B \end{bmatrix}$$

where A is k -by- n , B is m -by- n and V is m -by- k .

If $side = 'R'$:

$$C = [A \ B]$$

where A is m -by- k , B is m -by- n and V is n -by- k .

The real/complex orthogonal matrix Q is formed from V and T .

If $trans='N'$ and $side='L'$, c contains $Q * C$ on exit.

If $trans='T'$ and $side='L'$, c contains $Q^T * C$ on exit.

If $trans='C'$ and $side='L'$, c contains $Q^H * C$ on exit.

If $trans='N'$ and $side='R'$, c contains $C * Q$ on exit.

If $trans='T'$ and $side='R'$, c contains $C * Q^T$ on exit.

If $trans='C'$ and $side='R'$, c contains $C * Q^H$ on exit.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>side</i> | ='L': apply Q , Q^T , or Q^H from the left. ='R': apply Q , Q^T , or Q^H from the right. |
| <i>trans</i> | ='N', no transpose, apply Q . ='T', transpose, apply Q^T . ='C', transpose, apply Q^H . |
| <i>m</i> | The number of rows in the matrix B , ($m \geq 0$). |
| <i>n</i> | The number of columns in the matrix B , ($n \geq 0$). |
| <i>k</i> | The number of elementary reflectors whose product defines the matrix Q , ($k \geq 0$). |
| <i>l</i> | The order of the trapezoidal part of V ($k \geq l \geq 0$). |
| <i>nb</i> | The block size used for the storage of t , $k \geq nb \geq 1$. This must be the same value of nb used to generate t in <code>tpqrt</code> . |
| <i>v</i> | Size $ldv*k$ for column major layout; $ldv*m$ for row major layout and $side = 'L'$, $ldv*n$ for row major layout and $side = 'R'$. |

| | |
|-------|--|
| | The i th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by <code>tpqrt</code> in array argument b . |
| ldv | The leading dimension of the array v . If $side = 'L'$, ldv must be at least $\max(1, m)$ for column major layout and $\max(1, k)$ for row major layout; If $side = 'R'$, ldv must be at least $\max(1, n)$ for column major layout and $\max(1, k)$ for row major layout. |
| t | Array, size $ldt*k$ for column major layout and $ldt*nb$ for row major layout. The upper triangular factors of the block reflectors as returned by <code>tpqrt</code> |
| ldt | The leading dimension of the array t . ldt must be at least nb for column major layout and $\max(1, k)$ for row major layout. |
| a | If $side = 'L'$, size $lda*n$ for column major layout and $lda*k$ for row major layout .. If $side = 'R'$, size $lda*k$ for column major layout and $lda*m$ for row major layout .. The k -by- n or m -by- k matrix A . |
| lda | The leading dimension of the array a . If $side = 'L'$, lda must be at least $\max(1, k)$ for column major layout and $\max(1, n)$ for row major layout. If $side = 'R'$, lda must be at least $\max(1, m)$ for column major layout and $\max(1, k)$ for row major layout. |
| b | Size $ldb*n$ for column major layout and $ldb*m$ for row major layout. The m -by- n matrix B . |
| ldb | The leading dimension of the array b . ldb must be at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |

Output Parameters

| | |
|-----|--|
| a | Overwritten by the corresponding block of the product $Q*C$, $C*Q$, Q^T*C , $C*Q^T$, Q^H*C , or $C*Q^H$. |
| b | Overwritten by the corresponding block of the product $Q*C$, $C*Q$, Q^T*C , $C*Q^T$, Q^H*C , or $C*Q^H$. |

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Singular Value Decomposition: LAPACK Computational Routines

This section describes LAPACK routines for computing the *singular value decomposition* (SVD) of a general m -by- n matrix A :

$$A = U\Sigma V^H.$$

In this decomposition, U and V are unitary (for complex A) or orthogonal (for real A); Σ is an m -by- n diagonal matrix with real diagonal elements σ_i :

$$\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_{\min(m, n)} \geq 0.$$

The diagonal elements σ_i are *singular values* of A . The first $\min(m, n)$ columns of the matrices U and V are, respectively, *left* and *right singular vectors* of A . The singular values and singular vectors satisfy

$$AV_i = \sigma_i u_i \text{ and } A^H u_i = \sigma_i v_i$$

where u_i and v_i are the i -th columns of U and V , respectively.

To find the SVD of a general matrix A , call the LAPACK routine `?gebrd` or `?gbbbrd` for reducing A to a bidiagonal matrix B by a unitary (orthogonal) transformation: $A = QBP^H$. Then call `?bdsqr`, which forms the SVD of a bidiagonal matrix: $B = U_1 \Sigma V_1^H$.

Thus, the sought-for SVD of A is given by $A = U\Sigma V^H = (QU_1)\Sigma(V_1^H P^H)$.

Table "Computational Routines for Singular Value Decomposition (SVD)" lists LAPACK routines that perform singular value decomposition of matrices.

Computational Routines for Singular Value Decomposition (SVD)

| Operation | Real matrices | Complex matrices |
|--|---|----------------------|
| Reduce A to a bidiagonal matrix B : $A = QBP^H$ (full storage) | <code>?gebrd</code> | <code>?gebrd</code> |
| Reduce A to a bidiagonal matrix B : $A = QBP^H$ (band storage) | <code>?gbbbrd</code> | <code>?gbbbrd</code> |
| Generate the orthogonal (unitary) matrix Q or P | <code>?orgbr</code> | <code>?ungbr</code> |
| Apply the orthogonal (unitary) matrix Q or P | <code>?ormbr</code> | <code>?unmbr</code> |
| Form singular value decomposition of the bidiagonal matrix B : $B = U_1 \Sigma V_1^H$ | <code>?bdsqr</code> <code>?bdsdc</code> | <code>?bdsqr</code> |

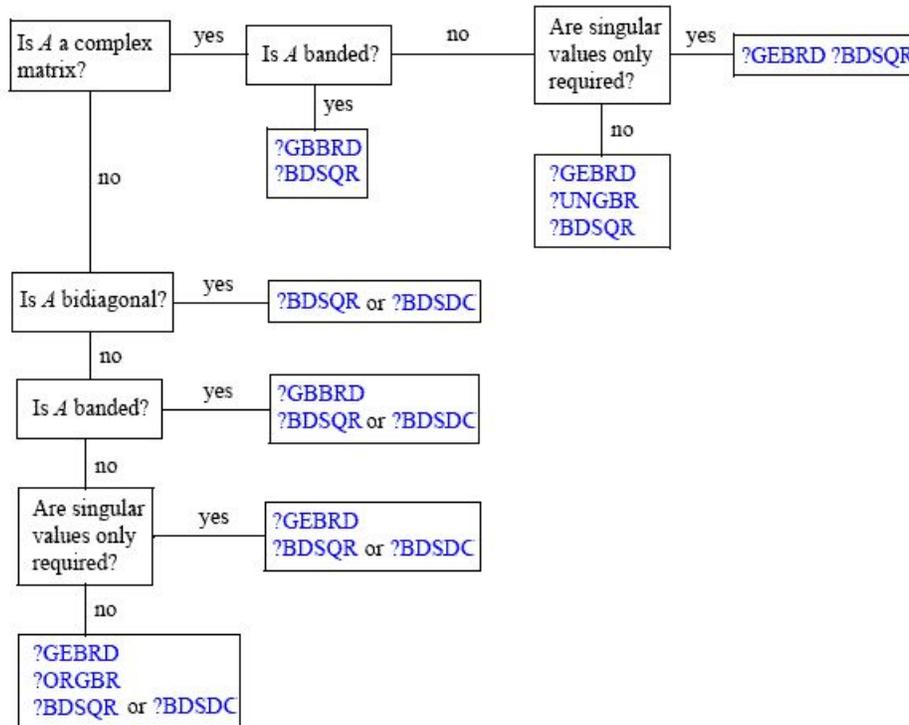

Decision Tree: Singular Value Decomposition

Figure "Decision Tree: Singular Value Decomposition" presents a decision tree that helps you choose the right sequence of routines for SVD, depending on whether you need singular values only or singular vectors as well, whether A is real or complex, and so on.

You can use the SVD to find a minimum-norm solution to a (possibly) rank-deficient least squares problem of minimizing $\|Ax - b\|^2$. The effective rank k of the matrix A can be determined as the number of singular values which exceed a suitable threshold. The minimum-norm solution is

$$x = V_k(\Sigma_k)^{-1}c$$

where Σ_k is the leading k -by- k submatrix of Σ , the matrix V_k consists of the first k columns of $V = PV_1$, and the vector c consists of the first k elements of $U^H b = U_1^H Q^H b$.

?gebrd

Reduces a general matrix to bidiagonal form.

Syntax

```
lapack_int LAPACKE_sgebrd( int matrix_layout, lapack_int m, lapack_int n, float* a,
lapack_int lda, float* d, float* e, float* tauq, float* tauq );
```

```
lapack_int LAPACKE_dgebrd( int matrix_layout, lapack_int m, lapack_int n, double* a,
lapack_int lda, double* d, double* e, double* tauq, double* tauq );
```

```
lapack_int LAPACKE_cgebrd( int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, float* d, float* e, lapack_complex_float*
tauq, lapack_complex_float* tauq );
```

```
lapack_int LAPACKE_zgebrd( int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, double* d, double* e, lapack_complex_double*
tauq, lapack_complex_double* tauq );
```

Include Files

- `mkl.h`

Description

The routine reduces a general m -by- n matrix A to a bidiagonal matrix B by an orthogonal (unitary) transformation.

$$A = QBP^H = Q \begin{pmatrix} B_1 \\ 0 \end{pmatrix} P^H = Q_1 B_1 P^H,$$

If $m \geq n$, the reduction is given by

where B_1 is an n -by- n upper diagonal matrix, Q and P are orthogonal or, for a complex A , unitary matrices; Q_1 consists of the first n columns of Q .

If $m < n$, the reduction is given by

$$A = Q^* B^* P^H = Q^* (B_1 0) P^H = Q_1^* B_1^* P_1^H,$$

where B_1 is an m -by- m lower diagonal matrix, Q and P are orthogonal or, for a complex A , unitary matrices; P_1 consists of the first m columns of P .

The routine does not form the matrices Q and P explicitly, but represents them as products of elementary reflectors. Routines are provided to work with the matrices Q and P in this representation:

If the matrix A is real,

- to compute Q and P explicitly, call [orgbr](#).
- to multiply a general matrix by Q or P , call [ormbr](#).

If the matrix A is complex,

- to compute Q and P explicitly, call [ungbr](#).
- to multiply a general matrix by Q or P , call [unmbr](#).

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>m</code> | The number of rows in the matrix A ($m \geq 0$). |
| <code>n</code> | The number of columns in A ($n \geq 0$). |
| <code>a</code> | Arrays: <code>a</code> (size $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout) contains the matrix A . |
| <code>lda</code> | The leading dimension of <code>a</code> ; at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout. |

Output Parameters

| | |
|----------------|---|
| <code>a</code> | If $m \geq n$, the diagonal and first super-diagonal of <code>a</code> are overwritten by the upper bidiagonal matrix B . The elements below the diagonal, with the array <code>tauq</code> , represent the orthogonal matrix Q as a product of elementary |
|----------------|---|

reflectors, and the elements above the first superdiagonal, with the array tau_p , represent the orthogonal matrix P as a product of elementary reflectors.

If $m < n$, the diagonal and first sub-diagonal of a are overwritten by the lower bidiagonal matrix B . The elements below the first subdiagonal, with the array tau_q , represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array tau_p , represent the orthogonal matrix P as a product of elementary reflectors.

| | |
|------------------------------|--|
| d | Array, size at least $\max(1, \min(m, n))$. Contains the diagonal elements of B . |
| e | Array, size at least $\max(1, \min(m, n) - 1)$. Contains the off-diagonal elements of B . |
| $\text{tau}_q, \text{tau}_p$ | Arrays, size at least $\max(1, \min(m, n))$. The scalar factors of the elementary reflectors which represent the orthogonal or unitary matrices P and Q . |

Return Values

This function returns a value info .

If $\text{info}=0$, the execution is successful.

If $\text{info} = -i$, the i -th parameter had an illegal value.

Application Notes

The computed matrices Q , B , and P satisfy $QB P^H = A + E$, where $\|E\|_2 = c(n)\varepsilon \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ε is the machine precision.

The approximate number of floating-point operations for real flavors is

$$(4/3) * n^2 * (3 * m - n) \text{ for } m \geq n,$$

$$(4/3) * m^2 * (3 * n - m) \text{ for } m < n.$$

The number of operations for complex flavors is four times greater.

If n is much less than m , it can be more efficient to first form the QR factorization of A by calling [geqrf](#) and then reduce the factor R to bidiagonal form. This requires approximately $2 * n^2 * (m + n)$ floating-point operations.

If m is much less than n , it can be more efficient to first form the LQ factorization of A by calling [gelqf](#) and then reduce the factor L to bidiagonal form. This requires approximately $2 * m^2 * (m + n)$ floating-point operations.

?gbbbrd

Reduces a general band matrix to bidiagonal form.

Syntax

```
lapack_int LAPACKE_sgbbrd( int matrix_layout, char vect, lapack_int m, lapack_int n,
lapack_int ncc, lapack_int kl, lapack_int ku, float* ab, lapack_int ldab, float* d,
float* e, float* q, lapack_int ldq, float* pt, lapack_int ldpt, float* c, lapack_int
ldc );
```

```
lapack_int LAPACKE_dgbbrd( int matrix_layout, char vect, lapack_int m, lapack_int n,
lapack_int ncc, lapack_int kl, lapack_int ku, double* ab, lapack_int ldab, double* d,
double* e, double* q, lapack_int ldq, double* pt, lapack_int ldpt, double* c,
lapack_int ldc );
```

```
lapack_int LAPACKE_cgbbbrd( int matrix_layout, char vect, lapack_int m, lapack_int n,
lapack_int ncc, lapack_int kl, lapack_int ku, lapack_complex_float* ab, lapack_int
ldab, float* d, float* e, lapack_complex_float* q, lapack_int ldq,
lapack_complex_float* pt, lapack_int ldpt, lapack_complex_float* c, lapack_int ldc );
```

```
lapack_int LAPACKE_zgbbrd( int matrix_layout, char vect, lapack_int m, lapack_int n,
lapack_int ncc, lapack_int kl, lapack_int ku, lapack_complex_double* ab, lapack_int
ldab, double* d, double* e, lapack_complex_double* q, lapack_int ldq,
lapack_complex_double* pt, lapack_int ldpt, lapack_complex_double* c, lapack_int ldc );
```

Include Files

- mkl.h

Description

The routine reduces an m -by- n band matrix A to upper bidiagonal matrix B : $A = Q*B*P^H$. Here the matrices Q and P are orthogonal (for real A) or unitary (for complex A). They are determined as products of Givens rotation matrices, and may be formed explicitly by the routine if required. The routine can also update a matrix C as follows: $C = Q^H*C$.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>vect</i> | Must be 'N' or 'Q' or 'P' or 'B'. If <i>vect</i> = 'N', neither Q nor P^H is generated. If <i>vect</i> = 'Q', the routine generates the matrix Q . If <i>vect</i> = 'P', the routine generates the matrix P^H . If <i>vect</i> = 'B', the routine generates both Q and P^H . |
| <i>m</i> | The number of rows in the matrix A ($m \geq 0$). |
| <i>n</i> | The number of columns in A ($n \geq 0$). |
| <i>ncc</i> | The number of columns in C ($ncc \geq 0$). |
| <i>kl</i> | The number of sub-diagonals within the band of A ($kl \geq 0$). |
| <i>ku</i> | The number of super-diagonals within the band of A ($ku \geq 0$). |
| <i>ab, c</i> | Arrays: <i>ab</i> (size $\max(1, ldab*n)$ for column major layout and $\max(1, ldab*m)$ for row major layout) contains the matrix A in band storage (see Matrix Storage Schemes). <i>c</i> (size $\max(1, ldc*ncc)$ for column major layout and $\max(1, ldc*m)$ for row major layout) contains an m -by- ncc matrix C . |

| | |
|--------|--|
| | If $ncc = 0$, the array c is not referenced. |
| $ldab$ | The leading dimension of the array ab ($ldab \geq kl + ku + 1$). |
| ldq | The leading dimension of the output array q . $ldq \geq \max(1, m)$ if $vect = 'Q'$ or $'B'$, $ldq \geq 1$ otherwise. |
| $ldpt$ | The leading dimension of the output array pt . $ldpt \geq \max(1, n)$ if $vect = 'P'$ or $'B'$, $ldpt \geq 1$ otherwise. |
| ldc | The leading dimension of the array c . $ldc \geq \max(1, m)$ if $ncc > 0$; $ldc \geq 1$ if $ncc = 0$. |

Output Parameters

| | |
|---------|--|
| ab | Overwritten by values generated during the reduction. |
| d | Array, size at least $\max(1, \min(m, n))$. Contains the diagonal elements of the matrix B . |
| e | Array, size at least $\max(1, \min(m, n) - 1)$. Contains the off-diagonal elements of B . |
| q, pt | Arrays: $qsize \max(1, ldq * m)$ contains the output m -by- m matrix Q . $psize \max(1, ldpt * n)$ contains the output n -by- n matrix P^T . |
| c | Overwritten by the product $Q^H * C$. c is not referenced if $ncc = 0$. |

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

The computed matrices Q , B , and P satisfy $Q * B * P^H = A + E$, where $\|E\|_2 = c(n)\epsilon \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision.

If $m = n$, the total number of floating-point operations for real flavors is approximately the sum of:

$6 * n^2 * (kl + ku)$ if $vect = 'N'$ and $ncc = 0$,

$3 * n^2 * ncc * (kl + ku - 1) / (kl + ku)$ if C is updated, and

$3 * n^3 * (kl + ku - 1) / (kl + ku)$ if either Q or P^H is generated (double this if both).

To estimate the number of operations for complex flavors, use the same formulas with the coefficients 20 and 10 (instead of 6 and 3).

?orgbr

Generates the real orthogonal matrix Q or P^T determined by ?gebrd.

Syntax

```
lapack_int LAPACKE_sorgbr (int matrix_layout, char vect, lapack_int m, lapack_int n,
lapack_int k, float* a, lapack_int lda, const float* tau);
```

```
lapack_int LAPACKE_dorgbr (int matrix_layout, char vect, lapack_int m, lapack_int n,
lapack_int k, double* a, lapack_int lda, const double* tau);
```

Include Files

- mkl.h

Description

The routine generates the whole or part of the orthogonal matrices Q and P^T formed by the routines [gebrd](#)/[gebrd](#). Use this routine after a call to [sgebrd](#)/[dgebrd](#). All valid combinations of arguments are described in *Input parameters*. In most cases you need the following:

To compute the whole m -by- m matrix Q :

```
LAPACKE_?orgbr(matrix_layout, 'Q', m, m, n, a, lda, tau )
```

(note that the array a must have at least m columns).

To form the n leading columns of Q if $m > n$:

```
LAPACKE_?orgbr(matrix_layout, 'Q', m, n, n, a, lda, tau )
```

To compute the whole n -by- n matrix P^T :

```
LAPACKE_?orgbr(matrix_layout, 'P', n, n, m, a, lda, tau )
```

(note that the array a must have at least n rows).

To form the m leading rows of P^T if $m < n$:

```
LAPACKE_?orgbr(matrix_layout, 'P', m, n, m, a, lda, tau )
```

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>vect</i> | Must be 'Q' or 'P'. If <i>vect</i> = 'Q', the routine generates the matrix Q . If <i>vect</i> = 'P', the routine generates the matrix P^T . |
| <i>m, n</i> | The number of rows (m) and columns (n) in the matrix Q or P^T to be returned ($m \geq 0, n \geq 0$). If <i>vect</i> = 'Q', $m \geq n \geq \min(m, k)$. If <i>vect</i> = 'P', $n \geq m \geq \min(n, k)$. |
| <i>k</i> | If <i>vect</i> = 'Q', the number of columns in the original m -by- k matrix reduced by gebrd . |

| | |
|------------|--|
| | If <i>vect</i> = 'P', the number of rows in the original <i>k</i> -by- <i>n</i> matrix reduced by <i>gebrd</i> . |
| <i>a</i> | Array, size at least <i>lda</i> * <i>n</i> for column major layout and <i>lda</i> * <i>m</i> for row major layout. The vectors which define the elementary reflectors, as returned by <i>gebrd</i> . |
| <i>lda</i> | The leading dimension of the array <i>a</i> . $lda \geq \max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout . |
| <i>tau</i> | Array, size $\min(m, k)$ if <i>vect</i> = 'Q', $\min(n, k)$ if <i>vect</i> = 'P'. Scalar factor of the elementary reflector <i>H</i> (<i>i</i>) or <i>G</i> (<i>i</i>), which determines <i>Q</i> and <i>P</i> ^T as returned by <i>gebrd</i> in the array <i>tauq</i> or <i>taup</i> . |

Output Parameters

| | |
|----------|---|
| <i>a</i> | Overwritten by the orthogonal matrix <i>Q</i> or <i>P</i> ^T (or the leading rows or columns thereof) as specified by <i>vect</i> , <i>m</i> , and <i>n</i> . |
|----------|---|

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The computed matrix *Q* differs from an exactly orthogonal matrix by a matrix *E* such that $\|E\|_2 = O(\epsilon)$.

The approximate numbers of floating-point operations for the cases listed in *Description* are as follows:

To form the whole of *Q*:

$(4/3) * n * (3m^2 - 3m * n + n^2)$ if $m > n$;

$(4/3) * m^3$ if $m \leq n$.

To form the *n* leading columns of *Q* when $m > n$:

$(2/3) * n^2 * (3m - n^2)$ if $m > n$.

To form the whole of *P*^T:

$(4/3) * n^3$ if $m \geq n$;

$(4/3) * m * (3n^2 - 3m * n + m^2)$ if $m < n$.

To form the *m* leading columns of *P*^T when $m < n$:

$(2/3) * n^2 * (3m - n^2)$ if $m > n$.

The complex counterpart of this routine is *ungbr*.

?ormbr

Multiplies an arbitrary real matrix by the real orthogonal matrix Q or P^T determined by ?gebrd.

Syntax

```

Description

Given an arbitrary real matrix C , this routine forms one of the matrix products Q^*C , $Q^{T*}C$, C^*Q , C^*Q^T , P^*C , $P^{T*}C$, C^*P , C^*P^T , where Q and P are orthogonal matrices computed by a call to [gebrd](#). The routine overwrites the product on C .

Input Parameters

In the descriptions below, r denotes the order of Q or P^T :

If $side = 'L'$, $r = m$; if $side = 'R'$, $r = n$.

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>vect</i> | Must be 'Q' or 'P'. If <i>vect</i> = 'Q', then Q or Q^T is applied to C . If <i>vect</i> = 'P', then P or P^T is applied to C . |
| <i>side</i> | Must be 'L' or 'R'. If <i>side</i> = 'L', multipliers are applied to C from the left. If <i>side</i> = 'R', they are applied to C from the right. |
| <i>trans</i> | Must be 'N' or 'T'. If <i>trans</i> = 'N', then Q or P is applied to C . If <i>trans</i> = 'T', then Q^T or P^T is applied to C . |
| <i>m</i> | The number of rows in C . |
| <i>n</i> | The number of columns in C . |
| <i>k</i> | One of the dimensions of A in ?gebrd : If <i>vect</i> = 'Q', the number of columns in A ; If <i>vect</i> = 'P', the number of rows in A . Constraints: $m \geq 0$, $n \geq 0$, $k \geq 0$. |
| <i>a, c</i> | Arrays: <i>a</i> is the array <i>a</i> as returned by ?gebrd . The size of <i>a</i> depends on the value of the <i>matrix_layout</i> , <i>vect</i> , and <i>side</i> parameters: |

| <i>matrix_layout</i> | <i>vect</i> | <i>side</i> | size |
|----------------------|-------------|-------------|------------------|
| column major | 'Q' | - | $\max(1, lda*k)$ |

| <i>matrix_layout</i> | <i>vect</i> | <i>side</i> | size |
|----------------------|-------------|-------------|------------------|
| column major | 'P' | 'L' | $\max(1, lda*m)$ |
| column major | 'P' | 'R' | $\max(1, lda*n)$ |
| row major | 'Q' | 'L' | $\max(1, lda*m)$ |
| row major | 'Q' | 'R' | $\max(1, lda*n)$ |
| row major | 'P' | - | $\max(1, lda*k)$ |

c (size $\max(1, ldc*n)$ for column major layout and $\max(1, ldc*m)$ for row major layout) holds the matrix *C*.

lda

The leading dimension of *a*. Constraints:

$lda \geq \max(1, r)$ for column major layout and at least $\max(1, k)$ for row major layout if *vect* = 'Q';

$lda \geq \max(1, \min(r, k))$ for column major layout and at least $\max(1, r)$ for row major layout if *vect* = 'P'.

ldc

The leading dimension of *c*; $ldc \geq \max(1, m)$ for column major layout and $ldc \geq \max(1, n)$ for row major layout .

tau

Array, size at least $\max(1, \min(r, k))$.

For *vect* = 'Q', the array *tauq* as returned by ?gebrd. For *vect* = 'P', the array *taup* as returned by ?gebrd.

Output Parameters

c

Overwritten by the product Q^*C , Q^T*C , $C*Q$, $C*Q^T$, P^*C , P^T*C , C^*P , or C^*P^T , as specified by *vect*, *side*, and *trans*.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The computed product differs from the exact product by a matrix *E* such that $\|E\|_2 = O(\epsilon) * \|C\|_2$.

The total number of floating-point operations is approximately

$2*n*k(2*m - k)$ if *side* = 'L' and $m \geq k$;

$2*m*k(2*n - k)$ if *side* = 'R' and $n \geq k$;

$2*m^2*n$ if *side* = 'L' and $m < k$;

$2*n^2*m$ if *side* = 'R' and $n < k$.

The complex counterpart of this routine is [unmbr](#).

?ungbr

Generates the complex unitary matrix Q or P^H determined by ?gebrd.

Syntax

```
lapack_int LAPACKE_cungbr (int matrix_layout, char vect, lapack_int m, lapack_int n,
lapack_int k, lapack_complex_float* a, lapack_int lda, const lapack_complex_float*
tau);
```

```
lapack_int LAPACKE_zungbr (int matrix_layout, char vect, lapack_int m, lapack_int n,
lapack_int k, lapack_complex_double* a, lapack_int lda, const lapack_complex_double*
tau);
```

Include Files

- mkl.h

Description

The routine generates the whole or part of the unitary matrices Q and P^H formed by the routines [gebrd/](#)[gebrd](#). Use this routine after a call to [cgebrd/zgebrd](#). All valid combinations of arguments are described in *Input Parameters*; in most cases you need the following:

To compute the whole m -by- m matrix Q , use:

```
LAPACKE_?ungbr(matrix_layout, 'Q', m, m, n, a, lda, tau)
```

(note that the array a must have at least m columns).

To form the n leading columns of Q if $m > n$, use:

```
LAPACKE_?ungbr(matrix_layout, 'Q', m, n, n, a, lda, tau)
```

To compute the whole n -by- n matrix P^H , use:

```
LAPACKE_?ungbr(matrix_layout, 'P', n, n, m, a, lda, tau)
```

(note that the array a must have at least n rows).

To form the m leading rows of P^H if $m < n$, use:

```
LAPACKE_?ungbr(matrix_layout, 'P', m, m, n, a, lda, tau)
```

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>vect</i> | Must be 'Q' or 'P'. If <i>vect</i> = 'Q', the routine generates the matrix Q . If <i>vect</i> = 'P', the routine generates the matrix P^H . |
| <i>m</i> | The number of required rows of Q or P^H . |
| <i>n</i> | The number of required columns of Q or P^H . |
| <i>k</i> | One of the dimensions of A in ?gebrd: If <i>vect</i> = 'Q', the number of columns in A ; If <i>vect</i> = 'P', the number of rows in A . |

Constraints: $m \geq 0$, $n \geq 0$, $k \geq 0$.

For $vect = 'Q'$: $k \leq n \leq m$ if $m > k$, or $m = n$ if $m \leq k$.

For $vect = 'P'$: $k \leq m \leq n$ if $n > k$, or $m = n$ if $n \leq k$.

a

Arrays:

a, size at least $lda*n$ for column major layout and $lda*m$ for row major layout, is the array *a* as returned by ?gebrd.

lda

The leading dimension of *a*; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

tau

For $vect = 'Q'$, the array *tauq* as returned by ?gebrd. For $vect = 'P'$, the array *taup* as returned by ?gebrd.

The dimension of *tau* must be at least $\max(1, \min(m, k))$ for $vect = 'Q'$, or $\max(1, \min(m, k))$ for $vect = 'P'$.

Output Parameters

a

Overwritten by the orthogonal matrix Q or P^T (or the leading rows or columns thereof) as specified by *vect*, *m*, and *n*.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The computed matrix Q differs from an exactly orthogonal matrix by a matrix E such that $\|E\|_2 = O(\epsilon)$.

The approximate numbers of possible floating-point operations are listed below:

To compute the whole matrix Q :

$(16/3)n(3m^2 - 3m*n + n^2)$ if $m > n$;

$(16/3)m^3$ if $m \leq n$.

To form the n leading columns of Q when $m > n$:

$(8/3)n^2(3m - n^2)$.

To compute the whole matrix P^H :

$(16/3)n^3$ if $m \geq n$;

$(16/3)m(3n^2 - 3m*n + m^2)$ if $m < n$.

To form the m leading columns of P^H when $m < n$:

$(8/3)n^2(3m - n^2)$ if $m > n$.

The real counterpart of this routine is [orgbr](#).

?unmbr

Multiplies an arbitrary complex matrix by the unitary matrix Q or P determined by ?gebrd.

Syntax

```
lapack_int LAPACKE_cunmbr (int matrix_layout, char vect, char side, char trans,
lapack_int m, lapack_int n, lapack_int k, const lapack_complex_float* a, lapack_int
lda, const lapack_complex_float* tau, lapack_complex_float* c, lapack_int ldc);
```

```
lapack_int LAPACKE_zunmbr (int matrix_layout, char vect, char side, char trans,
lapack_int m, lapack_int n, lapack_int k, const lapack_complex_double* a, lapack_int
lda, const lapack_complex_double* tau, lapack_complex_double* c, lapack_int ldc);
```

Include Files

- mkl.h

Description

Given an arbitrary complex matrix C , this routine forms one of the matrix products Q^*C , Q^H*C , $C*Q$, $C*Q^H$, $P*C$, P^H*C , $C*P$, or $C*P^H$, where Q and P are unitary matrices computed by a call to [gebrd/gebrd](#). The routine overwrites the product on C .

Input Parameters

In the descriptions below, r denotes the order of Q or P^H :

If $side = 'L'$, $r = m$; if $side = 'R'$, $r = n$.

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>vect</i> | Must be 'Q' or 'P'. If $vect = 'Q'$, then Q or Q^H is applied to C . If $vect = 'P'$, then P or P^H is applied to C . |
| <i>side</i> | Must be 'L' or 'R'. If $side = 'L'$, multipliers are applied to C from the left. If $side = 'R'$, they are applied to C from the right. |
| <i>trans</i> | Must be 'N' or 'C'. If $trans = 'N'$, then Q or P is applied to C . If $trans = 'C'$, then Q^H or P^H is applied to C . |
| <i>m</i> | The number of rows in C . |
| <i>n</i> | The number of columns in C . |
| <i>k</i> | One of the dimensions of A in ?gebrd : If $vect = 'Q'$, the number of columns in A ; If $vect = 'P'$, the number of rows in A . Constraints: $m \geq 0$, $n \geq 0$, $k \geq 0$. |
| <i>a, c</i> | Arrays: a is the array a as returned by ?gebrd . |

The size of a depends on the value of the `matrix_layout`, `vect`, and `side` parameters:

| <code>matrix_layout</code> | <code>vect</code> | <code>side</code> | size |
|----------------------------|-------------------|-------------------|------------------|
| column major | 'Q' | - | $\max(1, lda*k)$ |
| column major | 'P' | 'L' | $\max(1, lda*m)$ |
| column major | 'P' | 'R' | $\max(1, lda*n)$ |
| row major | 'Q' | 'L' | $\max(1, lda*m)$ |
| row major | 'Q' | 'R' | $\max(1, lda*n)$ |
| row major | 'P' | - | $\max(1, lda*k)$ |
| | | | |
| | | | |

c (size $\max(1, ldc*n)$ for column major layout and $\max(1, ldc*m$ for row major layout) holds the matrix C .

`lda`

The leading dimension of a . Constraints:

$lda \geq \max(1, r)$ for column major layout and at least $\max(1, k)$ for row major layout if `vect` = 'Q';

$lda \geq \max(1, \min(r,k))$ for column major layout and at least $\max(1, r)$ for row major layout if `vect` = 'P'.

`ldc`

The leading dimension of c ; $ldc \geq \max(1, m)$.

`tau`

Array, size at least $\max(1, \min(r, k))$.

For `vect` = 'Q', the array `tauq` as returned by `?gebrd`. For `vect` = 'P', the array `taup` as returned by `?gebrd`.

Output Parameters

`c`

Overwritten by the product $Q*C$, Q^H*C , $C*Q$, $C*Q^H$, $P*C$, P^H*C , $C*P$, or $C*P^H$, as specified by `vect`, `side`, and `trans`.

Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

Application Notes

The computed product differs from the exact product by a matrix E such that $\|E\|_2 = O(\epsilon) * \|C\|_2$.

The total number of floating-point operations is approximately

$8*n*k(2*m - k)$ if `side` = 'L' and $m \geq k$;

$8*m*k(2*n - k)$ if `side` = 'R' and $n \geq k$;

$8*m^2*n$ if `side` = 'L' and $m < k$;

$8*n^2*m$ if $side = 'R'$ and $n < k$.

The real counterpart of this routine is [ormbr](#).

?bdsqr

Computes the singular value decomposition of a general matrix that has been reduced to bidiagonal form.

Syntax

```
lapack_int LAPACKE_sbdsqr( int matrix_layout, char uplo, lapack_int n, lapack_int ncv,
lapack_int nru, lapack_int ncc, float* d, float* e, float* vt, lapack_int ldvt, float*
u, lapack_int ldu, float* c, lapack_int ldc );
```

```
lapack_int LAPACKE_dbdsqr( int matrix_layout, char uplo, lapack_int n, lapack_int ncv,
lapack_int nru, lapack_int ncc, double* d, double* e, double* vt, lapack_int ldvt,
double* u, lapack_int ldu, double* c, lapack_int ldc );
```

```
lapack_int LAPACKE_cbdsqr( int matrix_layout, char uplo, lapack_int n, lapack_int ncv,
lapack_int nru, lapack_int ncc, float* d, float* e, lapack_complex_float* vt,
lapack_int ldvt, lapack_complex_float* u, lapack_int ldu, lapack_complex_float* c,
lapack_int ldc );
```

```
lapack_int LAPACKE_zbdsqr( int matrix_layout, char uplo, lapack_int n, lapack_int ncv,
lapack_int nru, lapack_int ncc, double* d, double* e, lapack_complex_double* vt,
lapack_int ldvt, lapack_complex_double* u, lapack_int ldu, lapack_complex_double* c,
lapack_int ldc );
```

Include Files

- mkl.h

Description

The routine computes the singular values and, optionally, the right and/or left singular vectors from the [Singular Value Decomposition](#) (SVD) of a real n -by- n (upper or lower) bidiagonal matrix B using the implicit zero-shift QR algorithm. The SVD of B has the form $B = Q*S*P^H$ where S is the diagonal matrix of singular values, Q is an orthogonal matrix of left singular vectors, and P is an orthogonal matrix of right singular vectors. If left singular vectors are requested, this subroutine actually returns $U*Q$ instead of Q , and, if right singular vectors are requested, this subroutine returns P^H*VT instead of P^H , for given real/complex input matrices U and VT . When U and VT are the orthogonal/unitary matrices that reduce a general matrix A to bidiagonal form: $A = U*B*VT$, as computed by `?gebrd`, then

$$A = (U*Q) * S * (P^H*VT)$$

is the SVD of A . Optionally, the subroutine may also compute Q^H*C for a given real/complex input matrix C .

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', B is an upper bidiagonal matrix. If <i>uplo</i> = 'L', B is a lower bidiagonal matrix. |
| <i>n</i> | The order of the matrix B ($n \geq 0$). |

| | |
|-----------------|--|
| <i>ncvt</i> | The number of columns of the matrix VT , that is, the number of right singular vectors ($ncvt \geq 0$). Set $ncvt = 0$ if no right singular vectors are required. |
| <i>nru</i> | The number of rows in U , that is, the number of left singular vectors ($nru \geq 0$). Set $nru = 0$ if no left singular vectors are required. |
| <i>ncc</i> | The number of columns in the matrix C used for computing the product $Q^H * C$ ($ncc \geq 0$). Set $ncc = 0$ if no matrix C is supplied. |
| <i>d, e</i> | Arrays: d contains the diagonal elements of B . The size of d must be at least $\max(1, n)$. e contains the $(n-1)$ off-diagonal elements of B . The size of e must be at least $\max(1, n - 1)$. |
| <i>vt, u, c</i> | Arrays: vt , size $\max(1, ldvt * ncvt)$ for column major layout and $\max(1, ldvt * n)$ for row major layout, contains an n -by- $ncvt$ matrix VT . vt is not referenced if $ncvt = 0$. u , size $\max(1, ldu * n)$ for column major layout and $\max(1, ldu * nru)$ for row major layout, contains an nru by n matrix U . u is not referenced if $nru = 0$. c , size $\max(1, ldc * ncc)$ for column major layout and $\max(1, ldc * n)$ for row major layout, contains the n -by- ncc matrix C for computing the product $Q^H * C$. |
| <i>ldvt</i> | The leading dimension of vt . Constraints: $ldvt \geq \max(1, n)$ if $ncvt > 0$ for column major layout and $ldvt \geq \max(1, ncvt)$ for row major layout; $ldvt \geq 1$ if $ncvt = 0$. |
| <i>ldu</i> | The leading dimension of u . Constraint: $ldu \geq \max(1, nru)$ for column major layout and $ldu \geq \max(1, n)$ for row major layout . |
| <i>ldc</i> | The leading dimension of c . Constraints: $ldc \geq \max(1, n)$ if $ncc > 0$ for column major layout and $ldc \geq \max(1, ncc)$ for row major layout; $ldc \geq 1$ otherwise. |

Output Parameters

| | |
|----------|---|
| <i>d</i> | On exit, if $info = 0$, overwritten by the singular values in decreasing order (see <i>info</i>). |
| <i>e</i> | On exit, if $info = 0$, e is destroyed. See also <i>info</i> below. |

| | |
|------|---|
| c | Overwritten by the product $Q^H * C$. |
| vt | On exit, this array is overwritten by $P^H * VT$. Not referenced if $ncvt = 0$. |
| u | On exit, this array is overwritten by $U * Q$. Not referenced if $nru = 0$. |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0,

If *ncvt* = *nru* = *ncc* = 0,

- *info* = 1, a split was marked by a positive value in *e*
- *info* = 2, the current block of *z* not diagonalized after 100**n* iterations (in the inner `while` loop)
- *info* = 3, termination criterion of the outer `while` loop is not met (the program created more than *n* unreduced blocks).

In all other cases when *ncvt*, *nru*, or *ncc* > 0, the algorithm did not converge; *d* and *e* contain the elements of a bidiagonal matrix that is orthogonally similar to the input matrix *B*; if *info* = *i*, *i* elements of *e* have not converged to zero.

Application Notes

Each singular value and singular vector is computed to high relative accuracy. However, the reduction to bidiagonal form (prior to calling the routine) may decrease the relative accuracy in the small singular values of the original matrix if its singular values vary widely in magnitude.

If s_i is an exact singular value of *B*, and \hat{s}_i is the corresponding computed value, then

$$|s_i - \hat{s}_i| \leq p(m, n) * \varepsilon * s_i$$

where $p(m, n)$ is a modestly increasing function of *m* and *n*, and ε is the machine precision.

If only singular values are computed, they are computed more accurately than when some singular vectors are also computed (that is, the function $p(m, n)$ is smaller).

If u_i is the corresponding exact left singular vector of *B*, and w_i is the corresponding computed left singular vector, then the angle $\theta(u_i, w_i)$ between them is bounded as follows:

$$\theta(u_i, w_i) \leq p(m, n) * \varepsilon / \min_{i \neq j} (|\sigma_i - \sigma_j| / |\sigma_i + \sigma_j|).$$

Here $\min_{i \neq j} (|\sigma_i - \sigma_j| / |\sigma_i + \sigma_j|)$ is the *relative gap* between σ_i and the other singular values. A similar error bound holds for the right singular vectors.

The total number of real floating-point operations is roughly proportional to n^2 if only the singular values are computed. About $6n^2 * nru$ additional operations ($12n^2 * nru$ for complex flavors) are required to compute the left singular vectors and about $6n^2 * ncvt$ operations ($12n^2 * ncvt$ for complex flavors) to compute the right singular vectors.

?bdsdc

Computes the singular value decomposition of a real bidiagonal matrix using a divide and conquer method.

Syntax

```
lapack_int LAPACKE_sbdsdc (int matrix_layout, char uplo, char compq, lapack_int n,
float* d, float* e, float* u, lapack_int ldu, float* vt, lapack_int ldvt, float* q,
lapack_int* iq);
```

```
lapack_int LAPACKE_dbdsdc (int matrix_layout, char uplo, char compq, lapack_int n,
double* d, double* e, double* u, lapack_int ldu, double* vt, lapack_int ldvt, double*
q, lapack_int* iq);
```

Include Files

- mkl.h

Description

The routine computes the [Singular Value Decomposition](#) (SVD) of a real n -by- n (upper or lower) bidiagonal matrix B : $B = U \Sigma V^T$, using a divide and conquer method, where Σ is a diagonal matrix with non-negative diagonal elements (the singular values of B), and U and V are orthogonal matrices of left and right singular vectors, respectively. `?bdsdc` can be used to compute all singular values, and optionally, singular vectors or singular vectors in compact form.

This routine uses `?lasd0`, `?lasd1`, `?lasd2`, `?lasd3`, `?lasd4`, `?lasd5`, `?lasd6`, `?lasd7`, `?lasd8`, `?lasd9`, `?lasda`, `?lasdq`, `?lasdt`.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', B is an upper bidiagonal matrix. If <i>uplo</i> = 'L', B is a lower bidiagonal matrix. |
| <i>compq</i> | Must be 'N', 'P', or 'I'. If <i>compq</i> = 'N', compute singular values only. If <i>compq</i> = 'P', compute singular values and compute singular vectors in compact form. If <i>compq</i> = 'I', compute singular values and singular vectors. |
| <i>n</i> | The order of the matrix B ($n \geq 0$). |
| <i>d, e</i> | Arrays: d contains the n diagonal elements of the bidiagonal matrix B . The size of d must be at least $\max(1, n)$. e contains the off-diagonal elements of the bidiagonal matrix B . The size of e must be at least $\max(1, n)$. |
| <i>ldu</i> | The leading dimension of the output array u ; $ldu \geq 1$. If singular vectors are desired, then $ldu \geq \max(1, n)$, regardless of the value of <i>matrix_layout</i> . |
| <i>ldvt</i> | The leading dimension of the output array vt ; $ldvt \geq 1$. If singular vectors are desired, then $ldvt \geq \max(1, n)$, regardless of the value of <i>matrix_layout</i> . |

Output Parameters

| | |
|-----------------|--|
| <i>d</i> | If <i>info</i> = 0, overwritten by the singular values of <i>B</i> . |
| <i>e</i> | On exit, <i>e</i> is overwritten. |
| <i>u, vt, q</i> | <p>Arrays: <i>u</i>(size <i>ldu</i>*<i>n</i>), <i>vt</i>(size <i>ldvt</i>*<i>n</i>), <i>q</i>(size $\geq n \cdot (11 + 2 \cdot \text{smlsiz} + 8 \cdot \text{int}(\log_2(n/(\text{smlsiz}+1))))$) where <i>smlsiz</i> is returned by <i>ilaenv</i> and is equal to maximum size of the subproblems at the bottom of the computation tree).</p> <p>If <i>compq</i> = 'I', then on exit <i>u</i> contains the left singular vectors of the bidiagonal matrix <i>B</i>, unless <i>info</i> ≠ 0 (<i>seeinfo</i>). For other values of <i>compq</i>, <i>u</i> is not referenced.</p> <p>if <i>compq</i> = 'I', then on exit <i>vt</i>^T contains the right singular vectors of the bidiagonal matrix <i>B</i>, unless <i>info</i> ≠ 0 (<i>seeinfo</i>). For other values of <i>compq</i>, <i>vt</i> is not referenced.</p> <p>If <i>compq</i> = 'P', then on exit, if <i>info</i> = 0, <i>q</i> and <i>iq</i> contain the left and right singular vectors in a compact form. Specifically, <i>q</i> contains all the float (for <i>sbdsc</i>) or double (for <i>dbdsc</i>) data for singular vectors. For other values of <i>compq</i>, <i>q</i> is not referenced.</p> |
| <i>iq</i> | <p>Array: <i>iq</i>(size $\geq n \cdot (3 + 3 \cdot \text{int}(\log_2(n/(\text{smlsiz}+1))))$) where <i>smlsiz</i> is returned by <i>ilaenv</i> and is equal to maximum size of the subproblems at the bottom of the computation tree.).</p> <p>If <i>compq</i> = 'P', then on exit, if <i>info</i> = 0, <i>q</i> and <i>iq</i> contain the left and right singular vectors in a compact form. Specifically, <i>iq</i> contains all the <i>lapack_int</i> data for singular vectors. For other values of <i>compq</i>, <i>iq</i> is not referenced.</p> |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, the algorithm failed to compute a singular value. The update process of divide and conquer failed.

Symmetric Eigenvalue Problems: LAPACK Computational Routines

Symmetric eigenvalue problems are posed as follows: given an *n*-by-*n* real symmetric or complex Hermitian matrix *A*, find the *eigenvalues* λ and the corresponding *eigenvectors* *z* that satisfy the equation

$$Az = \lambda z \text{ (or, equivalently, } z^H A = \lambda z^H \text{)}.$$

In such eigenvalue problems, all *n* eigenvalues are real not only for real symmetric but also for complex Hermitian matrices *A*, and there exists an orthonormal system of *n* eigenvectors. If *A* is a symmetric or Hermitian positive-definite matrix, all eigenvalues are positive.

To solve a symmetric eigenvalue problem with LAPACK, you usually need to reduce the matrix to tridiagonal form and then solve the eigenvalue problem with the tridiagonal matrix obtained. LAPACK includes routines for reducing the matrix to a tridiagonal form by an orthogonal (or unitary) similarity transformation $A = QTQ^H$ as well as for solving tridiagonal symmetric eigenvalue problems. These routines are listed in [Table "Computational Routines for Solving Symmetric Eigenvalue Problems"](#).

There are different routines for symmetric eigenvalue problems, depending on whether you need all eigenvectors or only some of them or eigenvalues only, whether the matrix A is positive-definite or not, and so on.

These routines are based on three primary algorithms for computing eigenvalues and eigenvectors of symmetric problems: the divide and conquer algorithm, the QR algorithm, and bisection followed by inverse iteration. The divide and conquer algorithm is generally more efficient and is recommended for computing all eigenvalues and eigenvectors. Furthermore, to solve an eigenvalue problem using the divide and conquer algorithm, you need to call only one routine. In general, more than one routine has to be called if the QR algorithm or bisection followed by inverse iteration is used.

Computational Routines for Solving Symmetric Eigenvalue Problems

| Operation | Real symmetric matrices | Complex Hermitian matrices |
|---|-------------------------|----------------------------|
| Reduce to tridiagonal form $A = QTQ^H$ (full storage) | sytrd | hetrd |
| Reduce to tridiagonal form $A = QTQ^H$ (packed storage) | sptrd | hptrd |
| Reduce to tridiagonal form $A = QTQ^H$ (band storage). | sbtrd | hbtrd |
| Generate matrix Q (full storage) | orgtr | ungtr |
| Generate matrix Q (packed storage) | opgtr | upgtr |
| Apply matrix Q (full storage) | ormtr | unmtr |
| Apply matrix Q (packed storage) | opmtr | upmtr |
| Find all eigenvalues of a tridiagonal matrix T | sterf | |
| Find all eigenvalues and eigenvectors of a tridiagonal matrix T | steqr stedc | steqr stedc |
| Find all eigenvalues and eigenvectors of a tridiagonal positive-definite matrix T . | pteqr | pteqr |
| Find selected eigenvalues of a tridiagonal matrix T | stebz stegr | stegr |
| Find selected eigenvectors of a tridiagonal matrix T | stein stegr | stein stegr |
| Find selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix T | stemr | stemr |
| Compute the reciprocal condition numbers for the eigenvectors | disna | disna |

?sytrd

Reduces a real symmetric matrix to tridiagonal form.

Syntax

```
lapack_int LAPACKE_ssytrd (int matrix_layout, char uplo, lapack_int n, float* a,
lapack_int lda, float* d, float* e, float* tau);
```

```
lapack_int LAPACKE_dsytrd (int matrix_layout, char uplo, lapack_int n, double* a,
lapack_int lda, double* d, double* e, double* tau);
```

Include Files

- mkl.h

Description

The routine reduces a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $A = Q^T Q$. The orthogonal matrix Q is not formed explicitly but is represented as a product of $n-1$ elementary reflectors. Routines are provided for working with Q in this representation (see *Application Notes* below).

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of A . |
| <i>n</i> | The order of the matrix A ($n \geq 0$). |
| <i>a</i> | <i>a</i> (size $\max(1, lda * n)$) is an array containing either upper or lower triangular part of the matrix A , as specified by <i>uplo</i> . If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of <i>a</i> contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of <i>a</i> contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced. |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, n)$. |

Output Parameters

| | |
|------------------|--|
| <i>a</i> | On exit, if <i>uplo</i> = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements above the first superdiagonal, with the array <i>tau</i> , represent the orthogonal matrix Q as a product of elementary reflectors; if <i>uplo</i> = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements below the first subdiagonal, with the array <i>tau</i> , represent the orthogonal matrix Q as a product of elementary reflectors. |
| <i>d, e, tau</i> | Arrays: <i>d</i> contains the diagonal elements of the matrix T . The size of <i>d</i> must be at least $\max(1, n)$. <i>e</i> contains the off-diagonal elements of T . The size of <i>e</i> must be at least $\max(1, n-1)$. <i>tau</i> stores ($n-1$) scalars that define elementary reflectors in decomposition of the orthogonal matrix Q in a product of $n-1$ elementary reflectors. <i>tau</i> (n) is used as workspace. |

The size of τ must be at least $\max(1, n)$.

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

The computed matrix T is exactly similar to a matrix $A+E$, where $\|E\|_2 = c(n) * \epsilon * \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision.

The approximate number of floating-point operations is $(4/3)n^3$.

After calling this routine, you can call the following:

`orgtr` to form the computed matrix Q explicitly

`ormtr` to multiply a real matrix by Q .

The complex counterpart of this routine is [?hetrd](#).

?orgtr

Generates the real orthogonal matrix Q determined by ?sytrd.

Syntax

```
lapack_int LAPACKE_sorgtr (int matrix_layout, char uplo, lapack_int n, float* a,
lapack_int lda, const float* tau);
```

```
lapack_int LAPACKE_dorgtr (int matrix_layout, char uplo, lapack_int n, double* a,
lapack_int lda, const double* tau);
```

Include Files

- mkl.h

Description

The routine explicitly generates the n -by- n orthogonal matrix Q formed by [sytrd](#) when reducing a real symmetric matrix A to tridiagonal form: $A = Q * T * Q^T$. Use this routine after a call to [?sytrd](#).

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Use the same <i>uplo</i> as supplied to ?sytrd . |
| <i>n</i> | The order of the matrix Q ($n \geq 0$). |
| <i>a, tau</i> | Arrays: <i>a</i> (size $\max(1, lda * n)$) is the array <i>a</i> as returned by ?sytrd . |

tau is the array *tau* as returned by `?sytrd`.

The size of *tau* must be at least $\max(1, n-1)$.

lda The leading dimension of *a*; at least $\max(1, n)$.

Output Parameters

a Overwritten by the orthogonal matrix *Q*.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = $-i$, the *i*-th parameter had an illegal value.

Application Notes

The computed matrix *Q* differs from an exactly orthogonal matrix by a matrix *E* such that $\|E\|_2 = O(\varepsilon)$, where ε is the machine precision.

The approximate number of floating-point operations is $(4/3)n^3$.

The complex counterpart of this routine is [ungtr](#).

?ormtr

Multiplies a real matrix by the real orthogonal matrix Q determined by ?sytrd.

Syntax

```
lapack_int LAPACKE_sormtr (int matrix_layout, char side, char uplo, char trans,
lapack_int m, lapack_int n, const float* a, lapack_int lda, const float* tau, float*
c, lapack_int ldc);
```

