Description

The routine computes the singular value decomposition (SVD) of a real/complex m -by- n matrix A , optionally computing the left and/or right singular vectors. The SVD is written as

$$A = U^* \Sigma^* V^T \text{ for real routines}$$

$$A = U^* \Sigma^* V^H \text{ for complex routines}$$

where Σ is an m -by- n matrix which is zero except for its $\min(m, n)$ diagonal elements, U is an m -by- m orthogonal/unitary matrix, and V is an n -by- n orthogonal/unitary matrix. The diagonal elements of Σ are the singular values of A ; they are real and non-negative, and are returned in descending order. The first $\min(m, n)$ columns of U and V are the left and right singular vectors of A .

Note that the routine returns V^T (for real flavors) or V^H (for complex flavors), not V .

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobu</i> | <p>Must be 'A', 'S', 'O', or 'N'. Specifies options for computing all or part of the matrix U.</p> <p>If <i>jobu</i> = 'A', all m columns of U are returned in the array u;</p> <p>if <i>jobu</i> = 'S', the first $\min(m, n)$ columns of U (the left singular vectors) are returned in the array u;</p> <p>if <i>jobu</i> = 'O', the first $\min(m, n)$ columns of U (the left singular vectors) are overwritten on the array a;</p> <p>if <i>jobu</i> = 'N', no columns of U (no left singular vectors) are computed.</p> |
| <i>jobvt</i> | <p>Must be 'A', 'S', 'O', or 'N'. Specifies options for computing all or part of the matrix V^T/V^H.</p> <p>If <i>jobvt</i> = 'A', all n rows of V^T/V^H are returned in the array vt;</p> <p>if <i>jobvt</i> = 'S', the first $\min(m, n)$ rows of V^T/V^H (the right singular vectors) are returned in the array vt;</p> <p>if <i>jobvt</i> = 'O', the first $\min(m, n)$ rows of V^T/V^H (the right singular vectors) are overwritten on the array a;</p> <p>if <i>jobvt</i> = 'N', no rows of V^T/V^H (no right singular vectors) are computed.</p> <p><i>jobvt</i> and <i>jobu</i> cannot both be 'O'.</p> |
| <i>m</i> | The number of rows of the matrix A ($m \geq 0$). |
| <i>n</i> | The number of columns in A ($n \geq 0$). |
| <i>a</i> | <p>Arrays:</p> <p>a(size at least $\max(1, lda * n)$ for column major layout and $\max(1, lda * m)$ for row major layout) is an array containing the m-by-n matrix A.</p> |
| <i>lda</i> | <p>The leading dimension of the array a.</p> <p>Must be at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout .</p> |

ldu, ldvt

The leading dimensions of the output arrays *u* and *vt*, respectively.

Constraints:

$ldu \geq 1$; $ldvt \geq 1$.

If *jobu* = 'A', $ldu \geq m$;

If *jobu* = 'S', $ldu \geq m$ for column major layout and $ldu \geq \min(m, n)$ for row major layout;

If *jobvt* = 'A', $ldvt \geq n$;

If *jobvt* = 'S', $ldvt \geq \min(m, n)$ for column major layout and $ldvt \geq n$ for row major layout .

Output Parameters

a

On exit,

If *jobu* = 'O', *a* is overwritten with the first $\min(m, n)$ columns of *U* (the left singular vectors stored columnwise);

If *jobvt* = 'O', *a* is overwritten with the first $\min(m, n)$ rows of V^T/V^H (the right singular vectors stored rowwise);

If *jobu* ≠ 'O' and *jobvt* ≠ 'O', the contents of *a* are destroyed.

s

Array, size at least $\max(1, \min(m, n))$. Contains the singular values of *A* sorted so that $s[i] \geq s[i + 1]$.

u, vt

Arrays:

Array *u* minimum size:

| | Column major layout | Row major layout |
|-------------------|-----------------------------|--------------------|
| <i>jobu</i> = 'A' | $\max(1, ldu * m)$ | $\max(1, ldu * m)$ |
| <i>jobu</i> = 'S' | $\max(1, ldu * \min(m, n))$ | $\max(1, ldu * m)$ |

If *jobu* = 'A', *u* contains the *m*-by-*m* orthogonal/unitary matrix *U*.

If *jobu* = 'S', *u* contains the first $\min(m, n)$ columns of *U* (the left singular vectors stored column-wise).

If *jobu* = 'N' or 'O', *u* is not referenced.

Array *v* minimum size:

| | Column major layout | Row major layout |
|--------------------|------------------------------|---------------------|
| <i>jobvt</i> = 'A' | $\max(1, ldvt * n)$ | $\max(1, ldvt * n)$ |
| <i>jobvt</i> = 'S' | $\max(1, ldvt * \min(m, n))$ | $\max(1, ldvt * n)$ |

If *jobvt* = 'A', *vt* contains the *n*-by-*n* orthogonal/unitary matrix V^T/V^H .

If *jobvt* = 'S', *vt* contains the first $\min(m, n)$ rows of V^T/V^H (the right singular vectors stored row-wise).

If `jobvt = 'N'` or `'O'`, `vt` is not referenced.

superb

If `?bdsqr` does not converge (indicated by the return value `info > 0`), on exit `superb(0:min(m,n)-2)` contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in `s` (not necessarily sorted). B satisfies $A = u^*B^*v^T$ (real flavors) or $A = u^*B^*v^H$ (complex flavors), so it has the same singular values as A , and singular vectors related by u and vt .

Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, then if `?bdsqr` did not converge, i specifies how many superdiagonals of the intermediate bidiagonal form B did not converge to zero (see the description of the `superb` parameter for details).

?gesdd

Computes the singular value decomposition of a general rectangular matrix using a divide and conquer method.

Syntax

```
lapack_int LAPACKE_sgesdd( int matrix_layout, char jobz, lapack_int m, lapack_int n,
float* a, lapack_int lda, float* s, float* u, lapack_int ldu, float* vt, lapack_int
ldvt );
```

```
lapack_int LAPACKE_dgesdd( int matrix_layout, char jobz, lapack_int m, lapack_int n,
double* a, lapack_int lda, double* s, double* u, lapack_int ldu, double* vt,
lapack_int ldvt );
```

```
lapack_int LAPACKE_cgesdd( int matrix_layout, char jobz, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, float* s, lapack_complex_float* u, lapack_int
ldu, lapack_complex_float* vt, lapack_int ldvt );
```

```
lapack_int LAPACKE_zgesdd( int matrix_layout, char jobz, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, double* s, lapack_complex_double* u,
lapack_int ldu, lapack_complex_double* vt, lapack_int ldvt );
```

Description

The routine computes the singular value decomposition (SVD) of a real/complex m -by- n matrix A , optionally computing the left and/or right singular vectors.

If singular vectors are desired, it uses a divide-and-conquer algorithm. The SVD is written

$$A = U^* \Sigma^* V^T \text{ for real routines,}$$

$$A = U^* \Sigma^* V^H \text{ for complex routines,}$$

where Σ is an m -by- n matrix which is zero except for its $\min(m,n)$ diagonal elements, U is an m -by- m orthogonal/unitary matrix, and V is an n -by- n orthogonal/unitary matrix. The diagonal elements of Σ are the singular values of A ; they are real and non-negative, and are returned in descending order. The first $\min(m, n)$ columns of U and V are the left and right singular vectors of A .

Note that the routine returns $vt = V^T$ (for real flavors) or $vt = V^H$ (for complex flavors), not V .

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

jobz Must be 'A', 'S', 'O', or 'N'.
 Specifies options for computing all or part of the matrices U and V .
 If $jobz = 'A'$, all m columns of U and all n rows of V^T or V^H are returned in the arrays u and vt ;
 if $jobz = 'S'$, the first $\min(m, n)$ columns of U and the first $\min(m, n)$ rows of V^T or V^H are returned in the arrays u and vt ;
 if $jobz = 'O'$, then
 if $m \geq n$, the first n columns of U are overwritten in the array a and all rows of V^T or V^H are returned in the array vt ;
 if $m < n$, all columns of U are returned in the array u and the first m rows of V^T or V^H are overwritten in the array a ;
 if $jobz = 'N'$, no columns of U or rows of V^T or V^H are computed.

m The number of rows of the matrix A ($m \geq 0$).

n The number of columns in A ($n \geq 0$).

a $a(\text{size max}(1, lda*n)$ for column major layout and $\text{max}(1, lda*m)$ for row major layout) is an array containing the m -by- n matrix A .

lda The leading dimension of the array a . Must be at least $\text{max}(1, m)$ for column major layout and at least $\text{max}(1, n)$ for row major layout.

ldu, ldvt The leading dimensions of the output arrays u and vt , respectively.

The minimum size of *ldu* is

| <i>jobz</i> | $m \geq n$ | $m < n$ |
|-------------|---|---------|
| 'N' | 1 | 1 |
| 'A' | m | m |
| 'S' | m for column major layout; n for row major layout | m |
| 'O' | 1 | m |

The minimum size of *ldvt* is

| <i>jobz</i> | $m \geq n$ | $m < n$ |
|-------------|------------|---------|
| 'N' | 1 | 1 |
| 'A' | n | n |

| <i>jobz</i> | $m \geq n$ | $m < n$ |
|-------------|------------|---|
| 'S' | n | m for column major layout; n for row major layout |
| 'O' | n | 1 |

Output Parameters

a

On exit:

If $jobz = 'O'$, then if $m \geq n$, a is overwritten with the first n columns of U (the left singular vectors, stored columnwise). If $m < n$, a is overwritten with the first m rows of V^T (the right singular vectors, stored rowwise);

If $jobz \neq 'O'$, the contents of a are destroyed.

s

Array, size at least $\max(1, \min(m, n))$. Contains the singular values of A sorted so that $s(i) \geq s(i+1)$.

u, vt

Arrays:

Array u is of size:

| <i>jobz</i> | $m \geq n$ | $m < n$ |
|-------------|--|--------------------|
| 'N' | 1 | 1 |
| 'A' | $\max(1, ldu * m)$ | $\max(1, ldu * m)$ |
| 'S' | $\max(1, ldu * n)$ for column major layout; $\max(1, ldu * m)$ for row major layout | $\max(1, ldu * m)$ |
| 'O' | 1 | $\max(1, ldu * m)$ |

If $jobz = 'A'$ or $jobz = 'O'$ and $m < n$, u contains the m -by- m orthogonal/unitary matrix U .

If $jobz = 'S'$, u contains the first $\min(m, n)$ columns of U (the left singular vectors, stored columnwise).

If $jobz = 'O'$ and $m \geq n$, or $jobz = 'N'$, u is not referenced.

Array vt is of size:

| <i>jobz</i> | $m \geq n$ | $m < n$ |
|-------------|---------------------|---|
| 'N' | 1 | 1 |
| 'A' | $\max(1, ldvt * n)$ | $\max(1, ldvt * n)$ |
| 'S' | $\max(1, ldvt * n)$ | $\max(1, ldvt * n)$ for column major layout; $\max(1, ldvt * m)$ for row major layout; |

| <i>jobz</i> | $m \geq n$ | $m < n$ |
|-------------|-------------------|---------|
| 'O' | $\max(1, ldvt*n)$ | 1 |

If *jobz* = 'A' or *jobz* = 'O' and $m \geq n$, *vt* contains the *n*-by-*n* orthogonal/unitary matrix V^T .

If *jobz* = 'S', *vt* contains the first $\min(m, n)$ rows of V^T (the right singular vectors, stored rowwise).

If *jobz* = 'O' and $m < n$, or *jobz* = 'N', *vt* is not referenced.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, then ?bdsdc did not converge, updating process failed.

?gejsv

Computes the singular value decomposition using a preconditioned Jacobi SVD method.

Syntax

```
lapack_int LAPACKE_sgejsv (int matrix_layout, char joba, char jobu, char jobv, char jobr, char jobt, char jobp, lapack_int m, lapack_int n, float * a, lapack_int lda, float * sva, float * u, lapack_int ldu, float * v, lapack_int ldv, float * stat, lapack_int * istat);
```

```
lapack_int LAPACKE_dgejsv (int matrix_layout, char joba, char jobu, char jobv, char jobr, char jobt, char jobp, lapack_int m, lapack_int n, double * a, lapack_int lda, double * sva, double * u, lapack_int ldu, double * v, lapack_int ldv, double * stat, lapack_int * istat);
```

```
lapack_int LAPACKE_cgejsv (int matrix_layout, char joba, char jobu, char jobv, char jobr, char jobt, char jobp, lapack_int m, lapack_int n, lapack_complex_float * a, lapack_int lda, float * sva, lapack_complex_float * u, lapack_int ldu, lapack_complex_float * v, lapack_int ldv, float * stat, lapack_int * istat);
```

```
lapack_int LAPACKE_zgejsv (int matrix_layout, char joba, char jobu, char jobv, char jobr, char jobt, char jobp, lapack_int m, lapack_int n, lapack_complex_double * a, lapack_int lda, double * sva, lapack_complex_double * u, lapack_int ldu, lapack_complex_double * v, lapack_int ldv, double * stat, lapack_int * istat);
```

Include Files

Description

The routine computes the singular value decomposition (SVD) of a real/complex *m*-by-*n* matrix *A*, where $m \geq n$.

The SVD is written as

$$A = U * \Sigma * V^T, \text{ for real routines}$$

$$A = U * \Sigma * V^H, \text{ for complex routines}$$

where Σ is an m -by- n matrix which is zero except for its n diagonal elements, U is an m -by- n (or m -by- m) orthonormal matrix, and V is an n -by- n orthogonal matrix. The diagonal elements of Σ are the singular values of A ; the columns of U and V are the left and right singular vectors of A , respectively. The matrices U and V are computed and stored in the arrays u and v , respectively. The diagonal of Σ is computed and stored in the array sva .

The `?gejsv` routine can sometimes compute tiny singular values and their singular vectors much more accurately than other SVD routines.

The routine implements a preconditioned Jacobi SVD algorithm. It uses `?geqp3`, `?geqrf`, and `?gelqf` as preprocessors and preconditioners. Optionally, an additional row pivoting can be used as a preprocessor, which in some cases results in much higher accuracy. An example is matrix A with the structure $A = D_1 * C * D_2$, where D_1 , D_2 are arbitrarily ill-conditioned diagonal matrices and C is a well-conditioned matrix. In that case, complete pivoting in the first QR factorizations provides accuracy dependent on the condition number of C , and independent of D_1 , D_2 . Such higher accuracy is not completely understood theoretically, but it works well in practice.

If A can be written as $A = B * D$, with well-conditioned B and some diagonal D , then the high accuracy is guaranteed, both theoretically and in software, independent of D . For more details see [[Drmac08-1](#)], [[Drmac08-2](#)].

The computational range for the singular values can be the full range (`UNDERFLOW,OVERFLOW`), provided that the machine arithmetic and the BLAS and LAPACK routines called by `?gejsv` are implemented to work in that range. If that is not the case, the restriction for safe computation with the singular values in the range of normalized IEEE numbers is that the spectral condition number $\kappa(A) = \sigma_{\max}(A) / \sigma_{\min}(A)$ does not overflow. This code (`?gejsv`) is best used in this restricted range, meaning that singular values of magnitude below $\|A\|_2 / \text{slamch}('O')$ (for single precision) or $\|A\|_2 / \text{dlamch}('O')$ (for double precision) are returned as zeros. See `jobr` for details on this.

This implementation is slower than the one described in [[Drmac08-1](#)], [[Drmac08-2](#)] due to replacement of some non-LAPACK components, and because the choice of some tuning parameters in the iterative part (`?gesvj`) is left to the implementer on a particular machine.

The rank revealing QR factorization (in this code: `?geqp3`) should be implemented as in [[Drmac08-3](#)].

If m is much larger than n , it is obvious that the initial QRF with column pivoting can be preprocessed by the QRF without pivoting. That well known trick is not used in `?gejsv` because in some cases heavy row weighting can be treated with complete pivoting. The overhead in cases m much larger than n is then only due to pivoting, but the benefits in accuracy have prevailed. You can incorporate this extra QRF step easily and also improve data movement (matrix transpose, matrix copy, matrix transposed copy) - this implementation of `?gejsv` uses only the simplest, naive data movement.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | <p>Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).</p> |
| <i>joba</i> | <p>Must be 'C', 'E', 'F', 'G', 'A', or 'R'.</p> <p>Specifies the level of accuracy:</p> <p>If <i>joba</i> = 'C', high relative accuracy is achieved if $A = B \cdot D$ with well-conditioned B and arbitrary diagonal matrix D. The accuracy cannot be spoiled by column scaling. The accuracy of the computed output depends on the condition of B, and the procedure aims at the best theoretical accuracy. The relative error $\max_{i=1:N} \delta \sigma_i / \sigma_i$ is bounded by $f(M,N) \cdot \epsilon \cdot \text{cond}(B)$, independent of D. The input matrix is preprocessed with the QRF with column pivoting. This initial preprocessing and preconditioning by a rank revealing QR factorization is common for all values of <i>joba</i>. Additional actions are specified as follows:</p> <p>If <i>joba</i> = 'E', computation as with 'C' with an additional estimate of the condition number of B. It provides a realistic error bound.</p> <p>If <i>joba</i> = 'F', accuracy higher than in the 'C' option is achieved, if $A = D1 \cdot C \cdot D2$ with ill-conditioned diagonal scalings $D1$, $D2$, and a well-conditioned matrix C. This option is advisable, if the structure of the input matrix is not known and relative accuracy is desirable. The input matrix A is preprocessed with QR factorization with full (row and column) pivoting.</p> <p>If <i>joba</i> = 'G', computation as with 'F' with an additional estimate of the condition number of B, where $A = B \cdot D$. If A has heavily weighted rows, using this condition number gives too pessimistic error bound.</p> <p>If <i>joba</i> = 'A', small singular values are the noise and the matrix is treated as numerically rank deficient. The error in the computed singular values is bounded by $f(m,n) \cdot \epsilon \cdot \ A\$. The computed SVD $A = U \cdot S \cdot V^T$ (for real flavors) or $A = U \cdot S \cdot V^H$ (for complex flavors) restores A up to $f(m,n) \cdot \epsilon \cdot \ A\$. This enables the procedure to set all singular values below $n \cdot \epsilon \cdot \ A\$ to zero.</p> <p>If <i>joba</i> = 'R', the procedure is similar to the 'A' option. Rank revealing property of the initial QR factorization is used to reveal (using triangular factor) a gap $\sigma_{r+1} < \epsilon \cdot \sigma_r$, in which case the numerical rank is declared to be r. The SVD is computed with absolute error bounds, but more accurately than with 'A'.</p> |
| <i>jobu</i> | <p>Must be 'U', 'F', 'W', or 'N'.</p> <p>Specifies whether to compute the columns of the matrix U:</p> <p>If <i>jobu</i> = 'U', n columns of U are returned in the array u</p> <p>If <i>jobu</i> = 'F', a full set of m left singular vectors is returned in the array u.</p> <p>If <i>jobu</i> = 'W', u may be used as workspace of length $m \cdot n$. See the description of u.</p> <p>If <i>jobu</i> = 'N', u is not computed.</p> |
| <i>jobv</i> | <p>Must be 'V', 'J', 'W', or 'N'.</p> <p>Specifies whether to compute the matrix V:</p> |

If $jobv = 'V'$, n columns of V are returned in the array v ; Jacobi rotations are not explicitly accumulated.

If $jobv = 'J'$, n columns of V are returned in the array v but they are computed as the product of Jacobi rotations. This option is allowed only if $jobu \neq 'N'$

If $jobv = 'W'$, v may be used as workspace of length $n*n$. See the description of v .

If $jobv = 'N'$, v is not computed.

jobr

Must be 'N' or 'R'.

Specifies the range for the singular values. If small positive singular values are outside the specified range, they may be set to zero. If A is scaled so that the largest singular value of the scaled matrix is around $\sqrt{\text{big}}$, $\text{big} = ?\text{lamch}('O')$, the function can remove columns of A whose norm in the scaled matrix is less than $\sqrt{?\text{lamch}('S')}$ (for $jobr = 'R'$), or less than $\text{small} = ?\text{lamch}('S')/?\text{lamch}('E')$.

If $jobr = 'N'$, the function does not remove small columns of the scaled matrix. This option assumes that BLAS and QR factorizations and triangular solvers are implemented to work in that range. If the condition of A is greater than big , use $?\text{gesvj}$.

If $jobr = 'R'$, restricted range for singular values of the scaled matrix A is $[\sqrt{?\text{lamch}('S')}, \sqrt{\text{big}}]$, roughly as described above. This option is recommended.

For computing the singular values in the full range $[?\text{lamch}('S'), \text{big}]$, use $?\text{gesvj}$.

jobt

Must be 'T' or 'N'.

If the matrix is square, the procedure may determine to use a transposed A if A^T (for real flavors) or A^H (for complex flavors) seems to be better with respect to convergence. If the matrix is not square, $jobt$ is ignored. This is subject to changes in the future.

The decision is based on two values of entropy over the adjoint orbit of $A^T * A$ (for real flavors) or $A^H * A$ (for complex flavors). See the descriptions of $stat[5]$ and $stat[6]$.

If $jobt = 'T'$, the function performs transposition if the entropy test indicates possibly faster convergence of the Jacobi process, if A is taken as input. If A is replaced with A^T or A^H , the row pivoting is included automatically.

If $jobt = 'N'$, the functions attempts no speculations. This option can be used to compute only the singular values, or the full SVD (u , σ , and v). For only one set of singular vectors (u or v), the caller should provide both u and v , as one of the arrays is used as workspace if the matrix A is transposed. The implementer can easily remove this constraint and make the code more complicated. See the descriptions of u and v .

jobp

Must be 'P' or 'N'.

Enables structured perturbations of denormalized numbers. This option should be active if the denormals are poorly implemented, causing slow computation, especially in cases of fast convergence. For details, see [Drmac08-1], [Drmac08-2]. For simplicity, such perturbations are included only when the full SVD or only the singular values are requested. You can add the perturbation for the cases of computing one set of singular vectors.

If $jobp = 'P'$, the function introduces perturbation.

If $jobp = 'N'$, the function introduces no perturbation.

| | |
|-----------|---|
| m | The number of rows of the input matrix A ; $m \geq 0$. |
| n | The number of columns in the input matrix A ; $m \geq n \geq 0$. |
| a, u, v | <p>Array a (size $lda*n$ for column major layout and $lda*m$ for row major layout) is an array containing the m-by-n matrix A.</p> <p>u is a workspace array, its size for column major layout is $ldu*n$ for $jobu='U'$ or $'W'$ and $ldu*m$ for $jobu='F'$; for row major layout its size is at least $ldu*m$. When $jobt = 'T'$ and $m = n$, u must be provided even though $jobu = 'N'$.</p> <p>v is a workspace array, its size is $ldv*n$. When $jobt = 'T'$ and $m = n$, v must be provided even though $jobv = 'N'$.</p> |
| lda | The leading dimension of the array a . Must be at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout. |
| sva | sva is a workspace array, its size is n . |
| ldu | <p>The leading dimension of the array u; $ldu \geq 1$.</p> <p>$jobu = 'U'$ or $'F'$ or $'W'$, $ldu \geq m$ for column major layout; for row major layout if $jobu = 'U'$ or $jobu = 'W'$ $ldu \geq n$ and if $jobu = 'F'$ $ldu \geq m$.</p> |
| ldv | <p>The leading dimension of the array v; $ldv \geq 1$.</p> <p>$jobv = 'V'$ or $'J'$ or $'W'$, $ldv \geq n$.</p> |
| $cwork$ | $cwork$ is a workspace array, dimension is at least $lwork$. |
| $rwork$ | $rwork$ is an array, dimension is at least $\max(7, lrwork)$. |

Output Parameters

| | |
|-------|--|
| sva | <p>On exit:</p> <p>For $stat[0]/stat[1] = 1$: the singular values of A. During the computation sva contains Euclidean column norms of the iterated matrices in the array a.</p> <p>For $stat[0] \neq stat[1]$: the singular values of A are $(stat[0]/stat[1]) * sva[0:n - 1]$. This factored form is used if $\sigma_{max}(A)$ overflows or if small singular values have been saved from underflow by scaling the input matrix A.</p> |
|-------|--|

$jobr = 'R'$, some of the singular values may be returned as exact zeros obtained by 'setting to zero' because they are below the numerical rank threshold or are denormalized numbers.

u

On exit:

If $jobu = 'U'$, contains the m -by- n matrix of the left singular vectors.

If $jobu = 'F'$, contains the m -by- m matrix of the left singular vectors, including an orthonormal basis of the orthogonal complement of the range of A .

If $jobu = 'W'$ and $jobv = 'V'$, $jobt = 'T'$, and $m = n$, then u is used as workspace if the procedure replaces A with A^T (for real flavors) or A^H (for complex flavors). In that case, v is computed in u as left singular vectors of A^T or A^H and copied back to the v array. This 'W' option is just a reminder to the caller that in this case u is reserved as workspace of length $n*n$.

If $jobu = 'N'$, u is not referenced.

v

On exit:

If $jobv = 'V'$ or $'J'$, contains the n -by- n matrix of the right singular vectors.

If $jobv = 'W'$ and $jobu = 'U'$, $jobt = 'T'$, and $m = n$, then v is used as workspace if the procedure replaces A with A^T (for real flavors) or A^H (for complex flavors). In that case, u is computed in v as right singular vectors of A^T or A^H and copied back to the u array. This 'W' option is just a reminder to the caller that in this case v is reserved as workspace of length $n*n$.

If $jobv = 'N'$, v is not referenced.

$stat$

On exit,

$stat[0] = scale = stat[1]/stat[0]$ is the scaling factor such that $scale*sva(1:n)$ are the computed singular values of A . See the description of sva .

$stat[1] =$ see the description of $stat[0]$.

$stat[2] = sconda$ is an estimate for the condition number of column equilibrated A . If $joba = 'E'$ or $'G'$, $sconda$ is an estimate of $\sqrt{|| (R^T * R)^{-1} ||_1}$. It is computed using `?pocon`. It holds $n^{-1/4} * sconda \leq || R^{-1} ||_2 \leq n^{1/4} * sconda$, where R is the triangular factor from the QRF of A . However, if R is truncated and the numerical rank is determined to be strictly smaller than n , $sconda$ is returned as -1, indicating that the smallest singular values might be lost.

If full SVD is needed, the following two condition numbers are useful for the analysis of the algorithm. They are provided for a user who is familiar with the details of the method.

$stat[3] =$ an estimate of the scaled condition number of the triangular factor in the first QR factorization.

$stat[4] =$ an estimate of the scaled condition number of the triangular factor in the second QR factorization.

The following two parameters are computed if *jobt* = 'T'. They are provided for a user who is familiar with the details of the method.

stat[5] = the entropy of $A^T * A$: : this is the Shannon entropy of $\text{diag}(A^T * A) / \text{Trace}(A^T * A)$ taken as point in the probability simplex.

stat[6] = the entropy of $A * A^T$.

istat

On exit,

istat[0] = the numerical rank determined after the initial QR factorization with pivoting. See the descriptions of *joba* and *jobr*.

istat[1] = the number of the computed nonzero singular value.

istat[2] = if nonzero, a warning message. If *istat*[2]=1, some of the column norms of *A* were denormalized floats. The requested high accuracy is not warranted by the data.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, the function did not converge in the maximal number of sweeps. The computed values may be inaccurate.

- `mk1.h`

Description

The routine computes the singular value decomposition (SVD) of a real or complex m -by- n matrix A , where $m \geq n$.

The SVD of A is written as

$$A = U \Sigma^* V^T \text{ for real flavors, or}$$

$$A = U \Sigma^* V^H \text{ for complex flavors,}$$

where Σ is an m -by- n diagonal matrix, U is an m -by- n orthonormal matrix, and V is an n -by- n orthogonal/unitary matrix. The diagonal elements of Σ are the singular values of A ; the columns of U and V are the left and right singular vectors of A , respectively. The matrices U and V are computed and stored in the arrays u and v , respectively. The diagonal of Σ is computed and stored in the array `sva`.

The `?gesvj` routine can sometimes compute tiny singular values and their singular vectors much more accurately than other SVD routines.

The n -by- n orthogonal matrix V is obtained as a product of Jacobi plane rotations. The rotations are implemented as fast scaled rotations of Anda and Park [[AndaPark94](#)]. In the case of underflow of the Jacobi angle, a modified Jacobi transformation of Drmac ([[Drmac08-4](#)]) is used. Pivot strategy uses column interchanges of de Rijk ([[deRijk98](#)]). The relative accuracy of the computed singular values and the accuracy of the computed singular vectors (in angle metric) is as guaranteed by the theory of Demmel and Veselic [[Demmel92](#)]. The condition number that determines the accuracy in the full rank case is essentially

$$\left(\min_i d_{ii} \right) \cdot \kappa(A \cdot D)$$

where $\kappa(\cdot)$ is the spectral condition number. The best performance of this Jacobi SVD procedure is achieved if used in an accelerated version of Drmac and Veselic [[Drmac08-1](#)], [[Drmac08-2](#)].

The computational range for the nonzero singular values is the machine number interval (`UNDERFLOW,OVERFLOW`). In extreme cases, even denormalized singular values can be computed with the corresponding gradual loss of accurate digit.

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>joba</code> | Must be 'L', 'U' or 'G'. Specifies the structure of A : If <code>joba</code> = 'L', the input matrix A is lower triangular. If <code>joba</code> = 'U', the input matrix A is upper triangular. If <code>joba</code> = 'G', the input matrix A is a general m -by- n , $m \geq n$. |
| <code>jobu</code> | Must be 'U', 'C' or 'N'. Specifies whether to compute the left singular vectors (columns of U): |

If $jobu = 'U'$, the left singular vectors corresponding to the nonzero singular values are computed and returned in the leading columns of A . See more details in the description of a . The default numerical orthogonality threshold is set to approximately $TOL=CTOL*EPS$, $CTOL=\sqrt{m}$, $EPS = ?lamch('E')$

If $jobu = 'C'$, analogous to $jobu = 'U'$, except that you can control the level of numerical orthogonality of the computed left singular vectors. TOL can be set to $TOL=CTOL*EPS$, where $CTOL$ is given on input in the array $stat$. No $CTOL$ smaller than ONE is allowed. $CTOL$ greater than $1 / EPS$ is meaningless. The option 'C' can be used if $m*EPS$ is satisfactory orthogonality of the computed left singular vectors, so $CTOL=m$ could save a few sweeps of Jacobi rotations. See the descriptions of a and $stat[0]$.

If $jobu = 'N'$, u is not computed. However, see the description of a .

$jobv$

Must be 'V', 'A' or 'N'.

Specifies whether to compute the right singular vectors, that is, the matrix V :

If $jobv = 'V'$, the matrix V is computed and returned in the array v .

If $jobv = 'A'$, the Jacobi rotations are applied to the mv -by- n array v . In other words, the right singular vector matrix V is not computed explicitly, instead it is applied to an mv -by- n matrix initially stored in the first mv rows of V .

If $jobv = 'N'$, the matrix V is not computed and the array v is not referenced.

m

The number of rows of the input matrix A .

$1/\text{slamch}('E') > m \geq 0$ for $sgesvj$.

$1/\text{dlamch}('E') > m \geq 0$ for $dgesvj$.

n

The number of columns in the input matrix A ; $m \geq n \geq 0$.

a, v

Array a (size at least $lda*n$ for column major layout and $lda*m$ for row major layout) is an array containing the m -by- n matrix A .

Array v (size at least $\max(1, ldv*n)$) contains, if $jobv = 'A'$ the mv -by- n matrix to be post-multiplied by Jacobi rotations.

lda

The leading dimension of the array a . Must be at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout.

mv

If $jobv = 'A'$, the product of Jacobi rotations in $?gesvj$ is applied to the first mv rows of v . See the description of $jobv$. $0 \leq mv \leq ldv$.

ldv

The leading dimension of the array v ; $ldv \geq 1$.

$jobv = 'V', ldv \geq \max(1, n)$.

$jobv = 'A', ldv \geq \max(1, mv)$ for column major layout and $ldv \geq \max(1, n)$ for row major layout.

stat

Array size 6. If *jobu* = 'C', *stat*[0] = *CTOL*, where *CTOL* defines the threshold for convergence. The process stops if all columns of *A* are mutually orthogonal up to *CTOL***EPS*, where *EPS* = $\text{?lamch}('E')$. It is required that $CTOL \geq 1$ - that is, it is not allowed to force the routine to obtain orthogonality below ϵ .

Output Parameters

a

On exit:

If *jobu* = 'U' or *jobu* = 'C':

- if *info* = 0, the leading columns of *A* contain left singular vectors corresponding to the computed singular values of *a* that are above the underflow threshold $\text{?lamch}('S')$, that is, non-zero singular values. The number of the computed non-zero singular values is returned in *stat*[1]. Also see the descriptions of *sva* and *stat*. The computed columns of *u* are mutually numerically orthogonal up to approximately $TOL = \sqrt{m} * EPS$ (default); or $TOL = CTOL * EPS$ *jobu* = 'C', see the description of *jobu*.
- if *info* > 0, the procedure *?gesvj* did not converge in the given number of iterations (sweeps). In that case, the computed columns of *u* may not be orthogonal up to *TOL*. The output *u* (stored in *a*), *sigma* (given by the computed singular values in *sva*(1:n)) and *v* is still a decomposition of the input matrix *A* in the sense that the residual $\|A - scale * U * sigma * V^T\|_2 / \|A\|_2$ for real flavors or $\|A - scale * U * sigma * V^H\|_2 / \|A\|_2$ for complex flavors (where *scale* = *stat*[0]) is small.

If *jobu* = 'N':

- if *info* = 0, note that the left singular vectors are 'for free' in the one-sided Jacobi SVD algorithm. However, if only the singular values are needed, the level of numerical orthogonality of *u* is not an issue and iterations are stopped when the columns of the iterated matrix are numerically orthogonal up to approximately $m * EPS$. Thus, on exit, *a* contains the columns of *u* scaled with the corresponding singular values.
- if *info* > 0, the procedure *?gesvj* did not converge in the given number of iterations (sweeps).

*sva*Array size *n*.

If *info* = 0, depending on the value *scale* = *stat*[0], where *scale* is the scaling factor:

- if *scale* = 1, *sva*[0:n - 1] contains the computed singular values of *a*.
- if *scale* ≠ 1, the singular values of *a* are *scale***sva*(1:n), and this factored representation is due to the fact that some of the singular values of *a* might underflow or overflow.

If *info* > 0, the procedure *?gesvj* did not converge in the given number of iterations (sweeps) and *scale***sva*(1:n) may not be accurate.

v

On exit:

If *jobv* = 'V', contains the *n*-by-*n* matrix of the right singular vectors.

If *jobv* = 'A', then *v* contains the product of the computed right singular vector matrix and the initial matrix in the array *v*.

If *jobv* = 'N', *v* is not referenced.

stat

On exit,

stat[0] = *scale* is the scaling factor such that *scale***sva*(1:*n*) are the computed singular values of *A*. See the description of *sva*.

stat[1] is the number of the computed nonzero singular values.

stat[2] is the number of the computed singular values that are larger than the underflow threshold.

stat[3] is the number of sweeps of Jacobi rotations needed for numerical convergence.

stat[4] = $\max_{\{i \neq j\}} |\cos(A(:,i), A(:,j))|$ in the last sweep. This is useful information in cases when *?gesvj* did not converge, as it can be used to estimate whether the output is still useful and for post festum analysis.

stat[5] is the largest absolute value over all sines of the Jacobi rotation angles in the last sweep. It can be useful in a post festum analysis.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, the function did not converge in the maximal number (30) of sweeps. The output may still be useful. See the description of *stat*.

?ggsvd

Computes the generalized singular value decomposition of a pair of general rectangular matrices (deprecated).

Syntax

```
lapack_int LAPACKE_sggsvd( int matrix_layout, char jobu, char jobv, char jobq,
lapack_int m, lapack_int n, lapack_int p, lapack_int* k, lapack_int* l, float* a,
lapack_int lda, float* b, lapack_int ldb, float* alpha, float* beta, float* u,
lapack_int ldu, float* v, lapack_int ldv, float* q, lapack_int ldq, lapack_int*
iwork );
```

```
lapack_int LAPACKE_dggsvd( int matrix_layout, char jobu, char jobv, char jobq,
lapack_int m, lapack_int n, lapack_int p, lapack_int* k, lapack_int* l, double* a,
lapack_int lda, double* b, lapack_int ldb, double* alpha, double* beta, double* u,
lapack_int ldu, double* v, lapack_int ldv, double* q, lapack_int ldq, lapack_int*
iwork );
```

```
lapack_int LAPACKE_cggsvd( int matrix_layout, char jobu, char jobv, char jobq,
lapack_int m, lapack_int n, lapack_int p, lapack_int* k, lapack_int* l,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb,
```

$$C = \text{diag}(\alpha[k], \dots, \alpha[k + l - 1])$$

$$S = \text{diag}(\beta[k], \dots, \beta[k + l - 1])$$

$$C^2 + S^2 = I$$

Nonzero element r_{ij} ($1 \leq j \leq k + l$) of R is stored in $a[(i - 1) + (n - k - l + j - 1) * lda]$ for column major layout and in $a[(i - 1) * lda + (n - k - l + j - 1)]$ for row major layout.

If $m - k - l < 0$,

$$D_1 = \begin{matrix} & k & m - k & k + l - m \\ m - k & \begin{pmatrix} I & 0 & 0 \\ 0 & C & 0 \end{pmatrix} \end{matrix}$$

$$D_2 = \begin{matrix} & k & m - k & k + l - m \\ m - k & \begin{pmatrix} 0 & S & 0 \\ 0 & 0 & I \\ 0 & 0 & 0 \end{pmatrix} \\ k + l - m & \end{matrix}$$

$$(0 \ R) = \begin{matrix} & n - k - l & k & m - k & k + l - m \\ m - k & \begin{pmatrix} 0 & R_{11} & R_{12} & R_{13} \\ 0 & 0 & R_{22} & R_{23} \\ 0 & 0 & 0 & R_{33} \end{pmatrix} \\ k + l - m & \end{matrix}$$

where

$$C = \text{diag}(\alpha[k], \dots, \alpha[m]),$$

$$S = \text{diag}(\beta[k], \dots, \beta[m - 1]),$$

$$C_2 + S_2 = I$$

On exit, the location of nonzero element r_{ij} ($1 \leq j \leq k + l$) of R depends on the value of i . For $i \leq m$ this element is stored in $a[(i - 1) + (n - k - l + j - 1) * lda]$ for column major layout and in $a[(i - 1) * lda + (n - k - l + j - 1)]$ for row major layout. For $m < i \leq k + l$ it is stored in $b[(i - k - 1) + (n - k - l + j - 1) * ldb]$ for column major layout and in $b[(i - k - 1) * ldb + (n - k - l + j - 1)]$ for row major layout.

The routine computes C , S , R , and optionally the orthogonal/unitary transformation matrices U , V and Q .

In particular, if B is an n -by- n nonsingular matrix, then the GSVD of A and B implicitly gives the SVD of $A * B^{-1}$:

$$A * B^{-1} = U * (D_1 * D_2^{-1}) * V'$$

If (A', B') has orthonormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and B . Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

$$A' * A * x = \lambda * B' * B * x.$$

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobu</i> | Must be 'U' or 'N'. If <i>jobu</i> = 'U', orthogonal/unitary matrix <i>U</i> is computed. If <i>jobu</i> = 'N', <i>U</i> is not computed. |
| <i>jobv</i> | Must be 'V' or 'N'. If <i>jobv</i> = 'V', orthogonal/unitary matrix <i>V</i> is computed. If <i>jobv</i> = 'N', <i>V</i> is not computed. |
| <i>jobq</i> | Must be 'Q' or 'N'. If <i>jobq</i> = 'Q', orthogonal/unitary matrix <i>Q</i> is computed. If <i>jobq</i> = 'N', <i>Q</i> is not computed. |
| <i>m</i> | The number of rows of the matrix <i>A</i> ($m \geq 0$). |
| <i>n</i> | The number of columns of the matrices <i>A</i> and <i>B</i> ($n \geq 0$). |
| <i>p</i> | The number of rows of the matrix <i>B</i> ($p \geq 0$). |
| <i>a, b</i> | Arrays: <i>a</i> (size at least $\max(1, lda * n)$ for column major layout and $\max(1, lda * m)$ for row major layout) contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> . <i>b</i> (size at least $\max(1, ldb * n)$ for column major layout and $\max(1, ldb * p)$ for row major layout) contains the <i>p</i> -by- <i>n</i> matrix <i>B</i> . |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; at least $\max(1, p)$ for column major layout and $\max(1, n)$ for row major layout. |
| <i>ldu</i> | The leading dimension of the array <i>u</i> . $ldu \geq \max(1, m)$ if <i>jobu</i> = 'U'; $ldu \geq 1$ otherwise. |
| <i>ldv</i> | The leading dimension of the array <i>v</i> . $ldv \geq \max(1, p)$ if <i>jobv</i> = 'V'; $ldv \geq 1$ otherwise. |
| <i>ldq</i> | The leading dimension of the array <i>q</i> . $ldq \geq \max(1, n)$ if <i>jobq</i> = 'Q'; $ldq \geq 1$ otherwise. |

Output Parameters

| | |
|-------------|--|
| <i>k, l</i> | On exit, <i>k</i> and <i>l</i> specify the dimension of the subblocks. The sum <i>k+l</i> is equal to the effective numerical rank of (<i>A</i> , <i>B</i>). |
| <i>a</i> | On exit, <i>a</i> contains the triangular matrix <i>R</i> or part of <i>R</i> . |

b On exit, *b* contains part of the triangular matrix R if $m-k-l < 0$.

alpha, beta Arrays, size at least $\max(1, n)$ each.
 Contain the generalized singular value pairs of *A* and *B*:
 $alpha(1:k) = 1,$
 $beta(1:k) = 0,$
 and if $m-k-l \geq 0,$
 $alpha(k+1:k+l) = C,$
 $beta(k+1:k+l) = S,$
 or if $m-k-l < 0,$
 $alpha(k+1:m) = C, alpha(m+1:k+l) = 0$
 $beta(k+1:m) = S, beta(m+1:k+l) = 1$
 and
 $alpha(k+l+1:n) = 0$
 $beta(k+l+1:n) = 0.$

u, v, q Arrays:
u, size at least $\max(1, ldu*m)$.
 If *jobu* = 'U', *u* contains the *m*-by-*m* orthogonal/unitary matrix *U*.
 If *jobu* = 'N', *u* is not referenced.
v, size at least $\max(1, ldv*p)$.
 If *jobv* = 'V', *v* contains the *p*-by-*p* orthogonal/unitary matrix *V*.
 If *jobv* = 'N', *v* is not referenced.
q, size at least $\max(1, ldq*n)$.
 If *jobq* = 'Q', *q* contains the *n*-by-*n* orthogonal/unitary matrix *Q*.
 If *jobq* = 'N', *q* is not referenced.

iwork On exit, *iwork* stores the sorting information.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = 1, the Jacobi-type procedure failed to converge. For further details, see subroutine [tgsja](#).

?gesvdx

Computes the SVD and left and right singular vectors for a matrix.

Syntax

```

Include Files

- mkl.h

Description

`?gesvdx` computes the singular value decomposition (SVD) of a real or complex m -by- n matrix A , optionally computing the left and right singular vectors. The SVD is written

$$A = U * \Sigma * \text{transpose}(V)$$

where Σ is an m -by- n matrix which is zero except for its $\min(m,n)$ diagonal elements, U is an m -by- m matrix, and V is an n -by- n matrix. The matrices U and V are orthogonal for real A , and unitary for complex A . The diagonal elements of Σ are the singular values of A ; they are real and non-negative, and are returned in descending order. The first $\min(m,n)$ columns of U and V are the left and right singular vectors of A .

`?gesvdx` uses an eigenvalue problem for obtaining the SVD, which allows for the computation of a subset of singular values and vectors. See `?bdsvdx` for details.

Note that the routine returns V^T , not V .

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

jobu Specifies options for computing all or part of the matrix U :
 = 'V': the first $\min(m,n)$ columns of U (the left singular vectors) or as specified by *range* are returned in the array *u*;
 = 'N': no columns of U (no left singular vectors) are computed.

jobvt Specifies options for computing all or part of the matrix V^T :
 = 'V': the first $\min(m,n)$ rows of V^T (the right singular vectors) or as specified by *range* are returned in the array *vt*;

| | |
|--------------|---|
| | = 'N': no rows of V^T (no right singular vectors) are computed. |
| <i>range</i> | = 'A': find all singular values. = 'V': all singular values in the half-open interval $(v_l, v_u]$ are found. = 'I': the <i>il</i> -th through <i>iu</i> -th singular values are found. |
| <i>m</i> | The number of rows of the input matrix <i>A</i> . $m \geq 0$. |
| <i>n</i> | The number of columns of the input matrix <i>A</i> . $n \geq 0$. |
| <i>a</i> | Array, size $lda * n$ On entry, the <i>m</i> -by- <i>n</i> matrix <i>A</i> . |
| <i>lda</i> | The leading dimension of the array <i>a</i> . $lda \geq \max(1, m)$. |
| <i>v_l</i> | $v_l \geq 0$. |
| <i>v_u</i> | If <i>range</i> ='V', the lower and upper bounds of the interval to be searched for singular values. $v_u > v_l$. Not referenced if <i>range</i> = 'A' or 'I'. |
| <i>il</i> | |
| <i>iu</i> | If <i>range</i> ='I', the indices (in ascending order) of the smallest and largest singular values to be returned. $1 \leq il \leq iu \leq \min(m, n)$, if $\min(m, n) > 0$. Not referenced if <i>range</i> = 'A' or 'V'. |
| <i>ldu</i> | The leading dimension of the array <i>u</i> . $ldu \geq 1$; if <i>jobu</i> = 'V', $ldu \geq m$. |
| <i>ldvt</i> | The leading dimension of the array <i>vt</i> . $ldvt \geq 1$; if <i>jobvt</i> = 'V', $ldvt \geq ns$ (see above). |

Output Parameters

| | |
|-----------|---|
| <i>a</i> | On exit, the contents of <i>a</i> are destroyed. |
| <i>ns</i> | The total number of singular values found, $0 \leq ns \leq \min(m, n)$. If <i>range</i> = 'A', $ns = \min(m, n)$; if <i>range</i> = 'I', $ns = iu - il + 1$. |
| <i>s</i> | Array, size $(\min(m, n))$ The singular values of <i>A</i> , sorted so that $s[i] \geq s[i + 1]$. |
| <i>u</i> | Array, size $ldu * ucol$ If <i>jobu</i> = 'V', <i>u</i> contains columns of <i>U</i> (the left singular vectors, stored columnwise) as specified by <i>range</i> ; if <i>jobu</i> = 'N', <i>u</i> is not referenced. |

NOTE

Make sure that $ucol \geq ns$; if *range* = 'V', the exact value of *ns* is not known in advance and an upper bound must be used.

vt Array, size $ldvt*n$
 If *jobvt* = 'V', *vt* contains the rows of V^T (the right singular vectors, stored rowwise) as specified by *range*; if *jobvt* = 'N', *vt* is not referenced.

NOTE

Make sure that $ldvt \geq ns$; if *range* = 'V', the exact value of *ns* is not known in advance and an upper bound must be used.

superb Array, size $(12*\min(m, n))$.
 If *info* = 0, the first *ns* elements of *iwork* are zero. If *info* > 0, then *iwork* contains the indices of the eigenvectors that failed to converge in ?bdsvdx/?stevx.

Return Values

This function returns a value *info*.

= 0: successful exit.

< 0: if *info* = -*i*, the *i*-th argument had an illegal value.

> 0: if *info* = *i*, then *i* eigenvectors failed to converge in ?bdsvdx/?stevx. if *info* = $n*2 + 1$, an internal error occurred in ?bdsvdx.

?bdsvdx

Computes the SVD of a bidiagonal matrix.

Description

?bdsvdx computes the singular value decomposition (SVD) of a real n -by- n (upper or lower) bidiagonal matrix B , $B = U * S * VT$, where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and U and VT are orthogonal matrices of left and right singular vectors, respectively.

Given an upper bidiagonal B with diagonal $d = [d_1 d_2 \dots d_n]$ and superdiagonal $e = [e_1 e_2 \dots e_{n-1}]$, ?bdsvdx computes the singular value decomposition of B through the eigenvalues and eigenvectors of the $n*2$ -by- $n*2$ tridiagonal matrix

$$T G K = \begin{pmatrix} 0 & d_1 & & & \\ d_1 & 0 & e_1 & & \\ & e_1 & 0 & d_2 & \\ & & & d_2 & \ddots & \ddots \\ & & & & \ddots & \ddots \end{pmatrix}$$

If (s, u, v) is a singular triplet of B with $\|u\| = \|v\| = 1$, then $(\pm s, q)$, $\|q\| = 1$, are eigenpairs of TGK, with $q = P * \frac{(u \pm v)}{\sqrt{2}} = \frac{(v_1 \ u_1 \ v_2 \ u_2 \ \dots \ v_n \ u_n)}{\sqrt{2}}$, and $P = (e_{n+1} \ e_1 \ e_{n+2} \ e_2 \ \dots)$.

Given a TGK matrix, one can either

1. compute $-s$, $-v$ and change signs so that the singular values (and corresponding vectors) are already in descending order (as in `?gesvd/?gesdd`) or
2. compute s , v and reorder the values (and corresponding vectors).

`?bdsvd` implements (1) by calling `?stevx` (bisection plus inverse iteration, to be replaced with a version of the Multiple Relative Robust Representation algorithm. (See P. Willems and B. Lang, A framework for the MR³ algorithm: theory and implementation, SIAM J. Sci. Comput., 35:740-766, 2013.)

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>uplo</code> | = 'U': B is upper bidiagonal; = 'L': B is lower bidiagonal. |
| <code>jobz</code> | = 'N': Compute singular values only; = 'V': Compute singular values and singular vectors. |
| <code>range</code> | = 'A': Find all singular values. = 'V': all singular values in the half-open interval $[vl, vu)$ are found. = 'I': the il -th through iu -th singular values are found. |
| <code>n</code> | The order of the bidiagonal matrix. $n \geq 0$. |
| <code>d</code> | Array, size n . The n diagonal elements of the bidiagonal matrix B . |
| <code>e</code> | Array, size $(\max(1, n - 1))$ The $(n - 1)$ superdiagonal elements of the bidiagonal matrix B in elements 1 to $n - 1$. |
| <code>vl</code> | $vl \geq 0$. |
| <code>vu</code> | If <code>range='V'</code> , the lower and upper bounds of the interval to be searched for singular values. $vu > vl$. Not referenced if <code>range = 'A'</code> or <code>'I'</code> . |
| <code>il, iu</code> | If <code>range='I'</code> , the indices (in ascending order) of the smallest and largest singular values to be returned. $1 \leq il \leq iu \leq \min(m, n)$, if $\min(m, n) > 0$. Not referenced if <code>range = 'A'</code> or <code>'V'</code> . |
| <code>ldz</code> | The leading dimension of the array z . |

$ldz \geq 1$, and if $jobz = 'V'$, $ldz \geq \max(2, n*2)$.

Output Parameters

| | |
|-----------|---|
| <i>ns</i> | The total number of singular values found. $0 \leq ns \leq n$. If $range = 'A'$, $ns = n$, and if $range = 'I'$, $ns = iu - il + 1$. |
| <i>s</i> | Array, size (n) The first ns elements contain the selected singular values in ascending order. |
| <i>z</i> | Array, size $2*n*k$ If $jobz = 'V'$, then if $info = 0$ the first ns columns of z contain the singular vectors of the matrix B corresponding to the selected singular values, with U in rows 1 to n and V in rows $n+1$ to $n*2$, i.e. $z = \begin{pmatrix} U \\ V \end{pmatrix}$ If $jobz = 'N'$, then z is not referenced. |

NOTE

Make sure that at least $k = ns+1$ columns are supplied in the array z ; if $range = 'V'$, the exact value of ns is not known in advance and an upper bound must be used.

| | |
|---------------|--|
| <i>superb</i> | Array, size ($12*n$). If $jobz = 'V'$, then if $info = 0$, the first ns elements of $iwork$ are zero. If $info > 0$, then $iwork$ contains the indices of the eigenvectors that failed to converge in $?stevx$. |
|---------------|--|

Return Values

This function returns a value *info*.

= 0: successful exit.

< 0: if $info = -i$, the i -th argument had an illegal value.

> 0:

if $info = i$, then i eigenvectors failed to converge in $?stevx$. The indices of the eigenvectors (as returned by $?stevx$) are stored in the array *iwork*.

if $info = n*2 + 1$, an internal error occurred.

Cosine-Sine Decomposition: LAPACK Driver Routines

This section describes LAPACK driver routines for computing the *cosine-sine decomposition* (CS decomposition). You can also call the corresponding computational routines to perform the same task.

The computation has the following phases:

1. The matrix is reduced to a bidiagonal block form.
2. The blocks are simultaneously diagonalized using techniques from the bidiagonal SVD algorithms.

Table "Driver Routines for Cosine-Sine Decomposition (CSD)" lists LAPACK routines that perform CS decomposition of matrices.

Computational Routines for Cosine-Sine Decomposition (CSD)

| Operation | Real matrices | Complex matrices |
|---|---|---|
| Compute the CS decomposition of a block-partitioned orthogonal matrix | orcsd uncsd | |
| Compute the CS decomposition of a block-partitioned unitary matrix | | orcsd uncsd |

Description

The routines `?orcsd/?uncsd` compute the CS decomposition of an m -by- m partitioned orthogonal matrix X :

$$X = \begin{pmatrix} x_{11} & | & x_{12} \\ x_{21} & | & x_{22} \end{pmatrix} = \begin{pmatrix} u_1 & | \\ & | & u_2 \end{pmatrix} \left(\begin{array}{ccc|ccc} I & 0 & 0 & 0 & 0 & 0 \\ 0 & C & 0 & 0 & -S & 0 \\ \hline 0 & 0 & 0 & I & 0 & 0 \\ 0 & S & 0 & 0 & C & 0 \\ 0 & 0 & I & 0 & 0 & 0 \end{array} \right) \begin{pmatrix} v_1 & | \\ & | & v_2 \end{pmatrix}^T$$

or unitary matrix:

$$X = \begin{pmatrix} x_{11} & | & x_{12} \\ x_{21} & | & x_{22} \end{pmatrix} = \begin{pmatrix} u_1 & | \\ & | & u_2 \end{pmatrix} \left(\begin{array}{ccc|ccc} I & 0 & 0 & 0 & 0 & 0 \\ 0 & C & 0 & 0 & -S & 0 \\ \hline 0 & 0 & 0 & I & 0 & 0 \\ 0 & S & 0 & 0 & C & 0 \\ 0 & 0 & I & 0 & 0 & 0 \end{array} \right) \begin{pmatrix} v_1 & | \\ & | & v_2 \end{pmatrix}^H$$

x_{11} is p -by- q . The orthogonal/unitary matrices u_1 , u_2 , v_1 , and v_2 are p -by- p , $(m-p)$ -by- $(m-p)$, q -by- q , $(m-q)$ -by- $(m-q)$, respectively. C and S are r -by- r nonnegative diagonal matrices satisfying $C^2 + S^2 = I$, in which $r = \min(p, m-p, q, m-q)$.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobu1</i> | If equals Y, then u_1 is computed. Otherwise, u_1 is not computed. |
| <i>jobu2</i> | If equals Y, then u_2 is computed. Otherwise, u_2 is not computed. |
| <i>jobv1t</i> | If equals Y, then v_1^t is computed. Otherwise, v_1^t is not computed. |
| <i>jobv2t</i> | If equals Y, then v_2^t is computed. Otherwise, v_2^t is not computed. |
| <i>trans</i> | = 'T': X , u_1 , u_2 , v_1^t , v_2^t are stored in row-major order. otherwise X , u_1 , u_2 , v_1^t , v_2^t are stored in column-major order. |
| <i>signs</i> | = 'O': The lower-left block is made nonpositive (the "other" convention). otherwise The upper-right block is made nonpositive (the "default" convention). |
| <i>m</i> | The number of rows and columns of the matrix X . |
| <i>p</i> | The number of rows in x_{11} and x_{12} . $0 \leq p \leq m$. |

| | |
|--|--|
| q | The number of columns in x_{11} and x_{21} . $0 \leq q \leq m$. |
| $x_{11}, x_{12}, x_{21}, x_{22}$ | Arrays of size x_{11} (ldx_{11}, q), x_{12} ($ldx_{12}, m - q$), x_{21} (ldx_{21}, q), and x_{22} ($ldx_{22}, m - q$). Contain the parts of the orthogonal/unitary matrix whose CSD is desired. |
| $ldx_{11}, ldx_{12}, ldx_{21}, ldx_{22}$ | The leading dimensions of the parts of array X . $ldx_{11} \geq \max(1, p)$, $ldx_{12} \geq \max(1, p)$, $ldx_{21} \geq \max(1, m - p)$, $ldx_{22} \geq \max(1, m - p)$. |
| ldu_1 | The leading dimension of the array u_1 . If $jobu_1 = 'Y'$, $ldu_1 \geq \max(1, p)$. |
| ldu_2 | The leading dimension of the array u_2 . If $jobu_2 = 'Y'$, $ldu_2 \geq \max(1, m - p)$. |
| ldv_{1t} | The leading dimension of the array v_{1t} . If $jobv_{1t} = 'Y'$, $ldv_{1t} \geq \max(1, q)$. |
| ldv_{2t} | The leading dimension of the array v_{2t} . If $jobv_{2t} = 'Y'$, $ldv_{2t} \geq \max(1, m - q)$. |

Output Parameters

| | |
|----------|---|
| $theta$ | Array, size r , in which $r = \min(p, m - p, q, m - q)$. $C = \text{diag}(\cos(theta[0]), \dots, \cos(theta[r - 1]))$, and $S = \text{diag}(\sin(theta[0]), \dots, \sin(theta[r - 1]))$. |
| u_1 | Array, size at least $\max(1, ldu_1 * p)$. If $jobu_1 = 'Y'$, u_1 contains the p -by- p orthogonal/unitary matrix u_1 . |
| u_2 | Array, size at least $\max(1, ldu_2 * (m - p))$. If $jobu_2 = 'Y'$, u_2 contains the $(m - p)$ -by- $(m - p)$ orthogonal/unitary matrix u_2 . |
| v_{1t} | Array, size at least $\max(1, ldv_{1t} * q)$. If $jobv_{1t} = 'Y'$, v_{1t} contains the q -by- q orthogonal matrix v_{1t}^T or unitary matrix v_{1t}^H . |
| v_{2t} | Array, size at least $\max(1, ldv_{2t} * (m - q))$. If $jobv_{2t} = 'Y'$, v_{2t} contains the $(m - q)$ -by- $(m - q)$ orthogonal matrix v_{2t}^T or unitary matrix v_{2t}^H . |

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

> 0 : ?orcsd/?uncsd did not converge.

Description

The routines ?orcsd2by1/?uncsd2by1 compute the CS decomposition of an m -by- q matrix X with orthonormal columns that has been partitioned into a 2-by-1 block structure:

$$X = \begin{bmatrix} X_{11} \\ X_{21} \end{bmatrix} = \begin{bmatrix} U_1 & | & \\ \hline & & U_2 \end{bmatrix} \frac{\begin{bmatrix} I & 0 & 0 \\ 0 & C & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & S & 0 \\ 0 & 0 & I \end{bmatrix}}{V_1^H}$$

x_{11} is p -by- q . The orthogonal/unitary matrices u_1 , u_2 , v_1 , and v_2 are p -by- p , $(m-p)$ -by- $(m-p)$, q -by- q , $(m-q)$ -by- $(m-q)$, respectively. C and S are r -by- r nonnegative diagonal matrices satisfying $C^2 + S^2 = I$, in which $r = \min(p, m-p, q, m-q)$.

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

jobu1 If equal to 'Y', then u_1 is computed. Otherwise, u_1 is not computed.

| | |
|---------------|---|
| <i>jobu2</i> | If equal to 'Y', then u_2 is computed. Otherwise, u_2 is not computed. |
| <i>jobv1t</i> | If equal to 'Y', then v_1^t is computed. Otherwise, v_1^t is not computed. |
| <i>m</i> | The number of rows and columns of the matrix X . |
| <i>p</i> | The number of rows in x_{11} . $0 \leq p \leq m$. |
| <i>q</i> | The number of columns in x_{11} . $0 \leq q \leq m$. |
| <i>x11</i> | Array, size ($ldx11 * q$). On entry, the part of the orthogonal matrix whose CSD is desired. |
| <i>ldx11</i> | The leading dimension of the array $x11$. $ldx11 \geq \max(1, p)$. |
| <i>x21</i> | Array, size ($ldx21 * q$). On entry, the part of the orthogonal matrix whose CSD is desired. |
| <i>ldx21</i> | The leading dimension of the array X . $ldx21 \geq \max(1, m - p)$. |
| <i>ldu1</i> | The leading dimension of the array u_1 . If <i>jobu1</i> = 'Y', $ldu1 \geq \max(1, p)$. |
| <i>ldu2</i> | The leading dimension of the array u_2 . If <i>jobu2</i> = 'Y', $ldu2 \geq \max(1, m - p)$. |
| <i>ldv1t</i> | The leading dimension of the array $v1t$. If <i>jobv1t</i> = 'Y', $ldv1t \geq \max(1, q)$. |

Output Parameters

| | |
|--------------|---|
| <i>theta</i> | Array, size r , in which $r = \min(p, m - p, q, m - q)$. $C = \text{diag}(\cos(\text{theta}(1)), \dots, \cos(\text{theta}(r)))$, and $S = \text{diag}(\sin(\text{theta}(1)), \dots, \sin(\text{theta}(r)))$. |
| <i>u1</i> | Array, size ($ldu1 * p$). If <i>jobu1</i> = 'Y', <i>u1</i> contains the p -by- p orthogonal/unitary matrix u_1 . |
| <i>u2</i> | Array, size ($ldu2 * (m - p)$). If <i>jobu2</i> = 'Y', <i>u2</i> contains the $(m - p)$ -by- $(m - p)$ orthogonal/unitary matrix u_2 . |
| <i>v1t</i> | Array, size ($ldv1t * q$). If <i>jobv1t</i> = 'Y', <i>v1t</i> contains the q -by- q orthogonal matrix v_1^T or unitary matrix v_1^H . |

Generalized Symmetric Definite Eigenvalue Problems: LAPACK Driver Routines

This section describes LAPACK driver routines used for solving generalized symmetric definite eigenproblems. See also [computational routines](#) that can be called to solve these problems. [Table "Driver Routines for Solving Generalized Symmetric Definite Eigenproblems"](#) lists all such driver routines.

Driver Routines for Solving Generalized Symmetric Definite Eigenproblems

| Routine Name | Operation performed |
|-----------------------------|---|
| sygv/hegv | Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem. |
| sygvd/hegvd | Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem. If eigenvectors are desired, it uses a divide and conquer method. |
| sygvx/hegvx | Computes selected eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem. |
| spgv/hpgv | Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with matrices in packed storage. |
| spgvd/hpgvd | Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with matrices in packed storage. If eigenvectors are desired, it uses a divide and conquer method. |
| spgvx/hpgvx | Computes selected eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with matrices in packed storage. |
| sbgv/hbgv | Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with banded matrices. |
| sbgvd/hbgvd | Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with banded matrices. If eigenvectors are desired, it uses a divide and conquer method. |
| sbgvx/hbgvx | Computes selected eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with banded matrices. |

?sygv

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem.

Syntax

```

Include Files

- mkl.h

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A*x = \lambda*B*x, A*B*x = \lambda*x, \text{ or } B*A*x = \lambda*x.$$

Here A and B are assumed to be symmetric and B is also positive definite.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>itype</i> | Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$; if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$; if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$. |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors. |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of A and B ; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of A and B . |
| <i>n</i> | The order of the matrices A and B ($n \geq 0$). |
| <i>a, b</i> | Arrays: <i>a</i> (size at least $\max(1, lda*n)$) contains the upper or lower triangle of the symmetric matrix A , as specified by <i>uplo</i> . <i>b</i> (size at least $\max(1, ldb*n)$) contains the upper or lower triangle of the symmetric positive definite matrix B , as specified by <i>uplo</i> . |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, n)$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; at least $\max(1, n)$. |

Output Parameters

| | |
|----------|---|
| <i>a</i> | On exit, if <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>a</i> contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if <i>itype</i> = 1 or 2, $Z^T*B*Z = I$; if <i>itype</i> = 3, $Z^T*inv(B)*Z = I$; If <i>jobz</i> = 'N', then on exit the upper triangle (if <i>uplo</i> = 'U') or the lower triangle (if <i>uplo</i> = 'L') of A , including the diagonal, is destroyed. |
|----------|---|

| | |
|----------|--|
| <i>b</i> | On exit, if $info \leq n$, the part of <i>b</i> containing the matrix is overwritten by the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$. |
| <i>w</i> | Array, size at least $\max(1, n)$. If $info = 0$, contains the eigenvalues in ascending order. |

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = -i$, the *i*-th parameter had an illegal value.

If $info > 0$, `spotrf/dpotrf` or `ssyev/dsyev` returned an error code:

If $info = i \leq n$, `ssyev/dsyev` failed to converge, and *i* off-diagonal elements of an intermediate tridiagonal did not converge to zero;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order *i* of *B* is not positive-definite. The factorization of *B* could not be completed and no eigenvalues or eigenvectors were computed.

?hegv

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem.

Syntax

```
lapack_int LAPACKE_chegv( int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b,
lapack_int ldb, float* w );
```

```
lapack_int LAPACKE_zhegv( int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b,
lapack_int ldb, double* w );
```

Include Files

- `mkl.h`

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$A * x = \lambda * B * x, \quad A * B * x = \lambda * x, \quad \text{or} \quad B * A * x = \lambda * x.$$

Here *A* and *B* are assumed to be Hermitian and *B* is also positive definite.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <i>itype</i> | Must be 1 or 2 or 3. Specifies the problem type to be solved: if $itype = 1$, the problem type is $A * x = \lambda * B * x$; if $itype = 2$, the problem type is $A * B * x = \lambda * x$; |

| | |
|-------------|---|
| | if $itype = 3$, the problem type is $B^*A*x = lambda*x$. |
| <i>jobz</i> | Must be 'N' or 'V'. If $jobz = 'N'$, then compute eigenvalues only. If $jobz = 'V'$, then compute eigenvalues and eigenvectors. |
| <i>uplo</i> | Must be 'U' or 'L'. If $uplo = 'U'$, arrays <i>a</i> and <i>b</i> store the upper triangles of <i>A</i> and <i>B</i> ; If $uplo = 'L'$, arrays <i>a</i> and <i>b</i> store the lower triangles of <i>A</i> and <i>B</i> . |
| <i>n</i> | The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$). |
| <i>a, b</i> | Arrays: <i>a</i> (size at least $\max(1, lda*n)$) contains the upper or lower triangle of the Hermitian matrix <i>A</i> , as specified by <i>uplo</i> . <i>b</i> (size at least $\max(1, ldb*n)$) contains the upper or lower triangle of the Hermitian positive definite matrix <i>B</i> , as specified by <i>uplo</i> . |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, n)$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; at least $\max(1, n)$. |

Output Parameters

| | |
|----------|---|
| <i>a</i> | On exit, if $jobz = 'V'$, then if $info = 0$, <i>a</i> contains the matrix <i>Z</i> of eigenvectors. The eigenvectors are normalized as follows: if $itype = 1$ or 2 , $Z^H*B*Z = I$; if $itype = 3$, $Z^H*inv(B)*Z = I$; If $jobz = 'N'$, then on exit the upper triangle (if $uplo = 'U'$) or the lower triangle (if $uplo = 'L'$) of <i>A</i> , including the diagonal, is destroyed. |
| <i>b</i> | On exit, if $info \leq n$, the part of <i>b</i> containing the matrix is overwritten by the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^H*U$ or $B = L*L^H$. |
| <i>w</i> | Array, size at least $\max(1, n)$. If $info = 0$, contains the eigenvalues in ascending order. |

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = -i$, the *i*-th parameter had an illegal value.