```
lapack_int LAPACKE_dormtr (int matrix_layout, char side, char uplo, char trans,
lapack_int m, lapack_int n, const double* a, lapack_int lda, const double* tau,
double* c, lapack_int ldc);
```

Include Files

- mkl.h

Description

The routine multiplies a real matrix *C* by *Q* or Q^T , where *Q* is the orthogonal matrix *Q* formed by [sytrd](#) when reducing a real symmetric matrix *A* to tridiagonal form: $A = Q^T Q$. Use this routine after a call to `?sytrd`.

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products $Q^T C$, $Q^T C$, $C^T Q$, or $C^T Q$ (overwriting the result on *C*).

Input Parameters

In the descriptions below, *r* denotes the order of *Q*:

If *side* = 'L', $r = m$; if *side* = 'R', $r = n$.

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

| | |
|------------------|---|
| <i>side</i> | Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^T is applied to C from the left. If <i>side</i> = 'R', Q or Q^T is applied to C from the right. |
| <i>uplo</i> | Must be 'U' or 'L'. Use the same <i>uplo</i> as supplied to <code>?sytrd</code> . |
| <i>trans</i> | Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'T', the routine multiplies C by Q^T . |
| <i>m</i> | The number of rows in the matrix C ($m \geq 0$). |
| <i>n</i> | The number of columns in C ($n \geq 0$). |
| <i>a, c, tau</i> | <i>a</i> (size $\max(1, lda * r)$) and <i>tau</i> are the arrays returned by <code>?sytrd</code> . The size of <i>tau</i> must be at least $\max(1, r-1)$. <i>c</i> (size $\max(1, ldc * n)$ for column major layout and $\max(1, ldc * m)$ for row major layout) contains the matrix C . |
| <i>lda</i> | The leading dimension of <i>a</i> ; $lda \geq \max(1, r)$. |
| <i>ldc</i> | The leading dimension of <i>c</i> ; $ldc \geq \max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout . |

Output Parameters

| | |
|----------|--|
| <i>c</i> | Overwritten by the product $Q * C$, $Q^T * C$, $C * Q$, or $C * Q^T$ (as specified by <i>side</i> and <i>trans</i>). |
|----------|--|

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = $-i$, the *i*-th parameter had an illegal value.

Application Notes

The computed product differs from the exact product by a matrix E such that $\|E\|_2 = O(\epsilon) * \|C\|_2$.

The total number of floating-point operations is approximately $2 * m^2 * n$, if *side* = 'L', or $2 * n^2 * m$, if *side* = 'R'.

The complex counterpart of this routine is `unmtr`.

?hetrd

Reduces a complex Hermitian matrix to tridiagonal form.

Syntax

```
lapack_int LAPACKE_chetrd( int matrix_layout, char uplo, lapack_int n,
lapack_complex_float* a, lapack_int lda, float* d, float* e, lapack_complex_float*
tau );
```

```
lapack_int LAPACKE_zhetrd( int matrix_layout, char uplo, lapack_int n,
lapack_complex_double* a, lapack_int lda, double* d, double* e, lapack_complex_double*
tau );
```

Include Files

- mkl.h

Description

The routine reduces a complex Hermitian matrix A to symmetric tridiagonal form T by a unitary similarity transformation: $A = Q^*T^*Q^H$. The unitary matrix Q is not formed explicitly but is represented as a product of $n-1$ elementary reflectors. Routines are provided to work with Q in this representation. (They are described later in this section.)

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of A . |
| <i>n</i> | The order of the matrix A ($n \geq 0$). |
| <i>a</i> | <i>a</i> (size $\max(1, lda*n)$) is an array containing either upper or lower triangular part of the matrix A , as specified by <i>uplo</i> . If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of <i>a</i> contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of <i>a</i> contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced. |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, n)$. |

Output Parameters

| | |
|-------------|--|
| <i>a</i> | On exit, if <i>uplo</i> = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements above the first superdiagonal, with the array <i>tau</i> , represent the orthogonal matrix Q as a product of elementary reflectors; if <i>uplo</i> = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements below the first subdiagonal, with the array <i>tau</i> , represent the orthogonal matrix Q as a product of elementary reflectors. |
| <i>d, e</i> | Arrays: |

d contains the diagonal elements of the matrix T .

The dimension of d must be at least $\max(1, n)$.

e contains the off-diagonal elements of T .

The dimension of e must be at least $\max(1, n-1)$.

τ

Array, size at least $\max(1, n-1)$. Stores $(n-1)$ scalars that define elementary reflectors in decomposition of the unitary matrix Q in a product of $n-1$ elementary reflectors.

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

The computed matrix T is exactly similar to a matrix $A + E$, where $\|E\|_2 = c(n) * \epsilon * \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision.

The approximate number of floating-point operations is $(16/3)n^3$.

After calling this routine, you can call the following:

`ungtr` to form the computed matrix Q explicitly

`unmtr` to multiply a complex matrix by Q .

The real counterpart of this routine is [?sytrd](#).

?ungtr

Generates the complex unitary matrix Q determined by ?hetrd.

Syntax

```
lapack_int LAPACKE_cungtr (int matrix_layout, char uplo, lapack_int n,
lapack_complex_float* a, lapack_int lda, const lapack_complex_float* tau);
```

```
lapack_int LAPACKE_zungtr (int matrix_layout, char uplo, lapack_int n,
lapack_complex_double* a, lapack_int lda, const lapack_complex_double* tau);
```

Description

The routine multiplies a complex matrix C by Q or Q^H , where Q is the unitary matrix Q formed by [hetrd](#) when reducing a complex Hermitian matrix A to tridiagonal form: $A = Q^T Q^H$. Use this routine after a call to `?hetrd`.

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products $Q^H C$, $Q^H C Q$, $C Q$, or $C Q^H$ (overwriting the result on C).

Input Parameters

In the descriptions below, r denotes the order of Q :

If $side = 'L'$, $r = m$; if $side = 'R'$, $r = n$.

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>side</i> | Must be either 'L' or 'R'. If $side = 'L'$, Q or Q^H is applied to C from the left. If $side = 'R'$, Q or Q^H is applied to C from the right. |
| <i>uplo</i> | Must be 'U' or 'L'. Use the same <i>uplo</i> as supplied to <code>?hetrd</code> . |
| <i>trans</i> | Must be either 'N' or 'T'. If $trans = 'N'$, the routine multiplies C by Q . If $trans = 'C'$, the routine multiplies C by Q^H . |
| <i>m</i> | The number of rows in the matrix C ($m \geq 0$). |
| <i>n</i> | The number of columns in C ($n \geq 0$). |
| <i>a, c, tau</i> | a (size $\max(1, lda*r)$) and tau are the arrays returned by <code>?hetrd</code> . The dimension of tau must be at least $\max(1, r-1)$. c (size $\max(1, ldc*n)$ for column major layout and $\max(1, ldc*m)$ for row major layout) contains the matrix C . |
| <i>lda</i> | The leading dimension of a ; $lda \geq \max(1, r)$. |
| <i>ldc</i> | The leading dimension of c ; $ldc \geq \max(1, n)$ for column major layout and $ldc \geq \max(1, m)$ for row major layout. |

Output Parameters

c Overwritten by the product $Q*C$, Q^H*C , $C*Q$, or $C*Q^H$ (as specified by *side* and *trans*).

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

The computed product differs from the exact product by a matrix E such that $\|E\|_2 = O(\epsilon) * \|C\|_2$, where ϵ is the machine precision.

The total number of floating-point operations is approximately $8*m^2*n$ if $side = 'L'$ or $8*n^2*m$ if $side = 'R'$.

The real counterpart of this routine is [ormtr](#).

?sptrd

Reduces a real symmetric matrix to tridiagonal form using packed storage.

Syntax

```
lapack_int LAPACKE_ssptrd (int matrix_layout, char uplo, lapack_int n, float* ap,
float* d, float* e, float* tau);
```

```
lapack_int LAPACKE_dsptrd (int matrix_layout, char uplo, lapack_int n, double* ap,
double* d, double* e, double* tau);
```

Include Files

- mkl.h

Description

The routine reduces a packed real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $A = Q^*T^*Q^T$. The orthogonal matrix Q is not formed explicitly but is represented as a product of $n-1$ elementary reflectors. Routines are provided for working with Q in this representation. See *Application Notes* below for details.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangle of A . If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangle of A . |
| <i>n</i> | The order of the matrix A ($n \geq 0$). |
| <i>ap</i> | Array, size at least $\max(1, n(n+1)/2)$. Contains either upper or lower triangle of A (as specified by <i>uplo</i>) in the packed form described in Matrix Storage Schemes . |

Output Parameters

| | |
|------------------|---|
| <i>ap</i> | Overwritten by the tridiagonal matrix T and details of the orthogonal matrix Q , as specified by <i>uplo</i> . |
| <i>d, e, tau</i> | Arrays: <i>d</i> contains the diagonal elements of the matrix T . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> contains the off-diagonal elements of T . The dimension of <i>e</i> must be at least $\max(1, n-1)$. <i>tau</i> Stores $(n-1)$ scalars that define elementary reflectors in decomposition of the matrix Q in a product of $n-1$ reflectors. The dimension of <i>tau</i> must be at least $\max(1, n-1)$. |

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

The matrix Q is represented as a product of $n-1$ *elementary reflectors*, as follows :

- If $uplo = 'U'$, $Q = H(n-1) \dots H(2)H(1)$

Each $H(i)$ has the form

$$H(i) = I - \tau v v^T$$

where τ is a real scalar and v is a real vector with $v(i+1:n) = 0$ and $v(i) = 1$.

On exit, τ is stored in $\tau[i - 1]$, and $v(1:i-1)$ is stored in AP , overwriting $A(1:i-1, i+1)$.

- If $uplo = 'L'$, $Q = H(1)H(2) \dots H(n-1)$

Each $H(i)$ has the form

$$H(i) = I - \tau v v^T$$

where τ is a real scalar and v is a real vector with $v(1:i) = 0$ and $v(i+1) = 1$.

On exit, τ is stored in $\tau[i - 1]$, and $v(i+2:n)$ is stored in AP , overwriting $A(i+2:n, i)$.

The computed matrix T is exactly similar to a matrix $A+E$, where $\|E\|_2 = c(n) * \epsilon * \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision. The approximate number of floating-point operations is $(4/3)n^3$.

After calling this routine, you can call the following:

`opgtr` to form the computed matrix Q explicitly

`opmtr` to multiply a real matrix by Q .

The complex counterpart of this routine is `hptrd`.

?opgtr

Generates the real orthogonal matrix Q determined by ?sptrd.

Syntax

```
lapack_int LAPACKE_sopgtr (int matrix_layout, char uplo, lapack_int n, const float* ap,
const float* tau, float* q, lapack_int ldq);
```

```
lapack_int LAPACKE_dopgtr (int matrix_layout, char uplo, lapack_int n, const double*
ap, const double* tau, double* q, lapack_int ldq);
```

Include Files

Description

The routine multiplies a real matrix C by Q or Q^T , where Q is the orthogonal matrix Q formed by `sptrd` when reducing a packed real symmetric matrix A to tridiagonal form: $A = Q^T Q$. Use this routine after a call to `sptrd`.

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products $Q^T C$, $Q^T C$, $C^T Q$, or $C^T Q^T$ (overwriting the result on C).

Input Parameters

In the descriptions below, r denotes the order of Q :

If *side* = 'L', $r = m$; if *side* = 'R', $r = n$.

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>side</i> | Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^T is applied to C from the left. If <i>side</i> = 'R', Q or Q^T is applied to C from the right. |
| <i>uplo</i> | Must be 'U' or 'L'. Use the same <i>uplo</i> as supplied to <code>?sptrd</code> . |
| <i>trans</i> | Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'T', the routine multiplies C by Q^T . |
| <i>m</i> | The number of rows in the matrix C ($m \geq 0$). |
| <i>n</i> | The number of columns in C ($n \geq 0$). |
| <i>ap, tau, c</i> | <i>ap</i> and <i>tau</i> are the arrays returned by <code>?sptrd</code> . The dimension of <i>ap</i> must be at least $\max(1, r(r+1)/2)$. The dimension of <i>tau</i> must be at least $\max(1, r-1)$. <i>c</i> (size $\max(1, ldc*n)$ for column major layout and $\max(1, ldc*m)$ for row major layout) contains the matrix C . |
| <i>ldc</i> | The leading dimension of <i>c</i> ; $ldc \geq \max(1, n)$ for column major layout and $ldc \geq \max(1, m)$ for row major layout. |

Output Parameters

| | |
|----------|--|
| <i>c</i> | Overwritten by the product $Q^T C$, $Q^T C$, $C^T Q$, or $C^T Q^T$ (as specified by <i>side</i> and <i>trans</i>). |
|----------|--|

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = $-i$, the i -th parameter had an illegal value.

Application Notes

The computed product differs from the exact product by a matrix E such that $\|E\|_2 = O(\epsilon) \|C\|_2$, where ϵ is the machine precision.

The total number of floating-point operations is approximately $2*m^2*n$ if $side = 'L'$, or $2*n^2*m$ if $side = 'R'$.

The complex counterpart of this routine is [upmtr](#).

?hptrd

Reduces a complex Hermitian matrix to tridiagonal form using packed storage.

Syntax

```
lapack_int LAPACKE_chptrd( int matrix_layout, char uplo, lapack_int n,
lapack_complex_float* ap, float* d, float* e, lapack_complex_float* tau );

lapack_int LAPACKE_zhptrd( int matrix_layout, char uplo, lapack_int n,
lapack_complex_double* ap, double* d, double* e, lapack_complex_double* tau );
```

Include Files

- `mkl.h`

Description

The routine reduces a packed complex Hermitian matrix A to symmetric tridiagonal form T by a unitary similarity transformation: $A = Q^*T^*Q^H$. The unitary matrix Q is not formed explicitly but is represented as a product of $n-1$ elementary reflectors. Routines are provided for working with Q in this representation (see *Application Notes* below).

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>uplo</code> | Must be 'U' or 'L'. If <code>uplo = 'U'</code> , <code>ap</code> stores the packed upper triangle of A . If <code>uplo = 'L'</code> , <code>ap</code> stores the packed lower triangle of A . |
| <code>n</code> | The order of the matrix A ($n \geq 0$). |
| <code>ap</code> | Array, size at least $\max(1, n(n+1)/2)$. Contains either upper or lower triangle of A (as specified by <code>uplo</code>) in the packed form described in " Matrix Storage Schemes ". |

Output Parameters

| | |
|-------------------|--|
| <code>ap</code> | Overwritten by the tridiagonal matrix T and details of the unitary matrix Q , as specified by <code>uplo</code> . |
| <code>d, e</code> | Arrays: <code>d</code> contains the diagonal elements of the matrix T . The size of <code>d</code> must be at least $\max(1, n)$. |

e contains the off-diagonal elements of T .

The size of e must be at least $\max(1, n-1)$.

tau Array, size at least $\max(1, n-1)$. Stores $(n-1)$ scalars that define elementary reflectors in decomposition of the unitary matrix Q in a product of reflectors.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = $-i$, the i -th parameter had an illegal value.

Application Notes

The computed matrix T is exactly similar to a matrix $A + E$, where $\|E\|_2 = c(n) * \epsilon * \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision.

The approximate number of floating-point operations is $(16/3)n^3$.

After calling this routine, you can call the following:

[upgtr](#) to form the computed matrix Q explicitly

[upmtr](#) to multiply a complex matrix by Q .

The real counterpart of this routine is [sptrd](#).

?upgtr

Generates the complex unitary matrix Q determined by ?hptrd.

Syntax

```
lapack_int LAPACKE_cupgtr (int matrix_layout, char uplo, lapack_int n, const
lapack_complex_float* ap, const lapack_complex_float* tau, lapack_complex_float* q,
lapack_int ldq);
```

```
lapack_int LAPACKE_zupgtr (int matrix_layout, char uplo, lapack_int n, const
lapack_complex_double* ap, const lapack_complex_double* tau, lapack_complex_double* q,
lapack_int ldq);
```

Include Files

- `mkl.h`

Description

The routine explicitly generates the n -by- n unitary matrix Q formed by [hptrd](#) when reducing a packed complex Hermitian matrix A to tridiagonal form: $A = Q^*T^*Q^H$. Use this routine after a call to [?hptrd](#).

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

uplo Must be 'U' or 'L'. Use the same *uplo* as supplied to [?hptrd](#).

| | |
|------------|--|
| n | The order of the matrix Q ($n \geq 0$). |
| ap, τ | Arrays ap and τ , as returned by <code>?hptrd</code> . The dimension of ap must be at least $\max(1, n(n+1)/2)$. The dimension of τ must be at least $\max(1, n-1)$. |
| ldq | The leading dimension of the output array q ; at least $\max(1, n)$. |

Output Parameters

| | |
|-----|--|
| q | Array, size (size $\max(1, ldq*n)$) . Contains the computed matrix Q . |
|-----|--|

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

The computed matrix Q differs from an exactly orthogonal matrix by a matrix E such that $\|E\|_2 = O(\epsilon)$, where ϵ is the machine precision.

The approximate number of floating-point operations is $(16/3)n^3$.

The real counterpart of this routine is [opgtr](#).

?upmtr

Multiplies a complex matrix by the unitary matrix Q determined by ?hptrd.

Syntax

```
lapack_int LAPACKE_cupmtr (int matrix_layout, char side, char uplo, char trans,
lapack_int m, lapack_int n, const lapack_complex_float* ap, const lapack_complex_float*
tau, lapack_complex_float* c, lapack_int ldc);
```

```
lapack_int LAPACKE_zupmtr (int matrix_layout, char side, char uplo, char trans,
lapack_int m, lapack_int n, const lapack_complex_double* ap, const
lapack_complex_double* tau, lapack_complex_double* c, lapack_int ldc);
```

Include Files

- `mkl.h`

Description

The routine multiplies a complex matrix C by Q or Q^H , where Q is the unitary matrix formed by [hptrd](#) when reducing a packed complex Hermitian matrix A to tridiagonal form: $A = Q^*T^*Q^H$. Use this routine after a call to `?hptrd`.

Depending on the parameters $side$ and $trans$, the routine can form one of the matrix products Q^*C , Q^H^*C , C^*Q , or C^*Q^H (overwriting the result on C).

Input Parameters

In the descriptions below, r denotes the order of Q :

If $side = 'L'$, $r = m$; if $side = 'R'$, $r = n$.

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>side</i> | Must be either 'L' or 'R'. If $side = 'L'$, Q or Q^H is applied to C from the left. If $side = 'R'$, Q or Q^H is applied to C from the right. |
| <i>uplo</i> | Must be 'U' or 'L'. Use the same <i>uplo</i> as supplied to ?hptrd. |
| <i>trans</i> | Must be either 'N' or 'T'. If $trans = 'N'$, the routine multiplies C by Q . If $trans = 'T'$, the routine multiplies C by Q^H . |
| <i>m</i> | The number of rows in the matrix C ($m \geq 0$). |
| <i>n</i> | The number of columns in C ($n \geq 0$). |
| <i>ap, tau, c,</i> | <i>ap</i> and <i>tau</i> are the arrays returned by ?hptrd. The size of <i>ap</i> must be at least $\max(1, r(r+1)/2)$. The size of <i>tau</i> must be at least $\max(1, r-1)$. <i>c</i> (size $\max(1, ldc*n)$ for column major layout and $\max(1, ldc*m)$ for row major layout) contains the matrix C . |
| <i>ldc</i> | The leading dimension of <i>c</i> ; $ldc \geq \max(1, m)$ for column major layout and $ldc \geq \max(1, n)$ for row major layout . |

Output Parameters

| | |
|----------|--|
| <i>c</i> | Overwritten by the product $Q^H C$, $Q^H C$, $C^H Q$, or $C^H Q^H$ (as specified by <i>side</i> and <i>trans</i>). |
|----------|--|

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

The computed product differs from the exact product by a matrix E such that $\|E\|_2 = O(\epsilon) * \|C\|_2$, where ϵ is the machine precision.

The total number of floating-point operations is approximately $8*m^2*n$ if $side = 'L'$ or $8*n^2*m$ if $side = 'R'$.

The real counterpart of this routine is [opmtr](#).

?sbtrd

Reduces a real symmetric band matrix to tridiagonal form.

Syntax

```
lapack_int LAPACKE_ssbtrd (int matrix_layout, char vect, char uplo, lapack_int n,
lapack_int kd, float* ab, lapack_int ldab, float* d, float* e, float* q, lapack_int
ldq);

lapack_int LAPACKE_dsbtrd (int matrix_layout, char vect, char uplo, lapack_int n,
lapack_int kd, double* ab, lapack_int ldab, double* d, double* e, double* q,
lapack_int ldq);
```

Include Files

- mkl.h

Description

The routine reduces a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $A = Q^*T^*Q^T$. The orthogonal matrix Q is determined as a product of Givens rotations.

If required, the routine can also form the matrix Q explicitly.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>vect</i> | Must be 'V', 'N', or 'U'. If <i>vect</i> = 'V', the routine returns the explicit matrix Q . If <i>vect</i> = 'N', the routine does not return Q . If <i>vect</i> = 'U', the routine updates matrix X by forming X^*Q . |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of A . |
| <i>n</i> | The order of the matrix A ($n \geq 0$). |
| <i>kd</i> | The number of super- or sub-diagonals in A ($kd \geq 0$). |
| <i>ab, q</i> | <i>ab</i> (size at least $\max(1, ldab*n)$ for column major layout and at least $\max(1, ldab*(kd+1))$ for row major layout) is an array containing either upper or lower triangular part of the matrix A (as specified by <i>uplo</i>) in band storage format. <i>q</i> (size $\max(1, ldq*n)$) is an array. If <i>vect</i> = 'U', the <i>q</i> array must contain an n -by- n matrix X . If <i>vect</i> = 'N' or 'V', the <i>q</i> parameter need not be set. |

| | |
|-------------|--|
| <i>ldab</i> | The leading dimension of <i>ab</i> ; at least $kd+1$ for column major layout and n for row major layout . |
| <i>ldq</i> | The leading dimension of <i>q</i> . Constraints: $ldq \geq \max(1, n)$ if <i>vect</i> = 'V' or 'U'; $ldq \geq 1$ if <i>vect</i> = 'N'. |

Output Parameters

| | |
|----------------|---|
| <i>ab</i> | On exit, the diagonal elements of the array <i>ab</i> are overwritten by the diagonal elements of the tridiagonal matrix <i>T</i> . If $kd > 0$, the elements on the first superdiagonal (if <i>uplo</i> = 'U') or the first subdiagonal (if <i>uplo</i> = 'L') are overwritten by the off-diagonal elements of <i>T</i> . The rest of <i>ab</i> is overwritten by values generated during the reduction. |
| <i>d, e, q</i> | Arrays: <i>d</i> contains the diagonal elements of the matrix <i>T</i> . The size of <i>d</i> must be at least $\max(1, n)$. <i>e</i> contains the off-diagonal elements of <i>T</i> . The size of <i>e</i> must be at least $\max(1, n-1)$. <i>q</i> is not referenced if <i>vect</i> = 'N'. If <i>vect</i> = 'V', <i>q</i> contains the n -by- n matrix <i>Q</i> . If <i>vect</i> = 'U', <i>q</i> contains the product $X^* Q$. |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = $-i$, the i -th parameter had an illegal value.

Application Notes

The computed matrix *T* is exactly similar to a matrix $A+E$, where $\|E\|_2 = c(n)*\epsilon*\|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision. The computed matrix *Q* differs from an exactly orthogonal matrix by a matrix *E* such that $\|E\|_2 = O(\epsilon)$.

The total number of floating-point operations is approximately $6n^2*kd$ if *vect* = 'N', with $3n^3*(kd-1)/kd$ additional operations if *vect* = 'V'.

The complex counterpart of this routine is [hbtrd](#).

?hbtrd

Reduces a complex Hermitian band matrix to tridiagonal form.

Syntax

```
lapack_int LAPACKE_chbtrd( int matrix_layout, char vect, char uplo, lapack_int n,
lapack_int kd, lapack_complex_float* ab, lapack_int ldab, float* d, float* e,
lapack_complex_float* q, lapack_int ldq );
```

```
lapack_int LAPACKE_zhbtrd( int matrix_layout, char vect, char uplo, lapack_int n,
lapack_int kd, lapack_complex_double* ab, lapack_int ldab, double* d, double* e,
lapack_complex_double* q, lapack_int ldq );
```

Include Files

The rest of <i>ab</i> is overwritten by values generated during the reduction. |
| <i>d, e</i> | Arrays: <i>d</i> contains the diagonal elements of the matrix <i>T</i> . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> contains the off-diagonal elements of <i>T</i> . The dimension of <i>e</i> must be at least $\max(1, n-1)$. |
| <i>q</i> | If <i>vect</i> = 'N', <i>q</i> is not referenced. If <i>vect</i> = 'V', <i>q</i> contains the <i>n</i> -by- <i>n</i> matrix <i>Q</i> . If <i>vect</i> = 'U', <i>q</i> contains the product $X^* Q$. |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The computed matrix *T* is exactly similar to a matrix $A + E$, where $\|E\|_2 = c(n) * \epsilon * \|A\|_2$, $c(n)$ is a modestly increasing function of *n*, and ϵ is the machine precision. The computed matrix *Q* differs from an exactly unitary matrix by a matrix *E* such that $\|E\|_2 = O(\epsilon)$.

The total number of floating-point operations is approximately $20n^2 * kd$ if *vect* = 'N', with $10n^3 * (kd-1) / kd$ additional operations if *vect* = 'V'.

The real counterpart of this routine is [sbtrd](#).

?sterf

Computes all eigenvalues of a real symmetric tridiagonal matrix using QR algorithm.

Syntax

```
lapack_int LAPACKE_ssterf (lapack_int n, float* d, float* e);
lapack_int LAPACKE_dsterf (lapack_int n, double* d, double* e);
```

Include Files

- mkl.h

Description

The routine computes all the eigenvalues of a real symmetric tridiagonal matrix *T* (which can be obtained by reducing a symmetric or Hermitian matrix to tridiagonal form). The routine uses a square-root-free variant of the *QR* algorithm.

If you need not only the eigenvalues but also the eigenvectors, call [steqr](#).

Input Parameters

| | |
|--------|---|
| n | The order of the matrix T ($n \geq 0$). |
| d, e | Arrays: d contains the diagonal elements of T . The dimension of d must be at least $\max(1, n)$. e contains the off-diagonal elements of T . The dimension of e must be at least $\max(1, n-1)$. |

Output Parameters

| | |
|-----|---|
| d | The n eigenvalues in ascending order, unless $info > 0$. See also <i>info</i> . |
| e | On exit, the array is overwritten; see <i>info</i> . |

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = i$, the algorithm failed to find all the eigenvalues after $30n$ iterations:

i off-diagonal elements have not converged to zero. On exit, d and e contain, respectively, the diagonal and off-diagonal elements of a tridiagonal matrix orthogonally similar to T .

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $\|E\|_2 = O(\epsilon) * \|T\|_2$, where ϵ is the machine precision.

If λ_i is an exact eigenvalue, and m_i is the corresponding computed value, then

$$|\mu_i - \lambda_i| \leq c(n) * \epsilon * \|T\|_2$$

where $c(n)$ is a modestly increasing function of n .

The total number of floating-point operations depends on how rapidly the algorithm converges. Typically, it is about $14n^2$.

?steqr

Computes all eigenvalues and eigenvectors of a symmetric or Hermitian matrix reduced to tridiagonal form (QR algorithm).

Syntax

```
lapack_int LAPACKE_ssteqr( int matrix_layout, char compz, lapack_int n, float* d,
float* e, float* z, lapack_int ldz );
```

```
lapack_int LAPACKE_dsteqr( int matrix_layout, char compz, lapack_int n, double* d,
double* e, double* z, lapack_int ldz );
```

```
lapack_int LAPACKE_csteqr( int matrix_layout, char compz, lapack_int n, float* d,
float* e, lapack_complex_float* z, lapack_int ldz );
```

```
lapack_int LAPACKE_zsteqr( int matrix_layout, char compz, lapack_int n, double* d,
double* e, lapack_complex_double* z, lapack_int ldz );
```

Include Files

- mkl.h

Description

The routine computes all the eigenvalues and (optionally) all the eigenvectors of a real symmetric tridiagonal matrix T . In other words, the routine can compute the spectral factorization: $T = Z\Lambda Z^T$. Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i ; Z is an orthogonal matrix whose columns are eigenvectors. Thus,

$$T^*z_i = \lambda_i^*z_i \text{ for } i = 1, 2, \dots, n.$$

The routine normalizes the eigenvectors so that $\|z_i\|_2 = 1$.

You can also use the routine for computing the eigenvalues and eigenvectors of an arbitrary real symmetric (or complex Hermitian) matrix A reduced to tridiagonal form T : $A = Q^*T^*Q^H$. In this case, the spectral factorization is as follows: $A = Q^*T^*Q^H = (Q^*Z)^*\Lambda^*(Q^*Z)^H$. Before calling `?steqr`, you must reduce A to tridiagonal form and generate the explicit matrix Q by calling the following routines:

| | for real matrices: | for complex matrices: |
|-----------------------|---------------------------|---------------------------|
| full storage | ?sytrd, ?orgtr | ?hetrd, ?ungtr |
| packed storage | ?sptrd, ?opgtr | ?hptrd, ?upgtr |
| band storage | ?sbtrd(<i>vect</i> ='V') | ?hbtrd(<i>vect</i> ='V') |

If you need eigenvalues only, it's more efficient to call [sterf](#). If T is positive-definite, [pteqr](#) can compute small eigenvalues more accurately than `?steqr`.

To solve the problem by a single call, use one of the divide and conquer routines [stevd](#), [syevd](#), [spevd](#), or [sbevd](#) for real symmetric matrices or [heevd](#), [hpevd](#), or [hbevd](#) for complex Hermitian matrices.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>compz</i> | Must be 'N' or 'I' or 'V'. If <i>compz</i> = 'N', the routine computes eigenvalues only. If <i>compz</i> = 'I', the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix T . If <i>compz</i> = 'V', the routine computes the eigenvalues and eigenvectors of the original symmetric matrix. On entry, z must contain the orthogonal matrix used to reduce the original matrix to tridiagonal form. |
| <i>n</i> | The order of the matrix T ($n \geq 0$). |
| <i>d, e</i> | Arrays: d contains the diagonal elements of T . The size of d must be at least $\max(1, n)$. e contains the off-diagonal elements of T . |

The size of e must be at least $\max(1, n-1)$.

z Array, size $\max(1, ldz*n)$.

If $compz = 'N'$ or $'I'$, z need not be set.

If $vect = 'V'$, z must contain the orthogonal matrix used in the reduction to tridiagonal form.

ldz The leading dimension of z . Constraints:

$ldz \geq 1$ if $compz = 'N'$;

$ldz \geq \max(1, n)$ if $compz = 'V'$ or $'I'$.

Output Parameters

d The n eigenvalues in ascending order, unless $info > 0$.

See also *info*.

e On exit, the array is overwritten; see *info*.

z If $info = 0$, contains the n -by- n matrix the columns of which are orthonormal eigenvectors (the i -th column corresponds to the i -th eigenvalue).

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = i$, the algorithm failed to find all the eigenvalues after $30n$ iterations: i off-diagonal elements have not converged to zero. On exit, d and e contain, respectively, the diagonal and off-diagonal elements of a tridiagonal matrix orthogonally similar to T .

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $\|E\|_2 = O(\epsilon) * \|T\|_2$, where ϵ is the machine precision.

If λ_j is an exact eigenvalue, and μ_j is the corresponding computed value, then

$$|\mu_i - \lambda_i| \leq c(n) * \epsilon * \|T\|_2$$

where $c(n)$ is a modestly increasing function of n .

If z_i is the corresponding exact eigenvector, and w_i is the corresponding computed vector, then the angle $\theta(z_i, w_i)$ between them is bounded as follows:

$$\theta(z_i, w_i) \leq c(n) * \epsilon * \|T\|_2 / \min_{i \neq j} |\lambda_i - \lambda_j|.$$

The total number of floating-point operations depends on how rapidly the algorithm converges. Typically, it is about

$$24n^2 \text{ if } compz = 'N';$$

$$7n^3 \text{ (for complex flavors, } 14n^3) \text{ if } compz = 'V' \text{ or } 'I'.$$

?stemr

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

Syntax

```
lapack_int LAPACKE_sstemr( int matrix_layout, char jobz, char range, lapack_int n,

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T . Any such unreduced matrix has a well defined set of pairwise different real eigenvalues, the corresponding real eigenvectors are pairwise orthogonal.

The spectrum may be computed either completely or partially by specifying either an interval $(vl, vu]$ or a range of indices $il:iu$ for the desired eigenvalues.

Depending on the number of desired eigenvalues, these are computed either by bisection or the *dqds* algorithm. Numerically orthogonal eigenvectors are computed by the use of various suitable $L^*D^*L^T$ factorizations near clusters of close eigenvalues (referred to as RRRs, Relatively Robust Representations). An informal sketch of the algorithm follows.

For each unreduced block (submatrix) of T ,

- Compute $T - \sigma I = L^*D^*L^T$, so that L and D define all the wanted eigenvalues to high relative accuracy. This means that small relative changes in the entries of L and D cause only small relative changes in the eigenvalues and eigenvectors. The standard (unfactored) representation of the tridiagonal matrix T does not have this property in general.
- Compute the eigenvalues to suitable accuracy. If the eigenvectors are desired, the algorithm attains full accuracy of the computed eigenvalues only right before the corresponding vectors have to be computed, see steps c and d.
- For each cluster of close eigenvalues, select a new shift close to the cluster, find a new factorization, and refine the shifted eigenvalues to suitable accuracy.
- For each eigenvalue with a large enough relative separation compute the corresponding eigenvector by forming a rank revealing twisted factorization. Go back to step c for any clusters that remain.

For more details, see: [Dhillon04], [Dhillon04-02], [Dhillon97]

Input Parameters

| | |
|-----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobz</i> | <p>Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then only eigenvalues are computed.</p> <p>If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.</p> |
| <i>range</i> | <p>Must be 'A' or 'V' or 'I'.</p> <p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes all eigenvalues in the half-open interval: (<i>vl</i>, <i>vu</i>].</p> <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.</p> |
| <i>n</i> | The order of the matrix <i>T</i> ($n \geq 0$). |
| <i>d</i> | <p>Array, size <i>n</i>.</p> <p>Contains <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i>.</p> |
| <i>e</i> | <p>Array, size <i>n</i>.</p> <p>Contains (<i>n</i>-1) off-diagonal elements of the tridiagonal matrix <i>T</i> in elements 0 to <i>n</i>-2 of <i>e</i>. <i>e</i>[<i>n</i> - 1] need not be set on input, but is used internally as workspace.</p> |
| <i>vl</i> , <i>vu</i> | <p>If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$.</p> <p>If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.</p> |
| <i>il</i> , <i>iu</i> | <p>If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.</p> <p>Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$.</p> <p>If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.</p> |
| <i>ldz</i> | <p>The leading dimension of the output array <i>z</i>.</p> <p>if <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout ;</p> <p>$ldz \geq 1$ otherwise.</p> |
| <i>nzc</i> | <p>The number of eigenvectors to be held in the array <i>z</i>.</p> <p>If <i>range</i> = 'A', then $nzc \geq \max(1, n)$;</p> <p>If <i>range</i> = 'V', then <i>nzc</i> is greater than or equal to the number of eigenvalues in the half-open interval: (<i>vl</i>, <i>vu</i>].</p> <p>If <i>range</i> = 'I', then $nzc \geq iu - il + 1$.</p> <p>If <i>nzc</i> = -1, then a workspace query is assumed; the routine calculates the number of columns of the array <i>z</i> that are needed to hold the eigenvectors.</p> |

This value is returned as the first entry of the array z , and no error message related to nzc is issued by the routine `xerbla`.

tryrac

If *tryrac* is true, it indicates that the code should check whether the tridiagonal matrix defines its eigenvalues to high relative accuracy. If so, the code uses relative-accuracy preserving algorithms that might be (a bit) slower depending on the matrix. If the matrix does not define its eigenvalues to high relative accuracy, the code can use possibly faster algorithms.

If *tryrac* is not true, the code is not required to guarantee relatively accurate eigenvalues and can use the fastest possible techniques.

Output Parameters

d

On exit, the array d is overwritten.

e

On exit, the array e is overwritten.

m

The total number of eigenvalues found, $0 \leq m \leq n$.

If *range* = 'A', then $m=n$, and if *range* = 'I', then $m=i_u-i_l+1$.

w

Array, size n .

The first m elements contain the selected eigenvalues in ascending order.

z

Array z (size $\max(1, ldz*m)$ for column major layout and $\max(1, ldz*n)$ for row major layout).

If *jobz* = 'V', and *info* = 0, then the first m columns of z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.

If *jobz* = 'N', then z is not referenced.

Note: the exact value of m is not known in advance and can be computed with a workspace query by setting $nzc=-1$, see description of the parameter *nzc*.

isuppz

Array, size $(2*\max(1, m))$.

The support of the eigenvectors in z , that is the indices indicating the nonzero elements in z . The i -th computed eigenvector is nonzero only in elements $isuppz[2*i - 2]$ through $isuppz[2*i - 1]$. This is relevant in the case when the matrix is split. *isuppz* is only accessed when *jobz* = 'V' and $n>0$.

tryrac

On exit, , set to true. *tryrac* is set to false if the matrix does not define its eigenvalues to high relative accuracy.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info > 0$, an internal error occurred.

?stedc

Computes all eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method.

Syntax

```
lapack_int LAPACKE_sstedc( int matrix_layout, char compz, lapack_int n, float* d,
float* e, float* z, lapack_int ldz );
```

```
lapack_int LAPACKE_dstedc( int matrix_layout, char compz, lapack_int n, double* d,
double* e, double* z, lapack_int ldz );
```

```
lapack_int LAPACKE_cstedc( int matrix_layout, char compz, lapack_int n, float* d,
float* e, lapack_complex_float* z, lapack_int ldz );
```

```
lapack_int LAPACKE_zstedc( int matrix_layout, char compz, lapack_int n, double* d,
double* e, lapack_complex_double* z, lapack_int ldz );
```

Include Files

- mkl.h

Description

The routine computes all the eigenvalues and (optionally) all the eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band real symmetric or complex Hermitian matrix can also be found if [sytrd/hetrd](#) or [sptrd/hptrd](#) or [sbtrd/hbtrd](#) has been used to reduce this matrix to tridiagonal form.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>compz</i> | <p>Must be 'N' or 'I' or 'V'.</p> <p>If <i>compz</i> = 'N', the routine computes eigenvalues only.</p> <p>If <i>compz</i> = 'I', the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix.</p> <p>If <i>compz</i> = 'V', the routine computes the eigenvalues and eigenvectors of original symmetric/Hermitian matrix. On entry, the array <i>z</i> must contain the orthogonal/unitary matrix used to reduce the original matrix to tridiagonal form.</p> |
| <i>n</i> | The order of the symmetric tridiagonal matrix ($n \geq 0$). |
| <i>d, e</i> | <p>Arrays:</p> <p><i>d</i> contains the diagonal elements of the tridiagonal matrix.</p> <p>The dimension of <i>d</i> must be at least $\max(1, n)$.</p> <p><i>e</i> contains the subdiagonal elements of the tridiagonal matrix.</p> <p>The dimension of <i>e</i> must be at least $\max(1, n-1)$.</p> |

| | |
|------------|---|
| <i>z</i> | Array <i>z</i> is of size $\max(1, \text{ldz} * n)$. If <i>compz</i> = 'V', then, on entry, <i>z</i> must contain the orthogonal/unitary matrix used to reduce the original matrix to tridiagonal form. |
| <i>ldz</i> | The leading dimension of <i>z</i> . Constraints: <i>ldz</i> \geq 1 if <i>compz</i> = 'N'; <i>ldz</i> \geq $\max(1, n)$ if <i>compz</i> = 'V' or 'I'. |

Output Parameters

| | |
|----------|--|
| <i>d</i> | The <i>n</i> eigenvalues in ascending order, unless <i>info</i> \neq 0. See also <i>info</i> . |
| <i>e</i> | On exit, the array is overwritten; see <i>info</i> . |
| <i>z</i> | If <i>info</i> = 0, then if <i>compz</i> = 'V', <i>z</i> contains the orthonormal eigenvectors of the original symmetric/Hermitian matrix, and if <i>compz</i> = 'I', <i>z</i> contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If <i>compz</i> = 'N', <i>z</i> is not referenced. |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns *i*/(*n*+1) through $\text{mod}(i, n+1)$.

?stegr

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

Syntax

```
lapack_int LAPACKE_sstegr( int matrix_layout, char jobz, char range, lapack_int n,
float* d, float* e, float vl, float vu, lapack_int il, lapack_int iu, float abstol,
lapack_int* m, float* w, float* z, lapack_int ldz, lapack_int* isuppz );
```

```
lapack_int LAPACKE_dstegr( int matrix_layout, char jobz, char range, lapack_int n,
double* d, double* e, double vl, double vu, lapack_int il, lapack_int iu, double
abstol, lapack_int* m, double* w, double* z, lapack_int ldz, lapack_int* isuppz );
```

```
lapack_int LAPACKE_cstegr( int matrix_layout, char jobz, char range, lapack_int n,
float* d, float* e, float vl, float vu, lapack_int il, lapack_int iu, float abstol,
lapack_int* m, float* w, lapack_complex_float* z, lapack_int ldz, lapack_int* isuppz );
```

```
lapack_int LAPACKE_zstegr( int matrix_layout, char jobz, char range, lapack_int n,
double* d, double* e, double vl, double vu, lapack_int il, lapack_int iu, double
abstol, lapack_int* m, double* w, lapack_complex_double* z, lapack_int ldz,
lapack_int* isuppz );
```

Include Files

- `mkl.h`

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T .

The spectrum may be computed either completely or partially by specifying either an interval $(vl, vu]$ or a range of indices $il:iu$ for the desired eigenvalues.

`?stegr` is a compatibility wrapper around the improved `stemr` routine. See its description for further details.

Note that the `abstol` parameter no longer provides any benefit and hence is no longer used.

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>jobz</code> | Must be 'N' or 'V'. If <code>jobz = 'N'</code> , then only eigenvalues are computed. If <code>jobz = 'V'</code> , then eigenvalues and eigenvectors are computed. |
| <code>range</code> | Must be 'A' or 'V' or 'I'. If <code>range = 'A'</code> , the routine computes all eigenvalues. If <code>range = 'V'</code> , the routine computes eigenvalues $w[i]$ in the half-open interval: $vl < w[i] \leq vu$. If <code>range = 'I'</code> , the routine computes eigenvalues with indices il to iu . |
| <code>n</code> | The order of the matrix T ($n \geq 0$). |
| <code>d, e</code> | Arrays: <code>d</code> contains the diagonal elements of T . The dimension of <code>d</code> must be at least $\max(1, n)$. <code>e</code> contains the subdiagonal elements of T in elements 1 to $n-1$; <code>e(n)</code> need not be set on input, but it is used as a workspace. The dimension of <code>e</code> must be at least $\max(1, n)$. |
| <code>vl, vu</code> | If <code>range = 'V'</code> , the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$. If <code>range = 'A'</code> or 'I', <code>vl</code> and <code>vu</code> are not referenced. |
| <code>il, iu</code> | If <code>range = 'I'</code> , the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$. If <code>range = 'A'</code> or 'V', <code>il</code> and <code>iu</code> are not referenced. |

| | |
|---------------|--|
| <i>abstol</i> | Unused. Was the absolute error tolerance for the eigenvalues/eigenvectors in previous versions. |
| <i>ldz</i> | The leading dimension of the output array <i>z</i> . Constraints: $ldz \geq 1$ if <i>jobz</i> = 'N'; $ldz \geq \max(1, n)$ if <i>jobz</i> = 'V'. |

Output Parameters

| | |
|---------------|---|
| <i>d, e</i> | On exit, <i>d</i> and <i>e</i> are overwritten. |
| <i>m</i> | The total number of eigenvalues found, $0 \leq m \leq n$. If <i>range</i> = 'A', $m = n$, and if <i>range</i> = 'I', $m = iu - il + 1$. |
| <i>w</i> | Array, size at least $\max(1, n)$. The selected eigenvalues in ascending order, stored in <i>w</i> [0] to <i>w</i> [<i>m</i> - 1]. |
| <i>z</i> | Array <i>z</i> (size $\max(1, ldz * m)$). If <i>jobz</i> = 'V', and if <i>info</i> = 0, the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>T</i> corresponding to the selected eigenvalues, with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with <i>w</i> [<i>i</i> - 1]. If <i>jobz</i> = 'N', then <i>z</i> is not referenced. Note: if <i>range</i> = 'V', the exact value of <i>m</i> is not known in advance and an upper bound must be used. Using $n = m$ is always safe. |
| <i>isuppz</i> | Array, size at least $(2 * \max(1, m))$. The support of the eigenvectors in <i>z</i> , that is the indices indicating the nonzero elements in <i>z</i> . The <i>i</i> -th computed eigenvector is nonzero only in elements <i>isuppz</i> [2 * <i>i</i> - 2] through <i>isuppz</i> [2 * <i>i</i> - 1]. This is relevant in the case when the matrix is split. <i>isuppz</i> is only accessed when <i>jobz</i> = 'V', and $n > 0$. |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, an internal error occurred.

?pteqr

Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric positive-definite tridiagonal matrix.

Syntax

```
lapack_int LAPACKE_spteqr( int matrix_layout, char compz, lapack_int n, float* d,
float* e, float* z, lapack_int ldz );
```

```
lapack_int LAPACKE_dpteqr( int matrix_layout, char compz, lapack_int n, double* d,
double* e, double* z, lapack_int ldz );
```

```
lapack_int LAPACKE_cpteqr( int matrix_layout, char compz, lapack_int n, float* d,
float* e, lapack_complex_float* z, lapack_int ldz );
```

```
lapack_int LAPACKE_zpteqr( int matrix_layout, char compz, lapack_int n, double* d,
double* e, lapack_complex_double* z, lapack_int ldz );
```

Include Files

- mkl.h

Description

The routine computes all the eigenvalues and (optionally) all the eigenvectors of a real symmetric positive-definite tridiagonal matrix T . In other words, the routine can compute the spectral factorization: $T = Z^* \Lambda^* Z^T$.

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i ; Z is an orthogonal matrix whose columns are eigenvectors. Thus,

$$T^* z_i = \lambda_i^* z_i \text{ for } i = 1, 2, \dots, n.$$

(The routine normalizes the eigenvectors so that $\|z_i\|_2 = 1$.)

You can also use the routine for computing the eigenvalues and eigenvectors of real symmetric (or complex Hermitian) positive-definite matrices A reduced to tridiagonal form T : $A = Q^* T^* Q^H$. In this case, the spectral factorization is as follows: $A = Q^* T^* Q^H = (QZ)^* \Lambda^* (QZ)^H$. Before calling `?pteqr`, you must reduce A to tridiagonal form and generate the explicit matrix Q by calling the following routines:

| | for real matrices: | for complex matrices: |
|-----------------------|---------------------------|---------------------------|
| full storage | ?sytrd, ?orgtr | ?hetrd, ?ungtr |
| packed storage | ?sptrd, ?opgtr | ?hptrd, ?upgtr |
| band storage | ?sbtrd(<i>vect</i> ='V') | ?hbtrd(<i>vect</i> ='V') |

The routine first factorizes T as $L^* D^* L^H$ where L is a unit lower bidiagonal matrix, and D is a diagonal matrix. Then it forms the bidiagonal matrix $B = L^* D^{1/2}$ and calls `?bdsqr` to compute the singular values of B , which are the square roots of the eigenvalues of T .

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

compz Must be 'N' or 'I' or 'V'.
 If *compz* = 'N', the routine computes eigenvalues only.
 If *compz* = 'I', the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix T .
 If *compz* = 'V', the routine computes the eigenvalues and eigenvectors of A (and the array z must contain the matrix Q on entry).

n The order of the matrix T ($n \geq 0$).

d, e Arrays:

d contains the diagonal elements of T .

The size of d must be at least $\max(1, n)$.

e contains the off-diagonal elements of T .

The size of e must be at least $\max(1, n-1)$.

| | |
|-------|--|
| z | <p>Array, size $\max(1, ldz*n)$</p> <p>If $compz = 'N'$ or $'I'$, z need not be set.</p> <p>If $compz = 'V'$, z must contain the orthogonal matrix used in the reduction to tridiagonal form..</p> |
| ldz | <p>The leading dimension of z. Constraints:</p> <p>$ldz \geq 1$ if $compz = 'N'$;</p> <p>$ldz \geq \max(1, n)$ if $compz = 'V'$ or $'I'$.</p> |

Output Parameters

| | |
|-----|---|
| d | <p>The n eigenvalues in descending order, unless $info > 0$.</p> <p>See also <i>info</i>.</p> |
| e | <p>On exit, the array is overwritten.</p> |
| z | <p>If $info = 0$, contains an n-by-n matrix the columns of which are orthonormal eigenvectors. (The i-th column corresponds to the i-th eigenvalue.)</p> |

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = i$, the leading minor of order i (and hence T itself) is not positive-definite.

If $info = n + i$, the algorithm for computing singular values failed to converge; i off-diagonal elements have not converged to zero.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

If λ_j is an exact eigenvalue, and μ_j is the corresponding computed value, then

$$|\mu_j - \lambda_j| \leq c(n) * \varepsilon * K * \lambda_j$$

where $c(n)$ is a modestly increasing function of n , ε is the machine precision, and $K = \|(DTD)\|_2 * \|(DTD)^{-1}\|_2$, D is diagonal with $d_{ii} = t_{ii}^{-1/2}$.

If z_j is the corresponding exact eigenvector, and w_j is the corresponding computed vector, then the angle $\theta(z_j, w_j)$ between them is bounded as follows:

$$\theta(z_j, w_j) \leq c(n) \varepsilon K / \min_{i \neq j} (|\lambda_i - \lambda_j| / |\lambda_i + \lambda_j|).$$

Here $\min_{i \neq j} (|\lambda_i - \lambda_j| / |\lambda_i + \lambda_j|)$ is the *relative gap* between λ_j and the other eigenvalues.

The total number of floating-point operations depends on how rapidly the algorithm converges.

Typically, it is about

$30n^2$ if `compz = 'N'`;

$6n^3$ (for complex flavors, $12n^3$) if `compz = 'V' or 'I'`.

?stebz

Computes selected eigenvalues of a real symmetric tridiagonal matrix by bisection.

Syntax

```
lapack_int LAPACKE_sstebz (char range, char order, lapack_int n, float vl, float vu,
lapack_int il, lapack_int iu, float abstol, const float* d, const float* e,
lapack_int* m, lapack_int* nsplit, float* w, lapack_int* iblock, lapack_int* isplit);

lapack_int LAPACKE_dstebz (char range, char order, lapack_int n, double vl, double vu,
lapack_int il, lapack_int iu, double abstol, const double* d, const double* e,
lapack_int* m, lapack_int* nsplit, double* w, lapack_int* iblock, lapack_int* isplit);
```

Include Files

- mkl.h

Description

The routine computes some (or all) of the eigenvalues of a real symmetric tridiagonal matrix T by bisection. The routine searches for zero or negligible off-diagonal elements to see if T splits into block-diagonal form $T = \text{diag}(T_1, T_2, \dots)$. Then it performs bisection on each of the blocks T_i and returns the block index of each computed eigenvalue, so that a subsequent call to [stein](#) can also take advantage of the block structure.

Input Parameters

| | |
|---------------|--|
| <i>range</i> | <p>Must be 'A' or 'V' or 'I'.</p> <p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval: $vl < w[i] \leq vu$.</p> <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.</p> |
| <i>order</i> | <p>Must be 'B' or 'E'.</p> <p>If <i>order</i> = 'B', the eigenvalues are to be ordered from smallest to largest within each split-off block.</p> <p>If <i>order</i> = 'E', the eigenvalues for the entire matrix are to be ordered from smallest to largest.</p> |
| <i>n</i> | The order of the matrix T ($n \geq 0$). |
| <i>vl, vu</i> | <p>If <i>range</i> = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval:</p> $vl < w[i] \leq vu.$ <p>If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.</p> |
| <i>il, iu</i> | <p>Constraint: $1 \leq il \leq iu \leq n$.</p> <p>If <i>range</i> = 'I', the routine computes eigenvalues $w[i]$ such that $il \leq i \leq iu$ (assuming that the eigenvalues $w[i]$ are in ascending order).</p> |

If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol The absolute tolerance to which each eigenvalue is required. An eigenvalue (or cluster) is considered to have converged if it lies in an interval of width *abstol*.

If $abstol \leq 0.0$, then the tolerance is taken as $\epsilon_{ps} * |T|$, where ϵ_{ps} is the machine precision, and $|T|$ is the 1-norm of the matrix *T*.

d, e

Arrays:

d contains the diagonal elements of *T*.