If $info > 0$, *cpotrf/zpotrf* or *cheev/zheev* return an error code:

If $info = i \leq n$, *cheev/zheev* fails to converge, and *i* off-diagonal elements of an intermediate tridiagonal do not converge to zero;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order *i* of *B* is not positive-definite. The factorization of *B* can not be completed and no eigenvalues or eigenvectors are computed.

?sygvd

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem using a divide and conquer method.

Syntax

```
lapack_int LAPACKE_ssygvd (int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, float* a, lapack_int lda, float* b, lapack_int ldb, float* w);
```

```
lapack_int LAPACKE_dsygvd (int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, double* a, lapack_int lda, double* b, lapack_int ldb, double* w);
```

Include Files

- mkl.h

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A*x = \lambda*B*x, \quad A*B*x = \lambda*x, \quad \text{or} \quad B*A*x = \lambda*x.$$

Here A and B are assumed to be symmetric and B is also positive definite.

It uses a divide and conquer algorithm.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>itype</i> | Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$; if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$; if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$. |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors. |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of A and B ; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of A and B . |
| <i>n</i> | The order of the matrices A and B ($n \geq 0$). |
| <i>a, b</i> | Arrays: <i>a</i> (size at least $lda*n$) contains the upper or lower triangle of the symmetric matrix A , as specified by <i>uplo</i> . <i>b</i> (size at least $ldb*n$) contains the upper or lower triangle of the symmetric positive definite matrix B , as specified by <i>uplo</i> . |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, n)$. |

ldb The leading dimension of *b*; at least $\max(1, n)$.

Output Parameters

a On exit, if *jobz* = 'V', then if *info* = 0, *a* contains the matrix *Z* of eigenvectors. The eigenvectors are normalized as follows:
 if *itype* = 1 or 2, $Z^T * B * Z = I$;
 if *itype* = 3, $Z^T * \text{inv}(B) * Z = I$;
 If *jobz* = 'N', then on exit the upper triangle (if *uplo* = 'U') or the lower triangle (if *uplo* = 'L') of *A*, including the diagonal, is destroyed.

b On exit, if $\text{info} \leq n$, the part of *b* containing the matrix is overwritten by the triangular factor *U* or *L* from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$.

w Array, size at least $\max(1, n)$.
 If *info* = 0, contains the eigenvalues in ascending order.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, an error code is returned as specified below.

- For $\text{info} \leq n$:
 - If *info* = *i* and *jobz* = 'N', then the algorithm failed to converge; *i* off-diagonal elements of an intermediate tridiagonal form did not converge to zero.
 - If *jobz* = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns $\text{info}/(n+1)$ through $\text{mod}(\text{info}, n+1)$.
- For *info* > *n*:
 - If *info* = *n* + *i*, for $1 \leq i \leq n$, then the leading minor of order *i* of *B* is not positive-definite. The factorization of *B* could not be completed and no eigenvalues or eigenvectors were computed.

?hegvd

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem using a divide and conquer method.

Syntax

```
lapack_int LAPACKE_chegvd( int matrix_layout, lapack_int itype, char jobz, char uplo,

double* z, lapack_int ldz, lapack_int* ifail);
```

Include Files

- mkl.h

Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A * x = \lambda * B * x, A * B * x = \lambda * x, \text{ or } B * A * x = \lambda * x.$$

Here A and B are assumed to be symmetric and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>itype</i> | Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$; if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$; if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$. |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors. |
| <i>range</i> | Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval: $vl < w[i] \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> . |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of <i>A</i> and <i>B</i> ; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of <i>A</i> and <i>B</i> . |
| <i>n</i> | The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$). |
| <i>a, b</i> | Arrays: <i>a</i> (size at least $\max(1, lda*n)$) contains the upper or lower triangle of the symmetric matrix <i>A</i> , as specified by <i>uplo</i> . <i>b</i> (size at least $\max(1, ldb*n)$) contains the upper or lower triangle of the symmetric positive definite matrix <i>B</i> , as specified by <i>uplo</i> . |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, n)$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; at least $\max(1, n)$. |
| <i>vl, vu</i> | If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced. |
| <i>il, iu</i> | If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$. |

If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol

ldz

The leading dimension of the output array *z*. Constraints:

$ldz \geq 1$; if *jobz* = 'V', $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout .

Output Parameters

a

On exit, the upper triangle (if *uplo* = 'U') or the lower triangle (if *uplo* = 'L') of *A*, including the diagonal, is overwritten.

b

On exit, if $info \leq n$, the part of *b* containing the matrix is overwritten by the triangular factor *U* or *L* from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$.

m

The total number of eigenvalues found,

$0 \leq m \leq n$. If *range* = 'A', $m = n$, and if *range* = 'I',
 $m = iu - il + 1$.

w, z

Arrays:

w, size at least $\max(1, n)$.

The first *m* elements of *w* contain the selected eigenvalues in ascending order.

z (size at least $\max(1, ldz * m)$ for column major layout and $\max(1, ldz * n)$ for row major layout) .

If *jobz* = 'V', then if *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *A* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with $w[i - 1]$. The eigenvectors are normalized as follows:

if *itype* = 1 or 2, $Z^T * B * Z = I$;

if *itype* = 3, $Z^T * \text{inv}(B) * Z = I$;

If *jobz* = 'N', then *z* is not referenced.

If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array *z*; if *range* = 'V', the exact value of *m* is not known in advance and an upper bound must be used.

ifail

Array, size at least $\max(1, n)$.

If *jobz* = 'V', then if *info* = 0, the first *m* elements of *ifail* are zero; if *info* > 0, the *ifail* contains the indices of the eigenvectors that failed to converge.

If *jobz* = 'N', then *ifail* is not referenced.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, *spotrf/dpotrf* and *ssyevx/dsyevx* returned an error code:

If *info* = $i \leq n$, *ssyevx/dsyevx* failed to converge, and *i* eigenvectors failed to converge. Their indices are stored in the array *ifail*;

If *info* = $n + i$, for $1 \leq i \leq n$, then the leading minor of order *i* of *B* is not positive-definite. The factorization of *B* could not be completed and no eigenvalues or eigenvectors were computed.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon \|T\|_1$ is used as tolerance, where *T* is the tridiagonal matrix obtained by reducing *C* to tridiagonal form, where *C* is the symmetric matrix of the standard symmetric problem to which the generalized problem is transformed. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * \text{lamch}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, set *abstol* to $2 * \text{lamch}('S')$.

?hegvx

Computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem.

Syntax

```
lapack_int LAPACKC_chegvx( int matrix_layout, lapack_int itype, char jobz, char range,
char uplo, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_complex_float*
b, lapack_int ldb, float vl, float vu, lapack_int il, lapack_int iu, float abstol,
lapack_int* m, float* w, lapack_complex_float* z, lapack_int ldz, lapack_int* ifail );

Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$A^*x = \lambda B^*x, \quad A^*B^*x = \lambda^*x, \quad \text{or} \quad B^*A^*x = \lambda^*x.$$

Here *A* and *B* are assumed to be Hermitian and *B* is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>itype</i> | <p>Must be 1 or 2 or 3. Specifies the problem type to be solved:</p> <p>if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$;</p> <p>if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$;</p> <p>if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$.</p> |
| <i>jobz</i> | <p>Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then compute eigenvalues only.</p> <p>If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.</p> |
| <i>range</i> | <p>Must be 'A' or 'V' or 'I'.</p> <p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval:</p> $vl < w[i] \leq vu.$ <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.</p> |
| <i>uplo</i> | <p>Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of <i>A</i> and <i>B</i>;</p> <p>If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of <i>A</i> and <i>B</i>.</p> |
| <i>n</i> | The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$). |
| <i>a, b</i> | <p>Arrays:</p> <p><i>a</i> (size at least $\max(1, lda*n)$) contains the upper or lower triangle of the Hermitian matrix <i>A</i>, as specified by <i>uplo</i>.</p> <p><i>b</i> (size at least $\max(1, ldb*n)$) contains the upper or lower triangle of the Hermitian positive definite matrix <i>B</i>, as specified by <i>uplo</i>.</p> |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, n)$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; at least $\max(1, n)$. |
| <i>vl, vu</i> | <p>If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.</p> <p>Constraint: $vl < vu$.</p> <p>If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.</p> |
| <i>il, iu</i> | <p>If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.</p> <p>Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.</p> |

If $range = 'A'$ or $'V'$, il and iu are not referenced.

abstol

The absolute error tolerance for the eigenvalues. See *Application Notes* for more information.

ldz

The leading dimension of the output array z . Constraints:

$ldz \geq 1$; if $jobz = 'V'$, $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout.

Output Parameters

a

On exit, the upper triangle (if $uplo = 'U'$) or the lower triangle (if $uplo = 'L'$) of A , including the diagonal, is overwritten.

b

On exit, if $info \leq n$, the part of b containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$.

m

The total number of eigenvalues found,

$0 \leq m \leq n$. If $range = 'A'$, $m = n$, and if $range = 'I'$,
 $m = iu - il + 1$.

w

Array, size at least $\max(1, n)$.

The first m elements of w contain the selected eigenvalues in ascending order.

z

Array z (size at least $\max(1, ldz * m)$ for column major layout and $\max(1, ldz * n)$ for row major layout).

If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w[i - 1]$. The eigenvectors are normalized as follows:

if $itype = 1$ or 2 , $Z^H * B * Z = I$;

if $itype = 3$, $Z^H * \text{inv}(B) * Z = I$;

If $jobz = 'N'$, then z is not referenced.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

ifail

Array, size at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of *ifail* are zero; if $info > 0$, the *ifail* contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then *ifail* is not referenced.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, `cpotrf/zpotrf` and `cheevx/zheevx` returned an error code:

If *info* = *i* ≤ *n*, `cheevx/zheevx` failed to converge, and *i* eigenvectors failed to converge. Their indices are stored in the array *ifail*;

If *info* = *n* + *i*, for 1 ≤ *i* ≤ *n*, then the leading minor of order *i* of *B* is not positive-definite. The factorization of *B* could not be completed and no eigenvalues or eigenvectors were computed.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to $abstol + \epsilon \cdot \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon \cdot \|T\|_1$ will be used in its place, where *T* is the tridiagonal matrix obtained by reducing *C* to tridiagonal form, where *C* is the symmetric matrix of the standard symmetric problem to which the generalized problem is transformed. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * \text{lamch}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * \text{lamch}('S')$.

?spgv

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with matrices in packed storage.

Syntax

```
lapack_int LAPACKE_sspgv (int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, float* ap, float* bp, float* w, float* z, lapack_int ldz);
```

```
lapack_int LAPACKE_dspgv (int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, double* ap, double* bp, double* w, double* z, lapack_int ldz);
```

Include Files

- mkl.h

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A*x = \lambda*B*x, A*B*x = \lambda*x, \text{ or } B*A*x = \lambda*x.$$

Here *A* and *B* are assumed to be symmetric, stored in packed format, and *B* is also positive definite.

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

itype Must be 1 or 2 or 3. Specifies the problem type to be solved:
if *itype* = 1, the problem type is $A*x = \lambda*B*x$;

| | |
|---------------|---|
| | if $itype = 2$, the problem type is $A*B*x = lambda*x$; if $itype = 3$, the problem type is $B*A*x = lambda*x$. |
| <i>jobz</i> | Must be 'N' or 'V'. If $jobz = 'N'$, then compute eigenvalues only. If $jobz = 'V'$, then compute eigenvalues and eigenvectors. |
| <i>uplo</i> | Must be 'U' or 'L'. If $uplo = 'U'$, arrays <i>ap</i> and <i>bp</i> store the upper triangles of <i>A</i> and <i>B</i> ; If $uplo = 'L'$, arrays <i>ap</i> and <i>bp</i> store the lower triangles of <i>A</i> and <i>B</i> . |
| <i>n</i> | The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$). |
| <i>ap, bp</i> | Arrays: <i>ap</i> contains the packed upper or lower triangle of the symmetric matrix <i>A</i> , as specified by <i>uplo</i> . The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$. <i>bp</i> contains the packed upper or lower triangle of the symmetric matrix <i>B</i> , as specified by <i>uplo</i> . The dimension of <i>bp</i> must be at least $\max(1, n*(n+1)/2)$. |
| <i>ldz</i> | The leading dimension of the output array <i>z</i> ; $ldz \geq 1$. If $jobz = 'V'$, $ldz \geq \max(1, n)$. |

Output Parameters

| | |
|-------------|--|
| <i>ap</i> | On exit, the contents of <i>ap</i> are overwritten. |
| <i>bp</i> | On exit, contains the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^T*U$ or $B = L*L^T$, in the same storage format as <i>B</i> . |
| <i>w, z</i> | Arrays: <i>w</i> , size at least $\max(1, n)$. If $info = 0$, contains the eigenvalues in ascending order. <i>z</i> (size $\max(1, ldz*n)$) . If $jobz = 'V'$, then if $info = 0$, <i>z</i> contains the matrix <i>Z</i> of eigenvectors. The eigenvectors are normalized as follows: if $itype = 1$ or 2 , $Z^T*B*Z = I$; if $itype = 3$, $Z^T*inv(B)*Z = I$; If $jobz = 'N'$, then <i>z</i> is not referenced. |

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = -i$, the *i*-th parameter had an illegal value.

If $info > 0$, `sppstrf/dppstrf` and `sspev/dspev` returned an error code:

If $info = i \leq n$, `sspev/dspev` failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

?hpgv

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem with matrices in packed storage.

Syntax

```
lapack_int LAPACKE_chpgv( int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, lapack_complex_float* ap, lapack_complex_float* bp, float* w,
lapack_complex_float* z, lapack_int ldz );
```

```
lapack_int LAPACKE_zhpgv( int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, lapack_complex_double* ap, lapack_complex_double* bp, double* w,
lapack_complex_double* z, lapack_int ldz );
```

Include Files

- `mkl.h`

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$A*x = \lambda*B*x, A*B*x = \lambda*x, \text{ or } B*A*x = \lambda*x.$$

Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite.

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>itype</code> | Must be 1 or 2 or 3. Specifies the problem type to be solved: if <code>itype = 1</code> , the problem type is $A*x = \lambda*B*x$; if <code>itype = 2</code> , the problem type is $A*B*x = \lambda*x$; if <code>itype = 3</code> , the problem type is $B*A*x = \lambda*x$. |
| <code>jobz</code> | Must be 'N' or 'V'. If <code>jobz = 'N'</code> , then compute eigenvalues only. If <code>jobz = 'V'</code> , then compute eigenvalues and eigenvectors. |
| <code>uplo</code> | Must be 'U' or 'L'. If <code>uplo = 'U'</code> , arrays <code>ap</code> and <code>bp</code> store the upper triangles of A and B ; If <code>uplo = 'L'</code> , arrays <code>ap</code> and <code>bp</code> store the lower triangles of A and B . |

| | |
|----------|---|
| n | The order of the matrices A and B ($n \geq 0$). |
| ap, bp | Arrays: ap contains the packed upper or lower triangle of the Hermitian matrix A , as specified by $uplo$. The dimension of ap must be at least $\max(1, n*(n+1)/2)$. bp contains the packed upper or lower triangle of the Hermitian matrix B , as specified by $uplo$. The dimension of bp must be at least $\max(1, n*(n+1)/2)$. |
| ldz | The leading dimension of the output array z ; $ldz \geq 1$. If $jobz = 'V'$, $ldz \geq \max(1, n)$. |

Output Parameters

| | |
|------|--|
| ap | On exit, the contents of ap are overwritten. |
| bp | On exit, contains the triangular factor U or L from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$, in the same storage format as B . |
| w | Array, size at least $\max(1, n)$. If $info = 0$, contains the eigenvalues in ascending order. |
| z | Array z (size $\max(1, ldz*n)$). If $jobz = 'V'$, then if $info = 0$, z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if $itype = 1$ or 2 , $Z^H * B * Z = I$; if $itype = 3$, $Z^H * \text{inv}(B) * Z = I$; If $jobz = 'N'$, then z is not referenced. |

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info > 0$, `cpptrf/zpptrf` and `chpev/zhpev` returned an error code:

If $info = i \leq n$, `chpev/zhpev` failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

?spgvd

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with matrices in packed storage using a divide and conquer method.

Syntax

```
lapack_int LAPACKE_sspgvd (int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, float* ap, float* bp, float* w, float* z, lapack_int ldz);
```

```
lapack_int LAPACKE_dspgvd (int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, double* ap, double* bp, double* w, double* z, lapack_int ldz);
```

Include Files

lapack_int iu, double abstol, lapack_int* m, double* w, double* z, lapack_int ldz,
lapack_int* ifail);
```

Include Files

- `mkl.h`

Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A * x = \lambda * B * x, A * B * x = \lambda * x, \text{ or } B * A * x = \lambda * x.$$

Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite.

Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

itype Must be 1 or 2 or 3. Specifies the problem type to be solved:
 if $itype = 1$, the problem type is $A * x = \lambda * B * x$;

| | |
|---------------|--|
| | <p>if $itype = 2$, the problem type is $A*B*x = lambda*x$;</p> <p>if $itype = 3$, the problem type is $B*A*x = lambda*x$.</p> |
| <i>jobz</i> | <p>Must be 'N' or 'V'.</p> <p>If $jobz = 'N'$, then compute eigenvalues only.</p> <p>If $jobz = 'V'$, then compute eigenvalues and eigenvectors.</p> |
| <i>range</i> | <p>Must be 'A' or 'V' or 'I'.</p> <p>If $range = 'A'$, the routine computes all eigenvalues.</p> <p>If $range = 'V'$, the routine computes eigenvalues $w[i]$ in the half-open interval:</p> $vl < w[i] \leq vu.$ <p>If $range = 'I'$, the routine computes eigenvalues with indices il to iu.</p> |
| <i>uplo</i> | <p>Must be 'U' or 'L'.</p> <p>If $uplo = 'U'$, arrays ap and bp store the upper triangles of A and B;</p> <p>If $uplo = 'L'$, arrays ap and bp store the lower triangles of A and B.</p> |
| <i>n</i> | The order of the matrices A and B ($n \geq 0$). |
| <i>ap, bp</i> | <p>Arrays:</p> <p>ap contains the packed upper or lower triangle of the symmetric matrix A, as specified by $uplo$.</p> <p>The size of ap must be at least $\max(1, n*(n+1)/2)$.</p> <p>bp contains the packed upper or lower triangle of the symmetric matrix B, as specified by $uplo$.</p> <p>The size of bp must be at least $\max(1, n*(n+1)/2)$.</p> |
| <i>vl, vu</i> | <p>If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.</p> <p>Constraint: $vl < vu$.</p> <p>If $range = 'A'$ or 'I', vl and vu are not referenced.</p> |
| <i>il, iu</i> | <p>If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned.</p> <p>Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.</p> <p>If $range = 'A'$ or 'V', il and iu are not referenced.</p> |
| <i>abstol</i> | The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information. |
| <i>ldz</i> | <p>The leading dimension of the output array z. Constraints:</p> <p>$ldz \geq 1$; if $jobz = 'V'$, $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout .</p> |

Output Parameters

| | |
|--------------|---|
| <i>ap</i> | On exit, the contents of <i>ap</i> are overwritten. |
| <i>bp</i> | On exit, contains the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$, in the same storage format as <i>B</i> . |
| <i>m</i> | The total number of eigenvalues found, $0 \leq m \leq n$. If <i>range</i> = 'A', $m = n$, and if <i>range</i> = 'I', $m = i_u - i_l + 1$. |
| <i>w, z</i> | Arrays: <i>w</i> , size at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues in ascending order. <i>z</i> (size at least $\max(1, ldz * m)$ for column major layout and $\max(1, ldz * n)$ for row major layout) . If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>A</i> corresponding to the selected eigenvalues, with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with <i>w</i> (<i>i</i>). The eigenvectors are normalized as follows: if <i>itype</i> = 1 or 2, $Z^T * B * Z = I$; if <i>itype</i> = 3, $Z^T * \text{inv}(B) * Z = I$; If <i>jobz</i> = 'N', then <i>z</i> is not referenced. If an eigenvector fails to converge, then that column of <i>z</i> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i> . Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array <i>z</i> ; if <i>range</i> = 'V', the exact value of <i>m</i> is not known in advance and an upper bound must be used. |
| <i>ifail</i> | Array, size at least $\max(1, n)$. If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> elements of <i>ifail</i> are zero; if <i>info</i> > 0, the <i>ifail</i> contains the indices of the eigenvectors that failed to converge. If <i>jobz</i> = 'N', then <i>ifail</i> is not referenced. |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, *sppstrf/dppstrf* and *sspevx/dspevx* returned an error code:

If *info* = $i \leq n$, *sspevx/dspevx* failed to converge, and *i* eigenvectors failed to converge. Their indices are stored in the array *ifail*;

If *info* = $n + i$, for $1 \leq i \leq n$, then the leading minor of order *i* of *B* is not positive-definite. The factorization of *B* could not be completed and no eigenvalues or eigenvectors were computed.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \cdot \max(|a|, |b|)$, where ϵ is the machine precision.

If $abstol$ is less than or equal to zero, then $\epsilon \cdot \|T\|_1$ is used instead, where T is the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues are computed most accurately when $abstol$ is set to twice the underflow threshold $2 \cdot \text{?lamch}('S')$, not zero.

If this routine returns with $info > 0$, indicating that some eigenvectors did not converge, set $abstol$ to $2 \cdot \text{?lamch}('S')$.

?hpgvx

Computes selected eigenvalues and, optionally, eigenvectors of a generalized Hermitian positive-definite eigenproblem with matrices in packed storage.

Syntax

```
lapack_int LAPACKE_chpgvx( int matrix_layout, lapack_int itype, char jobz, char range,

Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$A^*x = \lambda B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>itype</i> | Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A^*x = \lambda B^*x$; if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda^*x$; if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda^*x$. |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. |

| | |
|---------------|---|
| | If $jobz = 'V'$, then compute eigenvalues and eigenvectors. |
| <i>range</i> | Must be 'A' or 'V' or 'I'. If $range = 'A'$, the routine computes all eigenvalues. If $range = 'V'$, the routine computes eigenvalues $w[i]$ in the half-open interval: $v_l < w[i] \leq v_u$. If $range = 'I'$, the routine computes eigenvalues with indices il to iu . |
| <i>uplo</i> | Must be 'U' or 'L'. If $uplo = 'U'$, arrays ap and bp store the upper triangles of A and B ; If $uplo = 'L'$, arrays ap and bp store the lower triangles of A and B . |
| <i>n</i> | The order of the matrices A and B ($n \geq 0$). |
| <i>ap, bp</i> | Arrays: ap contains the packed upper or lower triangle of the Hermitian matrix A , as specified by $uplo$. The dimension of ap must be at least $\max(1, n*(n+1)/2)$. bp contains the packed upper or lower triangle of the Hermitian matrix B , as specified by $uplo$. The dimension of bp must be at least $\max(1, n*(n+1)/2)$. |
| <i>vl, vu</i> | If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$. If $range = 'A'$ or 'I', vl and vu are not referenced. |
| <i>il, iu</i> | If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$. If $range = 'A'$ or 'V', il and iu are not referenced. |
| <i>abstol</i> | The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information. |
| <i>ldz</i> | The leading dimension of the output array z ; $ldz \geq 1$. If $jobz = 'V'$, $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout. |

Output Parameters

| | |
|-----------|---|
| <i>ap</i> | On exit, the contents of ap are overwritten. |
| <i>bp</i> | On exit, contains the triangular factor U or L from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$, in the same storage format as B . |

| | |
|--------------|--|
| <i>m</i> | <p>The total number of eigenvalues found, $0 \leq m \leq n$. If <i>range</i> = 'A', $m = n$, and if <i>range</i> = 'I', $m = i_u - i_l + 1$.</p> |
| <i>w</i> | <p>Array, size at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues in ascending order.</p> |
| <i>z</i> | <p>Array <i>z</i> (size at least $\max(1, ldz * m)$ for column major layout and $\max(1, ldz * n)$ for row major layout). If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>A</i> corresponding to the selected eigenvalues, with the <i>i</i>-th column of <i>z</i> holding the eigenvector associated with <i>w</i>(<i>i</i>). The eigenvectors are normalized as follows: if <i>itype</i> = 1 or 2, $Z^H * B * Z = I$; if <i>itype</i> = 3, $Z^H * \text{inv}(B) * Z = I$; If <i>jobz</i> = 'N', then <i>z</i> is not referenced. If an eigenvector fails to converge, then that column of <i>z</i> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i>. Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array <i>z</i>; if <i>range</i> = 'V', the exact value of <i>m</i> is not known in advance and an upper bound must be used.</p> |
| <i>ifail</i> | <p>Array, size at least $\max(1, n)$. If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> elements of <i>ifail</i> are zero; if <i>info</i> > 0, the <i>ifail</i> contains the indices of the eigenvectors that failed to converge. If <i>jobz</i> = 'N', then <i>ifail</i> is not referenced.</p> |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, *cpptrf/zpptrf* and *chpevx/zhpevx* returned an error code:

If *info* = $i \leq n$, *chpevx/zhpevx* failed to converge, and *i* eigenvectors failed to converge. Their indices are stored in the array *ifail*;

If *info* = $n + i$, for $1 \leq i \leq n$, then the leading minor of order *i* of *B* is not positive-definite. The factorization of *B* could not be completed and no eigenvalues or eigenvectors were computed.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to $abstol + \epsilon * \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon * ||T||_1$ is used as tolerance, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * ?lamch('S')$, not zero.

If this routine returns with $info > 0$, indicating that some eigenvectors did not converge, try setting $abstol$ to $2*?lamch('S')$.

?sbgv

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with banded matrices.

Syntax

```
lapack_int LAPACKE_ssbgv (int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_int ka, lapack_int kb, float* ab, lapack_int ldab, float* bb, lapack_int ldbb,
float* w, float* z, lapack_int ldz);
```

```
lapack_int LAPACKE_dsbgv (int matrix_layout, char jobz, char uplo, lapack_int n,

Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A*x = \lambda*B*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors. |
| <i>uplo</i> | Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of A and B ; If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of A and B . |
| <i>n</i> | The order of the matrices A and B ($n \geq 0$). |
| <i>ka</i> | The number of super- or sub-diagonals in A ($ka \geq 0$). |
| <i>kb</i> | The number of super- or sub-diagonals in B ($kb \geq 0$). |
| <i>ab, bb</i> | Arrays: <i>ab</i> (size at least $\max(1, ldab*n)$ for column major layout and $\max(1, ldab*(ka + 1))$ for row major layout) is an array containing either upper or lower triangular part of the symmetric matrix A (as specified by <i>uplo</i>) in band storage format. |

bb (size at least $\max(1, ldbb*n)$ for column major layout and $\max(1, ldbb*(kb + 1))$ for row major layout) is an array containing either upper or lower triangular part of the symmetric matrix B (as specified by $uplo$) in band storage format.

$ldab$ The leading dimension of the array ab ; must be at least $ka+1$ for column major layout and at least $\max(1, n)$ for row major layout .

$ldbb$ The leading dimension of the array bb ; must be at least $kb+1$ for column major layout and at least $\max(1, n)$ for row major layout.

ldz The leading dimension of the output array z ; $ldz \geq 1$. If $jobz = 'V'$, $ldz \geq \max(1, n)$.

Output Parameters

ab On exit, the contents of ab are overwritten.

bb On exit, contains the factor S from the split Cholesky factorization $B = S^T * S$, as returned by [pbstf/pbstf](#).

w, z Arrays:
 w , size at least $\max(1, n)$.
 If $info = 0$, contains the eigenvalues in ascending order.
 z (size at least $\max(1, ldz*n)$) .
 If $jobz = 'V'$, then if $info = 0$, z contains the matrix Z of eigenvectors, with the i -th column of z holding the eigenvector associated with $w(i)$. The eigenvectors are normalized so that $Z^T * B * Z = I$.
 If $jobz = 'N'$, then z is not referenced.

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info > 0$, and

if $i \leq n$, the algorithm failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if $info = n + i$, for $1 \leq i \leq n$, then [pbstf/pbstf](#) returned $info = i$ and B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

?hbgv

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem with banded matrices.

Syntax

```
lapack_int LAPACKE_chbgv( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_int ka, lapack_int kb, lapack_complex_float* ab, lapack_int ldab,
lapack_complex_float* bb, lapack_int ldbb, float* w, lapack_complex_float* z,
lapack_int ldz );
```

```
lapack_int LAPACKE_zhbgv( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_int ka, lapack_int kb, lapack_complex_double* ab, lapack_int ldab,
lapack_complex_double* bb, lapack_int ldbb, double* w, lapack_complex_double* z,
lapack_int ldz );

Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A*x = \lambda*B*x$. Here *A* and *B* are assumed to be symmetric and banded, and *B* is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

jobz Must be 'N' or 'V'.

| | |
|---------------|---|
| | If $jobz = 'N'$, then compute eigenvalues only. |
| | If $jobz = 'V'$, then compute eigenvalues and eigenvectors. |
| <i>range</i> | Must be 'A' or 'V' or 'I'. |
| | If $range = 'A'$, the routine computes all eigenvalues. |
| | If $range = 'V'$, the routine computes eigenvalues $w[i]$ in the half-open interval: $vl < w[i] \leq vu$. |
| | If $range = 'I'$, the routine computes eigenvalues in range il to iu . |
| <i>uplo</i> | Must be 'U' or 'L'. |
| | If $uplo = 'U'$, arrays <i>ab</i> and <i>bb</i> store the upper triangles of <i>A</i> and <i>B</i> ; |
| | If $uplo = 'L'$, arrays <i>ab</i> and <i>bb</i> store the lower triangles of <i>A</i> and <i>B</i> . |
| <i>n</i> | The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$). |
| <i>ka</i> | The number of super- or sub-diagonals in <i>A</i> ($ka \geq 0$). |
| <i>kb</i> | The number of super- or sub-diagonals in <i>B</i> ($kb \geq 0$). |
| <i>ab, bb</i> | Arrays: <i>ab</i> (size at least $\max(1, ldab * n)$ for column major layout and $\max(1, ldab * (ka + 1))$ for row major layout) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. <i>bb</i> (size at least $\max(1, ldbb * n)$ for column major layout and $\max(1, ldbb * (kb + 1))$ for row major layout) is an array containing either upper or lower triangular part of the symmetric matrix <i>B</i> (as specified by <i>uplo</i>) in band storage format. |
| <i>ldab</i> | The leading dimension of the array <i>ab</i> ; must be at least $ka+1$ for column major layout and at least $\max(1, n)$ for row major layout. |
| <i>ldbb</i> | The leading dimension of the array <i>bb</i> ; must be at least $kb+1$ for column major layout and at least $\max(1, n)$ for row major layout. |
| <i>vl, vu</i> | If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$. If $range = 'A'$ or 'I', <i>vl</i> and <i>vu</i> are not referenced. |
| <i>il, iu</i> | If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$. If $range = 'A'$ or 'V', <i>il</i> and <i>iu</i> are not referenced. |

| | |
|---------------|---|
| <i>abstol</i> | The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information. |
| <i>ldz</i> | The leading dimension of the output array <i>z</i> ; $ldz \geq 1$. If <i>jobz</i> = 'V', $ldz \geq \max(1, n)$. |
| <i>ldq</i> | The leading dimension of the output array <i>q</i> ; $ldq < 1$. If <i>jobz</i> = 'V', $ldq < \max(1, n)$. |

Output Parameters

| | |
|----------------|---|
| <i>ab</i> | On exit, the contents of <i>ab</i> are overwritten. |
| <i>bb</i> | On exit, contains the factor <i>S</i> from the split Cholesky factorization $B = S^T * S$, as returned by pbstf/pbstf . |
| <i>m</i> | The total number of eigenvalues found, $0 \leq m \leq n$. If <i>range</i> = 'A', $m = n$, and if <i>range</i> = 'I', $m = iu - il + 1$. |
| <i>w, z, q</i> | Arrays: <i>w</i> , size at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues in ascending order. <i>z</i> (size $\max(1, ldz * m)$ for column major layout and $\max(1, ldz * n)$ for row major layout) . If <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>z</i> contains the matrix <i>Z</i> of eigenvectors, with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with <i>w</i> (<i>i</i>). The eigenvectors are normalized so that $Z^T * B * Z = I$. If <i>jobz</i> = 'N', then <i>z</i> is not referenced. <i>q</i> (size $\max(1, ldq * n)$) . If <i>jobz</i> = 'V', then <i>q</i> contains the <i>n</i> -by- <i>n</i> matrix used in the reduction of $A * x = \lambda * B * x$ to standard form, that is, $C * x = \lambda * x$ and consequently <i>C</i> to tridiagonal form. If <i>jobz</i> = 'N', then <i>q</i> is not referenced. |
| <i>ifail</i> | Array, size <i>m</i> . If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> elements of <i>ifail</i> are zero; if <i>info</i> > 0, the <i>ifail</i> contains the indices of the eigenvectors that failed to converge. If <i>jobz</i> = 'N', then <i>ifail</i> is not referenced. |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, and

if $i \leq n$, the algorithm failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if $info = n + i$, for $1 \leq i \leq n$, then `pbstf/pbstf` returned $info = i$ and B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \varepsilon \max(|a|, |b|)$, where ε is the machine precision.

If $abstol$ is less than or equal to zero, then $\varepsilon * ||T||_1$ is used as tolerance, where T is the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues will be computed most accurately when $abstol$ is set to twice the underflow threshold $2 * ?lamch('S')$, not zero.

If this routine returns with $info > 0$, indicating that some eigenvectors did not converge, try setting $abstol$ to $2 * ?lamch('S')$.

?hbgvx

Computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem with banded matrices.

Syntax

```
lapack_int LAPACKE_chbgvx( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_int ka, lapack_int kb, lapack_complex_float* ab, lapack_int ldab,
lapack_complex_float* bb, lapack_int ldbb, lapack_complex_float* q, lapack_int ldq,
float vl, float vu, lapack_int il, lapack_int iu, float abstol, lapack_int* m, float*
w, lapack_complex_float* z, lapack_int ldz, lapack_int* ifail );
```

```
lapack_int LAPACKE_zhbgvx( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_int ka, lapack_int kb, lapack_complex_double* ab, lapack_int
ldab, lapack_complex_double* bb, lapack_int ldbb, lapack_complex_double* q, lapack_int
ldq, double vl, double vu, lapack_int il, lapack_int iu, double abstol, lapack_int* m,
double* w, lapack_complex_double* z, lapack_int ldz, lapack_int* ifail );
```

Include Files

- mkl.h

Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite banded eigenproblem, of the form $A*x = \lambda*B*x$. Here A and B are assumed to be Hermitian and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobz</i> | Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors. |

| | |
|---------------|--|
| <i>range</i> | <p>Must be 'A' or 'V' or 'I'.</p> <p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval:</p> $vl < w[i] \leq vu.$ <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.</p> |
| <i>uplo</i> | <p>Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of <i>A</i> and <i>B</i>;</p> <p>If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of <i>A</i> and <i>B</i>.</p> |
| <i>n</i> | The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$). |
| <i>ka</i> | The number of super- or sub-diagonals in <i>A</i> ($ka \geq 0$). |
| <i>kb</i> | The number of super- or sub-diagonals in <i>B</i> ($kb \geq 0$). |
| <i>ab, bb</i> | <p>Arrays:</p> <p><i>ab</i>(size at least $\max(1, ldab * n)$ for column major layout and $\max(1, ldab * (ka + 1))$ for row major layout) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format.</p> <p><i>bb</i>(size at least $\max(1, ldbb * n)$ for column major layout and $\max(1, ldbb * (kb + 1))$ for row major layout) is an array containing either upper or lower triangular part of the Hermitian matrix <i>B</i> (as specified by <i>uplo</i>) in band storage format.</p> |
| <i>ldab</i> | The leading dimension of the array <i>ab</i> ; must be at least $ka+1$ for column major layout and at least $\max(1, n)$ for row major layout. |
| <i>ldbb</i> | The leading dimension of the array <i>bb</i> ; must be at least $kb+1$ for column major layout and at least $\max(1, n)$ for row major layout. |
| <i>vl, vu</i> | <p>If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.</p> <p>Constraint: $vl < vu$.</p> <p>If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.</p> |
| <i>il, iu</i> | <p>If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.</p> <p>Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.</p> <p>If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.</p> |
| <i>abstol</i> | The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information. |

| | |
|------------|---|
| <i>ldz</i> | The leading dimension of the output array <i>z</i> ; $ldz \geq 1$. If <i>jobz</i> = 'V', $ldz \geq \max(1, n)$ for column major layout and at least $\max(1, m)$ for row major layout. |
| <i>ldq</i> | The leading dimension of the output array <i>q</i> ; $ldq \geq 1$. If <i>jobz</i> = 'V', $ldq \geq \max(1, n)$. |

Output Parameters

| | |
|--------------|---|
| <i>ab</i> | On exit, the contents of <i>ab</i> are overwritten. |
| <i>bb</i> | On exit, contains the factor <i>S</i> from the split Cholesky factorization $B = S^H * S$, as returned by pbstf/pbstf . |
| <i>m</i> | The total number of eigenvalues found, $0 \leq m \leq n$. If <i>range</i> = 'A', $m = n$, and if <i>range</i> = 'I', $m = iu - il + 1$. |
| <i>w</i> | Array <i>w</i> , size at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues in ascending order. |
| <i>z, q</i> | Arrays: <i>z</i> (size $\max(1, ldz * m)$ for column major layout and $\max(1, ldz * n)$ for row major layout). If <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>z</i> contains the matrix <i>Z</i> of eigenvectors, with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with $w[i - 1]$. The eigenvectors are normalized so that $Z^H * B * Z = I$. If <i>jobz</i> = 'N', then <i>z</i> is not referenced. <i>q</i> (size $\max(1, ldq * n)$). If <i>jobz</i> = 'V', then <i>q</i> contains the <i>n</i> -by- <i>n</i> matrix used in the reduction of $Ax = \lambda Bx$ to standard form, that is, $Cx = \lambda x$ and consequently <i>C</i> to tridiagonal form. If <i>jobz</i> = 'N', then <i>q</i> is not referenced. |
| <i>ifail</i> | Array, size at least $\max(1, n)$. If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> elements of <i>ifail</i> are zero; if <i>info</i> > 0, the <i>ifail</i> contains the indices of the eigenvectors that failed to converge. If <i>jobz</i> = 'N', then <i>ifail</i> is not referenced. |

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, and

if $i \leq n$, the algorithm failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if $info = n + i$, for $1 \leq i \leq n$, then `pbstf/pbstf` returned $info = i$ and B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If $abstol$ is less than or equal to zero, then $\epsilon * ||T||_1$ will be used in its place, where T is the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues will be computed most accurately when $abstol$ is set to twice the underflow threshold $2 * ?lamch('S')$, not zero.

If this routine returns with $info > 0$, indicating that some eigenvectors did not converge, try setting $abstol$ to $2 * ?lamch('S')$.

Generalized Nonsymmetric Eigenvalue Problems: LAPACK Driver Routines

This section describes LAPACK driver routines used for solving generalized nonsymmetric eigenproblems. See also [computational routines](#) that can be called to solve these problems. [Table "Driver Routines for Solving Generalized Nonsymmetric Eigenproblems"](#) lists all such driver routines.

Driver Routines for Solving Generalized Nonsymmetric Eigenproblems

| Routine Name | Operation performed |
|-----------------------|--|
| gges | Computes the generalized eigenvalues, Schur form, and the left and/or right Schur vectors for a pair of nonsymmetric matrices. |
| ggesx | Computes the generalized eigenvalues, Schur form, and, optionally, the left and/or right matrices of Schur vectors. |
| gges3 | Computes generalized Schur factorization for a pair of matrices. |
| ggev | Computes the generalized eigenvalues, and the left and/or right generalized eigenvectors for a pair of nonsymmetric matrices. |
| ggev3 | Computes the generalized eigenvalues, and, optionally, the left and/or right generalized eigenvectors. |
| ggev3 | Computes generalized Schur factorization for a pair of matrices. |

?gges

Computes the generalized eigenvalues, Schur form, and the left and/or right Schur vectors for a pair of nonsymmetric matrices.

Syntax

```
lapack_int LAPACKE_sgges( int matrix_layout, char jobvsl, char jobvsr, char sort,

Description

The `?gges` routine computes the generalized eigenvalues, the generalized real/complex Schur form (S,T) , optionally, the left and/or right matrices of Schur vectors (vsl and vsr) for a pair of n -by- n real/complex nonsymmetric matrices (A,B) . This gives the generalized Schur factorization

$$(A,B) = (vsl * S * vsr^H, vsl * T * vsr^H)$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T . The leading columns of vsl and vsr then form an orthonormal/unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

If only the generalized eigenvalues are needed, use the driver `ggev` instead, which is faster.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio $alpha / beta = w$, such that $A - w * B$ is singular. It is usually represented as the pair $(alpha, beta)$, as there is a reasonable interpretation for $beta=0$ or for both being zero. A pair of matrices (S,T) is in the generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S are "standardized" by making the corresponding elements of T have the form:

$$\begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues. A pair of matrices (S,T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal of T are non-negative real numbers.

The `?gges` routine replaces the deprecated `?gegs` routine.

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>jobvsl</code> | Must be 'N' or 'V'. If <code>jobvsl = 'N'</code> , then the left Schur vectors are not computed. |

| | |
|---------------------|--|
| | If <i>jobvsl</i> = 'V', then the left Schur vectors are computed. |
| <i>jobvsr</i> | Must be 'N' or 'V'. If <i>jobvsr</i> = 'N', then the right Schur vectors are not computed. If <i>jobvsr</i> = 'V', then the right Schur vectors are computed. |
| <i>sort</i> | Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. If <i>sort</i> = 'N', then eigenvalues are not ordered. If <i>sort</i> = 'S', eigenvalues are ordered (see <i>select</i>). |
| <i>select</i> | The <i>select</i> parameter is a pointer to a function returning a value of <code>lapack_logical</code> type. For different flavors the function has different arguments: <pre>LAPACKE_sggcs: lapack_logical (*LAPACK_S_SELECT3) (const float*, const float*, const float*);</pre> <pre>LAPACKE_dggcs: lapack_logical (*LAPACK_D_SELECT3) (const double*, const double*, const double*);</pre> <pre>LAPACKE_cggcs: lapack_logical (*LAPACK_C_SELECT2) (const lapack_complex_float*, const lapack_complex_float*);</pre> <pre>LAPACKE_zggcs: lapack_logical (*LAPACK_Z_SELECT2) (const lapack_complex_double*, const lapack_complex_double*);</pre> If <i>sort</i> = 'S', <i>select</i> is used to select eigenvalues to sort to the top left of the Schur form. If <i>sort</i> = 'N', <i>select</i> is not referenced. <i>For real flavors:</i> An eigenvalue $(\text{alphar}[j] + \text{alphai}[j])/beta[j]$ is selected if <i>select</i> (<i>alphar</i> [<i>j</i>], <i>alphai</i> [<i>j</i>], <i>beta</i> [<i>j</i>]) is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy <i>select</i> (<i>alphar</i> [<i>j</i>], <i>alphai</i> [<i>j</i>], <i>beta</i> [<i>j</i>]) = 1 after ordering. In this case <i>info</i> is set to <i>n</i> +2 . <i>For complex flavors:</i> An eigenvalue $\text{alpha}[j] / \text{beta}[j]$ is selected if <i>select</i> (<i>alpha</i> [<i>j</i>], <i>beta</i> [<i>j</i>]) is true. Note that a selected complex eigenvalue may no longer satisfy <i>select</i> (<i>alpha</i> [<i>j</i>], <i>beta</i> [<i>j</i>]) = 1 after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case <i>info</i> is set to <i>n</i> +2 (see <i>info</i> below). |
| <i>n</i> | The order of the matrices <i>A</i> , <i>B</i> , <i>vsl</i> , and <i>vsr</i> ($n \geq 0$). |
| <i>a</i> , <i>b</i> | Arrays: <i>a</i> (size at least $\max(1, lda*n)$) is an array containing the <i>n</i> -by- <i>n</i> matrix <i>A</i> (first of the pair of matrices). |

b (size at least $\max(1, l_{db}*n)$) is an array containing the n -by- n matrix B (second of the pair of matrices).

lda The leading dimension of the array a . Must be at least $\max(1, n)$.

ldb The leading dimension of the array b . Must be at least $\max(1, n)$.

$ldvsl, ldvsr$ The leading dimensions of the output matrices vsl and vsr , respectively. Constraints:

$ldvsl \geq 1$. If $jobvsl = 'V'$, $ldvsl \geq \max(1, n)$.

$ldvsr \geq 1$. If $jobvsr = 'V'$, $ldvsr \geq \max(1, n)$.

Output Parameters

a On exit, this array has been overwritten by its generalized Schur form S .

b On exit, this array has been overwritten by its generalized Schur form T .

$sdim$ If $sort = 'N'$, $sdim = 0$.

If $sort = 'S'$, $sdim$ is equal to the number of eigenvalues (after sorting) for which $select$ is true.

Note that for real flavors complex conjugate pairs for which $select$ is true for either eigenvalue count as 2.

$alphar, alphai$ Arrays, size at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors.

See $beta$.

$alpha$ Array, size at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See $beta$.

$beta$ Array, size at least $\max(1, n)$.

For real flavors:

On exit, $(alphar[j] + alphai[j]*i)/beta[j]$, $j=0, \dots, n-1$, will be the generalized eigenvalues.

$alphar[j] + alphai[j]*i$ and $beta[j]$, $j=0, \dots, n-1$ are the diagonals of the complex Schur form (S, T) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (A, B) were further reduced to triangular form using complex unitary transformations. If $alphai[j]$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -st eigenvalues are a complex conjugate pair, with $alphai[j+1]$ negative.

For complex flavors:

On exit, $alpha[j]/beta[j]$, $j=0, \dots, n-1$, will be the generalized eigenvalues. $alpha[j]$ and $beta[j]$, $j=0, \dots, n-1$ are the diagonals of the complex Schur form (S, T) output by $cggges/zggges$. The $beta[j]$ will be non-negative real.

See also *Application Notes* below.

vsl, vsr

Arrays:

vsl (size at least $\max(1, ldvsl*n)$).

If $jobvsl = 'V'$, this array will contain the left Schur vectors.

If `jobvsl = 'N'`, `vsl` is not referenced.

`vsr` (size at least $\max(1, ldvsr * n)$).

If `jobvsr = 'V'`, this array will contain the right Schur vectors.

If `jobvsr = 'N'`, `vsr` is not referenced.

Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, the *i*-th parameter had an illegal value.

If `info = i`, and

$i \leq n$:

the QZ iteration failed. (*A*, *B*) is not in Schur form, but `alphar[j]`, `alphai[j]` (for real flavors), or `alpha[j]` (for complex flavors), and `beta[j]`, $j = info, \dots, n - 1$ should be correct.

$i > n$: errors that usually indicate LAPACK problems:

$i = n+1$: other than QZ iteration failed in `hgeqz`;

$i = n+2$: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the generalized Schur form no longer satisfy `select = 1`. This could also be caused due to scaling;

$i = n+3$: reordering failed in `tgsen`.

Application Notes

The quotients `alphar[j]/beta[j]` and `alphai[j]/beta[j]` may easily over- or underflow, and `beta[j]` may even be zero. Thus, you should avoid simply computing the ratio. However, `alphar` and `alphai` will be always less than and usually comparable with `norm(A)` in magnitude, and `beta` always less than and usually comparable with `norm(B)`.

?ggesx

Computes the generalized eigenvalues, Schur form, and, optionally, the left and/or right matrices of Schur vectors.

Syntax

```
lapack_int LAPACKE_sggesx( int matrix_layout, char jobvsl, char jobvsr, char sort,

Description

The routine computes for a pair of n -by- n real/complex nonsymmetric matrices (A,B) , the generalized eigenvalues, the generalized real/complex Schur form (S,T) , optionally, the left and/or right matrices of Schur vectors ($vs1$ and vsr). This gives the generalized Schur factorization

$$(A,B) = (vs1 * S * vsr^H, vs1 * T * vsr^H)$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T ; computes a reciprocal condition number for the average of the selected eigenvalues ($rconde$); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues ($rcondv$). The leading columns of $vs1$ and vsr then form an orthonormal/unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio $alpha / beta = w$, such that $A - w*B$ is singular. It is usually represented as the pair $(alpha, beta)$, as there is a reasonable interpretation for $beta=0$ or for both being zero. A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

$$\begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues. A pair of matrices (S,T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal of T are non-negative real numbers.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobvsl</i> | Must be 'N' or 'V'. If <i>jobvsl</i> = 'N', then the left Schur vectors are not computed. If <i>jobvsl</i> = 'V', then the left Schur vectors are computed. |
| <i>jobvsr</i> | Must be 'N' or 'V'. If <i>jobvsr</i> = 'N', then the right Schur vectors are not computed. If <i>jobvsr</i> = 'V', then the right Schur vectors are computed. |

| | |
|---------------------|---|
| <i>sort</i> | <p>Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form.</p> <p>If <i>sort</i> = 'N', then eigenvalues are not ordered.</p> <p>If <i>sort</i> = 'S', eigenvalues are ordered (see <i>select</i>).</p> |
| <i>select</i> | <p>The <i>select</i> parameter is a pointer to a function returning a value of <code>lapack_logical</code> type. For different flavors the function has different arguments:</p> <pre>LAPACKE_sggesx: lapack_logical (*LAPACK_S_SELECT3) (const float*, const float*, const float*);</pre> <pre>LAPACKE_dggesx: lapack_logical (*LAPACK_D_SELECT3) (const double*, const double*, const double*);</pre> <pre>LAPACKE_cggesx: lapack_logical (*LAPACK_C_SELECT2) (const lapack_complex_float*, const lapack_complex_float*);</pre> <pre>LAPACKE_zggesx: lapack_logical (*LAPACK_Z_SELECT2) (const lapack_complex_double*, const lapack_complex_double*);</pre> <p>If <i>sort</i> = 'S', <i>select</i> is used to select eigenvalues to sort to the top left of the Schur form.</p> <p>If <i>sort</i> = 'N', <i>select</i> is not referenced.</p> <p><i>For real flavors:</i></p> <p>An eigenvalue $(\text{alphar}[j] + \text{alphai}[j])/beta[j]$ is selected if <i>select</i>(<i>alphar</i>[<i>j</i>], <i>alphai</i>[<i>j</i>], <i>beta</i>[<i>j</i>]) is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.</p> <p>Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy <i>select</i>(<i>alphar</i>[<i>j</i>], <i>alphai</i>[<i>j</i>], <i>beta</i>[<i>j</i>]) = 1 after ordering. In this case <i>info</i> is set to <i>n</i>+2.</p> <p><i>For complex flavors:</i></p> <p>An eigenvalue $\text{alpha}[j] / \text{beta}[j]$ is selected if <i>select</i>(<i>alpha</i>[<i>j</i>], <i>beta</i>[<i>j</i>]) is true.</p> <p>Note that a selected complex eigenvalue may no longer satisfy <i>select</i>(<i>alpha</i>[<i>j</i>], <i>beta</i>[<i>j</i>]) = 1 after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case <i>info</i> is set to <i>n</i>+2 (see <i>info</i> below).</p> |
| <i>sense</i> | <p>Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.</p> <p>If <i>sense</i> = 'N', none are computed;</p> <p>If <i>sense</i> = 'E', computed for average of selected eigenvalues only;</p> <p>If <i>sense</i> = 'V', computed for selected deflating subspaces only;</p> <p>If <i>sense</i> = 'B', computed for both.</p> <p>If <i>sense</i> is 'E', 'V', or 'B', then <i>sort</i> must equal 'S'.</p> |
| <i>n</i> | The order of the matrices <i>A</i> , <i>B</i> , <i>vsl</i> , and <i>vsr</i> ($n \geq 0$). |
| <i>a</i> , <i>b</i> | Arrays: |

a (size at least $\max(1, lda*n)$) is an array containing the n -by- n matrix A (first of the pair of matrices).

b (size at least $\max(1, ldb*n)$) is an array containing the n -by- n matrix B (second of the pair of matrices).

lda The leading dimension of the array a .
Must be at least $\max(1, n)$.

ldb The leading dimension of the array b .
Must be at least $\max(1, n)$.

$ldvsl, ldvsr$ The leading dimensions of the output matrices vs_l and vs_r , respectively.
Constraints:

$ldvsl \geq 1$. If $jobvsl = 'V'$, $ldvsl \geq \max(1, n)$.

$ldvsr \geq 1$. If $jobvsr = 'V'$, $ldvsr \geq \max(1, n)$.

Output Parameters

a On exit, this array has been overwritten by its generalized Schur form S .

b On exit, this array has been overwritten by its generalized Schur form T .

$sdim$ If $sort = 'N'$, $sdim = 0$.
If $sort = 'S'$, $sdim$ is equal to the number of eigenvalues (after sorting) for which $select$ is true.

Note that for real flavors complex conjugate pairs for which $select$ is true for either eigenvalue count as 2.

$alphan, alphan_i$ Arrays, size at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors.

See $beta$.

$alpha$ Array, size at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See $beta$.

$beta$ Array, size at least $\max(1, n)$.

For real flavors:

On exit, $(alphan[j] + alphan_i[j]*i)/beta[j]$, $j=0, \dots, n-1$ will be the generalized eigenvalues.

$alphan[j] + alphan_i[j]*i$ and $beta[j]$, $j=0, \dots, n-1$ are the diagonals of the complex Schur form (S, T) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (A, B) were further reduced to triangular form using complex unitary transformations. If $alphan_i[j]$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -st eigenvalues are a complex conjugate pair, with $alphan_i[j+1]$ negative.

For complex flavors:

On exit, $alpha[j]/beta[j]$, $j=0, \dots, n-1$ will be the generalized eigenvalues. $alpha[j]$ and $beta[j]$, $j=0, \dots, n-1$ are the diagonals of the complex Schur form (S, T) output by `cggexs/zggexs`. The $beta[j]$ will be non-negative real.

See also *Application Notes* below.

vsl, *vsr*

Arrays:

vsl (size at least $\max(1, ldvsl*n)$).

If *jobvsl* = 'V', this array will contain the left Schur vectors.

If *jobvsl* = 'N', *vsl* is not referenced.

vsr (size at least $\max(1, ldvsr*n)$).

If *jobvsr* = 'V', this array will contain the right Schur vectors.

If *jobvsr* = 'N', *vsr* is not referenced.

rconde, *rcondv*

Arrays, size 2 each

If *sense* = 'E' or 'B', *rconde*(1) and *rconde*(2) contain the reciprocal condition numbers for the average of the selected eigenvalues.

Not referenced if *sense* = 'N' or 'V'.

If *sense* = 'V' or 'B', *rcondv*[0] and *rcondv*[1] contain the reciprocal condition numbers for the selected deflating subspaces.

Not referenced if *sense* = 'N' or 'E'.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, and

$i \leq n$:

the QZ iteration failed. (*A*, *B*) is not in Schur form, but *alphar*[*j*], *alphai*[*j*] (for real flavors), or *alpha*[*j*] (for complex flavors), and *beta*[*j*], $j = info, \dots, n - 1$ should be correct.

$i > n$: errors that usually indicate LAPACK problems:

$i = n+1$: other than QZ iteration failed in [hgeqz](#);

$i = n+2$: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the generalized Schur form no longer satisfy *select* = 1. This could also be caused due to scaling;

$i = n+3$: reordering failed in [tgsen](#).

Application Notes

The quotients *alphar*[*j*]/*beta*[*j*] and *alphai*[*j*]/*beta*[*j*] may easily over- or underflow, and *beta*[*j*] may even be zero. Thus, you should avoid simply computing the ratio. However, *alphar* and *alphai* will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and *beta* always less than and usually comparable with $\text{norm}(B)$.

?gges3

Computes generalized Schur factorization for a pair of matrices.

Syntax

```

- mkl.h

Description

For a pair of n -by- n real or complex nonsymmetric matrices (A,B) , ?gges3 computes the generalized eigenvalues, the generalized real or complex Schur form (S,T) , and optionally the left or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

$$(A,B) = ((VSL)*S*(VSR)^T, (VSL)*T*(VSR)^T) \text{ for real } (A,B)$$

or

$$(A,B) = ((VSL)*S*(VSR)^H, (VSL)*T*(VSR)^H) \text{ for complex } (A,B)$$

where $(VSR)^H$ is the conjugate-transpose of VSR .

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T . The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

NOTE

If only the generalized eigenvalues are needed, use the driver ?ggeev instead, which is faster.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio $alpha/beta = w$, such that $A - w*B$ is singular. It is usually represented as the pair $(alpha,beta)$, as there is a reasonable interpretation for $beta=0$ or both being zero.

For real flavors:

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

$$\begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T have a complex conjugate pair of generalized eigenvalues.

For complex flavors:

A pair of matrices (S, T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal elements of T are non-negative real numbers.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobvsl</i> | = 'N': do not compute the left Schur vectors; |
| <i>jobvsr</i> | = 'N': do not compute the right Schur vectors; = 'V': compute the right Schur vectors. |
| <i>sort</i> | Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see <i>selctg</i>). |
| <i>selctg</i> | <i>selctg</i> is a function of three arguments for real flavors or two arguments for complex flavors. <i>selctg</i> must be declared EXTERNAL in the calling subroutine. If <i>sort</i> = 'N', <i>selctg</i> is not referenced. If <i>sort</i> = 'S', <i>selctg</i> is used to select eigenvalues to sort to the top left of the Schur form. For real flavors: An eigenvalue $(\text{alphan}[j - 1] + \text{alphai}[j - 1])/\text{betan}[j - 1]$ is selected if $\text{selctg}(\text{alphan}[j - 1], \text{alphai}[j - 1], \text{betan}[j - 1])$ is true. In other words, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy $\text{selctg}(\text{alphan}[j - 1], \text{alphai}[j - 1], \text{betan}[j - 1]) \neq 0$ after ordering. <i>info</i> is to be set to $n+2$ in this case. For complex flavors: An eigenvalue $\text{alpha}[j - 1]/\text{betan}[j - 1]$ is selected if $\text{selctg}(\text{alpha}[j - 1], \text{betan}[j - 1])$ is true. Note that a selected complex eigenvalue may no longer satisfy $\text{selctg}(\text{alpha}[j - 1], \text{betan}[j - 1]) \neq 0$ after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case <i>info</i> returns $n + 2$. |
| <i>n</i> | The order of the matrices A , B , VSL , and VSR . $n \geq 0$. |
| <i>a</i> | Array, size $(lda * n)$. On entry, the first of the pair of matrices. |
| <i>lda</i> | The leading dimension of a . $lda \geq \max(1, n)$. |
| <i>b</i> | Array, size $(ldb * n)$. On entry, the second of the pair of matrices. |

| | |
|--------------|--|
| <i>ldb</i> | The leading dimension of <i>b</i> . $ldb \geq \max(1, n)$. |
| <i>ldvsl</i> | The leading dimension of the matrix <i>VSL</i> . $ldvsl \geq 1$, and if <i>jobvsl</i> = 'V', $ldvsl \geq n$. |
| <i>ldvsr</i> | The leading dimension of the matrix <i>VSR</i> . $ldvsr \geq 1$, and if <i>jobvsr</i> = 'V', $ldvsr \geq n$. |

Output Parameters

| | |
|----------------|---|
| <i>a</i> | On exit, <i>a</i> is overwritten by its generalized Schur form <i>S</i> . |
| <i>b</i> | On exit, <i>b</i> is overwritten by its generalized Schur form <i>T</i> . |
| <i>sdim</i> | If <i>sort</i> = 'N', <i>sdim</i> = 0. If <i>sort</i> = 'S', <i>sdim</i> = number of eigenvalues (after sorting) for which <i>selctg</i> is true. |
| <i>alpha</i> | Array, size (<i>n</i>). |
| <i>alphar</i> | Array, size (<i>n</i>). |
| <i>alpha_i</i> | Array, size (<i>n</i>). |
| <i>beta</i> | Array, size (<i>n</i>). |

For real flavors:

On exit, $(\text{alphar}[j - 1] + \text{alpha}_i[j - 1]*i)/\text{beta}[j - 1]$, $j=1, \dots, n$, are the generalized eigenvalues. $\text{alphar}[j - 1] + \text{alpha}_i[j - 1]*i$, and $\text{beta}[j - 1]$, $j=1, \dots, n$ are the diagonals of the complex Schur form (*S*, *T*) that would result if the 2-by-2 diagonal blocks of the real Schur form of (*a*, *b*) were further reduced to triangular form using 2-by-2 complex unitary transformations. If $\text{alpha}_i[j - 1]$ is zero, then the *j*-th eigenvalue is real; if positive, then the *j*-th and (*j*+1)-st eigenvalues are a complex conjugate pair, with $\text{alpha}_i[j]$ negative.

Note: the quotients $\text{alphar}[j - 1]/\text{beta}[j - 1]$ and $\text{alpha}_i[j - 1]/\text{beta}[j - 1]$ can easily over- or underflow, and $\text{beta}[j - 1]$ might even be zero. Thus, you should avoid computing the ratio alpha/beta by simply dividing *alpha* by *beta*. However, *alphar* and *alpha_i* is always less than and usually comparable with $\text{norm}(a)$ in magnitude, and *beta* is always less than and usually comparable with $\text{norm}(b)$.

For complex flavors:

On exit, $\text{alpha}[j - 1][j - 1]/\text{beta}[j - 1]$, $j=1, \dots, n$, are the generalized eigenvalues. $\text{alpha}[j - 1]$, $j=1, \dots, n$ and $\text{beta}[j - 1]$, $j=1, \dots, n$ are the diagonals of the complex Schur form (*a*, *b*) output by *gges3*. The $\text{beta}[j - 1]$ is non-negative real.

Note: the quotient $\text{alpha}[j - 1][j - 1]/\text{beta}[j - 1]$ can easily over- or underflow, and $\text{beta}[j - 1]$ might even be zero. Thus, you should avoid computing the ratio alpha/beta by simply dividing *alpha* by *beta*. However, *alpha* is always less than and usually comparable with $\text{norm}(a)$ in magnitude, and *beta* is always less than and usually comparable with $\text{norm}(b)$.

Include Files

- `mk1.h`

Description

The `?ggeev` routine computes the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors for a pair of n -by- n real/complex nonsymmetric matrices (A,B) .

A generalized eigenvalue for a pair of matrices (A,B) is a scalar λ or a ratio $alpha / beta = \lambda$, such that $A - \lambda*B$ is singular. It is usually represented as the pair $(alpha, beta)$, as there is a reasonable interpretation for $beta = 0$ and even for both being zero.

The right generalized eigenvector $v(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A,B) satisfies $A*v(j) = \lambda(j)*B*v(j)$.

The left generalized eigenvector $u(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A,B) satisfies $u(j)^H*A = \lambda(j)*u(j)^H*B$

where $u(j)^H$ denotes the conjugate transpose of $u(j)$.

The `?ggeev` routine replaces the deprecated `?gegev` routine.

Input Parameters

| | |
|----------------------------|--|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <code>jobvl</code> | Must be 'N' or 'V'. If <code>jobvl = 'N'</code> , the left generalized eigenvectors are not computed; If <code>jobvl = 'V'</code> , the left generalized eigenvectors are computed. |
| <code>jobvr</code> | Must be 'N' or 'V'. If <code>jobvr = 'N'</code> , the right generalized eigenvectors are not computed; If <code>jobvr = 'V'</code> , the right generalized eigenvectors are computed. |
| <code>n</code> | The order of the matrices A , B , vl , and vr ($n \geq 0$). |
| <code>a, b</code> | Arrays: a (size at least $\max(1, lda*n)$) is an array containing the n -by- n matrix A (first of the pair of matrices). b (size at least $\max(1, ldb*n)$) is an array containing the n -by- n matrix B (second of the pair of matrices). |
| <code>lda</code> | The leading dimension of the array a . Must be at least $\max(1, n)$. |
| <code>ldb</code> | The leading dimension of the array b . Must be at least $\max(1, n)$. |
| <code>ldvl, ldvr</code> | The leading dimensions of the output matrices vl and vr , respectively. Constraints: $ldvl \geq 1$. If <code>jobvl = 'V'</code> , $ldvl \geq \max(1, n)$. $ldvr \geq 1$. If <code>jobvr = 'V'</code> , $ldvr \geq \max(1, n)$. |

Output Parameters

| | |
|-----------------------|---|
| <i>a, b</i> | On exit, these arrays have been overwritten. |
| <i>alphar, alphai</i> | Arrays, size at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors. See <i>beta</i> . |
| <i>alpha</i> | Array, size at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See <i>beta</i> . |
| <i>beta</i> | Array, size at least $\max(1, n)$. <i>For real flavors:</i> On exit, $(\text{alphar}[j] + \text{alphai}[j]*i)/\text{beta}[j]$, $j=0, \dots, n - 1$, are the generalized eigenvalues. If <i>alphai</i> [<i>j</i>] is zero, then the <i>j</i> -th eigenvalue is real; if positive, then the <i>j</i> -th and (<i>j</i> +1)-st eigenvalues are a complex conjugate pair, with <i>alphai</i> [<i>j</i> +1] negative. <i>For complex flavors:</i> On exit, $\text{alpha}[j]/\text{beta}[j]$, $j=0, \dots, n - 1$, are the generalized eigenvalues. See also <i>Application Notes</i> below. |
| <i>vl, vr</i> | Arrays: <i>vl</i> (size at least $\max(1, \text{ldvl}*n)$). Contains the matrix of left generalized eigenvectors <i>VL</i> . If <i>jobvl</i> = 'V', the left generalized eigenvectors u_j are stored one after another in the columns of <i>VL</i> , in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$. If <i>jobvl</i> = 'N', <i>vl</i> is not referenced. <i>For real flavors:</i> If the <i>j</i> -th eigenvalue is real, then the <i>k</i> -th component of the <i>j</i> -th left eigenvector u_j is stored in $\text{vl}[(k - 1) + (j - 1)*\text{ldvl}]$ for column major layout and in $\text{vl}[(k - 1)*\text{ldvl} + (j - 1)]$ for row major layout.. If the <i>j</i> -th and (<i>j</i> +1)-st eigenvalues form a complex conjugate pair, then for $i = \text{sqrt}(-1)$, the <i>k</i> -th components of the <i>j</i> -th left eigenvector u_j are $\text{vl}[(k - 1) + (j - 1)*\text{ldvl}] + i*\text{vl}[(k - 1) + j*\text{ldvl}]$ for column major layout and $\text{vl}[(k - 1)*\text{ldvl} + (j - 1)] + i*\text{vl}[(k - 1)*\text{ldvl} + j]$ for row major layout. Similarly, the <i>k</i> -th components of left eigenvector <i>j</i> +1 u_{j+1} are $\text{vl}[(k - 1) + (j - 1)*\text{ldvl}] - i*\text{vl}[(k - 1) + j*\text{ldvl}]$ for column major layout and $\text{vl}[(k - 1)*\text{ldvl} + (j - 1)] - i*\text{vl}[(k - 1)*\text{ldvl} + j]$ for row major layout.. <i>For complex flavors:</i> The <i>k</i> -th component of the <i>j</i> -th left eigenvector u_j is stored in $\text{vl}[(k - 1) + (j - 1)*\text{ldvl}]$ for column major layout and in $\text{vl}[(k - 1)*\text{ldvl} + (j - 1)]$ for row major layout. <i>vr</i> (size at least $\max(1, \text{ldvr}*n)$). Contains the matrix of right generalized eigenvectors <i>VR</i> . |

If $jobvr = 'V'$, the right generalized eigenvectors v_j are stored one after another in the columns of VR , in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.