The size of *d* must be at least $\max(1, n)$.

e contains the off-diagonal elements of *T*.

The size of *e* must be at least $\max(1, n-1)$.

Output Parameters

m The actual number of eigenvalues found.

nsplit The number of diagonal blocks detected in *T*.

w Array, size at least $\max(1, n)$. The computed eigenvalues, stored in *w*[0] to *w*[*m* - 1].

iblock, isplit

Arrays, size at least $\max(1, n)$.

A positive value *iblock*[*i*] is the block number of the eigenvalue stored in *w*[*i*] (see also *info*).

The leading *nsplit* elements of *isplit* contain points at which *T* splits into blocks *T_i*, as follows: the block *T₁* contains rows/columns 1 to *isplit*[0]; the block *T₂* contains rows/columns *isplit*[0]+1 to *isplit*[1], and so on.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = 1, for *range* = 'A' or 'V', the algorithm failed to compute some of the required eigenvalues to the desired accuracy; *iblock*[*i*] < 0 indicates that the eigenvalue stored in *w*[*i*] failed to converge.

If *info* = 2, for *range* = 'I', the algorithm failed to compute some of the required eigenvalues. Try calling the routine again with *range* = 'A'.

If *info* = 3:

for *range* = 'A' or 'V', same as *info* = 1;

for *range* = 'I', same as *info* = 2.

If *info* = 4, no eigenvalues have been computed. The floating-point arithmetic on the computer is not behaving as expected.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The eigenvalues of T are computed to high relative accuracy which means that if they vary widely in magnitude, then any small eigenvalues will be computed more accurately than, for example, with the standard QR method. However, the reduction to tridiagonal form (prior to calling the routine) may exclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix if its eigenvalues vary widely in magnitude.

?stein

Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix.

Syntax

```
lapack_int LAPACKE_sstein( int matrix_layout, lapack_int n, const float* d, const
float* e, lapack_int m, const float* w, const lapack_int* iblock, const lapack_int*
isplit, float* z, lapack_int ldz, lapack_int* ifailv );
```

```
lapack_int LAPACKE_dstein( int matrix_layout, lapack_int n, const double* d, const
double* e, lapack_int m, const double* w, const lapack_int* iblock, const lapack_int*
isplit, double* z, lapack_int ldz, lapack_int* ifailv );
```

```
lapack_int LAPACKE_cstein( int matrix_layout, lapack_int n, const float* d, const

Description

The routine computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, by inverse iteration. It is designed to be used in particular after the specified eigenvalues have been computed by ?stebz with *order* = 'B', but may also be used when the eigenvalues have been computed by other routines.

If you use this routine after ?stebz, it can take advantage of the block structure by performing inverse iteration on each block T_i separately, which is more efficient than using the whole matrix T .

If T has been formed by reduction of a full symmetric or Hermitian matrix A to tridiagonal form, you can transform eigenvectors of T to eigenvectors of A by calling ?ormtr or ?opmtr (for real flavors) or by calling ?unmtr or ?upmtr (for complex flavors).

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>n</i> | The order of the matrix T ($n \geq 0$). |
| <i>m</i> | The number of eigenvectors to be returned. |
| <i>d, e, w</i> | Arrays: |

d contains the diagonal elements of T .

The size of d must be at least $\max(1, n)$.

e contains the sub-diagonal elements of T stored in elements 1 to $n-1$

The size of e must be at least $\max(1, n-1)$.

w contains the eigenvalues of T , stored in $w[0]$ to $w[m - 1]$ (as returned by `stebz`). Eigenvalues of T_1 must be supplied first, in non-decreasing order; then those of T_2 , again in non-decreasing order, and so on.

Constraint:

if $iblock[i] = iblock[i+1]$, $w[i] \leq w[i+1]$.

The size of w must be at least $\max(1, n)$.

iblock, isplit

Arrays, size at least $\max(1, n)$. The arrays *iblock* and *isplit*, as returned by `?stebz` with *order* = 'B'.

If you did not call `?stebz` with *order* = 'B', set all elements of *iblock* to 1, and *isplit*[0] to n .)

ldz

The leading dimension of the output array z ; $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout.

Output Parameters

z

Array, size at least $\max(1, ldz * m)$ for column major layout and $\max(1, ldz * n)$ for row major layout.

If $info = 0$, z contains an n -by- n matrix the columns of which are orthonormal eigenvectors. (The i -th column corresponds to the i th eigenvalue.)

ifailv

Array, size at least $\max(1, m)$.

If $info = i > 0$, the first i elements of *ifailv* contain the indices of any eigenvectors that failed to converge.

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = i$, then i eigenvectors (as indicated by the parameter *ifailv*) each failed to converge in 5 iterations. The current iterates are stored in the corresponding columns/rows of the array z .

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

Each computed eigenvector z_i is an exact eigenvector of a matrix $T+E_i$, where $\|E_i\|_2 = O(\epsilon) * \|T\|_2$. However, a set of eigenvectors computed by this routine may not be orthogonal to so high a degree of accuracy as those computed by `?steqr`.

?disna

Computes the reciprocal condition numbers for the eigenvectors of a symmetric/ Hermitian matrix or for the left or right singular vectors of a general matrix.

Syntax

```
lapack_int LAPACKE_sdisna (char job, lapack_int m, lapack_int n, const float* d, float* sep);
```

```
lapack_int LAPACKE_ddisna (char job, lapack_int m, lapack_int n, const double* d, double* sep);
```

Include Files

- mkl.h

Description

The routine computes the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m -by- n matrix.

The reciprocal condition number is the 'gap' between the corresponding eigenvalue or singular value and the nearest other one.

The bound on the error, measured by angle in radians, in the i -th computed vector is given by

$$?lamch('E') * (anorm / sep(i))$$

where $anorm = ||A||_2 = \max(|d(j)|)$. $sep(i)$ is not allowed to be smaller than $slamch('E') * anorm$ in order to limit the size of the error bound.

$?disna$ may also be used to compute error bounds for eigenvectors of the generalized symmetric definite eigenproblem.

Input Parameters

| | |
|------------|--|
| <i>job</i> | Must be 'E', 'L', or 'R'. Specifies for which problem the reciprocal condition numbers should be computed: <i>job</i> = 'E': for the eigenvectors of a symmetric/Hermitian matrix; <i>job</i> = 'L': for the left singular vectors of a general matrix; <i>job</i> = 'R': for the right singular vectors of a general matrix. |
| <i>m</i> | The number of rows of the matrix ($m \geq 0$). |
| <i>n</i> | If <i>job</i> = 'L', or 'R', the number of columns of the matrix ($n \geq 0$). Ignored if <i>job</i> = 'E'. |
| <i>d</i> | Array, dimension at least $\max(1, m)$ if <i>job</i> = 'E', and at least $\max(1, \min(m, n))$ if <i>job</i> = 'L' or 'R'. This array must contain the eigenvalues (if <i>job</i> = 'E') or singular values (if <i>job</i> = 'L' or 'R') of the matrix, in either increasing or decreasing order. If singular values, they must be non-negative. |

Output Parameters

| | |
|------------|---|
| <i>sep</i> | Array, dimension at least $\max(1, m)$ if <i>job</i> = 'E', and at least $\max(1, \min(m, n))$ if <i>job</i> = 'L' or 'R'. The reciprocal condition numbers of the vectors. |
|------------|---|

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = *-i*, the *i*-th parameter had an illegal value.

Generalized Symmetric-Definite Eigenvalue Problems: LAPACK Computational Routines

Generalized symmetric-definite eigenvalue problems are as follows: find the eigenvalues λ and the corresponding eigenvectors z that satisfy one of these equations:

$$Az = \lambda Bz, ABz = \lambda z, \text{ or } BAz = \lambda z,$$

where A is an n -by- n symmetric or Hermitian matrix, and B is an n -by- n symmetric positive-definite or Hermitian positive-definite matrix.

In these problems, there exist n real eigenvectors corresponding to real eigenvalues (even for complex Hermitian matrices A and B).

Routines described in this section allow you to reduce the above generalized problems to standard symmetric eigenvalue problem $Cy = \lambda y$, which you can solve by calling LAPACK routines described earlier in this chapter (see [Symmetric Eigenvalue Problems](#)).

Different routines allow the matrices to be stored either conventionally or in packed storage. Prior to reduction, the positive-definite matrix B must first be factorized using either [potrf](#) or [pptrf](#).

The reduction routine for the banded matrices A and B uses a split Cholesky factorization for which a specific routine [pbstf](#) is provided. This refinement halves the amount of work required to form matrix C .

[Table "Computational Routines for Reducing Generalized Eigenproblems to Standard Problems"](#) lists LAPACK routines that can be used to solve generalized symmetric-definite eigenvalue problems.

Computational Routines for Reducing Generalized Eigenproblems to Standard Problems

| Matrix type | Reduce to standard problems (full storage) | Reduce to standard problems (packed storage) | Reduce to standard problems (band matrices) | Factorize band matrix |
|----------------------------|--|--|---|-----------------------|
| real symmetric matrices | sygst | spgst | sbgst | pbstf |
| complex Hermitian matrices | hegst | hpgst | hbgst | pbstf |

?sygst

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form.

Syntax

```
lapack_int LAPACKE_ssygst (int matrix_layout, lapack_int itype, char uplo, lapack_int n, float* a, lapack_int lda, const float* b, lapack_int ldb);
```

```
lapack_int LAPACKE_dsygst (int matrix_layout, lapack_int itype, char uplo, lapack_int n, double* a, lapack_int lda, const double* b, lapack_int ldb);
```

Include Files

- `mkl.h`

Description

The routine reduces real symmetric-definite generalized eigenproblems

$$A^*z = \lambda^*B^*z, \quad A^*B^*z = \lambda^*z, \quad \text{or} \quad B^*A^*z = \lambda^*z$$

to the standard form $C^*y = \lambda^*y$. Here A is a real symmetric matrix, and B is a real symmetric positive-definite matrix. Before calling this routine, call `?potrf` to compute the Cholesky factorization: $B = U^T*U$ or $B = L*L^T$.

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>itype</code> | Must be 1 or 2 or 3. If <code>itype = 1</code> , the generalized eigenproblem is $A^*z = \lambda^*B^*z$ for <code>uplo = 'U'</code> : $C = \text{inv}(U^T)*A*\text{inv}(U)$, $z = \text{inv}(U)*y$; for <code>uplo = 'L'</code> : $C = \text{inv}(L)*A*\text{inv}(L^T)$, $z = \text{inv}(L^T)*y$. If <code>itype = 2</code> , the generalized eigenproblem is $A^*B^*z = \lambda^*z$ for <code>uplo = 'U'</code> : $C = U^*A^*U^T$, $z = \text{inv}(U)*y$; for <code>uplo = 'L'</code> : $C = L^T*A*L$, $z = \text{inv}(L^T)*y$. If <code>itype = 3</code> , the generalized eigenproblem is $B^*A^*z = \lambda^*z$ for <code>uplo = 'U'</code> : $C = U^*A^*U^T$, $z = U^T*y$; for <code>uplo = 'L'</code> : $C = L^T*A*L$, $z = L*y$. |
| <code>uplo</code> | Must be 'U' or 'L'. If <code>uplo = 'U'</code> , the array <code>a</code> stores the upper triangle of A ; you must supply B in the factored form $B = U^T*U$. If <code>uplo = 'L'</code> , the array <code>a</code> stores the lower triangle of A ; you must supply B in the factored form $B = L*L^T$. |
| <code>n</code> | The order of the matrices A and B ($n \geq 0$). |
| <code>a, b</code> | Arrays: <code>a</code> (size $\max(1, lda*n)$) contains the upper or lower triangle of A . <code>b</code> (size $\max(1, ldb*n)$) contains the Cholesky-factored matrix B : $B = U^T*U$ or $B = L*L^T$ (as returned by <code>?potrf</code>). |
| <code>lda</code> | The leading dimension of <code>a</code> ; at least $\max(1, n)$. |
| <code>ldb</code> | The leading dimension of <code>b</code> ; at least $\max(1, n)$. |

Output Parameters

| | |
|----------------|--|
| <code>a</code> | The upper or lower triangle of A is overwritten by the upper or lower triangle of C , as specified by the arguments <code>itype</code> and <code>uplo</code> . |
|----------------|--|

Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

Forming the reduced matrix C is a stable procedure. However, it involves implicit multiplication by $\text{inv}(B)$ (if $itype = 1$) or B (if $itype = 2$ or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if B is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is n^3 .

?hegst

Reduces a complex Hermitian positive-definite generalized eigenvalue problem to the standard form.

Syntax

```
lapack_int LAPACKE_chegst (int matrix_layout, lapack_int itype, char uplo, lapack_int
n, lapack_complex_float* a, lapack_int lda, const lapack_complex_float* b, lapack_int
ldb);
```

```
lapack_int LAPACKE_zhegst (int matrix_layout, lapack_int itype, char uplo, lapack_int
n, lapack_complex_double* a, lapack_int lda, const lapack_complex_double* b, lapack_int
ldb);
```

Include Files

- mkl.h

Description

The routine reduces a complex Hermitian positive-definite generalized eigenvalue problem to standard form.

| <i>itype</i> | Problem | Result |
|--------------|---------------------|---|
| 1 | $A*x = \lambda*B*x$ | A overwritten by $\text{inv}(U^H)*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^H)$ |
| 2 | $A*B*x = \lambda*x$ | A overwritten by $U*A*U^H$ or L^H*A*L |
| 3 | $B*A*x = \lambda*x$ | |

Before calling this routine, you must call ?potrf to compute the Cholesky factorization: $B = U^H*U$ or $B = L*L^H$.

Input Parameters

itype Must be 1 or 2 or 3.
 If $itype = 1$, the generalized eigenproblem is $A*z = \text{lambda}*B*z$
 for $uplo = 'U'$: $C = (U^H)^{-1}*A*U^{-1}$;
 for $uplo = 'L'$: $C = L^{-1}*A*(L^H)^{-1}$.
 If $itype = 2$, the generalized eigenproblem is $A*B*z = \text{lambda}*z$
 for $uplo = 'U'$: $C = U*A*U^H$;
 for $uplo = 'L'$: $C = L^H*A*L$.
 If $itype = 3$, the generalized eigenproblem is $B*A*z = \text{lambda}*z$

| | |
|--------|--|
| | for $uplo = 'U'$: $C = U^*A^*U^H$; |
| | for $uplo = 'L'$: $C = L^H^*A^*L$. |
| $uplo$ | Must be 'U' or 'L'. |
| | If $uplo = 'U'$, the array a stores the upper triangle of A ; you must supply B in the factored form $B = U^H^*U$. |
| | If $uplo = 'L'$, the array a stores the lower triangle of A ; you must supply B in the factored form $B = L^*L^H$. |
| n | The order of the matrices A and B ($n \geq 0$). |
| a, b | Arrays: a (size $\max(1, lda*n)$) contains the upper or lower triangle of A . b (size $\max(1, ldb*n)$) contains the Cholesky-factored matrix B : $B = U^H^*U$ or $B = L^*L^H$ (as returned by <code>?potrf</code>). |
| lda | The leading dimension of a ; at least $\max(1, n)$. |
| ldb | The leading dimension of b ; at least $\max(1, n)$. |

Output Parameters

| | |
|-----|--|
| a | The upper or lower triangle of A is overwritten by the upper or lower triangle of C , as specified by the arguments $itype$ and $uplo$. |
|-----|--|

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

Forming the reduced matrix C is a stable procedure. However, it involves implicit multiplication by B^{-1} (if $itype = 1$) or B (if $itype = 2$ or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if B is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is n^3 .

?spgst

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form using packed storage.

Syntax

Description

The routine reduces generalized eigenproblems with Hermitian matrices

$$A^*z = \lambda^*B^*z, A^*B^*z = \lambda^*z, \text{ or } B^*A^*z = \lambda^*z.$$

to standard eigenproblems $C^*y = \lambda^*y$, using packed matrix storage. Here A is a complex Hermitian matrix, and B is a complex Hermitian positive-definite matrix. Before calling this routine, you must call ?pptrf to compute the Cholesky factorization: $B = U^H*U$ or $B = L*L^H$.

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

itype Must be 1 or 2 or 3.

If *itype* = 1, the generalized eigenproblem is $A^*z = \text{lambda}^*B^*z$

for *uplo* = 'U': $C = \text{inv}(U^H)*A*\text{inv}(U)$, $z = \text{inv}(U)*y$;

for *uplo* = 'L': $C = \text{inv}(L)*A*\text{inv}(L^H)$, $z = \text{inv}(L^H)*y$.

If $itype = 2$, the generalized eigenproblem is $A^*B^*z = \lambda z$

for $uplo = 'U'$: $C = U^*A^*U^H$, $z = \text{inv}(U)^*y$;

for $uplo = 'L'$: $C = L^H*A^*L$, $z = \text{inv}(L^H)^*y$.

If $itype = 3$, the generalized eigenproblem is $B^*A^*z = \lambda z$

for $uplo = 'U'$: $C = U^*A^*U^H$, $z = U^H*y$;

for $uplo = 'L'$: $C = L^H*A^*L$, $z = L*y$.

$uplo$

Must be 'U' or 'L'.

If $uplo = 'U'$, ap stores the packed upper triangle of A ; you must supply B in the factored form $B = U^H*U$.

If $uplo = 'L'$, ap stores the packed lower triangle of A ; you must supply B in the factored form $B = L*L^H$.

n

The order of the matrices A and B ($n \geq 0$).

ap, bp

Arrays:

ap contains the packed upper or lower triangle of A .

The dimension of a must be at least $\max(1, n*(n+1)/2)$.

bp contains the packed Cholesky factor of B (as returned by `?pptrf` with the same $uplo$ value).

The dimension of b must be at least $\max(1, n*(n+1)/2)$.

Output Parameters

ap

The upper or lower triangle of A is overwritten by the upper or lower triangle of C , as specified by the arguments $itype$ and $uplo$.

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

Forming the reduced matrix C is a stable procedure. However, it involves implicit multiplication by $\text{inv}(B)$ (if $itype = 1$) or B (if $itype = 2$ or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if B is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is n^3 .

?sbgst

Reduces a real symmetric-definite generalized eigenproblem for banded matrices to the standard form using the factorization performed by ?pbstf.

Syntax

```
lapack_int LAPACKE_ssbgst (int matrix_layout, char vect, char uplo, lapack_int n,
lapack_int ka, lapack_int kb, float* ab, lapack_int ldab, const float* bb, lapack_int
ldbb, float* x, lapack_int ldx);
```

```
lapack_int LAPACKE_dsbgst (int matrix_layout, char vect, char uplo, lapack_int n,
lapack_int ka, lapack_int kb, double* ab, lapack_int ldab, const double* bb,
lapack_int ldbb, double* x, lapack_int ldx);
```

Include Files

- mkl.h

Description

To reduce the real symmetric-definite generalized eigenproblem $A*z = \lambda*B*z$ to the standard form $C*y = \lambda*y$, where A , B and C are banded, this routine must be preceded by a call to [pbstf](#), which computes the split Cholesky factorization of the positive-definite matrix B : $B=S^T*S$. The split Cholesky factorization, compared with the ordinary Cholesky factorization, allows the work to be approximately halved.

This routine overwrites A with $C = X^T*A*X$, where $X = \text{inv}(S)*Q$ and Q is an orthogonal matrix chosen (implicitly) to preserve the bandwidth of A . The routine also has an option to allow the accumulation of X , and then, if z is an eigenvector of C , $X*z$ is an eigenvector of the original system.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>vect</i> | Must be 'N' or 'V'. If <i>vect</i> = 'N', then matrix X is not returned; If <i>vect</i> = 'V', then matrix X is returned. |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of A . |
| <i>n</i> | The order of the matrices A and B ($n \geq 0$). |
| <i>ka</i> | The number of super- or sub-diagonals in A ($ka \geq 0$). |
| <i>kb</i> | The number of super- or sub-diagonals in B ($ka \geq kb \geq 0$). |
| <i>ab, bb</i> | <i>ab</i> (size at least $\max(1, ldab*n)$ for column major layout and at least $\max(1, ldab*(ka + 1))$ for row major layout) is an array containing either upper or lower triangular part of the symmetric matrix A (as specified by <i>uplo</i>) in band storage format. |

bb (size at least $\max(1, l_{dbb} * n)$ for column major layout and at least $\max(1, l_{dbb} * (kb + 1))$ for row major layout) is an array containing the banded split Cholesky factor of B as specified by $uplo$, n and kb and returned by `pbstf/pbstf`.

| | |
|-----------|--|
| $ldab$ | The leading dimension of the array ab ; must be at least $ka+1$ for column major layout and $\max(1, n)$ for row major layout. |
| l_{dbb} | The leading dimension of the array bb ; must be at least $kb+1$ for column major layout and $\max(1, n)$ for row major layout. |
| ldx | The leading dimension of the output array x . Constraints: if $vect = 'N'$, then $ldx \geq 1$; if $vect = 'V'$, then $ldx \geq \max(1, n)$. |

Output Parameters

| | |
|------|---|
| ab | On exit, this array is overwritten by the upper or lower triangle of C as specified by $uplo$. |
| x | Array. If $vect = 'V'$, then x (size at least $\max(1, l_{dx} * n)$) contains the n -by- n matrix $X = \text{inv}(S) * Q$. If $vect = 'N'$, then x is not referenced. |

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

Forming the reduced matrix C involves implicit multiplication by $\text{inv}(B)$. When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if B is ill-conditioned with respect to inversion.

If ka and kb are much less than n then the total number of floating-point operations is approximately $6n^2 * kb$, when $vect = 'N'$. Additional $(3/2)n^3 * (kb/ka)$ operations are required when $vect = 'V'$.

?hbgst

Reduces a complex Hermitian positive-definite generalized eigenproblem for banded matrices to the standard form using the factorization performed by ?pbstf.

Syntax

```
lapack_int LAPACKE_chbgst (int matrix_layout, char vect, char uplo, lapack_int n,
lapack_int ka, lapack_int kb, lapack_complex_float* ab, lapack_int ldab, const

Description

To reduce the complex Hermitian positive-definite generalized eigenproblem $A^*z = \lambda^*B^*z$ to the standard form $C^*x = \lambda^*y$, where A , B and C are banded, this routine must be preceded by a call to [pbstf/pbstf](#), which computes the split Cholesky factorization of the positive-definite matrix B : $B = S^H * S$. The split Cholesky factorization, compared with the ordinary Cholesky factorization, allows the work to be approximately halved.

This routine overwrites A with $C = X^H * A * X$, where $X = \text{inv}(S) * Q$, and Q is a unitary matrix chosen (implicitly) to preserve the bandwidth of A . The routine also has an option to allow the accumulation of X , and then, if z is an eigenvector of C , X^*z is an eigenvector of the original system.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <i>vect</i> | Must be 'N' or 'V'. If <i>vect</i> = 'N', then matrix X is not returned; If <i>vect</i> = 'V', then matrix X is returned. |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of A . |
| <i>n</i> | The order of the matrices A and B ($n \geq 0$). |
| <i>ka</i> | The number of super- or sub-diagonals in A ($ka \geq 0$). |
| <i>kb</i> | The number of super- or sub-diagonals in B ($ka \geq kb \geq 0$). |
| <i>ab, bb</i> | <i>ab</i> (size at least $\max(1, ldab * n)$ for column major layout and at least $\max(1, ldab * (ka + 1))$ for row major layout) is an array containing either upper or lower triangular part of the Hermitian matrix A (as specified by <i>uplo</i>) in band storage format. <i>bb</i> (size at least $\max(1, ldbb * n)$ for column major layout and at least $\max(1, ldbb * (kb + 1))$ for row major layout) is an array containing the banded split Cholesky factor of B as specified by <i>uplo</i> , <i>n</i> and <i>kb</i> and returned by pbstf/pbstf . |
| <i>ldab</i> | The leading dimension of the array <i>ab</i> ; must be at least $ka+1$ for column major layout and $\max(1, n)$ for row major layout. |
| <i>ldbb</i> | The leading dimension of the array <i>bb</i> ; must be at least $kb+1$ for column major layout and $\max(1, n)$ for row major layout. |
| <i>ldx</i> | The leading dimension of the output array x . Constraints: if <i>vect</i> = 'N', then $ldx \geq 1$; |

if $vect = 'V'$, then $ldx \geq \max(1, n)$.

Output Parameters

| | |
|------|--|
| ab | On exit, this array is overwritten by the upper or lower triangle of C as specified by $uplo$. |
| x | Array. If $vect = 'V'$, then x (size at least $\max(1, ldx*n)$) contains the n -by- n matrix $X = \text{inv}(S)*Q$. If $vect = 'N'$, then x is not referenced. |

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

Forming the reduced matrix C involves implicit multiplication by $\text{inv}(B)$. When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if B is ill-conditioned with respect to inversion. The total number of floating-point operations is approximately $20n^2*kb$, when $vect = 'N'$. Additional $5n^3*(kb/ka)$ operations are required when $vect = 'V'$. All these estimates assume that both ka and kb are much less than n .

?pbstf

Computes a split Cholesky factorization of a real symmetric or complex Hermitian positive-definite banded matrix used in ?sbgst/?hbgst.

Syntax

```
lapack_int LAPACKE_spbstf (int matrix_layout, char uplo, lapack_int n, lapack_int kb,
float* bb, lapack_int ldbb);
```

```
lapack_int LAPACKE_dpbstf (int matrix_layout, char uplo, lapack_int n, lapack_int kb,
double* bb, lapack_int ldbb);
```

```
lapack_int LAPACKE_cpbstf (int matrix_layout, char uplo, lapack_int n, lapack_int kb,
lapack_complex_float* bb, lapack_int ldbb);
```

```
lapack_int LAPACKE_zpbstf (int matrix_layout, char uplo, lapack_int n, lapack_int kb,
lapack_complex_double* bb, lapack_int ldbb);
```

Include Files

- mkl.h

Description

The routine computes a split Cholesky factorization of a real symmetric or complex Hermitian positive-definite band matrix B . It is to be used in conjunction with [sbgst/hbgst](#).

The factorization has the form $B = S^T*S$ (or $B = S^H*S$ for complex flavors), where S is a band matrix of the same bandwidth as B and the following structure: S is upper triangular in the first $(n+kb)/2$ rows and lower triangular in the remaining rows.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>bb</i> stores the upper triangular part of <i>B</i> . If <i>uplo</i> = 'L', <i>bb</i> stores the lower triangular part of <i>B</i> . |
| <i>n</i> | The order of the matrix <i>B</i> ($n \geq 0$). |
| <i>kb</i> | The number of super- or sub-diagonals in <i>B</i> ($kb \geq 0$). |
| <i>bb</i> | <i>bb</i> (size at least $\max(1, lddb*n)$ for column major layout and at least $\max(1, lddb*(kb + 1))$ for row major layout) is an array containing either upper or lower triangular part of the matrix <i>B</i> (as specified by <i>uplo</i>) in band storage format. |
| <i>ldbb</i> | The leading dimension of <i>bb</i> ; must be at least $kb+1$ for column major and at least $\max(1, n)$ for row major. |

Output Parameters

| | |
|-----------|--|
| <i>bb</i> | On exit, this array is overwritten by the elements of the split Cholesky factor <i>S</i> . |
|-----------|--|

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = *i*, then the factorization could not be completed, because the updated element b_{ii} would be the square root of a negative number; hence the matrix *B* is not positive-definite.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The computed factor *S* is the exact factor of a perturbed matrix $B + E$, where

$$|E| \leq c(kb + 1)\epsilon \|S^H\| |S|, \quad |e_{ij}| \leq c(kb + 1)\epsilon \sqrt{b_{ii}b_{jj}}$$

$c(n)$ is a modest linear function of *n*, and ϵ is the machine precision.

The total number of floating-point operations for real flavors is approximately $n(kb+1)^2$. The number of operations for complex flavors is 4 times greater. All these estimates assume that *kb* is much less than *n*.

After calling this routine, you can call [sbgst/hbgst](#) to solve the generalized eigenproblem $Az = \lambda Bz$, where *A* and *B* are banded and *B* is positive-definite.

Nonsymmetric Eigenvalue Problems: LAPACK Computational Routines

This section describes LAPACK routines for solving nonsymmetric eigenvalue problems, computing the Schur factorization of general matrices, as well as performing a number of related computational tasks.

A nonsymmetric eigenvalue problem is as follows: given a nonsymmetric (or non-Hermitian) matrix A , find the eigenvalues λ and the corresponding eigenvectors z that satisfy the equation

$$Az = \lambda z \text{ (right eigenvectors } z)$$

or the equation

$$z^H A = \lambda z^H \text{ (left eigenvectors } z).$$

Nonsymmetric eigenvalue problems have the following properties:

- The number of eigenvectors may be less than the matrix order (but is not less than the number of *distinct eigenvalues* of A).
- Eigenvalues may be complex even for a real matrix A .
- If a real nonsymmetric matrix has a complex eigenvalue $a+bi$ corresponding to an eigenvector z , then $a-bi$ is also an eigenvalue. The eigenvalue $a-bi$ corresponds to the eigenvector whose elements are complex conjugate to the elements of z .

To solve a nonsymmetric eigenvalue problem with LAPACK, you usually need to reduce the matrix to the upper Hessenberg form and then solve the eigenvalue problem with the Hessenberg matrix obtained. [Table "Computational Routines for Solving Nonsymmetric Eigenvalue Problems"](#) lists LAPACK routines to reduce the matrix to the upper Hessenberg form by an orthogonal (or unitary) similarity transformation $A = QHQ^H$ as well as routines to solve eigenvalue problems with Hessenberg matrices, forming the Schur factorization of such matrices and computing the corresponding condition numbers.

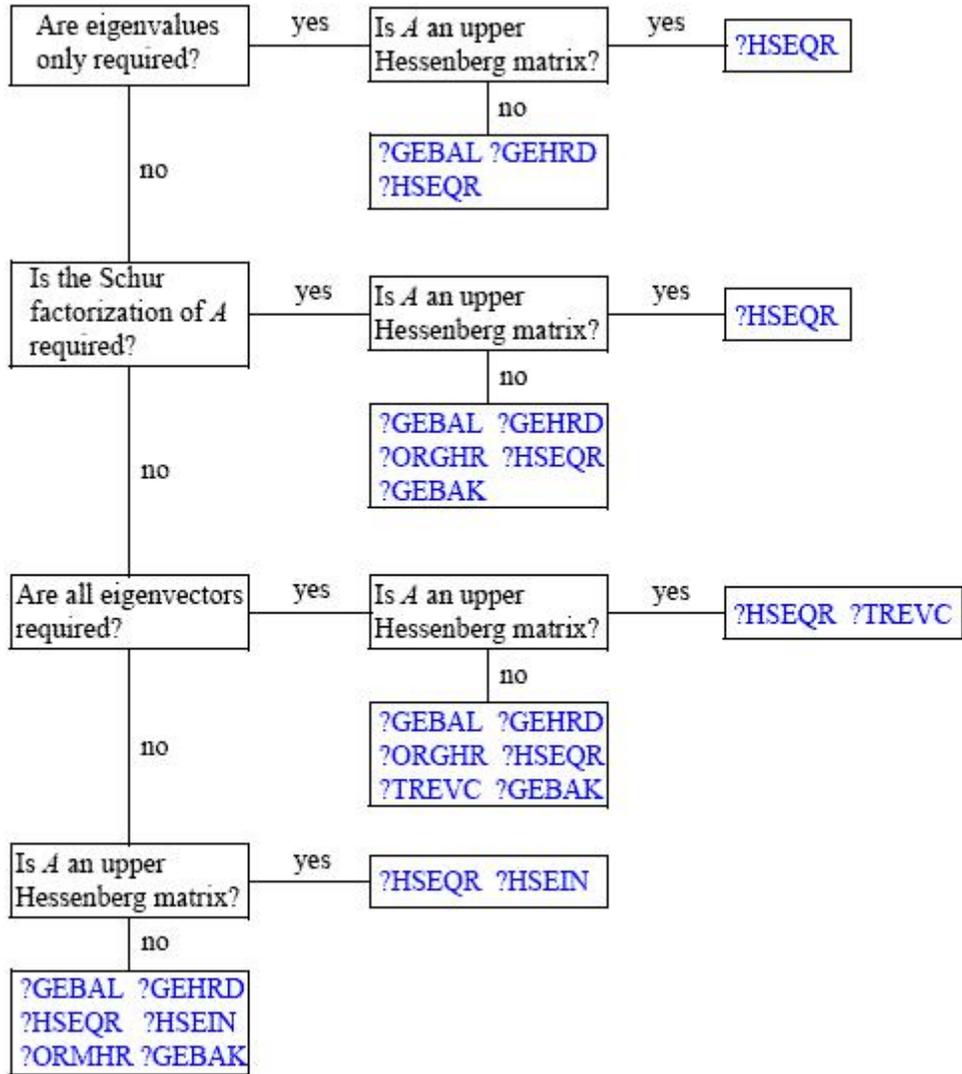

The decision tree in [Figure "Decision Tree: Real Nonsymmetric Eigenvalue Problems"](#) helps you choose the right routine or sequence of routines for an eigenvalue problem with a real nonsymmetric matrix. If you need to solve an eigenvalue problem with a complex non-Hermitian matrix, use the decision tree shown in [Figure "Decision Tree: Complex Non-Hermitian Eigenvalue Problems"](#).

```

Include Files

- `mkl.h`

Description

The routine reduces a general matrix A to upper Hessenberg form H by an orthogonal or unitary similarity transformation $A = Q^*H^*Q^H$. Here H has real subdiagonal elements.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of *elementary reflectors*. Routines are provided to work with Q in this representation.

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>n</code> | The order of the matrix A ($n \geq 0$). |
| <code>ilo, ihi</code> | If A is an output by <code>?gebal</code> , then <code>ilo</code> and <code>ihi</code> must contain the values returned by that routine. Otherwise <code>ilo = 1</code> and <code>ihi = n</code> . (If $n > 0$, then $1 \leq ilo \leq ihi \leq n$; if $n = 0$, <code>ilo = 1</code> and <code>ihi = 0</code> .) |
| <code>a</code> | Arrays: <code>a</code> (size $\max(1, lda * n)$) contains the matrix A . |
| <code>lda</code> | The leading dimension of <code>a</code> ; at least $\max(1, n)$. |

Output Parameters

| | |
|------------------|--|
| <code>a</code> | The elements on and above the subdiagonal contain the upper Hessenberg matrix H . The subdiagonal elements of H are real. The elements below the subdiagonal, with the array <code>tau</code> , represent the orthogonal matrix Q as a product of n elementary reflectors. |
| <code>tau</code> | Array, size at least $\max(1, n-1)$. Contains scalars that define elementary reflectors for the matrix Q . |

Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

Application Notes

The computed Hessenberg matrix H is exactly similar to a nearby matrix $A + E$, where $\|E\|_2 < c(n)\epsilon \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision.

The approximate number of floating-point operations for real flavors is $(2/3) * (ihi - ilo)^2 (2ihi + 2ilo + 3n)$; for complex flavors it is 4 times greater.

?orghr

Generates the real orthogonal matrix Q determined by `?gehrd`.

Syntax

```
lapack_int LAPACKE_sorghr (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int
ihi, float* a, lapack_int lda, const float* tau);
```

```
lapack_int LAPACKE_dorghr (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int
ihi, double* a, lapack_int lda, const double* tau);
```

Include Files

- mkl.h

Description

The routine explicitly generates the orthogonal matrix Q that has been determined by a preceding call to `sgehrd/dgehrd`. (The routine `?gehrd` reduces a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation, $A = Q^*H^*Q^T$, and represents the matrix Q as a product of ihi - ilo elementary reflectors. Here ilo and ihi are values determined by `sgebal/dgebal` when balancing the matrix; if the matrix has not been balanced, $ilo = 1$ and $ihi = n$.)

The matrix Q generated by `?orghr` has the structure:

$$Q = \begin{bmatrix} I & 0 & 0 \\ 0 & Q_{22} & 0 \\ 0 & 0 & I \end{bmatrix}$$

where Q_{22} occupies rows and columns ilo to ihi .

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>n</i> | The order of the matrix Q ($n \geq 0$). |
| <i>ilo, ihi</i> | These must be the same parameters ilo and ihi , respectively, as supplied to <code>?gehrd</code> . (If $n > 0$, then $1 \leq ilo \leq ihi \leq n$; if $n = 0$, $ilo = 1$ and $ihi = 0$.) |
| <i>a, tau</i> | Arrays: a (size $\max(1, lda*n)$) contains details of the vectors which define the elementary reflectors, as returned by <code>?gehrd</code> . tau contains further details of the elementary reflectors, as returned by <code>?gehrd</code> . The dimension of tau must be at least $\max(1, n-1)$. |
| <i>lda</i> | The leading dimension of a ; at least $\max(1, n)$. |

Output Parameters

| | |
|----------|---|
| <i>a</i> | Overwritten by the n -by- n orthogonal matrix Q . |
|----------|---|

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The computed matrix *Q* differs from the exact result by a matrix *E* such that $\|E\|_2 = O(\varepsilon)$, where ε is the machine precision.

The approximate number of floating-point operations is $(4/3)(ihi-ilo)^3$.

The complex counterpart of this routine is [unghr](#).

?ormhr

Multiplies an arbitrary real matrix C by the real orthogonal matrix Q determined by ?gehrd.

Syntax

```
lapack_int LAPACKE_sormhr (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int ilo, lapack_int ihi, const float* a, lapack_int lda, const
float* tau, float* c, lapack_int ldc);
```

```
lapack_int LAPACKE_dormhr (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int ilo, lapack_int ihi, const double* a, lapack_int lda, const
double* tau, double* c, lapack_int ldc);
```

Include Files

- mkl.h

Description

The routine multiplies a matrix *C* by the orthogonal matrix *Q* that has been determined by a preceding call to *sgehrd/dgehrd*. (The routine *?gehrd* reduces a real general matrix *A* to upper Hessenberg form *H* by an orthogonal similarity transformation, $A = Q^T H Q$, and represents the matrix *Q* as a product of *ihi-ilo* elementary reflectors. Here *ilo* and *ihi* are values determined by *sgebal/dgebal* when balancing the matrix; if the matrix has not been balanced, *ilo* = 1 and *ihi* = *n*.)

With *?ormhr*, you can form one of the matrix products $Q^T C$, $Q^T C^T$, $C^T Q$, or $C^T Q^T$, overwriting the result on *C* (which may be any real rectangular matrix).

A common application of *?ormhr* is to transform a matrix *V* of eigenvectors of *H* to the matrix *QV* of eigenvectors of *A*.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>side</i> | Must be 'L' or 'R'. If <i>side</i> = 'L', then the routine forms $Q^T C$ or $Q^T C^T$. If <i>side</i> = 'R', then the routine forms $C^T Q$ or $C^T Q^T$. |
| <i>trans</i> | Must be 'N' or 'T'. |

| | |
|------------------|--|
| | If <i>trans</i> = 'N', then <i>Q</i> is applied to <i>C</i> . |
| | If <i>trans</i> = 'T', then Q^T is applied to <i>C</i> . |
| <i>m</i> | The number of rows in <i>C</i> ($m \geq 0$). |
| <i>n</i> | The number of columns in <i>C</i> ($n \geq 0$). |
| <i>ilo, ihi</i> | These must be the same parameters <i>ilo</i> and <i>ihi</i> , respectively, as supplied to ?gehrd. If $m > 0$ and <i>side</i> = 'L', then $1 \leq ilo \leq ihi \leq m$. If $m = 0$ and <i>side</i> = 'L', then <i>ilo</i> = 1 and <i>ihi</i> = 0. If $n > 0$ and <i>side</i> = 'R', then $1 \leq ilo \leq ihi \leq n$. If $n = 0$ and <i>side</i> = 'R', then <i>ilo</i> = 1 and <i>ihi</i> = 0. |
| <i>a, tau, c</i> | Arrays: <i>a</i> (size $\max(1, lda*n)$ for <i>side</i> ='R' and size $\max(1, lda*m)$ for <i>side</i> ='L') contains details of the vectors which define the <i>elementary reflectors</i> , as returned by ?gehrd. <i>tau</i> contains further details of the <i>elementary reflectors</i> , as returned by ?gehrd. The dimension of <i>tau</i> must be at least $\max(1, m-1)$ if <i>side</i> = 'L' and at least $\max(1, n-1)$ if <i>side</i> = 'R'. <i>c</i> (size $\max(1, ldc*n)$ for column major layout and $\max(1, ldc*m)$ for row major layout) contains the <i>m</i> by <i>n</i> matrix <i>C</i> . |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, m)$ if <i>side</i> = 'L' and at least $\max(1, n)$ if <i>side</i> = 'R'. |
| <i>ldc</i> | The leading dimension of <i>c</i> ; at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout . |

Output Parameters

| | |
|----------|---|
| <i>c</i> | <i>C</i> is overwritten by product Q^*C , Q^T*C , $C*Q$, or $C*Q^T$ as specified by <i>side</i> and <i>trans</i> . |
|----------|---|

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = $-i$, the *i*-th parameter had an illegal value.

Application Notes

The computed matrix *Q* differs from the exact result by a matrix *E* such that $\|E\|_2 = O(\epsilon) \|C\|_2$, where ϵ is the machine precision.

The approximate number of floating-point operations is

$2n(ihi-ilo)^2$ if *side* = 'L';

$2m(ihi-ilo)^2$ if *side* = 'R'.

The complex counterpart of this routine is [unmhr](#).

?unghr

Generates the complex unitary matrix Q determined by ?gehrd.

Syntax

```
lapack_int LAPACKE_cunghr (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int
ihi, lapack_complex_float* a, lapack_int lda, const lapack_complex_float* tau);
lapack_int LAPACKE_zunghr (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int
ihi, lapack_complex_double* a, lapack_int lda, const lapack_complex_double* tau);
```

Include Files

- mkl.h

Description

The routine is intended to be used following a call to `cgehrd/zgehrd`, which reduces a complex matrix A to upper Hessenberg form H by a unitary similarity transformation: $A = Q^*H^*Q^H$. ?gehrd represents the matrix Q as a product of *ihi-ilo* elementary reflectors. Here *ilo* and *ihi* are values determined by `cgebal/zgebal` when balancing the matrix; if the matrix has not been balanced, $ilo = 1$ and $ihi = n$.

Use the routine [unghr](#) to generate Q explicitly as a square matrix. The matrix Q has the structure:

$$Q = \begin{bmatrix} I & 0 & 0 \\ 0 & Q_{22} & 0 \\ 0 & 0 & I \end{bmatrix}$$

where Q_{22} occupies rows and columns *ilo* to *ihi*.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>n</i> | The order of the matrix Q ($n \geq 0$). |
| <i>ilo, ihi</i> | These must be the same parameters <i>ilo</i> and <i>ihi</i> , respectively, as supplied to ?gehrd. (If $n > 0$, then $1 \leq ilo \leq ihi \leq n$. If $n = 0$, then $ilo = 1$ and $ihi = 0$.) |
| <i>a, tau</i> | <p>Arrays:</p> <p><i>a</i> (size $\max(1, lda * n)$) contains details of the vectors which define the <i>elementary reflectors</i>, as returned by ?gehrd.</p> <p><i>tau</i> contains further details of the <i>elementary reflectors</i>, as returned by ?gehrd.</p> <p>The dimension of <i>tau</i> must be at least $\max(1, n-1)$.</p> |

lda The leading dimension of *a*; at least $\max(1, n)$.

Output Parameters

a Overwritten by the *n*-by-*n* unitary matrix *Q*.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The computed matrix *Q* differs from the exact result by a matrix *E* such that $\|E\|_2 = O(\varepsilon)$, where ε is the machine precision.

The approximate number of real floating-point operations is $(16/3)(ihi-ilo)^3$.

The real counterpart of this routine is [orghr](#).

?unmhr

Multiplies an arbitrary complex matrix C by the complex unitary matrix Q determined by ?gehrd.

Syntax

```
lapack_int LAPACKE_cunmhr (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int ilo, lapack_int ihi, const lapack_complex_float* a, lapack_int
lda, const lapack_complex_float* tau, lapack_complex_float* c, lapack_int ldc);
```

```
lapack_int LAPACKE_zunmhr (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int ilo, lapack_int ihi, const lapack_complex_double* a,
lapack_int lda, const lapack_complex_double* tau, lapack_complex_double* c, lapack_int
ldc);
```

| <i>n</i> | The number of columns in C ($n \geq 0$). |
| <i>ilo, ihi</i> | <p>These must be the same parameters <i>ilo</i> and <i>ihi</i>, respectively, as supplied to <code>?gehrd</code>.</p> <p>If $m > 0$ and <i>side</i> = 'L', then $1 \leq ilo \leq ihi \leq m$.</p> <p>If $m = 0$ and <i>side</i> = 'L', then $ilo = 1$ and $ihi = 0$.</p> <p>If $n > 0$ and <i>side</i> = 'R', then $1 \leq ilo \leq ihi \leq n$.</p> <p>If $n = 0$ and <i>side</i> = 'R', then $ilo = 1$ and $ihi = 0$.</p> |
| <i>a, tau, c</i> | <p>Arrays:</p> <p><i>a</i>(size $\max(1, lda * n)$ for <i>side</i>='R' and size $\max(1, lda * m)$ for <i>side</i>='L') contains details of the vectors which define the elementary reflectors, as returned by <code>?gehrd</code>.</p> <p><i>tau</i> contains further details of the elementary reflectors, as returned by <code>?gehrd</code>.</p> <p>The dimension of <i>tau</i> must be at least $\max(1, m-1)$ if <i>side</i> = 'L' and at least $\max(1, n-1)$ if <i>side</i> = 'R'.</p> <p><i>c</i>(size $\max(1, ldc * n)$ for column major layout and $\max(1, ldc * m)$ for row major layout) contains the m-by-n matrix C.</p> |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, m)$ if <i>side</i> = 'L' and at least $\max(1, n)$ if <i>side</i> = 'R'. |
| <i>ldc</i> | The leading dimension of <i>c</i> ; at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout. |

Output Parameters

| | |
|----------|---|
| <i>c</i> | C is overwritten by $Q^H * C$, or $Q^H * C$, or $C * Q^H$, or $C * Q$ as specified by <i>side</i> and <i>trans</i> . |
|----------|---|

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = $-i$, the i -th parameter had an illegal value.

Application Notes

The computed matrix Q differs from the exact result by a matrix E such that $\|E\|_2 = O(\varepsilon) * \|C\|_2$, where ε is the machine precision.

The approximate number of floating-point operations is

$8n(ihi-ilo)^2$ if $side = 'L'$;

$8m(ihi-ilo)^2$ if $side = 'R'$.

The real counterpart of this routine is [ormhr](#).

?gebal

Balances a general matrix to improve the accuracy of computed eigenvalues and eigenvectors.

Syntax

```
lapack_int LAPACKE_sgebal( int matrix_layout, char job, lapack_int n, float* a,
lapack_int lda, lapack_int* ilo, lapack_int* ihi, float* scale );
```

```
lapack_int LAPACKE_dgebal( int matrix_layout, char job, lapack_int n, double* a,
lapack_int lda, lapack_int* ilo, lapack_int* ihi, double* scale );
```

```
lapack_int LAPACKE_cgebal( int matrix_layout, char job, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_int* ilo, lapack_int* ihi, float*
scale );
```

```
lapack_int LAPACKE_zgebal( int matrix_layout, char job, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_int* ilo, lapack_int* ihi, double*
scale );
```

Include Files

- mkl.h

Description

The routine *balances* a matrix A by performing either or both of the following two similarity transformations:

(1) The routine first attempts to permute A to block upper triangular form:

$$PAP^T = A' = \begin{bmatrix} A'_{11} & A'_{12} & A'_{13} \\ 0 & A'_{22} & A'_{23} \\ 0 & 0 & A'_{33} \end{bmatrix}$$

where P is a permutation matrix, and A'_{11} and A'_{33} are upper triangular. The diagonal elements of A'_{11} and A'_{33} are eigenvalues of A . The rest of the eigenvalues of A are the eigenvalues of the central diagonal block A'_{22} , in rows and columns ilo to ihi . Subsequent operations to compute the eigenvalues of A (or its Schur factorization) need only be applied to these rows and columns; this can save a significant amount of work if $ilo > 1$ and $ihi < n$.

If no suitable permutation exists (as is often the case), the routine sets $ilo = 1$ and $ihi = n$, and A'_{22} is the whole of A .

(2) The routine applies a diagonal similarity transformation to A' , to make the rows and columns of A'_{22} as close in norm as possible:

$$A'' = DA'D^{-1} = \begin{bmatrix} I & 0 & 0 \\ 0 & D_{22} & 0 \\ 0 & 0 & I \end{bmatrix} \times \begin{bmatrix} A'_{11} & A'_{12} & A'_{13} \\ 0 & A'_{22} & A'_{23} \\ 0 & 0 & A'_{33} \end{bmatrix} \times \begin{bmatrix} I & 0 & 0 \\ 0 & D_{22}^{-1} & 0 \\ 0 & 0 & I \end{bmatrix}$$

This scaling can reduce the norm of the matrix (that is, $\|A''_{22}\| < \|A'_{22}\|$), and hence reduce the effect of rounding errors on the accuracy of computed eigenvalues and eigenvectors.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>job</i> | Must be 'N' or 'P' or 'S' or 'B'. If <i>job</i> = 'N', then <i>A</i> is neither permuted nor scaled (but <i>ilo</i> , <i>ihi</i> , and <i>scale</i> get their values). If <i>job</i> = 'P', then <i>A</i> is permuted but not scaled. If <i>job</i> = 'S', then <i>A</i> is scaled but not permuted. If <i>job</i> = 'B', then <i>A</i> is both scaled and permuted. |
| <i>n</i> | The order of the matrix <i>A</i> ($n \geq 0$). |
| <i>a</i> | Array <i>a</i> (size $\max(1, lda*n)$) contains the matrix <i>A</i> . |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, n)$. |

Output Parameters

| | |
|-------------------------|--|
| <i>a</i> | Overwritten by the balanced matrix (<i>a</i> is not referenced if <i>job</i> = 'N'). |
| <i>ilo</i> , <i>ihi</i> | The values <i>ilo</i> and <i>ihi</i> such that on exit <i>a</i> (<i>i</i> , <i>j</i>) is zero if $i > j$ and $1 \leq j < ilo$ or $ihi < j \leq n$. If <i>job</i> = 'N' or 'S', then <i>ilo</i> = 1 and <i>ihi</i> = <i>n</i> . |
| <i>scale</i> | Array, size at least $\max(1, n)$. Contains details of the permutations and scaling factors. More precisely, if p_j is the index of the row and column interchanged with row and column <i>j</i> , and d_j is the scaling factor used to balance row and column <i>j</i> , then $scale[j - 1] = p_j$ for $j = 1, 2, \dots, ilo-1, ihi+1, \dots, n$; $scale[j - 1] = d_j$ for $j = ilo, ilo + 1, \dots, ihi$. The order in which the interchanges are made is <i>n</i> to <i>ihi</i> +1, then 1 to <i>ilo</i> -1. |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

The errors are negligible, compared with those in subsequent computations.

If the matrix A is balanced by this routine, then any eigenvectors computed subsequently are eigenvectors of the matrix A'' and hence you must call [gebak](#) to transform them back to eigenvectors of A .

If the Schur vectors of A are required, do not call this routine with $job = 'S'$ or $'B'$, because then the balancing transformation is not orthogonal (not unitary for complex flavors).

If you call this routine with $job = 'P'$, then any Schur vectors computed subsequently are Schur vectors of the matrix A'' , and you need to call [gebak](#) (with $side = 'R'$) to transform them back to Schur vectors of A .

The total number of floating-point operations is proportional to n^2 .

?gebak

Transforms eigenvectors of a balanced matrix to those of the original nonsymmetric matrix.

Syntax