If $jobvr = 'N'$, vr is not referenced.

For real flavors:

If the j -th eigenvalue is real, then The k -th component of the j -th right eigenvector v_j is stored in $vr[(k - 1) + (j - 1)*ldvr]$ for column major layout and in $vr[(k - 1)*ldvr + (j - 1)]$ for row major layout..

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then the k -th components of the j -th right eigenvector v_j can be computed as $vr[(k - 1) + (j - 1)*ldvr] + i*vr[(k - 1) + j*ldvr]$ for column major layout and $vr[(k - 1)*ldvr + (j - 1)] + i*vr[(k - 1)*ldvr + j]$ for row major layout. Similarly, the k -th components of the right eigenvector $j+1$ $v_{\{j+1\}}$ can be computed as $vr[(k - 1) + (j - 1)*ldvr] - i*vr[(k - 1) + j*ldvr]$ for column major layout and $vr[(k - 1)*ldvr + (j - 1)] - i*vr[(k - 1)*ldvr + j]$ for row major layout..

For complex flavors:

The k -th component of the j -th right eigenvector v_j is stored in $vr[(k - 1) + (j - 1)*ldvr]$ for column major layout and in $vr[(k - 1)*ldvr + (j - 1)]$ for row major layout.

Return Values

This function returns a value $info$.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, and

$i \leq n$: the QZ iteration failed. No eigenvectors have been calculated, but $alphan[j]$, $alphai[j]$ (for real flavors), or $alpha[j]$ (for complex flavors), and $beta[j]$, $j=info, \dots, n - 1$ should be correct.

$i > n$: errors that usually indicate LAPACK problems:

$i = n+1$: other than QZ iteration failed in [hgeqz](#);

$i = n+2$: error return from [tgevc](#).

Application Notes

The quotients $alphan[j]/beta[j]$ and $alphai[j]/beta[j]$ may easily over- or underflow, and $beta[j]$ may even be zero. Thus, you should avoid simply computing the ratio. However, $alphan$ and $alphai$ (for real flavors) or $alpha$ (for complex flavors) will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and $beta$ always less than and usually comparable with $\text{norm}(B)$.

?ggev

Computes the generalized eigenvalues, and, optionally, the left and/or right generalized eigenvectors.

Description

The routine computes for a pair of n -by- n real/complex nonsymmetric matrices (A,B) , the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ilo , ihi , $lscale$, $rscale$, $abnrm$, and $bbnrm$), reciprocal condition numbers for the eigenvalues ($rconde$), and reciprocal condition numbers for the right eigenvectors ($rcondv$).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar λ or a ratio $alpha / beta = \lambda$, such that $A - \lambda*B$ is singular. It is usually represented as the pair $(alpha, beta)$, as there is a reasonable interpretation for $beta=0$ and even for both being zero. The right generalized eigenvector $v(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A,B) satisfies

$$A*v(j) = \lambda(j)*B*v(j).$$

The left generalized eigenvector $u(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A,B) satisfies

$$u(j)^H*A = \lambda(j)*u(j)^H*B$$

where $u(j)^H$ denotes the conjugate transpose of $u(j)$.

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

| | |
|-------------------|--|
| <i>balanc</i> | <p>Must be 'N', 'P', 'S', or 'B'. Specifies the balance option to be performed.</p> <p>If <i>balanc</i> = 'N', do not diagonally scale or permute;</p> <p>If <i>balanc</i> = 'P', permute only;</p> <p>If <i>balanc</i> = 'S', scale only;</p> <p>If <i>balanc</i> = 'B', both permute and scale.</p> <p>Computed reciprocal condition numbers will be for the matrices after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.</p> |
| <i>jobvl</i> | <p>Must be 'N' or 'V'.</p> <p>If <i>jobvl</i> = 'N', the left generalized eigenvectors are not computed;</p> <p>If <i>jobvl</i> = 'V', the left generalized eigenvectors are computed.</p> |
| <i>jobvr</i> | <p>Must be 'N' or 'V'.</p> <p>If <i>jobvr</i> = 'N', the right generalized eigenvectors are not computed;</p> <p>If <i>jobvr</i> = 'V', the right generalized eigenvectors are computed.</p> |
| <i>sense</i> | <p>Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.</p> <p>If <i>sense</i> = 'N', none are computed;</p> <p>If <i>sense</i> = 'E', computed for eigenvalues only;</p> <p>If <i>sense</i> = 'V', computed for eigenvectors only;</p> <p>If <i>sense</i> = 'B', computed for eigenvalues and eigenvectors.</p> |
| <i>n</i> | The order of the matrices <i>A</i> , <i>B</i> , <i>vl</i> , and <i>vr</i> ($n \geq 0$). |
| <i>a, b</i> | <p>Arrays:</p> <p><i>a</i> (size at least $\max(1, lda*n)$) is an array containing the <i>n</i>-by-<i>n</i> matrix <i>A</i> (first of the pair of matrices).</p> <p><i>b</i> (size at least $\max(1, ldb*n)$) is an array containing the <i>n</i>-by-<i>n</i> matrix <i>B</i> (second of the pair of matrices).</p> |
| <i>lda</i> | <p>The leading dimension of the array <i>a</i>.</p> <p>Must be at least $\max(1, n)$.</p> |
| <i>ldb</i> | <p>The leading dimension of the array <i>b</i>.</p> <p>Must be at least $\max(1, n)$.</p> |
| <i>ldvl, ldvr</i> | <p>The leading dimensions of the output matrices <i>vl</i> and <i>vr</i>, respectively.</p> <p>Constraints:</p> <p><i>ldvl</i> ≥ 1. If <i>jobvl</i> = 'V', <i>ldvl</i> $\geq \max(1, n)$.</p> <p><i>ldvr</i> ≥ 1. If <i>jobvr</i> = 'V', <i>ldvr</i> $\geq \max(1, n)$.</p> |

Output Parameters

| | |
|-----------------------|--|
| <i>a, b</i> | <p>On exit, these arrays have been overwritten.</p> <p>If <i>jobvl</i> = 'V' or <i>jobvr</i> = 'V' or both, then <i>a</i> contains the first part of the real Schur form of the "balanced" versions of the input <i>A</i> and <i>B</i>, and <i>b</i> contains its second part.</p> |
| <i>alphar, alphas</i> | <p>Arrays, size at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors.</p> <p>See <i>beta</i>.</p> |
| <i>alpha</i> | <p>Array, size at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See <i>beta</i>.</p> |
| <i>beta</i> | <p>Array, size at least $\max(1, n)$.</p> <p><i>For real flavors:</i></p> <p>On exit, $(\text{alphar}[j] + \text{alphas}[j]*i)/\text{beta}[j]$, $j=0, \dots, n - 1$, will be the generalized eigenvalues.</p> <p>If <i>alphas</i>[<i>j</i>] is zero, then the <i>j</i>-th eigenvalue is real; if positive, then the <i>j</i>-th and (<i>j</i>+1)-st eigenvalues are a complex conjugate pair, with <i>alphas</i>[<i>j</i>+1] negative.</p> <p><i>For complex flavors:</i></p> <p>On exit, $\text{alpha}[j]/\text{beta}[j]$, $j=0, \dots, n - 1$, will be the generalized eigenvalues.</p> <p>See also <i>Application Notes</i> below.</p> |
| <i>vl, vr</i> | <p>Arrays:</p> <p><i>vl</i> (size at least $\max(1, \text{ldvl}*n)$).</p> <p>If <i>jobvl</i> = 'V', the left generalized eigenvectors $u(j)$ are stored one after another in the columns of <i>vl</i>, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component have $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.</p> <p>If <i>jobvl</i> = 'N', <i>vl</i> is not referenced.</p> <p><i>For real flavors:</i></p> <p>If the <i>j</i>-th eigenvalue is real, then <i>k</i>-th component of <i>j</i>-th left eigenvector u_j is stored in $\text{vl}[(k - 1) + (j - 1)*\text{ldvl}]$ for column major layout and in $\text{vl}[(k - 1)*\text{ldvl} + (j - 1)]$ for row major layout..</p> <p>If the <i>j</i>-th and (<i>j</i>+1)-st eigenvalues form a complex conjugate pair, then for $i = \text{sqrt}(-1)$, the <i>k</i>-th components of the <i>j</i>-th left eigenvector u_j can be computed as $\text{vl}[(k - 1) + (j - 1)*\text{ldvl}] + i*\text{vl}[(k - 1) + j*\text{ldvl}]$ for column major layout and $\text{vl}[(k - 1)*\text{ldvl} + (j - 1)] + i*\text{vl}[(k - 1)*\text{ldvl} + j]$ for row major layout. Similarly, the <i>k</i>-th components of the left eigenvector <i>j</i>+1 u_{j+1} can be computed as $\text{vl}[(k - 1) + (j - 1)*\text{ldvl}] - i*\text{vl}[(k - 1) + j*\text{ldvl}]$ for column major layout and $\text{vl}[(k - 1)*\text{ldvl} + (j - 1)] - i*\text{vl}[(k - 1)*\text{ldvl} + j]$ for row major layout..</p> <p><i>For complex flavors:</i></p> |

The k -th component of the j -th left eigenvector u_j is stored in $vl[(k - 1) + (j - 1)*ldvl]$ for column major layout and in $vl[(k - 1)*ldvl + (j - 1)]$ for row major layout.

vr (size at least $\max(1, ldvr*n)$).

If $jobvr = 'V'$, the right generalized eigenvectors $v(j)$ are stored one after another in the columns of vr , in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component have $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.

If $jobvr = 'N'$, vr is not referenced.

For real flavors:

If the j -th eigenvalue is real, then the k -th component of the j -th right eigenvector v_j is stored in $vr[(k - 1) + (j - 1)*ldvr]$ for column major layout and in $vr[(k - 1)*ldvr + (j - 1)]$ for row major layout..

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then The k -th components of the j -th right eigenvector v_j can be computed as $vr[(k - 1) + (j - 1)*ldvr] + i*vr[(k - 1) + j*ldvr]$ for column major layout and $vr[(k - 1)*ldvr + (j - 1)] + i*vr[(k - 1)*ldvr + j]$ for row major layout. Respectively, the k -th components of right eigenvector $j+1$ v_{j+1} can be computed as $vr[(k - 1) + (j - 1)*ldvr] - i*vr[(k - 1) + j*ldvr]$ for column major layout and $vr[(k - 1)*ldvr + (j - 1)] - i*vr[(k - 1)*ldvr + j]$ for row major layout..

For complex flavors:

The k -th component of the j -th right eigenvector v_j is stored in $vr[(k - 1) + (j - 1)*ldvr]$ for column major layout and in $vr[(k - 1)*ldvr + (j - 1)]$ for row major layout.

ilo, ihi

ilo and *ihi* are integer values such that on exit $A_{i j} = 0$ and $B_{i j} = 0$ if $i > j$ and $j = 1, \dots, ilo-1$ or $i = ihi+1, \dots, n$.

If *balanc* = 'N' or 'S', *ilo* = 1 and *ihi* = *n*.

lscale, rscale

Arrays, size at least $\max(1, n)$ each.

lscale contains details of the permutations and scaling factors applied to the left side of *A* and *B*.

If $PL(j)$ is the index of the row interchanged with row j , and $DL(j)$ is the scaling factor applied to row j , then

$lscale[j - 1] = PL(j)$, for $j = 1, \dots, ilo-1$

$= DL(j)$, for $j = ilo, \dots, ihi$

$= PL(j)$ for $j = ihi+1, \dots, n$.

The order in which the interchanges are made is n to $ihl+1$, then 1 to $ilo-1$.

rscale contains details of the permutations and scaling factors applied to the right side of *A* and *B*.

If $PR(j)$ is the index of the column interchanged with column j , and $DR(j)$ is the scaling factor applied to column j , then

$rscale[j - 1] = PR(j)$, for $j = 1, \dots, ilo-1$

$= DR(j)$, for $j = ilo, \dots, ihi$

= $PR(j)$ for $j = ihi+1, \dots, n$.

The order in which the interchanges are made is n to $ihi+1$, then 1 to $ilo-1$.

abnrm, bbnrm

The one-norms of the balanced matrices A and B , respectively.

rconde, rcondv

Arrays, size at least $\max(1, n)$ each.

If *sense* = 'E', or 'B', *rconde* contains the reciprocal condition numbers of the eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of *rconde* are set to the same value. Thus *rconde*[*j*], *rcondv*[*j*], and the *j*-th columns of *v*l and *v*r all correspond to the same eigenpair (but not in general the *j*-th eigenpair, unless all eigenpairs are selected).

If *sense* = 'N', or 'V', *rconde* is not referenced.

If *sense* = 'V', or 'B', *rcondv* contains the estimated reciprocal condition numbers of the eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of *rcondv* are set to the same value.

If the eigenvalues cannot be reordered to compute , *rcondv*[*j*] is set to 0; this can only occur when the true value would be very small anyway.

If *sense* = 'N', or 'E', *rcondv* is not referenced.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, and

$i \leq n$: the QZ iteration failed. No eigenvectors have been calculated, but *alphar*[*j*], *alphai*[*j*] (for real flavors), or *alpha*[*j*] (for complex flavors), and *beta*[*j*], $j=info, \dots, n - 1$ should be correct.

$i > n$: errors that usually indicate LAPACK problems:

$i = n+1$: other than QZ iteration failed in [hgeqz](#);

$i = n+2$: error return from [tgevc](#).

Application Notes

The quotients *alphar*[*j*]/*beta*[*j*] and *alphai*[*j*]/*beta*[*j*] may easily over- or underflow, and *beta*[*j*] may even be zero. Thus, you should avoid simply computing the ratio. However, *alphar* and *alphai* (for real flavors) or *alpha* (for complex flavors) will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and *beta* always less than and usually comparable with $\text{norm}(B)$.

?ggeev3

Computes the generalized eigenvalues and the left and right generalized eigenvectors for a pair of matrices.

Syntax

```
lapack_int LAPACKE_sggev3 (int matrix_layout, char jobvl, char jobvr, lapack_int n,
float * a, lapack_int lda, float * b, lapack_int ldb, float * alphar, float * alphai,
float * beta, float * vl, lapack_int ldvl, float * vr, lapack_int ldvr);
```

```

lapack_int LAPACKE_dggeev3 (int matrix_layout, char jobvl, char jobvr, lapack_int n,

Description

For a pair of n -by- n real or complex nonsymmetric matrices (A, B) , `?ggeev3` computes the generalized eigenvalues, and optionally, the left and right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A, B) is a scalar λ or a ratio $alpha/beta = \lambda$, such that $A - \lambda*B$ is singular. It is usually represented as the pair $(alpha, beta)$, as there is a reasonable interpretation for $beta=0$, and even for both being zero.

For real flavors:

The right eigenvector v_j corresponding to the eigenvalue λ_j of (A, B) satisfies

$$A * v_j = \lambda_j * B * v_j.$$

The left eigenvector u_j corresponding to the eigenvalue λ_j of (A, B) satisfies

$$u_j^H * A = \lambda_j * u_j^H * B$$

where u_j^H is the conjugate-transpose of u_j .

For complex flavors:

The right generalized eigenvector v_j corresponding to the generalized eigenvalue λ_j of (A, B) satisfies

$$A * v_j = \lambda_j * B * v_j.$$

The left generalized eigenvector u_j corresponding to the generalized eigenvalues λ_j of (A, B) satisfies

$$u_j^H * A = \lambda_j * u_j^H * B$$

where u_j^H is the conjugate-transpose of u_j .

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>jobvl</i> | = 'N': do not compute the left generalized eigenvectors; = 'V': compute the left generalized eigenvectors. |
| <i>jobvr</i> | = 'N': do not compute the right generalized eigenvectors; = 'V': compute the right generalized eigenvectors. |
| <i>n</i> | The order of the matrices A, B, VL , and VR . |

| | |
|-------------|---|
| | $n \geq 0$. |
| <i>a</i> | Array, size ($lda * n$). On entry, the matrix <i>A</i> in the pair (<i>A</i> , <i>B</i>). |
| <i>lda</i> | The leading dimension of <i>a</i> . $lda \geq \max(1, n)$. |
| <i>b</i> | Array, size ($ldb * n$). On entry, the matrix <i>B</i> in the pair (<i>A</i> , <i>B</i>). |
| <i>ldb</i> | The leading dimension of <i>b</i> . $ldb \geq \max(1, n)$. |
| <i>ldvl</i> | The leading dimension of the matrix <i>VL</i> . $ldvl \geq 1$, and if <i>jobvl</i> = 'V', $ldvl \geq n$. |
| <i>ldvr</i> | The leading dimension of the matrix <i>VR</i> . $ldvr \geq 1$, and if <i>jobvr</i> = 'V', $ldvr \geq n$. |

Output Parameters

| | |
|---------------|-----------------------------------|
| <i>a</i> | On exit, <i>a</i> is overwritten. |
| <i>b</i> | On exit, <i>b</i> is overwritten. |
| <i>alphar</i> | Array, size (<i>n</i>). |
| <i>alphai</i> | Array, size (<i>n</i>). |
| <i>alpha</i> | Array, size (<i>n</i>). |
| <i>beta</i> | Array, size (<i>n</i>). |

For real flavors:

On exit, $(\text{alphar}[j] + \text{alphai}[j]*i)/\text{beta}[j]$, $j=0, \dots, n-1$, are the generalized eigenvalues. If $\text{alphai}[j-1]$ is zero, then the *j*-th eigenvalue is real; if positive, then the *j*-th and (*j*+1)-st eigenvalues are a complex conjugate pair, with $\text{alphai}[j]$ negative.

Note: the quotients $\text{alphar}[j-1]/\text{beta}[j-1]$ and $\text{alphai}[j-1]/\text{beta}[j-1]$ can easily over- or underflow, and $\text{beta}(j)$ might even be zero. Thus, you should avoid computing the ratio alpha/beta by simply dividing *alpha* by *beta*. However, *alphar* and *alphai* are always less than and usually comparable with $\text{norm}(A)$ in magnitude, and *beta* is always less than and usually comparable with $\text{norm}(B)$.

For complex flavors:

On exit, $\text{alpha}[j]/\text{beta}[j]$, $j=0, \dots, n-1$, are the generalized eigenvalues.

Note: the quotients $\alpha[j - 1]/\beta[j - 1]$ may easily over- or underflow, and $\beta(j)$ can even be zero. Thus, you should avoid computing the ratio α/β by simply dividing α by β . However, α is always less than and usually comparable with $\text{norm}(A)$ in magnitude, and β is always less than and usually comparable with $\text{norm}(B)$.

vl

Array, size ($ldvl * n$).

For real flavors:

If $jobvl = 'V'$, the left eigenvectors u_j are stored one after another in the columns of *vl*, in the same order as their eigenvalues. If the j -th eigenvalue is real, then $u_j =$ the j -th column of *vl*. If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then the real part of $u_j =$ the j -th column of *vl* and the imaginary part of $v_j =$ the $(j + 1)$ -st column of *vl*.

Each eigenvector is scaled so the largest component has $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$.

Not referenced if $jobvl = 'N'$.

For complex flavors:

If $jobvl = 'V'$, the left generalized eigenvectors u_j are stored one after another in the columns of *vl*, in the same order as their eigenvalues.

Each eigenvector is scaled so the largest component has $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$.

Not referenced if $jobvl = 'N'$.

vr

Array, size ($ldvr * n$).

For real flavors:

If $jobvr = 'V'$, the right eigenvectors v_j are stored one after another in the columns of *vr*, in the same order as their eigenvalues. If the j -th eigenvalue is real, then $v_j =$ the j -th column of *vr*. If the j -th and $(j + 1)$ -st eigenvalues form a complex conjugate pair, then the real part of $v_j =$ the j -th column of *vr* and the imaginary part of $v_j =$ the $(j + 1)$ -st column of *vr*.

Each eigenvector is scaled so the largest component has $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$.

Not referenced if $jobvr = 'N'$.

For complex flavors:

If $jobvr = 'V'$, the right generalized eigenvectors v_j are stored one after another in the columns of *vr*, in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$.

Not referenced if $jobvr = 'N'$.

Return Values

This function returns a value *info*.

= 0: successful exit

< 0: if $info = -i$, the i -th argument had an illegal value.

= 1, ..., n:

for real flavors:

The QZ iteration failed. No eigenvectors have been calculated, but $\alpha[j]$, $\beta[j]$ and $\gamma[j]$ should be correct for $j = info, \dots, n - 1$.

for complex flavors:

The QZ iteration failed. No eigenvectors have been calculated, but $\alpha[j]$ and $\beta[j]$ should be correct for $j = info, \dots, n - 1$.

$> n$:

$= n + 1$: other than QZ iteration failed in `?hgeqz`,

$= n + 2$: error return from `?tgevc`.

LAPACK Auxiliary Routines

Routine naming conventions, mathematical notation, and matrix storage schemes used for LAPACK auxiliary routines are the same as for the driver and computational routines described in previous chapters.

?lacgv

Conjugates a complex vector.

Syntax

```
lapack_int LAPACKE_clacgv (lapack_int n, lapack_complex_float* x, lapack_int incx);
lapack_int LAPACKE_zlacgv (lapack_int n, lapack_complex_double* x, lapack_int incx);
```

Include Files

- `mkl.h`

Description

The routine conjugates a complex vector x of length n and increment $incx$ (see "[Vector Arguments in BLAS](#)" in Appendix B).

Input Parameters

| | |
|--------|--|
| n | The length of the vector x ($n \geq 0$). |
| x | Array, dimension $(1 + (n-1) * incx)$. Contains the vector of length n to be conjugated. |
| $incx$ | The spacing between successive elements of x . |

Output Parameters

| | |
|-----|---|
| x | On exit, overwritten with <code>conjg(x)</code> . |
|-----|---|

?syconv

Converts a symmetric matrix given by a triangular matrix factorization into two matrices and vice versa.

Syntax

```
lapack_int LAPACKE_ssyconv (int matrix_layout, char uplo, char way, lapack_int n, float
* a, lapack_int lda, const lapack_int * ipiv, float * e);
```

```
lapack_int LAPACKE_dsyconv (int matrix_layout, char uplo, char way, lapack_int n,
double* a, lapack_int lda, const lapack_int * ipiv, double * e);
```

```
lapack_int LAPACKE_csyconv (int matrix_layout, char uplo, char way, lapack_int n,
lapack_complex_float * a, lapack_int lda, const lapack_int * ipiv, lapack_complex_float
* e);
```

```
lapack_int LAPACKE_zsyconv (int matrix_layout, char uplo, char way, lapack_int n,
lapack_complex_double* a, lapack_int lda, const lapack_int * ipiv,
lapack_complex_double * e);
```

Include Files

- mkl.h

Description

The routine converts matrix A , which results from a triangular matrix factorization, into matrices L and D and vice versa. The routine returns non-diagonalized elements of D and applies or reverses permutation done with the triangular matrix factorization.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates whether the details of the factorization are stored as an upper or lower triangular matrix: If <i>uplo</i> = 'U': the upper triangular, $A = U * D * U^T$. If <i>uplo</i> = 'L': the lower triangular, $A = L * D * L^T$. |
| <i>way</i> | Must be 'C' or 'R'. |
| <i>n</i> | The order of matrix A ; $n \geq 0$. |
| <i>a</i> | Array of size $\max(1, lda * n)$. The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by <code>?sytrf</code> . |
| <i>lda</i> | The leading dimension of a ; $lda \geq \max(1, n)$. |
| <i>ipiv</i> | Array, size at least $\max(1, n)$. Details of the interchanges and the block structure of D , as returned by <code>?sytrf</code> . |

Output Parameters

| | |
|----------|--|
| <i>e</i> | Array of size $\max(1, n)$ containing the superdiagonal/subdiagonal of the symmetric 1-by-1 or 2-by-2 block diagonal matrix D in $L * D * L^T$. |
|----------|--|

Return Values

info If *info* = 0, the execution is successful.
 If *info* < 0, the *i*-th parameter had an illegal value.
 If *info* = -1011, memory allocation error occurred.

See Also

[?sytrf](#)

?syr

Performs the symmetric rank-1 update of a complex symmetric matrix.

Syntax

```
lapack_int LAPACKE_csyr (int matrix_layout, char uplo, lapack_int n,
lapack_complex_float alpha, const lapack_complex_float * x, lapack_int incx,
lapack_complex_float * a, lapack_int lda);
```

```
lapack_int LAPACKE_zsyr (int matrix_layout, char uplo, lapack_int n,
lapack_complex_double alpha, const lapack_complex_double * x, lapack_int incx,
lapack_complex_double * a, lapack_int lda);
```

Include Files

- mkl.h

Description

The routine performs the symmetric rank 1 operation defined as

$$a := \alpha * x * x^H + a,$$

where:

- *alpha* is a complex scalar.
- *x* is an *n*-element complex vector.
- *a* is an *n*-by-*n* complex symmetric matrix.

These routines have their real equivalents in BLAS (see [?syr](#) in Chapter 2).

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Specifies whether the upper or lower triangular part of the array <i>a</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'L' or 'l', then the lower triangular part of the array <i>a</i> is used. |
| <i>n</i> | Specifies the order of the matrix <i>a</i> . The value of <i>n</i> must be at least zero. |
| <i>alpha</i> | Specifies the scalar <i>alpha</i> . |

| | |
|-------------|---|
| <i>x</i> | Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> . |
| <i>incx</i> | Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero. |
| <i>a</i> | Array, size $\max(1, lda * n)$. Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of <i>a</i> is not referenced. |
| <i>lda</i> | Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$. |

Output Parameters

| | |
|----------|--|
| <i>a</i> | With <i>uplo</i> = 'U' or 'u', the upper triangular part of the array <i>a</i> is overwritten by the upper triangular part of the updated matrix. With <i>uplo</i> = 'L' or 'l', the lower triangular part of the array <i>a</i> is overwritten by the lower triangular part of the updated matrix. |
|----------|--|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

i?max1

Finds the index of the vector element whose real part has maximum absolute value.

Syntax

```
MKL_INT icmax1(const MKL_INT*n, const MKL_Complex8*cx, const MKL_INT*incx)
```

```
MKL_INT izmax1(const MKL_INT*n, const MKL_Complex16*cx, const MKL_INT*incx)
```

Include Files

- mkl.h

Description

Given a complex vector *cx*, the *i?max1* functions return the index of the first vector element of maximum absolute value. These functions are based on the BLAS functions *icamax/izamax*, but using the absolute value of components. They are designed for use with *clacon/zlacon*.

Input Parameters

| | |
|-------------|--|
| <i>n</i> | Specifies the number of elements in the vector <i>cx</i> . |
| <i>cx</i> | Array, size at least $(1+(n-1)*abs(incx))$. Contains the input vector. |
| <i>incx</i> | Specifies the spacing between successive elements of <i>cx</i> . |

Return Values

Index of the vector element of maximum absolute value.

?sum1

Forms the 1-norm of the complex vector using the true absolute value.

Syntax

```
float ssum1(const MKL_INT*n, const MKL_Complex8*cx, const MKL_INT*incx)
double dsum1(const MKL_INT*n, const MKL_Complex16*cx, const MKL_INT*incx)
```

Include Files

- mkl.h

Description

Given a complex vector *cx*, *ssum1*/*dsum1* functions take the sum of the absolute values of vector elements and return a single/double precision result, respectively. These functions are based on *scasum*/*dzasum* from Level 1 BLAS, but use the true absolute value and were designed for use with *clacon*/*zlacon*.

Input Parameters

| | |
|-------------|--|
| <i>n</i> | Specifies the number of elements in the vector <i>cx</i> . |
| <i>cx</i> | Array, size at least $(1+(n-1)*abs(incx))$. Contains the input vector whose elements will be summed. |
| <i>incx</i> | Specifies the spacing between successive elements of <i>cx</i> (<i>incx</i> > 0). |

Return Values

Sum of absolute values.

?gelq2

Computes the LQ factorization of a general rectangular matrix using an unblocked algorithm.

Syntax

```
lapack_int LAPACKE_sgelq2 (int matrix_layout, lapack_int m, lapack_int n, float* a,
lapack_int lda, float* tau);
lapack_int LAPACKE_dgelq2 (int matrix_layout, lapack_int m, lapack_int n, double* a,
lapack_int lda, double * tau);
```

```
lapack_int LAPACKE_cgelq2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* tau);

lapack_int LAPACKE_zgelq2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_complex_double* tau);
```

Include Files

- mkl.h

Description

The routine computes an LQ factorization of a real/complex m -by- n matrix A as $A = L^*Q$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors :

$Q = H(k) \dots H(2) H(1)$ (or $Q = H(k)^H \dots H(2)^H H(1)^H$ for complex flavors), where $k = \min(m, n)$

Each $H(i)$ has the form

$H(i) = I - \tau v v^T$ for real flavors, or

$H(i) = I - \tau v v^H$ for complex flavors,

where τ is a real/complex scalar stored in $\tau(i)$, and v is a real/complex vector with $v_{1:i-1} = 0$ and $v_i = 1$.

On exit, the j -th ($i+1 \leq j \leq n$) component of vector v (for real functions) or its conjugate (for complex functions) is stored in $a[i - 1 + lda*(j - 1)]$ for column major layout or in $a[j - 1 + lda*(i - 1)]$ for row major layout.

Input Parameters

| | |
|-------|--|
| m | The number of rows in the matrix A ($m \geq 0$). |
| n | The number of columns in A ($n \geq 0$). |
| a | Array, size at least $\max(1, lda*n)$ for column major and $\max(1, lda*m)$ for row major layout. Array a contains the m -by- n matrix A . |
| lda | The leading dimension of a ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |

Output Parameters

| | |
|--------|--|
| a | Overwritten by the factorization data as follows: on exit, the elements on and below the diagonal of the array a contain the m -by- $\min(n, m)$ lower trapezoidal matrix L (L is lower triangular if $n \geq m$); the elements above the diagonal, with the array τ , represent the orthogonal/unitary matrix Q as a product of $\min(n, m)$ elementary reflectors. |
| τ | Array, size at least $\max(1, \min(m, n))$. Contains scalar factors of the elementary reflectors. |

Return Values

This function returns a value *info*.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = -1011$, memory allocation error occurred.

?geqr2

Computes the QR factorization of a general rectangular matrix using an unblocked algorithm.

Syntax

```
lapack_int LAPACKE_sgeqr2 (int matrix_layout, lapack_int m, lapack_int n, float* a,
lapack_int lda, float* tau);
```

```
lapack_int LAPACKE_dgeqr2 (int matrix_layout, lapack_int m, lapack_int n, double* a,
lapack_int lda, double* tau);
```

```
lapack_int LAPACKE_cgeqr2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* tau);
```

```
lapack_int LAPACKE_zgeqr2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_complex_double* tau);
```

Include Files

- mkl.h

Description

The routine computes a QR factorization of a real/complex m -by- n matrix A as $A = Q^*R$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors :

$$Q = H(1) * H(2) * \dots * H(k), \text{ where } k = \min(m, n)$$

Each $H(i)$ has the form

$$H(i) = I - \tau v^* v^T \text{ for real flavors, or}$$

$$H(i) = I - \tau v^* v^H \text{ for complex flavors}$$

where τ is a real/complex scalar stored in $\tau[i]$, and v is a real/complex vector with $v_{1:i-1} = 0$ and $v_i = 1$.

On exit, $v_{i+1:m}$ is stored in $a(i+1:m, i)$.

Input Parameters

| | |
|-------|--|
| m | The number of rows in the matrix A ($m \geq 0$). |
| n | The number of columns in A ($n \geq 0$). |
| a | Array, size at least $\max(1, lda * n)$ for column major and $\max(1, lda * m)$ for row major layout. Array a contains the m -by- n matrix A . |
| lda | The leading dimension of a ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |

Output Parameters

| | |
|------------|---|
| <i>a</i> | Overwritten by the factorization data as follows: on exit, the elements on and above the diagonal of the array <i>a</i> contain the $\min(n,m)$ -by- <i>n</i> upper trapezoidal matrix <i>R</i> (<i>R</i> is upper triangular if $m \geq n$); the elements below the diagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors. |
| <i>tau</i> | Array, size at least $\max(1, \min(m, n))$. Contains scalar factors of the elementary reflectors. |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?geqrt2

Computes a QR factorization of a general real or complex matrix using the compact WY representation of *Q*.

Syntax

```
lapack_int LAPACKE_sgeqrt2 (int matrix_layout, lapack_int m, lapack_int n, float * a,
lapack_int lda, float * t, lapack_int ldt );

lapack_int LAPACKE_dgeqrt2 (int matrix_layout, lapack_int m, lapack_int n, double * a,
lapack_int lda, double * t, lapack_int ldt );

lapack_int LAPACKE_cgeqrt2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float * a, lapack_int lda, lapack_complex_float * t, lapack_int ldt );

lapack_int LAPACKE_zgeqrt2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double * a, lapack_int lda, lapack_complex_double * t, lapack_int ldt );
```

Include Files

- mkl.h

Description

The strictly lower triangular matrix *V* contains the elementary reflectors *H*(*i*) in the *i*th column below the diagonal. For example, if $m=5$ and $n=3$, the matrix *V* is

$$V = \begin{bmatrix} 1 & & & & \\ v_1 & 1 & & & \\ v_1 & v_2 & 1 & & \\ v_1 & v_2 & v_3 & & \\ v_1 & v_2 & v_3 & & \end{bmatrix}$$

where v_i represents the vector that defines $H(i)$. The vectors are returned in the lower triangular part of array a .

NOTE

The 1s along the diagonal of V are not stored in a .

The block reflector H is then given by

$$H = I - V^* T^* V^T \text{ for real flavors, and}$$

$$H = I - V^* T^* V^H \text{ for complex flavors,}$$

where V^T is the transpose and V^H is the conjugate transpose of V .

Input Parameters

| | |
|-------|--|
| m | The number of rows in the matrix A ($m \geq n$). |
| n | The number of columns in A ($n \geq 0$). |
| a | Array, size at least $\max(1, lda * n)$ for column major and $\max(1, lda * m)$ for row major layout. Array a contains the m -by- n matrix A . |
| lda | The leading dimension of a ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |
| ldt | The leading dimension of t ; at least $\max(1, n)$. |

Output Parameters

| | |
|-----|--|
| a | Overwritten by the factorization data as follows: The elements on and above the diagonal of the array contain the n -by- n upper triangular matrix R . The elements below the diagonal are the columns of V . |
| t | Array, size at least $\max(1, ldt * n)$. The n -by- n upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector T . The elements below the diagonal are not used. |

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info < 0$ and $info = -i$, the i th argument had an illegal value.

If $info = -1011$, memory allocation error occurred.

?geqrt3

Recursively computes a QR factorization of a general real or complex matrix using the compact WY representation of Q .

Syntax

```
lapack_int LAPACKE_sgeqrt3 (int matrix_layout , lapack_int m , lapack_int n , float *
a , lapack_int lda , float * t , lapack_int ldt );
```

```
lapack_int LAPACKE_dgeqrt3 (int matrix_layout , lapack_int m , lapack_int n , double *
a , lapack_int lda , double * t , lapack_int ldt );
```

```
lapack_int LAPACKE_cgeqrt3 (int matrix_layout , lapack_int m , lapack_int n ,
lapack_complex_float * a , lapack_int lda , lapack_complex_float * t , lapack_int
ldt );
```

```
lapack_int LAPACKE_zgeqrt3 (int matrix_layout , lapack_int m , lapack_int n ,
lapack_complex_double * a , lapack_int lda , lapack_complex_double * t , lapack_int
ldt );
```

Include Files

- mkl.h

Description

The strictly lower triangular matrix V contains the elementary reflectors $H(i)$ in the i th column below the diagonal. For example, if $m=5$ and $n=3$, the matrix V is

$$V = \begin{bmatrix} 1 & & & & \\ v_1 & 1 & & & \\ v_1 & v_2 & 1 & & \\ v_1 & v_2 & v_3 & & \\ v_1 & v_2 & v_3 & & \end{bmatrix}$$

where v_i represents one of the vectors that define $H(i)$. The vectors are returned in the lower part of triangular array a .

NOTE

The 1s along the diagonal of V are not stored in a .

The block reflector H is then given by

$H = I - V^* T^* V^T$ for real flavors, and

$H = I - V^* T^* V^H$ for complex flavors,

where V^T is the transpose and V^H is the conjugate transpose of V .

Input Parameters

m The number of rows in the matrix A ($m \geq n$).

n The number of columns in A ($n \geq 0$).

| | |
|------------|--|
| <i>a</i> | Array, size at least $\max(1, lda*n)$ for column major and $\max(1, lda*m)$ for row major layout. Array <i>a</i> contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> . |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |
| <i>ldt</i> | The leading dimension of <i>t</i> ; at least $\max(1, n)$. |

Output Parameters

| | |
|----------|--|
| <i>a</i> | The elements on and above the diagonal of the array contain the <i>n</i> -by- <i>n</i> upper triangular matrix <i>R</i> . The elements below the diagonal are the columns of <i>V</i> . |
| <i>t</i> | Array, size <i>ldt</i> by <i>n</i> . The <i>n</i> -by- <i>n</i> upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector <i>T</i> . The elements below the diagonal are not used. |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0 and *info* = -*i*, the *i*th argument had an illegal value.

If *info* = -1011, memory allocation error occurred.

?getf2

Computes the LU factorization of a general *m*-by-*n* matrix using partial pivoting with row interchanges (unblocked algorithm).

Syntax

```
lapack_int LAPACKE_sgetf2 (int matrix_layout, lapack_int m, lapack_int n, float* a,
lapack_int lda, lapack_int * ipiv);
```

```
lapack_int LAPACKE_dgetf2 (int matrix_layout, lapack_int m, lapack_int n, double* a,
lapack_int lda, lapack_int * ipiv);
```

```
lapack_int LAPACKE_cgetf2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_int * ipiv);
```

```
lapack_int LAPACKE_zgetf2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_int * ipiv);
```

Include Files

- mkl.h

Description

The routine computes the LU factorization of a general *m*-by-*n* matrix *A* using partial pivoting with row interchanges. The factorization has the form

$$A = P*LU$$

where p is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$).

Input Parameters

| | |
|-------|--|
| m | The number of rows in the matrix A ($m \geq 0$). |
| n | The number of columns in A ($n \geq 0$). |
| a | Array, size at least $\max(1, lda*n)$ for column major and $\max(1, lda*m)$ for row major layout. Array a contains the m -by- n matrix A . |
| lda | The leading dimension of a ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |

Output Parameters

| | |
|--------|--|
| a | Overwritten by L and U . The unit diagonal elements of L are not stored. |
| $ipiv$ | Array, size at least $\max(1, \min(m, n))$. The pivot indices: for $1 \leq i \leq n$, row i was interchanged with row $ipiv(i)$. |

Return Values

This function returns a value $info$.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i > 0$, u_{ij} is 0. The factorization has been completed, but U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

If $info = -1011$, memory allocation error occurred.

?lacn2

Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.

Syntax

C:

```
lapack_int LAPACKE_slacn2 (lapack_int n, float * v, float * x, lapack_int * isgn, float * est, lapack_int * kase, lapack_int * isave);
```

```
lapack_int LAPACKE_clacn2 (lapack_int n, lapack_complex_float * v, lapack_complex_float * x, float * est, lapack_int * kase, lapack_int * isave);
```

```
lapack_int LAPACKE_dlacn2 (lapack_int n, double * v, double * x, lapack_int * isgn, double * est, lapack_int * kase, lapack_int * isave);
```

```
lapack_int LAPACKE_zlacn2 (lapack_int n, lapack_complex_double * v, lapack_complex_double * x, double * est, lapack_int * kase, lapack_int * isave);
```

Include Files

- mkl.h

Description

The routine estimates the 1-norm of a square, real or complex matrix A . Reverse communication is used for evaluating matrix-vector products.

Input Parameters

| | |
|---------|---|
| n | The order of the matrix A ($n \geq 1$). |
| v, x | Arrays, size (n) each. v is a workspace array. x is used as input after an intermediate return. |
| $isgn$ | Workspace array, size (n), used with real flavors only. |
| est | On entry with $kase$ set to 1 or 2, and $isave(1) = 1$, est must be unchanged from the previous call to the routine. |
| $kase$ | On the initial call to the routine, $kase$ must be set to 0. |
| $isave$ | Array, size (3). Contains variables from the previous call to the routine. |

Output Parameters

| | |
|---------|--|
| est | An estimate (a lower bound) for $\text{norm}(A)$. |
| $kase$ | On an intermediate return, $kase$ is set to 1 or 2, indicating whether x is overwritten by $A*x$ or A^T*x for real flavors and $A*x$ or A^H*x for complex flavors. On the final return, $kase$ is set to 0. |
| v | On the final return, $v = A*w$, where $est = \text{norm}(v) / \text{norm}(w)$ (w is not returned). |
| x | On an intermediate return, x is overwritten by $A*x$, if $kase = 1$, A^T*x , if $kase = 2$ (for real flavors), A^H*x , if $kase = 2$ (for complex flavors), and the routine must be re-called with all the other parameters unchanged. |
| $isave$ | This parameter is used to save variables between calls to the routine. |

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

?lacpy

Copies all or part of one two-dimensional array to another.

Syntax

```
lapack_int LAPACKE_slacpy (int matrix_layout, char uplo, lapack_int m, lapack_int n,
const float* a, lapack_int lda, float* b, lapack_int ldb);
```

```
lapack_int LAPACKE_dlacpy (int matrix_layout, char uplo, lapack_int m, lapack_int n,
const double* a, lapack_int lda, double* b, lapack_int ldb);
```

```
lapack_int LAPACKE_clacpy (int matrix_layout, char uplo, lapack_int m, lapack_int n,
const lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int
ldb);
```

```
lapack_int LAPACKE_zlacpy (int matrix_layout, char uplo, lapack_int m, lapack_int n,
const lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int
ldb);
```

Include Files

- mkl.h

Description

The routine copies all or part of a two-dimensional matrix *A* to another matrix *B*.

Input Parameters

| | |
|-------------|---|
| <i>uplo</i> | Specifies the part of the matrix <i>A</i> to be copied to <i>B</i> . If <i>uplo</i> = 'U', the upper triangular part of <i>A</i> ; if <i>uplo</i> = 'L', the lower triangular part of <i>A</i> . Otherwise, all of the matrix <i>A</i> is copied. |
| <i>m</i> | The number of rows in the matrix <i>A</i> ($m \geq 0$). |
| <i>n</i> | The number of columns in <i>A</i> ($n \geq 0$). |
| <i>a</i> | Array, size at least $\max(1, lda \cdot n)$ for column major and $\max(1, lda \cdot m)$ for row major layout. <i>A</i> contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> . If <i>uplo</i> = 'U', only the upper triangle or trapezoid is accessed; if <i>uplo</i> = 'L', only the lower triangle or trapezoid is accessed. |
| <i>lda</i> | The leading dimension of <i>a</i> ; $lda \geq \max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |
| <i>ldb</i> | The leading dimension of the output array <i>b</i> ; $ldb \geq \max(1, m)$ for column major layout and $\max(1, n)$ for row major layout. |

Output Parameters

| | |
|----------|--|
| <i>b</i> | Array, size at least $\max(1, ldb \cdot n)$ for column major and $\max(1, ldb \cdot m)$ for row major layout. Array <i>a</i> contains the <i>m</i> -by- <i>n</i> matrix <i>B</i> . |
|----------|--|

On exit, $B = A$ in the locations specified by *uplo*.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

?lakf2

Forms a matrix containing Kronecker products between the given matrices.

Syntax

```
void slakf2 (lapack_int *m, lapack_int *n, float *a, lapack_int *lda, float *b, float
*d, float *e, float *z, lapack_int *ldz);
```

```
void dlakf2 (lapack_int *m, lapack_int *n, double *a, lapack_int *lda, double *b,
double *d, double *e, double *z, lapack_int *ldz);
```

```
void clakf2 (lapack_int *m, lapack_int *n, lapack_complex *a, lapack_int *lda,
lapack_complex *b, lapack_complex *d, lapack_complex *e, lapack_complex *z, lapack_int
*ldz);
```

```
void zlakf2 (lapack_int *m, lapack_int *n, lapack_complex_double *a, lapack_int *lda,
lapack_complex_double *b, lapack_complex_double *d, lapack_complex_double *e,
lapack_complex_double *z, lapack_int *ldz);
```

Include Files

- mkl.h

Description

The routine ?lakf2 forms the $2*m*n$ by $2*m*n$ matrix Z .

$$Z = \begin{bmatrix} \text{kron}(In, A) & -\text{kron}(B^T, Im) \\ \text{kron}(In, D) & -\text{kron}(E^T, Im) \end{bmatrix},$$

where In is the identity matrix of size n and X^T is the transpose of X . $\text{kron}(X, Y)$ is the Kronecker product between the matrices X and Y .

Input Parameters

| | |
|------------|---|
| <i>m</i> | Size of matrix, $m \geq 1$ |
| <i>n</i> | Size of matrix, $n \geq 1$ |
| <i>a</i> | Array, size <i>lda</i> -by- <i>n</i> . The matrix A in the output matrix Z . |
| <i>lda</i> | The leading dimension of <i>a</i> , <i>b</i> , <i>d</i> , and <i>e</i> . $lda \geq m+n$. |
| <i>b</i> | Array, size <i>lda</i> by <i>n</i> . Matrix used in forming the output matrix Z . |
| <i>d</i> | Array, size <i>lda</i> by <i>m</i> . Matrix used in forming the output matrix Z . |

| | |
|------------|--|
| <i>e</i> | Array, size <i>lda</i> by <i>n</i> . Matrix used in forming the output matrix <i>Z</i> . |
| <i>ldz</i> | The leading dimension of <i>Z</i> . $ldz \geq 2 * m * n$. |

Output Parameters

| | |
|----------|--|
| <i>z</i> | Array, size <i>ldz</i> -by- $2 * m * n$. The resultant Kronecker $m * n * 2$ -by- $m * n * 2$ matrix. |
|----------|--|

?lange

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general rectangular matrix.

Syntax

```
float LAPACKE_slange (int matrix_layout, char norm, lapack_int m, lapack_int n, const float * a, lapack_int lda);
```

```
double LAPACKE_dlange (int matrix_layout, char norm, lapack_int m, lapack_int n, const double * a, lapack_int lda);
```

```
float LAPACKE_clange (int matrix_layout, char norm, lapack_int m, lapack_int n, const lapack_complex_float * a, lapack_int lda);
```

```
double LAPACKE_zlange (int matrix_layout, char norm, lapack_int m, lapack_int n, const lapack_complex_double * a, lapack_int lda);
```

Include Files

- mkl.h

Description

The function ?lange returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex matrix *A*.

Input Parameters

| | |
|-------------|---|
| <i>norm</i> | Specifies the value to be returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix <i>A</i> . = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix <i>A</i> (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix <i>A</i> (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix <i>A</i> (square root of sum of squares). |
| <i>m</i> | The number of rows of the matrix <i>A</i> . $m \geq 0$. When $m = 0$, ?lange is set to zero. |
| <i>n</i> | The number of columns of the matrix <i>A</i> . |

$n \geq 0$. When $n = 0$, `?lange` is set to zero.

`a` Array, size at least $\max(1, lda * n)$ for column major and $\max(1, lda * m)$ for row major layout. Array `a` contains the m -by- n matrix A .

`lda` The leading dimension of the array `a`.
 $lda \geq \max(n, 1)$ for column major layout and $\max(1, n)$ for row major layout.

?lansy

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix.

Syntax

```
float LAPACKE_slansy (int matrix_layout, char norm, char uplo, lapack_int n, const float * a, lapack_int lda);
```

```
double LAPACKE_dlansy (int matrix_layout, char norm, char uplo, lapack_int n, const double * a, lapack_int lda);
```

```
float LAPACKE_clansy (int matrix_layout, char norm, char uplo, lapack_int n, const lapack_complex_float * a, lapack_int lda);
```

```
double LAPACKE_zlansy (int matrix_layout, char norm, char uplo, lapack_int n, const lapack_complex_double * a, lapack_int lda);
```

Include Files

- `mkl.h`

Description

The function `?lansy` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix A .

Input Parameters

`norm` Specifies the value to be returned by the routine:

- = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A .
- = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),
- = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),
- = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).

`uplo` Specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced.

- = 'U': Upper triangular part of A is referenced.

| | |
|-------|--|
| | = 'L': Lower triangular part of A is referenced |
| n | The order of the matrix A . $n \geq 0$. When $n = 0$, <code>?lanhsy</code> is set to zero. |
| a | Array, size at least $\max(1, lda * n)$. The symmetric matrix A . If <code>uplo = 'U'</code> , the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced. If <code>uplo = 'L'</code> , the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced. |
| lda | The leading dimension of the array a . $lda \geq \max(n, 1)$. |

?lanhe

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix.

Syntax

```
float LAPACKE_clanhe (int matrix_layout, char norm, char uplo, lapack_int n, const
lapack_complex_float * a, lapack_int lda);
```

```
double LAPACKE_zlanhe (int matrix_layout, char norm, char uplo, lapack_int n, const
lapack_complex_double * a, lapack_int lda);
```

Include Files

- `mk1.h`

Description

The function `?lanhe` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix A .

Input Parameters

| | |
|--------|---|
| $norm$ | Specifies the value to be returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A . = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares). |
| $uplo$ | Specifies whether the upper or lower triangular part of the Hermitian matrix A is to be referenced. = 'U': Upper triangular part of A is referenced. |

= 'L': Lower triangular part of A is referenced

n The order of the matrix A . $n \geq 0$. When $n = 0$, `?lanhe` is set to zero.

a Array, size at least $\max(1, lda*n)$. The Hermitian matrix A .
 If `uplo = 'U'`, the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced.

If `uplo = 'L'`, the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced.

lda The leading dimension of the array a .

$lda \geq \max(n, 1)$.

?lantr

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix.

Syntax

```
float LAPACKE_slantr (char * norm, char * uplo, char * diag, lapack_int * m, lapack_int * n, const float * a, lapack_int * lda, float * work);
```

```
double LAPACKE_dlantr (char * norm, char * uplo, char * diag, lapack_int * m, lapack_int * n, const double * a, lapack_int * lda, double * work);
```

```
float LAPACKE_clantr (char * norm, char * uplo, char * diag, lapack_int * m, lapack_int * n, const lapack_complex_float * a, lapack_int * lda, float * work);
```

```
double LAPACKE_zlantr (char * norm, char * uplo, char * diag, lapack_int * m, lapack_int * n, const lapack_complex_double * a, lapack_int * lda, double * work);
```

Include Files

- `mkl.h`

Description

The function `?lantr` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix A .

Input Parameters

$norm$ Specifies the value to be returned by the routine:

- = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A .
- = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),
- = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),

| | |
|-------------|--|
| | = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares). |
| <i>uplo</i> | Specifies whether the matrix A is upper or lower trapezoidal. = 'U': Upper trapezoidal = 'L': Lower trapezoidal. Note that A is triangular instead of trapezoidal if $m = n$. |
| <i>diag</i> | Specifies whether or not the matrix A has unit diagonal. = 'N': Non-unit diagonal = 'U': Unit diagonal. |
| <i>m</i> | The number of rows of the matrix A . $m \geq 0$, and if <i>uplo</i> = 'U', $m \leq n$. When $m = 0$, <i>?lantr</i> is set to zero. |
| <i>n</i> | The number of columns of the matrix A . $n \geq 0$, and if <i>uplo</i> = 'L', $n \leq m$. When $n = 0$, <i>?lantr</i> is set to zero. |
| <i>a</i> | Array, size at least $\max(1, lda * n)$ for column major and $\max(1, lda * m)$ for row major layout. The trapezoidal matrix A (A is triangular if $m = n$). If <i>uplo</i> = 'U', the leading m -by- n upper trapezoidal part of the array a contains the upper trapezoidal matrix, and the strictly lower triangular part of A is not referenced. If <i>uplo</i> = 'L', the leading m -by- n lower trapezoidal part of the array a contains the lower trapezoidal matrix, and the strictly upper triangular part of A is not referenced. Note that when <i>diag</i> = 'U', the diagonal elements of A are not referenced and are assumed to be one. |
| <i>lda</i> | The leading dimension of the array a . $lda \geq \max(m, 1)$ for column major layout and $\geq \max(1, n)$ for row major layout. |

?lapmr

Rearranges rows of a matrix as specified by a permutation vector.

Syntax

```
lapack_int LAPACKE_slapmr (int matrix_layout, lapack_logical forwr, lapack_int m,
lapack_int n, float* x, lapack_int ldx, lapack_int * k);
```

```
lapack_int LAPACKE_dlapmr (int matrix_layout, lapack_logical forwr, lapack_int m,
lapack_int n, double* x, lapack_int ldx, lapack_int * k);
```

```
lapack_int LAPACKE_clapmr (int matrix_layout, lapack_logical forwr, lapack_int m,
lapack_int n, lapack_complex_float* x, lapack_int ldx, lapack_int * k);
```

```
lapack_int LAPACKE_zlapmr (int matrix_layout, lapack_logical forwr, lapack_int m,
lapack_int n, lapack_complex_double* x, lapack_int ldx, lapack_int * k);
```

Include Files

- `mkl.h`

Description

The `?lapmr` routine rearranges the rows of the m -by- n matrix X as specified by the permutation $k[0], k[1], \dots, k[m-1]$ of the integers $1, \dots, m$.

If `forwrd` is true, forward permutation:

$X(k[i-1], :)$ is moved to $X(i, :)$ for $i = 1, 2, \dots, m$.

If `forwrd` is false, backward permutation:

$X(i, :)$ is moved to $X(k[i-1], :)$ for $i = 1, 2, \dots, m$.

Input Parameters

| | |
|---------------------|---|
| <code>forwrd</code> | If <code>forwrd</code> is true, forward permutation. If <code>forwrd</code> is false, backward permutation. |
| <code>m</code> | The number of rows of the matrix X . $m \geq 0$. |
| <code>n</code> | The number of columns of the matrix X . $n \geq 0$. |
| <code>x</code> | Array, size at least $\max(1, ldx * n)$ for column major and $\max(1, ldx * m)$ for row major layout. On entry, the m -by- n matrix X . |
| <code>ldx</code> | The leading dimension of the array X , $ldx \geq \max(1, m)$ for column major layout and $ldx \geq \max(1, n)$ for row major layout. |
| <code>k</code> | Array, size (m). On entry, k contains the permutation vector and is used as internal workspace. |

Output Parameters

| | |
|----------------|---|
| <code>x</code> | On exit, x contains the permuted matrix X . |
| <code>k</code> | On exit, k is reset to its original value. |

Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

If `info = -1011`, memory allocation error occurred.

See Also

?lapmt

Performs a forward or backward permutation of the columns of a matrix.

Syntax

```
lapack_int LAPACKE_slapmt (int matrix_layout, lapack_logical forwr, lapack_int m,
lapack_int n, float * x, lapack_int ldx, lapack_int * k);
```

```
lapack_int LAPACKE_dlapmt (int matrix_layout, lapack_logical forwr, lapack_int m,
lapack_int n, double * x, lapack_int ldx, lapack_int * k);
```

```
lapack_int LAPACKE_clapmt (int matrix_layout, lapack_logical forwr, lapack_int m,
lapack_int n, lapack_complex_float * x, lapack_int ldx, lapack_int * k);
```

```
lapack_int LAPACKE_zlapmt (int matrix_layout, lapack_logical forwr, lapack_int m,
lapack_int n, lapack_complex_double * x, lapack_int ldx, lapack_int * k);
```

Include Files

- mkl.h

Description

The routine `?lapmt` rearranges the columns of the m -by- n matrix X as specified by the permutation $k[i - 1]$ for $i = 1, \dots, n$.

If $forwr \neq 0$, forward permutation:

$X(*, k(j))$ is moved to $X(*, j)$ for $j=1, 2, \dots, n$.

If $forwr = 0$, backward permutation:

$X(*, j)$ is moved to $X(*, k(j))$ for $j = 1, 2, \dots, n$.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>forwr</i> | If $forwr \neq 0$, forward permutation If $forwr = 0$, backward permutation |
| <i>m</i> | The number of rows of the matrix X . $m \geq 0$. |
| <i>n</i> | The number of columns of the matrix X . $n \geq 0$. |
| <i>x</i> | Array, size $ldx*n$. On entry, the m -by- n matrix X . |
| <i>ldx</i> | The leading dimension of the array x , $ldx \geq \max(1, m)$. |
| <i>k</i> | Array, size (n). On entry, k contains the permutation vector and is used as internal workspace. |

Output Parameters

| | |
|----------|---|
| <i>x</i> | On exit, x contains the permuted matrix X . |
| <i>k</i> | On exit, k is reset to its original value. |

See Also

[?lapmr](#)

?lapy2

Returns $\text{sqrt}(x^2+y^2)$.

Syntax

```
float LAPACKE_slapy2 (floatx, floaty);  
double LAPACKE_dlapy2 (doublex, doubley);
```

Include Files

- mkl.h

Description

The function ?lapy2 returns $\text{sqrt}(x^2+y^2)$, avoiding unnecessary overflow or harmful underflow.

Input Parameters

x, y Specify the input values x and y .

Return Values

The function returns a value val .

If $val=-1D0$, the first argument was NaN.

If $val=-2D0$, the second argument was NaN.

?lapy3

Returns $\text{sqrt}(x^2+y^2+z^2)$.

Syntax

```
float LAPACKE_slapy3 (floatx, floaty, floatz);  
double LAPACKE_dlapy3 (double x, doubley, doublez);
```

Include Files

- mkl.h

Description

The function ?lapy3 returns $\text{sqrt}(x^2+y^2+z^2)$, avoiding unnecessary overflow or harmful underflow.

Input Parameters

x, y, z Specify the input values x, y and z .

Return Values

This function returns a value val .

If $val = -1D0$, the first argument was NaN.

If $val = -2D0$, the second argument was NaN.

If $val = -3D0$, the third argument was NaN.

Description

The real flavors of the routine `?larfb` apply a real block reflector H or its transpose H^T to a real m -by- n matrix C from either left or right.

The complex flavors of the routine `?larfb` apply a complex block reflector H or its conjugate transpose H^H to a complex m -by- n matrix C from either left or right.

Input Parameters

| | |
|---------------|--|
| <i>side</i> | <p>If <i>side</i> = 'L': apply H or H^T for real flavors and H or H^H for complex flavors from the left.</p> <p>If <i>side</i> = 'R': apply H or H^T for real flavors and H or H^H for complex flavors from the right.</p> |
| <i>trans</i> | <p>If <i>trans</i> = 'N': apply H (No transpose).</p> <p>If <i>trans</i> = 'C': apply H^H (Conjugate transpose).</p> <p>If <i>trans</i> = 'T': apply H^T (Transpose).</p> |
| <i>direct</i> | <p>Indicates how H is formed from a product of elementary reflectors</p> <p>If <i>direct</i> = 'F': $H = H(1) * H(2) * \dots * H(k)$ (forward)</p> <p>If <i>direct</i> = 'B': $H = H(k) * \dots * H(2) * H(1)$ (backward)</p> |
| <i>storev</i> | <p>Indicates how the vectors which define the elementary reflectors are stored:</p> <p>If <i>storev</i> = 'C': Column-wise</p> <p>If <i>storev</i> = 'R': Row-wise</p> |
| <i>m</i> | The number of rows of the matrix C . |
| <i>n</i> | The number of columns of the matrix C . |
| <i>k</i> | The order of the matrix T (equal to the number of elementary reflectors whose product defines the block reflector). |
| <i>v</i> | The size limitations depend on values of parameters <i>storev</i> and <i>side</i> as described in the following table: |

| | <i>storev</i> = C | | <i>storev</i> = R | |
|--------------|--------------------|--------------------|--------------------|--------------------|
| | <i>side</i> = L | <i>side</i> = R | <i>side</i> = L | <i>side</i> = R |
| Column major | $\max(1, ldv * k)$ | $\max(1, ldv * k)$ | $\max(1, ldv * m)$ | $\max(1, ldv * n)$ |
| Row major | $\max(1, ldv * m)$ | $\max(1, ldv * n)$ | $\max(1, ldv * k)$ | $\max(1, ldv * k)$ |

The matrix v . See *Application Notes* below.

ldv The leading dimension of the array v . It should satisfy the following conditions:

| | <i>storev</i> = C | | <i>storev</i> = R | |
|--------------|-------------------|-----------------|-------------------|-----------------|
| | <i>side</i> = L | <i>side</i> = R | <i>side</i> = L | <i>side</i> = R |
| Column major | $\max(1,m)$ | $\max(1,n)$ | $\max(1,k)$ | $\max(1,k)$ |
| Row major | $\max(1,k)$ | $\max(1,k)$ | $\max(1,m)$ | $\max(1,n)$ |

| | |
|------------|---|
| <i>t</i> | Array, size at least $\max(1, ldt * k)$. Contains the triangular k -by- k matrix T in the representation of the block reflector. |
| <i>ldt</i> | The leading dimension of the array <i>t</i> . $ldt \geq k$. |
| <i>c</i> | Array, size at least $\max(1, ldc * n)$ for column major layout and $\max(1, ldc * m)$ for row major layout. On entry, the m -by- n matrix C . |
| <i>ldc</i> | The leading dimension of the array <i>c</i> . $ldc \geq \max(1, m)$ for column major layout and $ldc \geq \max(1, n)$ for row major layout. |

Output Parameters

| | |
|----------|---|
| <i>c</i> | On exit, <i>c</i> is overwritten by the product of the following: <ul style="list-style-type: none"> $H * C$, or $H^T * C$, or $C * H$, or $C * H^T$ for real flavors $H * C$, or $H^H * C$, or $C * H$, or $C * H^H$ for complex flavors |
|----------|---|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

Application Notes

The shape of the matrix V and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

direct = 'F' and *storev* = 'C': *direct* = 'F' and *storev* = 'R':

$$\begin{bmatrix} 1 & & & & \\ v_1 & 1 & & & \\ v_1 & v_2 & 1 & & \\ v_1 & v_2 & v_3 & & \\ v_1 & v_2 & v_3 & & \end{bmatrix}$$

$$\begin{bmatrix} 1 & v_1 & v_1 & v_1 & v_1 \\ & 1 & v_2 & v_2 & v_2 \\ & & 1 & v_3 & v_3 \end{bmatrix}$$

direct = 'B' and *storev* = 'C': *direct* = 'B' and *storev* = 'R':

$$\begin{bmatrix} v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ 1 & v_2 & v_3 \\ & 1 & v_3 \\ & & 1 \end{bmatrix}$$

$$\begin{bmatrix} v_1 & v_1 & 1 & & \\ v_2 & v_2 & v_2 & 1 & \\ v_3 & v_3 & v_3 & v_3 & 1 \end{bmatrix}$$

?larfg

Generates an elementary reflector (Householder matrix).

Syntax

```
lapack_int LAPACKE_slarfg (lapack_int n , float * alpha , float * x , lapack_int incx , float * tau );
```

```
lapack_int LAPACKE_dlarfg (lapack_int n , double * alpha , double * x , lapack_int incx , double * tau );
```

```
lapack_int LAPACKE_clarfg (lapack_int n , lapack_complex_float * alpha , lapack_complex_float * x , lapack_int incx , lapack_complex_float * tau );
```

```
lapack_int LAPACKE_zlarfg (lapack_int n , lapack_complex_double * alpha , lapack_complex_double * x , lapack_int incx , lapack_complex_double * tau );
```

Include Files

- mkl.h

Description

The routine ?larfg generates a real/complex elementary reflector H of order n , such that

$$H^* \begin{bmatrix} \alpha \\ x \end{bmatrix} = \begin{bmatrix} \beta \\ 0 \end{bmatrix}, \quad H^T H = I, \quad \text{for real flavors and}$$

$$H^X * \begin{bmatrix} \text{alpha} \\ x \end{bmatrix} = \begin{bmatrix} \text{beta} \\ 0 \end{bmatrix}, \quad H^X * H = I, \quad \text{for complex flavors,}$$

where *alpha* and *beta* are scalars (with *beta* real for all flavors), and *x* is an (*n*-1)-element real/complex vector. *H* is represented in the form

$$H = I - \text{tau} * \begin{bmatrix} 1 \\ v \end{bmatrix} * \begin{bmatrix} 1 & v^T \end{bmatrix} \quad \text{for real flavors and}$$

$$H = I - \text{tau} * \begin{bmatrix} 1 \\ v \end{bmatrix} * \begin{bmatrix} 1 & v^H \end{bmatrix} \quad \text{for complex flavors,}$$

where *tau* is a real/complex scalar and *v* is a real/complex (*n*-1)-element vector, respectively. Note that for `clarfg/zlarfg`, *H* is not Hermitian.

If the elements of *x* are all zero (and, for complex flavors, *alpha* is real), then *tau* = 0 and *H* is taken to be the unit matrix.

Otherwise, $1 \leq \text{tau} \leq 2$ (for real flavors), or

$1 \leq \text{Re}(\text{tau}) \leq 2$ and $\text{abs}(\text{tau}-1) \leq 1$ (for complex flavors).

Input Parameters

| | |
|--------------|--|
| <i>n</i> | The order of the elementary reflector. |
| <i>alpha</i> | |
| <i>x</i> | Array, size $(1+(n-2)*\text{abs}(\text{incx}))$. On entry, the vector <i>x</i> . |
| <i>incx</i> | The increment between elements of <i>x</i> . <i>incx</i> > 0. |

Output Parameters

| | |
|--------------|---|
| <i>alpha</i> | On exit, it is overwritten with the value <i>beta</i> . |
| <i>x</i> | On exit, it is overwritten with the vector <i>v</i> . |
| <i>tau</i> | |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -2, *alpha* is NaN

If *info* = -3, array *x* contains NaN components.

?larft

Forms the triangular factor *T* of a block reflector $H = I - V * T * V^* * H$.

Syntax