```
lapack_int LAPACKE_sgebak( int matrix_layout, char job, char side, lapack_int n,
lapack_int ilo, lapack_int ihi, const float* scale, lapack_int m, float* v, lapack_int
ldv );

lapack_int LAPACKE_dgebak( int matrix_layout, char job, char side, lapack_int n,
lapack_int ilo, lapack_int ihi, const double* scale, lapack_int m, double* v,
lapack_int ldv );

lapack_int LAPACKE_cgebak( int matrix_layout, char job, char side, lapack_int n,
lapack_int ilo, lapack_int ihi, const float* scale, lapack_int m, lapack_complex_float*
v, lapack_int ldv );

lapack_int LAPACKE_zgebak( int matrix_layout, char job, char side, lapack_int n,
lapack_int ilo, lapack_int ihi, const double* scale, lapack_int m,
lapack_complex_double* v, lapack_int ldv );
```

Description

The routine is intended to be used after a matrix A has been balanced by a call to [?gebal](#), and eigenvectors of the balanced matrix A''_{22} have subsequently been computed. For a description of balancing, see [gebal](#). The balanced matrix A'' is obtained as $A'' = D*P*A*P^T*inv(D)$, where P is a permutation matrix and D is a diagonal scaling matrix. This routine transforms the eigenvectors as follows:

if x is a right eigenvector of A'' , then $P^T*inv(D)*x$ is a right eigenvector of A ; if y is a left eigenvector of A'' , then P^T*D*y is a left eigenvector of A .

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>job</i> | Must be 'N' or 'P' or 'S' or 'B'. The same parameter <i>job</i> as supplied to ?gebal . |

| | |
|-----------------|--|
| <i>side</i> | Must be 'L' or 'R'. If <i>side</i> = 'L', then left eigenvectors are transformed. If <i>side</i> = 'R', then right eigenvectors are transformed. |
| <i>n</i> | The number of rows of the matrix of eigenvectors ($n \geq 0$). |
| <i>ilo, ihi</i> | The values <i>ilo</i> and <i>ihi</i> , as returned by ?gebal. (If $n > 0$, then $1 \leq ilo \leq ihi \leq n$; if $n = 0$, then $ilo = 1$ and $ihi = 0$.) |
| <i>scale</i> | Array, size at least $\max(1, n)$. Contains details of the permutations and/or the scaling factors used to balance the original general matrix, as returned by ?gebal. |
| <i>m</i> | The number of columns of the matrix of eigenvectors ($m \geq 0$). |
| <i>v</i> | Arrays: <i>v</i> (size $\max(1, ldv * n)$ for column major layout and $\max(1, ldv * m)$ for row major layout) contains the matrix of left or right eigenvectors to be transformed. |
| <i>ldv</i> | The leading dimension of <i>v</i> ; at least $\max(1, n)$ for column major layout and at least $\max(1, m)$ for row major layout . |

Output Parameters

| | |
|----------|--|
| <i>v</i> | Overwritten by the transformed eigenvectors. |
|----------|--|

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The errors in this routine are negligible.

The approximate number of floating-point operations is approximately proportional to $m * n$.

?hseqr

Computes all eigenvalues and (optionally) the Schur factorization of a matrix reduced to Hessenberg form.

Syntax

```
lapack_int LAPACKE_shseqr( int matrix_layout, char job, char compz, lapack_int n,
lapack_int ilo, lapack_int ihi, float* h, lapack_int ldh, float* wr, float* wi, float*
z, lapack_int ldz );
```

```
lapack_int LAPACKE_dhseqr( int matrix_layout, char job, char compz, lapack_int n,
lapack_int ilo, lapack_int ihi, double* h, lapack_int ldh, double* wr, double* wi,
double* z, lapack_int ldz );
```

| | |
|-----------------|--|
| <i>compz</i> | <p>Must be 'N' or 'I' or 'V'.</p> <p>If <i>compz</i> = 'N', then no Schur vectors are computed (and the array <i>z</i> is not referenced).</p> <p>If <i>compz</i> = 'I', then the Schur vectors of <i>H</i> are computed (and the array <i>z</i> is initialized by the routine).</p> <p>If <i>compz</i> = 'V', then the Schur vectors of <i>A</i> are computed (and the array <i>z</i> must contain the matrix <i>Q</i> on entry).</p> |
| <i>n</i> | The order of the matrix <i>H</i> ($n \geq 0$). |
| <i>ilo, ihi</i> | If <i>A</i> has been balanced by <code>?gebal</code> , then <i>ilo</i> and <i>ihi</i> must contain the values returned by <code>?gebal</code> . Otherwise, <i>ilo</i> must be set to 1 and <i>ihi</i> to <i>n</i> . |
| <i>h, z</i> | <p>Arrays:</p> <p><i>h</i> (size $\max(1, ldh*n)$) The <i>n</i>-by-<i>n</i> upper Hessenberg matrix <i>H</i>.</p> <p><i>z</i> (size $\max(1, ldz*n)$)</p> <p>If <i>compz</i> = 'V', then <i>z</i> must contain the matrix <i>Q</i> from the reduction to Hessenberg form.</p> <p>If <i>compz</i> = 'I', then <i>z</i> need not be set.</p> <p>If <i>compz</i> = 'N', then <i>z</i> is not referenced.</p> |
| <i>ldh</i> | The leading dimension of <i>h</i> ; at least $\max(1, n)$. |
| <i>ldz</i> | <p>The leading dimension of <i>z</i>;</p> <p>If <i>compz</i> = 'N', then $ldz \geq 1$.</p> <p>If <i>compz</i> = 'V' or 'I', then $ldz \geq \max(1, n)$.</p> |

Output Parameters

| | |
|---------------|---|
| <i>w</i> | Array, size at least $\max(1, n)$. Contains the computed eigenvalues, unless <i>info</i> > 0. The eigenvalues are stored in the same order as on the diagonal of the Schur form <i>T</i> (if computed). |
| <i>wr, wi</i> | <p>Arrays, size at least $\max(1, n)$ each.</p> <p>Contain the real and imaginary parts, respectively, of the computed eigenvalues, unless <i>info</i> > 0. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first. The eigenvalues are stored in the same order as on the diagonal of the Schur form <i>T</i> (if computed).</p> |
| <i>h</i> | <p>If <i>info</i> = 0 and <i>job</i> = 'S', <i>h</i> contains the upper quasi-triangular matrix <i>T</i> from the Schur decomposition (the Schur form).</p> <p>If <i>info</i> = 0 and <i>job</i> = 'E', the contents of <i>h</i> are unspecified on exit. (The output value of <i>h</i> when <i>info</i> > 0 is given under the description of <i>info</i> below.)</p> |
| <i>z</i> | <p>If <i>compz</i> = 'V' and <i>info</i> = 0, then <i>z</i> contains <i>Q</i>*<i>Z</i>.</p> <p>If <i>compz</i> = 'I' and <i>info</i> = 0, then <i>z</i> contains the unitary or orthogonal matrix <i>Z</i> of the Schur vectors of <i>H</i>.</p> |

If `compz = 'N'`, then `z` is not referenced.

Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, `?hseqr` failed to compute all of the eigenvalues. Elements $1, 2, \dots, ilo-1$ and $i+1, i+2, \dots, n$ of the eigenvalue arrays (`wr` and `wi` for real flavors and `w` for complex flavors) contain the real and imaginary parts of those eigenvalues that have been successfully found.

If `info > 0`, and `job = 'E'`, then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns `ilo` through `info` of the final output value of `H`.

If `info > 0`, and `job = 'S'`, then on exit (initial value of `H`)*`U` = `U`*(final value of `H`), where `U` is a unitary matrix. The final value of `H` is upper Hessenberg and triangular in rows and columns `info+1` through `ihi`.

If `info > 0`, and `compz = 'V'`, then on exit (final value of `Z`) = (initial value of `Z`)*`U`, where `U` is the unitary matrix (regardless of the value of `job`).

If `info > 0`, and `compz = 'I'`, then on exit (final value of `Z`) = `U`, where `U` is the unitary matrix (regardless of the value of `job`).

If `info > 0`, and `compz = 'N'`, then `Z` is not accessed.

Application Notes

The computed Schur factorization is the exact factorization of a nearby matrix $H + E$, where $\|E\|_2 < O(\epsilon) \|H\|_2/s_i$, and ϵ is the machine precision.

If λ_j is an exact eigenvalue, and μ_j is the corresponding computed value, then $|\lambda_j - \mu_j| \leq c(n) * \epsilon * \|H\|_2/s_j$, where $c(n)$ is a modestly increasing function of n , and s_j is the reciprocal condition number of λ_j . The condition numbers s_j may be computed by calling `trsna`.

The total number of floating-point operations depends on how rapidly the algorithm converges; typical numbers are as follows.

| | |
|--|--|
| If only eigenvalues are computed: | $7n^3$ for real flavors $25n^3$ for complex flavors. |
| If the Schur form is computed: | $10n^3$ for real flavors $35n^3$ for complex flavors. |
| If the full Schur factorization is computed: | $20n^3$ for real flavors $70n^3$ for complex flavors. |

?hsein

Computes selected eigenvectors of an upper Hessenberg matrix that correspond to specified eigenvalues.

Syntax

```
lapack_int LAPACKE_shsein( int matrix_layout, char side, char eigsrc, char initv,
lapack_logical* select, lapack_int n, const float* h, lapack_int ldh, float* wr, const
float* wi, float* vl, lapack_int ldvl, float* vr, lapack_int ldvr, lapack_int mm,
lapack_int* m, lapack_int* ifaill, lapack_int* ifailr );
```

```
lapack_int LAPACKE_dhsein( int matrix_layout, char side, char eigsrc, char initv,
lapack_logical* select, lapack_int n, const double* h, lapack_int ldh, double* wr,
const double* wi, double* vl, lapack_int ldvl, double* vr, lapack_int ldvr, lapack_int
mm, lapack_int* m, lapack_int* ifaill, lapack_int* ifailr );
```

```
lapack_int LAPACKE_chsein( int matrix_layout, char side, char eigsrc, char initv, const
lapack_logical* select, lapack_int n, const lapack_complex_float* h, lapack_int ldh,
lapack_complex_float* w, lapack_complex_float* vl, lapack_int ldvl,
lapack_complex_float* vr, lapack_int ldvr, lapack_int mm, lapack_int* m, lapack_int*
ifaill, lapack_int* ifailr );
```

```
lapack_int LAPACKE_zhsein( int matrix_layout, char side, char eigsrc, char initv, const
lapack_logical* select, lapack_int n, const lapack_complex_double* h, lapack_int ldh,
lapack_complex_double* w, lapack_complex_double* vl, lapack_int ldvl,

ifaill, lapack_int* ifailr );
```

Include Files

- mkl.h

Description

The routine computes left and/or right eigenvectors of an upper Hessenberg matrix H , corresponding to selected eigenvalues.

The right eigenvector x and the left eigenvector y , corresponding to an eigenvalue λ , are defined by: $H^*x = \lambda^*x$ and $y^{H*}H = \lambda^*y^H$ (or $H^{H*}y = \lambda^*y^*$). Here λ^* denotes the conjugate of λ .

The eigenvectors are computed by inverse iteration. They are scaled so that, for a real eigenvector x , $\max |x_i| = 1$, and for a complex eigenvector, $\max(|\text{Re}x_i| + |\text{Im}x_i|) = 1$.

If H has been formed by reduction of a general matrix A to upper Hessenberg form, then eigenvectors of H may be transformed to eigenvectors of A by [ormhr](#) or [unmhr](#).

Input Parameters

| | |
|---------------|--|
| <i>side</i> | Must be 'R' or 'L' or 'B'. If <i>side</i> = 'R', then only right eigenvectors are computed. If <i>side</i> = 'L', then only left eigenvectors are computed. If <i>side</i> = 'B', then all eigenvectors are computed. |
| <i>eigsrc</i> | Must be 'Q' or 'N'. If <i>eigsrc</i> = 'Q', then the eigenvalues of H were found using hseqr ; thus if H has any zero sub-diagonal elements (and so is block triangular), then the j -th eigenvalue can be assumed to be an eigenvalue of the block containing the j -th row/column. This property allows the routine to perform inverse iteration on just one diagonal block. If <i>eigsrc</i> = 'N', then no such assumption is made and the routine performs inverse iteration using the whole matrix. |
| <i>initv</i> | Must be 'N' or 'U'. If <i>initv</i> = 'N', then no initial estimates for the selected eigenvectors are supplied. |

| | |
|------------------|---|
| | If <i>initv</i> = 'U', then initial estimates for the selected eigenvectors are supplied in <i>vl</i> and/or <i>vr</i> . |
| <i>select</i> | <p>Array, size at least $\max(1, n)$. Specifies which eigenvectors are to be computed.</p> <p><i>For real flavors:</i></p> <p>To obtain the real eigenvector corresponding to the real eigenvalue <i>wr</i>[<i>j</i>], set <i>select</i>[<i>j</i>] to 1</p> <p>To select the complex eigenvector corresponding to the complex eigenvalue (<i>wr</i>[<i>j</i> - 1], <i>wi</i>[<i>j</i> - 1]) with complex conjugate (<i>wr</i>[<i>j</i>], <i>wi</i>[<i>j</i>]), set <i>select</i>[<i>j</i> - 1] and/or <i>select</i>[<i>j</i>] to 1; the eigenvector corresponding to the first eigenvalue in the pair is computed.</p> <p><i>For complex flavors:</i></p> <p>To select the eigenvector corresponding to the eigenvalue <i>w</i>[<i>j</i>], set <i>select</i>[<i>j</i>] to 1</p> |
| <i>n</i> | The order of the matrix <i>H</i> ($n \geq 0$). |
| <i>h, vl, vr</i> | <p>Arrays:</p> <p><i>h</i> (size $\max(1, ldh*n)$) The <i>n</i>-by-<i>n</i> upper Hessenberg matrix <i>H</i>. If an NAN value is detected in <i>h</i>, the routine returns with <i>info</i> = -6.</p> <p><i>vl</i>(size $\max(1, ldvl*nm)$ for column major layout and $\max(1, ldvl*n)$ for row major layout)</p> <p>If <i>initv</i> = 'V' and <i>side</i> = 'L' or 'B', then <i>vl</i> must contain starting vectors for inverse iteration for the left eigenvectors. Each starting vector must be stored in the same column or columns as will be used to store the corresponding eigenvector.</p> <p>If <i>initv</i> = 'N', then <i>vl</i> need not be set.</p> <p>The array <i>vl</i> is not referenced if <i>side</i> = 'R'.</p> <p><i>vr</i>(size $\max(1, ldvr*nm)$ for column major layout and $\max(1, ldvr*n)$ for row major layout)</p> <p>If <i>initv</i> = 'V' and <i>side</i> = 'R' or 'B', then <i>vr</i> must contain starting vectors for inverse iteration for the right eigenvectors. Each starting vector must be stored in the same column or columns as will be used to store the corresponding eigenvector.</p> <p>If <i>initv</i> = 'N', then <i>vr</i> need not be set.</p> <p>The array <i>vr</i> is not referenced if <i>side</i> = 'L'.</p> |
| <i>ldh</i> | The leading dimension of <i>h</i> ; at least $\max(1, n)$. |
| <i>w</i> | <p>Array, size at least $\max(1, n)$.</p> <p>Contains the eigenvalues of the matrix <i>H</i>.</p> <p>If <i>eigsrc</i> = 'Q', the array must be exactly as returned by ?hseqr.</p> |
| <i>wr, wi</i> | Arrays, size at least $\max(1, n)$ each. |

Contain the real and imaginary parts, respectively, of the eigenvalues of the matrix H . Complex conjugate pairs of values must be stored in consecutive elements of the arrays. If $eigsrc = 'Q'$, the arrays must be exactly as returned by `?hseqr`.

ldvl

The leading dimension of vl .

If $side = 'L'$ or $'B'$, $ldvl \geq \max(1, n)$ for column major layout and $ldvl \geq \max(1, mm)$ for row major layout .

If $side = 'R'$, $ldvl \geq 1$.

ldvr

The leading dimension of vr .

If $side = 'R'$ or $'B'$, $ldvr \geq \max(1, n)$ for column major layout and $ldvr \geq \max(1, mm)$ for row major layout .

If $side = 'L'$, $ldvr \geq 1$.

mm

The number of columns in vl and/or vr .

Must be at least m , the actual number of columns required (see *Output Parameters* below).

For real flavors, m is obtained by counting 1 for each selected real eigenvector and 2 for each selected complex eigenvector (see *select*).

For complex flavors, m is the number of selected eigenvectors (see *select*).

Constraint:

$$0 \leq mm \leq n.$$

Output Parameters

select

Overwritten for real flavors only.

If a complex eigenvector was selected as specified above, then $select[j - 1]$ is set to 1 and $select[j]$ to 0

w

The real parts of some elements of w may be modified, as close eigenvalues are perturbed slightly in searching for independent eigenvectors.

wr

Some elements of wr may be modified, as close eigenvalues are perturbed slightly in searching for independent eigenvectors.

vl, vr

If $side = 'L'$ or $'B'$, vl contains the computed left eigenvectors (as specified by *select*).

If $side = 'R'$ or $'B'$, vr contains the computed right eigenvectors (as specified by *select*).

The eigenvectors treated column-wise form a rectangular n -by- mm matrix.

For real flavors: a real eigenvector corresponding to a real eigenvalue occupies one column of the matrix; a complex eigenvector corresponding to a complex eigenvalue occupies two columns: the first column holds the real part of the eigenvector and the second column holds the imaginary part of the eigenvector. The matrix is stored in a one-dimensional array as described by *matrix_layout* (using either column major or row major layout).

m For real flavors: the number of columns of *vl* and/or *vr* required to store the selected eigenvectors.
 For complex flavors: the number of selected eigenvectors.

ifaill, ifailr Arrays, size at least $\max(1, mm)$ each.
 $ifaill[i - 1] = 0$ if the *i*th column of *vl* converged;
 $ifaill[i - 1] = j > 0$ if the eigenvector stored in the *i*-th column of *vl* (corresponding to the *j*th eigenvalue) failed to converge.
 $ifailr[i - 1] = 0$ if the *i*th column of *vr* converged;
 $ifailr[i - 1] = j > 0$ if the eigenvector stored in the *i*-th column of *vr* (corresponding to the *j*th eigenvalue) failed to converge.
 For real flavors: if the *i*th and (*i*+1)th columns of *vl* contain a selected complex eigenvector, then $ifaill[i - 1]$ and $ifaill[i]$ are set to the same value. A similar rule holds for *vr* and *ifailr*.
 The array *ifaill* is not referenced if *side* = 'R'. The array *ifailr* is not referenced if *side* = 'L'.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, then *i* eigenvectors (as indicated by the parameters *ifaill* and/or *ifailr* above) failed to converge. The corresponding columns of *vl* and/or *vr* contain no useful information.

Application Notes

Each computed right eigenvector x_i is the exact eigenvector of a nearby matrix $A + E_i$, such that $\|E_i\| < O(\epsilon) \|A\|$. Hence the residual is small:

$$\|Ax_i - \lambda_i x_i\| = O(\epsilon) \|A\|.$$

However, eigenvectors corresponding to close or coincident eigenvalues may not accurately span the relevant subspaces.

Similar remarks apply to computed left eigenvectors.

?trevc

Computes selected eigenvectors of an upper (quasi-) triangular matrix computed by ?hseqr.

Syntax

```
lapack_int LAPACKE_strevc( int matrix_layout, char side, char howmny, lapack_logical*
select, lapack_int n, const float* t, lapack_int ldt, float* vl, lapack_int ldvl,

Description

The routine computes some or all of the right and/or left eigenvectors of an upper triangular matrix T (or, for real flavors, an upper quasi-triangular matrix T). Matrices of this type are produced by the Schur factorization of a general matrix: $A = Q^* T^* Q^H$, as computed by [hseqr](#).

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w , are defined by:

$$T^* x = w^* x, y^H T = w^* y^H, \text{ where } y^H \text{ denotes the conjugate transpose of } y.$$

The eigenvalues are not input to this routine, but are read directly from the diagonal blocks of T .

This routine returns the matrices X and/or Y of right and left eigenvectors of T , or the products $Q^* X$ and/or $Q^* Y$, where Q is an input matrix.

If Q is the orthogonal/unitary factor that reduces a matrix A to Schur form T , then $Q^* X$ and $Q^* Y$ are the matrices of right and left eigenvectors of A .

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>side</i> | Must be 'R' or 'L' or 'B'. If <i>side</i> = 'R', then only right eigenvectors are computed. If <i>side</i> = 'L', then only left eigenvectors are computed. If <i>side</i> = 'B', then all eigenvectors are computed. |
| <i>howmny</i> | Must be 'A' or 'B' or 'S'. If <i>howmny</i> = 'A', then all eigenvectors (as specified by <i>side</i>) are computed. If <i>howmny</i> = 'B', then all eigenvectors (as specified by <i>side</i>) are computed and backtransformed by the matrices supplied in <i>vl</i> and <i>vr</i> . If <i>howmny</i> = 'S', then selected eigenvectors (as specified by <i>side</i> and <i>select</i>) are computed. |
| <i>select</i> | Array, size at least $\max(1, n)$. If <i>howmny</i> = 'S', <i>select</i> specifies which eigenvectors are to be computed. If <i>howmny</i> = 'A' or 'B', <i>select</i> is not referenced. <i>For real flavors:</i> |

If $\omega[j]$ is a real eigenvalue, the corresponding real eigenvector is computed if $\text{select}[j]$ is 1.

If $\omega[j - 1]$ and $\omega[j]$ are the real and imaginary parts of a complex eigenvalue, the corresponding complex eigenvector is computed if either $\text{select}[j - 1]$ or $\text{select}[j]$ is 1, and on exit $\text{select}[j - 1]$ is set to 1 and $\text{select}[j]$ is set to 0.

For complex flavors:

The eigenvector corresponding to the j -th eigenvalue is computed if $\text{select}[j - 1]$ is 1.

n The order of the matrix T ($n \geq 0$).

t, vl, vr Arrays:

t (size $\max(1, ldt * n)$) contains the n -by- n matrix T in Schur canonical form. For complex flavors `ctrevc` and `ztrevc`, contains the upper triangular matrix T .

vl (size $\max(1, ldvl * mm)$ for column major layout and $\max(1, ldvl * n)$ for row major layout)

If $\text{howmny} = 'B'$ and $\text{side} = 'L'$ or $'B'$, then vl must contain an n -by- n matrix Q (usually the matrix of Schur vectors returned by `?hseqr`).

If $\text{howmny} = 'A'$ or $'S'$, then vl need not be set.

The array vl is not referenced if $\text{side} = 'R'$.

vr (size $\max(1, ldvr * mm)$ for column major layout and $\max(1, ldvr * n)$ for row major layout)

If $\text{howmny} = 'B'$ and $\text{side} = 'R'$ or $'B'$, then vr must contain an n -by- n matrix Q (usually the matrix of Schur vectors returned by `?hseqr`).

If $\text{howmny} = 'A'$ or $'S'$, then vr need not be set.

The array vr is not referenced if $\text{side} = 'L'$.

ldt The leading dimension of t ; at least $\max(1, n)$.

$ldvl$ The leading dimension of vl .

If $\text{side} = 'L'$ or $'B'$, $ldvl \geq n$.

If $\text{side} = 'R'$, $ldvl \geq 1$.

$ldvr$ The leading dimension of vr .

If $\text{side} = 'R'$ or $'B'$, $ldvr \geq n$.

If $\text{side} = 'L'$, $ldvr \geq 1$.

mm The number of columns in the arrays vl and/or vr . Must be at least m (the precise number of columns required).

If $\text{howmny} = 'A'$ or $'B'$, $mm = n$.

If $\text{howmny} = 'S'$: for real flavors, mm is obtained by counting 1 for each selected real eigenvector and 2 for each selected complex eigenvector;

for complex flavors, mm is the number of selected eigenvectors (see `select`).

Constraint: $0 \leq mm \leq n$.

Output Parameters

| | |
|---------------|---|
| <i>select</i> | If a complex eigenvector of a real matrix was selected as specified above, then <i>select</i> [<i>j</i>] is set to 1 and <i>select</i> [<i>j</i> + 1] to 0 |
| <i>t</i> | <i>ctrevc</i> / <i>ztrevc</i> modify the <i>t</i> array, which is restored on exit. |
| <i>vl, vr</i> | <p>If <i>side</i> = 'L' or 'B', <i>vl</i> contains the computed left eigenvectors (as specified by <i>howmny</i> and <i>select</i>).</p> <p>If <i>side</i> = 'R' or 'B', <i>vr</i> contains the computed right eigenvectors (as specified by <i>howmny</i> and <i>select</i>).</p> <p>The eigenvectors treated column-wise form a rectangular <i>n</i>-by-<i>mm</i> matrix.</p> <p><i>For real flavors:</i> a real eigenvector corresponding to a real eigenvalue occupies one column of the matrix; a complex eigenvector corresponding to a complex eigenvalue occupies two columns: the first column holds the real part of the eigenvector and the second column holds the imaginary part of the eigenvector. The matrix is stored in a one-dimensional array as described by <i>matrix_layout</i> (using either column major or row major layout).</p> |
| <i>m</i> | <p><i>For complex flavors:</i> the number of selected eigenvectors.</p> <p>If <i>howmny</i> = 'A' or 'B', <i>m</i> is set to <i>n</i>.</p> <p><i>For real flavors:</i> the number of columns of <i>vl</i> and/or <i>vr</i> actually used to store the selected eigenvectors.</p> <p>If <i>howmny</i> = 'A' or 'B', <i>m</i> is set to <i>n</i>.</p> |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

If x_i is an exact right eigenvector and y_i is the corresponding computed eigenvector, then the angle $\theta(y_i, x_i)$ between them is bounded as follows: $\theta(y_i, x_i) \leq (c(n)\epsilon ||T||_2) / \text{sep}_i$ where sep_i is the reciprocal condition number of x_i . The condition number sep_i may be computed by calling `?trsna`.

?trsna

Estimates condition numbers for specified eigenvalues and right eigenvectors of an upper (quasi-) triangular matrix.

Syntax

```
lapack_int LAPACKE_strsna( int matrix_layout, char job, char howmny, const
lapack_logical* select, lapack_int n, const float* t, lapack_int ldt, const float* vl,

Description

The routine estimates condition numbers for specified eigenvalues and/or right eigenvectors of an upper triangular matrix T (or, for real flavors, upper quasi-triangular matrix T in canonical Schur form). These are the same as the condition numbers of the eigenvalues and right eigenvectors of an original matrix $A = Z^* T^* Z^H$ (with unitary or, for real flavors, orthogonal Z), from which T may have been derived.

The routine computes the reciprocal of the condition number of an eigenvalue λ_i as $s_i = |v^T * u| / (||u||_E ||v||_E)$ for real flavors and $s_i = |v^H * u| / (||u||_E ||v||_E)$ for complex flavors,

where:

- u and v are the right and left eigenvectors of T , respectively, corresponding to λ_i .
- v^T/v^H denote transpose/conjugate transpose of v , respectively.

This reciprocal condition number always lies between zero (ill-conditioned) and one (well-conditioned).

An approximate error estimate for a computed eigenvalue λ_i is then given by $\epsilon^* ||T|| / s_i$, where ϵ is the *machine precision*.

To estimate the reciprocal of the condition number of the right eigenvector corresponding to λ_i , the routine first calls [trexc](#) to reorder the diagonal elements of matrix T so that λ_i is in the leading position:

$$T = Q \begin{bmatrix} \lambda_i & C^H \\ \mathbf{0} & T_{22} \end{bmatrix} Q^H$$

The reciprocal condition number of the eigenvector is then estimated as sep_i , the smallest singular value of the matrix $T_{22} - \lambda_i I$.

An approximate error estimate for a computed right eigenvector u corresponding to λ_i is then given by $\epsilon^* ||T|| / sep_i$.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>job</i> | Must be 'E' or 'V' or 'B'. |

If $job = 'E'$, then condition numbers for eigenvalues only are computed.
 If $job = 'V'$, then condition numbers for eigenvectors only are computed.
 If $job = 'B'$, then condition numbers for both eigenvalues and eigenvectors are computed.

howmny

Must be 'A' or 'S'.
 If $howmny = 'A'$, then the condition numbers for all eigenpairs are computed.
 If $howmny = 'S'$, then condition numbers for selected eigenpairs (as specified by *select*) are computed.

select

Array, size at least $\max(1, n)$ if $howmny = 'S'$ and at least 1 otherwise.
 Specifies the eigenpairs for which condition numbers are to be computed if $howmny = 'S'$.
For real flavors:
 To select condition numbers for the eigenpair corresponding to the real eigenvalue λ_j , $select[j]$ must be set 1;
 to select condition numbers for the eigenpair corresponding to a complex conjugate pair of eigenvalues λ_j and λ_{j+1} , $select[j - 1]$ and/or $select[j]$ must be set 1
For complex flavors
 To select condition numbers for the eigenpair corresponding to the eigenvalue λ_j , $select[j]$ must be set 1 *select* is not referenced if $howmny = 'A'$.

n

The order of the matrix T ($n \geq 0$).

t, vl, vr

Arrays:
t (size $\max(1, ldt * n)$) contains the n -by- n matrix T .
vl (size $\max(1, ldvl * mm)$ for column major layout and $\max(1, ldvl * n)$ for row major layout)
 If $job = 'E'$ or $'B'$, then *vl* must contain the left eigenvectors of T (or of any matrix $Q * T * Q^H$ with Q unitary or orthogonal) corresponding to the eigenpairs specified by *howmny* and *select*. The eigenvectors must be stored in consecutive columns of *vl*, as returned by [trevc](#) or [hsein](#).
 The array *vl* is not referenced if $job = 'V'$.
vr (size $\max(1, ldvr * mm)$ for column major layout and $\max(1, ldvr * n)$ for row major layout)
 If $job = 'E'$ or $'B'$, then *vr* must contain the right eigenvectors of T (or of any matrix $Q * T * Q^H$ with Q unitary or orthogonal) corresponding to the eigenpairs specified by *howmny* and *select*. The eigenvectors must be stored in consecutive columns of *vr*, as returned by [trevc](#) or [hsein](#).
 The array *vr* is not referenced if $job = 'V'$.

ldt

The leading dimension of *t*; at least $\max(1, n)$.

ldvl

The leading dimension of *vl*.

If $job = 'E'$ or $'B'$, $ldvl \geq \max(1, n)$ for column major layout and $ldvl \geq \max(1, mm)$ for row major layout .

If $job = 'V'$, $ldvl \geq 1$.

ldvr

The leading dimension of *vr*.

If $job = 'E'$ or $'B'$, $ldvr \geq \max(1, n)$ for column major layout and $ldvr \geq \max(1, mm)$ for row major layout .

If $job = 'R'$, $ldvr \geq 1$.

mm

The number of elements in the arrays *s* and *sep*, and the number of columns in *vl* and *vr* (if used). Must be at least *m* (the precise number required).

If *howmny* = 'A', $mm = n$;

if *howmny* = 'S', for *real flavors* *mm* is obtained by counting 1 for each selected real eigenvalue and 2 for each selected complex conjugate pair of eigenvalues.

for *complex flavors* *mm* is the number of selected eigenpairs (see *select*).

Constraint:

$0 \leq mm \leq n$.

Output Parameters

s

Array, size at least $\max(1, mm)$ if $job = 'E'$ or $'B'$ and at least 1 if $job = 'V'$.

Contains the reciprocal condition numbers of the selected eigenvalues if $job = 'E'$ or $'B'$, stored in consecutive elements of the array. Thus $s[j - 1]$, $sep[j - 1]$ and the *j*-th columns of *vl* and *vr* all correspond to the same eigenpair (but not in general the *j*th eigenpair unless all eigenpairs have been selected).

For *real flavors*: for a complex conjugate pair of eigenvalues, two consecutive elements of *s* are set to the same value. The array *s* is not referenced if $job = 'V'$.

sep

Array, size at least $\max(1, mm)$ if $job = 'V'$ or $'B'$ and at least 1 if $job = 'E'$. Contains the estimated reciprocal condition numbers of the selected right eigenvectors if $job = 'V'$ or $'B'$, stored in consecutive elements of the array.

For *real flavors*: for a complex eigenvector, two consecutive elements of *sep* are set to the same value; if the eigenvalues cannot be reordered to compute $sep[j - 1]$, then $sep[j - 1]$ is set to zero; this can only occur when the true value would be very small anyway. The array *sep* is not referenced if $job = 'E'$.

m

For *complex flavors*: the number of selected eigenpairs.

If *howmny* = 'A', *m* is set to *n*.

For *real flavors*: the number of elements of *s* and/or *sep* actually used to store the estimated condition numbers.

If $howmny = 'A'$, m is set to n .

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

The computed values sep_i may overestimate the true value, but seldom by a factor of more than 3.

?trexc

Reorders the Schur factorization of a general matrix.

Syntax

```
lapack_int LAPACKE_strexc( int matrix_layout, char compq, lapack_int n, float* t,
lapack_int ldt, float* q, lapack_int ldq, lapack_int* ifst, lapack_int* ilst );
```

```
lapack_int LAPACKE_dtrexc( int matrix_layout, char compq, lapack_int n, double* t,
lapack_int ldt, double* q, lapack_int ldq, lapack_int* ifst, lapack_int* ilst );
```

```
lapack_int LAPACKE_ctrexc( int matrix_layout, char compq, lapack_int n,
lapack_complex_float* t, lapack_int ldt, lapack_complex_float* q, lapack_int ldq,
lapack_int ifst, lapack_int ilst );
```

```
lapack_int LAPACKE_ztrexc( int matrix_layout, char compq, lapack_int n,
lapack_complex_double* t, lapack_int ldt, lapack_complex_double* q, lapack_int ldq,
lapack_int ifst, lapack_int ilst );
```

Include Files

- mkl.h

Description

The routine reorders the Schur factorization of a general matrix $A = Q^*T^*Q^H$, so that the diagonal element or block of T with row index $ifst$ is moved to row $ilst$.

The reordered Schur form S is computed by an unitary (or, for real flavors, orthogonal) similarity transformation: $S = Z^H * T * Z$. Optionally the updated matrix P of Schur vectors is computed as $P = Q * Z$, giving $A = P * S * P^H$.

Input Parameters

| | |
|------------------|--|
| $matrix_layout$ | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| $compq$ | Must be 'V' or 'N'. If $compq = 'V'$, then the Schur vectors (Q) are updated. If $compq = 'N'$, then no Schur vectors are updated. |
| n | The order of the matrix T ($n \geq 0$). |
| t, q | Arrays: |

t (size $\max(1, ldt*n)$) contains the n -by- n matrix T .

q (size $\max(1, ldq*n)$)

If $compq = 'V'$, then q must contain Q (Schur vectors).

If $compq = 'N'$, then q is not referenced.

ldt The leading dimension of t ; at least $\max(1, n)$.

ldq The leading dimension of q ;

If $compq = 'N'$, then $ldq \geq 1$.

If $compq = 'V'$, then $ldq \geq \max(1, n)$.

$ifst, ilst$ $1 \leq ifst \leq n$; $1 \leq ilst \leq n$.

Must specify the reordering of the diagonal elements (or blocks, which is possible for real flavors) of the matrix T . The element (or block) with row index $ifst$ is moved to row $ilst$ by a sequence of exchanges between adjacent elements (or blocks).

Output Parameters

t Overwritten by the updated matrix S .

q If $compq = 'V'$, q contains the updated matrix of Schur vectors.

$ifst, ilst$ Overwritten for real flavors only.

If $ifst$ pointed to the second row of a 2 by 2 block on entry, it is changed to point to the first row; $ilst$ always points to the first row of the block in its final position (which may differ from its input value by ± 1).

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

The computed matrix S is exactly similar to a matrix $T+E$, where $\|E\|_2 = O(\epsilon) * \|T\|_2$, and ϵ is the machine precision.

Note that if a 2 by 2 diagonal block is involved in the re-ordering, its off-diagonal elements are in general changed; the diagonal elements and the eigenvalues of the block are unchanged unless the block is sufficiently ill-conditioned, in which case they may be noticeably altered. It is possible for a 2 by 2 block to break into two 1 by 1 blocks, that is, for a pair of complex eigenvalues to become purely real.

The approximate number of floating-point operations is

for real flavors: $6n(ifst-ilst)$ if $compq = 'N'$;
 $12n(ifst-ilst)$ if $compq = 'V'$;

for complex flavors: $20n(ifst-ilst)$ if $compq = 'N'$;
 $40n(ifst-ilst)$ if $compq = 'V'$.

?trsen

Reorders the Schur factorization of a matrix and (optionally) computes the reciprocal condition numbers for the selected cluster of eigenvalues and respective invariant subspace.

Syntax

```
lapack_int LAPACKE_strsen( int matrix_layout, char job, char compq, const
lapack_logical* select, lapack_int n, float* t, lapack_int ldt, float* q, lapack_int
ldq, float* wr, float* wi, lapack_int* m, float* s, float* sep );

lapack_int LAPACKE_dtrsen( int matrix_layout, char job, char compq, const
lapack_logical* select, lapack_int n, double* t, lapack_int ldt, double* q, lapack_int
ldq, double* wr, double* wi, lapack_int* m, double* s, double* sep );

lapack_int LAPACKE_ctrsen( int matrix_layout, char job, char compq, const
lapack_logical* select, lapack_int n, lapack_complex_float* t, lapack_int ldt,
lapack_complex_float* q, lapack_int ldq, lapack_complex_float* w, lapack_int* m, float*
s, float* sep );

lapack_int LAPACKE_ztrsen( int matrix_layout, char job, char compq, const
lapack_logical* select, lapack_int n, lapack_complex_double* t, lapack_int ldt,
lapack_complex_double* q, lapack_int ldq, lapack_complex_double* w, lapack_int* m,
double* s, double* sep );
```

Include Files

- mkl.h

Description

The routine reorders the Schur factorization of a general matrix $A = Q^*T^*Q^T$ (for real flavors) or $A = Q^*T^*Q^H$ (for complex flavors) so that a selected cluster of eigenvalues appears in the leading diagonal elements (or, for real flavors, diagonal blocks) of the Schur form. The reordered Schur form R is computed by a unitary (orthogonal) similarity transformation: $R = Z^H * T * Z$. Optionally the updated matrix P of Schur vectors is computed as $P = Q * Z$, giving $A = P * R * P^H$.

Let

$$R = \begin{bmatrix} T_{11} & T_{12} \\ 0 & T_{13} \end{bmatrix}$$

where the selected eigenvalues are precisely the eigenvalues of the leading m -by- m submatrix T_{11} . Let P be correspondingly partitioned as $(Q_1 Q_2)$ where Q_1 consists of the first m columns of Q . Then $A^* Q_1 = Q_1^* T_{11}$, and so the m columns of Q_1 form an orthonormal basis for the invariant subspace corresponding to the selected cluster of eigenvalues.

Optionally the routine also computes estimates of the reciprocal condition numbers of the average of the cluster of eigenvalues and of the invariant subspace.

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

| | |
|---------------|---|
| <i>job</i> | <p>Must be 'N' or 'E' or 'V' or 'B'.</p> <p>If <i>job</i> = 'N', then no condition numbers are required.</p> <p>If <i>job</i> = 'E', then only the condition number for the cluster of eigenvalues is computed.</p> <p>If <i>job</i> = 'V', then only the condition number for the invariant subspace is computed.</p> <p>If <i>job</i> = 'B', then condition numbers for both the cluster and the invariant subspace are computed.</p> |
| <i>compq</i> | <p>Must be 'V' or 'N'.</p> <p>If <i>compq</i> = 'V', then <i>Q</i> of the Schur vectors is updated.</p> <p>If <i>compq</i> = 'N', then no Schur vectors are updated.</p> |
| <i>select</i> | <p>Array, size at least $\max(1, n)$.</p> <p>Specifies the eigenvalues in the selected cluster. To select an eigenvalue λ_j, <i>select</i>[<i>j</i>] must be 1</p> <p><i>For real flavors:</i> to select a complex conjugate pair of eigenvalues λ_j and λ_{j+1} (corresponding 2 by 2 diagonal block), <i>select</i>[<i>j</i> - 1] and/or <i>select</i>[<i>j</i>] must be 1; the complex conjugate λ_j and λ_{j+1} must be either both included in the cluster or both excluded.</p> |
| <i>n</i> | The order of the matrix <i>T</i> ($n \geq 0$). |
| <i>t, q</i> | <p>Arrays:</p> <p><i>t</i> (size $\max(1, ldt * n)$) The upper quasi-triangular <i>n</i>-by-<i>n</i> matrix <i>T</i>, in Schur canonical form.</p> <p><i>q</i> (size $\max(1, ldq * n)$)</p> <p>If <i>compq</i> = 'V', then <i>q</i> must contain the matrix <i>Q</i> of Schur vectors.</p> <p>If <i>compq</i> = 'N', then <i>q</i> is not referenced.</p> |
| <i>ldt</i> | The leading dimension of <i>t</i> ; at least $\max(1, n)$. |
| <i>ldq</i> | <p>The leading dimension of <i>q</i>;</p> <p>If <i>compq</i> = 'N', then $ldq \geq 1$.</p> <p>If <i>compq</i> = 'V', then $ldq \geq \max(1, n)$.</p> |

Output Parameters

| | |
|----------|---|
| <i>t</i> | Overwritten by the reordered matrix <i>R</i> in Schur canonical form with the selected eigenvalues in the leading diagonal blocks. |
| <i>q</i> | If <i>compq</i> = 'V', <i>q</i> contains the updated matrix of Schur vectors; the first <i>m</i> columns of the <i>Q</i> form an orthogonal basis for the specified invariant subspace. |
| <i>w</i> | Array, size at least $\max(1, n)$. The recorded eigenvalues of <i>R</i> . The eigenvalues are stored in the same order as on the diagonal of <i>R</i> . |

| | |
|---------------|--|
| <i>wr, wi</i> | Arrays, size at least $\max(1, n)$. Contain the real and imaginary parts, respectively, of the reordered eigenvalues of R . The eigenvalues are stored in the same order as on the diagonal of R . Note that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering. |
| <i>m</i> | <p><i>For complex flavors:</i> the dimension of the specified invariant subspaces, which is the same as the number of selected eigenvalues (see <i>select</i>).</p> <p><i>For real flavors:</i> the dimension of the specified invariant subspace. The value of m is obtained by counting 1 for each selected real eigenvalue and 2 for each selected complex conjugate pair of eigenvalues (see <i>select</i>).</p> <p>Constraint: $0 \leq m \leq n$.</p> |
| <i>s</i> | <p>If $job = 'E'$ or $'B'$, s is a lower bound on the reciprocal condition number of the average of the selected cluster of eigenvalues.</p> <p>If $m = 0$ or n, then $s = 1$.</p> <p><i>For real flavors:</i> if $info = 1$, then s is set to zero. s is not referenced if $job = 'N'$ or $'V'$.</p> |
| <i>sep</i> | <p>If $job = 'V'$ or $'B'$, sep is the estimated reciprocal condition number of the specified invariant subspace.</p> <p>If $m = 0$ or n, then $sep = T$.</p> <p><i>For real flavors:</i> if $info = 1$, then sep is set to zero.</p> <p>sep is not referenced if $job = 'N'$ or $'E'$.</p> |

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = 1$, the reordering of T failed because some eigenvalues are too close to separate (the problem is very ill-conditioned); T may have been partially reordered, and wr and wi contain the eigenvalues in the same order as in T ; s and sep (if requested) are set to zero.

Application Notes

The computed matrix R is exactly similar to a matrix $T+E$, where $\|E\|_2 = O(\epsilon) * \|T\|_2$, and ϵ is the machine precision. The computed s cannot underestimate the true reciprocal condition number by more than a factor of $(\min(m, n-m))_{1/2}$; sep may differ from the true value by $(m*n-m^2)_{1/2}$. The angle between the computed invariant subspace and the true subspace is $O(\epsilon) * \|A\|_2 / sep$. Note that if a 2-by-2 diagonal block is involved in the re-ordering, its off-diagonal elements are in general changed; the diagonal elements and the eigenvalues of the block are unchanged unless the block is sufficiently ill-conditioned, in which case they may be noticeably altered. It is possible for a 2-by-2 block to break into two 1-by-1 blocks, that is, for a pair of complex eigenvalues to become purely real.

?trsyl

Solves Sylvester equation for real quasi-triangular or complex triangular matrices.

Include Files

- mkl.h

Description

The routine solves the Sylvester matrix equation $\text{op}(A) * X \pm X * \text{op}(B) = \alpha * C$, where $\text{op}(A) = A$ or A^H , and the matrices A and B are upper triangular (or, for real flavors, upper quasi-triangular in canonical Schur form); $\alpha \leq 1$ is a scale factor determined by the routine to avoid overflow in X ; A is m -by- m , B is n -by- n , and C and X are both m -by- n . The matrix X is obtained by a straightforward process of back substitution.

The equation has a unique solution if and only if $\alpha_i \pm \beta_i \neq 0$, where $\{\alpha_i\}$ and $\{\beta_i\}$ are the eigenvalues of A and B , respectively, and the sign (+ or -) is the same as that used in the equation to be solved.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>trana</i> | Must be 'N' or 'T' or 'C'. If <i>trana</i> = 'N', then $\text{op}(A) = A$. If <i>trana</i> = 'T', then $\text{op}(A) = A^T$ (real flavors only). If <i>trana</i> = 'C' then $\text{op}(A) = A^H$. |
| <i>tranb</i> | Must be 'N' or 'T' or 'C'. If <i>tranb</i> = 'N', then $\text{op}(B) = B$. If <i>tranb</i> = 'T', then $\text{op}(B) = B^T$ (real flavors only). If <i>tranb</i> = 'C', then $\text{op}(B) = B^H$. |
| <i>isgn</i> | Indicates the form of the Sylvester equation. If <i>isgn</i> = +1, $\text{op}(A) * X + X * \text{op}(B) = \text{alpha} * C$. If <i>isgn</i> = -1, $\text{op}(A) * X - X * \text{op}(B) = \text{alpha} * C$. |
| <i>m</i> | The order of A , and the number of rows in X and C ($m \geq 0$). |

| | |
|-----------|--|
| n | The order of B , and the number of columns in X and C ($n \geq 0$). |
| a, b, c | Arrays: a (size $\max(1, lda * m)$) contains the matrix A . b (size $\max(1, ldb * n)$) contains the matrix B . c (size $\max(1, ldc * n)$ for column major layout and $\max(1, ldc * m)$ for row major layout) contains the matrix C . |
| lda | The leading dimension of a ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |
| ldb | The leading dimension of b ; at least $\max(1, n)$. |
| ldc | The leading dimension of c ; at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout . |

Output Parameters

| | |
|---------|--|
| c | Overwritten by the solution matrix X . |
| $scale$ | The value of the scale factor α . |

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = 1$, A and B have common or close eigenvalues; perturbed values were used to solve the equation.

Application Notes

Let X be the exact, Y the corresponding computed solution, and R the residual matrix: $R = C - (AY \pm YB)$. Then the residual is always small:

$$\|R\|_F = O(\epsilon) * (\|A\|_F + \|B\|_F) * \|Y\|_F.$$

However, Y is not necessarily the exact solution of a slightly perturbed equation; in other words, the solution is not backwards stable.

For the forward error, the following bound holds:

$$\|Y - X\|_F \leq \|R\|_F / \text{sep}(A, B)$$

but this may be a considerable overestimate. See [Golub96] for a definition of $\text{sep}(A, B)$.

The approximate number of floating-point operations for real flavors is $m * n * (m + n)$. For complex flavors it is 4 times greater.

Generalized Nonsymmetric Eigenvalue Problems: LAPACK Computational Routines

This section describes LAPACK routines for solving generalized nonsymmetric eigenvalue problems, reordering the generalized Schur factorization of a pair of matrices, as well as performing a number of related computational tasks.

A *generalized nonsymmetric eigenvalue problem* is as follows: given a pair of nonsymmetric (or non-Hermitian) n -by- n matrices A and B , find the *generalized eigenvalues* λ and the corresponding *generalized eigenvectors* x and y that satisfy the equations

$$Ax = \lambda Bx \text{ (right generalized eigenvectors } x)$$

and

$y^H A = \lambda y^H B$ (left generalized eigenvectors y).

Table "Computational Routines for Solving Generalized Nonsymmetric Eigenvalue Problems" lists LAPACK routines used to solve the generalized nonsymmetric eigenvalue problems and the generalized Sylvester equation.

Computational Routines for Solving Generalized Nonsymmetric Eigenvalue Problems

| Routine name | Operation performed |
|------------------------|--|
| ggghrd | Reduces a pair of matrices to generalized upper Hessenberg form using orthogonal/unitary transformations. |
| ggbal | Balances a pair of general real or complex matrices. |
| ggbak | Forms the right or left eigenvectors of a generalized eigenvalue problem. |
| ggghd3 | Reduces a pair of matrices to generalized upper Hessenberg form. |
| hgeqz | Implements the QZ method for finding the generalized eigenvalues of the matrix pair (H,T). |
| tgevc | Computes some or all of the right and/or left generalized eigenvectors of a pair of upper triangular matrices |
| tgexc | Reorders the generalized Schur decomposition of a pair of matrices (A,B) so that one diagonal block of (A,B) moves to another row index. |
| tgsen | Reorders the <i>generalized</i> Schur decomposition of a pair of matrices (A,B) so that a selected cluster of eigenvalues appears in the leading diagonal blocks of (A,B). |
| tgsyl | Solves the generalized Sylvester equation. |
| tgsyl | Estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a pair of matrices in generalized real Schur canonical form. |

?ggghrd

Reduces a pair of matrices to generalized upper Hessenberg form using orthogonal/unitary transformations.

Description

The routine reduces a pair of real/complex matrices (A, B) to generalized upper Hessenberg form using orthogonal/unitary transformations, where A is a general matrix and B is upper triangular. The form of the generalized eigenvalue problem is $A^*x = \lambda^*B^*x$, and B is typically made upper triangular by computing its QR factorization and moving the orthogonal matrix Q to the left side of the equation.

This routine simultaneously reduces A to a Hessenberg matrix H :

$$Q^H A Z = H$$

and transforms B to another upper triangular matrix T :

$$Q^H B Z = T$$

in order to reduce the problem to its standard form $H^*y = \lambda^*T^*y$, where $y = Z^H x$.

The orthogonal/unitary matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q_1 and Z_1 , so that

$$Q_1^* A Z_1^H = (Q_1^* Q)^* H^* (Z_1^* Z)^H$$

$$Q_1^* B Z_1^H = (Q_1^* Q)^* T^* (Z_1^* Z)^H$$

If Q_1 is the orthogonal/unitary matrix from the QR factorization of B in the original equation $A^*x = \lambda^*B^*x$, then the routine `?gghrd` reduces the original problem to generalized Hessenberg form.

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>compq</code> | <p>Must be 'N', 'I', or 'V'.</p> <p>If <code>compq = 'N'</code>, matrix Q is not computed.</p> <p>If <code>compq = 'I'</code>, Q is initialized to the unit matrix, and the orthogonal/unitary matrix Q is returned;</p> <p>If <code>compq = 'V'</code>, Q must contain an orthogonal/unitary matrix Q_1 on entry, and the product Q_1^*Q is returned.</p> |
| <code>compz</code> | <p>Must be 'N', 'I', or 'V'.</p> <p>If <code>compz = 'N'</code>, matrix Z is not computed.</p> <p>If <code>compz = 'I'</code>, Z is initialized to the unit matrix, and the orthogonal/unitary matrix Z is returned;</p> <p>If <code>compz = 'V'</code>, Z must contain an orthogonal/unitary matrix Z_1 on entry, and the product Z_1^*Z is returned.</p> |
| <code>n</code> | The order of the matrices A and B ($n \geq 0$). |
| <code>ilo, ihi</code> | <p><code>ilo</code> and <code>ihi</code> mark the rows and columns of A which are to be reduced. It is assumed that A is already upper triangular in rows and columns $1:ilo-1$ and $ihi+1:n$. Values of <code>ilo</code> and <code>ihi</code> are normally set by a previous call to <code>ggbal</code>; otherwise they should be set to 1 and n respectively.</p> <p>Constraint:</p> |

| | |
|--------------|---|
| | <p>If $n > 0$, then $1 \leq ilo \leq ihi \leq n$;</p> <p>if $n = 0$, then $ilo = 1$ and $ihi = 0$.</p> |
| a, b, q, z | <p>Arrays:</p> <p>a (size $\max(1, lda*n)$) contains the n-by-n general matrix A.</p> <p>b (size $\max(1, ldb*n)$) contains the n-by-n upper triangular matrix B.</p> <p>q (size $\max(1, ldq*n)$)</p> <p>If $compq = 'N'$, then q is not referenced.</p> <p>If $compq = 'V'$, then q must contain the orthogonal/unitary matrix Q_1, typically from the QR factorization of B.</p> <p>z (size $\max(1, ldz*n)$)</p> <p>If $compz = 'N'$, then z is not referenced.</p> <p>If $compz = 'V'$, then z must contain the orthogonal/unitary matrix Z_1.</p> |
| lda | The leading dimension of a ; at least $\max(1, n)$. |
| ldb | The leading dimension of b ; at least $\max(1, n)$. |
| ldq | <p>The leading dimension of q;</p> <p>If $compq = 'N'$, then $ldq \geq 1$.</p> <p>If $compq = 'I'$ or $'V'$, then $ldq \geq \max(1, n)$.</p> |
| ldz | <p>The leading dimension of z;</p> <p>If $compz = 'N'$, then $ldz \geq 1$.</p> <p>If $compz = 'I'$ or $'V'$, then $ldz \geq \max(1, n)$.</p> |

Output Parameters

| | |
|-----|--|
| a | On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H , and the rest is set to zero. |
| b | On exit, overwritten by the upper triangular matrix $T = Q^H * B * Z$. The elements below the diagonal are set to zero. |
| q | <p>If $compq = 'I'$, then q contains the orthogonal/unitary matrix Q;</p> <p>If $compq = 'V'$, then q is overwritten by the product $Q_1 * Q$.</p> |
| z | <p>If $compz = 'I'$, then z contains the orthogonal/unitary matrix Z;</p> <p>If $compz = 'V'$, then z is overwritten by the product $Z_1 * Z$.</p> |

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

?ggbal

Balances a pair of general real or complex matrices.

Syntax

```
lapack_int LAPACKE_sggbal( int matrix_layout, char job, lapack_int n, float* a,
lapack_int lda, float* b, lapack_int ldb, lapack_int* ilo, lapack_int* ihi, float*
lscale, float* rscale );
```

```
lapack_int LAPACKE_dggbal( int matrix_layout, char job, lapack_int n, double* a,
lapack_int lda, double* b, lapack_int ldb, lapack_int* ilo, lapack_int* ihi, double*
lscale, double* rscale );
```

```
lapack_int LAPACKE_cggbal( int matrix_layout, char job, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb,
lapack_int* ilo, lapack_int* ihi, float* lscale, float* rscale );
```

```
lapack_int LAPACKE_zggbal( int matrix_layout, char job, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb,
lapack_int* ilo, lapack_int* ihi, double* lscale, double* rscale );
```

Include Files

- mkl.h

Description

The routine balances a pair of general real/complex matrices (A, B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to $ilo-1$ and last $ihi+1$ to n elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ilo to ihi to make the rows and columns as close in norm as possible. Both steps are optional. Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem $A*x = \lambda*B*x$.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>job</i> | Specifies the operations to be performed on A and B . Must be 'N' or 'P' or 'S' or 'B'. If <i>job</i> = 'N', then no operations are done; simply set $ilo = 1$, $ihi = n$, $lscale[i] = 1.0$ and $rscale[i] = 1.0$ for $i = 0, \dots, n - 1$. If <i>job</i> = 'P', then permute only. If <i>job</i> = 'S', then scale only. If <i>job</i> = 'B', then both permute and scale. |
| <i>n</i> | The order of the matrices A and B ($n \geq 0$). |
| <i>a, b</i> | Arrays: a (size $\max(1, lda*n)$) contains the matrix A . b (size $\max(1, ldb*n)$) contains the matrix B . If <i>job</i> = 'N', a and b are not referenced. |

lda The leading dimension of *a*; at least $\max(1, n)$.

ldb The leading dimension of *b*; at least $\max(1, n)$.

Output Parameters

a, b Overwritten by the balanced matrices *A* and *B*, respectively.

ilo, ihi *ilo* and *ihi* are set to integers such that on exit $A_{i,j} = 0$ and $B_{i,j} = 0$ if $i > j$ and $j=1, \dots, ilo-1$ or $i=ihi+1, \dots, n$.
If *job* = 'N' or 'S', then *ilo* = 1 and *ihi* = *n*.

lscale, rscale Arrays, size at least $\max(1, n)$.
lscale contains details of the permutations and scaling factors applied to the left side of *A* and *B*.
If P_j is the index of the row interchanged with row *j*, and D_j is the scaling factor applied to row *j*, then

$$lscale[j - 1] = P_j, \text{ for } j = 1, \dots, ilo-1$$

$$= D_j, \text{ for } j = ilo, \dots, ihi$$

$$= P_j, \text{ for } j = ihi+1, \dots, n.$$
rscale contains details of the permutations and scaling factors applied to the right side of *A* and *B*.
If P_j is the index of the column interchanged with column *j*, and D_j is the scaling factor applied to column *j*, then

$$rscale[j - 1] = P_j, \text{ for } j = 1, \dots, ilo-1$$

$$= D_j, \text{ for } j = ilo, \dots, ihi$$

$$= P_j, \text{ for } j = ihi+1, \dots, n$$
The order in which the interchanges are made is *n* to *ihi+1*, then 1 to *ilo-1*.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

?ggbak

Forms the right or left eigenvectors of a generalized eigenvalue problem.

Syntax

```
lapack_int LAPACKE_sggbak( int matrix_layout, char job, char side, lapack_int n,
lapack_int ilo, lapack_int ihi, const float* lscale, const float* rscale, lapack_int
m, float* v, lapack_int ldv );
```

```
lapack_int LAPACKE_dggbak( int matrix_layout, char job, char side, lapack_int n,
lapack_int ilo, lapack_int ihi, const double* lscale, const double* rscale, lapack_int
m, double* v, lapack_int ldv );
```

```
lapack_int LAPACKE_cggbak( int matrix_layout, char job, char side, lapack_int n,
lapack_int ilo, lapack_int ihi, const float* lscale, const float* rscale, lapack_int
m, lapack_complex_float* v, lapack_int ldv );
```

```
lapack_int LAPACKE_zggbak( int matrix_layout, char job, char side, lapack_int n,
lapack_int ilo, lapack_int ihi, const double* lscale, const double* rscale, lapack_int
m, lapack_complex_double* v, lapack_int ldv );
```

Include Files

- mkl.h

Description

The routine forms the right or left eigenvectors of a real/complex generalized eigenvalue problem

$$A*x = \lambda*B*x$$

by backward transformation on the computed eigenvectors of the balanced pair of matrices output by [ggbal](#).

Input Parameters

| | |
|-----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>job</i> | Specifies the type of backward transformation required. Must be 'N', 'P', 'S', or 'B'. If <i>job</i> = 'N', then no operations are done; return. If <i>job</i> = 'P', then do backward transformation for permutation only. If <i>job</i> = 'S', then do backward transformation for scaling only. If <i>job</i> = 'B', then do backward transformation for both permutation and scaling. This argument must be the same as the argument <i>job</i> supplied to ? ggbal . |
| <i>side</i> | Must be 'L' or 'R'. If <i>side</i> = 'L', then <i>v</i> contains left eigenvectors. If <i>side</i> = 'R', then <i>v</i> contains right eigenvectors. |
| <i>n</i> | The number of rows of the matrix <i>V</i> ($n \geq 0$). |
| <i>ilo, ihi</i> | The integers <i>ilo</i> and <i>ihi</i> determined by ? ggbal . Constraint: If $n > 0$, then $1 \leq ilo \leq ihi \leq n$; if $n = 0$, then $ilo = 1$ and $ihi = 0$. |
| <i>lscale, rscale</i> | Arrays, size at least $\max(1, n)$. The array <i>lscale</i> contains details of the permutations and/or scaling factors applied to the left side of <i>A</i> and <i>B</i> , as returned by ? ggbal . The array <i>rscale</i> contains details of the permutations and/or scaling factors applied to the right side of <i>A</i> and <i>B</i> , as returned by ? ggbal . |
| <i>m</i> | The number of columns of the matrix <i>V</i> ($m \geq 0$). |

| | |
|------------|---|
| <i>v</i> | Array <i>v</i> (size $\max(1, ldv*m)$ for column major layout and $\max(1, ldv*n)$ for row major layout) . Contains the matrix of right or left eigenvectors to be transformed, as returned by <code>tgevc</code> . |
| <i>ldv</i> | The leading dimension of <i>v</i> ; at least $\max(1, n)$ for column major layout and at least $\max(1, m)$ for row major layout . |

Output Parameters

| | |
|----------|---|
| <i>v</i> | Overwritten by the transformed eigenvectors |
|----------|---|

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

?gghd3

Reduces a pair of matrices to generalized upper Hessenberg form.

Syntax

```
lapack_int LAPACKE_sgghd3 (int matrix_layout, char compq, char compz, lapack_int n,

Description

?gghd3 reduces a pair of real or complex matrices (*A*, *B*) to generalized upper Hessenberg form using orthogonal/unitary transformations, where *A* is a general matrix and *B* is upper triangular. The form of the generalized eigenvalue problem is

$$A*x = \lambda*B*x,$$

and *B* is typically made upper triangular by computing its QR factorization and moving the orthogonal/unitary matrix *Q* to the left side of the equation.