```
lapack_int LAPACKE_slarft (int matrix_layout , char direct , char storev , lapack_int
n , lapack_int k , const float * v , lapack_int ldv , const float * tau , float * t ,
lapack_int ldt );
```

```
lapack_int LAPACKE_dlarft (int matrix_layout , char direct , char storev , lapack_int
n , lapack_int k , const double * v , lapack_int ldv , const double * tau , double *
t , lapack_int ldt );
```

```
lapack_int LAPACKE_clarft (int matrix_layout , char direct , char storev , lapack_int

```

Include Files

- mkl.h

Description

The routine `?larft` forms the triangular factor T of a real/complex block reflector H of order n , which is defined as a product of k elementary reflectors.

If $direct = 'F'$, $H = H(1)*H(2)* \dots *H(k)$ and T is upper triangular;

If $direct = 'B'$, $H = H(k)* \dots *H(2)*H(1)$ and T is lower triangular.

If $storev = 'C'$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th column of the array v , and $H = I - V*T*V^T$ (for real flavors) or $H = I - V*T*V^H$ (for complex flavors) .

If $storev = 'R'$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th row of the array v , and $H = I - V^T*T*V$ (for real flavors) or $H = I - V^H*T*V$ (for complex flavors).

Input Parameters

| | |
|---------------|---|
| <i>direct</i> | Specifies the order in which the elementary reflectors are multiplied to form the block reflector: = 'F': $H = H(1)*H(2)* \dots *H(k)$ (forward) = 'B': $H = H(k)* \dots *H(2)*H(1)$ (backward) |
| <i>storev</i> | Specifies how the vectors which define the elementary reflectors are stored (see also <i>Application Notes</i> below): = 'C': column-wise = 'R': row-wise. |
| <i>n</i> | The order of the block reflector H . $n \geq 0$. |
| <i>k</i> | The order of the triangular factor T (equal to the number of elementary reflectors). $k \geq 1$. |
| <i>v</i> | The size limitations depend on values of parameters <i>storev</i> and <i>side</i> as described in the following table: |

| | <i>storev</i> = C | <i>storev</i> = R |
|--------------|-------------------|-------------------|
| Column major | $\max(1, ldv*k)$ | $\max(1, ldv*n)$ |
| Row major | $\max(1, ldv*n)$ | $\max(1, ldv*k)$ |

The matrix *v*. See *Application Notes* below.

ldv

The leading dimension of the array *v*.

If *storev* = 'C', $ldv \geq \max(1, n)$ for column major and $ldv \geq \max(1, k)$ for row major;

if *storev* = 'R', $ldv \geq k$ for column major and $ldv \geq \max(1, n)$ for row major.

tau

Array, size (*k*). *tau*[*i*-1] must contain the scalar factor of the elementary reflector *H*(*i*).

ldt

The leading dimension of the output array *t*. $ldt \geq k$.

Output Parameters

t

Array, size *ldt* * *k*. The *k*-by-*k* triangular factor *T* of the block reflector. If *direct* = 'F', *T* is upper triangular; if *direct* = 'B', *T* is lower triangular. The rest of the array is not used.

v

The matrix *V*.

Application Notes

The shape of the matrix *V* and the storage of the vectors which define the *H*(*i*) is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

direct = 'F' and *storev* = 'C': *direct* = 'F' and *storev* = 'R':

$$\begin{bmatrix} 1 & & & & \\ v_1 & 1 & & & \\ v_1 & v_2 & 1 & & \\ v_1 & v_2 & v_3 & & \\ v_1 & v_2 & v_3 & & \end{bmatrix}$$

$$\begin{bmatrix} 1 & v_1 & v_1 & v_1 & v_1 \\ & 1 & v_2 & v_2 & v_2 \\ & & 1 & v_3 & v_3 \end{bmatrix}$$

| | |
|-------------|--|
| <i>n</i> | The number of columns of the matrix <i>C</i> . |
| <i>v</i> | Array, size (<i>m</i>) if <i>side</i> = 'L' or (<i>n</i>) if <i>side</i> = 'R'. The vector <i>v</i> in the representation of <i>H</i> . |
| <i>tau</i> | The value <i>tau</i> in the representation of <i>H</i> . |
| <i>c</i> | Array, size at least max(1, <i>ldc</i> * <i>n</i>) for column major layout and max (1, <i>ldc</i> * <i>m</i>) for row major layout. On entry, the <i>m</i> -by- <i>n</i> matrix <i>C</i> . |
| <i>ldc</i> | The leading dimension of the array <i>c</i> . <i>lda</i> ≥ (1, <i>m</i>). |
| <i>work</i> | Workspace array, size (<i>n</i>) if <i>side</i> = 'L' or (<i>m</i>) if <i>side</i> = 'R'. <i>work</i> is not referenced if <i>H</i> has order < 11. |

Output Parameters

| | |
|----------|---|
| <i>c</i> | On exit, <i>C</i> is overwritten by the matrix H^*C if <i>side</i> = 'L', or C^*H if <i>side</i> = 'R'. |
|----------|---|

?large

Pre- and post-multiplies a real general matrix with a random orthogonal matrix.

Syntax

```
void slarge (lapack_int *n, float *a, lapack_int *lda, lapack_int *iseed, float * work,
lapack_int *info);
```

```
void dlarge (lapack_int *n, double *a, lapack_int *lda, lapack_int *iseed, double *
work, lapack_int *info);
```

```
void clarge (lapack_int *n, lapack_complex *a, lapack_int *lda, lapack_int *iseed,
lapack_complex * work, lapack_int *info);
```

```
void zlarge (lapack_int *n, lapack_complex_double *a, lapack_int *lda, lapack_int
*iseed, lapack_complex_double * work, lapack_int *info);
```

Include Files

- mkl.h

Description

The routine ?large pre- and post-multiplies a general *n*-by-*n* matrix *A* with a random orthogonal or unitary matrix: $A = U^*D^*U^T$.

Input Parameters

| | |
|--------------|---|
| <i>n</i> | The order of the matrix <i>A</i> . $n \geq 0$ |
| <i>a</i> | Array, size <i>lda</i> by <i>n</i> . On entry, the original <i>n</i> -by- <i>n</i> matrix <i>A</i> . |
| <i>lda</i> | The leading dimension of the array <i>a</i> . $lda \geq n$. |
| <i>iseed</i> | Array, size 4. On entry, the seed of the random number generator. The array elements must be between 0 and 4095, and <i>iseed</i> [3] must be odd. |
| <i>work</i> | Workspace array, size $2*n$. |

Output Parameters

| | |
|--------------|--|
| <i>a</i> | On exit, <i>A</i> is overwritten by $U*A*U'$ for some random orthogonal matrix <i>U</i> . |
| <i>iseed</i> | On exit, the seed is updated. |
| <i>info</i> | If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, the <i>i</i> -th parameter had an illegal value. |

?larnd

Returns a random real number from a uniform or normal distribution.

Syntax

```
float slarnd (lapack_int *idist, lapack_int *iseed);
double dlarnd (lapack_int *idist, lapack_int *iseed);
```

The data types for complex variations depend on whether or not the application links with Gnu Fortran (gfortran) libraries.

For non-gfortran (libmkl_intel_*) interface libraries:

```
void clarnd (lapack_complex_float *res, lapack_int *idist, lapack_int *iseed);
void zlarnd (lapack_complex_double *res, lapack_int *idist, lapack_int *iseed);
```

For gfortran (libmkl_gf_*) interface libraries:

```
lapack_complex_float clarnd (lapack_int *idist, lapack_int *iseed);
lapack_complex_double zlarnd (lapack_int *idist, lapack_int *iseed);
```

To understand the difference between the non-gfortran and gfortran interfaces and when to use each of them, see Dynamic Libraries in the lib/intel64 Directory in the *Intel MKL Developer Guide*.

Include Files

- mkl.h

Description

The routine ?larnd returns a random number from a uniform or normal distribution.

Input Parameters

| | |
|--------------|---|
| <i>idist</i> | <p>Specifies the distribution of the random numbers. For <code>slarnv</code> and <code>dlarnv</code>:</p> <ul style="list-style-type: none"> = 1: uniform (0,1) = 2: uniform (-1,1) = 3: normal (0,1). <p>For <code>clarnv</code> and <code>zlarnv</code>:</p> <ul style="list-style-type: none"> = 1: real and imaginary parts each uniform (0,1) = 2: real and imaginary parts each uniform (-1,1) = 3: real and imaginary parts each normal (0,1) = 4: uniformly distributed on the disc $\text{abs}(z) \leq 1$ = 5: uniformly distributed on the circle $\text{abs}(z) = 1$ |
| <i>iseed</i> | <p>Array, size 4.</p> <p>On entry, the seed of the random number generator. The array elements must be between 0 and 4095, and <code>iseed[3]</code> must be odd.</p> |

Output Parameters

| | |
|--------------|-------------------------------|
| <i>iseed</i> | On exit, the seed is updated. |
|--------------|-------------------------------|

Return Values

The function returns a random number (for complex variations `libmkl_gf_*` interface layer/libraries return the result as the parameter `res`).

?larnv

Returns a vector of random numbers from a uniform or normal distribution.

Syntax

```
lapack_int LAPACKE_slarnv (lapack_int idist , lapack_int * iseed , lapack_int n , float
* x );

lapack_int LAPACKE_dlarnv (lapack_int idist , lapack_int * iseed , lapack_int n ,
double * x );

lapack_int LAPACKE_clarnv (lapack_int idist , lapack_int * iseed , lapack_int n ,
lapack_complex_float * x );

lapack_int LAPACKE_zlarnv (lapack_int idist , lapack_int * iseed , lapack_int n ,
lapack_complex_double * x );
```

Include Files

- `mkl.h`

Description

The routine `?larnv` returns a vector of n random real/complex numbers from a uniform or normal distribution.

This routine calls the auxiliary routine `?laruv` to generate random real numbers from a uniform (0,1) distribution, in batches of up to 128 using vectorisable code. The Box-Muller method is used to transform numbers from a uniform to a normal distribution.

Input Parameters

| | |
|--------------|--|
| <i>idist</i> | Specifies the distribution of the random numbers: for <code>slarnv</code> and <code>dlarnv</code> : = 1: uniform (0,1) = 2: uniform (-1,1) = 3: normal (0,1). for <code>clarv</code> and <code>zlarnv</code> : = 1: real and imaginary parts each uniform (0,1) = 2: real and imaginary parts each uniform (-1,1) = 3: real and imaginary parts each normal (0,1) = 4: uniformly distributed on the disc $abs(z) < 1$ = 5: uniformly distributed on the circle $abs(z) = 1$ |
| <i>iseed</i> | Array, size (4). On entry, the seed of the random number generator; the array elements must be between 0 and 4095, and <i>iseed</i> (4) must be odd. |
| <i>n</i> | The number of random numbers to be generated. |

Output Parameters

| | |
|--------------|---|
| <i>x</i> | Array, size (<i>n</i>). The generated random numbers. |
| <i>iseed</i> | On exit, the seed is updated. |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

?laror

Pre- or post-multiplies an m-by-n matrix by a random orthogonal/unitary matrix.

Syntax

```
void slaror (char *side, char *init, lapack_int *m, lapack_int *n, float *a, lapack_int
*lda, lapack_int *iseed, float *x, lapack_int *info);
void dlaror (char *side, char *init, lapack_int *m, lapack_int *n, double *a,
lapack_int *lda, lapack_int *iseed, double *x, lapack_int *info);
void claror (char *side, char *init, lapack_int *m, lapack_int *n, lapack_complex *a,
lapack_int *lda, lapack_int *iseed, lapack_complex *x, lapack_int *info);
void zlaror (char *side, char *init, lapack_int *m, lapack_int *n,
lapack_complex_double *a, lapack_int *lda, lapack_int *iseed, lapack_complex_double *x,
lapack_int *info);
```

Include Files

- `mkl.h`

Description

The routine `?laror` pre- or post-multiplies an m -by- n matrix A by a random orthogonal or unitary matrix U , overwriting A . A may optionally be initialized to the identity matrix before multiplying by U . U is generated using the method of G.W. Stewart (SIAM J. Numer. Anal. 17, 1980, 403-409).

Input Parameters

| | |
|-------------|--|
| <i>side</i> | <p>Specifies whether A is multiplied by U on the left or right.</p> <p>for <code>slaror</code> and <code>dlaror</code>:</p> <p>If <i>side</i> = 'L', multiply A on the left (premultiply) by U.</p> <p>If <i>side</i> = 'R', multiply A on the right (postmultiply) by U^T.</p> <p>If <i>side</i> = 'C' or 'T', multiply A on the left by U and the right by U^T.</p> <p>for <code>claror</code> and <code>zlaror</code>:</p> <p>If <i>side</i> = 'L', multiply A on the left (premultiply) by U.</p> <p>If <i>side</i> = 'R', multiply A on the right (postmultiply) by $UC^>$.</p> <p>If <i>side</i> = 'C', multiply A on the left by U and the right by $UC^>$.</p> <p>If <i>side</i> = 'T', multiply A on the left by U and the right by U^T.</p> |
| <i>init</i> | <p>Specifies whether or not a should be initialized to the identity matrix.</p> <p>If <i>init</i> = 'I', initialize a to (a section of) the identity matrix before applying U.</p> <p>If <i>init</i> = 'N', no initialization. Apply U to the input matrix A.</p> <p><i>init</i> = 'I' generates square or rectangular orthogonal matrices:</p> <p>For $m = n$ and <i>side</i> = 'L' or 'R', the rows and the columns are orthogonal to each other.</p> <p>For rectangular matrices where $m < n$:</p> <ul style="list-style-type: none"> • If <i>side</i> = 'R', <code>?laror</code> produces a dense matrix in which rows are orthogonal and columns are not. • If <i>side</i> = 'L', <code>?laror</code> produces a matrix in which rows are orthogonal, first m columns are orthogonal, and remaining columns are zero. <p>For rectangular matrices where $m > n$:</p> <ul style="list-style-type: none"> • If <i>side</i> = 'L', <code>?laror</code> produces a dense matrix in which columns are orthogonal and rows are not. • If <i>side</i> = 'R', <code>?laror</code> produces a matrix in which columns are orthogonal, first m rows are orthogonal, and remaining rows are zero. |
| <i>m</i> | The number of rows of A . |
| <i>n</i> | The number of columns of A . |
| <i>a</i> | Array, size <i>lda</i> by n . |

lda The leading dimension of the array *a*.

$$lda \geq \max(1, m).$$

iseed Array, size (4).

On entry, specifies the seed of the random number generator. The array elements must be between 0 and 4095; if not they are reduced mod 4096. Also, *iseed*[3] must be odd.

x Workspace array, size $(3 * \max(m, n))$.

| Value of <i>side</i> | Length of workspace |
|----------------------|---------------------|
| 'L' | $2 * m + n$ |
| 'R' | $2 * n + m$ |
| 'C' or 'T' | $3 * n$ |

Output Parameters

a On exit, overwritten
 by *UA* (if *side* = 'L'),
 by *AU* (if *side* = 'R'),
 by *UAU^T* (if *side* = 'C' or 'T').

iseed The values of *iseed* are changed on exit, and can be used in the next call to continue the same random number sequence.

info Array, size (4).
 For *slaror* and *dlaror*:
 If *info* = 0, the execution is successful.
 If *info* < 0, the *i*-th parameter had an illegal value.
 If *info* = 1, the random numbers generated by *?laror* are bad.
 For *claror* and *zlaror*:
 If *info* = 0, the execution is successful.
 If *info* = -1, *side* is not 'L', 'R', 'C', or 'T'.
 If *info* = -3, if *m* is negative.
 If *info* = -4, if *m* is negative or if *side* is 'C' or 'T' and *n* is not equal to *m*.
 If *info* = -6, if *lda* is less than *m*.

?larot

Applies a Givens rotation to two adjacent rows or columns.

If *lrows* = 0, *?larot* rotates two columns.

lleft

If *lleft* = 1, *xleft* is used instead of the corresponding element of *a* for the first element in the second row (if *lrows* = 0) or column (if *lrows*=1).

If *lleft* = 0, the corresponding element of *a* is used.

lright

If *lleft* = 1, *xright* is used instead of the corresponding element of *a* for the first element in the second row (if *lrows* = 0) or column (if *lrows*=1).

If *lright* = 0, the corresponding element of *a* is used.

nl

The length of the rows (if *lrows*=1) or columns (if *lrows*=1) to be rotated.

If *xleft* or *xright* are used, the columns or rows they are in should be included in *nl*, e.g., if *lleft* = *lright* = 1, then *nl* must be at least 2.

The number of rows or columns to be rotated exclusive of those involving *xleft* and/or *xright* may not be negative, i.e., *nl* minus how many of *lleft* and *lright* are 1 must be at least zero; if not, *xerbla* is called.

c, s

Specify the Givens rotation to be applied.

If *lrows* = 1, then the matrix

$$\begin{bmatrix} c & s \\ -s & c \end{bmatrix}$$

is applied from the left.

If *lrows* = 0, then the transpose thereof is applied from the right.

a

The array containing the rows or columns to be rotated. The first element of *a* should be the upper left element to be rotated.

lda

The "effective" leading dimension of *a*.

If *a* contains a matrix stored in GE or SY format, then this is just the leading dimension of *A*.

If *a* contains a matrix stored in band (GB or SB) format, then this should be one less than the leading dimension used in the calling routine. Thus, if *a* in *?larot* is of size *lda***n*, then *a[(j - 1)*lda]* would be the *j*-th element in the first of the two rows to be rotated, and *a[(j - 1)*lda + 1]* would be the *j*-th in the second, regardless of how the array may be stored in the calling routine. *a* cannot be dimensioned, because for band format the row number may exceed *lda*, which is not legal FORTRAN.

If *lrows* = 1, then *lda* must be at least 1, otherwise it must be at least *nl* minus the number of 1 values in *xleft* and *xright*.

xleft

If *lrows* = 1, *xleft* is used and modified instead of *a[1]* (if *lrows* = 1) or *a[lda + 1]* (if *lrows* = 0).

xright

If *lright* = 1, *xright* is used and modified instead of *a[(nl - 1)*lda]* (if *lrows* = 1) or *a[nl - 1]* (if *lrows* = 0).

Output Parameters

a On exit, modified array *A*.

?lartgp

Generates a plane rotation.

Syntax

```
lapack_int LAPACKE_slartgp (float f, float g, float* cs, float* sn, float* r);
lapack_int LAPACKE_dlartgp (double f, double g, double* cs, double* sn, double* r);
```

Include Files

- mkl.h

Description

The routine generates a plane rotation so that

$$\begin{bmatrix} cs & sn \\ -sn & cs \end{bmatrix} \cdot \begin{bmatrix} f \\ g \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix}$$

where $cs^2 + sn^2 = 1$

This is a slower, more accurate version of the BLAS Level 1 routine ?rotg, except for the following differences:

- *f* and *g* are unchanged on return.
- If *g*=0, then *cs*=(+/-)1 and *sn*=0.
- If *f*=0 and *g*≠ 0, then *cs*=0 and *sn*=(+/-)1.

The sign is chosen so that $r \geq 0$.

Input Parameters

f, g The first and second component of the vector to be rotated.

Output Parameters

cs The cosine of the rotation.

sn The sine of the rotation.

r The nonzero component of the rotated vector.

Return Values

If *info* = 0, the execution is successful.

If *info* = -1, *f* is NaN.

If *info* = -2, *g* is NaN.

See Also

[cblas_?rotg](#)
[?lartgs](#)

?lartgs

Generates a plane rotation designed to introduce a bulge in implicit QR iteration for the bidiagonal SVD problem.

Syntax

```
lapack_int LAPACKE_slartgs (floatx, floaty, floatsigma, float* cs, float* sn);
lapack_int LAPACKE_dlartgs (doublex, doubley, doublesigma, double* cs, double* sn);
```

Include Files

- `mkl.h`

Description

The routine generates a plane rotation designed to introduce a bulge in Golub-Reinsch-style implicit QR iteration for the bidiagonal SVD problem. x and y are the top-row entries, and $sigma$ is the shift. The computed cs and sn define a plane rotation that satisfies the following:

$$\begin{bmatrix} cs & sn \\ -sn & cs \end{bmatrix} \cdot \begin{bmatrix} x^2 - sigma \\ x * y \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix}$$

with r nonnegative.

If $x^2 - sigma$ and $x * y$ are 0, the rotation is by $\pi/2$

Input Parameters

| | |
|---------|--|
| x, y | The (1,1) and (1,2) entries of an upper bidiagonal matrix, respectively. |
| $sigma$ | Shift |

Output Parameters

| | |
|------|-----------------------------|
| cs | The cosine of the rotation. |
| sn | The sine of the rotation. |

Return Values

If $info = 0$, the execution is successful.

If $info = - 1$, x is NaN.

If $info = - 2$, y is NaN.

If $info = - 3$, $sigma$ is NaN.

See Also

[?lartgp](#)

?lascl

Multiplies a general rectangular matrix by a real scalar defined as c_{to}/c_{from} .

Syntax

```
lapack_int LAPACKE_slascl (int matrix_layout, char type, lapack_int kl, lapack_int ku, float cfrom, float cto, lapack_int m, lapack_int n, float * a, lapack_int lda);
```

```
lapack_int LAPACKE_dlascl (int matrix_layout, char type, lapack_int kl, lapack_int ku, double cfrom, double cto, lapack_int m, lapack_int n, double * a, lapack_int lda);
```

```
lapack_int LAPACKE_clascl (int matrix_layout, char type, lapack_int kl, lapack_int ku, float cfrom, float cto, lapack_int m, lapack_int n, lapack_complex_float * a, lapack_int lda);
```

```
lapack_int LAPACKE_zlascl (int matrix_layout, char type, lapack_int kl, lapack_int ku, double cfrom, double cto, lapack_int m, lapack_int n, lapack_complex_double * a, lapack_int lda);
```

Include Files

- mkl.h

Description

The routine ?lascl multiplies the m -by- n real/complex matrix A by the real scalar c_{to}/c_{from} . The operation is performed without over/underflow as long as the final result $c_{to} * A(i, j) / c_{from}$ does not over/underflow.

type specifies that A may be full, upper triangular, lower triangular, upper Hessenberg, or banded.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>type</i> | This parameter specifies the storage type of the input matrix. = 'G': A is a full matrix. = 'L': A is a lower triangular matrix. = 'U': A is an upper triangular matrix. = 'H': A is an upper Hessenberg matrix. = 'B': A is a symmetric band matrix with lower bandwidth kl and upper bandwidth ku and with the only the lower half stored = 'Q': A is a symmetric band matrix with lower bandwidth kl and upper bandwidth ku and with the only the upper half stored. = 'Z': A is a band matrix with lower bandwidth kl and upper bandwidth ku . See description of the ?gbtrf function for storage details. |
| <i>kl</i> | The lower bandwidth of A . Referenced only if <i>type</i> = 'B', 'Q' or 'Z'. |
| <i>ku</i> | The upper bandwidth of A . Referenced only if <i>type</i> = 'B', 'Q' or 'Z'. |

| | |
|-------------------|--|
| <i>cfrom, cto</i> | The matrix A is multiplied by $cto/cfrom$. $A(i, j)$ is computed without over/underflow if the final result $cto * A(i, j) / cfrom$ can be represented without over/underflow. $cfrom$ must be nonzero. |
| <i>m</i> | The number of rows of the matrix A . $m \geq 0$. |
| <i>n</i> | The number of columns of the matrix A . $n \geq 0$. |
| <i>a</i> | Array, size $(lda * n)$. The matrix to be multiplied by $cto/cfrom$. See <i>type</i> for the storage type. |
| <i>lda</i> | The leading dimension of the array a . $lda \geq \max(1, m)$. |

Output Parameters

| | |
|-------------|--|
| <i>a</i> | The multiplied matrix A . |
| <i>info</i> | If $info = 0$ - successful exit If $info = -i < 0$, the i -th argument had an illegal value. |

See Also

[?gbtrf](#)

?laset

Initializes the off-diagonal elements and the diagonal elements of a matrix to given values.

Syntax

```
lapack_int LAPACKE_slaset (int matrix_layout , char uplo , lapack_int m , lapack_int n , float alpha , float beta , float * a , lapack_int lda );
```

```
lapack_int LAPACKE_dlaset (int matrix_layout , char uplo , lapack_int m , lapack_int n , double alpha , double beta , double * a , lapack_int lda );
```

```
lapack_int LAPACKE_claset (int matrix_layout , char uplo , lapack_int m , lapack_int n , lapack_complex_float alpha , lapack_complex_float beta , lapack_complex_float * a , lapack_int lda );
```

```
lapack_int LAPACKE_zlaset (int matrix_layout , char uplo , lapack_int m , lapack_int n , lapack_complex_double alpha , lapack_complex_double beta , lapack_complex_double * a , lapack_int lda );
```

Include Files

- `mkl.h`

Description

The routine initializes an m -by- n matrix A to $beta$ on the diagonal and $alpha$ on the off-diagonals.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Specifies the part of the matrix <i>A</i> to be set. If <i>uplo</i> = 'U', upper triangular part is set; the strictly lower triangular part of <i>A</i> is not changed. If <i>uplo</i> = 'L': lower triangular part is set; the strictly upper triangular part of <i>A</i> is not changed. Otherwise: All of the matrix <i>A</i> is set. |
| <i>m</i> | The number of rows of the matrix <i>A</i> . $m \geq 0$. |
| <i>n</i> | The number of columns of the matrix <i>A</i> . $n \geq 0$. |
| <i>alpha, beta</i> | The constants to which the off-diagonal and diagonal elements are to be set, respectively. |
| <i>a</i> | Array, size at least $\max(1, lda*n)$ for column major and $\max(1, lda*m)$ for row major layout. The array <i>a</i> contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> . |
| <i>lda</i> | The leading dimension of the array <i>a</i> . $lda \geq \max(1, m)$ for column major layout and $lda \geq \max(1, n)$ for row major layout. |

Output Parameters

| | |
|----------|---|
| <i>a</i> | On exit, the leading <i>m</i> -by- <i>n</i> submatrix of <i>A</i> is set as follows: if <i>uplo</i> = 'U', $A_{ij} = \alpha, 1 \leq i \leq j-1, 1 \leq j \leq n$, if <i>uplo</i> = 'L', $A_{ij} = \alpha, j+1 \leq i \leq m, 1 \leq j \leq n$, otherwise, $A_{ij} = \alpha, 1 \leq i \leq m, 1 \leq j \leq n, i \neq j$, and, for all <i>uplo</i> , $A_{ij} = \beta, 1 \leq i \leq \min(m, n)$. |
|----------|---|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = *i* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?lasrt

Sorts numbers in increasing or decreasing order.

Syntax

```
lapack_int LAPACKE_slasrt (char id , lapack_int n , float * d );
lapack_int LAPACKE_dlasrt (char id , lapack_int n , double * d );
```

Include Files

- `mkl.h`

Description

The routine `?lasrt` sorts the numbers in d in increasing order (if $id = 'I'$) or in decreasing order (if $id = 'D'$). It uses Quick Sort, reverting to Insertion Sort on arrays of size ≤ 20 . Dimension of `stack` limits n to about 2^{32} .

Input Parameters

| | |
|------|--|
| id | = 'I': sort d in increasing order; = 'D': sort d in decreasing order. |
| n | The length of the array d . |
| d | On entry, the array to be sorted. |

Output Parameters

| | |
|-----|--|
| d | On exit, d has been sorted into increasing order ($d[0] \leq d[1] \leq \dots \leq d[n-1]$) or into decreasing order ($d[0] \geq d[1] \geq \dots \geq d[n-1]$), depending on id . |
|-----|--|

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info < 0$, the i -th parameter had an illegal value.

?laswp

Performs a series of row interchanges on a general rectangular matrix.

Syntax

```
lapack_int LAPACKE_slaswp (int matrix_layout , lapack_int n , float * a , lapack_int
lda , lapack_int k1 , lapack_int k2 , const lapack_int * ipiv , lapack_int incx );
lapack_int LAPACKE_dlaswp (int matrix_layout , lapack_int n , double * a , lapack_int
lda , lapack_int k1 , lapack_int k2 , const lapack_int * ipiv , lapack_int incx );
lapack_int LAPACKE_claswp (int matrix_layout , lapack_int n , lapack_complex_float *
a , lapack_int lda , lapack_int k1 , lapack_int k2 , const lapack_int * ipiv ,
lapack_int incx );
lapack_int LAPACKE_zlaswp (int matrix_layout , lapack_int n , lapack_complex_double *
a , lapack_int lda , lapack_int k1 , lapack_int k2 , const lapack_int * ipiv ,
lapack_int incx );
```

Include Files

- `mkl.h`

Description

The routine performs a series of row interchanges on the matrix A . One row interchange is initiated for each of rows $k1$ through $k2$ of A .

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>n</i> | The number of columns of the matrix A . |
| <i>a</i> | Array, size $\max(1, lda*n)$ for column major and $\max(1, lda*mm)$ for row major layout. Here mm is not less than maximum of values $ipiv[k1-1+j* incx]$, $0 \leq j < k2-k1$. Array a contains the m -by- n matrix A . |
| <i>lda</i> | The leading dimension of the array a . |
| <i>k1</i> | The first element of $ipiv$ for which a row interchange will be done. |
| <i>k2</i> | The last element of $ipiv$ for which a row interchange will be done. |
| <i>ipiv</i> | Array, size $k1+(k2-k1)* incx $. The vector of pivot indices. Only the elements in positions $k1$ through $k2$ of $ipiv$ are accessed. $ipiv(k) = l$ implies rows k and l are to be interchanged. |
| <i>incx</i> | The increment between successive values of $ipiv$. If $ipiv$ is negative, the pivots are applied in reverse order. |

Output Parameters

| | |
|----------|-------------------------------|
| <i>a</i> | On exit, the permuted matrix. |
|----------|-------------------------------|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?latm1

Computes the entries of a matrix as specified.

Syntax

```
void slatm1 (lapack_int *mode, *cond, lapack_int *irsign, lapack_int *idist, lapack_int *iseed, float *d, lapack_int *n, lapack_int *info);
```

```
void dlatm1 (lapack_int *mode, *cond, lapack_int *irsign, lapack_int *idist, lapack_int *iseed, double *d, lapack_int *n, lapack_int *info);
```

```
void clatm1 (lapack_int *mode, *cond, lapack_int *irsign, lapack_int *idist, lapack_int
*iseed, lapack_complex *d, lapack_int *n, lapack_int *info);

void zlatm1 (lapack_int *mode, *cond, lapack_int *irsign, lapack_int *idist, lapack_int
*iseed, lapack_complex_double *d, lapack_int *n, lapack_int *info);
```

Include Files

- mkl.h

Description

The ?latm1 routine computes the entries of $D(1..n)$ as specified by *mode*, *cond* and *irsign*. *idist* and *iseed* determine the generation of random numbers.

?latm1 is called by slatmr (for slatm1 and dlatm1), and by clatmr (for clatm1 and zlatm1) to generate random test matrices for LAPACK programs.

Input Parameters

| | |
|---------------|---|
| <i>mode</i> | <p>On entry describes how <i>d</i> is to be computed:</p> <p><i>mode</i> = 0 means do not change <i>d</i>.</p> <p><i>mode</i> = 1 sets $d[0] = 1$ and $d[1:n - 1] = 1.0/cond$</p> <p><i>mode</i> = 2 sets $d[0:n - 2] = 1$ and $d[n - 1] = 1.0/cond$</p> <p><i>mode</i> = 3 sets $d[i - 1] = cond^{-(i-1)/(n-1)}$</p> <p><i>mode</i> = 4 sets $d[i - 1] = 1 - (i-1)/(n-1) * (1 - 1/cond)$</p> <p><i>mode</i> = 5 sets <i>d</i> to random numbers in the range ($1/cond$, 1) such that their logarithms are uniformly distributed.</p> <p><i>mode</i> = 6 sets <i>d</i> to random numbers from same distribution as the rest of the matrix.</p> <p><i>mode</i> < 0 has the same meaning as $abs(mode)$, except that the order of the elements of <i>d</i> is reversed.</p> <p>Thus if <i>mode</i> is positive, <i>d</i> has entries ranging from 1 to $1/cond$, if negative, from $1/cond$ to 1.</p> |
| <i>cond</i> | On entry, used as described under <i>mode</i> above. If used, it must be ≥ 1 . |
| <i>irsign</i> | <p>On entry, if <i>mode</i> is not -6, 0, or 6, determines sign of entries of <i>d</i>.</p> <p>If <i>irsign</i> = 0, entries of <i>d</i> are unchanged.</p> <p>If <i>irsign</i> = 1, each entry of <i>d</i> is multiplied by a random complex number uniformly distributed with absolute value 1.</p> |
| <i>idist</i> | <p>Specifies the distribution of the random numbers.</p> <p>For slatm1 and dlatm1:</p> <p>= 1: uniform (0,1)</p> <p>= 2: uniform (-1,1)</p> <p>= 3: normal (0,1)</p> <p>For clatm1 and zlatm1:</p> |

- = 1: real and imaginary parts each uniform (0,1)
- = 2: real and imaginary parts each uniform (-1,1)
- = 3: real and imaginary parts each normal (0,1)
- = 4: complex number uniform in disk(0, 1)

| | |
|--------------|---|
| <i>iseed</i> | Array, size (4). Specifies the seed of the random number generator. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers. The values of <i>iseed</i> [3] are changed on exit, and can be used in the next call to ?latm1 to continue the same random number sequence. |
| <i>d</i> | Array, size <i>n</i> . |
| <i>n</i> | Number of entries of <i>d</i> . |

Output Parameters

| | |
|--------------|--|
| <i>iseed</i> | On exit, the seed is updated. |
| <i>d</i> | On exit, <i>d</i> is updated, unless <i>mode</i> = 0. |
| <i>info</i> | If <i>info</i> = 0, the execution is successful. If <i>info</i> = -1, <i>mode</i> is not in range -6 to 6. If <i>info</i> = -2, <i>mode</i> is neither -6, 0 nor 6, and <i>irsign</i> is neither 0 nor 1. If <i>info</i> = -3, <i>mode</i> is neither -6, 0 nor 6 and <i>cond</i> is less than 1. If <i>info</i> = -4, <i>mode</i> equals 6 or -6 and <i>idist</i> is not in range 1 to 4. If <i>info</i> = -7, <i>n</i> is negative. |

?latm2

Returns an entry of a random matrix.

Syntax

```
float slatm2 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int
*kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed, float *d, lapack_int
*igrade, float *dl, float *dr, lapack_int *ipvtng, lapack_int *iwork, float *sparse);

double dlatm2 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int
*kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed, double *d, lapack_int
*igrade, double *dl, double *dr, lapack_int *ipvtng, lapack_int *iwork, double
*sparse);
```

The data types for complex variations depend on whether or not the application links with Gnu Fortran (gfortran) libraries.

For non-gfortran (libmkl_intel_*) interface libraries:

```
void clatm2 (lapack_complex_float *res, lapack_int *m, lapack_int *n, lapack_int *i,
lapack_int *j, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed,
lapack_complex_float *d, lapack_int *igrade, lapack_complex_float *dl,
lapack_complex_float *dr, lapack_int *ipvtng, lapack_int *iwork, float *sparse);
```

```
void zlatm2 (lapack_complex_double *res, lapack_int *m, lapack_int *n, lapack_int *i,
lapack_int *j, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed,
lapack_complex_double *d, lapack_int *igrade, lapack_complex_double *dl,
lapack_complex_double *dr, lapack_int *ipvtng, lapack_int *iwork, double *sparse);
```

For gfortran (libmkl_gf_*) interface libraries:

```
lapack_complex_float clatm2 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int
*j, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed,
lapack_complex_float *d, lapack_int *igrade, lapack_complex_float *dl,
lapack_complex_float *dr, lapack_int *ipvtng, lapack_int *iwork, float *sparse);

lapack_complex_double zlatm2 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int
*j, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed,
lapack_complex_double *d, lapack_int *igrade, lapack_complex_double *dl,
lapack_complex_double *dr, lapack_int *ipvtng, lapack_int *iwork, double *sparse);
```

To understand the difference between the non-gfortran and gfortran interfaces and when to use each of them, see Dynamic Libraries in the lib/intel64 Directory in the *Intel MKL Developer Guide*.

Include Files

- mkl.h

Description

The `?latm2` routine returns entry (i, j) of a random matrix of dimension (m, n) . It is called by the `?latmr` routine in order to build random test matrices. No error checking on parameters is done, because this routine is called in a tight loop by `?latmr` which has already checked the parameters.

Use of `?latm2` differs from `?latm3` in the order in which the random number generator is called to fill in random matrix entries. With `?latm2`, the generator is called to fill in the pivoted matrix columnwise. With `?latm3`, the generator is called to fill in the matrix columnwise, after which it is pivoted. Thus, `?latm3` can be used to construct random matrices which differ only in their order of rows and/or columns. `?latm2` is used to construct band matrices while avoiding calling the random number generator for entries outside the band (and therefore generating random numbers).

The matrix whose (i, j) entry is returned is constructed as follows (this routine only computes one entry):

- If i is outside $(1..m)$ or j is outside $(1..n)$, returns zero (this is convenient for generating matrices in band format).
- Generate a matrix A with random entries of distribution $idist$.
- Set the diagonal to D .
- Grade the matrix, if desired, from the left (by dl) and/or from the right (by dr or dl) as specified by $igrade$.
- Permute, if desired, the rows and/or columns as specified by $ipvtng$ and $iwork$.
- Band the matrix to have lower bandwidth kl and upper bandwidth ku .
- Set random entries to zero as specified by $sparse$.

Input Parameters

| | |
|-----|-------------------------------------|
| m | Number of rows of the matrix. |
| n | Number of columns of the matrix. |
| i | Row of the entry to be returned. |
| j | Column of the entry to be returned. |

| | |
|---------------|---|
| <i>kl</i> | Lower bandwidth. |
| <i>ku</i> | Upper bandwidth. |
| <i>idist</i> | On entry, <i>idist</i> specifies the type of distribution to be used to generate a random matrix . for <i>slatm2</i> and <i>dlatm2</i> : = 1: uniform (0,1) = 2: uniform (-1,1) = 3: normal (0,1) for <i>clatm2</i> and <i>zlatm2</i> : = 1: real and imaginary parts each uniform (0,1) = 2: real and imaginary parts each uniform (-1,1) = 3: real and imaginary parts each normal (0,1) = 4: complex number uniform in disk (0, 1) |
| <i>iseed</i> | Array, size 4. Seed for the random number generator. |
| <i>d</i> | Array, size $(\min(i, j))$. Diagonal entries of matrix. |
| <i>igrade</i> | Specifies grading of matrix as follows: = 0: no grading = 1: matrix premultiplied by $\text{diag}(dl)$ = 2: matrix postmultiplied by $\text{diag}(dr)$ = 3: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dr)$ = 4: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{inv}(\text{diag}(dl))$ For <i>slatm2</i> and <i>slatm2</i> : = 5: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dl)$ For <i>clatm2</i> and <i>zlatm2</i> : = 5: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(\text{conjg}(dl))$ = 6: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dl)$ |
| <i>dl</i> | Array, size $(i \text{ or } j)$, as appropriate. Left scale factors for grading matrix. |
| <i>dr</i> | Array, size $(i \text{ or } j)$, as appropriate. Right scale factors for grading matrix. |
| <i>ipvtng</i> | On entry specifies pivoting permutations as follows: = 0: none = 1: row pivoting |

- = 2: column pivoting
- = 3: full pivoting, i.e., on both sides

iwork Array, size (*i* or *j*), as appropriate. This array specifies the permutation used. The row (or column) in position *k* was originally in position *iwork*[*k* - 1]. This differs from *iwork* for ?latm3.

sparse Specifies the sparsity of the matrix. If sparse matrix is to be generated, *sparse* should lie between 0 and 1. A uniform (0, 1) random number *x* is generated and compared to *sparse*. If *x* is larger the matrix entry is unchanged and if *x* is smaller the entry is set to zero. Thus on the average a fraction *sparse* of the entries will be set to zero.

Output Parameters

iseed On exit, the seed is updated.

Return Values

The function returns an entry of a random matrix (for complex variations libmkl_gf_* interface layer/ libraries return the result as the parameter *res*).

?latm3

Returns set entry of a random matrix.

Syntax

```
float slatm3 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int
*isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int
*iseed, float *d, lapack_int *igrade, float *dl, float *dr, lapack_int *ipvtng,
lapack_int *iwork, float *sparse);
```

```
double dlatm3 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int
*isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int
*iseed, double *d, lapack_int *igrade, double *dl, double *dr, lapack_int *ipvtng,
lapack_int *iwork, double *sparse);
```

The data types for complex variations depend on whether or not the application links with Gnu Fortran (gfortran) libraries.

For non-gfortran (libmkl_intel_*) interface libraries:

```
void clatm3 (lapack_complex_float *res, lapack_int *m, lapack_int *n, lapack_int *i,
lapack_int *j, lapack_int *isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku,
lapack_int *idist, lapack_int *iseed, lapack_complex_float *d, lapack_int *igrade,
lapack_complex_float *dl, lapack_complex_float *dr, lapack_int *ipvtng, lapack_int
*iwork, float *sparse);
```

```
void zlatm3 (lapack_complex_double *res, lapack_int *m, lapack_int *n, lapack_int *i,
lapack_int *j, lapack_int *isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku,
lapack_int *idist, lapack_int *iseed, lapack_complex_double *d, lapack_int *igrade,
lapack_complex_double *dl, lapack_complex_double *dr, lapack_int *ipvtng, lapack_int
*iwork, double *sparse);
```

For gfortran (libmkl_gf_*) interface libraries:

```
lapack_complex_float clatm3 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int
*j, lapack_int *isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku, lapack_int
*idist, lapack_int *iseed, lapack_complex_float *d, lapack_int *igrade,
lapack_complex_float *dl, lapack_complex_float *dr, lapack_int *ipvtng, lapack_int
*iwork, float *sparse);
```

```
lapack_complex_double zlatm3 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int
*j, lapack_int *isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku, lapack_int
*idist, lapack_int *iseed, lapack_complex_double *d, lapack_int *igrade,
lapack_complex_double *dl, lapack_complex_double *dr, lapack_int *ipvtng, lapack_int
*iwork, double *sparse);
```

To understand the difference between the non-gfortran and gfortran interfaces and when to use each of them, see Dynamic Libraries in the lib/intel64 Directory in the *Intel MKL Developer Guide*.

Include Files

- mkl.h

Description

The `?latm3` routine returns the $(isub, jsub)$ entry of a random matrix of dimension (m, n) described by the other parameters. $(isub, jsub)$ is the final position of the (i, j) entry after pivoting according to *ipvtng* and *iwork*. `?latm3` is called by the `?latmr` routine in order to build random test matrices. No error checking on parameters is done, because this routine is called in a tight loop by `?latmr` which has already checked the parameters.

Use of `?latm3` differs from `?latm2` in the order in which the random number generator is called to fill in random matrix entries. With `?latm2`, the generator is called to fill in the pivoted matrix columnwise. With `?latm3`, the generator is called to fill in the matrix columnwise, after which it is pivoted. Thus, `?latm3` can be used to construct random matrices which differ only in their order of rows and/or columns. `?latm2` is used to construct band matrices while avoiding calling the random number generator for entries outside the band (and therefore generating random numbers in different orders for different pivot orders).

The matrix whose $(isub, jsub)$ entry is returned is constructed as follows (this routine only computes one entry):

- If *isub* is outside $(1..m)$ or *jsub* is outside $(1..n)$, returns zero (this is convenient for generating matrices in band format).
- Generate a matrix *A* with random entries of distribution *idist*.
- Set the diagonal to *D*.
- Grade the matrix, if desired, from the left (by *dl*) and/or from the right (by *dr* or *dl*) as specified by *igrade*.
- Permute, if desired, the rows and/or columns as specified by *ipvtng* and *iwork*.
- Band the matrix to have lower bandwidth *kl* and upper bandwidth *ku*.
- Set random entries to zero as specified by *sparse*.

Input Parameters

| | |
|----------|---|
| <i>m</i> | Number of rows of matrix. |
| <i>n</i> | Number of columns of matrix. |
| <i>i</i> | Row of unpivoted entry to be returned. |
| <i>j</i> | Column of unpivoted entry to be returned. |

| | |
|---------------|---|
| <i>isub</i> | Row of pivoted entry to be returned. |
| <i>jsub</i> | Column of pivoted entry to be returned. |
| <i>kl</i> | Lower bandwidth. |
| <i>ku</i> | Upper bandwidth. |
| <i>idist</i> | <p>On entry, <i>idist</i> specifies the type of distribution to be used to generate a random matrix.</p> <p>for <i>slatm2</i> and <i>dlatm2</i>:</p> <ul style="list-style-type: none"> = 1: uniform (0,1) = 2: uniform (-1,1) = 3: normal (0,1) <p>for <i>clatm2</i> and <i>zlatm2</i>:</p> <ul style="list-style-type: none"> = 1: real and imaginary parts each uniform (0,1) = 2: real and imaginary parts each uniform (-1,1) = 3: real and imaginary parts each normal (0,1) = 4: complex number uniform in disk(0, 1) |
| <i>iseed</i> | <p>Array, size 4.</p> <p>Seed for random number generator.</p> |
| <i>d</i> | Array, size $(\min(i, j))$. Diagonal entries of matrix. |
| <i>igrade</i> | <p>Specifies grading of matrix as follows:</p> <ul style="list-style-type: none"> = 0: no grading = 1: matrix premultiplied by $\text{diag}(dl)$ = 2: matrix postmultiplied by $\text{diag}(dr)$ = 3: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dr)$ = 4: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{inv}(\text{diag}(dl))$ <p>For <i>slatm2</i> and <i>slatm2</i>:</p> <ul style="list-style-type: none"> = 5: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dl)$ <p>For <i>clatm2</i> and <i>zlatm2</i>:</p> <ul style="list-style-type: none"> = 5: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(\text{conjg}(dl))$ = 6: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dl)$ |
| <i>dl</i> | <p>Array, size $(i$ or j, as appropriate).</p> <p>Left scale factors for grading matrix.</p> |
| <i>dr</i> | <p>Array, size $(i$ or j, as appropriate).</p> <p>Right scale factors for grading matrix.</p> |

| | |
|---------------|---|
| <i>ipvtng</i> | On entry specifies pivoting permutations as follows: If <i>ipvtng</i> = 0: none. If <i>ipvtng</i> = 1: row pivoting. If <i>ipvtng</i> = 2: column pivoting. If <i>ipvtng</i> = 3: full pivoting, i.e., on both sides. |
| <i>sparse</i> | On entry, specifies the sparsity of the matrix if sparse matrix is to be generated. <i>sparse</i> should lie between 0 and 1. A uniform(0, 1) random number <i>x</i> is generated and compared to <i>sparse</i> ; if <i>x</i> is larger the matrix entry is unchanged and if <i>x</i> is smaller the entry is set to zero. Thus on the average a fraction <i>sparse</i> of the entries will be set to zero. |
| <i>iwork</i> | Array, size (<i>i</i> or <i>j</i> , as appropriate). This array specifies the permutation used. The row (or column) originally in position <i>k</i> is in position <i>iwork</i> [<i>k</i> - 1] after pivoting. This differs from <i>iwork</i> for ?latm2. |

Output Parameters

| | |
|--------------|--|
| <i>isub</i> | On exit, row of pivoted entry is updated. |
| <i>jsub</i> | On exit, column of pivoted entry is updated. |
| <i>iseed</i> | On exit, the seed is updated. |

Return Values

The function returns an entry of a random matrix (for complex variations libmkl_gf_* interface layer/libraries return the result as the parameter *res*).

?latm5

Generates matrices involved in the Generalized Sylvester equation.

Syntax

```

Description

The `zlatm5` routine generates matrices involved in the Generalized Sylvester equation:

$$A * R - L * B = C$$

$$D * R - L * E = F$$

They also satisfy the diagonalization condition:

$$\begin{bmatrix} I & -L \\ & I \end{bmatrix} \begin{bmatrix} A & -C \\ & B \end{bmatrix} \begin{bmatrix} I & R \\ & I \end{bmatrix} = \begin{bmatrix} A & \\ & B \end{bmatrix}$$

$$\begin{bmatrix} I & -L \\ & I \end{bmatrix} \begin{bmatrix} D & -F \\ & E \end{bmatrix} \begin{bmatrix} I & R \\ & I \end{bmatrix} = \begin{bmatrix} D & \\ & E \end{bmatrix}$$

Input Parameters

prtype

Specifies the type of matrices to generate.

- If *prtype* = 1, *A* and *B* are Jordan blocks, *D* and *E* are identity matrices.

A:

If (*i* == *j*) then $A_{i,j} = 1.0$.

If (*j* == *i* + 1) then $A_{i,j} = -1.0$.

Otherwise $A_{i,j} = 0.0$, *i*, *j* = 1...*m*

B:

If (*i* == *j*) then $B_{i,j} = 1.0 - \alpha$.

If (*j* == *i* + 1) then $B_{i,j} = 1.0$.

Otherwise $B_{i,j} = 0.0$, *i*, *j* = 1...*n*.

D:

If (*i* == *j*) then $D_{i,j} = 1.0$.

Otherwise $D_{i,j} = 0.0$, *i*, *j* = 1...*m*.

E:

If (*i* == *j*) then $E_{i,j} = 1.0$

Otherwise $E_{i,j} = 0.0$, *i*, *j* = 1...*n*.

L = *R* are chosen from [-10...10], which specifies the right hand sides (*C*, *F*).

- If *prtype* = 2 or 3: Triangular and/or quasi- triangular.

A:

If $(i \leq j)$ then $A_{i,j} = [-1 \dots 1]$.

Otherwise $A_{i,j} = 0.0$, $i, j = 1 \dots M$.

If $(prtype = 3)$ then $A_{k+1,k+1} = A_{k,k}$;

$A_{k+1,k} = [-1 \dots 1]$;

$\text{sign}(A_{k,k+1}) = -(\text{sign}(A_{k+1,k}))$.

$k = 1, m-1, qblcka$

B :

If $(i \leq j)$ then $B_{i,j} = [-1 \dots 1]$.

Otherwise $B_{i,j} = 0.0$, $i, j = 1 \dots n$.

If $(prtype = 3)$ then $B_{k+1,k+1} = B_{k,k}$

$B_{k+1,k} = [-1 \dots 1]$

$\text{sign}(B_{k,k+1}) = -(\text{sign}(B_{k+1,k}))$

$k = 1, n-1, qblckb$.

D:

If $(i \leq j)$ then $D_{i,j} = [-1 \dots 1]$.

Otherwise $D_{i,j} = 0.0$, $i, j = 1 \dots m$.

E:

If $(i \leq j)$ then $E_{i,j} = [-1 \dots 1]$.

Otherwise $E_{i,j} = 0.0$, $i, j = 1 \dots N$.

L, R are chosen from $[-10 \dots 10]$, which specifies the right hand sides (C, F).

- If $prtype = 4$ Full

$A_{i,j} = [-10 \dots 10]$

$D_{i,j} = [-1 \dots 1]$ $i, j = 1 \dots m$

$B_{i,j} = [-10 \dots 10]$

$E_{i,j} = [-1 \dots 1]$ $i, j = 1 \dots n$

$R_{i,j} = [-10 \dots 10]$

$L_{i,j} = [-1 \dots 1]$ $i = 1 \dots m, j = 1 \dots n$

L and R specifies the right hand sides (C, F).

- If $prtype = 5$ special case common and/or close eigs.

m Specifies the order of A and D and the number of rows in C, F, R and L .

n Specifies the order of B and E and the number of columns in C, F, R and L .

lda The leading dimension of a .

ldb The leading dimension of b .

ldc The leading dimension of c .

| | |
|--------------------|---|
| <i>l</i> <i>dd</i> | The leading dimension of <i>d</i> . |
| <i>l</i> <i>de</i> | The leading dimension of <i>e</i> . |
| <i>l</i> <i>df</i> | The leading dimension of <i>f</i> . |
| <i>l</i> <i>dr</i> | The leading dimension of <i>r</i> . |
| <i>l</i> <i>dl</i> | The leading dimension of <i>l</i> . |
| <i>alpha</i> | Parameter used in generating <i>prtype</i> = 1 and 5 matrices. |
| <i>qblcka</i> | When <i>prtype</i> = 3, specifies the distance between 2-by-2 blocks on the diagonal in <i>A</i> . Otherwise, <i>qblcka</i> is not referenced. <i>qblcka</i> > 1. |
| <i>qblckb</i> | When <i>prtype</i> = 3, specifies the distance between 2-by-2 blocks on the diagonal in <i>B</i> . Otherwise, <i>qblckb</i> is not referenced. <i>qblckb</i> > 1. |

Output Parameters

| | |
|----------|--|
| <i>a</i> | Array, size <i>lda</i> * <i>m</i> . On exit <i>a</i> contains them-by- <i>m</i> array <i>A</i> initialized according to <i>prtype</i> . |
| <i>b</i> | Array, size <i>ldb</i> * <i>n</i> . On exit <i>b</i> contains the <i>n</i> -by- <i>n</i> array <i>B</i> initialized according to <i>prtype</i> . |
| <i>c</i> | Array, size <i>ldc</i> * <i>n</i> . On exit <i>c</i> contains the <i>m</i> -by- <i>n</i> array <i>C</i> initialized according to <i>prtype</i> . |
| <i>d</i> | Array, size <i>l</i> <i>dd</i> * <i>m</i> . On exit <i>d</i> contains the <i>m</i> -by- <i>m</i> array <i>D</i> initialized according to <i>prtype</i> . |
| <i>e</i> | Array, size <i>l</i> <i>de</i> * <i>n</i> . On exit <i>e</i> contains the <i>n</i> -by- <i>n</i> array <i>E</i> initialized according to <i>prtype</i> . |
| <i>f</i> | Array, size <i>l</i> <i>df</i> * <i>n</i> . On exit <i>f</i> contains the <i>m</i> -by- <i>n</i> array <i>F</i> initialized according to <i>prtype</i> . |
| <i>r</i> | Array, size <i>l</i> <i>dr</i> * <i>n</i> . On exit <i>R</i> contains the <i>m</i> -by- <i>n</i> array <i>R</i> initialized according to <i>prtype</i> . |
| <i>l</i> | Array, size <i>l</i> <i>dl</i> * <i>n</i> . On exit <i>l</i> contains the <i>m</i> -by- <i>n</i> array <i>L</i> initialized according to <i>prtype</i> . |

?latm6

Generates test matrices for the generalized eigenvalue problem, their corresponding right and left eigenvector matrices, and also reciprocal condition numbers for all eigenvalues and the reciprocal condition numbers of eigenvectors corresponding to the 1th and 5th eigenvalues.

Syntax

```
void slatm6 (lapack_int *type, lapack_int *n, float *a, lapack_int *lda, float *b,
float *x, lapack_int *ldx, float *y, lapack_int *ldy, float *alpha, float *beta, float
*wx, float *wy, float *s, float *dif);
```

```
void dlatm6 (lapack_int *type, lapack_int *n, double *a, lapack_int *lda, double *b,
double *x, lapack_int *ldx, double *y, lapack_int *ldy, double *alpha, double *beta,
double *wx, double *wy, double *s, double *dif);
```

```
void clatm6 (lapack_int *type, lapack_int *n, lapack_complex_float *a, lapack_int *lda,
lapack_complex_float *b, lapack_complex_float *x, lapack_int *ldx, lapack_complex_float
*y, lapack_int *ldy, lapack_complex_float *alpha, lapack_complex_float *beta,
lapack_complex_float *wx, lapack_complex_float *wy, float *s, float *dif);
```

```
void zlatm6 (lapack_int *type, lapack_int *n, lapack_complex_double *a, lapack_int
*lda, lapack_complex_double *b, lapack_complex_double *x, lapack_int *ldx,
lapack_complex_double *y, lapack_int *ldy, lapack_complex_double *alpha,
lapack_complex_double *beta, lapack_complex_double *wx, lapack_complex_double *wy,
double *s, double *dif);
```

Include Files

- mkl.h

Description

The `?latm6` routine generates test matrices for the generalized eigenvalue problem, their corresponding right and left eigenvector matrices, and also reciprocal condition numbers for all eigenvalues and the reciprocal condition numbers of eigenvectors corresponding to the 1th and 5th eigenvalues.

There two kinds of test matrix pairs:

$$(A, B) = \text{inverse}(YH) * (Da, Db) * \text{inverse}(X)$$

Type 1:

$$Da = \begin{bmatrix} 1+a & 0 & 0 & 0 & 0 \\ 0 & 2+a & 0 & 0 & 0 \\ 0 & 0 & 3+a & 0 & 0 \\ 0 & 0 & 0 & 4+a & 0 \\ 0 & 0 & 0 & 0 & 5+2 \end{bmatrix} \quad Db = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

Type 2:

$$Da = \begin{bmatrix} 1+i & 0 & 0 & 0 & 0 \\ 0 & 1-i & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & (1+a)+(1+b)i & 0 \\ 0 & 0 & 0 & 0 & (1+a)-(1+b)i \end{bmatrix} \quad Db = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

In both cases the same `inverse(YH)` and `inverse(X)` are used to compute (A, B) , giving the exact eigenvectors to (A, B) as (YH, X) :

$$YH = \begin{bmatrix} 1 & 0 & -y & y & -y \\ 0 & 1 & -y & y & -y \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad X = \begin{bmatrix} 1 & 0 & -x & -x & x \\ 0 & 1 & x & -x & -x \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix},$$

where a , b , x and y will have all values independently of each other.

Input Parameters

| | |
|--------------------|---|
| <i>type</i> | Specifies the problem type. |
| <i>n</i> | Size of the matrices A and B . |
| <i>lda</i> | The leading dimension of a and of b . |
| <i>ldx</i> | The leading dimension of x . |
| <i>ldy</i> | The leading dimension of y . |
| <i>alpha, beta</i> | Weighting constants for matrix A . |
| <i>wx</i> | Constant for right eigenvector matrix. |
| <i>wy</i> | Constant for left eigenvector matrix. |

Output Parameters

| | |
|------------|--|
| <i>a</i> | Array, size $lda*n$. On exit, a contains the n -by- n matrix initialized according to <i>type</i> . |
| <i>b</i> | Array, size $lda*n$. On exit, b contains the n -by- n matrix initialized according to <i>type</i> . |
| <i>x</i> | Array, size $ldx*n$. On exit, x contains the n -by- n matrix of right eigenvectors. |
| <i>y</i> | Array, size $ldy*n$. On exit, y is the n -by- n matrix of left eigenvectors. |
| <i>s</i> | Array, size (n) . $s[i - 1]$ is the reciprocal condition number for eigenvalue i . |
| <i>dif</i> | Array, size (n) . $dif[i - 1]$ is the reciprocal condition number for eigenvector i . |

?latme

Generates random non-symmetric square matrices with specified eigenvalues.

Syntax

```
void slatme (lapack_int *n, char *dist, lapack_int *iseed, float *d, lapack_int *mode,

```

Include Files

- mkl.h

Description

The `?latme` routine generates random non-symmetric square matrices with specified eigenvalues. `?latme` operates by applying the following sequence of operations:

1. Set the diagonal to d , where d may be input or computed according to $mode$, $cond$, $dmax$, and $rsign$ as described below.
2. If $upper = 'T'$, the upper triangle of a is set to random values out of distribution $dist$.
3. If $sim='T'$, a is multiplied on the left by a random matrix X , whose singular values are specified by ds , $modes$, and $conds$, and on the right by X inverse.
4. If $kl < n-1$, the lower bandwidth is reduced to kl using Householder transformations. If $ku < n-1$, the upper bandwidth is reduced to ku .
5. If $anorm$ is not negative, the matrix is scaled to have maximum-element-norm $anorm$.

NOTE

Since the matrix cannot be reduced beyond Hessenberg form, no packing options are available.

Input Parameters

| | |
|--------|---|
| n | The number of columns (or rows) of A . |
| $dist$ | On entry, $dist$ specifies the type of distribution to be used to generate the random eigen-/singular values, and on the upper triangle (see $upper$). If $dist = 'U'$: uniform(0, 1) If $dist = 'S'$: uniform(-1, 1) If $dist = 'N'$: normal(0, 1) If $dist = 'D'$: uniform on the complex disc $ z < 1$. |

| | |
|--------------|---|
| <i>iseed</i> | <p>Array, size 4.</p> <p>On entry <i>iseed</i> specifies the seed of the random number generator. The elements should lie between 0 and 4095 inclusive, and <i>iseed</i>[3] should be odd. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers.</p> |
| <i>d</i> | <p>Array, size (<i>n</i>). This array is used to specify the eigenvalues of <i>A</i>.</p> <p>If <i>mode</i> = 0, then <i>d</i> is assumed to contain the eigenvalues. Otherwise they are computed according to <i>mode</i>, <i>cond</i>, <i>dmax</i>, and <i>rsign</i> and placed in <i>d</i>.</p> |
| <i>mode</i> | <p>On entry <i>mode</i> describes how the eigenvalues are to be specified:</p> <p><i>mode</i> = 0 means use <i>d</i> (with <i>ei</i> for <i>slatme</i> and <i>dlatme</i>) as input.</p> <p><i>mode</i> = 1 sets <i>d</i>[0] = 1 and <i>d</i>(2:<i>n</i>)=1.0/<i>cond</i>.</p> <p><i>mode</i> = 2 sets <i>d</i>[0:<i>n</i> - 2] = 1 and <i>d</i>[<i>n</i> - 1]=1.0/<i>cond</i>.</p> <p><i>mode</i> = 3 sets <i>d</i>[<i>i</i> - 1] = <i>cond</i>**(-(<i>i</i>-1)/(<i>n</i>-1)).</p> <p><i>mode</i> = 4 sets <i>d</i>[<i>i</i> - 1] = 1 - (<i>i</i>-1)/(<i>n</i>-1)*(1 - 1/<i>cond</i>).</p> <p><i>mode</i> = 5 sets <i>d</i> to random numbers in the range (1/<i>cond</i> , 1) such that their logarithms are uniformly distributed.</p> <p><i>mode</i> = 6 sets <i>d</i> to random numbers from same distribution as the rest of the matrix.</p> <p><i>mode</i> < 0 has the same meaning as <i>abs(mode)</i>, except that the order of the elements of <i>d</i> is reversed.</p> <p>Thus if <i>mode</i> is between 1 and 4, <i>d</i> has entries ranging from 1 to 1/<i>cond</i>, if between -1 and -4, <i>d</i> has entries ranging from 1/<i>cond</i> to 1.</p> |
| <i>cond</i> | <p>On entry, this is used as described under <i>mode</i> above. If used, it must be ≥ 1.</p> |
| <i>dmax</i> | <p>If <i>mode</i> is not -6, 0 or 6, the contents of <i>d</i> as computed according to <i>mode</i> and <i>cond</i> are scaled by <i>dmax</i> / max(abs(<i>d</i>[<i>i</i> - 1])). Note that <i>dmax</i> needs not be positive or real: if <i>dmax</i> is negative or complex (or zero), <i>d</i> will be scaled by a negative or complex number (or zero). If <i>rsign</i>='F' then the largest (absolute) eigenvalue will be equal to <i>dmax</i>.</p> |
| <i>ei</i> | <p>Used by <i>slatme</i> and <i>dlatme</i> only.</p> <p>Array, size (<i>n</i>).</p> <p>If <i>mode</i> = 0, and <i>ei</i>[0] is not ' ' (space character), this array specifies which elements of <i>d</i> (on input) are real eigenvalues and which are the real and imaginary parts of a complex conjugate pair of eigenvalues. The elements of <i>ei</i> may then only have the values 'R' and 'I'.</p> <p>If <i>ei</i>[<i>j</i> - 1] = 'R' and <i>ei</i>[<i>j</i>] = 'I', then the <i>j</i>-th eigenvalue is <i>cmplx(d[j - 1] , d[j])</i>, and the (<i>j</i>+1)-th is the complex conjugate thereof.</p> <p>If <i>ei</i>[<i>j</i> - 1] = <i>ei</i>[<i>j</i>]='R', then the <i>j</i>-th eigenvalue is <i>d</i>[<i>j</i> - 1] (i.e., real). <i>ei</i>[0] may not be 'I', nor may two adjacent elements of <i>ei</i> both have the value 'I'.</p> |

| | |
|--------------|--|
| | If <i>mode</i> is not 0, then <i>ei</i> is ignored. If <i>mode</i> is 0 and <i>ei</i> [0] = ' ', then the eigenvalues will all be real. |
| <i>rsign</i> | <p>If <i>mode</i> is not 0, 6, or -6, and <i>rsign</i> = 'T', then the elements of <i>d</i>, as computed according to <i>mode</i> and <i>cond</i>, are multiplied by a random sign (+1 or -1) for <i>slatme</i> and <i>dlatme</i> or by a complex number from the unit circle $z = 1$ for <i>clatme</i> and <i>zlatme</i>.</p> <p>If <i>rsign</i> = 'F', the elements of <i>d</i> are not multiplied. <i>rsign</i> may only have the values 'T' or 'F'.</p> |
| <i>upper</i> | <p>If <i>upper</i> = 'T', then the elements of <i>a</i> above the diagonal will be set to random numbers out of <i>dist</i>.</p> <p>If <i>upper</i> = 'F', they will not. <i>upper</i> may only have the values 'T' or 'F'.</p> |
| <i>sim</i> | <p>If <i>sim</i> = 'T', then <i>a</i> will be operated on by a "similarity transform", i.e., multiplied on the left by a matrix <i>X</i> and on the right by <i>X</i> inverse. $X = USV$, where <i>U</i> and <i>V</i> are random unitary matrices and <i>S</i> is a (diagonal) matrix of singular values specified by <i>ds</i>, <i>modes</i>, and <i>conds</i>.</p> <p>If <i>sim</i> = 'F', then <i>a</i> will not be transformed.</p> |
| <i>ds</i> | This array is used to specify the singular values of <i>X</i> , in the same way that <i>d</i> specifies the eigenvalues of <i>a</i> . If <i>mode</i> = 0, the <i>ds</i> contains the singular values, which may not be zero. |
| <i>modes</i> | Similar to <i>mode</i> , but for specifying the diagonal of <i>S</i> . <i>modes</i> = -6 and +6 are not allowed (since they would result in randomly ill-conditioned eigenvalues.) |
| <i>conds</i> | Similar to <i>cond</i> , but for specifying the diagonal of <i>S</i> . |
| <i>kl</i> | This specifies the lower bandwidth of the matrix. <i>kl</i> = 1 specifies upper Hessenberg form. If <i>kl</i> is at least <i>n</i> -1, then <i>A</i> will have full lower bandwidth. |
| <i>ku</i> | <p>This specifies the upper bandwidth of the matrix. <i>ku</i> = 1 specifies lower Hessenberg form.</p> <p>If <i>ku</i> is at least <i>n</i>-1, then <i>a</i> will have full upper bandwidth.</p> <p>If <i>ku</i> and <i>kl</i> are both at least <i>n</i>-1, then <i>a</i> will be dense. Only one of <i>ku</i> and <i>kl</i> may be less than <i>n</i>-1.</p> |
| <i>anorm</i> | If <i>anorm</i> is not negative, then <i>a</i> is scaled by a non-negative real number to make the maximum-element-norm of <i>a</i> to be <i>anorm</i> . |
| <i>lda</i> | Number of rows of matrix <i>A</i> . |
| <i>work</i> | Array, size (3*n) . Workspace. |

Output Parameters

| | |
|--------------|-------------------------------------|
| <i>iseed</i> | On exit, the seed is updated. |
| <i>d</i> | Modified if <i>mode</i> is nonzero. |

| | |
|-------------|---|
| <i>ds</i> | Modified if <i>mode</i> is nonzero. |
| <i>a</i> | Array, size <i>lda*n</i> . On exit, <i>a</i> is the desired test matrix. |
| <i>info</i> | <p>If <i>info</i> = 0, execution is successful.</p> <p>If <i>info</i> = -1, <i>n</i> is negative .</p> <p>If <i>info</i> = -2, <i>dist</i> is an illegal string.</p> <p>If <i>info</i> = -5, <i>mode</i> is not in range -6 to 6.</p> <p>If <i>info</i> = -6, <i>cond</i> is less than 1.0, and <i>mode</i> is not -6, 0, or 6 .</p> <p>If <i>info</i> = -9, <i>rsign</i> is not 'T' or 'F' .</p> <p>If <i>info</i> = -10, <i>upper</i> is not 'T' or 'F'.</p> <p>If <i>info</i> = -11, <i>sim</i> is not 'T' or 'F'.</p> <p>If <i>info</i> = -12, <i>modes</i> = 0 and <i>ds</i> has a zero singular value.</p> <p>If <i>info</i> = -13, <i>modes</i> is not in the range -5 to 5.</p> <p>If <i>info</i> = -14, <i>modes</i> is nonzero and <i>conds</i> is less than 1. .</p> <p>If <i>info</i> = -15, <i>kl</i> is less than 1.</p> <p>If <i>info</i> = -16, <i>ku</i> is less than 1, or <i>kl</i> and <i>ku</i> are both less than <i>n</i>-1.</p> <p>If <i>info</i> = -19, <i>lda</i> is less than <i>m</i>.</p> <p>If <i>info</i> = 1, error return from ?latm1 (computing <i>d</i>) .</p> <p>If <i>info</i> = 2, cannot scale to <i>dmax</i> (max. eigenvalue is 0) .</p> <p>If <i>info</i> = 3, error return from slatm1(for slatme and clatme), dlatm1 (for dlatme and zlatme) .</p> <p>If <i>info</i> = 4, error return from ?large.</p> <p>If <i>info</i> = 5, zero singular value from slatm1(for slatme and clatme), dlatm1(for dlatme and zlatme).</p> |

?latmr

Generates random matrices of various types.