This subroutine simultaneously reduces *A* to a Hessenberg matrix *H*:

$$Q^T*A*Z = H \text{ for real flavors}$$

or

$$Q^T * A * Z = H \text{ for complex flavors}$$

and transforms B to another upper triangular matrix T :

$$Q^T * B * Z = T \text{ for real flavors}$$

or

$$Q^T * B * Z = T \text{ for complex flavors}$$

in order to reduce the problem to its standard form

$$H * y = \lambda * T * y$$

where $y = Z^T * x$ for real flavors

or

$$y = Z^T * x \text{ for complex flavors.}$$

The orthogonal/unitary matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q_1 and Z_1 , so that

for real flavors:

$$Q_1 * A * Z_1^T = (Q_1 * Q) * H * (Z_1 * Z)^T$$

$$Q_1 * B * Z_1^T = (Q_1 * Q) * T * (Z_1 * Z)^T$$

for complex flavors:

$$Q_1 * A * Z_1^H = (Q_1 * Q) * H * (Z_1 * Z)^T$$

$$Q_1 * B * Z_1^T = (Q_1 * Q) * T * (Z_1 * Z)^T$$

If Q_1 is the orthogonal/unitary matrix from the QR factorization of B in the original equation $A * x = \lambda * B * x$, then `?ggghd3` reduces the original problem to generalized Hessenberg form.

This is a blocked variant of `?ggghrd`, using matrix-matrix multiplications for parts of the computation to enhance performance.

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>compq</code> | <ul style="list-style-type: none"> = 'N': do not compute q; = 'I': q is initialized to the unit matrix, and the orthogonal/unitary matrix Q is returned; = 'V': q must contain an orthogonal/unitary matrix Q_1 on entry, and the product $Q_1 * q$ is returned. |
| <code>compz</code> | <ul style="list-style-type: none"> = 'N': do not compute z; = 'I': z is initialized to the unit matrix, and the orthogonal/unitary matrix Z is returned; = 'V': z must contain an orthogonal/unitary matrix Z_1 on entry, and the product $Z_1 * z$ is returned. |
| <code>n</code> | <p>The order of the matrices A and B.</p> <p>$n \geq 0$.</p> |

| | |
|-----------------|---|
| <i>ilo, ihi</i> | <i>ilo</i> and <i>ihi</i> mark the rows and columns of <i>a</i> which are to be reduced. It is assumed that <i>a</i> is already upper triangular in rows and columns 1: <i>ilo</i> - 1 and <i>ihi</i> + 1: <i>n</i> . <i>ilo</i> and <i>ihi</i> are normally set by a previous call to ?ggbal; otherwise they should be set to 1 and <i>n</i> , respectively. $1 \leq ilo \leq ihi \leq n$, if $n > 0$; $ilo=1$ and $ihi=0$, if $n=0$. |
| <i>a</i> | Array, size (<i>lda</i> * <i>n</i>). On entry, the <i>n</i> -by- <i>n</i> general matrix to be reduced. |
| <i>lda</i> | The leading dimension of the array <i>a</i> . $lda \geq \max(1, n)$. |
| <i>b</i> | Array, (<i>ldb</i> * <i>n</i>). On entry, the <i>n</i> -by- <i>n</i> upper triangular matrix <i>B</i> . |
| <i>ldb</i> | The leading dimension of the array <i>b</i> . $ldb \geq \max(1, n)$. |
| <i>q</i> | Array, size (<i>ldq</i> * <i>n</i>). On entry, if <i>compq</i> = 'V', the orthogonal/unitary matrix Q_1 , typically from the QR factorization of <i>b</i> . |
| <i>ldq</i> | The leading dimension of the array <i>q</i> . $ldq \geq n$ if <i>compq</i> ='V' or 'I'; $ldq \geq 1$ otherwise. |
| <i>z</i> | Array, size (<i>ldz</i> * <i>n</i>). On entry, if <i>compz</i> = 'V', the orthogonal/unitary matrix Z_1 . Not referenced if <i>compz</i> ='N'. |
| <i>ldz</i> | The leading dimension of the array <i>z</i> . $ldz \geq n$ if <i>compz</i> ='V' or 'I'; $ldz \geq 1$ otherwise. |

Output Parameters

| | |
|----------|--|
| <i>a</i> | On exit, the upper triangle and the first subdiagonal of <i>a</i> are overwritten with the upper Hessenberg matrix <i>H</i> , and the rest is set to zero. |
| <i>b</i> | On exit, the upper triangular matrix $T = Q^T B Z$ for real flavors or $T = Q^H B Z$ for complex flavors. The elements below the diagonal are set to zero. |
| <i>q</i> | On exit, if <i>compq</i> ='I', the orthogonal/unitary matrix <i>Q</i> , and if <i>compq</i> = 'V', the product $Q_1 * Q$. Not referenced if <i>compq</i> ='N'. |
| <i>z</i> | On exit, if <i>compz</i> ='I', the orthogonal/unitary matrix <i>Z</i> , and if <i>compz</i> = 'V', the product $Z_1 * Z$. Not referenced if <i>compz</i> ='N'. |

Return Values

This function returns a value *info*.

= 0: successful exit.

< 0: if *info* = -*i*, the *i*-th argument had an illegal value.

Application Notes

This routine reduces *A* to Hessenberg form and maintains *B* in using a blocked variant of Moler and Stewart's original algorithm, as described by Kagstrom, Kressner, Quintana-Orti, and Quintana-Orti (BIT 2008).

?hgeqz

Implements the QZ method for finding the generalized eigenvalues of the matrix pair (H,T).

Syntax

```
lapack_int LAPACKE_shgeqz( int matrix_layout, char job, char compq, char compz,
lapack_int n, lapack_int ilo, lapack_int ihi, float* h, lapack_int ldh, float* t,
lapack_int ldt, float* alphas, float* alphai, float* beta, float* q, lapack_int ldq,
float* z, lapack_int ldz );
```

```
lapack_int LAPACKE_dhgeqz( int matrix_layout, char job, char compq, char compz,
lapack_int n, lapack_int ilo, lapack_int ihi, double* h, lapack_int ldh, double* t,
lapack_int ldt, double* alphas, double* alphai, double* beta, double* q, lapack_int
ldq, double* z, lapack_int ldz );
```

```
lapack_int LAPACKE_chgeqz( int matrix_layout, char job, char compq, char compz,
lapack_int n, lapack_int ilo, lapack_int ihi, lapack_complex_float* h, lapack_int ldh,
lapack_complex_float* t, lapack_int ldt, lapack_complex_float* alpha,
lapack_complex_float* beta, lapack_complex_float* q, lapack_int ldq,
lapack_complex_float* z, lapack_int ldz );
```

```
lapack_int LAPACKE_zhgeqz( int matrix_layout, char job, char compq, char compz,

Description

The routine computes the eigenvalues of a real/complex matrix pair (*H,T*), where *H* is an upper Hessenberg matrix and *T* is upper triangular, using the double-shift version (for real flavors) or single-shift version (for complex flavors) of the QZ method. Matrix pairs of this type are produced by the reduction to generalized upper Hessenberg form of a real/complex matrix pair (*A,B*):

$$A = Q_1 * H * Z_1^H, B = Q_1 * T * Z_1^H,$$

as computed by ?gghrd.

For real flavors:

If *job* = 'S', then the Hessenberg-triangular pair (*H,T*) is reduced to generalized Schur form,

$$H = Q * S * Z^T, T = Q * P * Z^T,$$

where Q and Z are orthogonal matrices, P is an upper triangular matrix, and S is a quasi-triangular matrix with 1-by-1 and 2-by-2 diagonal blocks. The 1-by-1 blocks correspond to real eigenvalues of the matrix pair (H,T) and the 2-by-2 blocks correspond to complex conjugate pairs of eigenvalues.

Additionally, the 2-by-2 upper triangular diagonal blocks of P corresponding to 2-by-2 blocks of S are reduced to positive diagonal form, that is, if $S_{j+1,j}$ is non-zero, then $P_{j+1,j} = P_{j,j+1} = 0$, $P_{j,j} > 0$, and $P_{j+1,j+1} > 0$.

For complex flavors:

If $job = 'S'$, then the Hessenberg-triangular pair (H,T) is reduced to generalized Schur form,

$$H = Q^* S^* Z^H, T = Q^* P^* Z^H,$$

where Q and Z are unitary matrices, and S and P are upper triangular.

For all function flavors:

Optionally, the orthogonal/unitary matrix Q from the generalized Schur factorization may be post-multiplied by an input matrix Q_1 , and the orthogonal/unitary matrix Z may be post-multiplied by an input matrix Z_1 .

If Q_1 and Z_1 are the orthogonal/unitary matrices from `?gghrd` that reduced the matrix pair (A,B) to generalized upper Hessenberg form, then the output matrices Q_1Q and Z_1Z are the orthogonal/unitary factors from the generalized Schur factorization of (A,B) :

$$A = (Q_1Q)^* S^* (Z_1Z)^H, B = (Q_1Q)^* P^* (Z_1Z)^H.$$

To avoid overflow, eigenvalues of the matrix pair (H,T) (equivalently, of (A,B)) are computed as a pair of values $(alpha,beta)$. For `chgeqz/zhgeqz`, $alpha$ and $beta$ are complex, and for `shgeqz/dhgeqz`, $alpha$ is complex and $beta$ real. If $beta$ is nonzero, $\lambda = alpha/beta$ is an eigenvalue of the generalized nonsymmetric eigenvalue problem (GNEP)

$$A^*x = \lambda^* B^*x$$

and if $alpha$ is nonzero, $\mu = beta/alpha$ is an eigenvalue of the alternate form of the GNEP

$$\mu^* A^*y = B^*y.$$

Real eigenvalues (for real flavors) or the values of $alpha$ and $beta$ for the i -th eigenvalue (for complex flavors) can be read directly from the generalized Schur form:

$$alpha = S_{i,i}, beta = P_{i,i}.$$

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>job</code> | Specifies the operations to be performed. Must be 'E' or 'S'. If <code>job = 'E'</code> , then compute eigenvalues only; If <code>job = 'S'</code> , then compute eigenvalues and the Schur form. |
| <code>compq</code> | Must be 'N', 'I', or 'V'. If <code>compq = 'N'</code> , left Schur vectors (q) are not computed; If <code>compq = 'I'</code> , q is initialized to the unit matrix and the matrix of left Schur vectors of (H,T) is returned; If <code>compq = 'V'</code> , q must contain an orthogonal/unitary matrix Q_1 on entry and the product Q_1^*Q is returned. |
| <code>compz</code> | Must be 'N', 'I', or 'V'. |

If *compz* = 'N', right Schur vectors (*z*) are not computed;
 If *compz* = 'I', *z* is initialized to the unit matrix and the matrix of right Schur vectors of (*H*,*T*) is returned;
 If *compz* = 'V', *z* must contain an orthogonal/unitary matrix Z_1 on entry and the product $Z_1 * Z$ is returned.

n The order of the matrices *H*, *T*, *Q*, and *Z*
 ($n \geq 0$).

ilo, *ihi* *ilo* and *ihi* mark the rows and columns of *H* which are in Hessenberg form. It is assumed that *H* is already upper triangular in rows and columns 1:*ilo*-1 and *ihi*+1:*n*.

Constraint:

If $n > 0$, then $1 \leq ilo \leq ihi \leq n$;
 if $n = 0$, then $ilo = 1$ and $ihi = 0$.

h, *t*, *q*, *z*

Arrays:

On entry, *h* (size $\max(1, ldh * n)$) contains the *n*-by-*n* upper Hessenberg matrix *H*.

On entry, *t* (size $\max(1, ldt * n)$) contains the *n*-by-*n* upper triangular matrix *T*.

q (size $\max(1, ldq * n)$) :

On entry, if *compq* = 'V', this array contains the orthogonal/unitary matrix Q_1 used in the reduction of (*A*,*B*) to generalized Hessenberg form.

If *compq* = 'N', then *q* is not referenced.

z (size $\max(1, ldz * n)$) :

On entry, if *compz* = 'V', this array contains the orthogonal/unitary matrix Z_1 used in the reduction of (*A*,*B*) to generalized Hessenberg form.

If *compz* = 'N', then *z* is not referenced.

ldh The leading dimension of *h*; at least $\max(1, n)$.

ldt The leading dimension of *t*; at least $\max(1, n)$.

ldq The leading dimension of *q*;
 If *compq* = 'N', then $ldq \geq 1$.
 If *compq* = 'I' or 'V', then $ldq \geq \max(1, n)$.

ldz The leading dimension of *z*;
 If *compz* = 'N', then $ldz \geq 1$.
 If *compz* = 'I' or 'V', then $ldz \geq \max(1, n)$.

Output Parameters

h For real flavors:

If $job = 'S'$, then on exit h contains the upper quasi-triangular matrix S from the generalized Schur factorization.

If $job = 'E'$, then on exit the diagonal blocks of h match those of S , but the rest of h is unspecified.

For complex flavors:

If $job = 'S'$, then, on exit, h contains the upper triangular matrix S from the generalized Schur factorization.

If $job = 'E'$, then on exit the diagonal of h matches that of S , but the rest of h is unspecified.

t If $job = 'S'$, then, on exit, t contains the upper triangular matrix P from the generalized Schur factorization.

For real flavors:

2-by-2 diagonal blocks of P corresponding to 2-by-2 blocks of S are reduced to positive diagonal form, that is, if $h(j+1,j)$ is non-zero, then $t(j+1,j) = t(j,j+1) = 0$ and $t(j,j)$ and $t(j+1,j+1)$ will be positive.

If $job = 'E'$, then on exit the diagonal blocks of t match those of P , but the rest of t is unspecified.

For complex flavors:

if $job = 'E'$, then on exit the diagonal of t matches that of P , but the rest of t is unspecified.

$alphan, alphan$

Arrays, size at least $\max(1, n)$. The real and imaginary parts, respectively, of each scalar $alpha$ defining an eigenvalue of GNEP.

If $alphan[j - 1]$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -th eigenvalues are a complex conjugate pair, with

$$alphan[j] = -alphan[j - 1].$$

$alpha$

Array, size at least $\max(1, n)$.

The complex scalars $alpha$ that define the eigenvalues of GNEP. $alphan[i - 1] = S_i, i$ in the generalized Schur factorization.

$beta$

Array, size at least $\max(1, n)$.

For real flavors:

The scalars $beta$ that define the eigenvalues of GNEP.

Together, the quantities $alpha = (alphan[j - 1], alphan[j - 1])$ and $beta = beta[j - 1]$ represent the j -th eigenvalue of the matrix pair (A,B) , in one of the forms $lambda = alpha/beta$ or $mu = beta/alpha$. Since either $lambda$ or mu may overflow, they should not, in general, be computed.

For complex flavors:

The real non-negative scalars $beta$ that define the eigenvalues of GNEP.

$\beta[i - 1] = P_{i, i}$ in the generalized Schur factorization. Together, the quantities $\alpha = \alpha[j - 1]$ and $\beta = \beta[j - 1]$ represent the j -th eigenvalue of the matrix pair (A, B) , in one of the forms $\lambda = \alpha/\beta$ or $\mu = \beta/\alpha$. Since either λ or μ may overflow, they should not, in general, be computed.

- q On exit, if $compq = 'I'$, q is overwritten by the orthogonal/unitary matrix of left Schur vectors of the pair (H, T) , and if $compq = 'V'$, q is overwritten by the orthogonal/unitary matrix of left Schur vectors of (A, B) .
- z On exit, if $compz = 'I'$, z is overwritten by the orthogonal/unitary matrix of right Schur vectors of the pair (H, T) , and if $compz = 'V'$, z is overwritten by the orthogonal/unitary matrix of right Schur vectors of (A, B) .

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = 1, \dots, n$, the QZ iteration did not converge.

(H, T) is not in Schur form, but α_{i-1} , β_{i-1} (for real flavors), $\alpha[i - 1]$ (for complex flavors), and $\beta[i - 1]$, $i=info+1, \dots, n$ should be correct.

If $info = n+1, \dots, 2n$, the shift calculation failed.

(H, T) is not in Schur form, but α_{i-1} , β_{i-1} (for real flavors), $\alpha[i - 1]$ (for complex flavors), and $\beta[i - 1]$, $i = info-n+1, \dots, n$ should be correct.

?tgevc

Computes some or all of the right and/or left generalized eigenvectors of a pair of upper triangular matrices.

Syntax

```
lapack_int LAPACKE_stgevc (int matrix_layout, char side, char howmny, const
lapack_logical* select, lapack_int n, const float* s, lapack_int lds, const float* p,

Description

The routine computes some or all of the right and/or left eigenvectors of a pair of real/complex matrices (S,P) , where S is quasi-triangular (for real flavors) or upper triangular (for complex flavors) and P is upper triangular.

Matrix pairs of this type are produced by the generalized Schur factorization of a real/complex matrix pair (A,B) :

$$A = Q^* S^* Z^H, B = Q^* P^* Z^H$$

as computed by `?gghrd` plus `?hgeqz`.

The right eigenvector x and the left eigenvector y of (S,P) corresponding to an eigenvalue w are defined by:

$$S^* x = w^* P^* x, y^H S = w^* y^H P$$

The eigenvalues are not input to this routine, but are computed directly from the diagonal blocks or diagonal elements of S and P .

This routine returns the matrices X and/or Y of right and left eigenvectors of (S,P) , or the products $Z^* X$ and/or $Q^* Y$, where Z and Q are input matrices.

If Q and Z are the orthogonal/unitary factors from the generalized Schur factorization of a matrix pair (A,B) , then $Z^* X$ and $Q^* Y$ are the matrices of right and left eigenvectors of (A,B) .

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <i>side</i> | Must be 'R', 'L', or 'B'. If <i>side</i> = 'R', compute right eigenvectors only. If <i>side</i> = 'L', compute left eigenvectors only. If <i>side</i> = 'B', compute both right and left eigenvectors. |
| <i>howmny</i> | Must be 'A', 'B', or 'S'. If <i>howmny</i> = 'A', compute all right and/or left eigenvectors. If <i>howmny</i> = 'B', compute all right and/or left eigenvectors, backtransformed by the matrices in <i>vr</i> and/or <i>vl</i> . If <i>howmny</i> = 'S', compute selected right and/or left eigenvectors, specified by the logical array <i>select</i> . |
| <i>select</i> | Array, size at least $\max(1, n)$. If <i>howmny</i> = 'S', <i>select</i> specifies the eigenvectors to be computed. If <i>howmny</i> = 'A' or 'B', <i>select</i> is not referenced. <i>For real flavors:</i> If $w[j]$ is a real eigenvalue, the corresponding real eigenvector is computed if <i>select</i> [j] is 1. |

If $w[j]$ and $omega[j + 1]$ are the real and imaginary parts of a complex eigenvalue, the corresponding complex eigenvector is computed if either $select[j]$ or $select[j + 1]$ is 1, and on exit $select[j]$ is set to 1 and $select[j + 1]$ is set to 0.

For complex flavors:

The eigenvector corresponding to the j -th eigenvalue is computed if $select[j]$ is 1.

n

The order of the matrices S and P ($n \geq 0$).

s, p, vl, vr

Arrays:

s (size $\max(1, lds*n)$) contains the matrix S from a generalized Schur factorization as computed by `?hgeqz`. This matrix is upper quasi-triangular for real flavors, and upper triangular for complex flavors.

p (size $\max(1, ldp*n)$) contains the upper triangular matrix P from a generalized Schur factorization as computed by `?hgeqz`.

For real flavors, 2-by-2 diagonal blocks of P corresponding to 2-by-2 blocks of S must be in positive diagonal form.

For complex flavors, P must have real diagonal elements.

If $side = 'L'$ or $'B'$ and $howmny = 'B'$, vl (size $\max(1, ldvl*mm)$ for column major layout and $\max(1, ldvl*n)$ for row major layout) must contain an n -by- n matrix Q (usually the orthogonal/unitary matrix Q of left Schur vectors returned by `?hgeqz`).

If $side = 'R'$, vl is not referenced.

If $side = 'R'$ or $'B'$ and $howmny = 'B'$, vr (size $\max(1, ldvr*mm)$ for column major layout and $\max(1, ldvr*n)$ for row major layout) must contain an n -by- n matrix Z (usually the orthogonal/unitary matrix Z of right Schur vectors returned by `?hgeqz`).

If $side = 'L'$, vr is not referenced.

lds

The leading dimension of s ; at least $\max(1, n)$.

ldp

The leading dimension of p ; at least $\max(1, n)$.

$ldvl$

The leading dimension of vl ;

If $side = 'L'$ or $'B'$, then $ldvl \geq n$ for column major layout and $ldvl \geq \max(1, mm)$ for row major layout.

If $side = 'R'$, then $ldvl \geq 1$.

$ldvr$

The leading dimension of vr ;

If $side = 'R'$ or $'B'$, then $ldvr \geq n$ for column major layout and $ldvr \geq \max(1, mm)$ for row major layout.

If $side = 'L'$, then $ldvr \geq 1$.

mm

The number of columns in the arrays vl and/or vr ($mm \geq m$).

Output Parameters

- vl* On exit, if *side* = 'L' or 'B', *vl* contains:
 if *howmny* = 'A', the matrix *Y* of left eigenvectors of (*S,P*);
 if *howmny* = 'B', the matrix *Q*Y*;
 if *howmny* = 'S', the left eigenvectors of (*S,P*) specified by *select*, stored consecutively in the columns of *vl*, in the same order as their eigenvalues.
For real flavors:
 A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.
- vr* On exit, if *side* = 'R' or 'B', *vr* contains:
 if *howmny* = 'A', the matrix *X* of right eigenvectors of (*S,P*);
 if *howmny* = 'B', the matrix *Z*X*;
 if *howmny* = 'S', the right eigenvectors of (*S,P*) specified by *select*, stored consecutively in the columns of *vr*, in the same order as their eigenvalues.
For real flavors:
 A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.
- m* The number of columns in the arrays *vl* and/or *vr* actually used to store the eigenvectors.
 If *howmny* = 'A' or 'B', *m* is set to *n*.
For real flavors:
 Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.
For complex flavors:
 Each selected eigenvector occupies one column.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

For real flavors:

if *info* = *i*>0, the 2-by-2 block (*i*:*i*+1) does not have a complex eigenvalue.

?tgexc

Reorders the generalized Schur decomposition of a pair of matrices (*A,B*) so that one diagonal block of (*A,B*) moves to another row index.

Syntax

```
lapack_int LAPACKE_stgexc (int matrix_layout, lapack_logical wantq, lapack_logical wantz, lapack_int n, float* a, lapack_int lda, float* b, lapack_int ldb, float* q, lapack_int ldq, float* z, lapack_int ldz, lapack_int* ifst, lapack_int* ilst);
```

```
lapack_int LAPACKE_dtgexc (int matrix_layout, lapack_logical wantq, lapack_logical wantz, lapack_int n, double* a, lapack_int lda, double* b, lapack_int ldb, double* q, lapack_int ldq, double* z, lapack_int ldz, lapack_int* ifst, lapack_int* ilst);
```

```
lapack_int LAPACKE_ctgexc (int matrix_layout, lapack_logical wantq, lapack_logical wantz, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb, lapack_complex_float* q, lapack_int ldq, lapack_complex_float* z, lapack_int ldz, lapack_int ifst, lapack_int ilst);
```

```
lapack_int LAPACKE_ztgexc (int matrix_layout, lapack_logical wantq, lapack_logical wantz, lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb, lapack_complex_double* q, lapack_int ldq, lapack_complex_double* z, lapack_int ldz, lapack_int ifst, lapack_int ilst);
```

Include Files

- mkl.h

Description

The routine reorders the generalized real-Schur/Schur decomposition of a real/complex matrix pair (A, B) using an orthogonal/unitary equivalence transformation

$$(A, B) = Q^* (A, B) Z^H,$$

so that the diagonal block of (A, B) with row index *ifst* is moved to row *ilst*. Matrix pair (A, B) must be in a generalized real-Schur/Schur canonical form (as returned by [gges](#)), that is, A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks and B is upper triangular. Optionally, the matrices Q and Z of generalized Schur vectors are updated.

$$Q_{in} * A_{in} * Z_{in}^T = Q_{out} * A_{out} * Z_{out}^T$$

$$Q_{in} * B_{in} * Z_{in}^T = Q_{out} * B_{out} * Z_{out}^T.$$

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

wantq, wantz If *wantq* = 1, update the left transformation matrix Q ;
 If *wantq* = 0, do not update Q ;
 If *wantz* = 1, update the right transformation matrix Z ;
 If *wantz* = 0, do not update Z .

n The order of the matrices A and B ($n \geq 0$).

a, b, q, z Arrays:
a (size $\max(1, lda * n)$) contains the matrix A .
b (size $\max(1, ldb * n)$) contains the matrix B .
q (size at least 1 if *wantq* = 0 and at least $\max(1, ldq * n)$ if *wantq* = 1)

If $wantq = 0$, then q is not referenced.

If $wantq = 1$, then q must contain the orthogonal/unitary matrix Q .

z (size at least 1 if $wantz = 0$ and at least $\max(1, ldz*n)$ if $wantz = 1$)

If $wantz = 0$, then z is not referenced.

If $wantz = 1$, then z must contain the orthogonal/unitary matrix Z .

lda The leading dimension of a ; at least $\max(1, n)$.

ldb The leading dimension of b ; at least $\max(1, n)$.

ldq The leading dimension of q ;

If $wantq = 0$, then $ldq \geq 1$.

If $wantq = 1$, then $ldq \geq \max(1, n)$.

ldz The leading dimension of z ;

If $wantz = 0$, then $ldz \geq 1$.

If $wantz = 1$, then $ldz \geq \max(1, n)$.

$ifst, ilst$ Specify the reordering of the diagonal blocks of (A, B) . The block with row index $ifst$ is moved to row $ilst$, by a sequence of swapping between adjacent blocks. Constraint: $1 \leq ifst, ilst \leq n$.

Output Parameters

a, b, q, z Overwritten by the updated matrices A, B, Q , and Z respectively.

$ifst, ilst$ Overwritten for real flavors only.

If $ifst$ pointed to the second row of a 2 by 2 block on entry, it is changed to point to the first row; $ilst$ always points to the first row of the block in its final position (which may differ from its input value by ± 1).

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = 1$, the transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is ill-conditioned. (A, B) may have been partially reordered, and $ilst$ points to the first row of the current position of the block being moved.

?tgsen

Reorders the generalized Schur decomposition of a pair of matrices (A, B) so that a selected cluster of eigenvalues appears in the leading diagonal blocks of (A, B) .

Description

The routine reorders the generalized real-Schur/Schur decomposition of a real/complex matrix pair (A, B) (in terms of an orthogonal/unitary equivalence transformation $Q^T(A, B) * Z$ for real flavors or $Q^H(A, B) * Z$ for complex flavors), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair (A, B) . The leading columns of Q and Z form orthonormal/unitary bases of the corresponding left and right eigenspaces (deflating subspaces).

(A, B) must be in generalized real-Schur/Schur canonical form (as returned by [gges](#)), that is, A and B are both upper triangular.

?tgsen also computes the generalized eigenvalues

$$\omega_j = (\text{alphar}(j) + \text{alphai}(j)*i)/\text{beta}(j) \text{ (for real flavors)}$$

$$\omega_j = \text{alpha}(j)/\text{beta}(j) \text{ (for complex flavors)}$$

of the reordered matrix pair (A, B) .

Optionally, the routine computes the estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are $\text{Difu}[(A_{11}, B_{11}), (A_{22}, B_{22})]$ and $\text{Difl}[(A_{11}, B_{11}), (A_{22}, B_{22})]$, that is, the separation(s) between the matrix pairs (A_{11}, B_{11}) and (A_{22}, B_{22}) that correspond to the selected cluster and the eigenvalues outside the cluster, respectively, and norms of "projections" onto left and right eigenspaces with respect to the selected cluster in the (1,1)-block.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>ijob</i> | <p>Specifies whether condition numbers are required for the cluster of eigenvalues (<i>pl</i> and <i>pr</i>) or the deflating subspaces <i>Difu</i> and <i>Difl</i>.</p> <p>If <i>ijob</i> = 0, only reorder with respect to <i>select</i>;</p> <p>If <i>ijob</i> = 1, reciprocal of norms of "projections" onto left and right eigenspaces with respect to the selected cluster (<i>pl</i> and <i>pr</i>);</p> <p>If <i>ijob</i> = 2, compute upper bounds on <i>Difu</i> and <i>Difl</i>, using F-norm-based estimate (<i>dif</i> (1:2));</p> <p>If <i>ijob</i> = 3, compute estimate of <i>Difu</i> and <i>Difl</i>, using 1-norm-based estimate (<i>dif</i> (1:2)). This option is about 5 times as expensive as <i>ijob</i> = 2;</p> <p>If <i>ijob</i> = 4, compute <i>pl</i>, <i>pr</i> and <i>dif</i> (i.e., options 0, 1 and 2 above). This is an economic version to get it all;</p> <p>If <i>ijob</i> = 5, compute <i>pl</i>, <i>pr</i> and <i>dif</i> (i.e., options 0, 1 and 3 above).</p> |
| <i>wantq, wantz</i> | <p>If <i>wantq</i> = 1, update the left transformation matrix <i>Q</i>;</p> <p>If <i>wantq</i> = 0, do not update <i>Q</i>;</p> <p>If <i>wantz</i> = 1, update the right transformation matrix <i>Z</i>;</p> <p>If <i>wantz</i> = 0, do not update <i>Z</i>.</p> |
| <i>select</i> | <p>Array, size at least $\max(1, n)$. Specifies the eigenvalues in the selected cluster.</p> <p>To select an eigenvalue ω_j, <i>select</i>[<i>j</i> - 1] must be 1. For real flavors: to select a complex conjugate pair of eigenvalues ω_j and ω_{j+1} (corresponding 2 by 2 diagonal block), <i>select</i>[<i>j</i> - 1] and/or <i>select</i>[<i>j</i>] must be set to 1; the complex conjugate ω_j and ω_{j+1} must be either both included in the cluster or both excluded.</p> |
| <i>n</i> | The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$). |
| <i>a, b, q, z</i> | <p>Arrays:</p> <p><i>a</i> (size $\max(1, lda * n)$) contains the matrix <i>A</i>.</p> <p>For real flavors: <i>A</i> is upper quasi-triangular, with (<i>A</i>, <i>B</i>) in generalized real Schur canonical form.</p> <p>For complex flavors: <i>A</i> is upper triangular, in generalized Schur canonical form.</p> <p><i>b</i> (size $\max(1, ldb * n)$) contains the matrix <i>B</i>.</p> <p>For real flavors: <i>B</i> is upper triangular, with (<i>A</i>, <i>B</i>) in generalized real Schur canonical form.</p> <p>For complex flavors: <i>B</i> is upper triangular, in generalized Schur canonical form.</p> <p><i>q</i> (size at least 1 if <i>wantq</i> = 0 and at least $\max(1, ldq * n)$ if <i>wantq</i> = 1)</p> <p>If <i>wantq</i> = 1, then <i>q</i> is an <i>n</i>-by-<i>n</i> matrix;</p> |

If $wantq = 0$, then q is not referenced.
 z (size at least 1 if $wantz = 0$ and at least $\max(1, ldz*n)$ if $wantz = 1$)
 If $wantz = 1$, then z is an n -by- n matrix;
 If $wantz = 0$, then z is not referenced.

lda The leading dimension of a ; at least $\max(1, n)$.

ldb The leading dimension of b ; at least $\max(1, n)$.

ldq The leading dimension of q ; $ldq \geq 1$.
 If $wantq = 1$, then $ldq \geq \max(1, n)$.

ldz The leading dimension of z ; $ldz \geq 1$.
 If $wantz = 1$, then $ldz \geq \max(1, n)$.

Output Parameters

a, b Overwritten by the reordered matrices A and B , respectively.

$alphar, alphai$ Arrays, size at least $\max(1, n)$. Contain values that form generalized eigenvalues in real flavors.
 See *beta*.

$alpha$ Array, size at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors.
 See *beta*.

$beta$ Array, size at least $\max(1, n)$.
For real flavors:
 On exit, $(alphar[j] + alphai[j]*i)/beta[j], j=0, \dots, n-1$, will be the generalized eigenvalues.

$alphar[j] + alphai[j]*i$ and $beta[j], j=0, \dots, n-1$ are the diagonals of the complex Schur form (S, T) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (A, B) were further reduced to triangular form using complex unitary transformations.

If $alphai[j-1]$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -st eigenvalues are a complex conjugate pair, with $alphai[j]$ negative.

For complex flavors:

The diagonal elements of A and B , respectively, when the pair (A, B) has been reduced to generalized Schur form. $alpha[i]/beta[i], i=0, \dots, n-1$ are the generalized eigenvalues.

q If $wantq = 1$, then, on exit, Q has been postmultiplied by the left orthogonal transformation matrix which reorder (A, B) . The leading m columns of Q form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces).

| | |
|-----------------------|--|
| <i>z</i> | If <i>wantz</i> = 1, then, on exit, <i>Z</i> has been postmultiplied by the left orthogonal transformation matrix which reorder (<i>A</i> , <i>B</i>). The leading <i>m</i> columns of <i>Z</i> form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). |
| <i>m</i> | The dimension of the specified pair of left and right eigen-spaces (deflating subspaces); $0 \leq m \leq n$. |
| <i>pl</i> , <i>pr</i> | If <i>ijob</i> = 1, 4, or 5, <i>pl</i> and <i>pr</i> are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspaces with respect to the selected cluster. $0 < pl, pr \leq 1$. If $m = 0$ or $m = n$, $pl = pr = 1$. If <i>ijob</i> = 0, 2 or 3, <i>pl</i> and <i>pr</i> are not referenced |
| <i>dif</i> | Array, size (2). If <i>ijob</i> ≥ 2, <i>dif</i> (1:2) store the estimates of Difu and Difl. If <i>ijob</i> = 2 or 4, <i>dif</i> (1:2) are F-norm-based upper bounds on Difu and Difl. If <i>ijob</i> = 3 or 5, <i>dif</i> (1:2) are 1-norm-based estimates of Difu and Difl. If $m = 0$ or $m = n$, <i>dif</i> (1:2) = F-norm([<i>A</i> , <i>B</i>]). If <i>ijob</i> = 0 or 1, <i>dif</i> is not referenced. |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = 1, Reordering of (*A*, *B*) failed because the transformed matrix pair (*A*, *B*) would be too far from generalized Schur form; the problem is very ill-conditioned. (*A*, *B*) may have been partially reordered.

If *ijob* > 0, 0 is returned in *dif*, *pl* and *pr*.

?tgsyl

Solves the generalized Sylvester equation.

Include Files

- mkl.h

Description

The routine solves the generalized Sylvester equation:

$$A^*R - L^*B = scale^*C$$

$$D^*R - L^*E = scale^*F$$

where R and L are unknown m -by- n matrices, (A, D) , (B, E) and (C, F) are given matrix pairs of size m -by- m , n -by- n and m -by- n , respectively, with real/complex entries. (A, D) and (B, E) must be in generalized real-Schur/Schur canonical form, that is, A, B are upper quasi-triangular/triangular and D, E are upper triangular.

The solution (R, L) overwrites (C, F) . The factor $scale$, $0 \leq scale \leq 1$, is an output scaling factor chosen to avoid overflow.

In matrix notation the above equation is equivalent to the following: solve $Z^*x = scale^*b$, where Z is defined as

$$Z = \begin{pmatrix} \text{kron}(I_n, A) & -\text{kron}(B^T, I_m) \\ \text{kron}(I_n, D) & -\text{kron}(E^T, I_m) \end{pmatrix}$$

Here I_k is the identity matrix of size k and X^T is the transpose/conjugate-transpose of X . $\text{kron}(X, Y)$ is the Kronecker product between the matrices X and Y .

If $trans = 'T'$ (for real flavors), or $trans = 'C'$ (for complex flavors), the routine `?tgsyl` solves the transposed/conjugate-transposed system $Z^T*y = scale^*b$, which is equivalent to solve for R and L in

$$A^T*R + D^T*L = scale^*C$$

$$R*B^T + L*E^T = scale^*(-F)$$

This case ($trans = 'T'$ for `stgsyl/dtgsyl` or $trans = 'C'$ for `ctgsyl/ztgsyl`) is used to compute an one-norm-based estimate of $\text{Dif}[(A, D), (B, E)]$, the separation between the matrix pairs (A, D) and (B, E) .

If $ijob \geq 1$, `?tgsyl` computes a Frobenius norm-based estimate of $\text{Dif}[(A, D), (B, E)]$. That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of Z . This is a level 3 BLAS algorithm.

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>trans</code> | Must be <code>'N'</code> , <code>'T'</code> , or <code>'C'</code> . If $trans = 'N'$, solve the generalized Sylvester equation. If $trans = 'T'$, solve the 'transposed' system (for real flavors only). |

| | |
|-------------------------|--|
| | If <i>trans</i> = 'C', solve the 'conjugate transposed' system (for complex flavors only). |
| <i>ijob</i> | Specifies what kind of functionality to be performed: If <i>ijob</i> =0, solve the generalized Sylvester equation only; If <i>ijob</i> =1, perform the functionality of <i>ijob</i> =0 and <i>ijob</i> =3; If <i>ijob</i> =2, perform the functionality of <i>ijob</i> =0 and <i>ijob</i> =4; If <i>ijob</i> =3, only an estimate of $\text{Dif}[(A, D), (B, E)]$ is computed (look ahead strategy is used); If <i>ijob</i> =4, only an estimate of $\text{Dif}[(A, D), (B, E)]$ is computed (?gecon on sub-systems is used). If <i>trans</i> = 'T' or 'C', <i>ijob</i> is not referenced. |
| <i>m</i> | The order of the matrices <i>A</i> and <i>D</i> , and the row dimension of the matrices <i>C</i> , <i>F</i> , <i>R</i> and <i>L</i> . |
| <i>n</i> | The order of the matrices <i>B</i> and <i>E</i> , and the column dimension of the matrices <i>C</i> , <i>F</i> , <i>R</i> and <i>L</i> . |
| <i>a, b, c, d, e, f</i> | Arrays: <i>a</i> (size $\max(1, lda * m)$) contains the upper quasi-triangular (for real flavors) or upper triangular (for complex flavors) matrix <i>A</i> . <i>b</i> (size $\max(1, ldb * n)$) contains the upper quasi-triangular (for real flavors) or upper triangular (for complex flavors) matrix <i>B</i> . <i>c</i> (size $\max(1, ldc * n)$ for column major layout and $\max(1, ldc * m)$ for row major layout) contains the right-hand-side of the first matrix equation in the generalized Sylvester equation (as defined by <i>trans</i>) <i>d</i> (size $\max(1, ldd * m)$) contains the upper triangular matrix <i>D</i> . <i>e</i> (size $\max(1, lde * n)$) contains the upper triangular matrix <i>E</i> . <i>f</i> (size $\max(1, ldf * n)$ for column major layout and $\max(1, ldf * m)$ for row major layout) contains the right-hand-side of the second matrix equation in the generalized Sylvester equation (as defined by <i>trans</i>) |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, m)$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; at least $\max(1, n)$. |
| <i>ldc</i> | The leading dimension of <i>c</i> ; at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout . |
| <i>ldd</i> | The leading dimension of <i>d</i> ; at least $\max(1, m)$. |
| <i>lde</i> | The leading dimension of <i>e</i> ; at least $\max(1, n)$. |
| <i>ldf</i> | The leading dimension of <i>f</i> ; at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout . |

Output Parameters

| | |
|----------|--|
| <i>c</i> | If <i>ijob</i> =0, 1, or 2, overwritten by the solution <i>R</i> . |
|----------|--|

| | |
|---------|---|
| | If $ijob=3$ or 4 and $trans = 'N'$, c holds R , the solution achieved during the computation of the Dif-estimate. |
| f | If $ijob=0, 1,$ or 2 , overwritten by the solution L . If $ijob=3$ or 4 and $trans = 'N'$, f holds L , the solution achieved during the computation of the Dif-estimate. |
| dif | On exit, dif is the reciprocal of a lower bound of the reciprocal of the Dif-function, that is, dif is an upper bound of $\text{Dif}[(A, D), (B, E)] = \text{sigma_min}(Z)$, where Z as defined in the description. If $ijob = 0$, or $trans = 'T'$ (for real flavors), or $trans = 'C'$ (for complex flavors), dif is not touched. |
| $scale$ | On exit, $scale$ is the scaling factor in the generalized Sylvester equation. If $0 < scale < 1$, c and f hold the solutions R and L , respectively, to a slightly perturbed system but the input matrices A, B, D and E have not been changed. If $scale = 0$, c and f hold the solutions R and L , respectively, to the homogeneous system with $C = F = 0$. Normally, $scale = 1$. |

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info > 0$, (A, D) and (B, E) have common or close eigenvalues.

?tgsna

Estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a pair of matrices in generalized real Schur canonical form.

Description

The real flavors `stgsna/dtgsna` of this routine estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair $(Q^*A^*Z^T, Q^*B^*Z^T)$ with orthogonal matrices Q and Z).

(A, B) must be in generalized real Schur form (as returned by `gges/gges`), that is, A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

The complex flavors `ctgsna/ztgsna` estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) . (A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>job</code> | Specifies whether condition numbers are required for eigenvalues or eigenvectors. Must be 'E' or 'V' or 'B'. If <code>job = 'E'</code> , for eigenvalues only (compute s). If <code>job = 'V'</code> , for eigenvectors only (compute dif). If <code>job = 'B'</code> , for both eigenvalues and eigenvectors (compute both s and dif). |
| <code>howmny</code> | Must be 'A' or 'S'. If <code>howmny = 'A'</code> , compute condition numbers for all eigenpairs. If <code>howmny = 'S'</code> , compute condition numbers for selected eigenpairs specified by the logical array <code>select</code> . |
| <code>select</code> | Array, size at least $\max(1, n)$. If <code>howmny = 'S'</code> , <code>select</code> specifies the eigenpairs for which condition numbers are required. If <code>howmny = 'A'</code> , <code>select</code> is not referenced. <i>For real flavors:</i> To select condition numbers for the eigenpair corresponding to a real eigenvalue ω_j , <code>select[j - 1]</code> must be set to 1; to select condition numbers corresponding to a complex conjugate pair of eigenvalues ω_j and ω_{j+1} , either <code>select[j - 1]</code> or <code>select[j]</code> must be set to 1. <i>For complex flavors:</i> |

| | |
|---------------------------|--|
| | To select condition numbers for the corresponding j -th eigenvalue and/or eigenvector, <code>select[j - 1]</code> must be set to 1. |
| <code>n</code> | The order of the square matrix pair (A, B) ($n \geq 0$). |
| <code>a, b, vl, vr</code> | <p>Arrays:</p> <p><code>a</code> (size $\max(1, lda * n)$) contains the upper quasi-triangular (for real flavors) or upper triangular (for complex flavors) matrix A in the pair (A, B).</p> <p><code>b</code> (size $\max(1, ldb * n)$) contains the upper triangular matrix B in the pair (A, B).</p> <p>If <code>job = 'E'</code> or <code>'B'</code>, <code>vl</code> (size $\max(1, ldvl * m)$ for column major layout and $\max(1, ldvl * n)$ for row major layout) must contain left eigenvectors of (A, B), corresponding to the eigenpairs specified by <code>howmny</code> and <code>select</code>. The eigenvectors must be stored in consecutive columns of <code>vl</code>, as returned by <code>?tgevc</code>.</p> <p>If <code>job = 'V'</code>, <code>vl</code> is not referenced.</p> <p>If <code>job = 'E'</code> or <code>'B'</code>, <code>vr</code> (size $\max(1, ldvr * m)$ for column major layout and $\max(1, ldvr * n)$ for row major layout) must contain right eigenvectors of (A, B), corresponding to the eigenpairs specified by <code>howmny</code> and <code>select</code>. The eigenvectors must be stored in consecutive columns of <code>vr</code>, as returned by <code>?tgevc</code>.</p> <p>If <code>job = 'V'</code>, <code>vr</code> is not referenced.</p> |
| <code>lda</code> | The leading dimension of <code>a</code> ; at least $\max(1, n)$. |
| <code>ldb</code> | The leading dimension of <code>b</code> ; at least $\max(1, n)$. |
| <code>ldvl</code> | <p>The leading dimension of <code>vl</code>; $ldvl \geq 1$.</p> <p>If <code>job = 'E'</code> or <code>'B'</code>, then $ldvl \geq \max(1, n)$ for column major layout and $ldvl \geq \max(1, m)$ for row major layout .</p> |
| <code>ldvr</code> | <p>The leading dimension of <code>vr</code>; $ldvr \geq 1$.</p> <p>If <code>job = 'E'</code> or <code>'B'</code>, then $ldvr \geq \max(1, n)$ for column major layout and $ldvr \geq \max(1, m)$ for row major layout.</p> |
| <code>mm</code> | The number of elements in the arrays <code>s</code> and <code>dif</code> ($mm \geq m$). |

Output Parameters

| | |
|----------------|---|
| <code>s</code> | <p>Array, size <code>mm</code>.</p> <p>If <code>job = 'E'</code> or <code>'B'</code>, contains the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array.</p> <p>If <code>job = 'V'</code>, <code>s</code> is not referenced.</p> <p><i>For real flavors:</i></p> |
|----------------|---|

For a complex conjugate pair of eigenvalues two consecutive elements of s are set to the same value. Thus, $s[j - 1]$, $dif[j - 1]$, and the j -th columns of vl and vr all correspond to the same eigenpair (but not in general the j -th eigenpair, unless all eigenpairs are selected).

dif

Array, size mm .