Syntax

```
void slatmr (lapack_int *m, lapack_int *n, char *dist, lapack_int *iseed, char *sym,
float *d, lapack_int *mode, float *cond, float *dmax, char *rsign, char *grade, float

```

Description

The ?latmr routine operates by applying the following sequence of operations:

1. Generate a matrix A with random entries of distribution $dist$:
 - If $sym = 'S'$, the matrix is symmetric,
 - If $sym = 'H'$, the matrix is Hermitian,
 - If $sym = 'N'$, the matrix is nonsymmetric.
2. Set the diagonal to D , where D may be input or computed according to $mode$, $cond$, $dmax$ and $rsign$ as described below.
3. Grade the matrix, if desired, from the left or right as specified by $grade$. The inputs dl , $model$, $concl$, dr , $moder$ and $condr$ also determine the grading as described below.
4. Permute, if desired, the rows and/or columns as specified by $pivtng$ and $ipivot$.
5. Set random entries to zero, if desired, to get a random sparse matrix as specified by $sparse$.
6. Make A a band matrix, if desired, by zeroing out the matrix outside a band of lower bandwidth kl and upper bandwidth ku .
7. Scale A , if desired, to have maximum entry $anorm$.
8. Pack the matrix if desired. See options specified by the $pack$ parameter.

NOTE

If two calls to ?latmr differ only in the $pack$ parameter, they generate mathematically equivalent matrices. If two calls to ?latmr both have full bandwidth ($kl = m-1$ and $ku = n-1$), and differ only in the $pivtng$ and $pack$ parameters, then the matrices generated differ only in the order of the rows and columns, and otherwise contain the same data. This consistency cannot be and is not maintained with less than full bandwidth.

Input Parameters

| | |
|--------|---|
| m | Number of rows of A . |
| n | Number of columns of A . |
| $dist$ | On entry, $dist$ specifies the type of distribution to be used to generate a random matrix . If $dist = 'U'$, real and imaginary parts are independent uniform(0, 1). If $dist = 'S'$, real and imaginary parts are independent uniform(-1, 1). |

If $dist = 'N'$, real and imaginary parts are independent normal(0, 1).

If $dist = 'D'$, distribution is uniform on interior of unit disk.

iseed

Array, size 4.

On entry, *iseed* specifies the seed of the random number generator. They should lie between 0 and 4095 inclusive, and *iseed*[3] should be odd. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers.

sym

If $sym = 'S'$, generated matrix is symmetric.

If $sym = 'H'$, generated matrix is Hermitian.

If $sym = 'N'$, generated matrix is nonsymmetric.

d

On entry this array specifies the diagonal entries of the diagonal of *A*. *d* may either be specified on entry, or set according to *mode* and *cond* as described below. If the matrix is Hermitian, the real part of *d* is taken. May be changed on exit if *mode* is nonzero.

mode

On entry describes how *d* is to be used:

mode = 0 means use *d* as input.

mode = 1 sets $d[0]=1$ and $d[1:n - 1]=1.0/cond$.

mode = 2 sets $d[0:n - 2]=1$ and $d[n - 1]=1.0/cond$.

mode = 3 sets $d[i - 1]=cond^{*(-(i-1)/(n-1))}$.

mode = 4 sets $d[i - 1]=1 - (i-1)/(n-1)*(1 - 1/cond)$.

mode = 5 sets *d* to random numbers in the range ($1/cond$, 1) such that their logarithms are uniformly distributed.

mode = 6 sets *d* to random numbers from same distribution as the rest of the matrix.

mode < 0 has the same meaning as $abs(mode)$, except that the order of the elements of *d* is reversed.

Thus if *mode* is between 1 and 4, *d* has entries ranging from 1 to $1/cond$, if between -1 and -4, *D* has entries ranging from $1/cond$ to 1.

cond

On entry, used as described under *mode* above. If used, *cond* must be ≥ 1 .

dmax

If *mode* is not -6, 0, or 6, the diagonal is scaled by $dmax / \max(abs(d[i]))$, so that maximum absolute entry of diagonal is $abs(dmax)$. If *dmax* is complex (or zero), the diagonal is scaled by a complex number (or zero).

rsign

If *mode* is not -6, 0, or 6, specifies the sign of the diagonal as follows:

For *slatmr* and *dlatmr*, if $rsign = 'T'$, diagonal entries are multiplied 1 or -1 with a probability of 0.5.

For *clatmr* and *zlatmr*, if $rsign = 'T'$, diagonal entries are multiplied by a random complex number uniformly distributed with absolute value 1.

If *rsign* = 'F', diagonal entries are unchanged.

grade

Specifies grading of matrix as follows:

If *grade* = 'N', there is no grading

If *grade* = 'L', matrix is premultiplied by $\text{diag}(dl)$ (only if matrix is nonsymmetric)

If *grade* = 'R', matrix is postmultiplied by $\text{diag}(dr)$ (only if matrix is nonsymmetric)

If *grade* = 'B', matrix is premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dr)$ (only if matrix is nonsymmetric)

If *grade* = 'H', matrix is premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(\text{conjg}(dl))$ (only if matrix is Hermitian or nonsymmetric)

If *grade* = 'S', matrix is premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dl)$ (only if matrix is symmetric or nonsymmetric)

If *grade* = 'E', matrix is premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{inv}(\text{diag}(dl))$ (only if matrix is nonsymmetric)

NOTE

if *grade* = 'E', then *m* must equal *n*.

dl

Array, size (*m*).

If *model* = 0, then on entry this array specifies the diagonal entries of a diagonal matrix used as described under *grade* above.

If *model* is not zero, then *dl* is set according to *model* and *condl*, analogous to the way *D* is set according to *mode* and *cond* (except there is no *dmax* parameter for *dl*).

If *grade* = 'E', then *dl* cannot have zero entries.

Not referenced if *grade* = 'N' or 'R'. Changed on exit.

model

This specifies how the diagonal array *dl* is computed, just as *mode* specifies how *D* is computed.

condl

When *model* is not zero, this specifies the condition number of the computed *dl*.

dr

If *moder* = 0, then on entry this array specifies the diagonal entries of a diagonal matrix used as described under *grade* above.

If *moder* is not zero, then *dr* is set according to *moder* and *condr*, analogous to the way *d* is set according to *mode* and *cond* (except there is no *dmax* parameter for *dr*).

Not referenced if *grade* = 'N', 'L', 'H', 'S' or 'E'.

moder

This specifies how the diagonal array *dr* is to be computed, just as *mode* specifies how *d* is to be computed.

| | |
|-------------------------|--|
| <i>con_{dr}</i> | When <i>moder</i> is not zero, this specifies the condition number of the computed <i>dr</i> . |
| <i>piv_{tn}</i> | <p>On entry specifies pivoting permutations as follows:</p> <p>If <i>piv_{tn}</i> = 'N' or ' ': no pivoting permutation.</p> <p>If <i>piv_{tn}</i> = 'L': left or row pivoting (matrix must be nonsymmetric).</p> <p>If <i>piv_{tn}</i> = 'R': right or column pivoting (matrix must be nonsymmetric).</p> <p>If <i>piv_{tn}</i> = 'B' or 'F': both or full pivoting, i.e., on both sides. In this case, <i>m</i> must equal <i>n</i>.</p> <p>If two calls to ?<i>latmr</i> both have full bandwidth ($k_l = m - 1$ and $k_u = n - 1$), and differ only in the <i>piv_{tn}</i> and <i>pack</i> parameters, then the matrices generated differs only in the order of the rows and columns, and otherwise contain the same data. This consistency cannot be maintained with less than full bandwidth.</p> |
| <i>ipivot</i> | <p>Array, size (<i>n</i> or <i>m</i>) This array specifies the permutation used. After the basic matrix is generated, the rows, columns, or both are permuted.</p> <p>If row pivoting is selected, ?<i>latmr</i> starts with the last row and interchanges row <i>m</i> and row <i>ipivot</i>[<i>m</i> - 1], then moves to the next-to-last row, interchanging rows [<i>m</i> - 2] and row <i>ipivot</i>[<i>m</i> - 2], and so on. In terms of "2-cycles", the permutation is (1 <i>ipivot</i>[0]) (2 <i>ipivot</i>[1]) ... (<i>mipivot</i>[<i>m</i> - 1]) where the rightmost cycle is applied first. This is the inverse of the effect of pivoting in LINPACK. The idea is that factoring (with pivoting) an identity matrix which has been inverse-pivoted in this way should result in a pivot vector identical to <i>ipivot</i>. Not referenced if <i>piv_{tn}</i> = 'N'.</p> |
| <i>sparse</i> | On entry, specifies the sparsity of the matrix if a sparse matrix is to be generated. <i>sparse</i> should lie between 0 and 1. To generate a sparse matrix, for each matrix entry a uniform (0, 1) random number <i>x</i> is generated and compared to <i>sparse</i> ; if <i>x</i> is larger the matrix entry is unchanged and if <i>x</i> is smaller the entry is set to zero. Thus on the average a fraction <i>sparse</i> of the entries is set to zero. |
| <i>k_l</i> | On entry, specifies the lower bandwidth of the matrix. For example, $k_l = 0$ implies upper triangular, $k_l = 1$ implies upper Hessenberg, and k_l at least <i>m</i> -1 implies the matrix is not banded. Must equal <i>k_u</i> if matrix is symmetric or Hermitian. |
| <i>k_u</i> | On entry, specifies the upper bandwidth of the matrix. For example, $k_u = 0$ implies lower triangular, $k_u = 1$ implies lower Hessenberg, and k_u at least <i>n</i> -1 implies the matrix is not banded. Must equal <i>k_l</i> if matrix is symmetric or Hermitian. |
| <i>anorm</i> | On entry, specifies maximum entry of output matrix (output matrix is multiplied by a constant so that its largest absolute entry equal <i>anorm</i>) if <i>anorm</i> is nonnegative. If <i>anorm</i> is negative no scaling is done. |
| <i>pack</i> | <p>On entry, specifies packing of matrix as follows:</p> <p>If <i>pack</i> = 'N': no packing</p> <p>If <i>pack</i> = 'U': zero out all subdiagonal entries (if symmetric or Hermitian)</p> |

If $pack = 'L'$: zero out all superdiagonal entries (if symmetric or Hermitian)

If $pack = 'C'$: store the upper triangle columnwise (only if matrix symmetric or Hermitian or square upper triangular)

If $pack = 'R'$: store the lower triangle columnwise (only if matrix symmetric or Hermitian or square lower triangular) (same as upper half rowwise if symmetric) (same as conjugate upper half rowwise if Hermitian)

If $pack = 'B'$: store the lower triangle in band storage scheme (only if matrix symmetric or Hermitian)

If $pack = 'Q'$: store the upper triangle in band storage scheme (only if matrix symmetric or Hermitian)

If $pack = 'Z'$: store the entire matrix in band storage scheme (pivoting can be provided for by using this option to store A in the trailing rows of the allocated storage)

Using these options, the various LAPACK packed and banded storage schemes can be obtained:

| LAPACK storage scheme | Value of $pack$ |
|-----------------------|-----------------|
| GB | 'Z' |
| PB, HB or TB | 'B' or 'Q' |
| PP, HP or TP | 'C' or 'R' |

If two calls to `?latmr` differ only in the $pack$ parameter, they generate mathematically equivalent matrices.

lda

On entry, lda specifies the first dimension of a as declared in the calling program.

If $pack = 'N', 'U'$ or $'L'$, lda must be at least $\max(1, m)$.

If $pack = 'C'$ or $'R'$, lda must be at least 1.

If $pack = 'B',$ or $'Q'$, lda must be $\min(ku + 1, n)$.

If $pack = 'Z'$, lda must be at least $k_{uu} + k_{ll} + 1$, where $k_{uu} = \min(ku, n-1)$ and $k_{ll} = \min(kl, n-1)$.

$iwork$

Array, size $(n$ or $m)$. Workspace. Not referenced if $pivtnq = 'N'$. Changed on exit.

Output Parameters

$iseed$

On exit, the seed is changed.

d

May be changed on exit if $mode$ is nonzero.

dl

On exit, array is changed.

dr

On exit, array is changed.

a

On exit, a is the desired test matrix. Only those entries of a which are significant on output is referenced (even if a is in packed or band storage format). The unoccupied corners of a in band format are zeroed out.

info

- If *info* = 0, the execution is successful.
- If *info* = -1, *m* is negative or unequal to *n* and *sym* = 'S' or 'H'.
- If *info* = -2, *n* is negative .
- If *info* = -3, *dist* is an illegal string.
- If *info* = -5, *sym* is an illegal string..
- If *info* = -7, *mode* is not in range -6 to 6.
- If *info* = -8, *cond* is less than 1.0, and *mode* is neither -6, 0 nor 6.
- If *info* = -10, *mode* is neither -6, 0 nor 6 and *rsign* is an illegal string.
- If *info* = -11, *grade* is an illegal string, or *grade* = 'E' and *m* is not equal to *n*, or *grade*='L', 'R', 'B', 'S' or 'E' and *sym* = 'H', or *grade* = 'L', 'R', 'B', 'H' or 'E' and *sym* = 'S'
- If *info* = -12, *grade* = 'E' and *dl* contains zero .
- If *info* = -13, *model* is not in range -6 to 6 and *grade* = 'L', 'B', 'H', 'S' or 'E' .
- If *info* = -14, *concl* is less than 1.0, *grade* = 'L', 'B', 'H', 'S' or 'E', and *model* is neither -6, 0 nor 6.
- If *info* = -16, *moder* is not in range -6 to 6 and *grade* = 'R' or 'B' .
- If *info* = -17, *condr* is less than 1.0, *grade* = 'R' or 'B', and *moder* is neither -6, 0 nor 6 .
- If *info* = -18, *pivtnng* is an illegal string, or *pivtnng* = 'B' or 'F' and *m* is not equal to *n*, or *pivtnng* = 'L' or 'R' and *sym* = 'S' or 'H'.
- If *info* = -19, *ipivot* contains out of range number and *pivtnng* is not equal to 'N' .
- If *info* = -20, *kl* is negative.
- If *info* = -21, *ku* is negative, or *sym* = 'S' or 'H' and *ku* not equal to *kl* .
- If *info* = -22, *sparse* is not in range 0 to 1.
- If *info* = -24, *pack* is an illegal string, or *pack* = 'U', 'L', 'B' or 'Q' and *sym* = 'N', or *pack* = 'C' and *sym* = 'N' and either *kl* is not equal to 0 or *n* is not equal to *m*, or *pack* = 'R' and *sym* = 'N', and either *ku* is not equal to 0 or *n* is not equal to *m* .
- If *info* = -26, *lda* is too small .
- If *info* = 1, error return from ?latm1 (computing *D*) .
- If *info* = 2, cannot scale to *dmax* (max. entry is 0) .
- If *info* = 3, error return from ?latm1(computing *dl*) .
- If *info* = 4, error return from ?latm1(computing *dr*) .
- If *info* = 5, *anorm* is positive, but matrix constructed prior to attempting to scale it to have norm *anorm*, is zero .

?lauum

Computes the product $U^*U^T(U^*U^H)$ or $L^T*L(L^H*L)$, where U and L are upper or lower triangular matrices (blocked algorithm).

Syntax

```
lapack_int LAPACKE_slauum (int matrix_layout , char uplo , lapack_int n , float * a ,
lapack_int lda );

lapack_int LAPACKE_dlauum (int matrix_layout , char uplo , lapack_int n , double * a ,
lapack_int lda );

lapack_int LAPACKE_clauum (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_float * a , lapack_int lda );

lapack_int LAPACKE_zlauum (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_double * a , lapack_int lda );
```

Include Files

- mkl.h

Description

The routine ?lauum computes the product U^*U^T or L^T*L for real flavors, and U^*U^H or L^H*L for complex flavors. Here the triangular factor U or L is stored in the upper or lower triangular part of the array a .

If $uplo = 'U'$ or $'u'$, then the upper triangle of the result is stored, overwriting the factor U in A .

If $uplo = 'L'$ or $'l'$, then the lower triangle of the result is stored, overwriting the factor L in A .

This is the blocked form of the algorithm, calling [BLAS Level 3 Routines](#).

Input Parameters

| | |
|--------|---|
| $uplo$ | Specifies whether the triangular factor stored in the array a is upper or lower triangular: = 'U': Upper triangular = 'L': Lower triangular |
| n | The order of the triangular factor U or L . $n \geq 0$. |
| a | Array of size $\max(1, lda * n)$. On entry, the triangular factor U or L . |
| lda | The leading dimension of the array a . $lda \geq \max(1, n)$. |

Output Parameters

| | |
|-----|--|
| a | On exit, if $uplo = 'U'$, then the upper triangle of a is overwritten with the upper triangle of the product $U^*U^T(U^*U^H)$; if $uplo = 'L'$, then the lower triangle of a is overwritten with the lower triangle of the product $L^T*L(L^H*L)$. |
|-----|--|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*k*, the *k*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?syswapr

Applies an elementary permutation on the rows and columns of a symmetric matrix.

Syntax

```
lapack_int LAPACKE_ssyswapr (int matrix_layout , char uplo , lapack_int n , float * a ,
lapack_int i1 , lapack_int i2 );
```

```
lapack_int LAPACKE_dsyswapr (int matrix_layout , char uplo , lapack_int n , double *
a , lapack_int i1 , lapack_int i2 );
```

```
lapack_int LAPACKE_csyswapr (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_float * a , lapack_int i1 , lapack_int i2 );
```

```
lapack_int LAPACKE_zsyswapr (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_double * a , lapack_int i1 , lapack_int i2 );
```

Include Files

- mkl.h

Description

The routine applies an elementary permutation on the rows and columns of a symmetric matrix.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Must be 'U' or 'L'. Indicates how the input matrix <i>A</i> has been factored: If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular factor <i>U</i> of the factorization $A = U * D * U^T$. If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular factor <i>L</i> of the factorization $A = L * D * L^T$. |
| <i>n</i> | The order of matrix <i>A</i> ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; $nrhs \geq 0$. |
| <i>a</i> | Array of size at least $\max(1, lda * n)$. The array <i>a</i> contains the block diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> or <i>L</i> as computed by ?sytrf. |
| <i>i1</i> | Index of the first row to swap. |

i2 Index of the second row to swap.

Output Parameters

a If *info* = 0, the symmetric inverse of the original matrix.
 If *info* = 'U', the upper triangular part of the inverse is formed and the part of *A* below the diagonal is not referenced.
 If *info* = 'L', the lower triangular part of the inverse is formed and the part of *A* above the diagonal is not referenced.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?sytrf

?heswapr

Applies an elementary permutation on the rows and columns of a Hermitian matrix.

Syntax

```
lapack_int LAPACKE_cheswapr (int matrix_layout, char uplo, lapack_int n,
lapack_complex_float* a, lapack_int i1, lapack_int i2);
```

```
lapack_int LAPACKE_zheswapr (int matrix_layout, char uplo, lapack_int n,
lapack_complex_double* a, lapack_int i1, lapack_int i2);
```

Include Files

- mkl.h

Description

The routine applies an elementary permutation on the rows and columns of a Hermitian matrix.

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

uplo Must be 'U' or 'L'.
 Indicates how the input matrix *A* has been factored:
 If *uplo* = 'U', the array *a* stores the upper triangular factor *U* of the factorization $A = U^*D^*U^H$.
 If *uplo* = 'L', the array *a* stores the lower triangular factor *L* of the factorization $A = L^*D^*L^H$.

| | |
|-------------|---|
| <i>n</i> | The order of matrix <i>A</i> ; $n \geq 0$. |
| <i>nrhs</i> | The number of right-hand sides; $nrhs \geq 0$. |
| <i>a</i> | Array of size at least $\max(1, lda * n)$. The array <i>a</i> contains the block diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> or <i>L</i> as computed by ?hetrf. |
| <i>i1</i> | Index of the first row to swap. |
| <i>i2</i> | Index of the second row to swap. |

Output Parameters

| | |
|----------|---|
| <i>a</i> | If <i>info</i> = 0, the inverse of the original matrix. If <i>info</i> = 'U', the upper triangular part of the inverse is formed and the part of <i>A</i> below the diagonal is not referenced. If <i>info</i> = 'L', the lower triangular part of the inverse is formed and the part of <i>A</i> above the diagonal is not referenced. |
|----------|---|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

[?hetrf](#)

?sfrk

Performs a symmetric rank-k operation for matrix in RFP format.

Syntax

```
lapack_int LAPACKE_ssfrk (int matrix_layout , char transr , char uplo , char trans ,
lapack_int n , lapack_int k , float alpha , const float * a , lapack_int lda , float
beta , float * c );
```

```
lapack_int LAPACKE_dsfrk (int matrix_layout , char transr , char uplo , char trans ,
lapack_int n , lapack_int k , double alpha , const double * a , lapack_int lda ,
double beta , double * c );
```

Include Files

- mkl.h

Description

The ?sfrk routines perform a matrix-matrix operation using symmetric matrices. The operation is defined as

$$C := \alpha * A * A^T + \beta * C,$$

or

$$C := \alpha * A^T * A + \beta * C,$$

where:

α and β are scalars,

C is an n -by- n symmetric matrix in rectangular full packed (RFP) format,

A is an n -by- k matrix in the first case and a k -by- n matrix in the second case.

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

transr if *transr* = 'N' or 'n', the normal form of RFP C is stored;
if *transr* = 'T' or 't', the transpose form of RFP C is stored.

uplo Specifies whether the upper or lower triangular part of the array c is used.
If *uplo* = 'U' or 'u', then the upper triangular part of the array c is used.
If *uplo* = 'L' or 'l', then the low triangular part of the array c is used.

trans Specifies the operation:
if *trans* = 'N' or 'n', then $C := \alpha * A * A^T + \beta * C$;
if *trans* = 'T' or 't', then $C := \alpha * A^T * A + \beta * C$;

n Specifies the order of the matrix C . The value of n must be at least zero.

k On entry with *trans* = 'N' or 'n', k specifies the number of columns of the matrix A , and on entry with *trans* = 'T' or 't', k specifies the number of rows of the matrix A .
The value of k must be at least zero.

alpha Specifies the scalar α .

a Array, size $\max(1, lda * ka)$, where ka is in the following table:

| | Col_major | Row_major |
|--------------------|-----------|-----------|
| <i>trans</i> = 'N' | k | n |
| <i>trans</i> = 'T' | n | k |

Before entry with *trans* = 'N' or 'n', the leading n -by- k part of the array a must contain the matrix A , otherwise the leading k -by- n part of the array a must contain the matrix A .

lda Specifies the leading dimension of a as declared in the calling (sub)program. lda is defined by the following table:

| | Col_major | Row_major |
|--------------------|--------------|--------------|
| <i>trans</i> = 'N' | $\max(1, n)$ | $\max(1, k)$ |
| <i>trans</i> = 'T' | $\max(1, k)$ | $\max(1, n)$ |

| | |
|-------------|--|
| <i>beta</i> | Specifies the scalar <i>beta</i> . |
| <i>c</i> | Array, size $(n*(n+1)/2)$. Before entry contains the symmetric matrix <i>C</i> in RFP format. |

Output Parameters

| | |
|----------|--|
| <i>c</i> | If <i>trans</i> = 'N' or 'n', then <i>c</i> contains $C := \alpha*A*A' + \beta*C$; if <i>trans</i> = 'T' or 't', then <i>c</i> contains $C := \alpha*A'*A + \beta*C$; |
|----------|--|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?hfrk

Performs a Hermitian rank-*k* operation for matrix in RFP format.

Syntax

```
lapack_int LAPACKE_chfrk( int matrix_layout, char transr, char uplo, char trans,
lapack_int n, lapack_int k, float alpha, const lapack_complex_float* a, lapack_int
lda, float beta, lapack_complex_float* c );
```

```
lapack_int LAPACKE_zhfrk( int matrix_layout, char transr, char uplo, char trans,
lapack_int n, lapack_int k, double alpha, const lapack_complex_double* a, lapack_int
lda, double beta, lapack_complex_double* c );
```

Include Files

- mkl.h

Description

The ?hfrk routines perform a matrix-matrix operation using Hermitian matrices. The operation is defined as

$$C := \alpha*A*A^H + \beta*C,$$

or

$$C := \alpha*A^H*A + \beta*C,$$

where:

alpha and *beta* are real scalars,

C is an *n*-by-*n* Hermitian matrix in RFP format,

A is an *n*-by-*k* matrix in the first case and a *k*-by-*n* matrix in the second case.

Input Parameters

- matrix_layout* Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
- transr* if *transr* = 'N' or 'n', the normal form of RFP *C* is stored;
if *transr* = 'C' or 'c', the conjugate-transpose form of RFP *C* is stored.
- uplo* Specifies whether the upper or lower triangular part of the array *c* is used.
If *uplo* = 'U' or 'u', then the upper triangular part of the array *c* is used.
If *uplo* = 'L' or 'l', then the low triangular part of the array *c* is used.
- trans* Specifies the operation:
if *trans* = 'N' or 'n', then $C := \alpha * A * A^H + \beta * C$;
if *trans* = 'C' or 'c', then $C := \alpha * A^H * A + \beta * C$.
- n* Specifies the order of the matrix *C*. The value of *n* must be at least zero.
- k* On entry with *trans* = 'N' or 'n', *k* specifies the number of columns of the matrix *a*, and on entry with *trans* = 'T' or 't' or 'C' or 'c', *k* specifies the number of rows of the matrix *a*.
The value of *k* must be at least zero.
- alpha* Specifies the scalar *alpha*.
- a* Array, size $\max(1, lda * ka)$, where *ka* is in the following table:
- | | Col_major | Row_major |
|--------------------|-----------|-----------|
| <i>trans</i> = 'N' | <i>k</i> | <i>n</i> |
| <i>trans</i> = 'T' | <i>n</i> | <i>k</i> |
- Before entry with *trans* = 'N' or 'n', the leading *n*-by-*k* part of the array *a* must contain the matrix *A*, otherwise the leading *k*-by-*n* part of the array *a* must contain the matrix *A*.
- lda* Specifies the leading dimension of *a* as declared in the calling (sub)program. *lda* is defined by the following table:
- | | Col_major | Row_major |
|--------------------|--------------|--------------|
| <i>trans</i> = 'N' | $\max(1, n)$ | $\max(1, k)$ |
| <i>trans</i> = 'T' | $\max(1, k)$ | $\max(1, n)$ |
- beta* Specifies the scalar *beta*.
- c* Array, size $(n * (n + 1) / 2)$. Before entry contains the Hermitian matrix *C* in [RFP format](#).

Output Parameters

- c* If *trans* = 'N' or 'n', then *c* contains $C := \alpha * A * A^H + \beta * C$;

if $trans = 'C'$ or $'c'$, then c contains $C := \alpha * A^H * A + \beta * C$;

Return Values

This function returns a value *info*.

If $info = 0$, the execution is successful.

If $info < 0$, the i -th parameter had an illegal value.

If $info = -1011$, memory allocation error occurred.

?tfsm

Solves a matrix equation (one operand is a triangular matrix in RFP format).

Syntax

```
lapack_int LAPACKE_stfsm (int matrix_layout , char transr , char side , char uplo ,
char trans , char diag , lapack_int m , lapack_int n , float alpha , const float * a ,
float * b , lapack_int ldb );
```

```
lapack_int LAPACKE_dtfsm (int matrix_layout , char transr , char side , char uplo ,
char trans , char diag , lapack_int m , lapack_int n , double alpha , const double *
a , double * b , lapack_int ldb );
```

```
lapack_int LAPACKE_ctfsm (int matrix_layout , char transr , char side , char uplo ,
char trans , char diag , lapack_int m , lapack_int n , lapack_complex_float alpha ,
const lapack_complex_float * a , lapack_complex_float * b , lapack_int ldb );
```

```
lapack_int LAPACKE_ztfsm (int matrix_layout , char transr , char side , char uplo ,
char trans , char diag , lapack_int m , lapack_int n , lapack_complex_double alpha ,
const lapack_complex_double * a , lapack_complex_double * b , lapack_int ldb );
```

Include Files

- mkl.h

Description

The ?tfsm routines solve one of the following matrix equations:

$$\text{op}(A) * X = \alpha * B,$$

or

$$X * \text{op}(A) = \alpha * B,$$

where:

α is a scalar,

X and B are m -by- n matrices,

A is a unit, or non-unit, upper or lower triangular matrix in [rectangular full packed \(RFP\) format](#).

$\text{op}(A)$ can be one of the following:

- $\text{op}(A) = A$ or $\text{op}(A) = A^T$ for real flavors
- $\text{op}(A) = A$ or $\text{op}(A) = A^H$ for complex flavors

The matrix B is overwritten by the solution matrix X .

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>transr</i> | <p>if <i>transr</i> = 'N' or 'n', the normal form of RFP <i>A</i> is stored;</p> <p>if <i>transr</i> = 'T' or 't', the transpose form of RFP <i>A</i> is stored;</p> <p>if <i>transr</i> = 'C' or 'c', the conjugate-transpose form of RFP <i>A</i> is stored.</p> |
| <i>side</i> | <p>Specifies whether $\text{op}(A)$ appears on the left or right of <i>X</i> in the equation:</p> <p>if <i>side</i> = 'L' or 'l', then $\text{op}(A) * X = \alpha * B$;</p> <p>if <i>side</i> = 'R' or 'r', then $X * \text{op}(A) = \alpha * B$.</p> |
| <i>uplo</i> | <p>Specifies whether the RFP matrix <i>A</i> is upper or lower triangular:</p> <p>if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular;</p> <p>if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.</p> |
| <i>trans</i> | <p>Specifies the form of $\text{op}(A)$ used in the matrix multiplication:</p> <p>if <i>trans</i> = 'N' or 'n', then $\text{op}(A) = A$;</p> <p>if <i>trans</i> = 'T' or 't', then $\text{op}(A) = A'$;</p> <p>if <i>trans</i> = 'C' or 'c', then $\text{op}(A) = \text{conjg}(A')$.</p> |
| <i>diag</i> | <p>Specifies whether the RFP matrix <i>A</i> is unit triangular:</p> <p>if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular;</p> <p>if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.</p> |
| <i>m</i> | Specifies the number of rows of <i>B</i> . The value of <i>m</i> must be at least zero. |
| <i>n</i> | Specifies the number of columns of <i>B</i> . The value of <i>n</i> must be at least zero. |
| <i>alpha</i> | <p>Specifies the scalar <i>alpha</i>.</p> <p>When <i>alpha</i> is zero, then <i>a</i> is not referenced and <i>b</i> need not be set before entry.</p> |
| <i>a</i> | Array, size $(n * (n + 1) / 2)$. Contains the matrix <i>A</i> in RFP format. |
| <i>b</i> | <p>Array, size $\max(1, ldb * n)$ for column major and $\max(1, ldb * m)$ for row major.</p> <p>Before entry, the leading <i>m</i>-by-<i>n</i> part of the array <i>b</i> must contain the right-hand side matrix <i>B</i>.</p> |
| <i>ldb</i> | Specifies the leading dimension of <i>b</i> as declared in the calling (sub)program. The value of <i>ldb</i> must be at least $\max(1, m)$ for column major and $\max(1, n)$ for row major. |

Output Parameters

| | |
|----------|---|
| <i>b</i> | Overwritten by the solution matrix <i>X</i> . |
|----------|---|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?tfttp

Copies a triangular matrix from the rectangular full packed format (TF) to the standard packed format (TP).

Syntax

```
lapack_int LAPACKE_stfttp (int matrix_layout , char transr , char uplo , lapack_int n ,
const float * arf , float * ap );
```

```
lapack_int LAPACKE_dtfttp (int matrix_layout , char transr , char uplo , lapack_int n ,
const double * arf , double * ap );
```

```
lapack_int LAPACKE_ctfttp (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_float * arf , lapack_complex_float * ap );
```

```
lapack_int LAPACKE_ztfttp (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_double * arf , lapack_complex_double * ap );
```

Include Files

- mkl.h

Description

The routine copies a triangular matrix *A* from the Rectangular Full Packed (RFP) format to the standard packed format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>transr</i> | = 'N': <i>arf</i> is in the Normal format, = 'T': <i>arf</i> is in the Transpose format (for stfttp and dtfttp), = 'C': <i>arf</i> is in the Conjugate-transpose format (for ctfttp and ztfttp). |
| <i>uplo</i> | Specifies whether <i>A</i> is upper or lower triangular: = 'U': <i>A</i> is upper triangular, = 'L': <i>A</i> is lower triangular. |
| <i>n</i> | The order of the matrix <i>A</i> . $n \geq 0$. |
| <i>arf</i> | Array, size at least $\max(1, n*(n+1)/2)$. On entry, the upper or lower triangular matrix <i>A</i> stored in the RFP format. |

Output Parameters

ap Array, size at least $\max(1, n*(n+1)/2)$.
On exit, the upper or lower triangular matrix *A*, packed columnwise in a linear array.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?tfttr

Copies a triangular matrix from the rectangular full packed format (TF) to the standard full format (TR) .

Syntax

```
lapack_int LAPACKE_stfttr (int matrix_layout , char transr , char uplo , lapack_int n ,
const float * arf , float * a , lapack_int lda );
```

```
lapack_int LAPACKE_dftttr (int matrix_layout , char transr , char uplo , lapack_int n ,
const double * arf , double * a , lapack_int lda );
```

```
lapack_int LAPACKE_ctfttr (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_float * arf , lapack_complex_float * a , lapack_int lda );
```

```
lapack_int LAPACKE_zftttr (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_double * arf , lapack_complex_double * a , lapack_int lda );
```

Include Files

- mkl.h

Description

The routine copies a triangular matrix *A* from the Rectangular Full Packed (RFP) format to the standard full format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

transr = 'N': *arf* is in the Normal format,
= 'T': *arf* is in the Transpose format (for stfttr and dtfttr),
= 'C': *arf* is in the Conjugate-transpose format (for ctfttr and zftttr).

uplo Specifies whether *A* is upper or lower triangular:
= 'U': *A* is upper triangular,
= 'L': *A* is lower triangular.

| | |
|------------|--|
| <i>n</i> | The order of the matrices <i>arf</i> and <i>a</i> . $n \geq 0$. |
| <i>arf</i> | Array, size at least $\max(1, n*(n+1)/2)$. On entry, the upper or lower triangular matrix <i>A</i> stored in the RFP format. |
| <i>lda</i> | The leading dimension of the array <i>a</i> . $lda \geq \max(1, n)$. |

Output Parameters

| | |
|----------|---|
| <i>a</i> | Array, size $\max(1, lda * n)$. On exit, the triangular matrix <i>A</i> . If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> contains the upper triangular matrix, and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> contains the lower triangular matrix, and the strictly upper triangular part of <i>a</i> is not referenced. |
|----------|---|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?tpqrt2

Computes a QR factorization of a real or complex "triangular-pentagonal" matrix, which is composed of a triangular block and a pentagonal block, using the compact WY representation for *Q*.

Syntax

```
lapack_int LAPACKE_stpqrt2 (int matrix_layout, lapack_int m, lapack_int n, lapack_int l, float * a, lapack_int lda, float * b, lapack_int ldb, float * t, lapack_int ldt);
```

```
lapack_int LAPACKE_dtpqrt2 (int matrix_layout, lapack_int m, lapack_int n, lapack_int l, double * a, lapack_int lda, double * b, lapack_int ldb, double * t, lapack_int ldt);
```

```
lapack_int LAPACKE_ctpqrt2 (int matrix_layout, lapack_int m, lapack_int n, lapack_int l, lapack_complex_float * a, lapack_int lda, lapack_complex_float * b, lapack_int ldb, lapack_complex_float * t, lapack_int ldt );
```

```
lapack_int LAPACKE_ztpqrt2 (int matrix_layout, lapack_int m, lapack_int n, lapack_int l, lapack_complex_double * a, lapack_int lda, lapack_complex_double * b, lapack_int ldb, lapack_complex_double * t, lapack_int ldt );
```

Include Files

- mkl.h

Description

The input matrix *C* is an $(n+m)$ -by-*n* matrix

$$C = \begin{bmatrix} A \\ B \end{bmatrix} \left\{ \begin{array}{l} \leftarrow n \times n \text{ upper triangular} \\ \leftarrow m \times n \text{ pentagonal} \end{array} \right.$$

where A is an n -by- n upper triangular matrix, and B is an m -by- n pentagonal matrix consisting of an $(m-1)$ -by- n rectangular matrix $B1$ on top of an 1 -by- n upper trapezoidal matrix $B2$:

$$B = \begin{bmatrix} B1 \\ B2 \end{bmatrix} \left\{ \begin{array}{l} \leftarrow (m-1) \times n \text{ rectangular} \\ \leftarrow 1 \times n \text{ upper trapezoidal} \end{array} \right.$$

The upper trapezoidal matrix $B2$ consists of the first l rows of an n -by- n upper triangular matrix, where $0 \leq l \leq \min(m, n)$. If $l=0$, B is an m -by- n rectangular matrix. If $m=l=n$, B is upper triangular. The matrix W contains the elementary reflectors $H(i)$ in the i th column below the diagonal (of A) in the $(n+m)$ -by- n input matrix C so that W can be represented as

$$W = \begin{bmatrix} I \\ V \end{bmatrix} \left\{ \begin{array}{l} \leftarrow n \times n \text{ identity} \\ \leftarrow m \times n \text{ pentagonal} \end{array} \right.$$

Thus, V contains all of the information needed for W , and is returned in array b .

NOTE

V has the same form as B :

$$V = \begin{bmatrix} V1 \\ V2 \end{bmatrix} \left\{ \begin{array}{l} \leftarrow (m-1) \times n \text{ rectangular} \\ \leftarrow l \times n \text{ upper trapezoidal} \end{array} \right.$$

The columns of V represent the vectors which define the $H(i)$ s.

The $(m+n)$ -by- $(m+n)$ block reflector H is then given by

$$H = I - W^* T^* W^T \text{ for real flavors, and}$$

$$H = I - W^* T^* W^H \text{ for complex flavors}$$

where W^T is the transpose of W , W^H is the conjugate transpose of W , and T is the upper triangular factor of the block reflector.

Input Parameters

| | |
|----------------------------|---|
| <code>matrix_layout</code> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <code>m</code> | The total number of rows in the matrix B ($m \geq 0$). |
| <code>n</code> | The number of columns in B and the order of the triangular matrix A ($n \geq 0$). |

| | |
|-------------|---|
| <i>l</i> | The number of rows of the upper trapezoidal part of <i>B</i> ($\min(m, n) \geq l \geq 0$). |
| <i>a, b</i> | Arrays: <i>a</i> , size $\max(1, lda * n)$ contains the <i>n</i> -by- <i>n</i> upper triangular matrix <i>A</i> . <i>b</i> , size $\max(1, ldb * n)$ for column major and $\max(1, ldb * m)$ for row major, the pentagonal <i>m</i> -by- <i>n</i> matrix <i>B</i> . The first (<i>m</i> -1) rows contain the rectangular <i>B1</i> matrix, and the next <i>l</i> rows contain the upper trapezoidal <i>B2</i> matrix. |
| <i>lda</i> | The leading dimension of <i>a</i> ; at least $\max(1, n)$. |
| <i>ldb</i> | The leading dimension of <i>b</i> ; at least $\max(1, m)$ for column major and $\max(1, n)$ for row major. |
| <i>ldt</i> | The leading dimension of <i>t</i> ; at least $\max(1, n)$. |

Output Parameters

| | |
|----------|---|
| <i>a</i> | The elements on and above the diagonal of the array contain the upper triangular matrix <i>R</i> . |
| <i>b</i> | The pentagonal matrix <i>V</i> . |
| <i>t</i> | Array, size $\max(1, ldt * n)$. The upper <i>n</i> -by- <i>n</i> upper triangular factor <i>T</i> of the block reflector. |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0 and *info* = -*i*, the *i*th argument had an illegal value.

If *info* = -1011, memory allocation error occurred.

?tprfb

Applies a real or complex "triangular-pentagonal" blocked reflector to a real or complex matrix, which is composed of two blocks.

Syntax

```
lapack_int LAPACKE_stprfb (int matrix_layout, char side, char trans, char direct, char storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const float * v, lapack_int ldv, const float * t, lapack_int ldt, float * a, lapack_int lda, float * b, lapack_int ldb);
```

```
lapack_int LAPACKE_dtprfb (int matrix_layout, char side, char trans, char direct, char storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const double * v, lapack_int ldv, const double * t, lapack_int ldt, double * a, lapack_int lda, double * b, lapack_int ldb);
```

```
lapack_int LAPACKE_ctprfb (int matrix_layout, char side, char trans, char direct, char
storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const
lapack_complex_float * v, lapack_int ldv, const lapack_complex_float * t, lapack_int
ldt, lapack_complex_float * a, lapack_int lda, lapack_complex_float * b, lapack_int
ldb);
```

```
lapack_int LAPACKE_ztprfb (int matrix_layout, char side, char trans, char direct, char
storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const
lapack_complex_double * v, lapack_int ldv, const lapack_complex_double * t, lapack_int
ldt, lapack_complex_double * a, lapack_int lda, lapack_complex_double * b, lapack_int
ldb);
```

Include Files

- mkl.h

Description

The ?tprfb routine applies a real or complex "triangular-pentagonal" block reflector H , H^T , or H^H from either the left or the right to a real or complex matrix C , which is composed of two blocks A and B .

The block B is m -by- n . If $side = 'R'$, A is m -by- k , and if $side = 'L'$, A is of size k -by- n .

$$\begin{array}{l}
 \text{direct} = 'F' \quad \text{direct} = 'B' \\
 \text{side} = 'R' \quad C = \begin{bmatrix} A & B \end{bmatrix} \quad C = \begin{bmatrix} B & A \end{bmatrix} \\
 \text{side} = 'L' \quad C = \begin{bmatrix} A \\ B \end{bmatrix} \quad C = \begin{bmatrix} B \\ A \end{bmatrix}
 \end{array}$$

The pentagonal matrix V is composed of a rectangular block $V1$ and a trapezoidal block $V2$. The size of the trapezoidal block is determined by the parameter l , where $0 \leq l \leq k$. if $l=k$, the $V2$ block of V is triangular; if $l=0$, there is no trapezoidal block, thus $V = V1$ is rectangular.

| | |
|---|--|
| <i>direct</i> ='F' | <i>direct</i> ='B' |
| <i>storev</i> ='C' | <i>storev</i> ='C' |
| $V = \begin{bmatrix} V1 \\ V2 \end{bmatrix}$ | $V = \begin{bmatrix} V2 \\ V1 \end{bmatrix}$ |
| V2 is upper trapezoidal (first l rows of k -by- k upper triangular) | V2 is lower trapezoidal (last l rows of k -by- k lower triangular matrix) |
| <i>storev</i> ='R' | <i>storev</i> ='R' |
| $V = \begin{bmatrix} V1 & V2 \end{bmatrix}$ | $V = \begin{bmatrix} V2 & V1 \end{bmatrix}$ |
| V2 is lower trapezoidal (first l columns of k -by- k lower triangular matrix) | V2 is upper trapezoidal (last l columns of k -by- k upper triangular matrix) |

| | |
|---------------------|---------------------|
| <i>side</i> ='L' | <i>side</i> ='R' |
| <i>storev</i> ='C' | <i>storev</i> ='C' |
| V is m -by- k | V is n -by- k |

| | | |
|--------------------|--------------|--------------|
| <i>storev</i> ='R' | V2 is 1-by-k | V2 is 1-by-k |
| | V is k-by-m | V is k-by-n |
| | V2 is k-by-l | V2 is k-by-l |

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>side</i> | = 'L': apply H , H^T , or H^H from the left, = 'R': apply H , H^T , or H^H from the right. |
| <i>trans</i> | = 'N': apply H (no transpose), = 'T': apply H^T (transpose), = 'C': apply H^H (conjugate transpose). |
| <i>direct</i> | Indicates how H is formed from a product of elementary reflectors: = 'F': $H = H(1) H(2) \dots H(k)$ (Forward), = 'B': $H = H(k) \dots H(2) H(1)$ (Backward). |
| <i>storev</i> | Indicates how the vectors that define the elementary reflectors are stored: = 'C': Columns, = 'R': Rows. |
| <i>m</i> | The total number of rows in the matrix B ($m \geq 0$). |
| <i>n</i> | The number of columns in B ($n \geq 0$). |
| <i>k</i> | The order of the matrix T , which is the number of elementary reflectors whose product defines the block reflector. ($k \geq 0$) |
| <i>l</i> | The order of the trapezoidal part of V . ($k \geq l \geq 0$). |
| <i>v</i> | An array containing the pentagonal matrix V (the elementary reflectors $H(1), H(2), \dots, H(k)$). The size limitations depend on values of parameters <i>storev</i> and <i>side</i> as described in the following table |

| | <i>storev</i> = C | | <i>storev</i> = R | |
|--------------|--------------------|--------------------|--------------------|--------------------|
| | <i>side</i> = L | <i>side</i> = R | <i>side</i> = L | <i>side</i> = R |
| Column major | $\max(1, ldv * k)$ | $\max(1, ldv * k)$ | $\max(1, ldv * m)$ | $\max(1, ldv * n)$ |
| Row major | $\max(1, ldv * m)$ | $\max(1, ldv * n)$ | $\max(1, ldv * k)$ | $\max(1, ldv * k)$ |

ldv The leading dimension of the array *v*. It should satisfy the following conditions:

| | |
|-------------------|-------------------|
| <i>storev</i> = C | <i>storev</i> = R |
|-------------------|-------------------|

| | $side = L$ | $side = R$ | $side = L$ | $side = R$ |
|--------------|--------------|--------------|--------------|--------------|
| Column major | $\max(1, m)$ | $\max(1, n)$ | $\max(1, k)$ | $\max(1, k)$ |
| Row major | $\max(1, k)$ | $\max(1, k)$ | $\max(1, m)$ | $\max(1, n)$ |

t Array size $\max(1, ldt * k)$. The triangular k -by- k matrix T in the representation of the block reflector.

ldt The leading dimension of the array t ($ldt \geq k$).

a size should satisfy the following conditions:
 k if $side = 'R'$.

| | $side = L$ | $side = R$ |
|--------------|--------------------|--------------------|
| Column major | $\max(1, lda * n)$ | $\max(1, lda * k)$ |
| Row major | $\max(1, lda * k)$ | $\max(1, lda * m)$ |

The k -by- n or m -by- k matrix A .

lda The leading dimension of the array a should satisfy the following conditions:

| | $side = L$ | $side = R$ |
|--------------|--------------|--------------|
| Column major | $\max(1, k)$ | $\max(1, m)$ |
| Row major | $\max(1, n)$ | $\max(1, k)$ |

b Array size at least $\max(1, ldb * n)$ for column major layout and $\max(1, ldb * m)$ for row major layout, the m -by- n matrix B .

ldb The leading dimension of the array b ($ldb \geq \max(1, m)$ for column major layout and $ldb \geq \max(1, n)$ for row major layout).

Output Parameters

a Contains the corresponding block of H^*C , $H^T * C$, $H^H * C$, C^*H , C^*H^T , or C^*H^H .

b Contains the corresponding block of H^*C , $H^T * C$, $H^H * C$, C^*H , C^*H^T , or C^*H^H .

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info < 0$, the i -th parameter had an illegal value.

If $info = -1011$, memory allocation error occurred.

?tpdff

Copies a triangular matrix from the standard packed format (TP) to the rectangular full packed format (TF).

Syntax

```
lapack_int LAPACKE_stpttf (int matrix_layout , char transr , char uplo , lapack_int n ,
const float * ap , float * arf );
```

```
lapack_int LAPACKE_dtpttf (int matrix_layout , char transr , char uplo , lapack_int n ,
const double * ap , double * arf );
```

```
lapack_int LAPACKE_ctpttf (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_float * ap , lapack_complex_float * arf );
```

```
lapack_int LAPACKE_ztpttf (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_double * ap , lapack_complex_double * arf );
```

Include Files

- mkl.h

Description

The routine copies a triangular matrix A from the standard packed format to the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>transr</i> | = 'N': <i>arf</i> must be in the Normal format, = 'T': <i>arf</i> must be in the Transpose format (for <i>stpttf</i> and <i>dtpttf</i>), = 'C': <i>arf</i> must be in the Conjugate-transpose format (for <i>ctpttf</i> and <i>ztpttf</i>). |
| <i>uplo</i> | Specifies whether A is upper or lower triangular: = 'U': A is upper triangular, = 'L': A is lower triangular. |
| <i>n</i> | The order of the matrix A . $n \geq 0$. |
| <i>ap</i> | Array, size at least $\max(1, n*(n+1)/2)$. On entry, the upper or lower triangular matrix A , packed in a linear array. See Matrix Storage Schemes for more information. |

Output Parameters

| | |
|------------|--|
| <i>arf</i> | Array, size at least $\max(1, n*(n+1)/2)$. On exit, the upper or lower triangular matrix A stored in the RFP format. |
|------------|--|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

< 0: if *info* = -*i*, the *i*-th parameter had an illegal value.

If `info = -1011`, memory allocation error occurred.

?tptr

Copies a triangular matrix from the standard packed format (TP) to the standard full format (TR) .

Syntax

```
lapack_int LAPACKE_stptr (int matrix_layout , char uplo , lapack_int n , const float *
ap , float * a , lapack_int lda );
```

```
lapack_int LAPACKE_dtptr (int matrix_layout , char uplo , lapack_int n , const double
* ap , double * a , lapack_int lda );
```

```
lapack_int LAPACKE_ctptr (int matrix_layout , char uplo , lapack_int n , const
lapack_complex_float * ap , lapack_complex_float * a , lapack_int lda );
```

```
lapack_int LAPACKE_ztptr (int matrix_layout , char uplo , lapack_int n , const
lapack_complex_double * ap , lapack_complex_double * a , lapack_int lda );
```

Include Files

- `mkl.h`

Description

The routine copies a triangular matrix *A* from the standard packed format to the standard full format.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>). |
| <i>uplo</i> | Specifies whether <i>A</i> is upper or lower triangular: = 'U': <i>A</i> is upper triangular, = 'L': <i>A</i> is lower triangular. |
| <i>n</i> | The order of the matrices <i>ap</i> and <i>a</i> . $n \geq 0$. |
| <i>ap</i> | Array, size at least $\max(1, n*(n+1)/2)$. (see Matrix Storage Schemes). |
| <i>lda</i> | The leading dimension of the array <i>a</i> . $lda \geq \max(1,n)$. |

Output Parameters

| | |
|----------|--|
| <i>a</i> | Array, size $\max(1,lda*n)$. On exit, the triangular matrix <i>A</i> . If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> contains the upper triangular part of the matrix <i>A</i> , and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> contains the lower triangular part of the matrix <i>A</i> , and the strictly upper triangular part of <i>a</i> is not referenced. |
|----------|--|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?trttf

Copies a triangular matrix from the standard full format (TR) to the rectangular full packed format (TF).

Syntax

```
lapack_int LAPACKE_strttf (int matrix_layout , char transr , char uplo , lapack_int n ,
const float * a , lapack_int lda , float * arf );
```

```
lapack_int LAPACKE_dtrttf (int matrix_layout , char transr , char uplo , lapack_int n ,
const double * a , lapack_int lda , double * arf );
```

```
lapack_int LAPACKE_ctrttf (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_float * a , lapack_int lda , lapack_complex_float * arf );
```

```
lapack_int LAPACKE_ztrttf (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_double * a , lapack_int lda , lapack_complex_double * arf );
```

Include Files

- mkl.h

Description

The routine copies a triangular matrix *A* from the standard full format to the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>transr</i> | = 'N': <i>arf</i> must be in the Normal format, = 'T': <i>arf</i> must be in the Transpose format (for <i>strttf</i> and <i>dtrttf</i>), = 'C': <i>arf</i> must be in the Conjugate-transpose format (for <i>ctrttf</i> and <i>ztrttf</i>). |
| <i>uplo</i> | Specifies whether <i>A</i> is upper or lower triangular: = 'U': <i>A</i> is upper triangular, = 'L': <i>A</i> is lower triangular. |
| <i>n</i> | The order of the matrix <i>A</i> . $n \geq 0$. |
| <i>a</i> | Array, size $\max(1, (lda * n))$. |

On entry, the triangular matrix A . If $uplo = 'U'$, the leading n -by- n upper triangular part of the array a contains the upper triangular matrix, and the strictly lower triangular part of a is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of the array a contains the lower triangular matrix, and the strictly upper triangular part of a is not referenced.

lda The leading dimension of the array a . $lda \geq \max(1, n)$.

Output Parameters

arf Array, size at least $\max(1, n*(n+1)/2)$.
On exit, the upper or lower triangular matrix A stored in the RFP format.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info < 0$, the i -th parameter had an illegal value.

If $info = -1011$, memory allocation error occurred.

?trttp

Copies a triangular matrix from the standard full format (TR) to the standard packed format (TP).

Syntax

```
lapack_int LAPACKE_strttp (int matrix_layout , char uplo , lapack_int n , const float *
a , lapack_int lda , float * ap );
```

```
lapack_int LAPACKE_dtrttp (int matrix_layout , char uplo , lapack_int n , const double
* a , lapack_int lda , double * ap );
```

```
lapack_int LAPACKE_ctrttp (int matrix_layout , char uplo , lapack_int n , const
lapack_complex_float * a , lapack_int lda , lapack_complex_float * ap );
```

```
lapack_int LAPACKE_ztrttp (int matrix_layout , char uplo , lapack_int n , const
lapack_complex_double * a , lapack_int lda , lapack_complex_double * ap );
```

Include Files

- mkl.h

Description

The routine copies a triangular matrix A from the standard full format to the standard packed format.

Input Parameters

$uplo$ Specifies whether A is upper or lower triangular:
= 'U': A is upper triangular,
= 'L': A is lower triangular.

| | |
|------------|--|
| <i>n</i> | The order of the matrix <i>A</i> , $n \geq 0$. |
| <i>a</i> | Array, size $\max(1, lda * n)$. On entry, the triangular matrix <i>A</i> . If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> contains the upper triangular matrix, and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> contains the lower triangular matrix, and the strictly upper triangular part of <i>a</i> is not referenced. |
| <i>lda</i> | The leading dimension of the array <i>a</i> . $lda \geq \max(1, n)$. |

Output Parameters

| | |
|-----------|--|
| <i>ap</i> | Array, size at least $\max(1, n*(n+1)/2)$. On exit, the upper or lower triangular matrix <i>A</i> , packed columnwise in a linear array. (see Matrix Storage Schemes) |
|-----------|--|

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?zlacp2

Copies all or part of a real two-dimensional array to a complex array.

Syntax

```
lapack_int LAPACKE_clacp2 (int matrix_layout , char uplo , lapack_int m , lapack_int
n , const float * a , lapack_int lda , lapack_complex_float * b , lapack_int ldb );
lapack_int LAPACKE_zlacp2 (int matrix_layout , char uplo , lapack_int m , lapack_int
n , const double * a , lapack_int lda , lapack_complex_double * b , lapack_int ldb );
```

Include Files

- mkl.h

Description

The routine copies all or part of a real matrix *A* to another matrix *B*.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>uplo</i> | Specifies the part of the matrix <i>A</i> to be copied to <i>B</i> . If <i>uplo</i> = 'U', the upper triangular part of <i>A</i> ; if <i>uplo</i> = 'L', the lower triangular part of <i>A</i> . |

| | |
|-------|--|
| | Otherwise, all of the matrix A is copied. |
| m | The number of rows in the matrix A ($m \geq 0$). |
| n | The number of columns in A ($n \geq 0$). |
| a | Array, size at least $\max(1, lda*n)$ for column major and $\max(1, lda*m)$ for row major, contains the m -by- n matrix A . If $uplo = 'U'$, only the upper triangle or trapezoid is accessed; if $uplo = 'L'$, only the lower triangle or trapezoid is accessed. |
| lda | The leading dimension of a ; $lda \geq \max(1, m)$ for column major and $lda \geq \max(1, n)$ for row major. |
| ldb | The leading dimension of the output array b ; $ldb \geq \max(1, m)$ for column major and $ldb \geq \max(1, n)$ for row major. |

Output Parameters

| | |
|-----|--|
| b | Array, size at least $\max(1, ldb*n)$ for column major layout and $\max(1, ldb*m)$ for row major layout, contains the m -by- n matrix B . On exit, $B = A$ in the locations specified by $uplo$. |
|-----|--|

Return Values

This function returns a value *info*.

If $info = 0$, the execution is successful.

If $info < 0$, the i -th parameter had an illegal value.

If $info = -1011$, memory allocation error occurred.

mkl_?tppack

Copies a triangular/symmetric matrix or submatrix from standard full format to standard packed format.

Syntax

```
lapack_int LAPACKE_mkl_stppack (int matrix_layout, char uplo, char trans, lapack_int n,
float* ap, lapack_int i, lapack_int j, lapack_int rows, lapack_int cols, const float*
a, lapack_int lda);
```

```
lapack_int LAPACKE_mkl_dtpack (int matrix_layout, char uplo, char trans, lapack_int n,
double* ap, lapack_int i, lapack_int j, lapack_int rows, lapack_int cols, const
double* a, lapack_int lda);
```

```
lapack_int LAPACKE_mkl_ctppack (int matrix_layout, char uplo, char trans, lapack_int n,
MKL_Complex8* ap, lapack_int i, lapack_int j, lapack_int rows, lapack_int cols, const
MKL_Complex8* a, lapack_int lda);
```

```
lapack_int LAPACKE_mkl_ztpack (int matrix_layout, char uplo, char trans, lapack_int n,
MKL_Complex16* ap, lapack_int i, lapack_int j, lapack_int rows, lapack_int cols, const
MKL_Complex16* a, lapack_int lda);
```

Include Files

- `mk1.h`

Description

The routine copies a triangular or symmetric matrix or its submatrix from standard full format to packed format

$$AP_{i:i+rows-1, j:j+cols-1} := \text{op}(A)$$

Standard packed formats include:

- TP: triangular packed storage
- SP: symmetric indefinite packed storage
- HP: Hermitian indefinite packed storage
- PP: symmetric or Hermitian positive definite packed storage

Full formats include:

- GE: general
- TR: triangular
- SY: symmetric indefinite
- HE: Hermitian indefinite
- PO: symmetric or Hermitian positive definite

NOTE

Any elements of the copied submatrix rectangular outside of the triangular part of the matrix AP are skipped.

Input Parameters

| | |
|--------------|---|
| <i>uplo</i> | Specifies whether the matrix AP is upper or lower triangular. If <i>uplo</i> = 'U', AP is upper triangular. If <i>uplo</i> = 'L': AP is lower triangular. |
| <i>trans</i> | Specifies whether or not the copied block of A is transposed or not. If <i>trans</i> = 'N', no transpose: $\text{op}(A) = A$. If <i>trans</i> = 'T', transpose: $\text{op}(A) = A^T$. If <i>trans</i> = 'C', conjugate transpose: $\text{op}(A) = A^H$. For real data this is the same as <i>trans</i> = 'T'. |
| <i>n</i> | The order of the matrix AP ; $n \geq 0$ |
| <i>i, j</i> | Coordinates of the left upper corner of the destination submatrix in AP . If <i>uplo</i> = 'U', $1 \leq i \leq j \leq n$. If <i>uplo</i> = 'L', $1 \leq j \leq i \leq n$. |
| <i>rows</i> | Number of rows in the destination submatrix. $0 \leq \text{rows} \leq n - i + 1$. |
| <i>cols</i> | Number of columns in the destination submatrix. $0 \leq \text{cols} \leq n - j + 1$. |
| <i>a</i> | Pointer to the source submatrix. |

Array *a* contains the *rows*-by-*cols* submatrix stored as unpacked rows-by-columns if *trans* = 'N', or unpacked columns-by-rows if *trans* = 'T' or *trans* = 'C'.

The size of *a* is

| | <i>trans</i> = 'N' | <i>trans</i> ='T' or <i>trans</i> ='C' |
|--|--------------------------|---|
| <i>matrix_layout</i> = LAPACK_COL_MAJOR | <i>lda</i> * <i>cols</i> | <i>lda</i> * <i>rows</i> |
| <i>matrix_layout</i> = LAPACK_ROW_MAJOR | <i>lda</i> * <i>rows</i> | <i>lda</i> * <i>cols</i> |

NOTE

If there are elements outside of the triangular part of *AP*, they are skipped and are not copied from *a*.

lda

The leading dimension of the array *a*.

| | <i>trans</i> = 'N' | <i>trans</i> ='T' or <i>trans</i> ='C' |
|--|--------------------------------------|---|
| <i>matrix_layout</i> = LAPACK_COL_MAJOR | <i>lda</i> ≥ max(1, <i>rows</i>) | <i>lda</i> ≥ max(1, <i>cols</i>) |
| <i>matrix_layout</i> = LAPACK_ROW_MAJOR | <i>lda</i> ≥ max(1, <i>cols</i>) | <i>lda</i> ≥ max(1, <i>rows</i>) |

Output Parameters

ap

Array of size at least max(1, *n*(*n*+1)/2). The array *ap* contains either the upper or the lower triangular part of the matrix *AP* (as specified by *uplo*) in packed storage (see [Matrix Storage Schemes](#)). The submatrix of *ap* from row *i* to row *i* + *rows* - 1 and column *j* to column *j* + *cols* - 1 is overwritten with a copy of the source matrix.

Return Values

This function returns a value *info*. If *info*=0, the execution is successful. If *info* = -*i*, the *i*-th parameter had an illegal value.

mkl_?tpunpack

Copies a triangular/symmetric matrix or submatrix from standard packed format to full format.

Syntax

```
lapack_int LAPACKE_mkl_stpunpack ( int matrix_layout, char uplo, char trans,
    lapack_int n, const float* ap, lapack_int i, lapack_int j, lapack_int rows,
    lapack_int cols, float* a, lapack_int lda );
```

```
lapack_int LAPACKE_mkl_dtpunpack ( int matrix_layout, char uplo, char trans,
    lapack_int n, const double* ap, lapack_int i, lapack_int j, lapack_int rows,
    lapack_int cols, double* a, lapack_int lda );

lapack_int LAPACKE_mkl_ctpunpack ( int matrix_layout, char uplo, char trans,
    lapack_int n, const MKL_Complex8* ap, lapack_int i, lapack_int j, lapack_int rows,
    lapack_int cols, MKL_Complex8* a, lapack_int lda );

lapack_int LAPACKE_mkl_ztpunpack ( int matrix_layout, char uplo, char trans,
    lapack_int n, const MKL_Complex16* ap, lapack_int i, lapack_int j, lapack_int rows,
    lapack_int cols, MKL_Complex16* a, lapack_int lda );
```

Include Files

- mkl.h

Description

The routine copies a triangular or symmetric matrix or its submatrix from standard packed format to full format.

$A := \text{op}(AP_{i:i+\text{rows}-1, j:j+\text{cols}-1})$

Standard packed formats include:

- TP: triangular packed storage
- SP: symmetric indefinite packed storage
- HP: Hermitian indefinite packed storage
- PP: symmetric or Hermitian positive definite packed storage

Full formats include:

- GE: general
- TR: triangular
- SY: symmetric indefinite
- HE: Hermitian indefinite
- PO: symmetric or Hermitian positive definite

NOTE

Any elements of the copied submatrix rectangular outside of the triangular part of AP are skipped.

Input Parameters

| | |
|--------------|---|
| <i>uplo</i> | Specifies whether matrix AP is upper or lower triangular. If <i>uplo</i> = 'U', AP is upper triangular. If <i>uplo</i> = 'L': AP is lower triangular. |
| <i>trans</i> | Specifies whether or not the copied block of AP is transposed. If <i>trans</i> = 'N', no transpose: $\text{op}(AP) = AP$. If <i>trans</i> = 'T', transpose: $\text{op}(AP) = AP^T$. If <i>trans</i> = 'C', conjugate transpose: $\text{op}(AP) = AP^H$. For real data this is the same as <i>trans</i> = 'T'. |
| <i>n</i> | The order of the matrix AP ; $n \geq 0$. |

ap Array, size at least $\max(1, n(n+1)/2)$. The array *ap* contains either the upper or the lower triangular part of the matrix *AP* (as specified by *uplo*) in packed storage (see [Matrix Storage Schemes](#)). It is the source for the submatrix of *AP* from row *i* to row *i + rows - 1* and column *j* to column *j + cols - 1* to be copied.

i, j Coordinates of left upper corner of the submatrix in *AP* to copy.
 If *uplo*='U', $1 \leq i \leq j \leq n$.
 If *uplo*='L', $1 \leq j \leq i \leq n$.

rows Number of rows to copy. $0 \leq rows \leq n - i + 1$.

cols Number of columns to copy. $0 \leq cols \leq n - j + 1$.

lda The leading dimension of array *a*.

| | <i>trans</i> = 'N' | <i>trans</i> ='T' or <i>trans</i> ='C' |
|--|-----------------------------------|---|
| <i>matrix_layout</i> = LAPACK_COL_MAJOR | <i>lda</i> ≥ max(1, <i>rows</i>) | <i>lda</i> ≥ max(1, <i>cols</i>) |
| <i>matrix_layout</i> = LAPACK_ROW_MAJOR | <i>lda</i> ≥ max(1, <i>cols</i>) | <i>lda</i> ≥ max(1, <i>rows</i>) |

Output Parameters

a Pointer to the destination matrix. On exit, array *a* is overwritten with a copy of the unpacked *rows*-by-*cols* submatrix of *ap* unpacked rows-by-columns if *trans* = 'N', or unpacked columns-by-rows if *trans* = 'T' or *trans* = 'C'.
 The size of *a* is

| | <i>trans</i> = 'N' | <i>trans</i> ='T' or <i>trans</i> ='C' |
|--|--------------------------|---|
| <i>matrix_layout</i> = LAPACK_COL_MAJOR | <i>lda</i> * <i>cols</i> | <i>lda</i> * <i>rows</i> |
| <i>matrix_layout</i> = LAPACK_ROW_MAJOR | <i>lda</i> * <i>rows</i> | <i>lda</i> * <i>cols</i> |

NOTE

If there are elements outside of the triangular part of *ap* indicated by *uplo*, they are skipped and are not copied to *a*.

Return Values

This function returns a value *info*. If *info*=0, the execution is successful. If *info* = -*i*, the *i*-th parameter had an illegal value.

LAPACK Utility Functions and Routines

This section describes LAPACK utility functions and routines.

See Also

[lsame](#) Tests two characters for equality regardless of the case.

[lsamen](#) Tests two character strings for equality regardless of the case.

[second/dsecond](#) Returns elapsed time in seconds. Use to estimate real time between two calls to this function.

[xerbla](#) Error handling function called by BLAS, LAPACK, Vector Math, and Vector Statistics functions.

ilaver

Returns the version of the LAPACK library.

Syntax

```
void LAPACKE_ilaver (lapack_int * vers_major, lapack_int * vers_minor, lapack_int * vers_patch);
```

Include Files

- mkl.h

Description

This routine returns the version of the LAPACK library.

Output Parameters

| | |
|-------------------|---|
| <i>vers_major</i> | Returns the major version of the LAPACK library. |
| <i>vers_minor</i> | Returns the minor version from the major version of the LAPACK library. |
| <i>vers_patch</i> | Returns the patch version from the minor version of the LAPACK library. |

?lamch

Determines machine parameters for floating-point arithmetic.

Syntax

```
float LAPACKE_slamch (char cmach );  
double LAPACKE_dlamch (char cmach );
```

Include Files

- mkl.h

Description

The function ?lamch determines single precision and double precision machine parameters.

Input Parameters

cmach

Specifies the value to be returned by `?lamch`:

- = 'E' or 'e', *val* = *eps*
- = 'S' or 's', *val* = *sfmin*
- = 'B' or 'b', *val* = *base*
- = 'P' or 'p', *val* = *eps*base*
- = 'n' or 'n', *val* = *t*
- = 'R' or 'r', *val* = *rnd*
- = 'M' or 'm', *val* = *emin*
- = 'U' or 'u', *val* = *rmin*
- = 'L' or 'l', *val* = *emax*
- = 'O' or 'o', *val* = *rmax*

where

eps = relative machine precision;

sfmin = safe minimum, such that $1/sfmin$ does not overflow;

base = base of the machine;

prec = $eps*base$;

t = number of (base) digits in the mantissa;

rnd = 1.0 when rounding occurs in addition, 0.0 otherwise;

emin = minimum exponent before (gradual) underflow;

rmin = $underflow_threshold - base**(emin-1)$;

emax = largest exponent before overflow;

rmax = $overflow_threshold - (base**emax)*(1-eps)$.

NOTE

You can use a character string for *cmach* instead of a single character in order to make your code more readable. The first character of the string determines the value to be returned. For example, 'Precision' is interpreted as 'p'.

Output Parameters

val

Value returned by the function.

LAPACK Test Functions and Routines

This section describes LAPACK test functions and routines.

?lagge

Generates a general m-by-n matrix .

Syntax

```
lapack_int LAPACKE_slagge (int matrix_layout , lapack_int m , lapack_int n , lapack_int
kl , lapack_int ku , const float * d , float * a , lapack_int lda , lapack_int *
iseed );
```

```
lapack_int LAPACKE_dlagge (int matrix_layout , lapack_int m , lapack_int n , lapack_int
kl , lapack_int ku , const double * d , double * a , lapack_int lda , lapack_int *
iseed );
```

```
lapack_int LAPACKE_clagge (int matrix_layout , lapack_int m , lapack_int n , lapack_int
kl , lapack_int ku , const float * d , lapack_complex_float * a , lapack_int lda ,
lapack_int * iseed );
```

```

- mkl.h

Description

The routine generates a general m -by- n matrix A , by pre- and post- multiplying a real diagonal matrix D with random matrices U and V :

$$A := U * D * V,$$

where U and V are orthogonal for real flavors and unitary for complex flavors. The lower and upper bandwidths may then be reduced to kl and ku by additional orthogonal transformations.

Input Parameters

| | |
|---------|--|
| m | The number of rows of the matrix A ($m \geq 0$). |
| n | The number of columns of the matrix A ($n \geq 0$). |
| kl | The number of nonzero subdiagonals within the band of A ($0 \leq kl \leq m-1$). |
| ku | The number of nonzero superdiagonals within the band of A ($0 \leq ku \leq n-1$). |
| d | The array d with the dimension of $(\min(m, n))$ contains the diagonal elements of the diagonal matrix D . |
| lda | The leading dimension of the array a ($lda \geq m$) for column major layout and ($lda \geq n$) for row major layout. |
| $iseed$ | The array $iseed$ with the dimension of 4 contains the seed of the random number generator. The elements must be between 0 and 4095 and $iseed$ must be odd. |

Output Parameters

| | |
|--------------|--|
| <i>a</i> | The array <i>a</i> with size at least $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout contains the generated <i>m</i> -by- <i>n</i> matrix <i>A</i> . |
| <i>iseed</i> | The array <i>iseed</i> contains the updated seed on exit. |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?laghe

Generates a complex Hermitian matrix .

Syntax

```
lapack_int LAPACKE_claghe (int matrix_layout , lapack_int n , lapack_int k , const
float * d , lapack_complex_float * a , lapack_int lda , lapack_int * iseed );
```

```
lapack_int LAPACKE_zlaghe (int matrix_layout , lapack_int n , lapack_int k , const
double * d , lapack_complex_double * a , lapack_int lda , lapack_int * iseed );
```

Include Files

- mkl.h

Description

The routine generates a complex Hermitian matrix *A*, by pre- and post- multiplying a real diagonal matrix *D* with random unitary matrix:

$$A := U * D * U^H$$

The semi-bandwidth may then be reduced to *k* by additional unitary transformations.

Input Parameters

| | |
|----------------------|--|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>n</i> | The order of the matrix <i>A</i> ($n \geq 0$). |
| <i>k</i> | The number of nonzero subdiagonals within the band of <i>A</i> ($0 \leq k \leq n-1$). |
| <i>d</i> | The array <i>d</i> with the dimension of (<i>n</i>) contains the diagonal elements of the diagonal matrix <i>D</i> . |
| <i>lda</i> | The leading dimension of the array <i>a</i> ($lda \geq n$). |

iseed The array *iseed* with the dimension of 4 contains the seed of the random number generator. The elements must be between 0 and 4095 and *iseed*[3] must be odd.

Output Parameters

a The array *a* of size at least $\max(1, lda*n)$ contains the generated *n*-by-*n* Hermitian matrix *D*.

iseed The array *iseed* contains the updated seed on exit.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?lagsy

Generates a symmetric matrix by pre- and post-multiplying a real diagonal matrix with a random unitary matrix .

Syntax

```
lapack_int LAPACKE_slagsy (int matrix_layout , lapack_int n , lapack_int k , const float * d , float * a , lapack_int lda , lapack_int * iseed );
```

```
lapack_int LAPACKE_dlagsy (int matrix_layout , lapack_int n , lapack_int k , const double * d , double * a , lapack_int lda , lapack_int * iseed );
```

```
lapack_int LAPACKE_clagsy (int matrix_layout , lapack_int n , lapack_int k , const float * d , lapack_complex_float * a , lapack_int lda , lapack_int * iseed );
```

```
lapack_int LAPACKE_zlagsy (int matrix_layout , lapack_int n , lapack_int k , const double * d , lapack_complex_double * a , lapack_int lda , lapack_int * iseed );
```

Include Files

- mkl.h

Description

The ?lagsy routine generates a symmetric matrix *A* by pre- and post- multiplying a real diagonal matrix *D* with a random matrix *U*:

$$A := U * D * U^T,$$

where *U* is orthogonal for real flavors and unitary for complex flavors. The semi-bandwidth may then be reduced to *k* by additional unitary transformations.

Input Parameters

n The order of the matrix *A* ($n \geq 0$).

k The number of nonzero subdiagonals within the band of *A* ($0 \leq k \leq n-1$).

| | |
|--------------|--|
| <i>d</i> | The array <i>d</i> with the dimension of (<i>n</i>) contains the diagonal elements of the diagonal matrix <i>D</i> . |
| <i>lda</i> | The leading dimension of the array <i>a</i> ($lda \geq n$). |
| <i>iseed</i> | The array <i>iseed</i> with the dimension of 4 contains the seed of the random number generator. The elements must be between 0 and 4095 and <i>iseed</i> [3] must be odd. |

Output Parameters

| | |
|--------------|--|
| <i>a</i> | The array <i>a</i> of size max (1, <i>lda</i> * <i>n</i>) contains the generated symmetric <i>n</i> -by- <i>n</i> matrix <i>D</i> . |
| <i>iseed</i> | The array <i>iseed</i> contains the updated seed on exit. |

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?latms

Generates a general m-by-n matrix with specific singular values.

Syntax

```
lapack_int LAPACKE_slatms (int matrix_layout, lapack_int m, lapack_int n, char dist,
lapack_int * iseed, char sym, float * d, lapack_int mode, float cond, float dmax,
lapack_int kl, lapack_int ku, char pack, float * a, lapack_int lda);

lapack_int LAPACKE_dlatms (int matrix_layout, lapack_int m, lapack_int n, char dist,
lapack_int * iseed, char sym, double * d, lapack_int mode, double cond, double dmax,
lapack_int kl, lapack_int ku, char pack, double * a, lapack_int lda);

lapack_int LAPACKE_clatms (int matrix_layout, lapack_int m, lapack_int n, char dist,
lapack_int * iseed, char sym, float * d, lapack_int mode, float cond, float dmax,
lapack_int kl, lapack_int ku, char pack, lapack_complex_float * a, lapack_int lda);

lapack_int LAPACKE_zlatms (int matrix_layout, lapack_int m, lapack_int n, char dist,
lapack_int * iseed, char sym, double * d, lapack_int mode, double cond, double dmax,
lapack_int kl, lapack_int ku, char pack, lapack_complex_double * a, lapack_int lda);
```

Include Files

- mkl.h

Description

The ?latms routine generates random matrices with specified singular values, or symmetric/Hermitian matrices with specified eigenvalues for testing LAPACK programs.

It applies this sequence of operations:

1. Set the diagonal to d , where d is input or computed according to $mode$, $cond$, $dmax$, and sym as described in Input Parameters.
2. Generate a matrix with the appropriate band structure, by one of two methods:

Method A

1. Generate a dense m -by- n matrix by multiplying d on the left and the right by random unitary matrices, then:
2. Reduce the bandwidth according to kl and ku , using Householder transformations.

Method B:

Convert the bandwidth-0 (i.e., diagonal) matrix to a bandwidth-1 matrix using Givens rotations, "chasing" out-of-band elements back, much as in QR; then convert the bandwidth-1 to a bandwidth-2 matrix, etc.

Note that for reasonably small bandwidths (relative to m and n) this requires less storage, as a dense matrix is not generated. Also, for symmetric or Hermitian matrices, only one triangle is generated.

Method A is chosen if the bandwidth is a large fraction of the order of the matrix, and lda is at least m (so a dense matrix can be stored.) Method B is chosen if the bandwidth is small (less than $(1/2)*n$ for symmetric or Hermitian or less than $.3*n+m$ for nonsymmetric), or lda is less than m and not less than the bandwidth.

Pack the matrix if desired, using one of the methods specified by the $pack$ parameter.

If Method B is chosen and band format is specified, then the matrix is generated in the band format and no repacking is necessary.

Input Parameters

| | |
|----------------------|---|
| <i>matrix_layout</i> | Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR). |
| <i>m</i> | The number of rows of the matrix A ($m \geq 0$). |
| <i>n</i> | The number of columns of the matrix A ($n \geq 0$). |
| <i>dist</i> | Specifies the type of distribution to be used to generate the random singular values or eigenvalues: <ul style="list-style-type: none"> • 'U': uniform distribution (0, 1) • 'S': symmetric uniform distribution (-1, 1) • 'N': normal distribution (0, 1) |
| <i>iseed</i> | Array with size 4. Specifies the seed of the random number generator. Values should lie between 0 and 4095 inclusive, and <i>iseed</i> [3] should be odd. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers. The values of the array are modified, and can be used in the next call to <code>latms</code> to continue the same random number sequence. |
| <i>sym</i> | If <i>sym</i> ='S' or 'H', the generated matrix is symmetric or Hermitian, with eigenvalues specified by d , $cond$, $mode$, and $dmax$; they can be positive, negative, or zero. |

If *sym*='P', the generated matrix is symmetric or Hermitian, with eigenvalues (which are singular, non-negative values) specified by *d*, *cond*, *mode*, and *dmax*.

If *sym*='N', the generated matrix is nonsymmetric, with singular, non-negative values specified by *d*, *cond*, *mode*, and *dmax*.

| | |
|---|--|
| <i>d</i> | <p>Array, size (MIN(<i>m</i>, <i>n</i>))</p> <p>This array is used to specify the singular values or eigenvalues of <i>A</i> (see the description of <i>sym</i>). If <i>mode</i>=0, then <i>d</i> is assumed to contain the eigenvalues or singular values, otherwise elements of <i>d</i> are computed according to <i>mode</i>, <i>cond</i>, and <i>dmax</i>.</p> |
| <i>mode</i> | <p>Describes how the singular/eigenvalues are specified.</p> <ul style="list-style-type: none"> • <i>mode</i> = 0: use <i>d</i> as input • <i>mode</i> = 1: set $d[0] = 1$ and $d[1:n - 1] = 1.0/cond$ • <i>mode</i> = 2: set $d[0:n - 2] = 1$ and $d[n - 1] = 1.0/cond$ • <i>mode</i> = 3: set $d[i] = cond^{-i/(n - 1)}$ • <i>mode</i> = 4: set $d[i] = 1 - i/(n - 1) * (1 - 1/cond)$ • <i>mode</i> = 5: set elements of <i>d</i> to random numbers in the range (1/<i>cond</i>, 1) such that their logarithms are uniformly distributed. • <i>mode</i> = 6: set elements of <i>d</i> to random numbers from same distribution as the rest of the matrix. <p><i>mode</i> < 0 has the same meaning as ABS(<i>mode</i>), except that the order of the elements of <i>d</i> is reversed. Thus, if <i>mode</i> is positive, <i>d</i> has entries ranging from 1 to 1/<i>cond</i>, if negative, from 1/<i>cond</i> to 1.</p> <p>If <i>sym</i>='S' or 'H', and <i>mode</i> is not 0, 6, nor -6, then the elements of <i>d</i> are also given a random sign (multiplied by +1 or -1).</p> |
| <i>cond</i> | Used in setting <i>d</i> as described for the <i>mode</i> parameter. If used, $cond \geq 1$. |
| <i>dmax</i> | If <i>mode</i> is not -6, 0 nor 6, the contents of <i>d</i> , as computed according to <i>mode</i> and <i>cond</i> , are scaled by $dmax / \max(\text{abs}(d[i-1]))$; thus, the maximum absolute eigenvalue or singular value (the norm) is $\text{abs}(dmax)$. |
| <p>NOTE</p> <p><i>dmax</i> need not be positive: if <i>dmax</i> is negative (or zero), <i>d</i> will be scaled by a negative number (or zero).</p> | |
| <i>kl</i> | Specifies the lower bandwidth of the matrix. For example, <i>kl</i> =0 implies upper triangular, <i>kl</i> =1 implies upper Hessenberg, and <i>kl</i> being at least <i>m</i> - 1 means that the matrix has full lower bandwidth. <i>kl</i> must equal <i>ku</i> if the matrix is symmetric or Hermitian. |
| <i>ku</i> | Specifies the upper bandwidth of the matrix. For example, <i>ku</i> =0 implies lower triangular, <i>ku</i> =1 implies lower Hessenberg, and <i>ku</i> being at least <i>n</i> - 1 means that the matrix has full upper bandwidth. <i>kl</i> must equal <i>ku</i> if the matrix is symmetric or Hermitian. |
| <i>pack</i> | Specifies packing of matrix: |

- 'N': no packing
- 'U': zero out all subdiagonal entries (if symmetric or Hermitian)
- 'L': zero out all superdiagonal entries (if symmetric or Hermitian)
- 'B': store the lower triangle in band storage scheme (only if matrix symmetric, Hermitian, or lower triangular)
- 'Q': store the upper triangle in band storage scheme (only if matrix symmetric, Hermitian, or upper triangular)
- 'Z': store the entire matrix in band storage scheme (pivoting can be provided for by using this option to store *A* in the trailing rows of the allocated storage)

Using these options, the various LAPACK packed and banded storage schemes can be obtained:

| | 'Z' | 'B' | 'Q' | 'C' | 'R' |
|--|-----|-----|-----|-----|-----|
| GB: general band | x | | | | |
| PB: symmetric positive definite band | | x | x | | |
| SB: symmetric band | | x | x | | |
| HB: Hermitian band | | x | x | | |
| TB: triangular band | | x | x | | |
| PP: symmetric positive definite packed | | | | x | x |
| SP: symmetric packed | | | | x | x |
| HP: Hermitian packed | | | | x | x |
| TP: triangular packed | | | | x | x |

If two calls to `?latms` differ only in the `pack` parameter, they generate mathematically equivalent matrices.

lda

lda specifies the first dimension of *a* as declared in the calling program.

If `pack='N', 'U', 'L', 'C', or 'R'`, then *lda* must be at least *m* for column major or at least *n* for row major.

If `pack='B' or 'Q'`, then *lda* must be at least $\text{MIN}(kl, m - 1)$ (which is equal to $\text{MIN}(ku, n - 1)$).

If `pack='Z'`, *lda* must be large enough to hold the packed array: $\text{MIN}(ku, n - 1) + \text{MIN}(kl, m - 1) + 1$.

Output Parameters

iseed

The array *iseed* contains the updated seed.

d

The array *d* contains the updated seed.

NOTE

The array *d* is not modified if `mode = 0`.

a

Array of size *lda* by *n*.

The array a contains the generated m -by- n matrix A .

a is first generated in full (unpacked) form, and then packed, if so specified by $pack$. Thus, the first m elements of the first n columns are always modified. If $pack$ specifies a packed or banded storage scheme, all lda elements of the first n columns are modified; the elements of the array which do not correspond to elements of the generated matrix are set to zero.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info < 0$, the i -th parameter had an illegal value.

If $info = -1011$, memory allocation error occurred.

If $info = 2$, cannot scale to $dmax$ (maximum singular value is 0).

If $info = 3$, error return from [lagge](#), [?laghe](#), or [lagsy](#).

ScaLAPACK Routines

Intel® Math Kernel Library implements routines from the ScaLAPACK package for distributed-memory architectures. Routines are supported for both real and complex dense and band matrices to perform the tasks of solving systems of linear equations, solving linear least-squares problems, eigenvalue and singular value problems, as well as performing a number of related computational tasks.

Intel MKL ScaLAPACK routines are written in FORTRAN 77 with exception of a few utility routines written in C to exploit the IEEE arithmetic. All routines are available in all precision types: single precision, double precision, complexm, and double complex precision. See the `mkl_scalapack.h` header file for C declarations of ScaLAPACK routines.

NOTE

ScaLAPACK routines are provided only for Intel® 64 or Intel® Many Integrated Core architectures.

See descriptions of ScaLAPACK [computational routines](#) that perform distinct computational tasks, as well as [driver routines](#) for solving standard types of problems in one call. Additionally, Intel® Math Kernel Library implements ScaLAPACK [Auxiliary Routines](#), [Utility Functions and Routines](#), and [Matrix Redistribution/Copy Routines](#). The library includes routines for both real and complex data.

The `<install_directory>/examples/scalapackf` directory contains sample code demonstrating the use of ScaLAPACK routines.

Generally, ScaLAPACK runs on a network of computers using MPI as a message-passing layer and a set of prebuilt communication subprograms (BLACS), as well as a set of BLAS optimized for the target architecture. Intel MKL version of ScaLAPACK is optimized for Intel® processors. For the detailed system and environment requirements, see *Intel® MKL Release Notes* and *Intel® MKL Developer Guide*.

For full reference on ScaLAPACK routines and related information, see [\[SLUG\]](#).

Optimization Notice

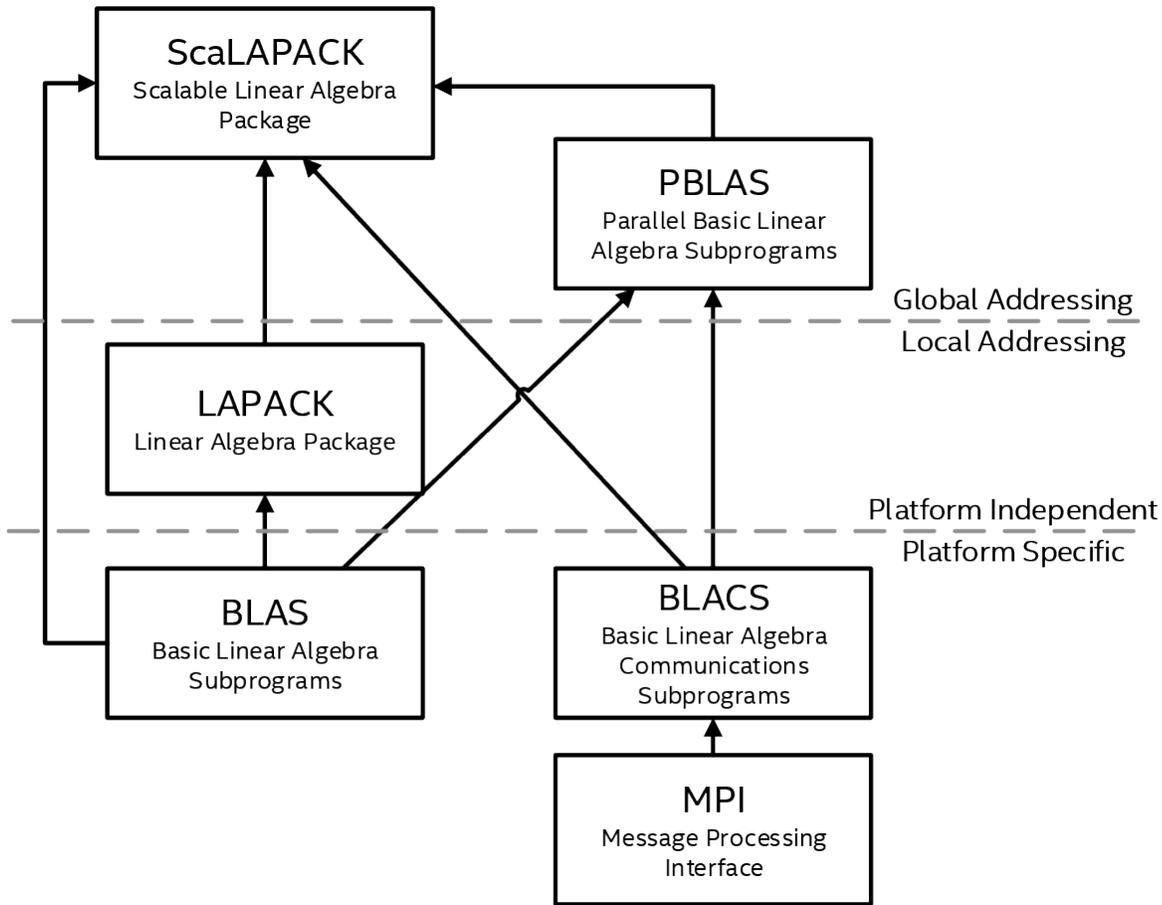

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Overview of ScaLAPACK Routines

The model of the computing environment for ScaLAPACK is represented as a one-dimensional array of processes (for operations on band or tridiagonal matrices) or also a two-dimensional process grid (for operations on dense matrices). To use ScaLAPACK, all global matrices or vectors should be distributed on this array or grid prior to calling the ScaLAPACK routines.

ScaLAPACK is closely tied to other components, including BLAS, BLACS, LAPACK, and PBLAS.

ScaLAPACK Array Descriptors

ScaLAPACK uses two-dimensional block-cyclic data distribution as a layout for dense matrix computations. This distribution provides good work balance between available processors, and also allows use of BLAS Level 3 routines for optimal local computations. Information about the data distribution that is required to establish the mapping between each global matrix and its corresponding process and memory location is contained in the array called the *array descriptor* associated with each global matrix. The size of the array descriptor is denoted as *dlen_*.

Let A be a two-dimensional block cyclicly distributed matrix with the array descriptor array *desca*. The meaning of each array descriptor element depends on the type of the matrix A . The tables "Array descriptor for dense matrices" and "Array descriptor for narrow-band and tridiagonal matrices" describe the meaning of each element for the different types of matrices.

Array descriptor for dense matrices (*dlen_=9*)

| Element Name | Stored in | Description | Element Index Number |
|----------------|----------------------|--|----------------------|
| <i>dtype_a</i> | <i>desca[dtype_]</i> | Descriptor type (=1 for dense matrices). | 0 |
| <i>ctxt_a</i> | <i>desca[ctxt_]</i> | BLACS context handle for the process grid. | 1 |
| <i>m_a</i> | <i>desca[m_]</i> | Number of rows in the global matrix A . | 2 |
| <i>n_a</i> | <i>desca[n_]</i> | Number of columns in the global matrix A . | 3 |
| <i>mb_a</i> | <i>desca[mb_]</i> | Row blocking factor. | 4 |
| <i>nb_a</i> | <i>desca[nb_]</i> | Column blocking factor. | 5 |

| Element Name | Stored in | Description | Element Index Number |
|---------------|---------------------|--|----------------------|
| <i>rsrc_a</i> | <i>desca[rsrc_]</i> | Process row over which the first row of the global matrix <i>A</i> is distributed. | 6 |
| <i>csrc_a</i> | <i>desca[csrc_]</i> | Process column over which the first column of the global matrix <i>A</i> is distributed. | 7 |
| <i>lld_a</i> | <i>desca[lld_]</i> | Leading dimension of the local matrix <i>A</i> . | 8 |

Array descriptor for narrow-band and tridiagonal matrices (*dlen_=7*)

| Element Name | Stored in | Description | Element Index Number |
|----------------|----------------------|--|----------------------|
| <i>dtype_a</i> | <i>desca[dtype_]</i> | Descriptor type <ul style="list-style-type: none"> <i>dtype_a</i>=501: 1-by-<i>P</i> grid, <i>dtype_a</i>=502: <i>P</i>-by-1 grid. | 0 |
| <i>ctxt_a</i> | <i>desca[ctxt_]</i> | BLACS context handle indicating the BLACS process grid over which the global matrix <i>A</i> is distributed. The context itself is global, but the handle (the integer value) can vary. | 1 |
| <i>n_a</i> | <i>desca[n_]</i> | The size of the matrix dimension being distributed. | 2 |
| <i>nb_a</i> | <i>desca[nb_]</i> | The blocking factor used to distribute the distributed dimension of the matrix <i>A</i> . | 3 |
| <i>src_a</i> | <i>desca[src_]</i> | The process row or column over which the first row or column of the matrix <i>A</i> is distributed. | 4 |
| <i>lld_a</i> | <i>desca[lld_]</i> | The leading dimension of the local matrix storing the local blocks of the distributed matrix <i>A</i> . The minimum value of <i>lld_a</i> depends on <i>dtype_a</i> . <ul style="list-style-type: none"> <i>dtype_a</i>=501: $lld_a \geq \max(\text{size of undistributed dimension}, 1)$, <i>dtype_a</i>=502: $lld_a \geq \max(nb_a, 1)$. | 5 |
| Not applicable | | Reserved for future use. | 6 |

Similar notations are used for different matrices. For example: *lld_b* is the leading dimension of the local matrix storing the local blocks of the distributed matrix *B* and *dtype_z* is the type of the global matrix *Z*.

The number of rows and columns of a global dense matrix that a particular process in a grid receives after data distributing is denoted by $LOC_r()$ and $LOC_c()$, respectively. To compute these numbers, you can use the ScaLAPACK tool routine `numroc`.

After the block-cyclic distribution of global data is done, you may choose to perform an operation on a submatrix $sub(A)$ of the global matrix *A* defined by the following 6 values (for dense matrices):

| | |
|-----------|--|
| <i>m</i> | The number of rows of $sub(A)$ |
| <i>n</i> | The number of columns of $sub(A)$ |
| <i>a</i> | A pointer to the local matrix containing the entire global matrix <i>A</i> |
| <i>ia</i> | The row index of $sub(A)$ in the global matrix <i>A</i> |
| <i>ja</i> | The column index of $sub(A)$ in the global matrix <i>A</i> |

*desca*The array descriptor for the global matrix *A***Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Naming Conventions for ScaLAPACK Routines

For each routine introduced in this chapter, you can use the ScaLAPACK name. The naming convention for ScaLAPACK routines is similar to that used for LAPACK routines. A general rule is that each routine name in ScaLAPACK, which has an LAPACK equivalent, is simply the LAPACK name prefixed by initial letter *p*.

ScaLAPACK names have the structure *p?yyzzz* or *p?yyzz*, which is described below.

The initial letter *p* is a distinctive prefix of ScaLAPACK routines and is present in each such routine.

The second symbol *?* indicates the data type:

| | |
|----------|---------------------------|
| <i>s</i> | real, single precision |
| <i>d</i> | real, double precision |
| <i>c</i> | complex, single precision |
| <i>z</i> | complex, double precision |

The second and third letters *yy* indicate the matrix type as:

| | |
|-----------|--|
| <i>ge</i> | general |
| <i>gb</i> | general band |
| <i>gg</i> | a pair of general matrices (for a generalized problem) |
| <i>dt</i> | general tridiagonal (diagonally dominant-like) |
| <i>db</i> | general band (diagonally dominant-like) |
| <i>po</i> | symmetric or Hermitian positive-definite |
| <i>pb</i> | symmetric or Hermitian positive-definite band |
| <i>pt</i> | symmetric or Hermitian positive-definite tridiagonal |
| <i>sy</i> | symmetric |
| <i>st</i> | symmetric tridiagonal (real) |
| <i>he</i> | Hermitian |
| <i>or</i> | orthogonal |

| | |
|----|----------------------------------|
| tr | triangular (or quasi-triangular) |
| tz | trapezoidal |
| un | unitary |

For computational routines, the last three letters **zzz** indicate the computation performed and have the same meaning as for LAPACK routines.

For driver routines, the last two letters **zz** or three letters **zzz** have the following meaning:

| | |
|-----|--|
| sv | a <i>simple</i> driver for solving a linear system |
| svx | an <i>expert</i> driver for solving a linear system |
| ls | a driver for solving a linear least squares problem |
| ev | a simple driver for solving a symmetric eigenvalue problem |
| evd | a simple driver for solving an eigenvalue problem using a divide and conquer algorithm |
| evx | an expert driver for solving a symmetric eigenvalue problem |
| svd | a driver for computing a singular value decomposition |
| gvx | an expert driver for solving a generalized symmetric definite eigenvalue problem |

Simple driver here means that the driver just solves the general problem, whereas an *expert* driver is more versatile and can also optionally perform some related computations (such, for example, as refining the solution and computing error bounds after the linear system is solved).

ScaLAPACK Computational Routines

In the sections that follow, the descriptions of ScaLAPACK computational routines are given. These routines perform distinct computational tasks that can be used for:

- [Solving Systems of Linear Equations](#)
- [Orthogonal Factorizations and LLS Problems](#)
- [Symmetric Eigenproblems](#)
- [Nonsymmetric Eigenproblems](#)
- [Singular Value Decomposition](#)
- [Generalized Symmetric-Definite Eigenproblems](#)

See also the respective [driver routines](#).

Systems of Linear Equations: ScaLAPACK Computational Routines

ScaLAPACK supports routines for the systems of equations with the following types of matrices:

- general
- general banded
- general diagonally dominant-like banded (including general tridiagonal)
- symmetric or Hermitian positive-definite
- symmetric or Hermitian positive-definite banded
- symmetric or Hermitian positive-definite tridiagonal

A *diagonally dominant-like* matrix is defined as a matrix for which it is known in advance that pivoting is not required in the *LU* factorization of this matrix.

For the above matrix types, the library includes routines for performing the following computations: *factoring* the matrix; *equilibrating* the matrix; *solving* a system of linear equations; *estimating the condition number* of a matrix; *refining* the solution of linear equations and computing its error bounds; *inverting* the matrix. Note that for some of the listed matrix types only part of the computational routines are provided (for example, routines that refine the solution are not provided for band or tridiagonal matrices). See [Table “Computational Routines for Systems of Linear Equations”](#) for full list of available routines.

To solve a particular problem, you can either call two or more computational routines or call a corresponding [driver routine](#) that combines several tasks in one call. Thus, to solve a system of linear equations with a general matrix, you can first call `p?getrf` (LU factorization) and then `p?getrs` (computing the solution). Then, you might wish to call `p?gerfs` to refine the solution and get the error bounds. Alternatively, you can just use the driver routine `p?gesvx` which performs all these tasks in one call.

[Table “Computational Routines for Systems of Linear Equations”](#) lists the ScaLAPACK computational routines for factorizing, equilibrating, and inverting matrices, estimating their condition numbers, solving systems of equations with real matrices, refining the solution, and estimating its error.

Computational Routines for Systems of Linear Equations

| Matrix type, storage scheme | Factorize matrix | Equilibrate matrix | Solve system | Condition number | Estimate error | Invert matrix |
|--|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|
| general (partial pivoting) | <code>p?getrf</code> | <code>p?geequ</code> | <code>p?getrs</code> | <code>p?gecon</code> | <code>p?gerfs</code> | <code>p?getri</code> |
| general band (partial pivoting) | <code>p?gbtrf</code> | | <code>p?gbtrs</code> | | | |
| general band (no pivoting) | <code>p?dbtrf</code> | | <code>p?dbtrs</code> | | | |
| general tridiagonal (no pivoting) | <code>p?dttrf</code> | | <code>p?dttrs</code> | | | |
| symmetric/Hermitian positive-definite | <code>p?potrf</code> | <code>p?poequ</code> | <code>p?potrs</code> | <code>p?pocon</code> | <code>p?porfs</code> | <code>p?potri</code> |
| symmetric/Hermitian positive-definite, band | <code>p?pbtrf</code> | | <code>p?pbtrs</code> | | | |
| symmetric/Hermitian positive-definite, tridiagonal | <code>p?pttrf</code> | | <code>p?pttrs</code> | | | |
| triangular | | | <code>p?trtrs</code> | <code>p?trcon</code> | <code>p?trrfs</code> | <code>p?trtri</code> |

In this table ? stands for s (single precision real), d (double precision real), c (single precision complex), or z (double precision complex).

Matrix Factorization: ScaLAPACK Computational Routines

This section describes the ScaLAPACK routines for matrix factorization. The following factorizations are supported:

- LU factorization of general matrices
- LU factorization of diagonally dominant-like matrices
- Cholesky factorization of real symmetric or complex Hermitian positive-definite matrices

You can compute the factorizations using full and band storage of matrices.

`p?getrf`

Computes the LU factorization of a general m-by-n distributed matrix.

Syntax

```
void psgetrf (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
```

```
void pdgetrf (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
```

```
void pcgetrf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );

void pzgetrf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?getrf` function forms the LU factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia} + m - 1, \text{ja}:\text{ja} + n - 1)$ as

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$). L and U are stored in $\text{sub}(A)$.

The function uses partial pivoting, with row interchanges.

NOTE

This function supports the Progress Routine feature. See [mkl_progress](#) for details.

Input Parameters

| | |
|---------------|---|
| <i>m</i> | (global) The number of rows in the distributed matrix $\text{sub}(A)$; $m \geq 0$. |
| <i>n</i> | (global) The number of columns in the distributed matrix $\text{sub}(A)$; $n \geq 0$. |
| <i>a</i> | (local) Pointer into the local memory to an array of local size $lld_a * LOCC(ja + n - 1)$. Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively. |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |

Output Parameters

| | |
|-------------|--|
| <i>a</i> | Overwritten by local pieces of the factors L and U from the factorization $A = P * L * U$. The unit diagonal elements of L are not stored. |
| <i>ipiv</i> | (local) Array of size $LOCr(m_a) + mb_a$. Contains the pivoting information: local row i was interchanged with global row $ipiv[i - 1]$. This array is tied to the distributed matrix A . |
| <i>info</i> | (global) If $info = 0$, the execution is successful. |

$info < 0$: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

If $info = i > 0$, $u_{ia+i, ja+j-1}$ is 0. The factorization has been completed, but the factor U is exactly singular. Division by zero will occur if you use the factor U for solving a system of linear equations.

p?gbtrf

Computes the LU factorization of a general n -by- n banded distributed matrix.

Syntax

```
void psgbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , float *a , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , float *af , MKL_INT *laf , float *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pdgbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , double *a , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , double *af , MKL_INT *laf , double *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pcgbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , MKL_Complex8 *a , MKL_INT
*ja , MKL_INT *desca , MKL_INT *ipiv , MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8
*work , MKL_INT *lwork , MKL_INT *info );
```

```
void pzgbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , MKL_Complex16 *a , MKL_INT
*ja , MKL_INT *desca , MKL_INT *ipiv , MKL_Complex16 *af , MKL_INT *laf ,
MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?gbtrf` function computes the LU factorization of a general n -by- n real/complex banded distributed matrix $A(1:n, ja:ja+n-1)$ using partial pivoting with row interchanges.

The resulting factorization is not the same factorization as returned from the LAPACK function `?gbtrf`. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form

$$A(1:n, ja:ja+n-1) = P*L*U*Q$$

where P and Q are permutation matrices, and L and U are banded lower and upper triangular matrices, respectively. The matrix Q represents reordering of columns for the sake of parallelism, while P represents reordering of rows for numerical stability using classic partial pivoting.

*lwork , MKL_INT *info );

void pzdbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , MKL_Complex16 *a , MKL_INT
*ja , MKL_INT *desca , MKL_Complex16 *af , MKL_INT *laf , MKL_Complex16 *work ,
MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?dbtrff` function computes the LU factorization of a n -by- n real/complex diagonally dominant-like banded distributed matrix $A(1:n, ja:ja+n-1)$ without pivoting.

NOTE

A matrix is called *diagonally dominant-like* if pivoting is not required for LU to be numerically stable.

Note that the resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

Optimization Notice

Notice revision #20110804

Input Parameters

| | |
|---------|---|
| n | (global) The number of rows and columns in the distributed submatrix $A(1:n, ja:ja+n-1)$; $n \geq 0$. |
| bwl | (global) The number of sub-diagonals within the band of A ($0 \leq bwl \leq n-1$). |
| bwu | (global) The number of super-diagonals within the band of A ($0 \leq bwu \leq n-1$). |
| a | (local) Pointer into the local memory to an array of local size $lld_a * LOCC(ja+n-1)$. Contains the local pieces of the n -by- n distributed banded matrix $A(1:n, ja:ja+n-1)$ to be factored. |
| ja | (global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A). |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . If $dtype_a = 501$, then $dlen_ \geq 7$; else if $dtype_a = 1$, then $dlen_ \geq 9$. |
| laf | (local) The size of the array af . |

Must be $laf \geq NB * (bwl + bwu) + 6 * (\max(bwl, bwu))^2$.

If laf is not large enough, an error code will be returned and the minimum acceptable size will be returned in $af[0]$.

work (local) Workspace array of size *lwork*.

lwork (local or global) The size of the *work* array, must be $lwork \geq (\max(bwl, bwu))^2$. If *lwork* is too small, the minimal acceptable size will be returned in $work[0]$ and an error code is returned.

Output Parameters

a On exit, this array contains details of the factorization. Note that additional permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.

af (local)
 Array of size *laf*.
 Auxiliary fill-in space. The fill-in space is created in a call to the factorization function `p?dbtrf` and is stored in *af*.
 Note that if a linear system is to be solved using `p?dbtrs` after the factorization function, *af* must not be altered after the factorization.

work[0] On exit, *work[0]* contains the minimum value of *lwork* required for optimum performance.

info (global)
 If *info*=0, the execution is successful.
info < 0:
 If the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then $info = -(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then $info = -i$.
info > 0:
 If $info = k \leq NPROCS$, the submatrix stored on processor *info* and factored locally was not diagonally dominant-like, and the factorization was not completed.
 If $info = k > NPROCS$, the submatrix stored on processor $info - NPROCS$ representing interactions with other processors was not nonsingular, and the factorization was not completed.

Notice revision #20110804

Input Parameters

- n (global) The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$ ($n \geq 0$).
- dl, d, du (local)
Pointers to the local arrays of size nb_a each.
On entry, the array dl contains the local part of the global vector storing the subdiagonal elements of the matrix. Globally, $dl[0]$ is not referenced, and dl must be aligned with d .
On entry, the array d contains the local part of the global vector storing the diagonal elements of the matrix.

On entry, the array *du* contains the local part of the global vector storing the super-diagonal elements of the matrix. *du*[*n*-1] is not referenced, and *du* must be aligned with *d*.

| | |
|--------------|--|
| <i>ja</i> | (global) The index in the global matrix <i>A</i> indicating the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>). |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>dtype_a</i> = 501, then <i>dlen_</i> ≥ 7; else if <i>dtype_a</i> = 1, then <i>dlen_</i> ≥ 9. |
| <i>laf</i> | (local) The size of the array <i>af</i> . Must be <i>laf</i> ≥ 2*(NB+2) . If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> [0]. |
| <i>work</i> | (local) Same type as <i>d</i> . Workspace array of size <i>lwork</i> . |
| <i>lwork</i> | (local or global) The size of the <i>work</i> array, must be at least <i>lwork</i> ≥ 8*NPCOL. |

Output Parameters

| | |
|------------------|--|
| <i>dl, d, du</i> | On exit, overwritten by the information containing the factors of the matrix. |
| <i>af</i> | (local) Array of size <i>laf</i> . Auxiliary fill-in space. The fill-in space is created in a call to the factorization function <code>p?dttrf</code> and is stored in <i>af</i> . Note that if a linear system is to be solved using <code>p?dttrs</code> after the factorization function, <i>af</i> must not be altered. |
| <i>work</i> [0] | On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance. |
| <i>info</i> | (global) If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>j</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . <i>info</i> > 0: If <i>info</i> = <i>k</i> ≤ NPROCS, the submatrix stored on processor <i>info</i> and factored locally was not diagonally dominant-like, and the factorization was not completed. |

If $info = k > NPROCS$, the submatrix stored on processor $info - NPROCS$ representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?potrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite distributed matrix.

Syntax

```
void pspotrf (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *info );

void pdpotrf (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *info );

void pcpotrf (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *info );

void pzpotrf (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?potrf` function computes the Cholesky factorization of a real symmetric or complex Hermitian positive-definite distributed n -by- n matrix $A(ia:ia+n-1, ja:ja+n-1)$, denoted below as $sub(A)$.

The factorization has the form

$sub(A) = U^H * U$ if $uplo = 'U'$, or

$sub(A) = L * L^H$ if $uplo = 'L'$

where L is a lower triangular matrix and U is upper triangular.

Input Parameters

| | |
|-------------------|---|
| <code>uplo</code> | (global) |
| | Indicates whether the upper or lower triangular part of $sub(A)$ is stored. Must be 'U' or 'L'. |
| | If $uplo = 'U'$, the array a stores the upper triangular part of the matrix $sub(A)$ that is factored as $U^H * U$. |
| | If $uplo = 'L'$, the array a stores the lower triangular part of the matrix $sub(A)$ that is factored as $L * L^H$. |
| <code>n</code> | (global) The order of the distributed matrix $sub(A)$ ($n \geq 0$). |
| <code>a</code> | (local) |
| | Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$. |

On entry, this array contains the local pieces of the n -by- n symmetric/Hermitian distributed matrix $\text{sub}(A)$ to be factored.

Depending on *uplo*, the array *a* contains either the upper or the lower triangular part of the matrix $\text{sub}(A)$ (see *uplo*).

| | |
|---------------|---|
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |

Output Parameters

| | |
|-------------|---|
| <i>a</i> | The upper or lower triangular part of <i>a</i> is overwritten by the Cholesky factor <i>U</i> or <i>L</i> , as specified by <i>uplo</i> . |
| <i>info</i> | (global) . If <i>info</i> =0, the execution is successful; <i>info</i> < 0: if the <i>i</i> -th argument is an array, and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . If <i>info</i> = <i>k</i> > 0, the leading minor of order <i>k</i> , $A(\text{ia}:\text{ia}+\text{k}-1, \text{ja}:\text{ja}+\text{k}-1)$, is not positive-definite, and the factorization could not be completed. |

- `mkl_scalapack.h`

Description

The `p?pbtrf` function computes the Cholesky factorization of an n -by- n real symmetric or complex Hermitian positive-definite banded distributed matrix $A(1:n, ja:ja+n-1)$.

The resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form:

$$A(1:n, ja:ja+n-1) = P*U^H*U*P^T, \text{ if } uplo='U', \text{ or}$$

$$A(1:n, ja:ja+n-1) = P*L*L^H*P^T, \text{ if } uplo='L',$$

where P is a permutation matrix and U and L are banded upper and lower triangular matrices, respectively.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

| | |
|--------------|--|
| <i>uplo</i> | (global) Must be 'U' or 'L'. If <i>uplo</i> = 'U', upper triangle of $A(1:n, ja:ja+n-1)$ is stored; If <i>uplo</i> = 'L', lower triangle of $A(1:n, ja:ja+n-1)$ is stored. |
| <i>n</i> | (global) The order of the distributed submatrix $A(1:n, ja:ja+n-1)$. ($n \geq 0$). |
| <i>bw</i> | (global) The number of superdiagonals of the distributed matrix if <i>uplo</i> = 'U', or the number of subdiagonals if <i>uplo</i> = 'L' ($bw \geq 0$). |
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a*LOCc(ja+n-1)$. On entry, this array contains the local pieces of the upper or lower triangle of the symmetric/Hermitian band distributed matrix $A(1:n, ja:ja+n-1)$ to be factored. |
| <i>ja</i> | (global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A). |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A . If <i>dtype_a</i> = 501, then $dlen_ \geq 7$; else if <i>dtype_a</i> = 1, then $dlen_ \geq 9$. |

| | |
|--------------|--|
| <i>laf</i> | (local) The size of the array <i>af</i> . Must be $laf \geq (NB+2*bw) * bw$. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> [0]. |
| <i>work</i> | (local) Workspace array of size <i>lwork</i> . |
| <i>lwork</i> | (local or global) The size of the <i>work</i> array, must be $lwork \geq bw^2$. |

Output Parameters

| | |
|-----------------|---|
| <i>a</i> | On exit, if <i>info</i> =0, contains the permuted triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization of the band matrix $A(1:n, ja:ja+n-1)$, as specified by <i>uplo</i> . |
| <i>af</i> | (local) Array of size <i>laf</i> . Auxiliary fill-in space. The fill-in space is created in a call to the factorization function <i>p?pbtrf</i> and stored in <i>af</i> . Note that if a linear system is to be solved using <i>p?pbtrs</i> after the factorization function, <i>af</i> must not be altered. |
| <i>work</i> [0] | On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance. |
| <i>info</i> | (global) If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then $info = -(i*100+j)$; if the <i>i</i> -th argument is a scalar and had an illegal value, then $info = -i$. <i>info</i> >0: If $info = k \leq NPROCS$, the submatrix stored on processor <i>info</i> and factored locally was not positive definite, and the factorization was not completed. If $info = k > NPROCS$, the submatrix stored on processor <i>info</i> -NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed. |

Notice revision #20110804

Input Parameters

| | |
|--------|--|
| n | (global) The order of the distributed submatrix $A(1:n, ja:ja+n-1)$ ($n \geq 0$). |
| d, e | (local) Pointers into the local memory to arrays of size nb_a each. On entry, the array d contains the local part of the global vector storing the main diagonal of the distributed matrix A . On entry, the array e contains the local part of the global vector storing the upper diagonal of the distributed matrix A . |
| ja | (global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A). |

| | |
|--------------|--|
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>dtype_a</i> = 501, then <i>dlen_</i> ≥ 7; else if <i>dtype_a</i> = 1, then <i>dlen_</i> ≥ 9. |
| <i>laf</i> | (local) The size of the array <i>af</i> . Must be <i>laf</i> ≥ <i>nb_a</i> + 2. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> [0]. |
| <i>work</i> | (local) Workspace array of size <i>lwork</i> . |
| <i>lwork</i> | (local or global) The size of the <i>work</i> array, must be at least <i>lwork</i> ≥ 8 * NPCOL. |

Output Parameters

| | |
|-----------------|---|
| <i>d, e</i> | On exit, overwritten by the details of the factorization. |
| <i>af</i> | (local) Array of size <i>laf</i> . Auxiliary fill-in space. The fill-in space is created in a call to the factorization function <code>p?pttrf</code> and stored in <i>af</i> . Note that if a linear system is to be solved using <code>p?pttrs</code> after the factorization function, <i>af</i> must not be altered. |
| <i>work</i> [0] | On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance. |
| <i>info</i> | (global) If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>j</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . <i>info</i> > 0: If <i>info</i> = <i>k</i> ≤ NPCROCS, the submatrix stored on processor <i>info</i> and factored locally was not positive definite, and the factorization was not completed. If <i>info</i> = <i>k</i> > NPCROCS, the submatrix stored on processor <i>info</i> -NPCROCS representing interactions with other processors was not nonsingular, and the factorization was not completed. |

Solving Systems of Linear Equations: ScaLAPACK Computational Routines

This section describes the ScaLAPACK routines for solving systems of linear equations. Before calling most of these routines, you need to factorize the matrix of your system of equations (see [Routines for Matrix Factorization](#) in this chapter). However, the factorization is not necessary if your system of equations has a triangular matrix.

p?getrs

Solves a system of distributed linear equations with a general square matrix, using the LU factorization computed by p?getrf.

Syntax

```
void psgetrs (char *trans , MKL_INT *n , MKL_INT *nrhs , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , float *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , MKL_INT *info );
```

```
void pdgetrs (char *trans , MKL_INT *n , MKL_INT *nrhs , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , double *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , MKL_INT *info );
```

```
void pcgetrs (char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex8 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_Complex8 *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , MKL_INT *info );
```

```
void pzgetrs (char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex16 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_Complex16 *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , MKL_INT *info );
```

Include Files

Description

The p?getrs function solves a system of distributed linear equations with a general n -by- n distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ using the LU factorization computed by p?getrf.

The system has one of the following forms specified by *trans*:

$\text{sub}(A)*X = \text{sub}(B)$ (no transpose),

$\text{sub}(A)^T*X = \text{sub}(B)$ (transpose),

$\text{sub}(A)^H*X = \text{sub}(B)$ (conjugate transpose),

where $\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1)$.

Before calling this function, you must call p?getrf to compute the LU factorization of $\text{sub}(A)$.

Input Parameters

trans (global) Must be 'N' or 'T' or 'C'.
Indicates the form of the equations:
If *trans* = 'N', then $\text{sub}(A)*X = \text{sub}(B)$ is solved for X .
If *trans* = 'T', then $\text{sub}(A)^T*X = \text{sub}(B)$ is solved for X .
If *trans* = 'C', then $\text{sub}(A)^H *X = \text{sub}(B)$ is solved for X .

| | |
|---------------|---|
| <i>n</i> | (global) The number of linear equations; the order of the matrix sub(<i>A</i>) ($n \geq 0$). |
| <i>nrhs</i> | (global) The number of right hand sides; the number of columns of the distributed matrix sub(<i>B</i>) ($nrhs \geq 0$). |
| <i>a, b</i> | (local) Pointers into the local memory to arrays of local sizes $lld_a * LOCC(ja+n-1)$ and $lld_b * LOCC(jb+nrhs-1)$, respectively. On entry, the array <i>a</i> contains the local pieces of the factors <i>L</i> and <i>U</i> from the factorization $sub(A) = P * L * U$; the unit diagonal elements of <i>L</i> are not stored. On entry, the array <i>b</i> contains the right hand sides sub(<i>B</i>). |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix sub(<i>A</i>), respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>ipiv</i> | (local) Array of size of $LOCr(m_a) + mb_a$. Contains the pivoting information: local row <i>i</i> of the matrix was interchanged with the global row <i>ipiv</i> [<i>i</i> -1]. This array is tied to the distributed matrix <i>A</i> . |
| <i>ib, jb</i> | (global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the matrix sub(<i>B</i>), respectively. |
| <i>descb</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> . |

Output Parameters

| | |
|-------------|--|
| <i>b</i> | On exit, overwritten by the solution distributed matrix <i>X</i> . |
| <i>info</i> | If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . |

Description

The `p?gbtrs` function solves a system of distributed linear equations with a general band distributed matrix $\text{sub}(A) = A(1:n, ja:ja+n-1)$ using the LU factorization computed by `p?gbtrf`.

The system has one of the following forms specified by `trans`:

$\text{sub}(A)*X = \text{sub}(B)$ (no transpose),

$\text{sub}(A)^T*X = \text{sub}(B)$ (transpose),

$\text{sub}(A)^H*X = \text{sub}(B)$ (conjugate transpose),

where $\text{sub}(B) = B(ib:ib+n-1, 1:nrhs)$.

Before calling this function, you must call `p?gbtrf` to compute the LU factorization of $\text{sub}(A)$.

Input Parameters

| | |
|--------------------|---|
| <code>trans</code> | (global) Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <code>trans</code> = 'N', then $\text{sub}(A)*X = \text{sub}(B)$ is solved for X . If <code>trans</code> = 'T', then $\text{sub}(A)^T*X = \text{sub}(B)$ is solved for X . If <code>trans</code> = 'C', then $\text{sub}(A)^H *X = \text{sub}(B)$ is solved for X . |
| <code>n</code> | (global) The number of linear equations; the order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$). |
| <code>bwl</code> | (global) The number of sub-diagonals within the band of A ($0 \leq bwl \leq n-1$). |
| <code>bwu</code> | (global) The number of super-diagonals within the band of A ($0 \leq bwu \leq n-1$). |
| <code>nrhs</code> | (global) The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ($nrhs \geq 0$). |
| <code>a, b</code> | (local) |

Pointers into the local memory to arrays of local sizes $lld_a*LOCc(j_a+n-1)$ and $lld_b*LOCc(nrhs)$, respectively.

The array a contains details of the LU factorization of the distributed band matrix A .

On entry, the array b contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$.

| | |
|---------|--|
| ja | (global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A). |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . If $dtype_a = 501$, then $dlen_ \geq 7$; else if $dtype_a = 1$, then $dlen_ \geq 9$. |
| ib | (global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A). |
| $descb$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . If $dtype_b = 502$, then $dlen_ \geq 7$; else if $dtype_b = 1$, then $dlen_ \geq 9$. |
| laf | (local) The size of the array af . Must be $laf \geq nb_a*(bwl+bwu)+6*(bwl+bwu)*(bwl+2*bwu)$. If laf is not large enough, an error code will be returned and the minimum acceptable size will be returned in $af[0]$. |
| $work$ | (local) Same type as a . Workspace array of size $lwork$. |
| $lwork$ | (local or global) The size of the $work$ array, must be at least $lwork \geq nrhs*(nb_a+2*bwl+4*bwu)$. |

Output Parameters

| | |
|--------|---|
| $ipiv$ | (local) array. The size of $ipiv$ must be $\geq nb_a$. Contains pivot indices for local factorizations. Note that you should not alter the contents of this array between factorization and solve. |
| b | On exit, overwritten by the local pieces of the solution distributed matrix X . |
| af | (local) Array of size laf . Auxiliary Fill-in space. The fill-in space is created in a call to the factorization function $p?gbtrf$ and is stored in af . Note that if a linear system is to be solved using $p?gbtrs$ after the factorization function, af must not be altered after the factorization. |

`work[0]` On exit, `work[0]` contains the minimum value of `lwork` required for optimum performance.

`info` If `info=0`, the execution is successful.
`info < 0`:
 If the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then `info = -(i*100+j)`; if the i -th argument is a scalar and had an illegal value, then `info = -i`.

Description

The `p?dbtrs` function solves for X one of the systems of equations:

$$\text{sub}(A) * X = \text{sub}(B),$$

$$(\text{sub}(A))^T * X = \text{sub}(B), \text{ or}$$

$$(\text{sub}(A))^H * X = \text{sub}(B),$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is a diagonally dominant-like banded distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This function uses the LU factorization computed by `p?dbtrf`.

Input Parameters

| | |
|-----------------|--|
| <i>trans</i> | (global) Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $\text{sub}(A)*X = \text{sub}(B)$ is solved for X . If <i>trans</i> = 'T', then $(\text{sub}(A))^T*X = \text{sub}(B)$ is solved for X . If <i>trans</i> = 'C', then $(\text{sub}(A))^H*X = \text{sub}(B)$ is solved for X . |
| <i>n</i> | (global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$). |
| <i>bwl</i> | (global) The number of subdiagonals within the band of A ($0 \leq bwl \leq n-1$). |
| <i>bwu</i> | (global) The number of superdiagonals within the band of A ($0 \leq bwu \leq n-1$). |
| <i>nrhs</i> | (global) The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ($nrhs \geq 0$). |
| <i>a, b</i> | (local) Pointers into the local memory to arrays of local sizes $lld_a*LOCc(ja+n-1)$ and $lld_b*LOCc(nrhs)$, respectively. On entry, the array <i>a</i> contains details of the LU factorization of the band matrix A , as computed by <code>p?dbtrf</code> . On entry, the array <i>b</i> contains the local pieces of the right hand side distributed matrix $\text{sub}(B)$. |
| <i>ja</i> | (global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A). |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A . If <i>dtype_a</i> = 501, then $dlen_ \geq 7$; else if <i>dtype_a</i> = 1, then $dlen_ \geq 9$. |
| <i>ib</i> | (global) The row index in the global matrix B indicating the first row of the matrix to be operated on (which may be either all of B or a submatrix of B). |
| <i>descb</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix B . If <i>dtype_b</i> = 502, then $dlen_ \geq 7$; else if <i>dtype_b</i> = 1, then $dlen_ \geq 9$. |
| <i>af, work</i> | (local) Arrays of size <i>laf</i> and <i>lwork</i> , respectively The array <i>af</i> contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function <code>p?dbtrf</code> and is stored in <i>af</i> . The array <i>work</i> is a workspace array. |

| | |
|--------------|---|
| <i>laf</i> | (local) The size of the array <i>af</i> . Must be $laf \geq NB * (bwl + bwu) + 6 * (\max(bwl, bwu))^2$. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> [0]. |
| <i>lwork</i> | (local or global) The size of the array <i>work</i> , must be at least $lwork \geq (\max(bwl, bwu))^2$. |

Output Parameters

| | |
|-----------------|--|
| <i>b</i> | On exit, this array contains the local pieces of the solution distributed matrix <i>X</i> . |
| <i>work</i> [0] | On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance. |
| <i>info</i> | If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>j</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . |

Description

The `p?dttrs` function solves for X one of the systems of equations:

$$\text{sub}(A)*X = \text{sub}(B),$$

$$(\text{sub}(A))^T*X = \text{sub}(B), \text{ or}$$

$$(\text{sub}(A))^H*X = \text{sub}(B),$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is a diagonally dominant-like tridiagonal distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This function uses the LU factorization computed by `p?dttrf`.

Input Parameters

| | |
|------------------|--|
| <i>trans</i> | (global) Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $\text{sub}(A)*X = \text{sub}(B)$ is solved for X . If <i>trans</i> = 'T', then $(\text{sub}(A))^T*X = \text{sub}(B)$ is solved for X . If <i>trans</i> = 'C', then $(\text{sub}(A))^H*X = \text{sub}(B)$ is solved for X . |
| <i>n</i> | (global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$). |
| <i>nrhs</i> | (global) The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ($nrhs \geq 0$). |
| <i>d1, d, du</i> | (local) Pointers to the local arrays of size <i>nb_a</i> each. On entry, these arrays contain details of the factorization. Globally, <i>d1</i> [0] and <i>du</i> [<i>n</i> -1] are not referenced; <i>d1</i> and <i>du</i> must be aligned with <i>d</i> . |
| <i>ja</i> | (global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A). |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A . If <i>dtype_a</i> = 501 or <i>dtype_a</i> = 502, then $dlen_ \geq 7$; else if <i>dtype_a</i> = 1, then $dlen_ \geq 9$. |
| <i>b</i> | (local) Same type as <i>d</i> . Pointer into the local memory to an array of local size $lld_b*LOCc(nrhs)$ On entry, the array <i>b</i> contains the local pieces of the n -by- <i>nrhs</i> right hand side distributed matrix $\text{sub}(B)$. |
| <i>ib</i> | (global) The row index in the global matrix B indicating the first row of the matrix to be operated on (which may be either all of B or a submatrix of B). |
| <i>descb</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix B . If <i>dtype_b</i> = 502, then $dlen_ \geq 7$; else if <i>dtype_b</i> = 1, then $dlen_ \geq 9$. |

| | |
|-----------------|--|
| <i>af, work</i> | (local) Arrays of size <i>laf</i> and (<i>lwork</i>), respectively. The array <i>af</i> contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function <i>p?dttrf</i> and is stored in <i>af</i> . If a linear system is to be solved using <i>p?dttrs</i> after the factorization function, <i>af</i> must not be altered. The array <i>work</i> is a workspace array. |
| <i>laf</i> | (local) The size of the array <i>af</i> . Must be $laf \geq NB * (bwl + bwu) + 6 * (bwl + bwu) * (bwl + 2 * bwu)$. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> [0]. |
| <i>lwork</i> | (local or global) The size of the array <i>work</i> , must be at least $lwork \geq 10 * NPCOL + 4 * nrhs$. |

Output Parameters

| | |
|-----------------|--|
| <i>b</i> | On exit, this array contains the local pieces of the solution distributed matrix <i>X</i> . |
| <i>work</i> [0] | On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance. |
| <i>info</i> | If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>j</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . |

MKL_INT *descb , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The pzpotrs function solves for X a system of distributed linear equations in the form:

$$\text{sub}(A)*X = \text{sub}(B) ,$$

where $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ is an n -by- n real symmetric or complex Hermitian positive definite distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1)$.

This function uses Cholesky factorization

$$\text{sub}(A) = U^H*U, \text{ or } \text{sub}(A) = L*L^H$$

computed by pzpotrf.

Input Parameters

| | |
|---------------|---|
| <i>uplo</i> | (global) Must be 'U' or 'L'. If <i>uplo</i> = 'U', upper triangle of sub(A) is stored; If <i>uplo</i> = 'L', lower triangle of sub(A) is stored. |
| <i>n</i> | (global) The order of the distributed matrix sub(A) ($n \geq 0$). |
| <i>nrhs</i> | (global) The number of right hand sides; the number of columns of the distributed matrix sub(B) ($nrhs \geq 0$). |
| <i>a, b</i> | (local) Pointers into the local memory to arrays of local sizes $lld_a*LOCc(ja+n-1)$ and $lld_b*LOCc(jb+nrhs-1)$, respectively. The array <i>a</i> contains the factors L or U from the Cholesky factorization $\text{sub}(A) = L*L^H$ or $\text{sub}(A) = U^H*U$, as computed by pzpotrf. On entry, the array <i>b</i> contains the local pieces of the right hand sides sub(B). |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix sub(A), respectively. |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <i>ib, jb</i> | (global) The row and column indices in the global matrix B indicating the first row and the first column of the matrix sub(B), respectively. |
| <i>descb</i> | (local) array of size $dlen_$. The array descriptor for the distributed matrix B . |

Output Parameters

b Overwritten by the local pieces of the solution matrix X .

info If *info*=0, the execution is successful.
info < 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Description

The p?pbtrs function solves for X a system of distributed linear equations in the form:

$$\text{sub}(A) * X = \text{sub}(B) ,$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is an n -by- n real symmetric or complex Hermitian positive definite distributed band matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This function uses Cholesky factorization

$$\text{sub}(A) = P * U^H * U * P^T, \text{ or } \text{sub}(A) = P * L * L^H * P^T$$

computed by p?pbtrf.