If $job = 'V'$ or $'B'$, contains the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array.

If the eigenvalues cannot be reordered to compute $dif[j]$, $dif[j]$ is set to 0; this can only occur when the true value would be very small anyway.

If $job = 'E'$, dif is not referenced.

For real flavors:

For a complex eigenvector, two consecutive elements of dif are set to the same value.

For complex flavors:

For each eigenvalue/vector specified by $select$, dif stores a Frobenius norm-based estimate of $Difl$.

m

The number of elements in the arrays s and dif used to store the specified condition numbers; for each selected eigenvalue one element is used.

If $howmny = 'A'$, m is set to n .

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Generalized Singular Value Decomposition: LAPACK Computational Routines

This section describes LAPACK computational routines used for finding the generalized singular value decomposition (GSVD) of two matrices A and B as

$$U^H A Q = D_1 * (0 \ R),$$

$$V^H B Q = D_2 * (0 \ R),$$

where U , V , and Q are orthogonal/unitary matrices, R is a nonsingular upper triangular matrix, and D_1 , D_2 are "diagonal" matrices of the structure detailed in the routines description section.

Table "Computational Routines for Generalized Singular Value Decomposition" lists LAPACK routines that perform generalized singular value decomposition of matrices.

Computational Routines for Generalized Singular Value Decomposition

| Routine name | Operation performed |
|------------------------|--|
| ggsvp | Computes the preprocessing decomposition for the generalized SVD |
| ggsvp3 | Performs preprocessing for a generalized SVD. |
| ggsvd3 | Computes generalized SVD. |
| tgsja | Computes the generalized SVD of two upper triangular or trapezoidal matrices |

You can use routines listed in the above table as well as the driver routine [ggsvd](#) to find the GSVD of a pair of general rectangular matrices.

?ggsvp

Computes the preprocessing decomposition for the generalized SVD (deprecated).

Syntax

```
lapack_int LAPACKE_sggsvp( int matrix_layout, char jobu, char jobv, char jobq,
lapack_int m, lapack_int p, lapack_int n, float* a, lapack_int lda, float* b,
lapack_int ldb, float tola, float tolb, lapack_int* k, lapack_int* l, float* u,
lapack_int ldu, float* v, lapack_int ldv, float* q, lapack_int ldq );
```

```
lapack_int LAPACKE_dggsvp( int matrix_layout, char jobu, char jobv, char jobq,

Description

This routine is deprecated; use [ggsvp3](#).

The routine computes orthogonal matrices U , V and Q such that

$$U^H A Q = \begin{matrix} & n - k - l & k & l \\ & k & & \\ & l & & \\ m - k - l & & & \end{matrix} \begin{pmatrix} 0 & A_{12} & A_{13} \\ 0 & 0 & A_{23} \\ 0 & 0 & 0 \end{pmatrix}, \quad \text{if } m - k - l \geq 0$$

$$= \begin{matrix} & n - k - l & k & l \\ & k & & \\ m - k & & & \end{matrix} \begin{pmatrix} 0 & A_{12} & A_{13} \\ 0 & 0 & A_{23} \end{pmatrix}, \quad \text{if } m - k - l < 0$$

$$V^H B Q = \begin{matrix} & n-k-l & k & l \\ & l & \begin{pmatrix} 0 & 0 & B_{13} \\ 0 & 0 & 0 \end{pmatrix} \\ p-l & & & \end{matrix}$$

where the k -by- k matrix A_{12} and l -by- l matrix B_{13} are nonsingular upper triangular; A_{23} is l -by- l upper triangular if $m-k-l \geq 0$, otherwise A_{23} is $(m-k)$ -by- l upper trapezoidal. The sum $k+l$ is equal to the effective numerical rank of the $(m+p)$ -by- n matrix $(A^H, B^H)^H$.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine [?tgsja](#).

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobu</i> | Must be 'U' or 'N'. If <i>jobu</i> = 'U', orthogonal/unitary matrix U is computed. If <i>jobu</i> = 'N', U is not computed. |
| <i>jobv</i> | Must be 'V' or 'N'. If <i>jobv</i> = 'V', orthogonal/unitary matrix V is computed. If <i>jobv</i> = 'N', V is not computed. |
| <i>jobq</i> | Must be 'Q' or 'N'. If <i>jobq</i> = 'Q', orthogonal/unitary matrix Q is computed. If <i>jobq</i> = 'N', Q is not computed. |
| <i>m</i> | The number of rows of the matrix A ($m \geq 0$). |
| <i>p</i> | The number of rows of the matrix B ($p \geq 0$). |
| <i>n</i> | The number of columns of the matrices A and B ($n \geq 0$). |
| <i>a, b</i> | Arrays: a (size at least $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout) contains the m -by- n matrix A . b (size at least $\max(1, ldb*n)$ for column major layout and $\max(1, ldb*p)$ for row major layout) contains the p -by- n matrix B . |
| <i>lda</i> | The leading dimension of a ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |
| <i>ldb</i> | The leading dimension of b ; at least $\max(1, p)$ for column major layout and $\max(1, n)$ for row major layout. |
| <i>tola, tol b</i> | <i>tola</i> and <i>tol b</i> are the thresholds to determine the effective numerical rank of matrix B and a subblock of A . Generally, they are set to $tola = \max(m, n) * A * \text{MACHEPS}$, |

$tolb = \max(p, n) * ||B|| * \text{MACHEPS}$.

The size of $tola$ and $tolb$ may affect the size of backward errors of the decomposition.

ldu The leading dimension of the output array u . $ldu \geq \max(1, m)$ if $jobu = 'U'$; $ldu \geq 1$ otherwise.

ldv The leading dimension of the output array v . $ldv \geq \max(1, p)$ if $jobv = 'V'$; $ldv \geq 1$ otherwise.

ldq The leading dimension of the output array q . $ldq \geq \max(1, n)$ if $jobq = 'Q'$; $ldq \geq 1$ otherwise.

Output Parameters

a Overwritten by the triangular (or trapezoidal) matrix described in the *Description* section.

b Overwritten by the triangular matrix described in the *Description* section.

k, l On exit, k and l specify the dimension of subblocks. The sum $k + l$ is equal to effective numerical rank of $(A^H, B^H)^H$.

u, v, q Arrays:

If $jobu = 'U'$, u (size $\max(1, ldu * m)$) contains the orthogonal/unitary matrix U .

If $jobu = 'N'$, u is not referenced.

If $jobv = 'V'$, v (size $\max(1, ldv * p)$) contains the orthogonal/unitary matrix V .

If $jobv = 'N'$, v is not referenced.

If $jobq = 'Q'$, q (size $\max(1, ldq * n)$) contains the orthogonal/unitary matrix Q .

If $jobq = 'N'$, q is not referenced.

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

?ggsvp3

Performs preprocessing for a generalized SVD.

Syntax

Description

?ggsvp3 computes orthogonal or unitary matrices U , V , and Q such that

for real flavors:

$$U^T A Q = \begin{matrix} & & n-k-l & k & l \\ & k & & & \\ & l & & & \\ m-k-l & & & & \end{matrix} \begin{pmatrix} 0 & A12 & A13 \\ 0 & 0 & A23 \\ 0 & 0 & 0 \end{pmatrix} \text{ if } m-k-l \geq 0;$$

$$U^T A Q = \begin{matrix} & & n-k-l & k & l \\ & k & & & \\ m-k & & & & \end{matrix} \begin{pmatrix} 0 & A12 & A13 \\ 0 & 0 & A23 \end{pmatrix} \text{ if } m-k-l < 0;$$

$$V^T B Q = \begin{matrix} & & n-k-l & k & l \\ l & & & & \\ p-l & & & & \end{matrix} \begin{pmatrix} 0 & 0 & B13 \\ 0 & 0 & 0 \end{pmatrix}$$

for complex flavors:

$$U^H A Q = \begin{matrix} & & n-k-l & k & l \\ & k & & & \\ & l & & & \\ m-k-l & & & & \end{matrix} \begin{pmatrix} 0 & A12 & A13 \\ 0 & 0 & A23 \\ 0 & 0 & 0 \end{pmatrix} \text{ if } m-k-l \geq 0;$$

$$U^H A Q = \begin{matrix} & & n-k-l & k & l \\ & k & & & \\ m-k & & & & \end{matrix} \begin{pmatrix} 0 & A12 & A13 \\ 0 & 0 & A23 \end{pmatrix} \text{ if } m-k-l < 0;$$

$$V^H B Q = \begin{matrix} & & n-k-l & k & l \\ l & & & & \\ p-l & & & & \end{matrix} \begin{pmatrix} 0 & 0 & B13 \\ 0 & 0 & 0 \end{pmatrix}$$

where the k -by- k matrix $A12$ and l -by- l matrix $B13$ are nonsingular upper triangular; $A23$ is l -by- l upper triangular if $m-k-l \geq 0$, otherwise $A23$ is $(m-k)$ -by- l upper trapezoidal. $k + l =$ the effective numerical rank of the $(m + p)$ -by- n matrix $(A^T, B^T)^T$ for real flavors or $(A^H, B^H)^H$ for complex flavors.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see `?ggsvd3`.

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>jobu</code> | = 'U': Orthogonal/unitary matrix U is computed; = 'N': U is not computed. |
| <code>jobv</code> | = 'V': Orthogonal/unitary matrix V is computed; = 'N': V is not computed. |
| <code>jobq</code> | = 'Q': Orthogonal/unitary matrix Q is computed; = 'N': Q is not computed. |
| <code>m</code> | The number of rows of the matrix A . $m \geq 0$. |
| <code>p</code> | The number of rows of the matrix B . $p \geq 0$. |
| <code>n</code> | The number of columns of the matrices A and B . $n \geq 0$. |
| <code>a</code> | Array, size $(lda * n)$. On entry, the m -by- n matrix A . |
| <code>lda</code> | The leading dimension of the array a . $lda \geq \max(1, m)$. |
| <code>b</code> | Array, size $(ldb * n)$. On entry, the p -by- n matrix B . |
| <code>ldb</code> | The leading dimension of the array b . $ldb \geq \max(1, p)$. |
| <code>tolu, tol</code> | $tolu$ and tol are the thresholds to determine the effective numerical rank of matrix B and a subblock of A . Generally, they are set to $tolu = \max(m, n) * \text{norm}(a) * \text{MACHEPS}$, $tol = \max(p, n) * \text{norm}(b) * \text{MACHEPS}$. The size of $tolu$ and tol may affect the size of backward errors of the decomposition. |
| <code>ldu</code> | The leading dimension of the array u . |

| | |
|-------|---|
| | $ldu \geq \max(1, m)$ if $jobu = 'U'$; $ldu \geq 1$ otherwise. |
| ldv | The leading dimension of the array v . $ldv \geq \max(1, p)$ if $jobv = 'V'$; $ldv \geq 1$ otherwise. |
| ldq | The leading dimension of the array q . $ldq \geq \max(1, n)$ if $jobq = 'Q'$; $ldq \geq 1$ otherwise. |

Output Parameters

| | |
|--------|---|
| a | On exit, a contains the triangular (or trapezoidal) matrix described in the Description section. |
| b | On exit, b contains the triangular matrix described in the Description section. |
| k, l | On exit, k and l specify the dimension of the subblocks described in Description section. $k + l =$ effective numerical rank of $(A^T, B^T)^T$ for real flavors or $(A^H, B^H)^H$ for complex flavors. |
| u | Array, size $(ldu * m)$. If $jobu = 'U'$, u contains the orthogonal/unitary matrix U . If $jobu = 'N'$, u is not referenced. |
| v | Array, size $(ldv * p)$. If $jobv = 'V'$, v contains the orthogonal/unitary matrix V . If $jobv = 'N'$, v is not referenced. |
| q | Array, size $(ldq * n)$. If $jobq = 'Q'$, q contains the orthogonal/unitary matrix Q . If $jobq = 'N'$, q is not referenced. |

Return Values

This function returns a value $info$.

= 0: successful exit.

< 0: if $info = -i$, the i -th argument had an illegal value.

Application Notes

The subroutine uses LAPACK subroutine `?geqp3` for the QR factorization with column pivoting to detect the effective numerical rank of the A matrix. It may be replaced by a better rank determination strategy.

`?ggsvp3` replaces the deprecated subroutine `?ggsvp`.

?ggsvd3

Computes generalized SVD.

Syntax

```

Include Files

- mkl.h

Description

?ggsvd3 computes the generalized singular value decomposition (GSVD) of an m -by- n real or complex matrix A and p -by- n real or complex matrix B :

$$U^T A Q = D_1 (0 R), V^T B Q = D_2 (0 R) \text{ for real flavors}$$

or

$$U^H A Q = D_1 (0 R), V^H B Q = D_2 (0 R) \text{ for complex flavors}$$

where U , V and Q are orthogonal/unitary matrices.

Let $k+1$ = the effective numerical rank of the matrix $(A^T B^T)^T$ for real flavors or the matrix $(A^H B^H)^H$ for complex flavors, then R is a $(k+1)$ -by- $(k+1)$ nonsingular upper triangular matrix, D_1 and D_2 are m -by- $(k+1)$ and p -by- $(k+1)$ "diagonal" matrices and of the following structures, respectively:

If $m-k-1 \geq 0$,

$$D_1 = \begin{matrix} & & k & l \\ & & \begin{pmatrix} I & 0 \\ 0 & C \end{pmatrix} \\ m-k-l & \begin{pmatrix} 0 & 0 \end{pmatrix} \end{matrix}$$

$$D_2 = \begin{matrix} & & k & l \\ & & \begin{pmatrix} 0 & S \end{pmatrix} \\ p-l & \begin{pmatrix} 0 & 0 \end{pmatrix} \end{matrix}$$

$$\begin{pmatrix} 0 & R \end{pmatrix} = \begin{matrix} & n-k-l & k & l \\ k & \begin{pmatrix} 0 & R11 & R12 \\ 0 & 0 & R22 \end{pmatrix} \end{matrix}$$

where

$$C = \text{diag}(\alpha(k+1), \dots, \alpha(k+l)),$$

$$S = \text{diag}(\beta(k+1), \dots, \beta(k+l)),$$

$$C^2 + S^2 = I.$$

If $m - k - l < 0$,

$$D_1 = \begin{matrix} & k & m-k & k+l-m \\ m-k & \begin{pmatrix} I & 0 & 0 \\ 0 & C & 0 \end{pmatrix} \end{matrix}$$

$$D_2 = \begin{matrix} & m-k & k+l-m & p-l \\ k+l-m & \begin{pmatrix} 0 & S & 0 \\ 0 & 0 & I \\ 0 & 0 & 0 \end{pmatrix} \end{matrix}$$

$$\begin{pmatrix} 0 & R \end{pmatrix} = \begin{matrix} & n-k-l & k & m-k & k+l-m \\ k & \begin{pmatrix} 0 & R11 & R12 & R13 \\ m-k & 0 & R22 & R23 \\ k+l-m & 0 & 0 & R33 \end{pmatrix} \end{matrix}$$

where

$$C = \text{diag}(\alpha(k+1), \dots, \alpha(m)),$$

$$S = \text{diag}(\beta(k+1), \dots, \beta(m)),$$

$$C^2 + S^2 = I.$$

The routine computes C , S , R , and optionally the orthogonal/unitary transformation matrices U , V and Q .

In particular, if B is an n -by- n nonsingular matrix, then the GSVD of A and B implicitly gives the SVD of $A \cdot \text{inv}(B)$:

$$A \cdot \text{inv}(B) = U \cdot (D_1 \cdot \text{inv}(D_2)) \cdot V^T \text{ for real flavors}$$

or

$$A \cdot \text{inv}(B) = U \cdot (D_1 \cdot \text{inv}(D_2)) \cdot V^H \text{ for complex flavors.}$$

If $(A^T, B^T)^T$ for real flavors or $(A^H, B^H)^H$ for complex flavors has orthonormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and B . Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

$$A^T \cdot A \cdot X = \lambda \cdot B^T \cdot B \cdot X \text{ for real flavors}$$

or

$$A^H \cdot A \cdot X = \lambda \cdot B^H \cdot B \cdot X \text{ for complex flavors}$$

In some literature, the GSVD of A and B is presented in the form

$$U^T \cdot A \cdot X = (0 \ D_1), \quad V^T \cdot B \cdot X = (0 \ D_2) \text{ for real } (A, B)$$

or

$$U^H \cdot A \cdot X = (0 \ D_1), \quad V^H \cdot B \cdot X = (0 \ D_2) \text{ for complex } (A, B)$$

where U and V are orthogonal and X is nonsingular, D_1 and D_2 are "diagonal". The former GSVD form can be converted to the latter form by taking the nonsingular matrix X as

$$X = Q * \begin{pmatrix} I & 0 \\ 0 & inv(R) \end{pmatrix}$$

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobu</i> | = 'U': Orthogonal/unitary matrix <i>U</i> is computed; = 'N': <i>U</i> is not computed. |
| <i>jobv</i> | = 'V': Orthogonal/unitary matrix <i>V</i> is computed; = 'N': <i>V</i> is not computed. |
| <i>jobq</i> | = 'Q': Orthogonal/unitary matrix <i>Q</i> is computed; = 'N': <i>Q</i> is not computed. |
| <i>m</i> | The number of rows of the matrix <i>A</i> . $m \geq 0$. |
| <i>n</i> | The number of columns of the matrices <i>A</i> and <i>B</i> . $n \geq 0$. |
| <i>p</i> | The number of rows of the matrix <i>B</i> . $p \geq 0$. |
| <i>a</i> | Array, size (<i>lda</i> * <i>n</i>). On entry, the <i>m</i> -by- <i>n</i> matrix <i>A</i> . |
| <i>lda</i> | The leading dimension of the array <i>a</i> . $lda \geq \max(1, m)$. |
| <i>b</i> | Array, size (<i>ldb</i> * <i>n</i>). On entry, the <i>p</i> -by- <i>n</i> matrix <i>B</i> . |
| <i>ldb</i> | The leading dimension of the array <i>b</i> . $ldb \geq \max(1, p)$. |
| <i>ldu</i> | The leading dimension of the array <i>u</i> . $ldu \geq \max(1, m)$ if <i>jobu</i> = 'U'; $ldu \geq 1$ otherwise. |
| <i>ldv</i> | The leading dimension of the array <i>v</i> . $ldv \geq \max(1, p)$ if <i>jobv</i> = 'V'; $ldv \geq 1$ otherwise. |
| <i>ldq</i> | The leading dimension of the array <i>q</i> . $ldq \geq \max(1, n)$ if <i>jobq</i> = 'Q'; $ldq \geq 1$ otherwise. |
| <i>iwork</i> | Array, size (<i>n</i>). |

Output Parameters

| | |
|--------------|--|
| <i>k, l</i> | <p>On exit, <i>k</i> and <i>l</i> specify the dimension of the subblocks described in the Description section.</p> <p>$k + l =$ effective numerical rank of $(A^T, B^T)^T$ for real flavors or $(A^H, B^H)^H$ for complex flavors.</p> |
| <i>a</i> | <p>On exit, <i>a</i> contains the triangular matrix <i>R</i>, or part of <i>R</i>.</p> <p>If $m - k - l \geq 0$, <i>R</i> is stored in the elements of array <i>a</i> corresponding to $A_{1:k+l, n-k-l+1:n}$.</p> <p>If $m - k - l < 0$, $\begin{pmatrix} R_{11} & R_{12} & R_{13} \\ 0 & R_{22} & R_{23} \end{pmatrix}$ is stored in the elements of array <i>a</i> corresponding to $A_{(1:m, n-k-l+1:n)}$, and <i>R33</i> is stored in the elements of array <i>a</i> corresponding to $A_{m-k+1:l, n+m-k-l+1:n}$ on exit.</p> |
| <i>b</i> | <p>On exit, <i>b</i> contains part of the triangular matrix <i>R</i> if $m - k - l < 0$.</p> <p>See Description for details.</p> |
| <i>alpha</i> | Array, size (<i>n</i>) |
| <i>beta</i> | <p>Array, size (<i>n</i>)</p> <p>On exit, <i>alpha</i> and <i>beta</i> contain the generalized singular value pairs of <i>a</i> and <i>b</i>;</p> <p>$alpha[0:k-1] = 1$,</p> <p>$beta[0:k-1] = 0$,</p> <p>and if $m - k - l \geq 0$,</p> <p>$alpha[k:k+l-1] = C$,</p> <p>$beta[k:k+l-1] = S$,</p> <p>or if $m - k - l < 0$,</p> <p>$alpha[k:m-1] = C$, $alpha[m:k+l-1] = 0$</p> <p>$beta[k:m-1] = S$, $beta[m:k+l-1] = 1$</p> <p>and</p> <p>$alpha[k+l:n-1] = 0$</p> <p>$beta[k+l:n-1] = 0$</p> |
| <i>u</i> | <p>Array, size (<i>ldu</i>*<i>m</i>).</p> <p>If <i>jobu</i> = 'U', <i>u</i> contains the <i>m</i>-by-<i>m</i> orthogonal/unitary matrix <i>U</i>.</p> <p>If <i>jobu</i> = 'N', <i>u</i> is not referenced.</p> |
| <i>v</i> | <p>Array, size (<i>ldv</i>*<i>p</i>).</p> <p>If <i>jobv</i> = 'V', <i>v</i> contains the <i>p</i>-by-<i>p</i> orthogonal/unitary matrix <i>V</i>.</p> <p>If <i>jobv</i> = 'N', <i>v</i> is not referenced.</p> |
| <i>q</i> | <p>Array, size (<i>ldq</i>*<i>n</i>).</p> <p>If <i>jobq</i> = 'Q', <i>q</i> contains the <i>n</i>-by-<i>n</i> orthogonal/unitary matrix <i>Q</i>.</p> |

If $jobq = 'N'$, q is not referenced.

iwork

On exit, *iwork* stores the sorting information. More precisely, the following loop uses *iwork* to sort *alpha*:

```
for (i = k; i < min(m, k + 1); i++) {
    swap (alpha[i], alpha[iwork[i] - 1]);
}
```

such that $alpha[0] \geq alpha[1] \geq \dots \geq alpha[n - 1]$.

Return Values

This function returns a value *info*.

= 0: successful exit.

< 0: if *info* = -*i*, the *i*-th argument had an illegal value.

> 0: if *info* = 1, the Jacobi-type procedure failed to converge.

For further details, see subroutine ?tgsja.

Application Notes

?ggsvd3 replaces the deprecated subroutine ?ggsvd.

?tgsja

Computes the generalized SVD of two upper triangular or trapezoidal matrices.

Syntax

```
lapack_int LAPACKE_stgsja( int matrix_layout, char jobu, char jobv, char jobq,
lapack_int m, lapack_int p, lapack_int n, lapack_int k, lapack_int l, float* a,

$$D_1 = \begin{matrix} & & k & l \\ & & & \\ & l & & \\ p-l & \begin{pmatrix} 0 & S \\ 0 & 0 \end{pmatrix} \end{matrix}$$

$$(0 R) = \begin{matrix} & n-k-l & k & l \\ & & & \\ k & \begin{pmatrix} 0 & R_{11} & R_{12} \\ 0 & 0 & R_{22} \end{pmatrix} \\ l & \end{matrix}$$

where

$$C = \text{diag}(\alpha[k], \dots, \alpha[k+l-1])$$

$$S = \text{diag}(\beta[k], \dots, \beta[k+l-1])$$

$$C^2 + S^2 = I$$

R is stored in $a(1:k+l, n-k-l+1:n)$ on exit.

If $m-k-l < 0$,

$$\begin{matrix} & & k & m-k & k+l-m \\ & & & & \\ k & \begin{pmatrix} I & 0 & 0 \\ 0 & C & 0 \end{pmatrix} \\ m-k & \end{matrix}$$

$$D_2 = \begin{matrix} & & k & m-k & k+l-m \\ & & & & \\ m-k & \begin{pmatrix} 0 & S & 0 \\ 0 & 0 & I \\ 0 & 0 & 0 \end{pmatrix} \\ k+l-m & \\ p-l & \end{matrix}$$

$$(0 R) = \begin{matrix} & & n-k-l & k & m-k & k+l-m \\ & & & & & \\ & & k & \begin{pmatrix} 0 & R_{11} & R_{12} & R_{13} \\ 0 & 0 & R_{22} & R_{23} \\ 0 & 0 & 0 & R_{33} \end{pmatrix} \\ m-k & \\ k+l-m & \end{matrix}$$

where

$$C = \text{diag}(\alpha[k], \dots, \alpha[m-1]),$$

$$S = \text{diag}(\beta[k], \dots, \beta[m-1]),$$

$$C^2 + S^2 = I$$

On exit, $\begin{pmatrix} R_{11} & R_{12} & R_{13} \\ \mathbf{0} & R_{22} & R_{23} \end{pmatrix}$ is stored in $a(1:m, n-k-l+1:n)$ and R_{33} is stored in $b(m-k+1:l, n+m-k-l+1:n)$.

The computation of the orthogonal/unitary transformation matrices U , V or Q is optional. These matrices may either be formed explicitly, or they *may* be postmultiplied into input matrices U_1 , V_1 , or Q_1 .

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobu</i> | <p>Must be 'U', 'I', or 'N'.</p> <p>If <i>jobu</i> = 'U', <i>u</i> must contain an orthogonal/unitary matrix U_1 on entry.</p> <p>If <i>jobu</i> = 'I', <i>u</i> is initialized to the unit matrix.</p> <p>If <i>jobu</i> = 'N', <i>u</i> is not computed.</p> |
| <i>jobv</i> | <p>Must be 'V', 'I', or 'N'.</p> <p>If <i>jobv</i> = 'V', <i>v</i> must contain an orthogonal/unitary matrix V_1 on entry.</p> <p>If <i>jobv</i> = 'I', <i>v</i> is initialized to the unit matrix.</p> <p>If <i>jobv</i> = 'N', <i>v</i> is not computed.</p> |
| <i>jobq</i> | <p>Must be 'Q', 'I', or 'N'.</p> <p>If <i>jobq</i> = 'Q', <i>q</i> must contain an orthogonal/unitary matrix Q_1 on entry.</p> <p>If <i>jobq</i> = 'I', <i>q</i> is initialized to the unit matrix.</p> <p>If <i>jobq</i> = 'N', <i>q</i> is not computed.</p> |
| <i>m</i> | The number of rows of the matrix A ($m \geq 0$). |
| <i>p</i> | The number of rows of the matrix B ($p \geq 0$). |
| <i>n</i> | The number of columns of the matrices A and B ($n \geq 0$). |
| <i>k, l</i> | Specify the subblocks in the input matrices A and B , whose GSVD is computed. |
| <i>a, b, u, v, q</i> | <p>Arrays:</p> <p><i>a</i> (size at least $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout) contains the m-by-n matrix A.</p> <p><i>b</i> (size at least $\max(1, ldb*n)$ for column major layout and $\max(1, ldb*p)$ for row major layout) contains the p-by-n matrix B.</p> <p>If <i>jobu</i> = 'U', <i>u</i> (size $\max(1, ldu*m)$) must contain a matrix U_1 (usually the orthogonal/unitary matrix returned by ?ggsvp).</p> <p>If <i>jobv</i> = 'V', <i>v</i> (size at least $\max(1, ldv*p)$) must contain a matrix V_1 (usually the orthogonal/unitary matrix returned by ?ggsvp).</p> <p>If <i>jobq</i> = 'Q', <i>q</i> (size at least $\max(1, ldq*n)$) must contain a matrix Q_1 (usually the orthogonal/unitary matrix returned by ?ggsvp).</p> |

| | |
|---|---|
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; at least $\max(1, p)$ for column major layout and $\max(1, n)$ for row major layout. |
| <i>ldu</i> | The leading dimension of the array <i>u</i> . <i>ldu</i> $\geq \max(1, m)$ if <i>jobu</i> = 'U'; <i>ldu</i> ≥ 1 otherwise. |
| <i>ldv</i> | The leading dimension of the array <i>v</i> . <i>ldv</i> $\geq \max(1, p)$ if <i>jobv</i> = 'V'; <i>ldv</i> ≥ 1 otherwise. |
| <i>ldq</i> | The leading dimension of the array <i>q</i> . <i>ldq</i> $\geq \max(1, n)$ if <i>jobq</i> = 'Q'; <i>ldq</i> ≥ 1 otherwise. |
| <i>tol</i> <i>a</i> , <i>tol</i> <i>b</i> | <i>tol</i> <i>a</i> and <i>tol</i> <i>b</i> are the convergence criteria for the Jacobi-Kogbetliantz iteration procedure. Generally, they are the same as used in ?ggsvp: <i>tol</i> <i>a</i> = $\max(m, n) * A * \text{MACHEPS}$, <i>tol</i> <i>b</i> = $\max(p, n) * B * \text{MACHEPS}$. |

Output Parameters

| | |
|----------------------------|---|
| <i>a</i> | On exit, <i>a</i> (<i>n</i> - <i>k</i> +1: <i>n</i> , 1:min(<i>k</i> +1, <i>m</i>)) contains the triangular matrix <i>R</i> or part of <i>R</i> . |
| <i>b</i> | On exit, if necessary, <i>b</i> (<i>m</i> - <i>k</i> +1: <i>l</i> , <i>n</i> + <i>m</i> - <i>k</i> - <i>l</i> +1: <i>n</i>)) contains a part of <i>R</i> . |
| <i>alpha</i> , <i>beta</i> | Arrays, size at least $\max(1, n)$. Contain the generalized singular value pairs of <i>A</i> and <i>B</i> : <i>alpha</i> (1: <i>k</i>) = 1, <i>beta</i> (1: <i>k</i>) = 0, and if <i>m</i> - <i>k</i> -1 ≥ 0 , <i>alpha</i> (<i>k</i> +1: <i>k</i> +1) = diag(<i>C</i>), <i>beta</i> (<i>k</i> +1: <i>k</i> +1) = diag(<i>S</i>), or if <i>m</i> - <i>k</i> -1 < 0, <i>alpha</i> (<i>k</i> +1: <i>m</i>) = diag(<i>C</i>), <i>alpha</i> (<i>m</i> +1: <i>k</i> +1) = 0 <i>beta</i> (<i>k</i> +1: <i>m</i>) = diag(<i>S</i>), <i>beta</i> (<i>m</i> +1: <i>k</i> +1) = 1. Furthermore, if <i>k</i> +1 < <i>n</i> , <i>alpha</i> (<i>k</i> +1+1: <i>n</i>) = 0 and <i>beta</i> (<i>k</i> +1+1: <i>n</i>) = 0. |
| <i>u</i> | If <i>jobu</i> = 'I', <i>u</i> contains the orthogonal/unitary matrix <i>U</i> . If <i>jobu</i> = 'U', <i>u</i> contains the product <i>U</i> ₁ * <i>U</i> . If <i>jobu</i> = 'N', <i>u</i> is not referenced. |

| | |
|----------|--|
| v | <p>If $jobv = 'I'$, v contains the orthogonal/unitary matrix U.</p> <p>If $jobv = 'V'$, v contains the product V_1*V.</p> <p>If $jobv = 'N'$, v is not referenced.</p> |
| q | <p>If $jobq = 'I'$, q contains the orthogonal/unitary matrix U.</p> <p>If $jobq = 'Q'$, q contains the product Q_1*Q.</p> <p>If $jobq = 'N'$, q is not referenced.</p> |
| $ncycle$ | The number of cycles required for convergence. |

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = 1$, the procedure does not converge after MAXIT cycles.

Cosine-Sine Decomposition: LAPACK Computational Routines

This section describes LAPACK computational routines for computing the *cosine-sine decomposition* (CS decomposition) of a partitioned unitary/orthogonal matrix. The algorithm computes a complete 2-by-2 CS decomposition, which requires simultaneous diagonalization of all the four blocks of a unitary/orthogonal matrix partitioned into a 2-by-2 block structure.

The computation has the following phases:

1. The matrix is reduced to a bidiagonal block form.
2. The blocks are simultaneously diagonalized using techniques from the bidiagonal SVD algorithms.

Table "Computational Routines for Cosine-Sine Decomposition (CSD)" lists LAPACK routines that perform CS decomposition of matrices.

Computational Routines for Cosine-Sine Decomposition (CSD)

| Operation | Real matrices | Complex matrices |
|---|-----------------------------|-----------------------------|
| Compute the CS decomposition of an orthogonal/unitary matrix in bidiagonal-block form | bbcsd/bbcsd | bbcsd/bbcsd |
| Simultaneously bidiagonalize the blocks of a partitioned orthogonal matrix | orbdb unbdb | |
| Simultaneously bidiagonalize the blocks of a partitioned unitary matrix | | orbdb unbdb |

Include Files

- mkl.h

Description

mkl_lapack.fi The routine ?bbcsd computes the CS decomposition of an orthogonal or unitary matrix in bidiagonal-block form:

$$X = \begin{pmatrix} b_{11}|b_{12} & 0 & 0 \\ 0 & 0 & -I & 0 \\ b_{21}|b_{22} & 0 & 0 \\ 0 & 0 & 0 & I \end{pmatrix} = \begin{pmatrix} u_1 & | & \\ & & u_2 \end{pmatrix} \begin{pmatrix} C & | & -S & 0 & 0 \\ 0 & 0 & -I & 0 \\ S & | & C & 0 & 0 \\ 0 & 0 & 0 & I \end{pmatrix} \begin{pmatrix} v_1 & | & \\ & & v_2 \end{pmatrix}^T$$

or

$$X = \begin{pmatrix} b_{11}|b_{12} & 0 & 0 \\ 0 & 0 & -I & 0 \\ b_{21}|b_{22} & 0 & 0 \\ 0 & 0 & 0 & I \end{pmatrix} = \begin{pmatrix} u_1 & | & \\ & & u_2 \end{pmatrix} \begin{pmatrix} C & | & -S & 0 & 0 \\ 0 & 0 & -I & 0 \\ S & | & C & 0 & 0 \\ 0 & 0 & 0 & I \end{pmatrix} \begin{pmatrix} v_1 & | & \\ & & v_2 \end{pmatrix}^H$$

respectively.

x is m -by- m with the top-left block p -by- q . Note that q must not be larger than p , $m-p$, or $m-q$. If q is not the smallest index, x must be transposed and/or permuted in constant time using the *trans* option. See ?
orcsd/?uncsd for details.

The bidiagonal matrices b_{11} , b_{12} , b_{21} , and b_{22} are represented implicitly by angles $theta(1:q)$ and $phi(1:q-1)$.

The orthogonal/unitary matrices u_1 , u_2 , v_1^t , and v_2^t are input/output. The input matrices are pre- or post-multiplied by the appropriate singular vector matrices.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobu1</i> | If equals <i>Y</i> , then u_1 is updated. Otherwise, u_1 is not updated. |
| <i>jobu2</i> | If equals <i>Y</i> , then u_2 is updated. Otherwise, u_2 is not updated. |
| <i>jobv1t</i> | If equals <i>Y</i> , then v_1^t is updated. Otherwise, v_1^t is not updated. |
| <i>jobv2t</i> | If equals <i>Y</i> , then v_2^t is updated. Otherwise, v_2^t is not updated. |
| <i>trans</i> | = 'T': X , u_1 , u_2 , v_1^t , v_2^t are stored in row-major order. otherwise X , u_1 , u_2 , v_1^t , v_2^t are stored in column-major order. |
| <i>m</i> | The number of rows and columns of the orthogonal/unitary matrix X in bidiagonal-block form. |
| <i>p</i> | The number of rows in the top-left block of x . $0 \leq p \leq m$. |
| <i>q</i> | The number of columns in the top-left block of x . $0 \leq q \leq \min(p, m-p, m-q)$. |
| <i>theta</i> | Array, size q . On entry, the angles $theta[0], \dots, theta[q-1]$ that, along with $phi[0], \dots, phi[q-2]$, define the matrix in bidiagonal-block form as returned by orbdb/unbdb . |
| <i>phi</i> | Array, size $q-1$. The angles $phi[0], \dots, phi[q-2]$ that, along with $theta[0], \dots, theta[q-1]$, define the matrix in bidiagonal-block form as returned by orbdb/unbdb . |
| <i>u1</i> | Array, size at least $\max(1, ldu1*p)$. On entry, a p -by- p matrix. |
| <i>ldu1</i> | The leading dimension of the array u_1 , $ldu1 \leq \max(1, p)$. |
| <i>u2</i> | Array, size $\max(1, ldu2*(m-p))$. On entry, an $(m-p)$ -by- $(m-p)$ matrix. |
| <i>ldu2</i> | The leading dimension of the array u_2 , $ldu2 \leq \max(1, m-p)$. |

| | |
|--------------|---|
| <i>v1t</i> | Array, size $\max(1, ldv1t * q)$. On entry, a q -by- q matrix. |
| <i>ldv1t</i> | The leading dimension of the array <i>v1t</i> , $ldv1t \leq \max(1, q)$. |
| <i>v2t</i> | Array, size. On entry, an $(m-q)$ -by- $(m-q)$ matrix. |
| <i>ldv2t</i> | The leading dimension of the array <i>v2t</i> , $ldv2t \leq \max(1, m-q)$. |

Output Parameters

| | |
|--------------|---|
| <i>theta</i> | On exit, the angles whose cosines and sines define the diagonal blocks in the CS decomposition. |
| <i>u1</i> | On exit, <i>u1</i> is postmultiplied by the left singular vector matrix common to $\begin{bmatrix} b11 & 0 \\ 0 & 0 \end{bmatrix}$ and $\begin{bmatrix} b12 & 0 & 0 \\ 0 & -I & 0 \end{bmatrix}$. |
| <i>u2</i> | On exit, <i>u2</i> is postmultiplied by the left singular vector matrix common to $\begin{bmatrix} b21 & 0 \\ 0 & 0 \end{bmatrix}$ and $\begin{bmatrix} b22 & 0 & 0 \\ 0 & 0 & I \end{bmatrix}$. |
| <i>v1t</i> | Array, size q . On exit, <i>v1t</i> is premultiplied by the transpose of the right singular vector matrix common to $\begin{bmatrix} b11 & 0 \\ 0 & 0 \end{bmatrix}$ and $\begin{bmatrix} b21 & 0 \\ 0 & 0 \end{bmatrix}$. |
| <i>v2t</i> | On exit, <i>v2t</i> is premultiplied by the transpose of the right singular vector matrix common to $\begin{bmatrix} b12 & 0 & 0 \\ 0 & -I & 0 \end{bmatrix}$ and $\begin{bmatrix} b22 & 0 & 0 \\ 0 & 0 & I \end{bmatrix}$. |
| <i>b11d</i> | Array, size q . When <code>?bbcsd</code> converges, <i>b11d</i> contains the cosines of $\theta[0], \dots, \theta[q - 1]$. If <code>?bbcsd</code> fails to converge, <i>b11d</i> contains the diagonal of the partially reduced top left block. |
| <i>b11e</i> | Array, size $q-1$. When <code>?bbcsd</code> converges, <i>b11e</i> contains zeros. If <code>?bbcsd</code> fails to converge, <i>b11e</i> contains the superdiagonal of the partially reduced top left block. |
| <i>b12d</i> | Array, size q . When <code>?bbcsd</code> converges, <i>b12d</i> contains the negative sines of $\theta[0], \dots, \theta[q - 1]$. If <code>?bbcsd</code> fails to converge, <i>b12d</i> contains the diagonal of the partially reduced top right block. |
| <i>b12e</i> | Array, size $q-1$. When <code>?bbcsd</code> converges, <i>b12e</i> contains zeros. If <code>?bbcsd</code> fails to converge, <i>b12e</i> contains the superdiagonal of the partially reduced top right block. |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = $-i$, the i -th parameter had an illegal value.

If $info > 0$ and if ?bbcsc did not converge, $info$ specifies the number of nonzero entries in phi , and $b11d$, $b11e$, etc. contain the partially reduced matrix.

Description

The routines ?orbdb/?unbdb simultaneously bidiagonalizes the blocks of an m -by- m partitioned orthogonal matrix X :

$$X = \begin{pmatrix} x_{11} & | & x_{12} \\ x_{21} & | & x_{22} \end{pmatrix} = \begin{pmatrix} p_1 & | & \\ & & p_2 \end{pmatrix} \begin{pmatrix} b_{11}|b_{12} & 0 & 0 \\ 0 & | & 0 & -I & 0 \\ b_{21}|b_{22} & 0 & 0 \\ 0 & | & 0 & 0 & I \end{pmatrix} \begin{pmatrix} q_1 & | & \\ & & q_2 \end{pmatrix}^T$$

or unitary matrix:

$$X = \left(\begin{array}{c|c} x_{11} & x_{12} \\ \hline x_{21} & x_{22} \end{array} \right) = \left(\begin{array}{c|c} p_1 & \\ \hline & p_2 \end{array} \right) \begin{pmatrix} b_{11} & b_{12} & 0 & 0 \\ 0 & 0 & -I & 0 \\ \hline b_{21} & b_{22} & 0 & 0 \\ 0 & 0 & 0 & I \end{pmatrix} \left(\begin{array}{c|c} q_1 & \\ \hline & q_2 \end{array} \right)^H$$

x_{11} is p -by- q . q must not be larger than p , $m-p$, or $m-q$. Otherwise, x must be transposed and/or permuted in constant time using the *trans* and *signs* options.

The orthogonal/unitary matrices p_1 , p_2 , q_1 , and q_2 are p -by- p , $(m-p)$ -by- $(m-p)$, q -by- q , $(m-q)$ -by- $(m-q)$, respectively. They are represented implicitly by Housholder vectors.

The bidiagonal matrices b_{11} , b_{12} , b_{21} , and b_{22} are q -by- q bidiagonal matrices represented implicitly by angles $\theta[0], \dots, \theta[q - 1]$ and $\phi[0], \dots, \phi[q - 2]$. b_{11} and b_{12} are upper bidiagonal, while b_{21} and b_{22} are lower bidiagonal. Every entry in each bidiagonal band is a product of a sine or cosine of θ with a sine or cosine of ϕ . See [Sutton09] for details.

p_1 , p_2 , q_1 , and q_2 are represented as products of elementary reflectors. .

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>trans</i> | = 'T': x , u_1 , u_2 , v_1^t , v_2^t are stored in row-major order. otherwise x , u_1 , u_2 , v_1^t , v_2^t are stored in column-major order. |
| <i>signs</i> | = 'O': The lower-left block is made nonpositive (the "other" convention). otherwise The upper-right block is made nonpositive (the "default" convention). |
| <i>m</i> | The number of rows and columns of the matrix X . |
| <i>p</i> | The number of rows in x_{11} and x_{12} . $0 \leq p \leq m$. |
| <i>q</i> | The number of columns in x_{11} and x_{21} . $0 \leq q \leq \min(p, m-p, m-q)$. |
| <i>x11</i> | Array, size (size $\max(1, ldx11 * q)$ for column major layout and $\max(1, ldx11 * p)$ for row major layout) . On entry, the top-left block of the orthogonal/unitary matrix to be reduced. |
| <i>ldx11</i> | The leading dimension of the array X_{11} . If <i>trans</i> = 'T', $ldx11 \geq p$ for column major layout and $ldx11 \geq q$ for row major layout. Otherwise, $ldx11 \geq q$. |
| <i>x12</i> | Array, size (size $\max(1, ldx12 * (m-q))$ for column major layout and $\max(1, ldx12 * p)$ for row major layout). On entry, the top-right block of the orthogonal/unitary matrix to be reduced. |

| | |
|--------------|---|
| <i>ldx12</i> | The leading dimension of the array X_{12} . If <i>trans</i> = 'N', $ldx12 \geq p$ for column major layout and $ldx12 \geq m - q$ for row major layout. . Otherwise, $ldx12 \geq m - q$. |
| <i>x21</i> | Array, size (size $\max(1, ldx21 * q)$ for column major layout and $\max(1, ldx21 * (m - p))$ for row major layout). On entry, the bottom-left block of the orthogonal/unitary matrix to be reduced. |
| <i>ldx21</i> | The leading dimension of the array X_{21} . If <i>trans</i> = 'N', $ldx21 \geq m - p$ for column major layout and $ldx21 \geq q$ for row major layout. . Otherwise, $ldx21 \geq q$. |
| <i>x22</i> | Array, size ((size $\max(1, ldx22 * (m - q))$ for column major layout and $\max(1, ldx22 * (m - p))$ for row major layout). On entry, the bottom-right block of the orthogonal/unitary matrix to be reduced. |
| <i>ldx22</i> | The leading dimension of the array X_{21} . If <i>trans</i> = 'N', $ldx22 \geq m - p$ for column major layout and $ldx22 \geq m - q$ for row major layout. . Otherwise, $ldx22 \geq m - q$. |

Output Parameters

| | |
|------------|---|
| <i>x11</i> | On exit, the form depends on <i>trans</i> : If <i>trans</i> ='N', the columns of the lower triangle of <i>x11</i> specify reflectors for p_1 , the rows of the upper triangle of $x11(1:q - 1, q:q - 1)$ specify reflectors for q_1 otherwise <i>trans</i> ='T', the rows of the upper triangle of <i>x11</i> specify reflectors for p_1 , the columns of the lower triangle of $x11(1:q - 1, q:q - 1)$ specify reflectors for q_1 |
| <i>x12</i> | On exit, the form depends on <i>trans</i> : If <i>trans</i> ='N', the columns of the upper triangle of <i>x12</i> specify the first p reflectors for q_2 otherwise <i>trans</i> ='T', the columns of the lower triangle of <i>x12</i> specify the first p reflectors for q_2 |
| <i>x21</i> | On exit, the form depends on <i>trans</i> : If <i>trans</i> ='N', the columns of the lower triangle of <i>x21</i> specify the reflectors for p_2 otherwise <i>trans</i> ='T', the columns of the upper triangle of <i>x21</i> specify the reflectors for p_2 |
| <i>x22</i> | On exit, the form depends on <i>trans</i> : If <i>trans</i> ='N', the rows of the upper triangle of $x22(q+1:m-p, p+1:m-q)$ specify the last $m-p-q$ reflectors for q_2 otherwise <i>trans</i> ='T', the columns of the lower triangle of $x22(p+1:m-q, q+1:m-p)$ specify the last $m-p-q$ reflectors for p_2 |

| | |
|--------------|---|
| <i>theta</i> | Array, size q . The entries of bidiagonal blocks b_{11} , b_{12} , b_{21} , and b_{22} can be computed from the angles <i>theta</i> and <i>phi</i> . See the Description section for details. |
| <i>phi</i> | Array, size $q-1$. The entries of bidiagonal blocks b_{11} , b_{12} , b_{21} , and b_{22} can be computed from the angles <i>theta</i> and <i>phi</i> . See the Description section for details. |
| <i>taup1</i> | Array, size p . Scalar factors of the elementary reflectors that define p_1 . |
| <i>taup2</i> | Array, size $m-p$. Scalar factors of the elementary reflectors that define p_2 . |
| <i>tauq1</i> | Array, size q . Scalar factors of the elementary reflectors that define q_1 . |
| <i>tauq2</i> | Array, size $m-q$. Scalar factors of the elementary reflectors that define q_2 . |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = $-i$, the i -th parameter had an illegal value.

LAPACK Least Squares and Eigenvalue Problem Driver Routines

Each of the LAPACK driver routines solves a complete problem. To arrive at the solution, driver routines typically call a sequence of appropriate [computational routines](#).

Driver routines are described in the following sections :

[Linear Least Squares \(LLS\) Problems](#)
[Generalized LLS Problems](#)
[Symmetric Eigenproblems](#)
[Nonsymmetric Eigenproblems](#)
[Singular Value Decomposition](#)
[Cosine-Sine Decomposition](#)
[Generalized Symmetric Definite Eigenproblems](#)
[Generalized Nonsymmetric Eigenproblems](#)

Linear Least Squares (LLS) Problems: LAPACK Driver Routines

This section describes LAPACK driver routines used for solving linear least squares problems. [Table "Driver Routines for Solving LLS Problems"](#) lists all such routines.

Driver Routines for Solving LLS Problems

| Routine Name | Operation performed |
|-----------------------|---|
| sgels | Uses QR or LQ factorization to solve a overdetermined or underdetermined linear system with full rank matrix. |
| gelsy | Computes the minimum-norm solution to a linear least squares problem using a complete orthogonal factorization of A. |
| gels | Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A. |
| gelsd | Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A and a divide and conquer method. |

[?sgels](#)

Uses QR or LQ factorization to solve a overdetermined or underdetermined linear system with full rank matrix.

Syntax

```
lapack_int LAPACKE_sgels (int matrix_layout, char trans, lapack_int m, lapack_int n,
lapack_int nrhs, float* a, lapack_int lda, float* b, lapack_int ldb);
```

```
lapack_int LAPACKE_dgels (int matrix_layout, char trans, lapack_int m, lapack_int n,
lapack_int nrhs, double* a, lapack_int lda, double* b, lapack_int ldb);
```

```
lapack_int LAPACKE_cgels (int matrix_layout, char trans, lapack_int m, lapack_int n,
lapack_int nrhs, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b,
lapack_int ldb);
```

```
lapack_int LAPACKE_zgels (int matrix_layout, char trans, lapack_int m, lapack_int n,
lapack_int nrhs, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b,
lapack_int ldb);
```

Include Files

- `mkl.h`

Description

The routine solves overdetermined or underdetermined real/ complex linear systems involving an m -by- n matrix A , or its transpose/ conjugate-transpose, using a QR or LQ factorization of A . It is assumed that A has full rank.

The following options are provided:

1. If $trans = 'N'$ and $m \geq n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem

$$\text{minimize } \|b - A*x\|_2$$

2. If $trans = 'N'$ and $m < n$: find the minimum norm solution of an underdetermined system $A*X = B$.
3. If $trans = 'T'$ or $'C'$ and $m \geq n$: find the minimum norm solution of an undetermined system $A^H*X = B$.
4. If $trans = 'T'$ or $'C'$ and $m < n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem

minimize $\|b - A^H x\|_2$

Several right hand side vectors b and solution vectors x can be handled in a single call; they are formed by the columns of the right hand side matrix B and the solution matrix X (when coefficient matrix is A , B is m -by- $nrhs$ and X is n -by- $nrhs$; if the coefficient matrix is A^T or A^H , B is n -by- $nrhs$ and X is m -by- $nrhs$).

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>trans</i> | Must be 'N', 'T', or 'C'. If <i>trans</i> = 'N', the linear system involves matrix A ; If <i>trans</i> = 'T', the linear system involves the transposed matrix A^T (for real flavors only); If <i>trans</i> = 'C', the linear system involves the conjugate-transposed matrix A^H (for complex flavors only). |
| <i>m</i> | The number of rows of the matrix A ($m \geq 0$). |
| <i>n</i> | The number of columns of the matrix A ($n \geq 0$). |
| <i>nrhs</i> | The number of right-hand sides; the number of columns in B ($nrhs \geq 0$). |
| <i>a, b</i> | Arrays: a (size $\max(1, lda * n)$ for column major layout and $\max(1, lda * m)$ for row major layout) contains the m -by- n matrix A . b (size $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * \max(m, n))$ for row major layout) contains the matrix B of right hand side vectors. |
| <i>lda</i> | The leading dimension of a ; at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout. |
| <i>ldb</i> | The leading dimension of b ; must be at least $\max(1, m, n)$ for column major layout if <i>trans</i> ='N' and at least $\max(1, n)$ if <i>trans</i> ='T' and at least $\max(1, nrhs)$ for row major layout regardless of the value of <i>trans</i> . |

Output Parameters

| | |
|----------|---|
| <i>a</i> | On exit, overwritten by the factorization data as follows: if $m \geq n$, array a contains the details of the QR factorization of the matrix A as returned by <code>?geqrf</code> ; if $m < n$, array a contains the details of the LQ factorization of the matrix A as returned by <code>?gelqf</code> . |
| <i>b</i> | If <i>info</i> = 0, b overwritten by the solution vectors, stored columnwise: if <i>trans</i> = 'N' and $m \geq n$, rows 1 to n of b contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of modulus of elements $n+1$ to m in that column; |

if $trans = 'N'$ and $m < n$, rows 1 to n of b contain the minimum norm solution vectors;

if $trans = 'T'$ or $'C'$ and $m \geq n$, rows 1 to m of b contain the minimum norm solution vectors;

if $trans = 'T'$ or $'C'$ and $m < n$, rows 1 to m of b contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of modulus of elements $m+1$ to n in that column.

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, the i -th diagonal element of the triangular factor of A is zero, so that A does not have full rank; the least squares solution could not be computed.

?gelsy

Computes the minimum-norm solution to a linear least squares problem using a complete orthogonal factorization of A .

Syntax