Input Parameters

uplo (global) Must be 'U' or 'L'.
 If *uplo* = 'U', upper triangle of $\text{sub}(A)$ is stored;
 If *uplo* = 'L', lower triangle of $\text{sub}(A)$ is stored.

| | |
|-----------------|--|
| <i>n</i> | (global) The order of the distributed matrix sub(<i>A</i>) ($n \geq 0$). |
| <i>bw</i> | (global) The number of superdiagonals of the distributed matrix if <i>uplo</i> = 'U', or the number of subdiagonals if <i>uplo</i> = 'L' ($bw \geq 0$). |
| <i>nrhs</i> | (global) The number of right hand sides; the number of columns of the distributed matrix sub(<i>B</i>) ($nrhs \geq 0$). |
| <i>a, b</i> | (local) Pointers into the local memory to arrays of local sizes $lld_a * LOCC(j_a + n - 1)$ and $lld_b * LOCC(nrhs - 1)$, respectively. The array <i>a</i> contains the permuted triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $sub(A) = P * U^H * U * P^T$, or $sub(A) = P * L * L^H * P^T$ of the band matrix <i>A</i> , as returned by <code>p?pbtrf</code> . On entry, the array <i>b</i> contains the local pieces of the <i>n</i> -by- <i>nrhs</i> right hand side distributed matrix sub(<i>B</i>). |
| <i>ja</i> | (global) The index in the global matrix <i>A</i> indicating the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>). |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>dtype_a</i> = 501, then $dlen_ \geq 7$; else if <i>dtype_a</i> = 1, then $dlen_ \geq 9$. |
| <i>ib</i> | (global) The row index in the global matrix <i>B</i> indicating the first row of the matrix sub(<i>B</i>). |
| <i>descb</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> . If <i>dtype_b</i> = 502, then $dlen_ \geq 7$; else if <i>dtype_b</i> = 1, then $dlen_ \geq 9$. |
| <i>af, work</i> | (local) Arrays, same type as <i>a</i> . The array <i>af</i> is of size <i>laf</i> . It contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function <code>p?dbtrf</code> and is stored in <i>af</i> . The array <i>work</i> is a workspace array of size <i>lwork</i> . |
| <i>laf</i> | (local) The size of the array <i>af</i> . Must be $laf \geq nrhs * bw$. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> [0]. |
| <i>lwork</i> | (local or global) The size of the array <i>work</i> , must be at least $lwork \geq bw^2$. |

Output Parameters

| | |
|-----------------|---|
| <i>b</i> | On exit, if <i>info</i> =0, this array contains the local pieces of the <i>n</i> -by- <i>nrhs</i> solution distributed matrix <i>X</i> . |
| <i>work</i> [0] | On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance. |
| <i>info</i> | If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . |

```

```
void pzpttrs (char *uplo , MKL_INT *n , MKL_INT *nrhs , double *d , MKL_Complex16 *e , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *descb , MKL_Complex16 *af , MKL_INT *laf , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?pttrs function solves for *X* a system of distributed linear equations in the form:

$$\text{sub}(A)*X = \text{sub}(B) ,$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is an *n*-by-*n* real symmetric or complex Hermitian positive definite tridiagonal distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This function uses the factorization

$$\text{sub}(A) = P*L*D*L^H*P^T, \text{ or } \text{sub}(A) = P*U^H*D*U*P^T$$

computed by `p?pttrf`.

Input Parameters

| | |
|-----------------------|--|
| <code>uplo</code> | (global, used in complex flavors only) Must be 'U' or 'L'. If <code>uplo = 'U'</code> , upper triangle of <code>sub(A)</code> is stored; If <code>uplo = 'L'</code> , lower triangle of <code>sub(A)</code> is stored. |
| <code>n</code> | (global) The order of the distributed matrix <code>sub(A)</code> ($n \geq 0$). |
| <code>nrhs</code> | (global) The number of right hand sides; the number of columns of the distributed matrix <code>sub(B)</code> ($nrhs \geq 0$). |
| <code>d, e</code> | (local) Pointers into the local memory to arrays of size <code>nb_a</code> each. These arrays contain details of the factorization as returned by <code>p?pttrf</code> |
| <code>ja</code> | (global) The index in the global matrix <code>A</code> indicating the start of the matrix to be operated on (which may be either all of <code>A</code> or a submatrix of <code>A</code>). |
| <code>desca</code> | (global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix <code>A</code> . If <code>dtype_a = 501</code> or <code>dtype_a = 502</code> , then <code>dlen_ ≥ 7</code> ; else if <code>dtype_a = 1</code> , then <code>dlen_ ≥ 9</code> . |
| <code>b</code> | (local) Same type as <code>d, e</code> . Pointer into the local memory to an array of local size <code>lld_b*LOCc(nrhs)</code> . On entry, the array <code>b</code> contains the local pieces of the <code>n</code> -by- <code>nrhs</code> right hand side distributed matrix <code>sub(B)</code> . |
| <code>ib</code> | (global) The row index in the global matrix <code>B</code> indicating the first row of the matrix to be operated on (which may be either all of <code>B</code> or a submatrix of <code>B</code>). |
| <code>descb</code> | (global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix <code>B</code> . If <code>dtype_b = 502</code> , then <code>dlen_ ≥ 7</code> ; else if <code>dtype_b = 1</code> , then <code>dlen_ ≥ 9</code> . |
| <code>af, work</code> | (local) Arrays of size <code>laf</code> and (<code>lwork</code>), respectively. The array <code>af</code> contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function <code>p?pttrf</code> and is stored in <code>af</code> . The array <code>work</code> is a workspace array. |
| <code>laf</code> | (local) The size of the array <code>af</code> . Must be <code>laf ≥ nb_a + 2</code> . |

If *laf* is not large enough, an error code is returned and the minimum acceptable size will be returned in *af*[0].

lwork (local or global) The size of the array *work*, must be at least
 $lwork \geq (10+2*\min(100,nrhs))*NPCOL+4*nrhs$.

Output Parameters

b On exit, this array contains the local pieces of the solution distributed matrix *X*.

work[0]) On exit, *work*[0] contains the minimum value of *lwork* required for optimum performance.

info If *info*=0, the execution is successful.
info < 0:
 if the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then *info* = $-(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

Description

The `p?trtrs` function solves for *X* one of the following systems of linear equations:

$$\text{sub}(A)*X = \text{sub}(B),$$

$$(\text{sub}(A))^T*X = \text{sub}(B), \text{ or}$$

$$(\text{sub}(A))^H*X = \text{sub}(B),$$

where $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ is a triangular distributed matrix of order n , and $\text{sub}(B)$ denotes the distributed matrix $B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1)$.

A check is made to verify that $\text{sub}(A)$ is nonsingular.

Input Parameters

| | |
|---------------|---|
| <i>uplo</i> | (global) Must be 'U' or 'L'. Indicates whether $\text{sub}(A)$ is upper or lower triangular: If <i>uplo</i> = 'U', then $\text{sub}(A)$ is upper triangular. If <i>uplo</i> = 'L', then $\text{sub}(A)$ is lower triangular. |
| <i>trans</i> | (global) Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $\text{sub}(A)*X = \text{sub}(B)$ is solved for X . If <i>trans</i> = 'T', then $\text{sub}(A)^T*X = \text{sub}(B)$ is solved for X . If <i>trans</i> = 'C', then $\text{sub}(A)^H*X = \text{sub}(B)$ is solved for X . |
| <i>diag</i> | (global) Must be 'N' or 'U'. If <i>diag</i> = 'N', then $\text{sub}(A)$ is not a unit triangular matrix. If <i>diag</i> = 'U', then $\text{sub}(A)$ is unit triangular. |
| <i>n</i> | (global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$). |
| <i>nrhs</i> | (global) The number of right-hand sides; i.e., the number of columns of the distributed matrix $\text{sub}(B)$ ($nrhs \geq 0$). |
| <i>a, b</i> | (local) Pointers into the local memory to arrays of local sizes $ld_a*LOCc(\text{ja}+n-1)$ and $ld_b*LOCc(\text{jb}+nrhs-1)$, respectively. The array <i>a</i> contains the local pieces of the distributed triangular matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced. If <i>diag</i> = 'U', the diagonal elements of $\text{sub}(A)$ are also not referenced and are assumed to be 1. On entry, the array <i>b</i> contains the local pieces of the right hand side distributed matrix $\text{sub}(B)$. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A . |

| | |
|---------------|--|
| <i>ib, jb</i> | (global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the matrix sub(<i>B</i>), respectively. |
| <i>descb</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> . |

Output Parameters

| | |
|-------------|---|
| <i>b</i> | On exit, if <i>info</i> =0, sub(<i>B</i>) is overwritten by the solution matrix <i>X</i> . |
| <i>info</i> | If <i>info</i> =0, the execution is successful. <i>info</i> < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . <i>info</i> > 0: if <i>info</i> = <i>i</i> , the <i>i</i> -th diagonal element of sub(<i>A</i>) is zero, indicating that the submatrix is singular and the solutions <i>X</i> have not been computed. |

Estimating the Condition Number: ScaLAPACK Computational Routines

This section describes the ScaLAPACK routines for estimating the condition number of a matrix. The condition number is used for analyzing the errors in the solution of a system of linear equations. Since the condition number may be arbitrarily large when the matrix is nearly singular, the routines actually compute the *reciprocal* condition number.

p?gecon

Estimates the reciprocal of the condition number of a general distributed matrix in either the 1-norm or the infinity-norm.

Syntax

```
void psgecon (char *norm , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *anorm , float *rcond , float *work , MKL_INT *lwork , MKL_INT *iwork ,
MKL_INT *liwork , MKL_INT *info );
```

```
void pdgecon (char *norm , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *anorm , double *rcond , double *work , MKL_INT *lwork ,
MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );
```

```
void pcgecon (char *norm , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *anorm , float *rcond , MKL_Complex8 *work , MKL_INT *lwork ,
float *rwork , MKL_INT *lrwork , MKL_INT *info );
```

```
void pzgecon (char *norm , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *anorm , double *rcond , MKL_Complex16 *work , MKL_INT
*lwork , double *rwork , MKL_INT *lrwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?gecon` function estimates the reciprocal of the condition number of a general distributed real/complex matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ in either the 1-norm or infinity-norm, using the *LU* factorization computed by `p?getrf`.

An estimate is obtained for $\|(\text{sub}(A))^{-1}\|$, and the reciprocal of the condition number is computed as

$$rcond = \frac{1}{\|\text{sub}(A)\| \times \|(\text{sub}(A))^{-1}\|}$$

Input Parameters

| | |
|---------------------|---|
| <code>norm</code> | (global) Must be '1' or 'O' or 'I'. Specifies whether the 1-norm condition number or the infinity-norm condition number is required. If <code>norm = '1'</code> or 'O', then the 1-norm is used; If <code>norm = 'I'</code> , then the infinity-norm is used. |
| <code>n</code> | (global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$). |
| <code>a</code> | (local) Pointer into the local memory to an array of size <code>lld_a*LOCc(ja+n-1)</code> . The array <code>a</code> contains the local pieces of the factors <i>L</i> and <i>U</i> from the factorization $\text{sub}(A) = P*L*U$; the unit diagonal elements of <i>L</i> are not stored. |
| <code>ia, ja</code> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively. |
| <code>desca</code> | (global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix <i>A</i> . |
| <code>anorm</code> | (global) If <code>norm = '1'</code> or 'O', the 1-norm of the original distributed matrix $\text{sub}(A)$; If <code>norm = 'I'</code> , the infinity-norm of the original distributed matrix $\text{sub}(A)$. |
| <code>work</code> | (local) The array <code>work</code> of size <code>lwork</code> is a workspace array. |
| <code>lwork</code> | (local or global) The size of the array <code>work</code> . <i>For real flavors:</i> <code>lwork</code> must be at least |

$$lwork \geq 2*LOCr(n+\text{mod}(ia-1,mb_a))+2*LOCc(n+\text{mod}(ja-1,nb_a)) + \max(2, \max(nb_a*\max(1, \text{iceil}(NPROW-1, NPCOL)), LOCc(n+\text{mod}(ja-1,nb_a)) + nb_a*\max(1, \text{iceil}(NPCOL-1, NPROW)))).$$

For complex flavors:

lwork must be at least

$$lwork \geq 2*LOCr(n+\text{mod}(ia-1,mb_a))+\max(2, \max(nb_a*\text{iceil}(NPROW-1, NPCOL), LOCc(n+\text{mod}(ja-1,nb_a))+ nb_a*\text{iceil}(NPCOL-1, NPROW))).$$

LOCr and *LOCc* values can be computed using the ScaLAPACK tool function `numroc`; *NPROW* and *NPCOL* can be determined by calling the function `blacs_gridinfo`.

NOTE

`iceil(x,y)` is the ceiling of x/y , and `mod(x,y)` is the integer remainder of x/y .

| | |
|---------------|---|
| <i>iwork</i> | (local) Workspace array of size <i>liwork</i> . Used in real flavors only. |
| <i>liwork</i> | (local or global) The size of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n+\text{mod}(ia-1,mb_a)).$ |
| <i>rwork</i> | (local) Workspace array of size <i>lrwork</i> . Used in complex flavors only. |
| <i>lrwork</i> | (local or global) The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq \max(1, 2*LOCc(n+\text{mod}(ja-1,nb_a))).$ |

Output Parameters

| | |
|------------------|---|
| <i>rcond</i> | (global) The reciprocal of the condition number of the distributed matrix <code>sub(A)</code> . See Description. |
| <i>work</i> [0] | On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance. |
| <i>iwork</i> [0] | On exit, <i>iwork</i> [0] contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors). |
| <i>rwork</i> [0] | On exit, <i>rwork</i> [0] contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors). |
| <i>info</i> | (global) If <i>info</i> =0, the execution is successful. <i>info</i> < 0: |

If the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?pocon

Estimates the reciprocal of the condition number (in the 1 - norm) of a symmetric / Hermitian positive-definite distributed matrix.

Syntax

```
void pspocon (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *anorm , float *rcond , float *work , MKL_INT *lwork , MKL_INT *iwork ,
MKL_INT *liwork , MKL_INT *info );
```

```
void pdpocon (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *anorm , double *rcond , double *work , MKL_INT *lwork ,
MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );
```

```
void pcpocon (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *anorm , float *rcond , MKL_Complex8 *work , MKL_INT *lwork ,
float *rwork , MKL_INT *lrwork , MKL_INT *info );
```

```
void pzpocon (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *anorm , double *rcond , MKL_Complex16 *work , MKL_INT
*iwork , double *rwork , MKL_INT *lrwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?pocon function estimates the reciprocal of the condition number (in the 1 - norm) of a real symmetric or complex Hermitian positive definite distributed matrix $sub(A) = A(ia:ia+n-1, ja:ja+n-1)$, using the Cholesky factorization $sub(A) = U^H * U$ or $sub(A) = L * L^H$ computed by p?potrf.

An estimate is obtained for $\|(sub(A))^{-1}\|$, and the reciprocal of the condition number is computed as

$$rcond = \frac{1}{\|sub(A)\| \times \|(sub(A))^{-1}\|}$$

Input Parameters

uplo

(global) Must be 'U' or 'L'.

Specifies whether the factor stored in $sub(A)$ is upper or lower triangular.

If *uplo* = 'U', $sub(A)$ stores the upper triangular factor U of the Cholesky factorization $sub(A) = U^H * U$.

If $uplo = 'L'$, $sub(A)$ stores the lower triangular factor L of the Cholesky factorization $sub(A) = L*L^H$.

| | |
|----------|--|
| n | (global) The order of the distributed matrix $sub(A)$ ($n \geq 0$). |
| a | (local) Pointer into the local memory to an array of size $lld_a*LOCc(ja+n-1)$. The array a contains the local pieces of the factors L or U from the Cholesky factorization $sub(A) = U^H*U$, or $sub(A) = L*L^H$, as computed by <code>p?potrf</code> . |
| ia, ja | (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $sub(A)$, respectively. |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| $anorm$ | (global) The 1-norm of the symmetric/Hermitian distributed matrix $sub(A)$. |
| $work$ | (local) The array $work$ of size $lwork$ is a workspace array. |
| $lwork$ | (local or global) The size of the array $work$. |

For real flavors:

$lwork$ must be at least

$$lwork \geq 2*LOCr(n+\text{mod}(ia-1, mb_a)) + 2*LOCc(n+\text{mod}(ja-1, nb_a)) + \max(2, \max(nb_a*\text{ceil}(NPROW-1, NPCOL), LOCc(n+\text{mod}(ja-1, nb_a)) + nb_a*\text{ceil}(NPCOL-1, NPROW))).$$

For complex flavors:

$lwork$ must be at least

$$lwork \geq 2*LOCr(n+\text{mod}(ia-1, mb_a)) + \max(2, \max(nb_a*\max(1, \text{ceil}(NPROW-1, NPCOL)), LOCc(n+\text{mod}(ja-1, nb_a)) + nb_a*\max(1, \text{ceil}(NPCOL-1, NPROW)))).$$

NOTE

$\text{ceil}(x, y)$ is the ceiling of x/y , and $\text{mod}(x, y)$ is the integer remainder of x/y .

| | |
|----------|--|
| $iwork$ | (local) Workspace array of size $liwork$. Used in real flavors only. |
| $liwork$ | (local or global) The size of the array $iwork$; used in real flavors only. Must be at least $liwork \geq LOCr(n+\text{mod}(ia-1, mb_a))$. |
| $rwork$ | (local) Workspace array of size $lrwork$. Used in complex flavors only. |
| $lrwork$ | (local or global) The size of the array $rwork$; used in complex flavors only. Must be at least $lrwork \geq 2*LOCc(n+\text{mod}(ja-1, nb_a))$. |

Output Parameters

| | |
|------------------|--|
| <i>rcond</i> | (global) The reciprocal of the condition number of the distributed matrix sub(A). |
| <i>work</i> [0] | On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance. |
| <i>iwork</i> [0] | On exit, <i>iwork</i> [0] contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors). |
| <i>rwork</i> [0] | On exit, <i>rwork</i> [0] contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors). |
| <i>info</i> | (global) If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . |

Description

The `p?trcon` function estimates the reciprocal of the condition number of a triangular distributed matrix sub(A) = A(*ia:ia+n-1, ja:ja+n-1*), in either the 1-norm or the infinity-norm.

The norm of sub(A) is computed and an estimate is obtained for $||(\text{sub}(A))^{-1}||$, then the reciprocal of the condition number is computed as

$$rcond = \frac{1}{\|sub(A)\| \times \|(sub(A))^{-1}\|}$$

Input Parameters

| | |
|---------------|--|
| <i>norm</i> | <p>(global) Must be '1' or 'O' or 'I'.</p> <p>Specifies whether the 1-norm condition number or the infinity-norm condition number is required.</p> <p>If <i>norm</i> = '1' or 'O', then the 1-norm is used;</p> <p>If <i>norm</i> = 'I', then the infinity-norm is used.</p> |
| <i>uplo</i> | <p>(global) Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', sub(A) is upper triangular. If <i>uplo</i> = 'L', sub(A) is lower triangular.</p> |
| <i>diag</i> | <p>(global) Must be 'N' or 'U'.</p> <p>If <i>diag</i> = 'N', sub(A) is non-unit triangular. If <i>diag</i> = 'U', sub(A) is unit triangular.</p> |
| <i>n</i> | (global) The order of the distributed matrix sub(A), ($n \geq 0$). |
| <i>a</i> | <p>(local)</p> <p>Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$.</p> <p>The array <i>a</i> contains the local pieces of the triangular distributed matrix sub(A).</p> <p>If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of this distributed matrix contains the upper triangular matrix, and its strictly lower triangular part is not referenced.</p> <p>If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of this distributed matrix contains the lower triangular matrix, and its strictly upper triangular part is not referenced.</p> <p>If <i>diag</i> = 'U', the diagonal elements of sub(A) are also not referenced and are assumed to be 1.</p> |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix sub(A), respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>work</i> | <p>(local)</p> <p>The array <i>work</i> of size <i>lwork</i> is a workspace array.</p> |
| <i>lwork</i> | <p>(local or global) The size of the array <i>work</i>.</p> <p><i>For real flavors:</i></p> <p><i>lwork</i> must be at least</p> |

$$lwork \geq 2 * LOCr(n + \text{mod}(ia - 1, mb_a)) + LOcc(n + \text{mod}(ja - 1, nb_a)) + \max(2, \max(nb_a * \max(1, \text{ceil}(\text{NPROW} - 1, \text{NPCOL})), LOcc(n + \text{mod}(ja - 1, nb_a)) + nb_a * \max(1, \text{ceil}(\text{NPCOL} - 1, \text{NPROW}))))).$$

For complex flavors:

lwork must be at least

$$lwork \geq 2 * LOCr(n + \text{mod}(ia - 1, mb_a)) + \max(2, \max(nb_a * \text{ceil}(\text{NPROW} - 1, \text{NPCOL}), LOcc(n + \text{mod}(ja - 1, nb_a)) + nb_a * \text{ceil}(\text{NPCOL} - 1, \text{NPROW}))).$$

NOTE

$\text{ceil}(x, y)$ is the ceiling of x/y , and $\text{mod}(x, y)$ is the integer remainder of x/y .

| | |
|---------------|--|
| <i>iwork</i> | (local) Workspace array of size <i>liwork</i> . Used in real flavors only. |
| <i>liwork</i> | (local or global) The size of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ia - 1, mb_a))$. |
| <i>rwork</i> | (local) Workspace array of size <i>lrwork</i> . Used in complex flavors only. |
| <i>lrwork</i> | (local or global) The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq LOcc(n + \text{mod}(ja - 1, nb_a))$. |

Output Parameters

| | |
|------------------|--|
| <i>rcond</i> | (global) The reciprocal of the condition number of the distributed matrix sub(A). |
| <i>work</i> [0] | On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance. |
| <i>iwork</i> [0] | On exit, <i>iwork</i> [0] contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors). |
| <i>rwork</i> [0] | On exit, <i>rwork</i> [0] contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors). |
| <i>info</i> | (global) If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>j</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . |

Refining the Solution and Estimating Its Error: ScaLAPACK Computational Routines

This section describes the ScaLAPACK routines for refining the computed solution of a system of linear equations and estimating the solution error. You can call these routines after factorizing the matrix of the system of equations and computing the solution (see [Routines for Matrix Factorization](#) and [Solving Systems of Linear Equations](#)).

p?gerfs

Improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

Syntax

```
void psgerfs (char *trans , MKL_INT *n , MKL_INT *nrhs , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *af , MKL_INT *iaf , MKL_INT *jaf , MKL_INT
*descaf , MKL_INT *ipiv , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb ,
float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , float *ferr , float *berr ,
float *work , MKL_INT *lwork , MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );
```

```
void pdgerfs (char *trans , MKL_INT *n , MKL_INT *nrhs , double *a , MKL_INT *ia ,

Description

The p?gerfs function improves the computed solution to one of the systems of linear equations

$$\text{sub}(A) \cdot \text{sub}(X) = \text{sub}(B),$$

$$\text{sub}(A)^T \cdot \text{sub}(X) = \text{sub}(B), \text{ or}$$

$$\text{sub}(A)^H \cdot \text{sub}(X) = \text{sub}(B) \text{ and provides error bounds and backward error estimates for the solution.}$$

Here $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$, $\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1)$, and $\text{sub}(X) = X(\text{ix}:\text{ix}+n-1, \text{jx}:\text{jx}+nrhs-1)$.

Input Parameters

| | |
|--------------------|---|
| <i>trans</i> | <p>(global) Must be 'N' or 'T' or 'C'.</p> <p>Specifies the form of the system of equations:</p> <p>If <i>trans</i> = 'N', the system has the form $\text{sub}(A) * \text{sub}(X) = \text{sub}(B)$ (No transpose);</p> <p>If <i>trans</i> = 'T', the system has the form $\text{sub}(A)^T * \text{sub}(X) = \text{sub}(B)$ (Transpose);</p> <p>If <i>trans</i> = 'C', the system has the form $\text{sub}(A)^H * \text{sub}(X) = \text{sub}(B)$ (Conjugate transpose).</p> |
| <i>n</i> | (global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$). |
| <i>nrhs</i> | (global) The number of right-hand sides, i.e., the number of columns of the matrices $\text{sub}(B)$ and $\text{sub}(X)$ ($nrhs \geq 0$). |
| <i>a, af, b, x</i> | <p>(local)</p> <p>Pointers into the local memory to arrays of local sizes</p> <p><i>a</i>: $lld_a * LOCC(ja+n-1)$,</p> <p><i>af</i>: $lld_af * LOCC(jaf+n-1)$,</p> <p><i>b</i>: $lld_b * LOCC(jb+nrhs-1)$,</p> <p><i>x</i>: $lld_x * LOCC(jx+nrhs-1)$.</p> <p>The array <i>a</i> contains the local pieces of the distributed matrix $\text{sub}(A)$.</p> <p>The array <i>af</i> contains the local pieces of the distributed factors of the matrix $\text{sub}(A) = P * L * U$ as computed by <code>p?getrf</code>.</p> <p>The array <i>b</i> contains the local pieces of the distributed matrix of right hand sides $\text{sub}(B)$.</p> <p>On entry, the array <i>x</i> contains the local pieces of the distributed solution matrix $\text{sub}(X)$.</p> |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>iaf, jaf</i> | (global) The row and column indices in the global matrix <i>AF</i> indicating the first row and the first column of the matrix $\text{sub}(AF)$, respectively. |
| <i>descaf</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>AF</i> . |
| <i>ib, jb</i> | (global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the matrix $\text{sub}(B)$, respectively. |
| <i>descb</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> . |

| | |
|---|--|
| <i>ix, jx</i> | (global) The row and column indices in the global matrix X indicating the first row and the first column of the matrix sub(X), respectively. |
| <i>descx</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix X . |
| <i>ipiv</i> | (local) Array of size $LOCr(m_af) + mb_af$. This array contains pivoting information as computed by <code>p?getrf</code> . If $ipiv[i]=j$, then the local row $i+1$ was swapped with the global row j where $i=0, \dots, LOCr(m_af) + mb_af - 1$. This array is tied to the distributed matrix A . |
| <i>work</i> | (local) The array <i>work</i> of size <i>lwork</i> is a workspace array. |
| <i>lwork</i> | (local or global) The size of the array <i>work</i> . <i>For real flavors:</i> <i>lwork</i> must be at least $lwork \geq 3 * LOCr(n + \text{mod}(ia-1, mb_a))$ <i>For complex flavors:</i> <i>lwork</i> must be at least $lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb_a))$ |
| <hr/> NOTE $\text{mod}(x, y)$ is the integer remainder of x/y . <hr/> | |
| <i>iwork</i> | (local) Workspace array, size <i>liwork</i> . Used in real flavors only. |
| <i>liwork</i> | (local or global) The size of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ib-1, mb_b))$. |
| <i>rwork</i> | (local) Workspace array, size <i>lrwork</i> . Used in complex flavors only. |
| <i>lrwork</i> | (local or global) The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq LOCr(n + \text{mod}(ib-1, mb_b))$. |

Output Parameters

| | |
|-------------------|--|
| <i>x</i> | On exit, contains the improved solution vectors. |
| <i>ferr, berr</i> | Arrays of size $LOCc(jb + nrhs - 1)$ each. The array <i>ferr</i> contains the estimated forward error bound for each solution vector of sub(X). |

If `XTRUE` is the true solution corresponding to `sub(X)`, `ferr` is an estimated upper bound for the magnitude of the largest element in `(sub(X) - XTRUE)` divided by the magnitude of the largest element in `sub(X)`. The estimate is as reliable as the estimate for `rcond`, and is almost always a slight overestimate of the true error.

This array is tied to the distributed matrix `X`.

The array `berr` contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of `sub(A)` or `sub(B)` that makes `sub(X)` an exact solution). This array is tied to the distributed matrix `X`.

`work[0]` On exit, `work[0]` contains the minimum value of `lwork` required for optimum performance.

`iwork[0]` On exit, `iwork[0]` contains the minimum value of `liwork` required for optimum performance (for real flavors).

`rwork[0]` On exit, `rwork[0]` contains the minimum value of `lrwork` required for optimum performance (for complex flavors).

`info` (global) If `info=0`, the execution is successful.

`info < 0`:

If the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then `info = -(i*100+j)`; if the *i*-th argument is a scalar and had an illegal value, then `info = -i`.

Description

The `pzporfs` function improves the computed solution to the system of linear equations

$$\text{sub}(A) \cdot \text{sub}(X) = \text{sub}(B),$$

where $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ is a real symmetric or complex Hermitian positive definite distributed matrix and

$$\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1),$$

$$\text{sub}(X) = X(\text{ix}:\text{ix}+n-1, \text{jx}:\text{jx}+nrhs-1)$$

are right-hand side and solution submatrices, respectively. This function also provides error bounds and backward error estimates for the solution.

Input Parameters

| | |
|--------------------|---|
| <i>uplo</i> | (global) Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored. If <i>uplo</i> = 'U', $\text{sub}(A)$ is upper triangular. If <i>uplo</i> = 'L', $\text{sub}(A)$ is lower triangular. |
| <i>n</i> | (global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$). |
| <i>nrhs</i> | (global) The number of right-hand sides, i.e., the number of columns of the matrices $\text{sub}(B)$ and $\text{sub}(X)$ ($nrhs \geq 0$). |
| <i>a, af, b, x</i> | (local) Pointers into the local memory to arrays of local sizes <i>a</i> : $lld_a * LOCC(\text{ja}+n-1)$, <i>af</i> : $lld_af * LOCC(\text{jaf}+n-1)$, <i>b</i> : $lld_b * LOCC(\text{jb}+nrhs-1)$, <i>x</i> : $lld_x * LOCC(\text{jx}+nrhs-1)$. The array <i>a</i> contains the local pieces of the <i>n</i> -by- <i>n</i> symmetric/Hermitian distributed matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. |

If $uplo = 'L'$, the leading n -by- n lower triangular part of $sub(A)$ contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced.

The array af contains the factors L or U from the Cholesky factorization $sub(A) = L * L^H$ or $sub(A) = U^H * U$, as computed by `p?potrf`.

On entry, the array b contains the local pieces of the distributed matrix of right hand sides $sub(B)$.

On entry, the array x contains the local pieces of the solution vectors $sub(X)$.

| | |
|------------|---|
| ia, ja | (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $sub(A)$, respectively. |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| iaf, jaf | (global) The row and column indices in the global matrix AF indicating the first row and the first column of the matrix $sub(AF)$, respectively. |
| $descaf$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix AF . |
| ib, jb | (global) The row and column indices in the global matrix B indicating the first row and the first column of the matrix $sub(B)$, respectively. |
| $descb$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix B . |
| ix, jx | (global) The row and column indices in the global matrix X indicating the first row and the first column of the matrix $sub(X)$, respectively. |
| $descx$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix X . |
| $work$ | (local) The array $work$ of size $lwork$ is a workspace array. |
| $lwork$ | (local) The size of the array $work$. |

For real flavors:

$lwork$ must be at least

$$lwork \geq 3 * LOCr(n + \text{mod}(ia-1, mb_a))$$

For complex flavors:

$lwork$ must be at least

$$lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb_a))$$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

| | |
|---------|---|
| $iwork$ | (local) Workspace array of size $liwork$. Used in real flavors only. |
|---------|---|

| | |
|---------------|--|
| <i>liwork</i> | (local or global) The size of the array <i>liwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ib-1, mb_b))$. |
| <i>rwork</i> | (local) Workspace array of size <i>lrwork</i> . Used in complex flavors only. |
| <i>lrwork</i> | (local or global) The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq LOCr(n + \text{mod}(ib-1, mb_b))$. |

Output Parameters

| | |
|-------------------|---|
| <i>x</i> | On exit, contains the improved solution vectors. |
| <i>ferr, berr</i> | Arrays of size $LOCc(jb + nrhs - 1)$ each. The array <i>ferr</i> contains the estimated forward error bound for each solution vector of sub(<i>X</i>). If <i>XTRUE</i> is the true solution corresponding to sub(<i>X</i>), <i>ferr</i> is an estimated upper bound for the magnitude of the largest element in (sub(<i>X</i>) - <i>XTRUE</i>) divided by the magnitude of the largest element in sub(<i>X</i>). The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error. This array is tied to the distributed matrix <i>X</i> . The array <i>berr</i> contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of sub(<i>A</i>) or sub(<i>B</i>) that makes sub(<i>X</i>) an exact solution). This array is tied to the distributed matrix <i>X</i> . |
| <i>work</i> [0] | On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance. |
| <i>iwork</i> [0] | On exit, <i>iwork</i> [0] contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors). |
| <i>rwork</i> [0] | On exit, <i>rwork</i> [0] contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors). |
| <i>info</i> | (global) If <i>info</i> =0, the execution is successful. $info < 0$: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then $info = -(j*100+j)$; if the <i>i</i> -th argument is a scalar and had an illegal value, then $info = -i$. |

Description

The `p?trrfs` function provides error bounds and backward error estimates for the solution to one of the systems of linear equations

$$\text{sub}(A) * \text{sub}(X) = \text{sub}(B),$$

$$\text{sub}(A)^T * \text{sub}(X) = \text{sub}(B), \text{ or}$$

$$\text{sub}(A)^H * \text{sub}(X) = \text{sub}(B),$$

where $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ is a triangular matrix,

$\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1)$, and

$\text{sub}(X) = X(\text{ix}:\text{ix}+n-1, \text{jx}:\text{jx}+nrhs-1)$.

The solution matrix X must be computed by `p?trtrs` or some other means before entering this function. The function `p?trrfs` does not do iterative refinement because doing so cannot improve the backward error.

Input Parameters

`uplo` (global) Must be 'U' or 'L'.
If `uplo = 'U'`, $\text{sub}(A)$ is upper triangular. If `uplo = 'L'`, $\text{sub}(A)$ is lower triangular.

`trans` (global) Must be 'N' or 'T' or 'C'.
Specifies the form of the system of equations:
If `trans = 'N'`, the system has the form $\text{sub}(A) * \text{sub}(X) = \text{sub}(B)$ (No transpose);

| | |
|----------------|---|
| | <p>If $trans = 'T'$, the system has the form $sub(A)^T * sub(X) = sub(B)$ (Transpose);</p> <p>If $trans = 'C'$, the system has the form $sub(A)^H * sub(X) = sub(B)$ (Conjugate transpose).</p> |
| <i>diag</i> | <p>Must be $'N'$ or $'U'$.</p> <p>If $diag = 'N'$, then $sub(A)$ is non-unit triangular.</p> <p>If $diag = 'U'$, then $sub(A)$ is unit triangular.</p> |
| <i>n</i> | (global) The order of the distributed matrix $sub(A)$ ($n \geq 0$). |
| <i>nrhs</i> | (global) The number of right-hand sides, that is, the number of columns of the matrices $sub(B)$ and $sub(X)$ ($nrhs \geq 0$). |
| <i>a, b, x</i> | <p>(local)</p> <p>Pointers into the local memory to arrays of local sizes</p> <p>$a: lld_a * LOCc(ja+n-1)$,</p> <p>$b: lld_b * LOCc(jb+nrhs-1)$,</p> <p>$x: lld_x * LOCc(jx+nrhs-1)$.</p> <p>The array a contains the local pieces of the original triangular distributed matrix $sub(A)$.</p> <p>If $uplo = 'U'$, the leading n-by-n upper triangular part of $sub(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.</p> <p>If $uplo = 'L'$, the leading n-by-n lower triangular part of $sub(A)$ contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced.</p> <p>If $diag = 'U'$, the diagonal elements of $sub(A)$ are also not referenced and are assumed to be 1.</p> <p>On entry, the array b contains the local pieces of the distributed matrix of right hand sides $sub(B)$.</p> <p>On entry, the array x contains the local pieces of the solution vectors $sub(X)$.</p> |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $sub(A)$, respectively. |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <i>ib, jb</i> | (global) The row and column indices in the global matrix B indicating the first row and the first column of the matrix $sub(B)$, respectively. |
| <i>descb</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix B . |
| <i>ix, jx</i> | (global) The row and column indices in the global matrix X indicating the first row and the first column of the matrix $sub(X)$, respectively. |

descx (global and local) array of size *dlen_*. The array descriptor for the distributed matrix *X*.

work (local)
The array *work* of size *lwork* is a workspace array.

lwork (local) The size of the array *work*.
For real flavors:
lwork must be at least $lwork \geq 3 * LOCr(n + \text{mod}(ia-1, mb_a))$
For complex flavors:
lwork must be at least $lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb_a))$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

iwork (local) Workspace array of size *liwork*. Used in real flavors only.

liwork (local or global) The size of the array *iwork*; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ib-1, mb_b))$.

rwork (local)
Workspace array of size *lrwork*. Used in complex flavors only.

lrwork (local or global) The size of the array *rwork*; used in complex flavors only. Must be at least $lrwork \geq LOCr(n + \text{mod}(ib-1, mb_b))$.

Output Parameters

ferr, berr Arrays of size $LOCc(jb + nrhs - 1)$ each.

The array *ferr* contains the estimated forward error bound for each solution vector of $\text{sub}(X)$.

If *XTRUE* is the true solution corresponding to $\text{sub}(X)$, *ferr* is an estimated upper bound for the magnitude of the largest element in $(\text{sub}(X) - XTRUE)$ divided by the magnitude of the largest element in $\text{sub}(X)$. The estimate is as reliable as the estimate for *rcond*, and is almost always a slight overestimate of the true error.

This array is tied to the distributed matrix *X*.

The array *berr* contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of $\text{sub}(A)$ or $\text{sub}(B)$ that makes $\text{sub}(X)$ an exact solution). This array is tied to the distributed matrix *X*.

work[0] On exit, *work[0]* contains the minimum value of *lwork* required for optimum performance.

| | |
|-----------------------|--|
| <code>iwork[0]</code> | On exit, <code>iwork[0]</code> contains the minimum value of <code>liwork</code> required for optimum performance (for real flavors). |
| <code>rwork[0]</code> | On exit, <code>rwork[0]</code> contains the minimum value of <code>lrwork</code> required for optimum performance (for complex flavors). |
| <code>info</code> | (global) If <code>info=0</code> , the execution is successful. <code>info < 0</code> : If the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info = -(i*100+j)</code> ; if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> . |

Matrix Inversion: ScaLAPACK Computational Routines

This sections describes ScaLAPACK routines that compute the inverse of a matrix based on the previously obtained factorization. Note that it is not recommended to solve a system of equations $Ax = b$ by first computing A^{-1} and then forming the matrix-vector product $x = A^{-1}b$. Call a solver routine instead (see [Solving Systems of Linear Equations](#)); this is more efficient and more accurate.

p?getri

Computes the inverse of a LU-factored distributed matrix.

Syntax

```
void psgetri (MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
MKL_INT *ipiv , float *work , MKL_INT *lwork , MKL_INT *iwork , MKL_INT *liwork ,
MKL_INT *info );
```

```
void pdgetri (MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
MKL_INT *ipiv , double *work , MKL_INT *lwork , MKL_INT *iwork , MKL_INT *liwork ,
MKL_INT *info );
```

```
void pcgetri (MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *ipiv , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *iwork ,
MKL_INT *liwork , MKL_INT *info );
```

```
void pzgetri (MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *ipiv , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *iwork ,
MKL_INT *liwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?getri` function computes the inverse of a general distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ using the LU factorization computed by `p?getrf`. This method inverts U and then computes the inverse of $\text{sub}(A)$ by solving the system

$$\text{inv}(\text{sub}(A)) * L = \text{inv}(U)$$

for $\text{inv}(\text{sub}(A))$.

Input Parameters

| | |
|---------------|--|
| <i>n</i> | (global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$). |
| <i>a</i> | (local) Pointer into the local memory to an array of local size $lld_a * LOCC(ja+n-1)$. On entry, the array <i>a</i> contains the local pieces of the <i>L</i> and <i>U</i> obtained by the factorization $\text{sub}(A) = P * L * U$ computed by <code>p?getrf</code> . |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>work</i> | (local) The array <i>work</i> of size <i>lwork</i> is a workspace array. |
| <i>lwork</i> | (local) The size of the array <i>work</i> . <i>lwork</i> must be at least $lwork \geq LOCr(n + \text{mod}(ia-1, mb_a)) * nb_a$. |

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

The array *work* is used to keep at most an entire column block of $\text{sub}(A)$.

| | |
|--------------|--|
| <i>iwork</i> | (local) Workspace array used for physically transposing the pivots, size <i>liwork</i> . |
|--------------|--|

| | |
|---------------|---|
| <i>liwork</i> | (local or global) The size of the array <i>iwork</i> . The minimal value <i>liwork</i> of is determined by the following code: |
|---------------|---|

```

if NPROW == NPCOL then
    liwork = LOCC(n_a + mod(ja-1, nb_a)) + nb_a
else
    liwork = LOCC(n_a + mod(ja-1, nb_a)) +
max(ceil(ceil(LOCr(m_a)/mb_a)/(lcm/NPROW)), nb_a)
end if

```

where *lcm* is the least common multiple of process rows and columns (NPROW and NPCOL).

Output Parameters

| | |
|-------------|--|
| <i>ipiv</i> | (local) Array of size $LOCr(m_a) + mb_a$. This array contains the pivoting information. |
|-------------|--|

If $ipiv[i]=j$, then the local row $i+1$ was swapped with the global row j where $i=0, \dots, LOCr(m_a) + mb_a - 1$.

This array is tied to the distributed matrix A .

`work[0]`

On exit, `work[0]` contains the minimum value of `lwork` required for optimum performance.

`iwork[0]`

On exit, `iwork[0]` contains the minimum value of `liwork` required for optimum performance.

`info`

(global) If `info=0`, the execution is successful.

`info < 0`:

If the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then `info = -(i*100+j)`; if the i -th argument is a scalar and had an illegal value, then `info = -i`.

`info > 0`:

If `info = i`, the matrix element $U(i,i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

p?potri

Computes the inverse of a symmetric/Hermitian positive definite distributed matrix.

Syntax

```
void pspotri (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pdpotri (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pcpotri (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pzpotri (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?potri` function computes the inverse of a real symmetric or complex Hermitian positive definite distributed matrix $sub(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the Cholesky factorization $sub(A) = U^H * U$ or $sub(A) = L * L^H$ computed by `p?potrf`.

Input Parameters

`uplo`

(global) Must be 'U' or 'L'.

| | |
|----------|--|
| | Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored. If $\text{uplo} = 'U'$, upper triangle of $\text{sub}(A)$ is stored. If $\text{uplo} = 'L'$, lower triangle of $\text{sub}(A)$ is stored. |
| n | (global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$). |
| a | (local) Pointer into the local memory to an array of local size $\text{lld}_a * \text{LOCc}(j_a + n - 1)$. On entry, the array a contains the local pieces of the triangular factor U or L from the Cholesky factorization $\text{sub}(A) = U^H * U$, or $\text{sub}(A) = L * L^H$, as computed by <code>p?potrf</code> . |
| ia, ja | (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively. |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |

Output Parameters

| | |
|--------|--|
| a | On exit, overwritten by the local pieces of the upper or lower triangle of the (symmetric/Hermitian) inverse of $\text{sub}(A)$. |
| $info$ | (global) If $info=0$, the execution is successful. $info < 0$: If the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$. $info > 0$: If $info = i$, the element (i, i) of the factor U or L is zero, and the inverse could not be computed. |

See Also

p?trtri

Computes the inverse of a triangular distributed matrix.

Syntax

```
void pstrtri (char *uplo , char *diag , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
void pdtrtri (char *uplo , char *diag , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
void pctrtri (char *uplo , char *diag , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pztrtri (char *uplo , char *diag , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `pztrtri` function computes the inverse of a real or complex upper or lower triangular distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$.

Input Parameters

| | |
|---------------|---|
| <i>uplo</i> | (global) Must be 'U' or 'L'. Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular. If <i>uplo</i> = 'U', $\text{sub}(A)$ is upper triangular. If <i>uplo</i> = 'L', $\text{sub}(A)$ is lower triangular. |
| <i>diag</i> | Must be 'N' or 'U'. Specifies whether or not the distributed matrix $\text{sub}(A)$ is unit triangular. If <i>diag</i> = 'N', then $\text{sub}(A)$ is non-unit triangular. If <i>diag</i> = 'U', then $\text{sub}(A)$ is unit triangular. |
| <i>n</i> | (global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$). |
| <i>a</i> | (local) Pointer into the local memory to an array of local size $lld_a * LOCc(\text{ja}+n-1)$. The array <i>a</i> contains the local pieces of the triangular distributed matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular matrix to be inverted, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |

Output Parameters

| | |
|-------------|--|
| <i>a</i> | On exit, overwritten by the (triangular) inverse of the original matrix. |
| <i>info</i> | (global) If <i>info</i> =0, the execution is successful. <i>info</i> < 0: |

If the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

$info > 0$:

If $info = k$, the matrix element $A(ia+k-1, ja+k-1)$ is exactly zero. The triangular matrix $sub(A)$ is singular and its inverse cannot be computed.

Matrix Equilibration: ScaLAPACK Computational Routines

ScaLAPACK routines described in this section are used to compute scaling factors needed to equilibrate a matrix. Note that these routines do not actually scale the matrices.

p?geequ

Computes row and column scaling factors intended to equilibrate a general rectangular distributed matrix and reduce its condition number.

Syntax

```
void psgeequ (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *r , float *c , float *rowcnd , float *colcnd , float *amax , MKL_INT
*info );
```

```
void pdgeequ (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *r , double *c , double *rowcnd , double *colcnd , double
*amax , MKL_INT *info );
```

```
void pcgeequ (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *r , float *c , float *rowcnd , float *colcnd , float *amax ,
MKL_INT *info );
```

```
void pzgeequ (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *r , double *c , double *rowcnd , double *colcnd , double
*amax , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?geequ` function computes row and column scalings intended to equilibrate an m -by- n distributed matrix $sub(A) = A(ia:ia+m-1, ja:ja+n-1)$ and reduce its condition number. The output array r returns the row scale factors r_i , and the array c returns the column scale factors c_j . These factors are chosen to try to make the largest element in each row and column of the matrix B with elements $b_{ij}=r_i*a_{ij}*c_j$ have absolute value 1.

r_i and c_j are restricted to be between $SMLNUM =$ smallest safe number and $BIGNUM =$ largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of $sub(A)$ but works well in practice.

SMLNUM and *BIGNUM* are parameters representing machine precision. You can use the `?slamch` routines to compute them. For example, compute single precision values of *SMLNUM* and *BIGNUM* as follows:

```
SMLNUM = slamch ('s')
BIGNUM = 1 / SMLNUM
```

The auxiliary function `p?laqge` uses scaling factors computed by `p?geequ` to scale a general rectangular matrix.

Input Parameters

| | |
|---------------|---|
| <i>m</i> | (global) The number of rows to be operated on, that is, the number of rows of the distributed matrix $\text{sub}(A)$ ($m \geq 0$). |
| <i>n</i> | (global) The number of columns to be operated on, that is, the number of columns of the distributed matrix $\text{sub}(A)$ ($n \geq 0$). |
| <i>a</i> | (local) Pointer into the local memory to an array of local size $lld_a * LOCC(ja+n-1)$. The array <i>a</i> contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix whose equilibration factors are to be computed. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |

Output Parameters

| | |
|-----------------------|--|
| <i>r, c</i> | (local) Arrays of sizes $LOCr(m_a)$ and $LOCC(n_a)$, respectively. If <i>info</i> = 0, or <i>info</i> > <i>ia</i> + <i>m</i> -1, <i>r</i> [<i>i</i>] contain the row scale factors for $\text{sub}(A)$ for $ia-1 \leq i < ia+m-1$. <i>r</i> is aligned with the distributed matrix <i>A</i> , and replicated across every process column. <i>r</i> is tied to the distributed matrix <i>A</i> . If <i>info</i> = 0, <i>c</i> [<i>i</i>] contain the column scale factors for $\text{sub}(A)$ for $ja-1 \leq i < ja+n-1$. <i>c</i> is aligned with the distributed matrix <i>A</i> , and replicated down every process row. <i>c</i> is tied to the distributed matrix <i>A</i> . |
| <i>rowcnd, colcnd</i> | (global) If <i>info</i> = 0 or <i>info</i> > <i>ia</i> + <i>m</i> -1, <i>rowcnd</i> contains the ratio of the smallest r_i to the largest r_i ($ia \leq i \leq ia+m-1$). If <i>rowcnd</i> ≥ 0.1 and <i>amax</i> is neither too large nor too small, it is not worth scaling by r_i . If <i>info</i> = 0, <i>colcnd</i> contains the ratio of the smallest c_j to the largest c_j ($ja \leq j \leq ja+n-1$). If <i>colcnd</i> ≥ 0.1 , it is not worth scaling by c_j . |
| <i>amax</i> | (global) Absolute value of the largest matrix element. If <i>amax</i> is very close to overflow or very close to underflow, the matrix should be scaled. |

info (global) If *info*=0, the execution is successful.

info < 0:

If the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

info > 0:

If *info* = *i* and

i ≤ *m*, the *i*-th row of the distributed matrix sub(*A*) is exactly zero;

i > *m*, the (*i* - *m*)-th column of the distributed matrix sub(*A*) is exactly zero.

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

p?poequ

Computes row and column scaling factors intended to equilibrate a symmetric (Hermitian) positive definite distributed matrix and reduce its condition number.

Syntax

```
void pspoequ (MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
float *sr , float *sc , float *scond , float *amax , MKL_INT *info );
void pdpoequ (MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
double *sr , double *sc , double *scond , double *amax , MKL_INT *info );
void pcspoequ (MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *sr , float *sc , float *scond , float *amax , MKL_INT *info );
void pzspoequ (MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , double *sr , double *sc , double *scond , double *amax , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?poequ function computes row and column scalings intended to equilibrate a real symmetric or complex Hermitian positive definite distributed matrix sub(*A*) = *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) and reduce its condition number (with respect to the two-norm). The output arrays *sr* and *sc* return the row and column scale factors

$$s(i) = \frac{1}{\sqrt{a_{i,i}}}$$

These factors are chosen so that the scaled distributed matrix *B* with elements *b*_{*ij*}=*s*(*i*)**a*_{*ij*}**s*(*j*) has ones on the diagonal.

This choice of sr and sc puts the condition number of B within a factor n of the smallest possible condition number over all possible diagonal scalings.

The auxiliary function `p?laqsy` uses scaling factors computed by `p?geequ` to scale a general rectangular matrix.

Input Parameters

| | |
|----------|--|
| n | (global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$). |
| a | (local) Pointer into the local memory to an array of local size $lld_a * LOCC(ja+n-1)$. The array a contains the n -by- n symmetric/Hermitian positive definite distributed matrix $\text{sub}(A)$ whose scaling factors are to be computed. Only the diagonal elements of $\text{sub}(A)$ are referenced. |
| ia, ja | (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively. |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |

Output Parameters

| | |
|----------|--|
| sr, sc | (local) Arrays of sizes $LOCr(m_a)$ and $LOCC(n_a)$, respectively. If $info = 0$, the array $sr(ia:ia+n-1)$ contains the row scale factors for $\text{sub}(A)$. sr is aligned with the distributed matrix A , and replicated across every process column. sr is tied to the distributed matrix A . If $info = 0$, the array $sc(ja:ja+n-1)$ contains the column scale factors for $\text{sub}(A)$. sc is aligned with the distributed matrix A , and replicated down every process row. sc is tied to the distributed matrix A . |
| $scond$ | (global) If $info = 0$, $scond$ contains the ratio of the smallest $sr[i]$ (or $sc[j]$) to the largest $sr[i]$ (or $sc[j]$), with $ia-1 \leq i < ia+n-1$ and $ja-1 \leq j < ja+n-1$. If $scond \geq 0.1$ and $amax$ is neither too large nor too small, it is not worth scaling by sr (or sc). |
| $amax$ | (global) Absolute value of the largest matrix element. If $amax$ is very close to overflow or very close to underflow, the matrix should be scaled. |
| $info$ | (global) If $info=0$, the execution is successful. $info < 0$: |

If the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

$info > 0$:

If $info = k$, the k -th diagonal entry of $sub(A)$ is nonpositive.

Orthogonal Factorizations: ScaLAPACK Computational Routines

This section describes the ScaLAPACK routines for the $QR(RQ)$ and $LQ(QL)$ factorization of matrices. Routines for the RZ factorization as well as for generalized QR and RQ factorizations are also included. For the mathematical definition of the factorizations, see the respective LAPACK sections or refer to [SLUG].

Table "Computational Routines for Orthogonal Factorizations" lists ScaLAPACK routines that perform orthogonal factorization of matrices.

Computational Routines for Orthogonal Factorizations

| Matrix type, factorization | Factorize without pivoting | Factorize with pivoting | Generate matrix Q | Apply matrix Q |
|--|----------------------------|-------------------------|--|--|

| pair of matrices, generalized RQ factorization | p?ggrqf | | | |

p?geqrf

Computes the QR factorization of a general m-by-n matrix.

Syntax

```
void psgeqrf (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdgeqrf (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pcgeqrf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT
*info );
```

```
void pzgeqrf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT
*info );
```

Include Files

- mkl_scalapack.h

Description

The `p?geqrf` function forms the QR factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia} + m - 1, \text{ja}:\text{ja} + n - 1)$ as

$$A = Q * R.$$

Input Parameters

| | |
|---------------|--|
| <i>m</i> | (global) The number of rows in the distributed matrix $\text{sub}(A)$; ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the distributed matrix $\text{sub}(A)$; ($n \geq 0$). |
| <i>a</i> | (local) Pointer into the local memory to an array of local size $lld_a * LOCC(ja + n - 1)$. Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix $A(\text{ia}:\text{ia} + m - 1, \text{ja}:\text{ja} + n - 1)$, respectively. |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A |
| <i>work</i> | (local). Workspace array of size $lwork$. |
| <i>lwork</i> | (local or global) size of $work$, must be at least $lwork \geq nb_a * (mp0 + nq0 + nb_a)$, where $iroff = \text{mod}(ia - 1, mb_a)$, $icoff = \text{mod}(ja - 1, nb_a)$, $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$, $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$, $mp0 = \text{numroc}(m + iroff, mb_a, MYROW, iarow, NPROW)$, $nq0 = \text{numroc}(n + icoff, nb_a, MYCOL, iacol, NPCOL)$, and numroc , indxg2p are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function <code>blacs_gridinfo</code> . |

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|----------------------|---|
| <code>a</code> | The elements on and above the diagonal of $\text{sub}(A)$ contain the $\min(m,n)$ -by- n upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array <code>tau</code> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below). |
| <code>tau</code> | (local) Array of size $LOCc(ja + \min(m, n) - 1)$. Contains the scalar factor of elementary reflectors. <code>tau</code> is tied to the distributed matrix A . |
| <code>work[0]</code> | On exit, <code>work[0]</code> contains the minimum value of $lwork$ required for optimum performance. |
| <code>info</code> | (global) = 0, the execution is successful. < 0, if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i * 100 + j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$. |

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja) * H(ja+1) * \dots * H(ja+k-1),$$

where $k = \min(m, n)$.

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$, and τ in $\tau[ja+i-2]$.

p?geqpf

Computes the QR factorization of a general m -by- n matrix with pivoting.

Syntax

```
void psgeqpf (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *ipiv , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );

void pdgeqpf (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , double *tau , double *work , MKL_INT *lwork , MKL_INT
*info );
```

```

void pcgeqpf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
*lwork , float *rwork , MKL_INT *lrwork , MKL_INT *info );

void pzgeqpf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT
*lwork , double *rwork , MKL_INT *lrwork , MKL_INT *info );

```

Include Files

- mkl_scalapack.h

Description

The `p?geqpf` function forms the *QR* factorization with column pivoting of a general m -by- n distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$ as

$\text{sub}(A)*P=Q*R$.

Input Parameters

| | |
|---------------|--|
| <i>m</i> | (global) The number of rows in the matrix $\text{sub}(A)$ ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the matrix $\text{sub}(A)$ ($n \geq 0$). |
| <i>a</i> | (local) Pointer into the local memory to an array of local size $lld_a*LOCc(ja+n-1)$. Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix $A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$, respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>work</i> | (local). Workspace array of size <i>lwork</i> . |
| <i>lwork</i> | (local or global) size of <i>work</i> , must be at least <i>For real flavors:</i> $lwork \geq \max(3, mp0+nq0) + LOCc(ja+n-1) + nq0$. <i>For complex flavors:</i> $lwork \geq \max(3, mp0+nq0)$. |

Here

```

iroff = mod(ia-1, mb_a), icoff = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mp0 = numroc(m+iroff, mb_a, MYROW, iarow, NPROW),
nq0 = numroc(n+icoff, nb_a, MYCOL, iacol, NPCOL),

```

$LOCc(ja+n-1) = \text{numroc}(ja+n-1, nb_a, MYCOL, csrc_a, NPCOL)$, and numroc , indxg2p are ScaLAPACK tool functions.

You can determine $MYROW$, $MYCOL$, $NPROW$ and $NPCOL$ by calling the `blacs_gridinfo` function.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

$rwork$

(local).

Workspace array of size $lrwork$ (complex flavors only).

$lrwork$

(local or global) size of $rwork$ (complex flavors only). The value of $lrwork$ must be at least

$$lwork \geq LOCc(ja+n-1) + nq0.$$

Here

$$iroff = \text{mod}(ia-1, mb_a), \quad icoff = \text{mod}(ja-1, nb_a),$$

$$iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW),$$

$$iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL),$$

$$mp0 = \text{numroc}(m+iroff, mb_a, MYROW, iarow, NPROW),$$

$$nq0 = \text{numroc}(n+icoff, nb_a, MYCOL, iacol, NPCOL),$$

$LOCc(ja+n-1) = \text{numroc}(ja+n-1, nb_a, MYCOL, csrc_a, NPCOL)$, and numroc , indxg2p are ScaLAPACK tool functions.

You can determine $MYROW$, $MYCOL$, $NPROW$ and $NPCOL$ by calling the `blacs_gridinfo` function.

If $lrwork = -1$, then $lrwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a

The elements on and above the diagonal of $\text{sub}(A)$ contain the $\min(m,n)$ -by- n upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array τ , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

$ipiv$

(local) Array of size $LOCc(ja+n-1)$.

$ipiv[i] = k$, the local $(i+1)$ -th column of $\text{sub}(A)*P$ was the global k -th column of $\text{sub}(A)$ ($0 \leq i < LOCc(ja+n-1)$). $ipiv$ is tied to the distributed matrix A .

τ

(local)

Array of size $LOCc(ja+\min(m, n)-1)$.

| | |
|-----------------------|--|
| | Contains the scalar factor τ of elementary reflectors. τ is tied to the distributed matrix A . |
| <code>work[0]</code> | On exit, <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance. |
| <code>rwork[0]</code> | On exit, <code>rwork[0]</code> contains the minimum value of <code>lrwork</code> required for optimum performance. |
| <code>info</code> | (global) = 0, the execution is successful. < 0, if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$. |

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1)*H(2)*...*H(k)$$

where $k = \min(m,n)$.

Each $H(i)$ has the form

$$H = I - \tau*v*v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$.

The matrix P is represented in `ipiv` as follows: if `ipiv[j]= i` then the $(j+1)$ -th column of P is the i -th canonical unit vector ($0 \leq j < LOCC(ja+n-1)$).

p?orgqr

Generates the orthogonal matrix Q of the QR factorization formed by p?geqrf.

Syntax

```
void psorgqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdorgqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?orgqr` function generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

$$Q = H(1)*H(2)*...*H(k)$$

as returned by `p?geqrf`.

Input Parameters

| | |
|---------------|---|
| <i>m</i> | (global) The number of rows in the matrix $\text{sub}(Q)$ ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the matrix $\text{sub}(Q)$ ($m \geq n \geq 0$). |
| <i>k</i> | (global) The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$). |
| <i>a</i> | (local) Pointer into the local memory to an array of local size $lld_a * LOCC(ja+n-1)$. The j -th column of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by <code>p?geqrf</code> in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A . |
| <i>tau</i> | (local) Array of size $LOCC(ja+k-1)$. Contains the scalar factor $\tau[j]$ of elementary reflectors $H(j+1)$ as returned by <code>p?geqrf</code> ($0 \leq j < LOCC(ja+k-1)$). <i>tau</i> is tied to the distributed matrix A . |
| <i>work</i> | (local) Workspace array of size of <i>lwork</i> . |
| <i>lwork</i> | (local or global) size of <i>work</i> . Must be at least $lwork \geq nb_a * (nqa0 + mpa0 + nb_a)$, where $irowfa = \text{mod}(ia-1, mb_a)$, $icoffa = \text{mod}(ja-1, nb_a)$, $irow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$, $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$, $mpa0 = \text{numroc}(m+irowfa, mb_a, MYROW, irow, NPROW)$, $nqa0 = \text{numroc}(n+icoffa, nb_a, MYCOL, iacol, NPCOL)$; indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function <code>blacs_gridinfo</code> . If $lwork = -1$, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> . |

Output Parameters

| | |
|-----------------|--|
| <i>a</i> | Contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix <i>Q</i> . |
| <i>work</i> [0] | On exit, [0] contains the minimum value of <i>lwork</i> required for optimum performance. |
| <i>info</i> | (global) = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . |

p?ungqr

Generates the complex unitary matrix Q of the QR factorization formed by p?geqrf.

Syntax

```
void pcungqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pzungqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT
*lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

This function generates the whole or part of *m*-by-*n* complex distributed matrix *Q* denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the first *n* columns of a product of *k* elementary reflectors of order *m*

$$Q = H(1)*H(2)*...*H(k)$$

as returned by [p?geqrf](#).

Input Parameters

| | |
|----------|---|
| <i>m</i> | (global) The number of rows in the matrix sub(<i>Q</i>); ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the matrix sub(<i>Q</i>) ($m \geq n \geq 0$). |
| <i>k</i> | (global) The number of elementary reflectors whose product defines the matrix <i>Q</i> ($n \geq k \geq 0$). |
| <i>a</i> | (local) |

Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$. The j -th column of the matrix stored in a must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by `p?geqrf` in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$.

ia, ja

(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

desca

(global and local) array of size $dlen_$. The array descriptor for the distributed matrix A .

tau

(local)

Array of size $LOCC(ja+k-1)$.

Contains the scalar factor $tau[j]$ of elementary reflectors $H(j+1)$ as returned by `p?geqrf` ($0 \leq j < LOCC(ja+k-1)$). tau is tied to the distributed matrix A .

work

(local)

Workspace array of size of $lwork$.

lwork

(local or global) size of $work$, must be at least $lwork \geq nb_a * (nqa0 + mpa0 + nb_a)$, where

$iroffa = \text{mod}(ia-1, mb_a)$,

$icoffa = \text{mod}(ja-1, nb_a)$,

$iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$,

$iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$,

$mpa0 = \text{numroc}(m+iroffa, mb_a, MYROW, iarow, NPROW)$,

$nqa0 = \text{numroc}(n+icoffa, nb_a, MYCOL, iacol, NPCOL)$

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a

Contains the local pieces of the m -by- n distributed matrix Q .

work[0]

On exit $work[0]$ contains the minimum value of $lwork$ required for optimum performance.

info

(global)

= 0: the execution is successful.

< 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Overview of ScaLAPACK Routines for details of ScaLAPACK array descriptor structures and related notations.

p?ormqr

Multiplies a general matrix by the orthogonal matrix Q of the QR factorization formed by p?geqrf.

Syntax

```
void psormqr (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork , MKL_INT *info );
void pdormqr (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , double
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?ormqr function overwrites the general real m -by- n distributed matrix sub(C) = C(ic:ic+m-1,jc:jc+n-1) with

| | | |
|---------------------|---------------------------|---------------------------|
| | <i>side</i> = 'L' | <i>side</i> = 'R' |
| <i>trans</i> = 'N': | $Q \cdot \text{sub}(C)$ | $\text{sub}(C) \cdot Q$ |
| <i>trans</i> = 'T': | $Q^T \cdot \text{sub}(C)$ | $\text{sub}(C) \cdot Q^T$ |

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by p?geqrf. Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

Input Parameters

| | |
|--------------|--|
| <i>side</i> | (global) = 'L' : Q or Q^T is applied from the left. = 'R' : Q or Q^T is applied from the right. |
| <i>trans</i> | (global) = 'N', no transpose, Q is applied. = 'T', transpose, Q^T is applied. |
| <i>m</i> | (global) The number of rows in the distributed matrix sub(C) ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the distributed matrix sub(C) ($n \geq 0$). |
| <i>k</i> | (global) The number of elementary reflectors whose product defines the matrix Q . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$. |

| | |
|---------------|--|

MKL_INT *lwork , MKL_INT *info );

```

Include Files

- `mkl_scalapack.h`

Description

This function overwrites the general complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

| | | |
|----------------|---------------------|---------------------|
| | $side = 'L'$ | $side = 'R'$ |
| $trans = 'N':$ | $Q*\text{sub}(C)$ | $\text{sub}(C)*Q$ |
| $trans = 'T':$ | $Q^H*\text{sub}(C)$ | $\text{sub}(C)*Q^H$ |

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(1) H(2) \dots H(k)$ as returned by `p?geqrf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

| | |
|----------|--|
| $side$ | (global) $= 'L'$: Q or Q^H is applied from the left. $= 'R'$: Q or Q^H is applied from the right. |
| $trans$ | (global) $= 'N'$, no transpose, Q is applied. $= 'C'$, conjugate transpose, Q^H is applied. |
| m | (global) The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$). |
| n | (global) The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$). |
| k | (global) The number of elementary reflectors whose product defines the matrix Q . Constraints: If $side = 'L'$, $m \geq k \geq 0$ If $side = 'R'$, $n \geq k \geq 0$. |
| a | (local) Pointer into the local memory to an array of size $lld_a * LOCr(ja+k-1)$. The j -th column of the matrix stored in a must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by <code>p?geqrf</code> in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. $A(ia:*, ja:ja+k-1)$ is modified by the function but restored on exit. If $side = 'L'$, $lld_a \geq \max(1, LOCr(ia+m-1))$ If $side = 'R'$, $lld_a \geq \max(1, LOCr(ia+n-1))$ |
| ia, ja | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| tau | (local) |

Array of size $LOCc(ja+k-1)$.

Contains the scalar factor $\tau[j]$ of elementary reflectors $H(j+1)$ as returned by `p?geqrf` ($0 \leq j < LOCc(ja+k-1)$). τ is tied to the distributed matrix A .

c

(local)

Pointer into the local memory to an array of local size $lld_c * LOCc(jc+n-1)$. Contains the local pieces of the distributed matrix sub(C) to be factored.

ic, jc

(global) The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C , respectively.

desc

(global and local) array of size $dlen_$. The array descriptor for the distributed matrix C .

work

(local)

Workspace array of size of *lwork*.

lwork

(local or global) size of *work*, must be at least:

If *side* = 'L',

$$lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + mpc0) * nb_a) + nb_a * nb_a$$

else if *side* = 'R',

$$lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + \max(npa0 + \text{numroc}(\text{numroc}(n + icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0)) * nb_a) + nb_a * nb_a$$

end if

where

$$lcmq = lcm / NPCOL \text{ with } lcm = ilcm(NPROW, NPCOL),$$

$$iroffa = \text{mod}(ia - 1, mb_a),$$

$$icoffa = \text{mod}(ja - 1, nb_a),$$

$$iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW),$$

$$npa0 = \text{numroc}(n + iroffa, mb_a, MYROW, iarow, NPROW),$$

$$iroffc = \text{mod}(ic - 1, mb_c),$$

$$icoffc = \text{mod}(jc - 1, nb_c),$$

$$icrow = \text{indxg2p}(ic, mb_c, MYROW, rsrc_c, NPROW),$$

$$iccol = \text{indxg2p}(jc, nb_c, MYCOL, csrc_c, NPCOL),$$

$$mpc0 = \text{numroc}(m + iroffc, mb_c, MYROW, icrow, NPROW),$$

$$nqc0 = \text{numroc}(n + icoffc, nb_c, MYCOL, iccol, NPCOL),$$

ilcm, *indxg2p* and *numroc* are ScaLAPACK tool functions; *MYROW*, *MYCOL*, *NPROW* and *NPCOL* can be determined by calling the function `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|----------------------|--|
| <code>c</code> | Overwritten by the product $Q*\text{sub}(C)$, or $Q^H*\text{sub}(C)$, or $\text{sub}(C)*Q^H$, or $\text{sub}(C)*Q$. |
| <code>work[0]</code> | On exit <code>work[0]</code> contains the minimum value of $lwork$ required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$. |

p?gelqf

Computes the LQ factorization of a general rectangular matrix.