```
lapack_int LAPACKE_sgelsy( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, float* a, lapack_int lda, float* b, lapack_int ldb, lapack_int* jpvt, float
rcond, lapack_int* rank );
```

```
lapack_int LAPACKE_dgelsy( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, double* a, lapack_int lda, double* b, lapack_int ldb, lapack_int* jpvt, double
rcond, lapack_int* rank );
```

```
lapack_int LAPACKE_cgelsy( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int
ldb, lapack_int* jpvt, float rcond, lapack_int* rank );
```

```
lapack_int LAPACKE_zgelsy( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int
ldb, lapack_int* jpvt, double rcond, lapack_int* rank );
```

Include Files

- mkl.h

Description

The ?gelsy routine computes the minimum-norm solution to a real/complex linear least squares problem:

minimize $\|b - A*x\|_2$

using a complete orthogonal factorization of A . A is an m -by- n matrix which may be rank-deficient. Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the m -by- $nrhs$ right hand side matrix B and the n -by- $nrhs$ solution matrix X .

The routine first computes a QR factorization with column pivoting:

$$AP = Q \begin{pmatrix} R_{11} & R_{12} \\ \mathbf{0} & R_{22} \end{pmatrix}$$

with R_{11} defined as the largest leading submatrix whose estimated condition number is less than $1/rcond$. The order of R_{11} , $rank$, is the effective rank of A . Then, R_{22} is considered to be negligible, and R_{12} is annihilated by orthogonal/unitary transformations from the right, arriving at the complete orthogonal factorization:

$$AP = Q \begin{pmatrix} T_{11} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{pmatrix} Z$$

The minimum-norm solution is then

$$X = PZ^T \begin{pmatrix} T_{11}^{-1} Q_1^T B \\ \mathbf{0} \end{pmatrix} \text{ for real flavors and}$$

$$X = PZ^H \begin{pmatrix} T_{11}^{-1} Q_1^H B \\ \mathbf{0} \end{pmatrix} \text{ for complex flavors,}$$

where Q_1 consists of the first $rank$ columns of Q .

The `?gelsy` routine is identical to the original deprecated `?gelsx` routine except for the following differences:

- The call to the subroutine `?geqpf` has been substituted by the call to the subroutine `?geqp3`, which is a BLAS-3 version of the QR factorization with column pivoting.
- The matrix B (the right hand side) is updated with BLAS-3.
- The permutation of the matrix B (the right hand side) is faster and more simple.

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>m</code> | The number of rows of the matrix A ($m \geq 0$). |
| <code>n</code> | The number of columns of the matrix A ($n \geq 0$). |
| <code>nrhs</code> | The number of right-hand sides; the number of columns in B ($nrhs \geq 0$). |
| <code>a, b</code> | Arrays: a (size $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout) contains the m -by- n matrix A . b (size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*\max(m, n))$ for row major layout) contains the m -by- $nrhs$ right hand side matrix B . |

| | |
|--------------|---|
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; must be at least $\max(1, m, n)$ for column major layout and at least $\max(1, nrhs)$ for row major layout. |
| <i>jpvt</i> | Array, size at least $\max(1, n)$. On entry, if <i>jpvt</i> [<i>i</i> - 1] $\neq 0$, the <i>i</i> -th column of <i>A</i> is permuted to the front of <i>AP</i> , otherwise the <i>i</i> -th column of <i>A</i> is a free column. |
| <i>rcond</i> | <i>rcond</i> is used to determine the effective rank of <i>A</i> , which is defined as the order of the largest leading triangular submatrix R_{11} in the <i>QR</i> factorization with pivoting of <i>A</i> , whose estimated condition number $< 1/rcond$. |

Output Parameters

| | |
|-------------|--|
| <i>a</i> | On exit, overwritten by the details of the complete orthogonal factorization of <i>A</i> . |
| <i>b</i> | Overwritten by the <i>n</i> -by- <i>nrhs</i> solution matrix <i>X</i> . |
| <i>jpvt</i> | On exit, if <i>jpvt</i> [<i>i</i> - 1] = <i>k</i> , then the <i>i</i> -th column of <i>AP</i> was the <i>k</i> -th column of <i>A</i> . |
| <i>rank</i> | The effective rank of <i>A</i> , that is, the order of the submatrix R_{11} . This is the same as the order of the submatrix T_{11} in the complete orthogonal factorization of <i>A</i> . |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

?gelss

Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of *A*.

Syntax

```
lapack_int LAPACKE_sgelss( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, float* a, lapack_int lda, float* b, lapack_int ldb, float* s, float rcond,
lapack_int* rank );
```

```
lapack_int LAPACKE_dgelss( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, double* a, lapack_int lda, double* b, lapack_int ldb, double* s, double rcond,
lapack_int* rank );
```

```
lapack_int LAPACKE_cgelss( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int
ldb, float* s, float rcond, lapack_int* rank );
```

```
lapack_int LAPACKE_zgelss( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int
ldb, double* s, double rcond, lapack_int* rank );
```

Include Files

- `mkl.h`

Description

The routine computes the minimum norm solution to a real linear least squares problem:

$$\text{minimize } \|b - A*x\|_2$$

using the singular value decomposition (SVD) of A . A is an m -by- n matrix which may be rank-deficient. Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the m -by- $nrhs$ right hand side matrix B and the n -by- $nrhs$ solution matrix X . The effective rank of A is determined by treating as zero those singular values which are less than $rcond$ times the largest singular value.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <i>m</i> | The number of rows of the matrix A ($m \geq 0$). |
| <i>n</i> | The number of columns of the matrix A ($n \geq 0$). |
| <i>nrhs</i> | The number of right-hand sides; the number of columns in B ($nrhs \geq 0$). |
| <i>a, b</i> | Arrays: a (size $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout) contains the m -by- n matrix A . b (size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*\max(m, n))$ for row major layout) contains the m -by- $nrhs$ right hand side matrix B . |
| <i>lda</i> | The leading dimension of a ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |
| <i>ldb</i> | The leading dimension of b ; must be at least $\max(1, m, n)$ for column major layout and at least $\max(1, nrhs)$ for row major layout. |
| <i>rcond</i> | $rcond$ is used to determine the effective rank of A . Singular values $s(i) \leq rcond * s(1)$ are treated as zero. If $rcond < 0$, machine precision is used instead. |

Output Parameters

| | |
|----------|---|
| <i>a</i> | On exit, the first $\min(m, n)$ rows of a are overwritten with the matrix of right singular vectors of A , stored row-wise. |
| <i>b</i> | Overwritten by the n -by- $nrhs$ solution matrix X . If $m \geq n$ and $rank = n$, the residual sum-of-squares for the solution in the i -th column is given by the sum of squares of modulus of elements $n+1:m$ in that column. |

| | |
|-------------|--|
| <i>s</i> | Array, size at least $\max(1, \min(m, n))$. The singular values of <i>A</i> in decreasing order. The condition number of <i>A</i> in the 2-norm is $k_2(A) = s(1) / s(\min(m, n))$. |
| <i>rank</i> | The effective rank of <i>A</i> , that is, the number of singular values which are greater than $rcond * s(1)$. |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, then the algorithm for computing the SVD failed to converge; *i* indicates the number of off-diagonal elements of an intermediate bidiagonal form which did not converge to zero.

?gelsd

Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A and a divide and conquer method.

Syntax

```
lapack_int LAPACKE_sgelsd( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, float* a, lapack_int lda, float* b, lapack_int ldb, float* s, float rcond,
lapack_int* rank );
```

```
lapack_int LAPACKE_dgelsd( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, double* a, lapack_int lda, double* b, lapack_int ldb, double* s, double rcond,
lapack_int* rank );
```

```
lapack_int LAPACKE_cgelsd( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int
ldb, float* s, float rcond, lapack_int* rank );
```

```
lapack_int LAPACKE_zgelsd( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int
ldb, double* s, double rcond, lapack_int* rank );
```

- mkl.h

Description

The routine computes the minimum-norm solution to a real linear least squares problem:

$$\text{minimize } \|b - A*x\|_2$$

using the singular value decomposition (SVD) of *A*. *A* is an *m*-by-*n* matrix which may be rank-deficient.

Several right hand side vectors *b* and solution vectors *x* can be handled in a single call; they are stored as the columns of the *m*-by-*nrhs* right hand side matrix *B* and the *n*-by-*nrhs* solution matrix *X*.

The problem is solved in three steps:

1. Reduce the coefficient matrix *A* to bidiagonal form with Householder transformations, reducing the original problem into a "bidiagonal least squares problem" (BLS).
2. Solve the BLS using a divide and conquer approach.

3. Apply back all the Householder transformations to solve the original least squares problem.

The effective rank of A is determined by treating as zero those singular values which are less than $rcond$ times the largest singular value.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>m</i> | The number of rows of the matrix A ($m \geq 0$). |
| <i>n</i> | The number of columns of the matrix A ($n \geq 0$). |
| <i>nrhs</i> | The number of right-hand sides; the number of columns in B ($nrhs \geq 0$). |
| <i>a, b</i> | Arrays: a (size $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout) contains the m -by- n matrix A . b (size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*\max(m, n))$ for row major layout) contains the m -by- $nrhs$ right hand side matrix B . |
| <i>lda</i> | The leading dimension of a ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |
| <i>ldb</i> | The leading dimension of b ; must be at least $\max(1, m, n)$ for column major layout and at least $\max(1, nrhs)$ for row major layout. |
| <i>rcond</i> | $rcond$ is used to determine the effective rank of A . Singular values $s(i) \leq rcond * s(1)$ are treated as zero. If $rcond \leq 0$, machine precision is used instead. |

Output Parameters

| | |
|-------------|---|
| <i>a</i> | On exit, A has been overwritten. |
| <i>b</i> | Overwritten by the n -by- $nrhs$ solution matrix X . If $m \geq n$ and $rank = n$, the residual sum-of-squares for the solution in the i -th column is given by the sum of squares of modulus of elements $n+1:m$ in that column. |
| <i>s</i> | Array, size at least $\max(1, \min(m, n))$. The singular values of A in decreasing order. The condition number of A in the 2-norm is $k_2(A) = s(1) / s(\min(m, n))$. |
| <i>rank</i> | The effective rank of A , that is, the number of singular values which are greater than $rcond * s(1)$. |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = $-i$, the i -th parameter had an illegal value.

If $info = i$, then the algorithm for computing the SVD failed to converge; i indicates the number of off-diagonal elements of an intermediate bidiagonal form that did not converge to zero.

Generalized Linear Least Squares (LLS) Problems: LAPACK Driver Routines

This section describes LAPACK driver routines used for solving generalized linear least squares problems. Table "Driver Routines for Solving Generalized LLS Problems" lists all such routines.

Driver Routines for Solving Generalized LLS Problems

| Routine Name | Operation performed |
|-----------------------|--|
| gglse | Solves the linear equality-constrained least squares problem using a generalized RQ factorization. |
| ggglm | Solves a general Gauss-Markov linear model problem using a generalized QR factorization. |

?gglse

Solves the linear equality-constrained least squares problem using a generalized RQ factorization.

Syntax

```
lapack_int LAPACKE_sgglse (int matrix_layout, lapack_int m, lapack_int n, lapack_int p,
float* a, lapack_int lda, float* b, lapack_int ldb, float* c, float* d, float* x);
```

```
lapack_int LAPACKE_dgglse (int matrix_layout, lapack_int m, lapack_int n, lapack_int p,
double* a, lapack_int lda, double* b, lapack_int ldb, double* c, double* d, double*
x);
```

```
lapack_int LAPACKE_cgglse (int matrix_layout, lapack_int m, lapack_int n, lapack_int p,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb,
lapack_complex_float* c, lapack_complex_float* d, lapack_complex_float* x);
```

```
lapack_int LAPACKE_zgglse (int matrix_layout, lapack_int m, lapack_int n, lapack_int p,
lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb,
lapack_complex_double* c, lapack_complex_double* d, lapack_complex_double* x);
```

Include Files

- mkl.h

Description

The routine solves the linear equality-constrained least squares (LSE) problem:

minimize $\|c - A*x\|^2$ subject to $B*x = d$

where A is an m -by- n matrix, B is a p -by- n matrix, c is a given m -vector, and d is a given p -vector. It is assumed that $p \leq n \leq m+p$, and

$$\text{rank}(B) = p \text{ and } \text{rank} \begin{pmatrix} A \\ B \end{pmatrix} = n.$$

These conditions ensure that the LSE problem has a unique solution, which is obtained using a generalized RQ factorization of the matrices (B, A) given by

$$B = \begin{pmatrix} 0 & R \end{pmatrix} * Q, \quad A = Z * T * Q$$

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <i>m</i> | The number of rows of the matrix <i>A</i> ($m \geq 0$). |
| <i>n</i> | The number of columns of the matrices <i>A</i> and <i>B</i> ($n \geq 0$). |
| <i>p</i> | The number of rows of the matrix <i>B</i> ($0 \leq p \leq n \leq m+p$). |
| <i>a, b, c, d</i> | Arrays: <i>a</i> (size $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout) contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> . <i>b</i> (size $\max(1, ldb*n)$ for column major layout and $\max(1, ldb*p)$ for row major layout) contains the <i>p</i> -by- <i>n</i> matrix <i>B</i> . <i>c</i> size at least $\max(1, m)$, contains the right hand side vector for the least squares part of the LSE problem. <i>d</i> , size at least $\max(1, p)$, contains the right hand side vector for the constrained equation. |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; at least $\max(1, p)$ for column major layout and $\max(1, n)$ for row major layout. |

Output Parameters

| | |
|----------|--|
| <i>a</i> | The elements on and above the diagonal contain the $\min(m, n)$ -by- <i>n</i> upper trapezoidal matrix <i>T</i> as returned by <code>?ggrqf</code> . |
| <i>x</i> | The solution of the LSE problem. |
| <i>b</i> | On exit, the upper right triangle contains the <i>p</i> -by- <i>p</i> upper triangular matrix <i>R</i> as returned by <code>?ggrqf</code> . |
| <i>d</i> | On exit, <i>d</i> is destroyed. |
| <i>c</i> | On exit, the residual sum-of-squares for the solution is given by the sum of squares of elements <i>n-p+1</i> to <i>m</i> of vector <i>c</i> . |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = 1, the upper triangular factor *R* associated with *B* in the generalized RQ factorization of the pair (*B*, *A*) is singular, so that $\text{rank}(B) < p$; the least squares solution could not be computed.

If $info = 2$, the $(n-p)$ -by- $(n-p)$ part of the upper trapezoidal factor T associated with A in the generalized RQ factorization of the pair (B, A) is singular, so that

$$\text{rank} \begin{pmatrix} A \\ B \end{pmatrix} < n$$

; the least squares solution could not be computed.

sggglm

Solves a general Gauss-Markov linear model problem using a generalized QR factorization.

Syntax

```
lapack_int LAPACKE_sggglm (int matrix_layout, lapack_int n, lapack_int m, lapack_int p,
float* a, lapack_int lda, float* b, lapack_int ldb, float* d, float* x, float* y);
```

```
lapack_int LAPACKE_dggglm (int matrix_layout, lapack_int n, lapack_int m, lapack_int p,
double* a, lapack_int lda, double* b, lapack_int ldb, double* d, double* x, double*
y);
```

```
lapack_int LAPACKE_cggglm (int matrix_layout, lapack_int n, lapack_int m, lapack_int p,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb,
lapack_complex_float* d, lapack_complex_float* x, lapack_complex_float* y);
```

```
lapack_int LAPACKE_zggglm (int matrix_layout, lapack_int n, lapack_int m, lapack_int p,
lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb,
lapack_complex_double* d, lapack_complex_double* x, lapack_complex_double* y);
```

Include Files

- mkl.h

Description

The routine solves a general Gauss-Markov linear model (GLM) problem:

minimize_x ||y||₂ subject to $d = A*x + B*y$

where A is an n -by- m matrix, B is an n -by- p matrix, and d is a given n -vector. It is assumed that $m \leq n \leq m+p$, and $\text{rank}(A) = m$ and $\text{rank}(AB) = n$.

Under these assumptions, the constrained equation is always consistent, and there is a unique solution x and a minimal 2-norm solution y , which is obtained using a generalized QR factorization of the matrices (A, B) given by

$$A = Q \begin{pmatrix} R \\ 0 \end{pmatrix}; \quad B = Q * T * Z.$$

In particular, if matrix B is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

minimize_x ||B⁻¹(d-A*x)||₂.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <i>n</i> | The number of rows of the matrices <i>A</i> and <i>B</i> ($n \geq 0$). |
| <i>m</i> | The number of columns in <i>A</i> ($m \geq 0$). |
| <i>p</i> | The number of columns in <i>B</i> ($p \geq n - m$). |
| <i>a, b, d</i> | Arrays: <i>a</i> (size $\max(1, lda * m)$ for column major layout and $\max(1, lda * n)$ for row major layout) contains the <i>n</i> -by- <i>m</i> matrix <i>A</i> . <i>b</i> (size $\max(1, ldb * p)$ for column major layout and $\max(1, ldb * n)$ for row major layout) contains the <i>n</i> -by- <i>p</i> matrix <i>B</i> . <i>d</i> , size at least $\max(1, n)$, contains the left hand side of the GLM equation. |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, n)$ for column major layout and $\max(1, m)$ for row major layout. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; at least $\max(1, n)$ for column major layout and $\max(1, p)$ for row major layout. |

Output Parameters

| | |
|-------------|---|
| <i>x, y</i> | Arrays <i>x, y</i> . size at least $\max(1, m)$ for <i>x</i> and at least $\max(1, p)$ for <i>y</i> . On exit, <i>x</i> and <i>y</i> are the solutions of the GLM problem. |
| <i>a</i> | On exit, the upper triangular part of the array <i>a</i> contains the <i>m</i> -by- <i>m</i> upper triangular matrix <i>R</i> . |
| <i>b</i> | On exit, if $n \leq p$, the upper right triangle contains the <i>n</i> -by- <i>n</i> upper triangular matrix <i>T</i> as returned by <code>?ggrqf</code> ; if $n > p$, the elements on and above the $(n-p)$ -th subdiagonal contain the <i>n</i> -by- <i>p</i> upper trapezoidal matrix <i>T</i> . |
| <i>d</i> | On exit, <i>d</i> is destroyed |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = 1, the upper triangular factor *R* associated with *A* in the generalized QR factorization of the pair (*A, B*) is singular, so that $\text{rank}(A) < m$; the least squares solution could not be computed.

If *info* = 2, the bottom $(n-m)$ -by- $(n-m)$ part of the upper trapezoidal factor *T* associated with *B* in the generalized QR factorization of the pair (*A, B*) is singular, so that $\text{rank}(AB) < n$; the least squares solution could not be computed.

Symmetric Eigenvalue Problems: LAPACK Driver Routines

This section describes LAPACK driver routines used for solving symmetric eigenvalue problems. See also [computational routines](#) that can be called to solve these problems. [Table "Driver Routines for Solving Symmetric Eigenproblems"](#) lists all such driver routines.

Driver Routines for Solving Symmetric Eigenproblems

| Routine Name | Operation performed |
|-----------------------------|---|
| syev/heev | Computes all eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix. |
| syevd/heevd | Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric / Hermitian matrix using divide and conquer algorithm. |
| syevx/heevx | Computes selected eigenvalues and, optionally, eigenvectors of a symmetric / Hermitian matrix. |
| syevr/heevr | Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix using the Relatively Robust Representations. |
| spev/hpev | Computes all eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix in packed storage. |
| spevd/hpevd | Uses divide and conquer algorithm to compute all eigenvalues and (optionally) all eigenvectors of a real symmetric / Hermitian matrix held in packed storage. |
| spevx/hpevx | Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix in packed storage. |
| sbev /hbev | Computes all eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian band matrix. |
| sbevd/hbevd | Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric / Hermitian band matrix using divide and conquer algorithm. |
| sbevz/hbevz | Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian band matrix. |
| stev | Computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix. |
| stevd | Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric tridiagonal matrix using divide and conquer algorithm. |
| stevx | Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix. |
| stevr | Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix using the Relatively Robust Representations. |

?syev

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix.

Syntax

```
lapack_int LAPACKE_ssyev (int matrix_layout, char jobz, char uplo, lapack_int n, float* a, lapack_int lda, float* w);
```

```
lapack_int LAPACKE_dsyev (int matrix_layout, char jobz, char uplo, lapack_int n, double* a, lapack_int lda, double* w);
```

Include Files

- `mkl.h`

Description

The routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A .

Note that for most cases of real symmetric eigenvalue problems the default choice should be `syevr` function as its underlying algorithm is faster and uses less workspace.

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>jobz</code> | Must be 'N' or 'V'. If <code>jobz = 'N'</code> , then only eigenvalues are computed. If <code>jobz = 'V'</code> , then eigenvalues and eigenvectors are computed. |
| <code>uplo</code> | Must be 'U' or 'L'. If <code>uplo = 'U'</code> , a stores the upper triangular part of A . If <code>uplo = 'L'</code> , a stores the lower triangular part of A . |
| <code>n</code> | The order of the matrix A ($n \geq 0$). |
| <code>a</code> | a (size $\max(1, lda * n)$) is an array containing either upper or lower triangular part of the symmetric matrix A , as specified by <code>uplo</code> . |
| <code>lda</code> | The leading dimension of the array a . Must be at least $\max(1, n)$. |

Output Parameters

| | |
|----------------|--|
| <code>a</code> | On exit, if <code>jobz = 'V'</code> , then if <code>info = 0</code> , array a contains the orthonormal eigenvectors of the matrix A . If <code>jobz = 'N'</code> , then on exit the lower triangle (if <code>uplo = 'L'</code>) or the upper triangle (if <code>uplo = 'U'</code>) of A , including the diagonal, is overwritten. |
| <code>w</code> | Array, size at least $\max(1, n)$. If <code>info = 0</code> , contains the eigenvalues of the matrix A in ascending order. |

Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

?heev

Computes all eigenvalues and, optionally, eigenvectors of a Hermitian matrix.

Syntax

```
lapack_int LAPACKE_cheev( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_complex_float* a, lapack_int lda, float* w );
```

```
lapack_int LAPACKE_zheev( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_complex_double* a, lapack_int lda, double* w );
```

Include Files

- mkl.h

Description

The routine computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A .

Note that for most cases of complex Hermitian eigenvalue problems the default choice should be [heevr](#) function as its underlying algorithm is faster and uses less workspace.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed. |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of A . |
| <i>n</i> | The order of the matrix A ($n \geq 0$). |
| <i>a</i> | <i>a</i> (size $\max(1, lda*n)$) is an array containing either upper or lower triangular part of the Hermitian matrix A , as specified by <i>uplo</i> . |
| <i>lda</i> | The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$. |

Output Parameters

| | |
|----------|--|
| <i>a</i> | On exit, if <i>jobz</i> = 'V', then if <i>info</i> = 0, array <i>a</i> contains the orthonormal eigenvectors of the matrix A . If <i>jobz</i> = 'N', then on exit the lower triangle (if <i>uplo</i> = 'L') or the upper triangle (if <i>uplo</i> = 'U') of A , including the diagonal, is overwritten. |
| <i>w</i> | Array, size at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues of the matrix A in ascending order. |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, then the algorithm failed to converge; *i* indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

?syevd

Computes all eigenvalues and, optionally, all eigenvectors of a real symmetric matrix using divide and conquer algorithm.

Syntax

```
lapack_int LAPACKE_ssyevd (int matrix_layout, char jobz, char uplo, lapack_int n,
float* a, lapack_int lda, float* w);
```

```
lapack_int LAPACKE_dsyevd (int matrix_layout, char jobz, char uplo, lapack_int n,
double* a, lapack_int lda, double* w);
```

Include Files

- mkl.h

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric matrix *A*. In other words, it can compute the spectral factorization of *A* as: $A = Z*\Lambda*Z^T$.

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i , and *Z* is the orthogonal matrix whose columns are the eigenvectors z_i . Thus,

$$A*z_i = \lambda_i*z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the *QL* or *QR* algorithm.

Note that for most cases of real symmetric eigenvalue problems the default choice should be [syevr](#) function as its underlying algorithm is faster and uses less workspace. `?syevd` requires more workspace but is faster in some cases, especially for large matrices.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed. |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> . |

| | |
|------------|--|
| <i>n</i> | The order of the matrix A ($n \geq 0$). |
| <i>a</i> | Array, size (<i>lda</i> , *). <i>a</i> (size $\max(1, lda * n)$) is an array containing either upper or lower triangular part of the symmetric matrix A , as specified by <i>uplo</i> . |
| <i>lda</i> | The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$. |

Output Parameters

| | |
|----------|---|
| <i>w</i> | Array, size at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues of the matrix A in ascending order. See also <i>info</i> . |
| <i>a</i> | If <i>jobz</i> = 'V', then on exit this array is overwritten by the orthogonal matrix Z which contains the eigenvectors of A . |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = *i*, and *jobz* = 'N', then the algorithm failed to converge; *i* indicates the number of off-diagonal elements of an intermediate tridiagonal form which did not converge to zero.

If *info* = *i*, and *jobz* = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns *info*/(*n*+1) through $\text{mod}(\text{info}, n+1)$.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $A+E$ such that $\|E\|_2 = O(\epsilon) * \|A\|_2$, where ϵ is the machine precision.

The complex analogue of this routine is [heevd](#)

?heevd

Computes all eigenvalues and, optionally, all eigenvectors of a complex Hermitian matrix using divide and conquer algorithm.

Syntax

```
lapack_int LAPACKE_cheevd( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_complex_float* a, lapack_int lda, float* w );
```

```
lapack_int LAPACKE_zheevd( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_complex_double* a, lapack_int lda, double* w );
```

Include Files

- mkl.h

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a complex Hermitian matrix A . In other words, it can compute the spectral factorization of A as: $A = Z^* \Lambda Z^H$.

Here Λ is a real diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the (complex) unitary matrix whose columns are the eigenvectors z_i . Thus,

$$A z_i = \lambda_i z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Note that for most cases of complex Hermitian eigenvalue problems the default choice should be `heevr` function as its underlying algorithm is faster and uses less workspace. `?heevd` requires more workspace but is faster in some cases, especially for large matrices.

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>jobz</code> | Must be 'N' or 'V'. If <code>jobz = 'N'</code> , then only eigenvalues are computed. If <code>jobz = 'V'</code> , then eigenvalues and eigenvectors are computed. |
| <code>uplo</code> | Must be 'U' or 'L'. If <code>uplo = 'U'</code> , <code>a</code> stores the upper triangular part of A . If <code>uplo = 'L'</code> , <code>a</code> stores the lower triangular part of A . |
| <code>n</code> | The order of the matrix A ($n \geq 0$). |
| <code>a</code> | <code>a</code> (size $\max(1, lda * n)$) is an array containing either upper or lower triangular part of the Hermitian matrix A , as specified by <code>uplo</code> . |
| <code>lda</code> | The leading dimension of the array <code>a</code> . Must be at least $\max(1, n)$. |

Output Parameters

| | |
|----------------|--|
| <code>w</code> | Array, size at least $\max(1, n)$. If <code>info = 0</code> , contains the eigenvalues of the matrix A in ascending order. See also <code>info</code> . |
| <code>a</code> | If <code>jobz = 'V'</code> , then on exit this array is overwritten by the unitary matrix Z which contains the eigenvectors of A . |

Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = i`, and `jobz = 'N'`, then the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero;

if `info = i`, and `jobz = 'V'`, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns `info/(n+1)` through `mod(info, n+1)`.

If `info = -i`, the i -th parameter had an illegal value.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $A + E$ such that $\|E\|_2 = O(\epsilon) * \|A\|_2$, where ϵ is the machine precision.

The real analogue of this routine is [syevd](#). See also [hpevd](#) for matrices held in packed storage, and [hbevd](#) for banded matrices.

?syevx

Computes selected eigenvalues and, optionally, eigenvectors of a symmetric matrix.

Syntax

```
lapack_int LAPACKE_ssyevx (int matrix_layout, char jobz, char range, char uplo,
lapack_int n, float* a, lapack_int lda, float vl, float vu, lapack_int il, lapack_int
iu, float abstol, lapack_int* m, float* w, float* z, lapack_int ldz, lapack_int*
ifail);
```

```
lapack_int LAPACKE_dsyevx (int matrix_layout, char jobz, char range, char uplo,
lapack_int n, double* a, lapack_int lda, double vl, double vu, lapack_int il,
lapack_int iu, double abstol, lapack_int* m, double* w, double* z, lapack_int ldz,
lapack_int* ifail);

- mkl.h

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Note that for most cases of real symmetric eigenvalue problems the default choice should be [syevr](#) function as its underlying algorithm is faster and uses less workspace. [?syevx](#) is faster for a few selected eigenvalues.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed. |
| <i>range</i> | Must be 'A', 'V', or 'I'. If <i>range</i> = 'A', all eigenvalues will be found. If <i>range</i> = 'V', all eigenvalues in the half-open interval $(vl, vu]$ will be found. If <i>range</i> = 'I', the eigenvalues with indices <i>il</i> through <i>iu</i> will be found. |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of A . |

| | |
|---------------|--|
| | If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> . |
| <i>n</i> | The order of the matrix <i>A</i> ($n \geq 0$). |
| <i>a</i> | <i>a</i> (size $\max(1, lda * n)$) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> , as specified by <i>uplo</i> . |
| <i>lda</i> | The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$. |
| <i>vl, vu</i> | If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; $vl \leq vu$. Not referenced if <i>range</i> = 'A' or 'I'. |
| <i>il, iu</i> | If <i>range</i> = 'I', the indices of the smallest and largest eigenvalues to be returned. Constraints: $1 \leq il \leq iu \leq n$, if $n > 0$; $il = 1$ and $iu = 0$, if $n = 0$. Not referenced if <i>range</i> = 'A' or 'V'. |
| <i>abstol</i> | The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information. |
| <i>ldz</i> | The leading dimension of the output array <i>z</i> ; $ldz \geq 1$. If <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$ for column major layout and $lda \geq \max(1, m)$ for row major layout. |

Output Parameters

| | |
|----------|---|
| <i>a</i> | On exit, the lower triangle (if <i>uplo</i> = 'L') or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten. |
| <i>m</i> | The total number of eigenvalues found; $0 \leq m \leq n$. If <i>range</i> = 'A', $m = n$, and if <i>range</i> = 'I', $m = iu - il + 1$. |
| <i>w</i> | Array, size at least $\max(1, n)$. The first <i>m</i> elements contain the selected eigenvalues of the matrix <i>A</i> in ascending order. |
| <i>z</i> | Array <i>z</i> (size $\max(1, ldz * m)$ for column major layout and $\max(1, ldz * n)$ for row major layout) contains eigenvectors. If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>A</i> corresponding to the selected eigenvalues, with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with <i>w</i> (<i>i</i>). If an eigenvector fails to converge, then that column of <i>z</i> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i> . If <i>jobz</i> = 'N', then <i>z</i> is not referenced. |

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

ifail

Array, size at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of *ifail* are zero; if $info > 0$, then *ifail* contains the indices of the eigenvectors that failed to converge.

If $jobz = 'V'$, then *ifail* is not referenced.

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then i eigenvectors failed to converge; their indices are stored in the array *ifail*.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \cdot \max(|a|, |b|)$, where ϵ is the machine precision.

If $abstol$ is less than or equal to zero, then $\epsilon \cdot ||T||$ is used as tolerance, where $||T||$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues are computed most accurately when $abstol$ is set to twice the underflow threshold $2 * \lambda_{\text{lamch}}('S')$, not zero.

If this routine returns with $info > 0$, indicating that some eigenvectors did not converge, try setting $abstol$ to $2 * \lambda_{\text{lamch}}('S')$.

?heevx

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix.

Syntax

```
lapack_int LAPACKC_cheevx( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_complex_float* a, lapack_int lda, float vl, float vu, lapack_int
il, lapack_int iu, float abstol, lapack_int* m, float* w, lapack_complex_float* z,
lapack_int ldz, lapack_int* ifail );
```

```
lapack_int LAPACKC_zheevx( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_complex_double* a, lapack_int lda, double vl, double vu,
lapack_int il, lapack_int iu, double abstol, lapack_int* m, double* w,
lapack_complex_double* z, lapack_int ldz, lapack_int* ifail );
```

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Note that for most cases of complex Hermitian eigenvalue problems the default choice should be `heevr` function as its underlying algorithm is faster and uses less workspace. `?heevx` is faster for a few selected eigenvalues.

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>jobz</code> | Must be 'N' or 'V'. If <code>jobz = 'N'</code> , then only eigenvalues are computed. If <code>jobz = 'V'</code> , then eigenvalues and eigenvectors are computed. |
| <code>range</code> | Must be 'A', 'V', or 'I'. If <code>range = 'A'</code> , all eigenvalues will be found. If <code>range = 'V'</code> , all eigenvalues in the half-open interval $(vl, vu]$ will be found. If <code>range = 'I'</code> , the eigenvalues with indices <code>il</code> through <code>iu</code> will be found. |
| <code>uplo</code> | Must be 'U' or 'L'. If <code>uplo = 'U'</code> , <code>a</code> stores the upper triangular part of <code>A</code> . If <code>uplo = 'L'</code> , <code>a</code> stores the lower triangular part of <code>A</code> . |
| <code>n</code> | The order of the matrix <code>A</code> ($n \geq 0$). |
| <code>a</code> | <code>a</code> (size $\max(1, lda * n)$) is an array containing either upper or lower triangular part of the Hermitian matrix <code>A</code> , as specified by <code>uplo</code> . |
| <code>lda</code> | The leading dimension of the array <code>a</code> . Must be at least $\max(1, n)$. |
| <code>vl, vu</code> | If <code>range = 'V'</code> , the lower and upper bounds of the interval to be searched for eigenvalues; $vl \leq vu$. Not referenced if <code>range = 'A'</code> or 'I'. |
| <code>il, iu</code> | If <code>range = 'I'</code> , the indices of the smallest and largest eigenvalues to be returned. Constraints: $1 \leq il \leq iu \leq n$, if $n > 0$; $il = 1$ and $iu = 0$, if $n = 0$. Not referenced if <code>range = 'A'</code> or 'V'. |
| <code>abstol</code> | |
| <code>ldz</code> | The leading dimension of the output array <code>z</code> ; $ldz \geq 1$. If <code>jobz = 'V'</code> , then $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout. |

Output Parameters

| | |
|----------------|---|
| <code>a</code> | On exit, the lower triangle (if <code>uplo = 'L'</code>) or the upper triangle (if <code>uplo = 'U'</code>) of <code>A</code> , including the diagonal, is overwritten. |
| <code>m</code> | The total number of eigenvalues found; $0 \leq m \leq n$. |

If *range* = 'A', $m = n$, and if *range* = 'I', $m = iu-il+1$.

w Array, size $\max(1, n)$. The first m elements contain the selected eigenvalues of the matrix A in ascending order.

z Array z (size $\max(1, ldz*m)$ for column major layout and $\max(1, ldz*n)$ for row major layout) contains eigenvectors.

If *jobz* = 'V', then if *info* = 0, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If *jobz* = 'N', then z is not referenced.

ifail Array, size at least $\max(1, n)$.

If *jobz* = 'V', then if *info* = 0, the first m elements of *ifail* are zero; if *info* > 0, then *ifail* contains the indices of the eigenvectors that failed to converge.

If *jobz* = 'V', then *ifail* is not referenced.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = $-i$, the i -th parameter had an illegal value.

If *info* = i , then i eigenvectors failed to converge; their indices are stored in the array *ifail*.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \cdot \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon \cdot ||T||$ will be used in its place, where $||T||$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * \text{?lamch}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * \text{?lamch}('S')$.

?syevr

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix using the Relatively Robust Representations.

Syntax

```
lapack_int LAPACKE_ssyevr (int matrix_layout, char jobz, char range, char uplo,
lapack_int n, float* a, lapack_int lda, float vl, float vu, lapack_int il, lapack_int
iu, float abstol, lapack_int* m, float* w, float* z, lapack_int ldz, lapack_int*
isuppz);
```

```
lapack_int LAPACKE_dsyevr (int matrix_layout, char jobz, char range, char uplo,
lapack_int n, double* a, lapack_int lda, double vl, double vu, lapack_int il,
lapack_int iu, double abstol, lapack_int* m, double* w, double* z, lapack_int ldz,
lapack_int* isuppz);
```

Include Files

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

The routine first reduces the matrix A to tridiagonal form T . Then, whenever possible, `?syevr` calls `stemr` to compute the eigenspectrum using Relatively Robust Representations. `stemr` computes eigenvalues by the *dqds* algorithm, while orthogonal eigenvectors are computed from various "good" L^*D*L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the each unreduced block of T :

- Compute $T - \sigma I = L^*D*L^T$, so that L and D define all the wanted eigenvalues to high relative accuracy. This means that small relative changes in the entries of D and L cause only small relative changes in the eigenvalues and eigenvectors. The standard (unfactored) representation of the tridiagonal matrix T does not have this property in general.
- Compute the eigenvalues to suitable accuracy. If the eigenvectors are desired, the algorithm attains full accuracy of the computed eigenvalues only right before the corresponding vectors have to be computed, see Steps c) and d).
- For each cluster of close eigenvalues, select a new shift close to the cluster, find a new factorization, and refine the shifted eigenvalues to suitable accuracy.
- For each eigenvalue with a large enough relative separation, compute the corresponding eigenvector by forming a rank revealing twisted factorization. Go back to Step c) for any clusters that remain.

The desired accuracy of the output can be specified by the input parameter *abstol*.

The routine `?syevr` calls `stemr` when the full spectrum is requested on machines that conform to the IEEE-754 floating point standard. `?syevr` calls `stebz` and `stein` on non-IEEE machines and when partial spectrum requests are made.

Note that `?syevr` is preferable for most cases of real symmetric eigenvalue problems as its underlying algorithm is fast and uses less workspace.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed. |
| <i>range</i> | Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval: |

| | |
|---------------|--|
| | $vl < w[i] \leq vu$. |
| | If $range = 'I'$, the routine computes eigenvalues with indices il to iu . |
| | For $range = 'V'$ or $'I'$ and $iu-il < n-1$, <code>sstebz/dstebz</code> and <code>sstein/dstein</code> are called. |
| <i>uplo</i> | Must be $'U'$ or $'L'$. |
| | If $uplo = 'U'$, a stores the upper triangular part of A . |
| | If $uplo = 'L'$, a stores the lower triangular part of A . |
| <i>n</i> | The order of the matrix A ($n \geq 0$). |
| <i>a</i> | a (size $\max(1, lda*n)$) is an array containing either upper or lower triangular part of the symmetric matrix A , as specified by $uplo$. |
| <i>lda</i> | The leading dimension of the array a . Must be at least $\max(1, n)$. |
| <i>vl, vu</i> | If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$. If $range = 'A'$ or $'I'$, vl and vu are not referenced. |
| <i>il, iu</i> | If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$, if $n = 0$. If $range = 'A'$ or $'V'$, il and iu are not referenced. |
| <i>abstol</i> | If $jobz = 'V'$, the eigenvalues and eigenvectors output have residual norms bounded by $abstol$, and the dot products between different eigenvectors are bounded by $abstol$. If $abstol < n * eps * T $, then $n * eps * T $ is used instead, where eps is the machine precision, and $ T $ is the 1-norm of the matrix T . The eigenvalues are computed to an accuracy of $eps * T $ irrespective of $abstol$. If high relative accuracy is important, set $abstol$ to <code>?lamch('S')</code> . |
| <i>ldz</i> | The leading dimension of the output array z . Constraints: $ldz \geq 1$ if $jobz = 'N'$ and $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout if $jobz = 'V'$. |

Output Parameters

| | |
|----------|--|
| <i>a</i> | On exit, the lower triangle (if $uplo = 'L'$) or the upper triangle (if $uplo = 'U'$) of A , including the diagonal, is overwritten. |
|----------|--|

| | |
|---------------|--|
| <i>m</i> | <p>The total number of eigenvalues found, $0 \leq m \leq n$.</p> <p>If <i>range</i> = 'A', $m = n$, if <i>range</i> = 'I', $m = iu-il+1$, and if <i>range</i> = 'V' the exact value of <i>m</i> is not known in advance.</p> |
| <i>w, z</i> | <p>Arrays:</p> <p><i>w</i>, size at least $\max(1, n)$, contains the selected eigenvalues in ascending order, stored in <i>w</i>[0] to <i>w</i>[<i>m</i> - 1];</p> <p><i>z</i>(size $\max(1, ldz*m)$ for column major layout and $\max(1, ldz*n)$ for row major layout) .</p> <p>If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>A</i> corresponding to the selected eigenvalues, with the <i>i</i>-th column of <i>z</i> holding the eigenvector associated with <i>w</i>[<i>i</i> - 1].</p> <p>If <i>jobz</i> = 'N', then <i>z</i> is not referenced.</p> |
| <i>isuppz</i> | <p>Array, size at least $2 * \max(1, m)$.</p> <p>The support of the eigenvectors in <i>z</i>, i.e., the indices indicating the nonzero elements in <i>z</i>. The <i>i</i>-th eigenvector is nonzero only in elements <i>isuppz</i>[2<i>i</i> - 2] through <i>isuppz</i>[2<i>i</i> - 1]. Referenced only if eigenvectors are needed (<i>jobz</i> = 'V') and all eigenvalues are needed, that is, <i>range</i> = 'A' or <i>range</i> = 'I' and <i>il</i> = 1 and <i>iu</i> = <i>n</i>.</p> |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, an internal error has occurred.

Application Notes

?heevr

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix using the Relatively Robust Representations.

Syntax

```
lapack_int LAPACKE_cheevr( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_complex_float* a, lapack_int lda, float vl, float vu, lapack_int
il, lapack_int iu, float abstol, lapack_int* m, float* w, lapack_complex_float* z,
lapack_int ldz, lapack_int* isuppz );
```

```
lapack_int LAPACKE_zheevr( int matrix_layout, char jobz, char range, char uplo,

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

The routine first reduces the matrix A to tridiagonal form T with a call to [hetrd](#). Then, whenever possible, `?heevr` calls [stegr](#) to compute the eigenspectrum using Relatively Robust Representations. `?stegr` computes eigenvalues by the *dqds* algorithm, while orthogonal eigenvectors are computed from various "good" $L^*D^*L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For each unreduced block (submatrix) of T :

- a.** Compute $T - \sigma I = L^*D^*L^T$, so that L and D define all the wanted eigenvalues to high relative accuracy. This means that small relative changes in the entries of D and L cause only small relative changes in the eigenvalues and eigenvectors. The standard (unfactored) representation of the tridiagonal matrix T does not have this property in general.
- b.** Compute the eigenvalues to suitable accuracy. If the eigenvectors are desired, the algorithm attains full accuracy of the computed eigenvalues only right before the corresponding vectors have to be computed, see Steps c) and d).
- c.** For each cluster of close eigenvalues, select a new shift close to the cluster, find a new factorization, and refine the shifted eigenvalues to suitable accuracy.
- d.** For each eigenvalue with a large enough relative separation, compute the corresponding eigenvector by forming a rank revealing twisted factorization. Go back to Step c) for any clusters that remain.

The desired accuracy of the output can be specified by the input parameter *abstol*.

The routine `?heevr` calls [stemr](#) when the full spectrum is requested on machines which conform to the IEEE-754 floating point standard, or [stebz](#) and [stein](#) on non-IEEE machines and when partial spectrum requests are made.

Note that the routine `?heevr` is preferable for most cases of complex Hermitian eigenvalue problems as its underlying algorithm is fast and uses less workspace.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed. |
| <i>range</i> | Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $v_l < \lambda(i) \leq v_u$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> . For <i>range</i> = 'V' or 'I', <code>sstebz/dstebz</code> and <code>cstein/zstein</code> are called. |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of A . |

| | |
|---------------|--|
| <i>n</i> | The order of the matrix <i>A</i> ($n \geq 0$). |
| <i>a</i> | <i>a</i> (size $\max(1, lda * n)$) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> , as specified by <i>uplo</i> . |
| <i>lda</i> | The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$. |
| <i>vl, vu</i> | If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced. |
| <i>il, iu</i> | If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$. If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced. |
| <i>abstol</i> | The absolute error tolerance to which each eigenvalue/eigenvector is required. If <i>jobz</i> = 'V', the eigenvalues and eigenvectors output have residual norms bounded by <i>abstol</i> , and the dot products between different eigenvectors are bounded by <i>abstol</i> . If $abstol < n * eps * T $, then $n * eps * T $ is used instead, where <i>eps</i> is the machine precision, and $ T $ is the 1-norm of the matrix <i>T</i> . The eigenvalues are computed to an accuracy of $eps * T $ irrespective of <i>abstol</i> . If high relative accuracy is important, set <i>abstol</i> to <code>?lamch('S')</code> . |
| <i>ldz</i> | The leading dimension of the output array <i>z</i> . Constraints: $ldz \geq 1$ if <i>jobz</i> = 'N'; $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout if <i>jobz</i> = 'V'. |

Output Parameters

| | |
|----------|---|
| <i>a</i> | On exit, the lower triangle (if <i>uplo</i> = 'L') or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten. |
| <i>m</i> | The total number of eigenvalues found, $0 \leq m \leq n$. If <i>range</i> = 'A', $m = n$, if <i>range</i> = 'I', $m = iu - il + 1$, and if <i>range</i> = 'V' the exact value of <i>m</i> is not known in advance. |
| <i>w</i> | Array, size at least $\max(1, n)$, contains the selected eigenvalues in ascending order, stored in <i>w</i> [0] to <i>w</i> [<i>m</i> - 1]. |
| <i>z</i> | Array <i>z</i> (size $\max(1, ldz * m)$ for column major layout and $\max(1, ldz * n)$ for row major layout) . |

If `jobz = 'V'`, then if `info = 0`, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w[i - 1]$.

If `jobz = 'N'`, then z is not referenced.

`isuppz`

Array, size at least $2 * \max(1, m)$.

The support of the eigenvectors in z , i.e., the indices indicating the nonzero elements in z . The i -th eigenvector is nonzero only in elements `isuppz[2i - 2]` through `isuppz[2i - 1]`. Referenced only if eigenvectors are needed (`jobz = 'V'`) and all eigenvalues are needed, that is, `range = 'A'` or `range = 'I'` and `il = 1` and `iu = n`.

Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, an internal error has occurred.

Application Notes

Normal execution of `?stemr` may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the IEEE standard default manner.

For more details, see `?stemr` and these references:

Description

The routine computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed. |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of <i>A</i> . |
| <i>n</i> | The order of the matrix <i>A</i> ($n \geq 0$). |
| <i>ap</i> | Array <i>ap</i> contains the packed upper or lower triangle of symmetric matrix <i>A</i> , as specified by <i>uplo</i> . The size of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$. |
| <i>ldz</i> | The leading dimension of the output array <i>z</i> . Constraints: if <i>jobz</i> = 'N', then $ldz \geq 1$; if <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$. |

Output Parameters

| | |
|-------------|--|
| <i>w, z</i> | Arrays: <i>w</i> , size at least $\max(1, n)$. If <i>info</i> = 0, <i>w</i> contains the eigenvalues of the matrix <i>A</i> in ascending order. <i>z</i> (size $\max(1, ldz*n)$). If <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>z</i> contains the orthonormal eigenvectors of the matrix <i>A</i> , with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with $w[i - 1]$. If <i>jobz</i> = 'N', then <i>z</i> is not referenced. |
| <i>ap</i> | On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of <i>A</i> . |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, then the algorithm failed to converge; *i* indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

?hpev

Computes all eigenvalues and, optionally, eigenvectors of a Hermitian matrix in packed storage.

Syntax

```
lapack_int LAPACKE_chpev( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_complex_float* ap, float* w, lapack_complex_float* z, lapack_int ldz );

lapack_int LAPACKE_zhpev( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_complex_double* ap, double* w, lapack_complex_double* z, lapack_int ldz );
```

Include Files

- mkl.h

Description

The routine computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed. |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of A . If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of A . |
| <i>n</i> | The order of the matrix A ($n \geq 0$). |
| <i>ap</i> | Array <i>ap</i> contains the packed upper or lower triangle of Hermitian matrix A , as specified by <i>uplo</i> . The size of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$. |
| <i>ldz</i> | The leading dimension of the output array <i>z</i> . Constraints: if <i>jobz</i> = 'N', then $ldz \geq 1$; if <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$. |

Output Parameters

| | |
|----------|--|
| <i>w</i> | Array, size at least $\max(1, n)$. If <i>info</i> = 0, <i>w</i> contains the eigenvalues of the matrix A in ascending order. |
| <i>z</i> | Array <i>z</i> (size at least $\max(1, ldz*n)$). |

If `jobz = 'V'`, then if `info = 0`, `z` contains the orthonormal eigenvectors of the matrix `A`, with the `i`-th column of `z` holding the eigenvector associated with `w[i - 1]`.

If `jobz = 'N'`, then `z` is not referenced.

`ap`

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of `A`.

Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, the `i`-th parameter had an illegal value.

If `info = i`, then the algorithm failed to converge; `i` indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

?spevd

Uses divide and conquer algorithm to compute all eigenvalues and (optionally) all eigenvectors of a real symmetric matrix held in packed storage.

Syntax

```
lapack_int LAPACKE_sspevd (int matrix_layout, char jobz, char uplo, lapack_int n,
float* ap, float* w, float* z, lapack_int ldz);
```

```
lapack_int LAPACKE_dspevd (int matrix_layout, char jobz, char uplo, lapack_int n,
double* ap, double* w, double* z, lapack_int ldz);
```

Include Files

- `mk1.h`

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric matrix `A` (held in packed storage). In other words, it can compute the spectral factorization of `A` as:

$$A = Z \Lambda Z^T.$$

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the orthogonal matrix whose columns are the eigenvectors z_i . Thus,

$$A z_i = \lambda_i z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the `QL` or `QR` algorithm.

Input Parameters

`matrix_layout`

Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

`jobz`

Must be `'N'` or `'V'`.

| | |
|--------|---|
| | If $jobz = 'N'$, then only eigenvalues are computed. |
| | If $jobz = 'V'$, then eigenvalues and eigenvectors are computed. |
| $uplo$ | Must be $'U'$ or $'L'$. |
| | If $uplo = 'U'$, ap stores the packed upper triangular part of A . |
| | If $uplo = 'L'$, ap stores the packed lower triangular part of A . |
| n | The order of the matrix A ($n \geq 0$). |
| ap | ap contains the packed upper or lower triangle of symmetric matrix A , as specified by $uplo$. |
| | The dimension of ap must be $\max(1, n*(n+1)/2)$ |
| ldz | The leading dimension of the output array z . |
| | Constraints: |
| | if $jobz = 'N'$, then $ldz \geq 1$; |
| | if $jobz = 'V'$, then $ldz \geq \max(1, n)$. |

Output Parameters

| | |
|--------|--|
| w, z | Arrays: |
| | w , size at least $\max(1, n)$. |
| | If $info = 0$, contains the eigenvalues of the matrix A in ascending order. See also $info$. |
| | z (size $\max(1, ldz*n)$). |
| | If $jobz = 'V'$, then this array is overwritten by the orthogonal matrix Z which contains the eigenvectors of A . If $jobz = 'N'$, then z is not referenced. |
| ap | On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of A . |

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $A+E$ such that $\|E\|_2 = O(\epsilon) * \|A\|_2$, where ϵ is the machine precision.

The complex analogue of this routine is [hpevd](#).

See also [syevd](#) for matrices held in full storage, and [sbevd](#) for banded matrices.

?hpevd

Uses divide and conquer algorithm to compute all eigenvalues and, optionally, all eigenvectors of a complex Hermitian matrix held in packed storage.

Syntax

```
lapack_int LAPACKE_chpevd( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_complex_float* ap, float* w, lapack_complex_float* z, lapack_int ldz );

lapack_int LAPACKE_zhpevd( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_complex_double* ap, double* w, lapack_complex_double* z, lapack_int ldz );
```

Include Files

- mkl.h

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a complex Hermitian matrix A (held in packed storage). In other words, it can compute the spectral factorization of A as: $A = Z^* \Lambda Z^H$.

Here Λ is a real diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the (complex) unitary matrix whose columns are the eigenvectors z_i . Thus,

$$A z_i = \lambda_i z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed. |

abstol, lapack_int* m, double* w, double* z, lapack_int ldz, lapack_int* ifail);
```

Include Files

- `mkl.h`

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix *A* in packed storage. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed. |
| <i>range</i> | Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval: $vl < w[i] \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> . |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of <i>A</i> . |
| <i>n</i> | The order of the matrix <i>A</i> ($n \geq 0$). |
| <i>ap</i> | Array <i>ap</i> contains the packed upper or lower triangle of the symmetric matrix <i>A</i> , as specified by <i>uplo</i> . The size of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$. |
| <i>vl, vu</i> | If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced. |
| <i>il, iu</i> | If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$. If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced. |
| <i>abstol</i> | The absolute error tolerance to which each eigenvalue is required. See <i>Application notes</i> for details on error tolerance. |
| <i>ldz</i> | The leading dimension of the output array <i>z</i> . Constraints: if <i>jobz</i> = 'N', then $ldz \geq 1$; if <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout. |

Output Parameters

| | |
|--------------|---|
| <i>ap</i> | On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of <i>A</i> . |
| <i>m</i> | The total number of eigenvalues found, $0 \leq m \leq n$. If <i>range</i> = 'A', $m = n$, if <i>range</i> = 'I', $m = i_u - i_l + 1$, and if <i>range</i> = 'V' the exact value of <i>m</i> is not known in advance.. |
| <i>w, z</i> | Arrays: <i>w</i> , size at least $\max(1, n)$. If <i>info</i> = 0, contains the selected eigenvalues of the matrix <i>A</i> in ascending order. <i>z</i> (size $\max(1, ldz * m)$ for column major layout and $\max(1, ldz * n)$ for row major layout). If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>A</i> corresponding to the selected eigenvalues, with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with $w[i - 1]$. If an eigenvector fails to converge, then that column of <i>z</i> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i> . If <i>jobz</i> = 'N', then <i>z</i> is not referenced. |
| <i>ifail</i> | Array, size at least $\max(1, n)$. If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> elements of <i>ifail</i> are zero; if <i>info</i> > 0, the <i>ifail</i> contains the indices the eigenvectors that failed to converge. If <i>jobz</i> = 'N', then <i>ifail</i> is not referenced. |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, then *i* eigenvectors failed to converge; their indices are stored in the array *ifail*.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to $abstol + \epsilon * \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon * ||T||_1$ will be used in its place, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * ?lamch('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * ?lamch('S')$.

?hpevx

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix in packed storage.

Syntax

```
lapack_int LAPACKE_chpevx( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_complex_float* ap, float vl, float vu, lapack_int il, lapack_int
iu, float abstol, lapack_int* m, float* w, lapack_complex_float* z, lapack_int ldz,
lapack_int* ifail );
```

```
lapack_int LAPACKE_zhpevx( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_complex_double* ap, double vl, double vu, lapack_int il,
lapack_int iu, double abstol, lapack_int* m, double* w, lapack_complex_double* z,
lapack_int ldz, lapack_int* ifail );
```

Include Files

- mkl.h

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>job</i> = 'N', then only eigenvalues are computed. If <i>job</i> = 'V', then eigenvalues and eigenvectors are computed. |
| <i>range</i> | Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval: $vl < w[i] \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> . |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of A . If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of A . |
| <i>n</i> | The order of the matrix A ($n \geq 0$). |
| <i>ap</i> | Array <i>ap</i> contains the packed upper or lower triangle of the Hermitian matrix A , as specified by <i>uplo</i> . The size of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$. |
| <i>vl, vu</i> | If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. |

Constraint: $vl < vu$.

If $range = 'A'$ or $'I'$, vl and vu are not referenced.

il, iu

If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.

If $range = 'A'$ or $'V'$, il and iu are not referenced.

$abstol$

The absolute error tolerance to which each eigenvalue is required. See *Application notes* for details on error tolerance.

ldz

The leading dimension of the output array z .

Constraints:

if $jobz = 'N'$, then $ldz \geq 1$;

if $jobz = 'V'$, then $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout.

Output Parameters

ap

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of A .

m

The total number of eigenvalues found, $0 \leq m \leq n$.

$0 \leq m \leq n$. If $range = 'A'$, $m = n$, if $range = 'I'$, $m = iu - il + 1$, and if $range = 'V'$ the exact value of m is not known in advance..

w

Array, size at least $\max(1, n)$.

If $info = 0$, contains the selected eigenvalues of the matrix A in ascending order.

z

Array z (size $\max(1, ldz * m)$ for column major layout and $\max(1, ldz * n)$ for row major layout).

If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If $jobz = 'N'$, then z is not referenced.

$ifail$

Array, size at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of *ifail* are zero; if $info > 0$, the *ifail* contains the indices the eigenvectors that failed to converge.

If $jobz = 'N'$, then *ifail* is not referenced.

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = -i$, the *i*-th parameter had an illegal value.

If $info = i$, then *i* eigenvectors failed to converge; their indices are stored in the array *ifail*.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon * ||T||_1$ will be used in its place, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * ?lamch('S')$, not zero.

If this routine returns with $info > 0$, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * ?lamch('S')$.

?sbev

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric band matrix.

Syntax

```
lapack_int LAPACKE_sbev (int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_int kd, float* ab, lapack_int ldab, float* w, float* z, lapack_int ldz);
lapack_int LAPACKE_dsbev (int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_int kd, double* ab, lapack_int ldab, double* w, double* z, lapack_int ldz);
```

Include Files

Description

The routine computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A .

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>jobz</code> | Must be 'N' or 'V'. If <code>jobz = 'N'</code> , then only eigenvalues are computed. If <code>jobz = 'V'</code> , then eigenvalues and eigenvectors are computed. |
| <code>uplo</code> | Must be 'U' or 'L'. If <code>uplo = 'U'</code> , <code>ab</code> stores the upper triangular part of A . If <code>uplo = 'L'</code> , <code>ab</code> stores the lower triangular part of A . |
| <code>n</code> | The order of the matrix A ($n \geq 0$). |
| <code>kd</code> | The number of super- or sub-diagonals in A ($kd \geq 0$). |
| <code>ab</code> | <code>ab</code> (size at least $\max(1, ldab*n)$ for column major layout and at least $\max(1, ldab*(kd + 1))$ for row major layout) is an array containing either upper or lower triangular part of the Hermitian matrix A (as specified by <code>uplo</code>) in band storage format. |
| <code>ldab</code> | The leading dimension of <code>ab</code> ; must be at least $kd + 1$ for column major layout and n for row major layout. |
| <code>ldz</code> | The leading dimension of the output array <code>z</code> . Constraints: if <code>jobz = 'N'</code> , then $ldz \geq 1$; if <code>jobz = 'V'</code> , then $ldz \geq \max(1, n)$. |

Output Parameters

| | |
|----------------|--|
| <code>w</code> | Array, size at least $\max(1, n)$. If <code>info = 0</code> , contains the eigenvalues in ascending order. |
| <code>z</code> | Array <code>z</code> (size $\max(1, ldz*n)$). If <code>jobz = 'V'</code> , then if <code>info = 0</code> , <code>z</code> contains the orthonormal eigenvectors of the matrix A , with the i -th column of <code>z</code> holding the eigenvector associated with <code>w[i - 1]</code> . If <code>jobz = 'N'</code> , then <code>z</code> is not referenced. |

ab On exit, this array is overwritten by the values generated during the reduction to tridiagonal form (see the description of [hbtrd](#)).

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, then the algorithm failed to converge;

i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

?sbevd

Computes all eigenvalues and, optionally, all eigenvectors of a real symmetric band matrix using divide and conquer algorithm.

Syntax

```
lapack_int LAPACKE_ssbevd (int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_int kd, float* ab, lapack_int ldab, float* w, float* z, lapack_int ldz);
lapack_int LAPACKE_dsbevd (int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_int kd, double* ab, lapack_int ldab, double* w, double* z, lapack_int ldz);
```

Include Files

- mkl.h

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric band matrix *A*. In other words, it can compute the spectral factorization of *A* as:

$$A = Z \Lambda Z^T$$

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i , and *Z* is the orthogonal matrix whose columns are the eigenvectors z_i . Thus,

$$A z_i = \lambda_i z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the *QL* or *QR* algorithm.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed. |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of <i>A</i> . |

| | |
|--------|--|
| | If $uplo = 'L'$, ab stores the lower triangular part of A . |
| n | The order of the matrix A ($n \geq 0$). |
| kd | The number of super- or sub-diagonals in A ($kd \geq 0$). |
| ab | ab (size at least $\max(1, ldab*n)$ for column major layout and at least $\max(1, ldab*(kd + 1))$ for row major layout) is an array containing either upper or lower triangular part of the symmetric matrix A (as specified by $uplo$) in band storage format. |
| $ldab$ | The leading dimension of ab ; must be at least $kd+1$ for column major layout and n for row major layout. |
| ldz | The leading dimension of the output array z . Constraints: if $jobz = 'N'$, then $ldz \geq 1$; if $jobz = 'V'$, then $ldz \geq \max(1, n)$. |

Output Parameters

| | |
|--------|---|
| w, z | Arrays: w , size at least $\max(1, n)$. If $info = 0$, contains the eigenvalues of the matrix A in ascending order. See also $info$. z (size $\max(1, ldz*n$ if $job = 'V'$ and at least 1 if $job = 'N'$). If $job = 'V'$, then this array is overwritten by the orthogonal matrix Z which contains the eigenvectors of A . The i -th column of Z contains the eigenvector which corresponds to the eigenvalue $w[i - 1]$. If $job = 'N'$, then z is not referenced. |
| ab | On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. |

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $A+E$ such that $\|E\|_2 = O(\epsilon) * \|A\|_2$, where ϵ is the machine precision.

The complex analogue of this routine is [hbevd](#).

See also [syevd](#) for matrices held in full storage, and [spevd](#) for matrices held in packed storage.

?hbevd

Computes all eigenvalues and, optionally, all eigenvectors of a complex Hermitian band matrix using divide and conquer algorithm.

Syntax

```
lapack_int LAPACKE_chbevd( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_int kd, lapack_complex_float* ab, lapack_int ldab, float* w,
lapack_complex_float* z, lapack_int ldz );
```

```
lapack_int LAPACKE_zhbevd( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_int kd, lapack_complex_double* ab, lapack_int ldab, double* w,
lapack_complex_double* z, lapack_int ldz );
```

Include Files

- mkl.h

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a complex Hermitian band matrix A . In other words, it can compute the spectral factorization of A as: $A = Z*\Lambda*Z^H$.

Here Λ is a real diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the (complex) unitary matrix whose columns are the eigenvectors z_i . Thus,

$$A*z_i = \lambda_i*z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed. |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of A . |
| <i>n</i> | The order of the matrix A ($n \geq 0$). |
| <i>kd</i> | The number of super- or sub-diagonals in A ($kd \geq 0$). |
| <i>ab</i> | <i>ab</i> (size at least $\max(1, ldab*n)$ for column major layout and at least $\max(1, ldab*(kd + 1))$ for row major layout) is an array containing either upper or lower triangular part of the Hermitian matrix A (as specified by <i>uplo</i>) in band storage format. |

ldab The leading dimension of *ab*; must be at least $kd+1$ for column major layout and n for row major layout.

ldz The leading dimension of the output array *z*.

Constraints:

if *jobz* = 'N', then $ldz \geq 1$;

if *jobz* = 'V', then $ldz \geq \max(1, n)$.

Output Parameters

w Array, size at least $\max(1, n)$.

If *info* = 0, contains the eigenvalues of the matrix *A* in ascending order. See also *info*.

z Array, size $\max(1, ldz*n)$ if *job* = 'V' and at least 1 if *job* = 'N'.

If *jobz* = 'V', then this array is overwritten by the unitary matrix *Z* which contains the eigenvectors of *A*. The *i*-th column of *Z* contains the eigenvector which corresponds to the eigenvalue $w[i - 1]$.

If *jobz* = 'N', then *z* is not referenced.

ab On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $A + E$ such that $\|E\|_2 = O(\epsilon) \|A\|_2$, where ϵ is the machine precision.

The real analogue of this routine is [sbevd](#).

See also [heevd](#) for matrices held in full storage, and [hpevd](#) for matrices held in packed storage.

?sbevz

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix.

Syntax

```

double* w, double* z, lapack_int ldz, lapack_int* ifail);
```

Include Files

- `mk1.h`

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed. |
| <i>range</i> | Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval: $vl < w[i] \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices in range <i>il</i> to <i>iu</i> . |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of A . |
| <i>n</i> | The order of the matrix A ($n \geq 0$). |
| <i>kd</i> | The number of super- or sub-diagonals in A ($kd \geq 0$). |
| <i>ab</i> | Arrays: Array <i>ab</i> (size at least $\max(1, ldab*n)$ for column major layout and at least $\max(1, ldab*(kd + 1))$ for row major layout) contains either upper or lower triangular part of the symmetric matrix A (as specified by <i>uplo</i>) in band storage format. |
| <i>ldab</i> | The leading dimension of <i>ab</i> ; must be at least $kd + 1$ for column major layout and n for row major layout. |
| <i>vl, vu</i> | If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced. |
| <i>il, iu</i> | |

If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$

if $n = 0$.

If $range = 'A'$ or $'V'$, il and iu are not referenced.

abstol

The absolute error tolerance to which each eigenvalue is required. See *Application notes* for details on error tolerance.

ldq, ldz

The leading dimensions of the output arrays q and z , respectively.

Constraints:

$ldq \geq 1$, $ldz \geq 1$;

If $jobz = 'V'$, then $ldq \geq \max(1, n)$ and $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout .

Output Parameters

q

Array, size $\max(1, ldz*n)$.

If $jobz = 'V'$, the n -by- n orthogonal matrix is used in the reduction to tridiagonal form.

If $jobz = 'N'$, the array q is not referenced.

m

The total number of eigenvalues found, $0 \leq m \leq n$.

If $range = 'A'$, $m = n$, if $range = 'I'$, $m = iu - il + 1$, and if $range = 'V'$, the exact value of m is not known in advance.

w, z

Arrays:

w , size at least $\max(1, n)$. The first m elements of w contain the selected eigenvalues of the matrix A in ascending order.

z (size at least $\max(1, ldz*m)$ for column major layout and $\max(1, ldz*n)$ for row major layout).

If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w[i - 1]$.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If $jobz = 'N'$, then z is not referenced.

ab

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.

ifail

Array, size at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of *ifail* are zero; if $info > 0$, the *ifail* contains the indices the eigenvectors that failed to converge.

If `jobz = 'N'`, then `ifail` is not referenced.

Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, then i eigenvectors failed to converge; their indices are stored in the array `ifail`.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If `abstol` is less than or equal to zero, then $\epsilon \|T\|_1$ is used as tolerance, where T is the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues will be computed most accurately when `abstol` is set to twice the underflow threshold $2 * \lambda_{\text{mach}}('S')$, not zero.

If this routine returns with `info > 0`, indicating that some eigenvectors did not converge, try setting `abstol` to $2 * \lambda_{\text{mach}}('S')$.

?hbev

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian band matrix.

Syntax

```
lapack_int LAPACKE_chbev( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_int kd, lapack_complex_float* ab, lapack_int ldab,
lapack_complex_float* q, lapack_int ldq, float vl, float vu, lapack_int il, lapack_int
iu, float abstol, lapack_int* m, float* w, lapack_complex_float* z, lapack_int ldz,
lapack_int* ifail );
```

```
lapack_int LAPACKE_zhbev( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_int kd, lapack_complex_double* ab, lapack_int ldab,
lapack_complex_double* q, lapack_int ldq, double vl, double vu, lapack_int il,
lapack_int iu, double abstol, lapack_int* m, double* w, lapack_complex_double* z,
lapack_int ldz, lapack_int* ifail );
```

Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric tridiagonal matrix T . In other words, the routine can compute the spectral factorization of T as: $T = Z\Lambda Z^T$.

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the orthogonal matrix whose columns are the eigenvectors z_i . Thus,

$$T^*z_i = \lambda_i^*z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

There is no complex analogue of this routine.

Input Parameters

$matrix_layout$ Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

$jobz$ Must be 'N' or 'V'.

If $jobz = 'N'$, then only eigenvalues are computed.

If $jobz = 'V'$, then eigenvalues and eigenvectors are computed.

n The order of the matrix T ($n \geq 0$).

| | |
|--------|---|
| d, e | <p>Arrays:</p> <p>d contains the n diagonal elements of the tridiagonal matrix T.</p> <p>The dimension of d must be at least $\max(1, n)$.</p> <p>e contains the $n-1$ off-diagonal elements of T.</p> <p>The dimension of e must be at least $\max(1, n)$. The n-th element of this array is used as workspace.</p> |
| ldz | <p>The leading dimension of the output array z. Constraints:</p> <p>$ldz \geq 1$ if $job = 'N'$;</p> <p>$ldz \geq \max(1, n)$ if $job = 'V'$.</p> |

Output Parameters

| | |
|-----|--|
| d | <p>On exit, if $info = 0$, contains the eigenvalues of the matrix T in ascending order.</p> <p>See also <i>info</i>.</p> |
| z | <p>Array, size $\max(1, ldz*n)$ if $jobz = 'V'$ and 1 if $jobz = 'N'$.</p> <p>If $jobz = 'V'$, then this array is overwritten by the orthogonal matrix Z which contains the eigenvectors of T.</p> <p>If $jobz = 'N'$, then z is not referenced.</p> |
| e | <p>On exit, this array is overwritten with intermediate results.</p> |

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

If $info = -i$, the i -th parameter had an illegal value.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $\|E\|_2 = O(\epsilon) * \|T\|_2$, where ϵ is the machine precision.

If λ_j is an exact eigenvalue, and μ_j is the corresponding computed value, then

$$|\mu_j - \lambda_j| \leq c(n) * \epsilon * \|T\|_2$$

where $c(n)$ is a modestly increasing function of n .

If z_i is the corresponding exact eigenvector, and w_i is the corresponding computed vector, then the angle $\theta(z_i, w_i)$ between them is bounded as follows:

$$\theta(z_i, w_i) \leq c(n) * \epsilon * \|T\|_2 / \min_{i \neq j} |\lambda_i - \lambda_j|.$$

Thus the accuracy of a computed eigenvector depends on the gap between its eigenvalue and all the other eigenvalues.

?stevx

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

Syntax

```
lapack_int LAPACKE_sstevx (int matrix_layout, char jobz, char range, lapack_int n,
float* d, float* e, float vl, float vu, lapack_int il, lapack_int iu, float abstol,
lapack_int* m, float* w, float* z, lapack_int ldz, lapack_int* ifail);

lapack_int LAPACKE_dstevx (int matrix_layout, char jobz, char range, lapack_int n,
double* d, double* e, double vl, double vu, lapack_int il, lapack_int iu, double
abstol, lapack_int* m, double* w, double* z, lapack_int ldz, lapack_int* ifail);
```

Include Files

- mkl.h

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>job</i> = 'N', then only eigenvalues are computed. If <i>job</i> = 'V', then eigenvalues and eigenvectors are computed. |
| <i>range</i> | Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval: $vl < w[i] \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> . |
| <i>n</i> | The order of the matrix A ($n \geq 0$). |
| <i>d, e</i> | Arrays: <i>d</i> contains the n diagonal elements of the tridiagonal matrix A . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> contains the $n-1$ subdiagonal elements of A . The dimension of <i>e</i> must be at least $\max(1, n-1)$. The n -th element of this array is used as workspace. |
| <i>vl, vu</i> | If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced. |

il, iu If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.
 Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.
 If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol

ldz The leading dimensions of the output array *z*; $ldz \geq 1$. If *jobz* = 'V', then $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout.

Output Parameters

m The total number of eigenvalues found,
 $0 \leq m \leq n$.
 If *range* = 'A', $m = n$, if *range* = 'I', $m = iu - il + 1$, and if *range* = 'V' the exact value of *m* is unknown.

w, z Arrays:
w, size at least $\max(1, n)$.
 The first *m* elements of *w* contain the selected eigenvalues of the matrix *A* in ascending order.
z (size at least $\max(1, ldz * m)$ for column major layout and $\max(1, ldz * n)$ for row major layout) .
 If *jobz* = 'V', then if *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *A* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with $w[i - 1]$.
 If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.
 If *jobz* = 'N', then *z* is not referenced.

d, e On exit, these arrays may be multiplied by a constant factor chosen to avoid overflow or underflow in computing the eigenvalues.

ifail Array, size at least $\max(1, n)$.
 If *jobz* = 'V', then if *info* = 0, the first *m* elements of *ifail* are zero; if *info* > 0, the *ifail* contains the indices of the eigenvectors that failed to converge.
 If *jobz* = 'N', then *ifail* is not referenced.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If $info = i$, then i eigenvectors failed to converge; their indices are stored in the array *ifail*.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If $abstol$ is less than or equal to zero, then $\epsilon * |A|_1$ is used instead. Eigenvalues are computed most accurately when $abstol$ is set to twice the underflow threshold $2 * \lambda_{\text{mach}}('S')$, not zero.

If this routine returns with $info > 0$, indicating that some eigenvectors did not converge, set $abstol$ to $2 * \lambda_{\text{mach}}('S')$.

?stevr

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix using the Relatively Robust Representations.

Syntax

```
lapack_int LAPACKE_sstevr (int matrix_layout, char jobz, char range, lapack_int n,
float* d, float* e, float vl, float vu, lapack_int il, lapack_int iu, float abstol,
lapack_int* m, float* w, float* z, lapack_int ldz, lapack_int* isuppz);
```

```
lapack_int LAPACKE_dstevr (int matrix_layout, char jobz, char range, lapack_int n,
double* d, double* e, double vl, double vu, lapack_int il, lapack_int iu, double
abstol, lapack_int* m, double* w, double* z, lapack_int ldz, lapack_int* isuppz);
```

Include Files

- mkl.h

Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, the routine calls [stemr](#) to compute the eigenspectrum using Relatively Robust Representations. [stegr](#) computes eigenvalues by the *dqds* algorithm, while orthogonal eigenvectors are computed from various "good" $L * D * L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i -th unreduced block of T :

- Compute $T - \sigma_i = L_i * D_i * L_i^T$, such that $L_i * D_i * L_i^T$ is a relatively robust representation.
- Compute the eigenvalues, λ_j , of $L_i * D_i * L_i^T$ to high relative accuracy by the *dqds* algorithm.
- If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to Step (a).
- Given the approximate eigenvalue λ_j of $L_i * D_i * L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter *abstol*.

The routine `?stevr` calls [stemr](#) when the full spectrum is requested on machines which conform to the IEEE-754 floating point standard. `?stevr` calls [stebz](#) and [stein](#) on non-IEEE machines and when partial spectrum requests are made.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobz</i> | <p>Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then only eigenvalues are computed.</p> <p>If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.</p> |
| <i>range</i> | <p>Must be 'A' or 'V' or 'I'.</p> <p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval:</p> $vl < w[i] \leq vu.$ <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.</p> <p>For <i>range</i> = 'V' or 'I' and $iu - il < n - 1$, <i>sstebz/dstebz</i> and <i>sstein/dstein</i> are called.</p> |
| <i>n</i> | The order of the matrix T ($n \geq 0$). |
| <i>d, e</i> | <p>Arrays:</p> <p><i>d</i> contains the n diagonal elements of the tridiagonal matrix T.</p> <p>The dimension of <i>d</i> must be at least $\max(1, n)$.</p> <p><i>e</i> contains the $n-1$ subdiagonal elements of A.</p> <p>The dimension of <i>e</i> must be at least $\max(1, n-1)$. The n-th element of this array is used as workspace.</p> |
| <i>vl, vu</i> | <p>If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.</p> <p>Constraint: $vl < vu$.</p> <p>If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.</p> |
| <i>il, iu</i> | <p>If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.</p> <p>Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.</p> <p>If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.</p> |
| <i>abstol</i> | <p>The absolute error tolerance to which each eigenvalue/eigenvector is required.</p> <p>If <i>jobz</i> = 'V', the eigenvalues and eigenvectors output have residual norms bounded by <i>abstol</i>, and the dot products between different eigenvectors are bounded by <i>abstol</i>. If $abstol < n * \text{eps} * T$, then $n * \text{eps} * T$ will be used in its place, where <i>eps</i> is the machine precision, and T is the 1-norm of the matrix T. The eigenvalues are computed to an accuracy of $\text{eps} * T$ irrespective of <i>abstol</i>.</p> <p>If high relative accuracy is important, set <i>abstol</i> to <code>?lamch('S')</code>.</p> |

ldz The leading dimension of the output array *z*.
 Constraints:
 $ldz \geq 1$ if *jobz* = 'N';
 $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout if *jobz* = 'V'.

Output Parameters

m The total number of eigenvalues found,
 $0 \leq m \leq n$. If *range* = 'A', $m = n$, if *range* = 'I', $m = iu - il + 1$, and if *range* = 'V' the exact value of *m* is unknown..

w, z Arrays:
w, size at least $\max(1, n)$.
 The first *m* elements of *w* contain the selected eigenvalues of the matrix *T* in ascending order.
z (size at least $\max(1, ldz * m)$ for column major layout and $\max(1, ldz * n)$ for row major layout).
 If *jobz* = 'V', then if *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *T* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with $w[i - 1]$.
 If *jobz* = 'N', then *z* is not referenced.

d, e On exit, these arrays may be multiplied by a constant factor chosen to avoid overflow or underflow in computing the eigenvalues.

isuppz Array, size at least $2 * \max(1, m)$.
 The support of the eigenvectors in *z*, i.e., the indices indicating the nonzero elements in *z*. The *i*-th eigenvector is nonzero only in elements *isuppz*[2*i* - 2] through *isuppz*[2*i* - 1].
 Implemented only for *range* = 'A' or 'I' and $iu - il = n - 1$.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, an internal error has occurred.

Application Notes

Normal execution of the routine `?stegr` may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the IEEE standard default manner.

Nonsymmetric Eigenvalue Problems: LAPACK Driver Routines

This section describes LAPACK driver routines used for solving nonsymmetric eigenproblems. See also [computational routines](#) that can be called to solve these problems.

Table "Driver Routines for Solving Nonsymmetric Eigenproblems" lists all such driver routines.

Driver Routines for Solving Nonsymmetric Eigenproblems

| Routine Name | Operation performed |
|-----------------------|--|
| gees | Computes the eigenvalues and Schur factorization of a general matrix, and orders the factorization so that selected eigenvalues are at the top left of the Schur form. |
| geesx | Computes the eigenvalues and Schur factorization of a general matrix, orders the factorization and computes reciprocal condition numbers. |
| geev | Computes the eigenvalues and left and right eigenvectors of a general matrix. |
| geevx | Computes the eigenvalues and left and right eigenvectors of a general matrix, with preliminary matrix balancing, and computes reciprocal condition numbers for the eigenvalues and right eigenvectors. |

?gees

Computes the eigenvalues and Schur factorization of a general matrix, and orders the factorization so that selected eigenvalues are at the top left of the Schur form.

Syntax

```
lapack_int LAPACKE_sgees( int matrix_layout, char jobvs, char sort, LAPACK_S_SELECT2
select, lapack_int n, float* a, lapack_int lda, lapack_int* sdim, float* wr, float*
wi, float* vs, lapack_int ldvs );
```

```
lapack_int LAPACKE_dgees( int matrix_layout, char jobvs, char sort, LAPACK_D_SELECT2
select, lapack_int n, double* a, lapack_int lda, lapack_int* sdim, double* wr, double*
wi, double* vs, lapack_int ldvs );
```

```
lapack_int LAPACKE_cgees( int matrix_layout, char jobvs, char sort, LAPACK_C_SELECT1
select, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_int* sdim,
lapack_complex_float* w, lapack_complex_float* vs, lapack_int ldvs );
```

```
lapack_int LAPACKE_zgees( int matrix_layout, char jobvs, char sort, LAPACK_Z_SELECT1
select, lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_int* sdim,
lapack_complex_double* w, lapack_complex_double* vs, lapack_int ldvs );
```

Include Files

- mkl.h

Description

The routine computes for an n -by- n real/complex nonsymmetric matrix A , the eigenvalues, the real Schur form T , and, optionally, the matrix of Schur vectors Z . This gives the Schur factorization $A = Z^* T^* Z^H$.

Optionally, it also orders the eigenvalues on the diagonal of the real-Schur/Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A real matrix is in real-Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

$$\begin{pmatrix} a & b \\ c & a \end{pmatrix}$$

where $b*c < 0$. The eigenvalues of such a block are $a \pm i\sqrt{bc}$

A complex matrix is in Schur form if it is upper triangular.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobvs</i> | Must be 'N' or 'V'. If <i>jobvs</i> = 'N', then Schur vectors are not computed. If <i>jobvs</i> = 'V', then Schur vectors are computed. |
| <i>sort</i> | Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. If <i>sort</i> = 'N', then eigenvalues are not ordered. If <i>sort</i> = 'S', eigenvalues are ordered (see <i>select</i>). |
| <i>select</i> | If <i>sort</i> = 'S', <i>select</i> is used to select eigenvalues to sort to the top left of the Schur form. If <i>sort</i> = 'N', <i>select</i> is not referenced. <i>For real flavors:</i> An eigenvalue $wr[j] + \sqrt{-1} * wi[j]$ is selected if <i>select</i> (<i>wr</i> [<i>j</i>], <i>wi</i> [<i>j</i>]) is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. <i>For complex flavors:</i> An eigenvalue <i>w</i> [<i>j</i>] is selected if <i>select</i> (<i>w</i> [<i>j</i>]) is true. Note that a selected complex eigenvalue may no longer satisfy <i>select</i> (<i>wr</i> [<i>j</i>], <i>wi</i> [<i>j</i>]) = 1 after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case <i>info</i> may be set to <i>n</i> +2 (see <i>info</i> below). |
| <i>n</i> | The order of the matrix <i>A</i> ($n \geq 0$). |
| <i>a</i> | Arrays: <i>a</i> (size at least $\max(1, lda*n)$) is an array containing the <i>n</i> -by- <i>n</i> matrix <i>A</i> . |
| <i>lda</i> | The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$. |
| <i>ldvs</i> | The leading dimension of the output array <i>vs</i> . Constraints: $ldvs \geq 1$; $ldvs \geq \max(1, n)$ if <i>jobvs</i> = 'V'. |

Output Parameters

| | |
|-------------|--|
| <i>a</i> | On exit, this array is overwritten by the real-Schur/Schur form <i>T</i> . |
| <i>sdim</i> | |

If *sort* = 'N', *sdim*= 0.

If *sort* = 'S', *sdim* is equal to the number of eigenvalues (after sorting) for which *select* is true.

Note that for real flavors complex conjugate pairs for which *select* is true for either eigenvalue count as 2.

wr, *wi*

Arrays, size at least $\max(1, n)$ each. Contain the real and imaginary parts, respectively, of the computed eigenvalues, in the same order that they appear on the diagonal of the output real-Schur form *T*. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

w

Array, size at least $\max(1, n)$. Contains the computed eigenvalues. The eigenvalues are stored in the same order as they appear on the diagonal of the output Schur form *T*.

vs

Array *vs* (size at least $\max(1, ldvs*n)$).

If *jobvs* = 'V', *vs* contains the orthogonal/unitary matrix *Z* of Schur vectors.

If *jobvs* = 'N', *vs* is not referenced.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, and

$i \leq n$:

the QR algorithm failed to compute all the eigenvalues; elements 1:*ilo*-1 and *i*+1:*n* of *wr* and *wi* (for real flavors) or *w* (for complex flavors) contain those eigenvalues which have converged; if *jobvs* = 'V', *vs* contains the matrix which reduces *A* to its partially converged Schur form;

$i = n+1$:

the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned);

$i = n+2$:

after reordering, round-off changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy *select* = 1. This could also be caused by underflow due to scaling.

?geesx

Computes the eigenvalues and Schur factorization of a general matrix, orders the factorization and computes reciprocal condition numbers.

Syntax

```
lapack_int LAPACKE_sgeesx( int matrix_layout, char jobvs, char sort, LAPACK_S_SELECT2
select, char sense, lapack_int n, float* a, lapack_int lda, lapack_int* sdim, float*
wr, float* wi, float* vs, lapack_int ldvs, float* rconde, float* rcondv );
```

```
lapack_int LAPACKE_dgeesx( int matrix_layout, char jobvs, char sort, LAPACK_D_SELECT2
select, char sense, lapack_int n, double* a, lapack_int lda, lapack_int* sdim, double*
wr, double* wi, double* vs, lapack_int ldvs, double* rconde, double* rcondv );
```

```
lapack_int LAPACKE_cgeesx( int matrix_layout, char jobvs, char sort, LAPACK_C_SELECT1
select, char sense, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_int*
sdim, lapack_complex_float* w, lapack_complex_float* vs, lapack_int ldvs, float*
rconde, float* rcondv );
```

```
lapack_int LAPACKE_zgeesx( int matrix_layout, char jobvs, char sort, LAPACK_Z_SELECT1
select, char sense, lapack_int n, lapack_complex_double* a, lapack_int lda,
lapack_int* sdim, lapack_complex_double* w, lapack_complex_double* vs, lapack_int ldvs,
double* rconde, double* rcondv );
```

Description

The routine computes for an n -by- n real/complex nonsymmetric matrix A , the eigenvalues, the real-Schur/Schur form T , and, optionally, the matrix of Schur vectors Z . This gives the Schur factorization $A = Z^* T^* Z^H$.

Optionally, it also orders the eigenvalues on the diagonal of the real-Schur/Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues ($rconde$); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues ($rcondv$). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers $rconde$ and $rcondv$, see [LUG], Section 4.10 (where these quantities are called s and sep respectively).

A real matrix is in real-Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

$$\begin{pmatrix} a & b \\ c & a \end{pmatrix}$$

where $b^*c < 0$. The eigenvalues of such a block are $a \pm i\sqrt{bc}$

A complex matrix is in Schur form if it is upper triangular.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobvs</i> | Must be 'N' or 'V'. If <i>jobvs</i> = 'N', then Schur vectors are not computed. If <i>jobvs</i> = 'V', then Schur vectors are computed. |
| <i>sort</i> | Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. If <i>sort</i> = 'N', then eigenvalues are not ordered. |

| | |
|---------------|---|
| | If <i>sort</i> = 'S', eigenvalues are ordered (see <i>select</i>). |
| <i>select</i> | <p>If <i>sort</i> = 'S', <i>select</i> is used to select eigenvalues to sort to the top left of the Schur form.</p> <p>If <i>sort</i> = 'N', <i>select</i> is not referenced.</p> <p><i>For real flavors:</i></p> <p>An eigenvalue $wr[j] + \sqrt{-1} * wi[j]$ is selected if <i>select</i>(<i>wr</i>[<i>j</i>], <i>wi</i>[<i>j</i>]) is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.</p> <p><i>For complex flavors:</i></p> <p>An eigenvalue <i>w</i>[<i>j</i>] is selected if <i>select</i>(<i>w</i>[<i>j</i>]) is true.</p> <p>Note that a selected complex eigenvalue may no longer satisfy <i>select</i>(<i>wr</i>[<i>j</i>], <i>wi</i>[<i>j</i>]) = 1 after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case <i>info</i> may be set to <i>n</i>+2 (see <i>info</i> below).</p> |
| <i>sense</i> | <p>Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.</p> <p>If <i>sense</i> = 'N', none are computed;</p> <p>If <i>sense</i> = 'E', computed for average of selected eigenvalues only;</p> <p>If <i>sense</i> = 'V', computed for selected right invariant subspace only;</p> <p>If <i>sense</i> = 'B', computed for both.</p> <p>If <i>sense</i> is 'E', 'V', or 'B', then <i>sort</i> must equal 'S'.</p> |
| <i>n</i> | The order of the matrix <i>A</i> ($n \geq 0$). |
| <i>a</i> | <p>Arrays:</p> <p><i>a</i> (size at least $\max(1, lda * n)$) is an array containing the <i>n</i>-by-<i>n</i> matrix <i>A</i>.</p> |
| <i>lda</i> | The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$. |
| <i>ldvs</i> | <p>The leading dimension of the output array <i>vs</i>. Constraints:</p> <p>$ldvs \geq 1$;</p> <p>$ldvs \geq \max(1, n)$ if <i>jobvs</i> = 'V'.</p> |

Output Parameters

| | |
|-------------|---|
| <i>a</i> | On exit, this array is overwritten by the real-Schur/Schur form <i>T</i> . |
| <i>sdim</i> | <p>If <i>sort</i> = 'N', <i>sdim</i> = 0.</p> <p>If <i>sort</i> = 'S', <i>sdim</i> is equal to the number of eigenvalues (after sorting) for which <i>select</i> is true.</p> <p>Note that for real flavors complex conjugate pairs for which <i>select</i> is true for either eigenvalue count as 2.</p> |

| | |
|-----------------------|--|
| <i>wr, wi</i> | Arrays, size at least $\max(1, n)$ each. Contain the real and imaginary parts, respectively, of the computed eigenvalues, in the same order that they appear on the diagonal of the output real-Schur form <i>T</i> . Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first. |
| <i>w</i> | Array, size at least $\max(1, n)$. Contains the computed eigenvalues. The eigenvalues are stored in the same order as they appear on the diagonal of the output Schur form <i>T</i> . |
| <i>vs</i> | Array <i>vs</i> (size at least $\max(1, ldvs*n)$) If <i>jobvs</i> = 'V', <i>vs</i> contains the orthogonal/unitary matrix <i>Z</i> of Schur vectors. If <i>jobvs</i> = 'N', <i>vs</i> is not referenced. |
| <i>rconde, rcondv</i> | If <i>sense</i> = 'E' or 'B', <i>rconde</i> contains the reciprocal condition number for the average of the selected eigenvalues. If <i>sense</i> = 'N' or 'V', <i>rconde</i> is not referenced. If <i>sense</i> = 'V' or 'B', <i>rcondv</i> contains the reciprocal condition number for the selected right invariant subspace. If <i>sense</i> = 'N' or 'E', <i>rcondv</i> is not referenced. |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, and

i ≤ *n*:

the QR algorithm failed to compute all the eigenvalues; elements 1:*ilo*-1 and *i*+1:*n* of *wr* and *wi* (for real flavors) or *w* (for complex flavors) contain those eigenvalues which have converged; if *jobvs* = 'V', *vs* contains the transformation which reduces *A* to its partially converged Schur form;

i = *n*+1:

the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned);

i = *n*+2:

after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy *select* = 1. This could also be caused by underflow due to scaling.

?ggev

Computes the eigenvalues and left and right eigenvectors of a general matrix.

Syntax

```
lapack_int LAPACKE_sgeev( int matrix_layout, char jobvl, char jobvr, lapack_int n,
float* a, lapack_int lda, float* wr, float* wi, float* vl, lapack_int ldvl, float* vr,
lapack_int ldvr );
```

```
lapack_int LAPACKE_dgeev( int matrix_layout, char jobvl, char jobvr, lapack_int n,
double* a, lapack_int lda, double* wr, double* wi, double* vl, lapack_int ldvl,
double* vr, lapack_int ldvr );
```

```
lapack_int LAPACKE_cgeev( int matrix_layout, char jobvl, char jobvr, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* w, lapack_complex_float*
vl, lapack_int ldvl, lapack_complex_float* vr, lapack_int ldvr );
```

```
lapack_int LAPACKE_zgeev( int matrix_layout, char jobvl, char jobvr, lapack_int n,

Description

The routine computes for an n -by- n real/complex nonsymmetric matrix A , the eigenvalues and, optionally, the left and/or right eigenvectors. The right eigenvector v of A satisfies

$$A*v = \lambda*v$$

where λ is its eigenvalue.

The left eigenvector u of A satisfies

$$u^H*A = \lambda*u^H$$

where u^H denotes the conjugate transpose of u . The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobvl</i> | Must be 'N' or 'V'. If <i>jobvl</i> = 'N', then left eigenvectors of A are not computed. If <i>jobvl</i> = 'V', then left eigenvectors of A are computed. |
| <i>jobvr</i> | Must be 'N' or 'V'. If <i>jobvr</i> = 'N', then right eigenvectors of A are not computed. If <i>jobvr</i> = 'V', then right eigenvectors of A are computed. |
| <i>n</i> | The order of the matrix A ($n \geq 0$). |
| <i>a</i> | a (size at least $\max(1, lda*n)$) is an array containing the n -by- n matrix A . |
| <i>lda</i> | The leading dimension of the array a . Must be at least $\max(1, n)$. |
| <i>ldvl, ldvr</i> | The leading dimensions of the output arrays vl and vr , respectively. Constraints: $ldvl \geq 1; ldvr \geq 1$. If <i>jobvl</i> = 'V', $ldvl \geq \max(1, n)$; |

If $jobvr = 'V'$, $ldvr \geq \max(1, n)$.

Output Parameters

| | |
|----------|--|
| a | On exit, this array is overwritten. |
| wr, wi | Arrays, size at least $\max(1, n)$ each. Contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first. |
| w | Array, size at least $\max(1, n)$. Contains the computed eigenvalues. |
| vl, vr | Arrays: vl (size at least $\max(1, ldvl*n)$). If $jobvl = 'N'$, vl is not referenced. <i>For real flavors:</i> If the j -th eigenvalue is real, the i -th component of the j -th eigenvector u_j is stored in $vl[(i - 1) + (j - 1)*ldvl]$ for column major layout and in $vl[(i - 1)*ldvl + (j - 1)]$ for row major layout.. If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then for $i = \text{sqrt}(-1)$, the k -th component of the j -th eigenvector u_j is $vl[(k - 1) + (j - 1)*ldvl] + i*vl[(k - 1) + j*ldvl]$ for column major layout and as $vl[(k - 1)*ldvl + (j - 1)] + i*vl[(k-1)*ldvl + j]$ for row major layout. Similarly, the k -th component of vector $(j+1)$ u_{j+1} is $vl[(k - 1) + (j - 1)*ldvl] - i*vl[(k - 1) + j*ldvl]$ for column major layout and as $vl[(k - 1)*ldvl + (j - 1)] - i*vl[(k - 1)*ldvl + j]$ for row major layout. . <i>For complex flavors:</i> The i -th component of the j -th eigenvector u_j is stored in $vl[(i - 1) + (j - 1)*ldvl]$ for column major layout and in $vl[(i - 1)*ldvl + (j - 1)]$ for row major layout. vr (size at least $\max(1, ldvr*n)$). If $jobvr = 'N'$, vr is not referenced. <i>For real flavors:</i> If the j -th eigenvalue is real, then the i -th component of j -th eigenvector v_j is stored in $vr[(i - 1) + (j - 1)*ldvr]$ for column major layout and in $vr[(i - 1)*ldvr + (j - 1)]$ for row major layout.. If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then for $i = \text{sqrt}(-1)$, the k -th component of the j -th eigenvector v_j is $vr[(k - 1) + (j - 1)*ldvr] + i*vr[(k - 1) + j*ldvr]$ for column major layout and as $vr[(k - 1)*ldvr + (j - 1)] + i*vr[(k - 1)*ldvr + j]$ for row major layout. Similarly, the k -th component of vector $j + 1$ v_{j+1} is $vr[(k - 1) + (j - 1)*ldvr] - i*vr[(k - 1) + j*ldvr]$ for column major layout and as $vr[(k - 1)*ldvr + (j - 1)] - i*vr[(k - 1)*ldvr + j]$ for row major layout. <i>For complex flavors:</i> |

The i -th component of the j -th eigenvector v_j is stored in $vr[(i - 1) + (j - 1)*ldvr]$ for column major layout and in $vr[(i - 1)*ldvr + (j - 1)]$ for row major layout.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = $-i$, the i -th parameter had an illegal value.

If *info* = i , the QR algorithm failed to compute all the eigenvalues, and no eigenvectors have been computed; elements $i+1:n$ of wr and wi (for real flavors) or w (for complex flavors) contain those eigenvalues which have converged.

?geevx

Computes the eigenvalues and left and right eigenvectors of a general matrix, with preliminary matrix balancing, and computes reciprocal condition numbers for the eigenvalues and right eigenvectors.

Syntax

```
lapack_int LAPACKE_sgeevx( int matrix_layout, char balanc, char jobvl, char jobvr, char
sense, lapack_int n, float* a, lapack_int lda, float* wr, float* wi, float* vl,
lapack_int ldvl, float* vr, lapack_int ldvr, lapack_int* ilo, lapack_int* ihi, float*
scale, float* abnrm, float* rconde, float* rcondv );
```

```
lapack_int LAPACKE_dgeevx( int matrix_layout, char balanc, char jobvl, char jobvr, char
sense, lapack_int n, double* a, lapack_int lda, double* wr, double* wi, double* vl,
lapack_int ldvl, double* vr, lapack_int ldvr, lapack_int* ilo, lapack_int* ihi,
double* scale, double* abnrm, double* rconde, double* rcondv );
```

```

Description

The routine computes for an n -by- n real/complex nonsymmetric matrix A , the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (*ilo*, *ihi*, *scale*, and *abnrm*), reciprocal condition numbers for the eigenvalues (*rconde*), and reciprocal condition numbers for the right eigenvectors (*rcondv*).

The right eigenvector v of A satisfies

$$A \cdot v = \lambda \cdot v$$

where λ is its eigenvalue.

The left eigenvector u of A satisfies

$$u^H A = \lambda u^H$$

where u^H denotes the conjugate transpose of u . The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation $D \cdot A \cdot \text{inv}(D)$, where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see [LUG], Section 4.10.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>balanc</i> | <p>Must be 'N', 'P', 'S', or 'B'. Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues.</p> <p>If <i>balanc</i> = 'N', do not diagonally scale or permute;</p> <p>If <i>balanc</i> = 'P', perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale;</p> <p>If <i>balanc</i> = 'S', diagonally scale the matrix, i.e. replace A by $D \cdot A \cdot \text{inv}(D)$, where D is a diagonal matrix chosen to make the rows and columns of A more equal in norm. Do not permute;</p> <p>If <i>balanc</i> = 'B', both diagonally scale and permute A.</p> <p>Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.</p> |
| <i>jobvl</i> | <p>Must be 'N' or 'V'.</p> <p>If <i>jobvl</i> = 'N', left eigenvectors of A are not computed;</p> <p>If <i>jobvl</i> = 'V', left eigenvectors of A are computed.</p> <p>If <i>sense</i> = 'E' or 'B', then <i>jobvl</i> must be 'V'.</p> |
| <i>jobvr</i> | <p>Must be 'N' or 'V'.</p> <p>If <i>jobvr</i> = 'N', right eigenvectors of A are not computed;</p> <p>If <i>jobvr</i> = 'V', right eigenvectors of A are computed.</p> <p>If <i>sense</i> = 'E' or 'B', then <i>jobvr</i> must be 'V'.</p> |
| <i>sense</i> | <p>Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.</p> <p>If <i>sense</i> = 'N', none are computed;</p> <p>If <i>sense</i> = 'E', computed for eigenvalues only;</p> |

If *sense* = 'V', computed for right eigenvectors only;
 If *sense* = 'B', computed for eigenvalues and right eigenvectors.
 If *sense* is 'E' or 'B', both left and right eigenvectors must also be computed (*jobvl* = 'V' and *jobvr* = 'V').

n The order of the matrix *A* ($n \geq 0$).

a Arrays:
a (size at least $\max(1, lda*n)$) is an array containing the *n*-by-*n* matrix *A*.

lda The leading dimension of the array *a*. Must be at least $\max(1, n)$.

ldvl, ldvr The leading dimensions of the output arrays *vl* and *vr*, respectively.
 Constraints:
 $ldvl \geq 1; ldvr \geq 1$.
 If *jobvl* = 'V', $ldvl \geq \max(1, n)$;
 If *jobvr* = 'V', $ldvr \geq \max(1, n)$.

Output Parameters

a On exit, this array is overwritten.
 If *jobvl* = 'V' or *jobvr* = 'V', it contains the real-Schur/Schur form of the balanced version of the input matrix *A*.

wr, wi Arrays, size at least $\max(1, n)$ each. Contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

w Array, size at least $\max(1, n)$. Contains the computed eigenvalues.

vl, vr Arrays:
vl (size at least $\max(1, ldvl*n)$).
 If *jobvl* = 'N', *vl* is not referenced.
For real flavors:
 If the *j*-th eigenvalue is real, the *i*-th component of the *j*-th eigenvector u_j is stored in $vl[(i - 1) + (j - 1)*ldvl]$ for column major layout and in $vl[(i - 1)*ldvl + (j - 1)]$ for row major layout..
 If the *j*-th and (*j*+1)-st eigenvalues form a complex conjugate pair, then for $i = \text{sqrt}(-1)$, the *k*-th component of the *j*-th eigenvector u_j is $vl[(k - 1) + (j - 1)*ldvl] + i*vl[(k - 1) + j*ldvl]$ for column major layout and as $vl[(k - 1)*ldvl + (j - 1)] + i*vl[(k-1)*ldvl + j]$ for row major layout.
 Similarly, the *k*-th component of vector (*j*+1) u_{j+1} is $vl[(k - 1) + (j - 1)*ldvl] - i*vl[(k - 1) + j*ldvl]$ for column major layout and as $vl[(k - 1)*ldvl + (j - 1)] - i*vl[(k - 1)*ldvl + j]$ for row major layout. .
For complex flavors:

The i -th component of the j -th eigenvector u_j is stored in $vl[(i - 1) + (j - 1)*ldvl]$ for column major layout and in $vl[(i - 1)*ldvl + (j - 1)]$ for row major layout.

vr (size at least $\max(1, ldvr*n)$).

If $jobvr = 'N'$, vr is not referenced.

For real flavors:

If the j -th eigenvalue is real, then the i -th component of j -th eigenvector v_j is stored in $vr[(i - 1) + (j - 1)*ldvr]$ for column major layout and in $vr[(i - 1)*ldvr + (j - 1)]$ for row major layout..

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then for $i = \text{sqrt}(-1)$, the k -th component of the j -th eigenvector v_j is $vr[(k - 1) + (j - 1)*ldvr] + i*vr[(k - 1) + j*ldvr]$ for column major layout and as $vr[(k - 1)*ldvr + (j - 1)] + i*vr[(k - 1)*ldvr + j]$ for row major layout. Similarly, the k -th component of vector $j + 1$ v_{j+1} is $vr[(k - 1) + (j - 1)*ldvr] - i*vr[(k - 1) + j*ldvr]$ for column major layout and as $vr[(k - 1)*ldvr + (j - 1)] - i*vr[(k - 1)*ldvr + j]$ for row major layout.

For complex flavors:

The i -th component of the j -th eigenvector v_j is stored in $vr[(i - 1) + (j - 1)*ldvr]$ for column major layout and in $vr[(i - 1)*ldvr + (j - 1)]$ for row major layout.

ilo, ihi

ilo and *ihi* are integer values determined when A was balanced.

The balanced $A(i, j) = 0$ if $i > j$ and $j = 1, \dots, ilo-1$ or $i = ihi+1, \dots, n$.

If $balanc = 'N'$ or $'S'$, $ilo = 1$ and $ihi = n$.

scale

Array, size at least $\max(1, n)$. Details of the permutations and scaling factors applied when balancing A .

If $P[j - 1]$ is the index of the row and column interchanged with row and column j , and $D[j - 1]$ is the scaling factor applied to row and column j , then

$scale[j - 1] = P[j - 1]$, for $j = 1, \dots, ilo-1$

$= D[j - 1]$, for $j = ilo, \dots, ihi$

$= P[j - 1]$ for $j = ihi+1, \dots, n$.

The order in which the interchanges are made is n to $ihi+1$, then 1 to $ilo-1$.

abnrm

The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

rconde, rcondv

Arrays, size at least $\max(1, n)$ each.

$rconde[j - 1]$ is the reciprocal condition number of the j -th eigenvalue.

$rcondv[j - 1]$ is the reciprocal condition number of the j -th right eigenvector.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors or condition numbers have been computed; elements 1:*ilo*-1 and *i*+1:*n* of *wr* and *wi* (for real flavors) or *w* (for complex flavors) contain eigenvalues which have converged.

Singular Value Decomposition: LAPACK Driver Routines

Table "Driver Routines for Singular Value Decomposition" lists the LAPACK driver routines that perform singular value decomposition .

Driver Routines for Singular Value Decomposition

| Routine Name | Operation performed |
|--------------|--|
| ?gesvd | Computes the singular value decomposition of a general rectangular matrix. |
| ?gesdd | Computes the singular value decomposition of a general rectangular matrix using a divide and conquer method. |
| ?gejsv | Computes the singular value decomposition of a real matrix using a preconditioned Jacobi SVD method. |
| ?gesvj | Computes the singular value decomposition of a real matrix using Jacobi plane rotations. |
| ?ggsvd | Computes the generalized singular value decomposition of a pair of general rectangular matrices. |
| ?gesvdx | Computes the SVD and left and right singular vectors for a matrix. |
| ?bdsvdx | Computes the SVD of a bidiagonal matrix. |

Singular Value Decomposition: LAPACK Computational Routines

?gesvd

Computes the singular value decomposition of a general rectangular matrix.

Syntax

```
lapack_int LAPACKE_sgesvd( int matrix_layout, char jobu, char jobvt, lapack_int m,
lapack_int n, float* a, lapack_int lda, float* s, float* u, lapack_int ldu, float* vt,
lapack_int ldvt, float* superb );
```

```
lapack_int LAPACKE_dgesvd( int matrix_layout, char jobu, char jobvt, lapack_int m,
lapack_int n, double* a, lapack_int lda, double* s, double* u, lapack_int ldu, double*
vt, lapack_int ldvt, double* superb );
```

```
lapack_int LAPACKE_cgesvd( int matrix_layout, char jobu, char jobvt, lapack_int m,