Syntax

```
void psgelqf (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdgelqf (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
void pcgelqf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *info );
void pzgelqf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?gelqf` function computes the LQ factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1,ja:ja+n-1) = L*Q$.

Input Parameters

`m` (global) The number of rows in the distributed submatrix $\text{sub}(A)$ ($m \geq 0$).

| | |
|---------------|---|
| <i>n</i> | (global) The number of columns in the distributed submatrix $\text{sub}(A)$ ($n \geq 0$). |
| <i>a</i> | (local) Pointer into the local memory to an array of local size $lld_a * LOCC(ja+n-1)$. Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored. |
| <i>ia, ja</i> | (global) The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>work</i> | (local) Workspace array of size of <i>lwork</i> . |
| <i>lwork</i> | (local or global) size of <i>work</i> , must be at least $lwork \geq mb_a * (mp0 + nq0 + mb_a)$, where $iroff = \text{mod}(ia-1, mb_a),$ $icoff = \text{mod}(ja-1, nb_a),$ $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL),$ $mp0 = \text{numroc}(m+iroff, mb_a, MYROW, iarow, NPROW),$ $nq0 = \text{numroc}(n+icoff, nb_a, MYCOL, iacol, NPCOL)$ indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function <code>blacs_gridinfo</code> . |

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

If $lwork = -1$, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|------------|--|
| <i>a</i> | The elements on and below the diagonal of $\text{sub}(A)$ contain the m -by- $\min(m, n)$ lower trapezoidal matrix <i>L</i> (<i>L</i> is lower trapezoidal if $m \leq n$); the elements above the diagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors (see <i>Application Notes</i> below). |
| <i>tau</i> | (local) Array of size $LOCr(ia+\min(m, n)-1)$. |

Contains the scalar factors of elementary reflectors. *tau* is tied to the distributed matrix *A*.

work[0]

On exit, *work*[0] contains the minimum value of *lwork* required for optimum performance.

info

(global)

= 0: the execution is successful.

< 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then *info* = $-(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

Application Notes

The matrix *Q* is represented as a product of elementary reflectors

$$Q = H(ia+k-1)*H(ia+k-2)*...*H(ia),$$

where $k = \min(m, n)$

Each *H*(*i*) has the form

$$H(i) = I - \tau * v * v'$$

where *tau* is a real/complex scalar, and *v* is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ is stored on exit in $A(ia+i-1, ja+i:ja+n-1)$, and *tau* in $\tau[ia+i-2]$.

p?orglq

Generates the real orthogonal matrix Q of the LQ factorization formed by p?gelqf.

Syntax

```
void psorglq (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdorglq (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?orglq function generates the whole or part of *m*-by-*n* real distributed matrix *Q* denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first *m* rows of a product of *k* elementary reflectors of order *n*

$$Q = H(k)*...*H(2)*H(1)$$

as returned by p?gelqf.

Input Parameters

m

(global) The number of rows in the matrix sub(*Q*); ($m \geq 0$).

| | |
|---------------|---|
| <i>n</i> | (global) The number of columns in the matrix sub(<i>Q</i>) ($n \geq m \geq 0$). |
| <i>k</i> | (global) The number of elementary reflectors whose product defines the matrix <i>Q</i> ($m \geq k \geq 0$). |
| <i>a</i> | (local) Pointer into the local memory to an array of local size $lld_a * LOCC(ja+n-1)$. On entry, the <i>i</i> -th row of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gelqf in the <i>k</i> rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>work</i> | (local) Workspace array of size of <i>lwork</i> . |
| <i>lwork</i> | (local or global) size of <i>work</i> , must be at least $lwork \geq mb_a * (mpa0 + nqa0 + mb_a)$, where $iroffa = \text{mod}(ia-1, mb_a),$ $icoffa = \text{mod}(ja-1, nb_a),$ $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL),$ $mpa0 = \text{numroc}(m + iroffa, mb_a, MYROW, iarow, NPROW),$ $nqa0 = \text{numroc}(n + icoffa, nb_a, MYCOL, iacol, NPCOL)$ |

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If $lwork = -1$, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

| | |
|------------|--|
| <i>a</i> | Contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix <i>Q</i> to be factored. |
| <i>tau</i> | (local) Array of size $LOCr(ia+k-1)$. Contains the scalar factors $\tau[j]$ of elementary reflectors $H(j+1)$, $0 \leq j < LOCr(ia+k-1)$. <i>tau</i> is tied to the distributed matrix <i>A</i> . |

`work[0]` On exit, `work[0]` contains the minimum value of `lwork` required for optimum performance.

`info` (global)

= 0: the execution is successful.

< 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then `info = -(i*100+j)`; if the i -th argument is a scalar and had an illegal value, then `info = -i`.

p?unglq

Generates the unitary matrix Q of the LQ factorization formed by `p?gelqf`.

Syntax

```
void pcunglq (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pzunglq (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT
*lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

This function generates the whole or part of m -by- n complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$Q = (H(k))^H \dots (H(2))^H (H(1))^H$ as returned by `p?gelqf`.

Input Parameters

m (global) The number of rows in the matrix `sub(Q)` ($m \geq 0$).

n (global) The number of columns in the matrix `sub(Q)` ($n \geq m \geq 0$).

k (global) The number of elementary reflectors whose product defines the matrix `Q` ($m \geq k \geq 0$).

a (local)

Pointer into the local memory to an array of local size `ld_a*LOCc(ja+n-1)`. On entry, the i -th row of the matrix stored in `a` must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by `p?gelqf` in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$.

| | |
|---------------|---|
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>tau</i> | (local) Array of size $LOCr(ia+k-1)$. Contains the scalar factors $\tau[j]$ of elementary reflectors $H(j+1)$, $0 \leq j < LOCr(ia+k-1)$. τ is tied to the distributed matrix <i>A</i> . |
| <i>work</i> | (local) Workspace array of size of <i>lwork</i> . |
| <i>lwork</i> | (local or global) size of <i>work</i> , must be at least $lwork \geq mb_a * (mpa0 + nqa0 + mb_a)$, where $iroffa = \text{mod}(ia-1, mb_a),$ $icoffa = \text{mod}(ja-1, nb_a),$ $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL),$ $mpa0 = \text{numroc}(m + iroffa, mb_a, MYROW, iarow, NPROW),$ $nqa0 = \text{numroc}(n + icoffa, nb_a, MYCOL, iacol, NPCOL)$ indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function <code>blacs_gridinfo</code> . |

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

If $lwork = -1$, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|-----------------|---|
| <i>a</i> | Contains the local pieces of the m -by- n distributed matrix <i>Q</i> to be factored. |
| <i>work</i> [0] | On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance. |
| <i>info</i> | (global) = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the <i>i</i> -th argument is a scalar and had an illegal value, then $info = -i$. |

p?ormlq

Multiplies a general matrix by the orthogonal matrix Q of the LQ factorization formed by p?gelqf.

Syntax

```
void psormlq (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork , MKL_INT *info );
void pdormlq (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , double
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?ormlq function overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C(\text{ic}:\text{ic}+m-1, \text{jc}:\text{jc}+n-1)$ with

| | | |
|---------------------|---------------------------|---------------------------|
| | <i>side</i> = 'L' | <i>side</i> = 'R' |
| <i>trans</i> = 'N': | $Q \cdot \text{sub}(C)$ | $\text{sub}(C) \cdot Q$ |
| <i>trans</i> = 'T': | $Q^T \cdot \text{sub}(C)$ | $\text{sub}(C) \cdot Q^T$ |

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(k) \dots H(2) H(1)$$

as returned by p?gelqf. Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

Input Parameters

| | |
|--------------|--|
| <i>side</i> | (global) = 'L': Q or Q^T is applied from the left. = 'R': Q or Q^T is applied from the right. |
| <i>trans</i> | (global) = 'N', no transpose, Q is applied. = 'T', transpose, Q^T is applied. |
| <i>m</i> | (global) The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$). |
| <i>k</i> | (global) The number of elementary reflectors whose product defines the matrix Q . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$. |

| | |
|---------------|---|
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a*LOCc(ja+m-1)$, if $side = 'L'$ and $lld_a*LOCc(ja+n-1)$, if $side = 'R'$. The i -th row of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?gelqf</code> in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <i>tau</i> | (local) Array of size $LOCc(ja+k-1)$. Contains the scalar factor $tau[j]$ of elementary reflectors $H(j+1)$ as returned by <code>p?gelqf</code> ($0 \leq j < LOCc(ja+k-1)$). <i>tau</i> is tied to the distributed matrix A . |
| <i>c</i> | (local) Pointer into the local memory to an array of local size $lld_c*LOCc(jc+n-1)$. Contains the local pieces of the distributed matrix $sub(C)$ to be factored. |
| <i>ic, jc</i> | (global) The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C , respectively. |
| <i>desc</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix C . |
| <i>work</i> | (local) Workspace array of size of <i>lwork</i> . |
| <i>lwork</i> | (local or global) size of the array <i>work</i> ; must be at least: If $side = 'L'$, $lwork \geq \max((mb_a*(mb_a-1))/2, (mpc0+\max(mqa0) + \text{numroc}(\text{numroc}(m + iroffa, mb_a, 0, 0, NPROW), mb_a, 0, 0, lcm), nqc0)) * mb_a) + mb_a*mb_a$ else if $side = 'R'$, $lwork \geq \max((mb_a*(mb_a-1))/2, (mpc0+nqc0)*mb_a + mb_a*mb_a$ end if where $lcm = lcm/NPROW$ with $lcm = ilcm(NPROW, NPCOL)$, $iroffa = \text{mod}(ia-1, mb_a)$, $icoffa = \text{mod}(ja-1, nb_a)$, $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$, $mqa0 = \text{numroc}(m+icoffa, nb_a, MYCOL, iacol, NPCOL)$, |

```

iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

NOTE

`mod(x, y)` is the integer remainder of x/y .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|----------------------|--|
| <code>c</code> | Overwritten by the product $Q \cdot \text{sub}(C)$, or $Q' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q'$, or $\text{sub}(C) \cdot Q$ |
| <code>work[0]</code> | On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info = -(i*100+j)</code> ; if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> . |

```

Include Files

- mkl_scalapack.h

Description

This function overwrites the general complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

| | | |
|----------------|-----------------------|-----------------------|
| | $side = 'L'$ | $side = 'R'$ |
| $trans = 'N':$ | $Q * \text{sub}(C)$ | $\text{sub}(C) * Q$ |
| $trans = 'T':$ | $Q^H * \text{sub}(C)$ | $\text{sub}(C) * Q^H$ |

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by [p?gelqf](#). Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

| | |
|---------------|--|
| <i>side</i> | (global) $= 'L'$: Q or Q^H is applied from the left. $= 'R'$: Q or Q^H is applied from the right. |
| <i>trans</i> | (global) $= 'N'$, no transpose, Q is applied. $= 'C'$, conjugate transpose, Q^H is applied. |
| <i>m</i> | (global) The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$). |
| <i>k</i> | (global) The number of elementary reflectors whose product defines the matrix Q . Constraints: If $side = 'L'$, $m \geq k \geq 0$ If $side = 'R'$, $n \geq k \geq 0$. |
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a * LOCC(ja+m-1)$, if $side = 'L'$ and $lld_a * LOCC(ja+n-1)$, if $side = 'R'$, where $lld_a \geq \max(1, LOCr(ia+k-1))$. The i -th column of the matrix stored in a must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gelqf in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |

| | |
|---------------|--|
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>tau</i> | (local) Array of size $LOCc(ia+k-1)$. Contains the scalar factor $\tau[j]$ of elementary reflectors $H(j+1)$ as returned by <code>p?gelqf</code> ($0 \leq j < LOCc(ia+k-1)$). <i>tau</i> is tied to the distributed matrix <i>A</i> . |
| <i>c</i> | (local) Pointer into the local memory to an array of local size $lld_c * LOCc(jc+n-1)$. Contains the local pieces of the distributed matrix sub(<i>C</i>) to be factored. |
| <i>ic, jc</i> | (global) The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively. |
| <i>desc</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> . |
| <i>work</i> | (local) Workspace array of size of <i>lwork</i> . |
| <i>lwork</i> | (local or global) size of the array <i>work</i> ; must be at least: If <i>side</i> = 'L', $lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + \max(mqa0) + \text{numroc}(\text{numroc}(m + iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0, lcm), nqc0)) * mb_a) + mb_a * mb_a$ else if <i>side</i> = 'R', $lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + nqc0) * mb_a + mb_a * mb_a$ end if where $lcmp = lcm / NPROW$ with $lcm = ilcm(NPROW, NPCOL)$, $iroffa = \text{mod}(ia-1, mb_a)$, $icoffa = \text{mod}(ja-1, nb_a)$, $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$, $mqa0 = \text{numroc}(m + icoffa, nb_a, MYCOL, iacol, NPCOL)$, $iroffc = \text{mod}(ic-1, mb_c)$, $icoffc = \text{mod}(jc-1, nb_c)$, $icrow = \text{indxg2p}(ic, mb_c, MYROW, rsrc_c, NPROW)$, $iccol = \text{indxg2p}(jc, nb_c, MYCOL, csrc_c, NPCOL)$, $mpc0 = \text{numroc}(m + iroffc, mb_c, MYROW, icrow, NPROW)$, $nqc0 = \text{numroc}(n + icoffc, nb_c, MYCOL, iccol, NPCOL)$, |

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?xerbla`.

Output Parameters

| | |
|----------------------|--|
| <code>c</code> | Overwritten by the product $Q \cdot \text{sub}(C)$, or $Q' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q'$, or $\text{sub}(C) \cdot Q$ |
| <code>work[0]</code> | On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info = -(i*100+j)</code> ; if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> . |

Description

The `p?geqlf` function forms the QL factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1) = Q * L$.

Input Parameters

| | |
|---------------|--|
| <i>m</i> | (global) The number of rows in the matrix $\text{sub}(Q)$; ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the matrix $\text{sub}(Q)$ ($n \geq 0$). |
| <i>a</i> | (local) Pointer into the local memory to an array of local size $\text{ld}_a * \text{LOCc}(\text{ja}+n-1)$. Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix $A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$, respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A . |
| <i>work</i> | (local) Workspace array of size of <i>lwork</i> . |
| <i>lwork</i> | (local or global) size of <i>work</i> , must be at least $\text{lwork} \geq \text{nb}_a * (\text{mp0} + \text{nq0} + \text{nb}_a)$, where $\text{iroff} = \text{mod}(\text{ia}-1, \text{mb}_a),$ $\text{icoff} = \text{mod}(\text{ja}-1, \text{nb}_a),$ $\text{iarow} = \text{indxg2p}(\text{ia}, \text{mb}_a, \text{MYROW}, \text{rsrc}_a, \text{NPROW}),$ $\text{iacol} = \text{indxg2p}(\text{ja}, \text{nb}_a, \text{MYCOL}, \text{csrc}_a, \text{NPCOL}),$ $\text{mp0} = \text{numroc}(\text{m}+\text{iroff}, \text{mb}_a, \text{MYROW}, \text{iarow}, \text{NPROW}),$ $\text{nq0} = \text{numroc}(\text{n}+\text{icoff}, \text{nb}_a, \text{MYCOL}, \text{iacol}, \text{NPCOL})$ |

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`numroc` and `indxg2p` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If $\text{lwork} = -1$, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|----------|---|
| <i>a</i> | On exit, if $m \geq n$, the lower triangle of the distributed submatrix $A(\text{ia}+m-n:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$ contains the n -by- n lower triangular matrix L ; if $m \leq n$, the elements on and below the $(n - m)$ -th superdiagonal contain the m -by- n |
|----------|---|

lower trapezoidal matrix L ; the remaining elements, with the array τ , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

| | |
|-----------|--|
| τ | (local) Array of size $LOC_c(ja+n-1)$. Contains the scalar factors of elementary reflectors. τ is tied to the distributed matrix A . |
| $work[0]$ | On exit, $work[0]$ contains the minimum value of $lwork$ required for optimum performance. |
| $info$ | (global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$. |

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja+k-1)*\dots*H(ja+1)*H(ja)$$

where $k = \min(m, n)$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(m-k+i+1:m) = 0$ and $v(m-k+i) = 1$; $v(1:m-k+i-1)$ is stored on exit in $A(ia:ia+m-k+i-2, ja+n-k+i-1)$, and τ in $\tau[ja+n-k+i-2]$.

p?orgql

Generates the orthogonal matrix Q of the QL factorization formed by p?geqlf.

Syntax

```
void psorgql (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdorgql (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?orgql` function generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$Q = H(k)*...*H(2)*H(1)$

as returned by `p?geqlf`.

Input Parameters

| | |
|---------------|---|
| <i>m</i> | (global) The number of rows in the matrix $\text{sub}(Q)$, ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the matrix $\text{sub}(Q)$, ($m \geq n \geq 0$). |
| <i>k</i> | (global) The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$). |
| <i>a</i> | (local) Pointer into the local memory to an array of local size $ld_a * LOCC(ja+n-1)$. On entry, the j -th column of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(j)$, $ja+n-k \leq j \leq ja+n-1$, as returned by <code>p?geqlf</code> in the k columns of its distributed matrix argument $A(ia:*, ja+n-k:ja+n-1)$. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A . |
| <i>tau</i> | (local) Array of size $LOCc(ja+n-1)$. Contains the scalar factors $\tau[j]$ of elementary reflectors $H(j+1)$, $0 \leq j < LOCc(ia+n-1)$. <i>tau</i> is tied to the distributed matrix A . |
| <i>work</i> | (local) Workspace array of size of <i>lwork</i> . |
| <i>lwork</i> | (local or global) size of <i>work</i> , must be at least $lwork \geq nb_a * (nqa0 + mpa0 + nb_a)$, where $iroffa = \text{mod}(ia-1, mb_a),$ $icoffa = \text{mod}(ja-1, nb_a),$ $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL),$ $mpa0 = \text{numroc}(m + iroffa, mb_a, MYROW, iarow, NPROW),$ $nqa0 = \text{numroc}(n + icoffa, nb_a, MYCOL, iacol, NPCOL)$ |

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|----------------------|--|
| <code>a</code> | Contains the local pieces of the m -by- n distributed matrix Q to be factored. |
| <code>work[0]</code> | On exit, <code>work[0]</code> contains the minimum value of $lwork$ required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$. |

p?ormql

Multiplies a general matrix by the orthogonal matrix Q of the QL factorization formed by p?geqlf.

Syntax

```
void psormql (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork , MKL_INT *info );
void pdormql (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , double
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?ormql function overwrites the general real m -by- n distributed matrix $sub(C) = C(ic:ic+m-1,jc:jc+n-1)$ with

| | | |
|----------------|--------------|--------------|
| | $side = 'L'$ | $side = 'R'$ |
| $trans = 'N':$ | $Q*sub(C)$ | $sub(C)*Q$ |
| $trans = 'T':$ | $Q^T*sub(C)$ | $sub(C)*Q^T$ |

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$Q = H(k)' \dots H(2)' H(1)'$

as returned by p?geqlf. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

| | |
|---------|---|
| $side$ | (global) = $'L'$: Q or Q^T is applied from the left. = $'R'$: Q or Q^T is applied from the right. |
| $trans$ | (global) = $'N'$, no transpose, Q is applied. = $'T'$, transpose, Q^T is applied. |
| m | (global) The number of rows in the distributed matrix $sub(C)$, ($m \geq 0$). |
| n | (global) The number of columns in the distributed matrix $sub(C)$, ($n \geq 0$). |

| | |
|---------------|--|
| <i>k</i> | <p>(global) The number of elementary reflectors whose product defines the matrix <i>Q</i>. Constraints:</p> <p>If <i>side</i> = 'L', $m \geq k \geq 0$</p> <p>If <i>side</i> = 'R', $n \geq k \geq 0$.</p> |
| <i>a</i> | <p>(local)</p> <p>Pointer into the local memory to an array of size $lld_a * LOCC(ja+k-1)$. The <i>j</i>-th column of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by <code>p?ge1qf</code> in the <i>k</i> columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. $A(ia:*, ja:ja+k-1)$ is modified by the function but restored on exit.</p> <p>If <i>side</i> = 'L', $lld_a \geq \max(1, LOCr(ia+m-1))$,</p> <p>If <i>side</i> = 'R', $lld_a \geq \max(1, LOCr(ia+n-1))$.</p> |
| <i>ia, ja</i> | <p>(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i>, respectively.</p> |
| <i>desca</i> | <p>(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>A</i>.</p> |
| <i>tau</i> | <p>(local)</p> <p>Array of size $LOCC(ja+n-1)$.</p> <p>Contains the scalar factor $\tau[j]$ of elementary reflectors $H(j+1)$ as returned by <code>p?geqlf</code> ($0 \leq j < LOCC(ja+k-1)$). <i>tau</i> is tied to the distributed matrix <i>A</i>.</p> |
| <i>c</i> | <p>(local)</p> <p>Pointer into the local memory to an array of local size $lld_c * LOCC(jc+n-1)$.</p> <p>Contains the local pieces of the distributed matrix sub(<i>C</i>) to be factored.</p> |
| <i>ic, jc</i> | <p>(global) The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the submatrix <i>C</i>, respectively.</p> |
| <i>descc</i> | <p>(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>C</i>.</p> |
| <i>work</i> | <p>(local)</p> <p>Workspace array of size of <i>lwork</i>.</p> |
| <i>lwork</i> | <p>(local or global) dimension of <i>work</i>, must be at least:</p> <p>If <i>side</i> = 'L',</p> $lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + mpc0) * nb_a + nb_a * nb_a)$ <p>else if <i>side</i> = 'R',</p> $lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + \max(npa0 + \text{numroc}(\text{numroc}(n + icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0)) * nb_a + nb_a * nb_a)$ <p>end if</p> <p>where</p> |

```

lcmq = lcm/NPCOL with lcm = ilcm (NPROW, NPCOL),
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
npa0 = numroc(n + iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

NOTE

`mod(x,y)` is the integer remainder of x/y .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `perbla`.

Output Parameters

| | |
|----------------------|--|
| <code>c</code> | Overwritten by the product $Q^* \text{sub}(C)$, or $Q^* \text{sub}(C)$, or $\text{sub}(C)^* Q'$, or $\text{sub}(C)^* Q$ |
| <code>work[0]</code> | On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $\text{info} = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $\text{info} = -i$. |

MKL_Complex16 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex16 *work ,
MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

This function overwrites the general complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

| | | |
|----------------|-----------------------|-----------------------|
| | $side = 'L'$ | $side = 'R'$ |
| $trans = 'N':$ | $Q * \text{sub}(C)$ | $\text{sub}(C) * Q$ |
| $trans = 'C':$ | $Q^H * \text{sub}(C)$ | $\text{sub}(C) * Q^H$ |

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by `p?geqlf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

| | |
|---------|--|
| $side$ | (global) = $'L'$: Q or Q^H is applied from the left. = $'R'$: Q or Q^H is applied from the right. |
| $trans$ | (global) = $'N'$, no transpose, Q is applied. = $'C'$, conjugate transpose, Q^H is applied. |
| m | (global) The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$). |
| n | (global) The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$). |
| k | (global) The number of elementary reflectors whose product defines the matrix Q . Constraints: If $side = 'L'$, $m \geq k \geq 0$ If $side = 'R'$, $n \geq k \geq 0$. |
| a | (local) |

Pointer into the local memory to an array of size $lld_a * LOCC(ja+k-1)$. The j -th column of the matrix stored in a must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by `p?geqlf` in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. $A(ia:*, ja:ja+k-1)$ is modified by the function but restored on exit.

If $side = 'L'$, $lld_a \geq \max(1, LOCr(ia+m-1))$,

If $side = 'R'$, $lld_a \geq \max(1, LOCr(ia+n-1))$.

ia, ja

(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

$desca$

(global and local) array of size $dlen_$. The array descriptor for the distributed matrix A .

tau

(local)

Array of size $LOCC(ia+n-1)$.

Contains the scalar factor $tau[j]$ of elementary reflectors $H(j+1)$ as returned by `p?geqlf` ($0 \leq j < LOCC(ia+n-1)$). tau is tied to the distributed matrix A .

c

(local)

Pointer into the local memory to an array of local size $lld_c * LOCC(jc+n-1)$.

Contains the local pieces of the distributed matrix $sub(C)$ to be factored.

ic, jc

(global) The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C , respectively.

$descC$

(global and local) array of size $dlen_$. The array descriptor for the distributed matrix C .

$work$

(local)

Workspace array of size of $lwork$.

$lwork$

(local or global) size of $work$, must be at least:

If $side = 'L'$,

$lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + mpc0) * nb_a + nb_a * nb_a)$

else if $side = 'R'$,

$lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + \max(npa0) + \text{numroc}(\text{numroc}(n + icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0)) * nb_a + nb_a * nb_a)$

end if

where

$lcmp = lcm / NPCOL$ with $lcm = \text{ilcm}(NPROW, NPCOL)$,

$iroffa = \text{mod}(ia - 1, mb_a)$,

$icoffa = \text{mod}(ja - 1, nb_a)$,

$iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$,

```

npa0 = numroc ( n + iroffa, mb_a, MYROW, iarow, NPROW ),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

NOTE

`mod(x, y)` is the integer remainder of x/y .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

NOTE

`mod(x, y)` is the integer remainder of x/y .

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|----------------------|--|
| <code>c</code> | Overwritten by the product $Q^* \text{sub}(C)$, or $Q' \text{sub}(C)$, or $\text{sub}(C)^* Q'$, or $\text{sub}(C)^* Q$ |
| <code>work[0]</code> | On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info = -(i*100+j)</code> ; if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> . |

p?gerqf

Computes the RQ factorization of a general rectangular matrix.

Syntax

```

void psggerqf (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );

```

```

void pdgerqf (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );

void pcgerqf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT
*info );

void pzgerqf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT
*info );

```

Include Files

- mkl_scalapack.h

Description

The `p?gerqf` function forms the QR factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia} + m - 1, \text{ja}:\text{ja} + n - 1)$ as

$$A = R * Q$$

Input Parameters

| | |
|---------------|--|
| <i>m</i> | (global) The number of rows in the distributed matrix $\text{sub}(A)$; ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the distributed matrix $\text{sub}(A)$; ($n \geq 0$). |
| <i>a</i> | (local) Pointer into the local memory to an array of local size $lld_a * LOCC(ja + n - 1)$. Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix $A(\text{ia}:\text{ia} + m - 1, \text{ja}:\text{ja} + n - 1)$, respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A |
| <i>work</i> | (local). Workspace array of size <i>lwork</i> . |
| <i>lwork</i> | (local or global) size of <i>work</i> , must be at least $lwork \geq mb_a * (mp0 + nq0 + mb_a)$, where $irow = \text{mod}(ia - 1, mb_a)$, $icol = \text{mod}(ja - 1, nb_a)$, $irow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$, $icol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$, $mp0 = \text{numroc}(m + irow, mb_a, MYROW, irow, NPROW)$, |

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`ng0 = numroc(n+icoff, nb_a, MYCOL, iacol, NPCOL)` and `numroc, indxg2p` are ScaLAPACK tool functions; `MYROW, MYCOL, NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|----------------------|--|
| <code>a</code> | On exit, if $m \leq n$, the upper triangle of $A(ia:ia+m-1, ja:ja+n-1)$ contains the m -by- m upper triangular matrix R ; if $m \geq n$, the elements on and above the $(m - n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix R ; the remaining elements, with the array <code>tau</code> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below). |
| <code>tau</code> | (local) Array of size <code>LOCr(ia+m-1)</code> . Contains the scalar factor of elementary reflectors. <code>tau</code> is tied to the distributed matrix A . |
| <code>work[0]</code> | On exit, <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance. |
| <code>info</code> | (global) = 0, the execution is successful. < 0, if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info = -(i*100+j)</code> ; if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> . |

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ia) * H(ia+1) * \dots * H(ia+k-1),$$

where $k = \min(m, n)$.

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ is stored on exit in $A(ia+m-k+i-1, ja:ja+n-k+i-2)$, and τ in `tau[ia+m-k+i-2]`.

p?orgrq

Generates the orthogonal matrix Q of the RQ factorization formed by `p?gerqf`.

Syntax

```
void psorgqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdorgqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?orgqr` function generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows that is defined as the last m rows of a product of k elementary reflectors of order n

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by `p?gerqf`.

Input Parameters

| | |
|----------|---|
| m | (global) The number of rows in the matrix $\text{sub}(Q)$, ($m \geq 0$). |
| n | (global) The number of columns in the matrix $\text{sub}(Q)$, ($n \geq m \geq 0$). |
| k | (global) The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$). |
| a | (local) Pointer into the local memory to an array of local size $lld_a * LOCC(ja+n-1)$. The i -th row of the matrix stored in a must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+m-1$, as returned by <code>p?gerqf</code> in the k rows of its distributed matrix argument $A(ia+m-k:ia+m-1, ja:*)$. |
| ia, ja | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| tau | (local) Array of size $LOCC(ja+k-1)$. Contains the scalar factor $tau[i]$ of elementary reflectors $H(i+1)$ as returned by <code>p?gerqf</code> , $0 \leq i < LOCC(ja+k-1)$. tau is tied to the distributed matrix A . |
| $work$ | (local) Workspace array of size of $lwork$. |
| $lwork$ | (local or global) size of $work$, must be at least $lwork \geq mb_a * (mpa0 + nqa0 + mb_a)$, where $iroffa = \text{mod}(ia-1, mb_a)$, $icoffa = \text{mod}(ja-1, nb_a)$, |

```

iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow, NPROW),
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol, NPCOL)
indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW
and NPCOL can be determined by calling the function blacs_gridinfo.

```

NOTE

`mod(x, y)` is the integer remainder of x/y .

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

| | |
|----------------------|--|
| <code>a</code> | Contains the local pieces of the m -by- n distributed matrix Q . |
| <code>work[0]</code> | On exit, <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info = -(i*100+j)</code> ; if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> . |

*lwork , MKL_INT *info );

```

Include Files

- `mkl_scalapack.h`

Description

This function generates the m -by- n complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors of order n

$Q = (H(1))^H * (H(2))^H * \dots * (H(k))^H$ as returned by `p?gerqf`.

Input Parameters

| | |
|----------|--|
| m | (global) The number of rows in the matrix sub(Q); ($m \geq 0$). |
| n | (global) The number of columns in the matrix sub(Q) ($n \geq m \geq 0$). |
| k | (global) The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$). |
| a | (local) Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$. The i -th row of the matrix stored in a must contain the vector that defines the elementary reflector $H(i)$, $ia+m-k \leq i \leq ia+m-1$, as returned by <code>p?gerqf</code> in the k rows of its distributed matrix argument $A(ia+m-k:ia+m-1, ja:*)$. |
| ia, ja | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| tau | (local) Array of size $LOCr(ia+m-1)$. Contains the scalar factor $tau[i]$ of elementary reflectors $H(i+1)$ as returned by <code>p?gerqf</code> , $0 \leq i < LOCr(ia+m-1)$. tau is tied to the distributed matrix A . |
| $work$ | (local) Workspace array of size of $lwork$. |
| $lwork$ | (local or global) size of $work$, must be at least $lwork \geq mb_a * (mpa0 + nqa0 + mb_a)$, where $iroffa = \text{mod}(ia-1, mb_a),$ $icoffa = \text{mod}(ja-1, nb_a),$ $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL),$ $mpa0 = \text{numroc}(m + iroffa, mb_a, MYROW, iarow, NPROW),$ $nqa0 = \text{numroc}(n + icoffa, nb_a, MYCOL, iacol, NPCOL)$ |

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|----------------------|--|
| <code>a</code> | Contains the local pieces of the m -by- n distributed matrix Q . |
| <code>work[0]</code> | On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info = -(i*100+j)</code> ; if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> . |

p?ormr3

Applies an orthogonal distributed matrix to a general m -by- n distributed matrix.

Syntax

```
void psormr3 (const char* side, const char* trans, const MKL_INT* m, const MKL_INT* n,
const MKL_INT* k, const MKL_INT* l, const float* a, const MKL_INT* ia, const MKL_INT*
ja, const MKL_INT* desca, const float* tau, float* c, const MKL_INT* ic, const
MKL_INT* jc, const MKL_INT* descc, float* work, const MKL_INT* lwork, MKL_INT* info);

void pdormr3 (const char* side, const char* trans, const MKL_INT* m, const MKL_INT* n,
const MKL_INT* k, const MKL_INT* l, const double* a, const MKL_INT* ia, const MKL_INT*
ja, const MKL_INT* desca, const double* tau, double* c, const MKL_INT* ic, const
MKL_INT* jc, const MKL_INT* descc, double* work, const MKL_INT* lwork, MKL_INT* info);
```

Include Files

- `mkl_scalapack.h`

Description

`p?ormr3` overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

| | | |
|--------------------------|-------------------------|-------------------------|
| | <code>side = 'L'</code> | <code>side = 'R'</code> |
| <code>trans = 'N'</code> | $Q * \text{sub}(C)$ | $\text{sub}(C) * Q$ |
| <code>trans = 'T'</code> | $Q^T * \text{sub}(C)$ | $\text{sub}(C) * Q^T$ |
| | $Q * \text{sub}(C)$ | |

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by `p?tzrzf`. Q is of order m if `side = 'L'` and of order n if `side = 'R'`.

Input Parameters

| | |
|--------------------|--|
| <code>side</code> | (global) = 'L': apply Q or Q^T from the Left; = 'R': apply Q or Q^T from the Right. |
| <code>trans</code> | (global) = 'N': No transpose, apply Q ; = 'T': Transpose, apply Q^T . |
| <code>m</code> | (global) The number of rows to be operated on i.e the number of rows of the distributed submatrix <code>sub(C)</code> . $m \geq 0$. |
| <code>n</code> | (global) The number of columns to be operated on i.e the number of columns of the distributed submatrix <code>sub(C)</code> . $n \geq 0$. |
| <code>k</code> | (global) The number of elementary reflectors whose product defines the matrix Q . If <code>side = 'L'</code> , $m \geq k \geq 0$, if <code>side = 'R'</code> , $n \geq k \geq 0$. |
| <code>l</code> | (global) The columns of the distributed submatrix <code>sub(A)</code> containing the meaningful part of the Householder reflectors. If <code>side = 'L'</code> , $m \geq l \geq 0$, if <code>side = 'R'</code> , $n \geq l \geq 0$. |
| <code>a</code> | (local) Pointer into the local memory to an array of size $lld_a * LOCC(ja+m-1)$ if <code>side='L'</code> , and $lld_a * LOCC(ja+n-1)$ if <code>side='R'</code> , where $lld_a \geq \text{MAX}(1, LOCr(ia+k-1))$; On entry, the i -th row must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?tzrzf</code> in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit. |
| <code>ia</code> | (global) The row index in the global array <code>a</code> indicating the first row of <code>sub(A)</code> . |
| <code>ja</code> | (global) |

| | |
|--------------|---|
| | The column index in the global array <i>a</i> indicating the first column of sub(<i>A</i>). |
| <i>desca</i> | (global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>tau</i> | (local) Array, size $LOCc(ia+k-1)$. This array contains the scalar factors <i>tau</i> (<i>i</i>) of the elementary reflectors <i>H</i> (<i>i</i>) as returned by <i>p?tzrzf</i> . <i>tau</i> is tied to the distributed matrix <i>A</i> . |
| <i>c</i> | (local) Pointer into the local memory to an array of size $lld_c*LOCc(jc+n-1)$. On entry, the local pieces of the distributed matrix sub(<i>C</i>). |
| <i>ic</i> | (global) The row index in the global array <i>c</i> indicating the first row of sub(<i>C</i>). |
| <i>jc</i> | (global) The column index in the global array <i>c</i> indicating the first column of sub(<i>C</i>). |
| <i>desc</i> | (global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> . |
| <i>work</i> | (local) Array, size (<i>lwork</i>) |
| <i>lwork</i> | (local) The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least If <i>side</i> = 'L', $lwork \geq MpCO + \text{MAX}(\text{MAX}(1, NqCO), \text{numroc}(\text{numroc}(m + IROFFC, mb_a, 0, 0, NPROW), mb_a, 0, 0, NqCO));$ if <i>side</i> = 'R', $lwork \geq NqCO + \text{MAX}(1, MpCO);$ where $LCMP = LCM / NPROW$ $LCM = \text{icl}m(NPROW, NPCOL),$ $IROFFC = \text{MOD}(ic-1, mb_c),$ $ICOFFC = \text{MOD}(jc-1, nb_c),$ $ICROW = \text{indxg2p}(ic, mb_c, MYROW, rsrc_c, NPROW),$ $ICCOL = \text{indxg2p}(jc, nb_c, MYCOL, csrc_c, NPCOL),$ $MpCO = \text{numroc}(m + IROFFC, mb_c, MYROW, ICROW, NPROW),$ $NqCO = \text{numroc}(n + ICOFFC, nb_c, MYCOL, ICCOL, NPCOL),$ |

`ilcm`, `indxg2p`, and `numroc` are ScaLAPACK tool functions;

`MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|-------------------|--|
| <code>c</code> | On exit, <code>sub(C)</code> is overwritten by $Q \cdot \text{sub}(C)$ or $Q' \cdot \text{sub}(C)$ or $\text{sub}(C) \cdot Q'$ or $\text{sub}(C) \cdot Q$. |
| <code>work</code> | On exit, <code>work[0]</code> returns the minimal and optimal <code>lwork</code> . |
| <code>info</code> | (local) = 0: successful exit < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <code>info = -(i*100+j)</code> , if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info = -i</code> . |

Application Notes

Alignment requirements

The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If `side = 'L'`,

$(nb_a = mb_c \text{ .AND. } ICOFFA = IROFFC)$

If `side = 'R'`,

$(nb_a = nb_c \text{ .AND. } ICOFFA = ICOFFC \text{ .AND. } IACOL = ICCOL)$

p?unmr3

Applies an orthogonal distributed matrix to a general m-by-n distributed matrix.

Syntax

```
void pcunmr3 (const char* side, const char* trans, const MKL_INT* m, const MKL_INT* n,
const MKL_INT* k, const MKL_INT* l, const MKL_Complex8* a, const MKL_INT* ia, const

Description

p?unmr3 overwrites the general complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

| | |
|------------------------------------|-----------------------|
| $side = 'L'$ | $side = 'R'$ |
| $trans = 'N': Q * \text{sub}(C)$ | $\text{sub}(C) * Q$ |
| $trans = 'C': Q^H * \text{sub}(C)$ | $\text{sub}(C) * Q^H$ |

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(1)' H(2)' \dots H(k)'$

as returned by p?tzzrf. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

| | |
|---------|--|
| $side$ | (global) = 'L': apply Q or Q^H from the Left; = 'R': apply Q or Q^H from the Right. |
| $trans$ | (global) = 'N': No transpose, apply Q ; = 'C': Conjugate transpose, apply Q^H . |
| m | (global) The number of rows to be operated on i.e the number of rows of the distributed submatrix $\text{sub}(C)$. $m \geq 0$. |
| n | (global) The number of columns to be operated on i.e the number of columns of the distributed submatrix $\text{sub}(C)$. $n \geq 0$. |
| k | (global) The number of elementary reflectors whose product defines the matrix Q . If $side = 'L'$, $m \geq k \geq 0$, if $side = 'R'$, $n \geq k \geq 0$. |
| l | (global) The columns of the distributed submatrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. If $side = 'L'$, $m \geq l \geq 0$, if $side = 'R'$, $n \geq l \geq 0$. |
| a | (local) Pointer into the local memory to an array of size $lld_a * LOCC(ja+m-1)$ if $side='L'$, and $lld_a * LOCC(ja+n-1)$ if $side='R'$, where $lld_a \geq \text{MAX}(1, LOCr(ia+k-1))$; On entry, the i -th row must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?tzzrf in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. |

$A(ia:ia+k-1,ja:*)$ is modified by the routine but restored on exit.

ia (global)
The row index in the global array *a* indicating the first row of *sub(A)*.

ja (global)
The column index in the global array *a* indicating the first column of *sub(A)*.

desca (global and local)
Array of size *dlen_*.
The array descriptor for the distributed matrix *A*.

tau (local)
Array, size $LOCc(ia+k-1)$.
This array contains the scalar factors *tau*(*i*) of the elementary reflectors *H*(*i*) as returned by `p?tzrzf`. *tau* is tied to the distributed matrix *A*.

c (local)
Pointer into the local memory to an array of size $lld_c*LOCc(jc+n-1)$.
On entry, the local pieces of the distributed matrix *sub(C)*.

ic (global)
The row index in the global array *c* indicating the first row of *sub(C)*.

jc (global)
The column index in the global array *c* indicating the first column of *sub(C)*.

descc (global and local)
Array of size *dlen_*.
The array descriptor for the distributed matrix *C*.

work (local)
Array, size (*lwork*)
On exit, *work*(1) returns the minimal and optimal *lwork*.

lwork (local or global)
The size of the array *work*.
lwork is local input and must be at least
If *side* = 'L', $lwork \geq MpC0 + \text{MAX}(\text{MAX}(1, NqC0), \text{numroc}(\text{numroc}(m + IROFFC, mb_a, 0, 0, NPROW), mb_a, 0, 0, LCMP))$;
if *side* = 'R', $lwork \geq NqC0 + \text{MAX}(1, MpC0)$;
where $LCMP = LCM / NPROW$ with $LCM = \text{ICLM}(NPROW, NPCOL)$,
 $IROFFC = \text{MOD}(ic-1, MB_C)$, $ICOFFC = \text{MOD}(jc-1, nb_c)$,
 $ICROW = \text{indxg2p}(ic, MB_C, MYROW, rsrc_c, NPROW)$,

```

ICCOL = indxg2p( jc, nb_c, MYCOL, csrc_c, NPCOL ),
MpC0 = numroc( m+IROFFC, MB_C, MYROW, ICROW, NPROW ),
NqC0 = numroc( n+ICOFFC, nb_c, MYCOL, ICCOL, NPCOL ),
ilcm, indxg2p, and numroc are ScaLAPACK tool functions;
MYROW, MYCOL, NPROW and NPCOL can be determined by calling the
subroutine blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|-------------|--|
| <i>c</i> | On exit, <code>sub(C)</code> is overwritten by <code>Q*sub(C)</code> or <code>Q'*sub(C)</code> or <code>sub(C)*Q'</code> or <code>sub(C)*Q</code> . |
| <i>work</i> | (local) Array, size (<i>lwork</i>) On exit, <code>work[0]</code> returns the minimal and optimal <i>lwork</i> . |
| <i>info</i> | (local) = 0: successful exit < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <code>info = -(i*100+j)</code> , if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info = -i</code> . |

Application Notes

Alignment requirements

The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If *side* = 'L', (*nb_a* = MB_C and ICOFFA = IROFFC)

If *side* = 'R', (*nb_a* = *nb_c* and ICOFFA = ICOFFC and IACOL = ICCOL)

p?ormrq

Multiplies a general matrix by the orthogonal matrix *Q* of the RQ factorization formed by `p?gerqf`.

Syntax

```

void psormrq (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork , MKL_INT *info );

void pdormrq (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , double
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT *lwork , MKL_INT *info );

```

Include Files

- `mkl_scalapack.h`

Description

The `p?ormrq` function overwrites the general real m -by- n distributed matrix sub(C) = $C(ic:ic+m-1, jc:jc+n-1)$ with

| | | |
|----------------|----------------|----------------|
| | $side = 'L'$ | $side = 'R'$ |
| $trans = 'N':$ | $Q * sub(C)$ | $sub(C) * Q$ |
| $trans = 'T':$ | $Q^T * sub(C)$ | $sub(C) * Q^T$ |

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by `p?gerqf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

| | |
|----------|---|
| $side$ | (global) = $'L'$: Q or Q^T is applied from the left. = $'R'$: Q or Q^T is applied from the right. |
| $trans$ | (global) = $'N'$, no transpose, Q is applied. = $'T'$, transpose, Q^T is applied. |
| m | (global) The number of rows in the distributed matrix sub(C) ($m \geq 0$). |
| n | (global) The number of columns in the distributed matrix sub(C) ($n \geq 0$). |
| k | (global) The number of elementary reflectors whose product defines the matrix Q . Constraints: If $side = 'L'$, $m \geq k \geq 0$ If $side = 'R'$, $n \geq k \geq 0$. |
| a | (local) Pointer into the local memory to an array of size $lld_a * LOCC(ja+m-1)$ if $side = 'L'$, and $lld_a * LOCC(ja+n-1)$ if $side = 'R'$. The i -th row of the matrix stored in a must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?gerqf</code> in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit. |
| ia, ja | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| tau | (local) |

Array of size $LOCc(ja+k-1)$.

Contains the scalar factor $\tau[i]$ of elementary reflectors $H(i+1)$ as returned by `p?gerqf` ($0 \leq i < LOCc(ja+k-1)$). τ is tied to the distributed matrix A .

c

(local)

Pointer into the local memory to an array of local size $lld_c * LOCc(jc+n-1)$.

Contains the local pieces of the distributed matrix sub(C) to be factored.

ic, jc

(global) The row and column indices in the global matrix C indicating the first row and the first column of the matrix sub(C), respectively.

desc

(global and local) array of size $dlen_$. The array descriptor for the distributed matrix C .

work

(local)

Workspace array of size of *lwork*.

lwork

(local or global) size of *work*, must be at least:

If *side* = 'L',

$$lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + \max(mqa0 + \text{numroc}(\text{numroc}(n + iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0, lcm), nqc0)) * mb_a) + mb_a * mb_a)$$

else if *side* = 'R',

$$lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + nqc0) * mb_a) + mb_a * mb_a$$

end if

where

$lcmp = lcm / NPROW$ with $lcm = ilcm(NPROW, NPCOL)$,

$iroffa = \text{mod}(ia - 1, mb_a)$,

$icoffa = \text{mod}(ja - 1, nb_a)$,

$iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$,

$mqa0 = \text{numroc}(n + icoffa, nb_a, MYCOL, iacol, NPCOL)$,

$iroffc = \text{mod}(ic - 1, mb_c)$,

$icoffc = \text{mod}(jc - 1, nb_c)$,

$icrow = \text{indxg2p}(ic, mb_c, MYROW, rsrc_c, NPROW)$,

$iccol = \text{indxg2p}(jc, nb_c, MYCOL, csrc_c, NPCOL)$,

$mpc0 = \text{numroc}(m + iroffc, mb_c, MYROW, icrow, NPROW)$,

$nqc0 = \text{numroc}(n + icoffc, nb_c, MYCOL, iccol, NPCOL)$,

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NP COL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|----------------------|--|
| <code>c</code> | Overwritten by the product $Q * \text{sub}(C)$, or $Q * \text{sub}(C)$, or $\text{sub}(C) * Q'$, or $\text{sub}(C) * Q$ |
| <code>work[0]</code> | On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i * 100 + j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$. |

```

```
void pctzrzf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pztzrzf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?tzrzf` function reduces the *m*-by-*n* ($m \leq n$) real/complex upper trapezoidal matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$ to upper triangular form by means of orthogonal/unitary transformations. The upper trapezoidal matrix *A* is factored as

$$A = (R \ 0) * Z,$$

where *Z* is an *n*-by-*n* orthogonal/unitary matrix and *R* is an *m*-by-*m* upper triangular matrix.

Input Parameters

m (global) The number of rows in the matrix $\text{sub}(A)$; ($m \geq 0$).

n (global) The number of columns in the matrix $\text{sub}(A)$ ($n \geq 0$).

a (local)

Pointer into the local memory to an array of size `lld_a*LOCc(ja+n-1)`. Contains the local pieces of the *m*-by-*n* distributed matrix $\text{sub}(A)$ to be factored.

| | |
|---------------|--|
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>work</i> | (local) Workspace array of size of <i>lwork</i> . |
| <i>lwork</i> | (local or global) size of <i>work</i> , must be at least $lwork \geq mb_a * (mp0 + nq0 + mb_a)$, where $iroff = \text{mod}(ia-1, mb_a)$, $icoff = \text{mod}(ja-1, nb_a)$, $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW)$, $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$, $mp0 = \text{numroc}(m + iroff, mb_a, MYROW, iarow, NPROW)$, $nq0 = \text{numroc}(n + icoff, nb_a, MYCOL, iacol, NPCOL)$ |

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

indxg2p and *numroc* are ScaLAPACK tool functions; *MYROW*, *MYCOL*, *NPROW* and *NPCOL* can be determined by calling the function *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *p_xerbla*.

Output Parameters

| | |
|-----------------|--|
| <i>a</i> | On exit, the leading <i>m</i> -by- <i>m</i> upper triangular part of <i>sub(A)</i> contains the upper triangular matrix <i>R</i> , and elements <i>m</i> +1 to <i>n</i> of the first <i>m</i> rows of <i>sub(A)</i> , with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Z</i> as a product of <i>m</i> elementary reflectors. |
| <i>work</i> [0] | On exit <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance. |
| <i>tau</i> | (local) Array of size $LOCr(ia+m-1)$. Contains the scalar factor of elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> . |
| <i>info</i> | (global) = 0: the execution is successful. |

< 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The factorization is obtained by the Householder's method. The k -th transformation matrix, $Z(k)$, which is or whose conjugate transpose is used to introduce zeros into the $(m - k + 1)$ -th row of $\text{sub}(A)$, is given in the form

$$Z(k) = \begin{bmatrix} i & 0 \\ 0 & T(k) \end{bmatrix}$$

where

$$T(k) = i - \tau * u(k) * u(k)',$$

$$u(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}$$

τ is a scalar and $Z(k)$ is an $(n - m)$ element vector. τ and $Z(k)$ are chosen to annihilate the elements of the k -th row of $\text{sub}(A)$. The scalar τ is returned in the k -th element of τ , indexed $k-1$, and the vector $u(k)$ in the k -th row of $\text{sub}(A)$, such that the elements of $Z(k)$ are in $a(k, m + 1), \dots, a(k, n)$. The elements of R are returned in the upper triangular part of $\text{sub}(A)$. Z is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

Description

This function overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

| | | |
|----------------|-----------------------|-----------------------|
| | $side = 'L'$ | $side = 'R'$ |
| $trans = 'N':$ | $Q * \text{sub}(C)$ | $\text{sub}(C) * Q$ |
| $trans = 'T':$ | $Q^T * \text{sub}(C)$ | $\text{sub}(C) * Q^T$ |

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by `p?tzrzf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

| | |
|---------|---|
| $side$ | (global) $= 'L'$: Q or Q^T is applied from the left. $= 'R'$: Q or Q^T is applied from the right. |
| $trans$ | (global) $= 'N'$, no transpose, Q is applied. $= 'T'$, transpose, Q^T is applied. |
| m | (global) The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$). |
| n | (global) The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$). |
| k | (global) The number of elementary reflectors whose product defines the matrix Q . Constraints: If $side = 'L'$, $m \geq k \geq 0$ If $side = 'R'$, $n \geq k \geq 0$. |
| l | (global) The columns of the distributed matrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. If $side = 'L'$, $m \geq l \geq 0$ If $side = 'R'$, $n \geq l \geq 0$. |
| a | (local) Pointer into the local memory to an array of size $lld_a * LOCC(ja+m-1)$ if $side = 'L'$, and $lld_a * LOCC(ja+n-1)$ if $side = 'R'$, where $lld_a \geq \max(1, LOCr(ia+k-1))$. The i -th row of the matrix stored in a must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?tzrzf</code> in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit. |

| | |
|---------------|---|
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>tau</i> | (local) Array of size <i>LOCc(ia+k-1)</i> . Contains the scalar factor <i>tau[i]</i> of elementary reflectors <i>H(i+1)</i> as returned by <i>p?tzrzf</i> ($0 \leq i < LOCc(ia+k-1)$). <i>tau</i> is tied to the distributed matrix <i>A</i> . |
| <i>c</i> | (local) Pointer into the local memory to an array of local size <i>lld_c*LOCc(jc+n-1)</i> . Contains the local pieces of the distributed matrix sub(<i>C</i>) to be factored. |
| <i>ic, jc</i> | (global) The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively. |
| <i>desc</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> . |
| <i>work</i> | (local) Workspace array of size of <i>lwork</i> . |
| <i>lwork</i> | (local or global) size of <i>work</i> , must be at least: If <i>side</i> = 'L', $lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + \max(mqa0 + \text{numroc}(\text{numroc}(n + iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0, lcmp), nqc0)) * mb_a) + mb_a * mb_a)$ else if <i>side</i> = 'R', $lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + nqc0) * mb_a) + mb_a * mb_a$ end if where $lcmp = lcm / NPROW$ with $lcm = ilcm(NPROW, NPCOL)$, $iroffa = \text{mod}(ia - 1, mb_a)$, $icoffa = \text{mod}(ja - 1, nb_a)$, $iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL)$, $mqa0 = \text{numroc}(n + icoffa, nb_a, MYCOL, iacol, NPCOL)$, $iroffc = \text{mod}(ic - 1, mb_c)$, $icoffc = \text{mod}(jc - 1, nb_c)$, $icrow = \text{indxg2p}(ic, mb_c, MYROW, rsrc_c, NPROW)$, $iccol = \text{indxg2p}(jc, nb_c, MYCOL, csrc_c, NPCOL)$, $mpc0 = \text{numroc}(m + iroffc, mb_c, MYROW, icrow, NPROW)$, $nqc0 = \text{numroc}(n + icoffc, nb_c, MYCOL, iccol, NPCOL)$, |

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|----------------------|--|
| <code>c</code> | Overwritten by the product $Q \cdot \text{sub}(C)$, or $Q' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q'$, or $\text{sub}(C) \cdot Q$ |
| <code>work[0]</code> | On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info = -(i*100+j)</code> ; if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> . |

MKL_Complex16 *tau , MKL_Complex16 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc ,
MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

This function overwrites the general complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

| | | |
|---------------------|-----------------------|-----------------------|
| | <i>side</i> = 'L' | <i>side</i> = 'R' |
| <i>trans</i> = 'N': | $Q * \text{sub}(C)$ | $\text{sub}(C) * Q$ |
| <i>trans</i> = 'C': | $Q^H * \text{sub}(C)$ | $\text{sub}(C) * Q^H$ |

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(1)' H(2)' \dots H(k)'$$

as returned by `pctzrzf/pztzrzf`. Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

Input Parameters

| | |
|---------------|---|
| <i>side</i> | (global) = 'L': Q or Q^H is applied from the left. = 'R': Q or Q^H is applied from the right. |
| <i>trans</i> | (global) = 'N', no transpose, Q is applied. = 'C', conjugate transpose, Q^H is applied. |
| <i>m</i> | (global) The number of rows in the distributed matrix $\text{sub}(C)$, ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the distributed matrix $\text{sub}(C)$, ($n \geq 0$). |
| <i>k</i> | (global) The number of elementary reflectors whose product defines the matrix Q . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$. |
| <i>l</i> | (global) The columns of the distributed matrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. If <i>side</i> = 'L', $m \geq l \geq 0$ If <i>side</i> = 'R', $n \geq l \geq 0$. |
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a * LOCc(ja+m-1)$ if <i>side</i> = 'L', and $lld_a * LOCc(ja+n-1)$ if <i>side</i> = 'R', where $lld_a \geq \max(1, LOCr(ja+k-1))$. The i -th row of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?gerqf</code> in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A . |
| <i>tau</i> | (local) Array of size $LOCc(ia+k-1)$. |

Contains the scalar factor $\tau[i]$ of elementary reflectors $H(i+1)$ as returned by `p?gerqf` ($0 \leq i < LOCC(ia+k-1)$). τ is tied to the distributed matrix A .

`c`

(local)

Pointer into the local memory to an array of local size $lld_c * LOCC(jc+n-1)$.

Contains the local pieces of the distributed matrix $\text{sub}(C)$ to be factored.

`ic, jc`

(global) The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C , respectively.

`desc`

(global and local) array of size $dlen_$. The array descriptor for the distributed matrix C .

`work`

(local)

Workspace array of size $lwork$.

`lwork`

(local or global) size of $work$, must be at least:

If $side = 'L'$,

$$lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + \max(mqa0 + \text{numroc}(\text{numroc}(n + iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0, lcmp), nqc0)) * mb_a + mb_a * mb_a)$$

else if $side = 'R'$,

$$lwork \geq \max((mb_a * (mb_a - 1)) / 2, (mpc0 + nqc0) * mb_a + mb_a * mb_a)$$

end if

where

$$lcmp = lcm / NPROW \text{ with } lcm = ilcm(NPROW, NPCOL),$$

$$iroffa = \text{mod}(ia - 1, mb_a),$$

$$icoffa = \text{mod}(ja - 1, nb_a),$$

$$iacol = \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL),$$

$$mqa0 = \text{numroc}(m + icoffa, nb_a, MYCOL, iacol, NPCOL),$$

$$iroffc = \text{mod}(ic - 1, mb_c),$$

$$icoffc = \text{mod}(jc - 1, nb_c),$$

$$icrow = \text{indxg2p}(ic, mb_c, MYROW, rsrc_c, NPROW),$$

$$iccol = \text{indxg2p}(jc, nb_c, MYCOL, csrc_c, NPCOL),$$

$$mpc0 = \text{numroc}(m + iroffc, mb_c, MYROW, icrow, NPROW),$$

$$nqc0 = \text{numroc}(n + icoffc, nb_c, MYCOL, iccol, NPCOL),$$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|----------------------|--|
| <code>c</code> | Overwritten by the product $Q^* \text{sub}(C)$, or $Q'^* \text{sub}(C)$, or $\text{sub}(C)^*Q'$, or $\text{sub}(C)^*Q$ |
| <code>work[0]</code> | On exit <code>work[0]</code> contains the minimum value of $lwork$ required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$. |

Description

The `p?ggqrf` function forms the generalized QR factorization of an n -by- m matrix

$$\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+m-1)$$

and an n -by- p matrix

| | |
|---------------|---|
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a * LOCC(j_{a+m}-1)$. Contains the local pieces of the n -by- m matrix sub(A) to be factored. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <i>b</i> | (local) Pointer into the local memory to an array of size $lld_b * LOCC(j_{b+p}-1)$. Contains the local pieces of the n -by- p matrix sub(B) to be factored. |
| <i>ib, jb</i> | (global) The row and column indices in the global matrix B indicating the first row and the first column of the submatrix B , respectively. |
| <i>descb</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix B . |
| <i>work</i> | (local) Workspace array of size of $lwork$. |
| <i>lwork</i> | (local or global) Size of $work$, must be at least |

$$lwork \geq \max(nb_a * (npa0 + mqa0 + nb_a), \max((nb_a * (nb_a - 1)) / 2, (pqb0 + npb0) * nb_a) + nb_a * nb_a, mb_b * (npb0 + pqb0 + mb_b)),$$

where

$$\begin{aligned} iroffa &= \text{mod}(ia-1, mb_A), \\ icoffa &= \text{mod}(ja-1, nb_a), \\ iarow &= \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW), \\ iacol &= \text{indxg2p}(ja, nb_a, MYCOL, csrc_a, NPCOL), \\ npa0 &= \text{numroc}(n + iroffa, mb_a, MYROW, iarow, NPROW), \\ mqa0 &= \text{numroc}(m + icoffa, nb_a, MYCOL, iacol, NPCOL), \\ iroffb &= \text{mod}(ib-1, mb_b), \\ icoffb &= \text{mod}(jb-1, nb_b), \\ ibrow &= \text{indxg2p}(ib, mb_b, MYROW, rsrc_b, NPROW), \\ ibcol &= \text{indxg2p}(jb, nb_b, MYCOL, csrc_b, NPCOL), \\ npb0 &= \text{numroc}(n + iroffb, mb_b, MYROW, ibrow, NPROW), \\ pqb0 &= \text{numroc}(m + icoffb, nb_b, MYCOL, ibcol, NPCOL) \end{aligned}$$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

and `numroc`, `indxg2p` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|-------------------------|--|
| <code>a</code> | On exit, the elements on and above the diagonal of sub (A) contain the $\min(n, m)$ -by- m upper trapezoidal matrix R (R is upper triangular if $n \geq m$); the elements below the diagonal, with the array <code>taua</code> , represent the orthogonal/unitary matrix Q as a product of $\min(n, m)$ elementary reflectors. (See Application Notes below). |
| <code>taua, taub</code> | (local) Arrays of size <code>LOCc(ja+min(n,m)-1)</code> for <code>taua</code> and <code>LOCr(ib+n-1)</code> for <code>taub</code> . The array <code>taua</code> contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Q . <code>taua</code> is tied to the distributed matrix A . (See Application Notes below). The array <code>taub</code> contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Z . <code>taub</code> is tied to the distributed matrix B . (See Application Notes below). |
| <code>work[0]</code> | On exit <code>work[0]</code> contains the minimum value of $lwork$ required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info</code> = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$. |

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(j_a) * H(j_a+1) * \dots * H(j_a+k-1),$$

where $k = \min(n, m)$.

Each $H(i)$ has the form

$$H(i) = I - \tau_{au} * v * v'$$

where τ_{au} is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ is stored on exit in $A(ia+i:ia+n-1, ja+i-1)$, and τ_{au} in `taua[ja+i-2]`. To form Q explicitly, use ScaLAPACK function `p?orgqr/p?ungqr`. To use Q to update another matrix, use ScaLAPACK function `p?ormqr/p?unmqr`.

The matrix Z is represented as a product of elementary reflectors

$$Z = H(i_b) * H(i_b+1) * \dots * H(i_b+k-1), \text{ where } k = \min(n, p).$$

Each $H(i)$ has the form

$$H(i) = I - \tau_{bu} * v * v'$$

where $taub$ is a real/complex scalar, and v is a real/complex vector with $v_{(p-k+i+1:p)} = 0$ and $v_{(p-k+i)} = 1$; $v_{(1:p-k+i-1)}$ is stored on exit in $B(ib+n-k+i-1, jb:jb+p-k+i-2)$, and $taub$ in $taub[ib+n-k+i-2]$. To form Z explicitly, use ScaLAPACK function `p?orgqr/p?ungrq`. To use Z to update another matrix, use ScaLAPACK function `p?ormrq/p?unmrq`.

*lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?ggrqf` function forms the generalized RQ factorization of an m -by- n matrix $sub(A) = A(ia:ia+m-1, ja:ja+n-1)$ and a p -by- n matrix $sub(B) = B(ib:ib+p-1, jb:jb+n-1)$:

$sub(A) = R*Q$, $sub(B) = Z*T*Q$,

where Q is an n -by- n orthogonal/unitary matrix, Z is a p -by- p orthogonal/unitary matrix, and R and T assume one of the forms:

$$R = \begin{matrix} m & (0 & R_{12}) \\ & n - m & m \end{matrix}, \text{ if } m \leq n,$$

or

$$R = \begin{matrix} (R_{11}) & m - n \\ & n \\ & & n \end{matrix}, \text{ if } m > n$$

where R_{11} or R_{21} is upper triangular, and

$$T = \begin{pmatrix} T_{11} & & n \\ & & p-n \\ 0 & & n \end{pmatrix}, \text{ if } p \geq n$$

or

$$T = \begin{pmatrix} p & (T_{11} & T_{12}) \\ & p & \text{if } p < n, \\ & p & n-p \end{pmatrix}$$

where T_{11} is upper triangular.

In particular, if $\text{sub}(B)$ is square and nonsingular, the GRQ factorization of $\text{sub}(A)$ and $\text{sub}(B)$ implicitly gives the RQ factorization of $\text{sub}(A) \cdot \text{inv}(\text{sub}(B))$:

$$\text{sub}(A) \cdot \text{inv}(\text{sub}(B)) = (R \cdot \text{inv}(T)) \cdot Z'$$

where $\text{inv}(\text{sub}(B))$ denotes the inverse of the matrix $\text{sub}(B)$, and Z' denotes the transpose (conjugate transpose) of matrix Z .

Input Parameters

| | |
|----------|---|
| m | (global) The number of rows in the distributed matrices $\text{sub}(A)$ ($m \geq 0$). |
| p | The number of rows in the distributed matrix $\text{sub}(B)$ ($p \geq 0$). |
| n | (global) The number of columns in the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$). |
| a | (local) Pointer into the local memory to an array of size $lld_a * LOCc(ja+n-1)$. Contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ to be factored. |
| ia, ja | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| b | (local) Pointer into the local memory to an array of size $lld_b * LOCc(jb+n-1)$. Contains the local pieces of the p -by- n matrix $\text{sub}(B)$ to be factored. |
| ib, jb | (global) The row and column indices in the global matrix B indicating the first row and the first column of the submatrix B , respectively. |

descb (global and local) array of size *dlen_*. The array descriptor for the distributed matrix *B*.

work (local)
Workspace array of size of *lwork*.

lwork (local or global)
Size of *work*, must be at least $lwork \geq \max(mb_a * (mpa0 + nqa0 + mb_a), \max((mb_a * (mb_a - 1)) / 2, (ppb0 + nqb0) * mb_a) + mb_a * mb_a, nb_b * (ppb0 + nqb0 + nb_b))$, where

```

iroffa = mod(ia-1, mb_A),
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow, NPROW),
nqa0 = numroc(m+icoffa, nb_a, MYCOL, iacol, NPCOL)
iroffb = mod(ib-1, mb_b),
icoffb = mod(jb-1, nb_b),
ibrow = indxg2p(ib, mb_b, MYROW, rsrc_b, NPROW),
ibcol = indxg2p(jb, nb_b, MYCOL, csrc_b, NPCOL),
ppb0 = numroc(p+iroffb, mb_b, MYROW, ibrow, NPROW),
nqb0 = numroc(n+icoffb, nb_b, MYCOL, ibcol, NPCOL)

```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

and `numroc`, `indxg2p` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a On exit, if $m \leq n$, the upper triangle of $A(ia:ia+m-1, ja+n-m:ja+n-1)$ contains the m -by- m upper triangular matrix R ; if $m \geq n$, the elements on and above the $(m-n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix R ; the remaining elements, with the array *taua*, represent the orthogonal/unitary matrix Q as a product of $\min(n, m)$ elementary reflectors (see *Application Notes* below).

taua, taub (local)
Arrays of size $LOCr(ia+m-1)$ for *taua* and $LOCc(jb+\min(p, n)-1)$ for *taub*.

The array *taua* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Q*. *taua* is tied to the distributed matrix *A*. (See *Application Notes* below).

The array *taub* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Z*. *taub* is tied to the distributed matrix *B*. (See *Application Notes* below).

work[0] On exit *work*[0] contains the minimum value of *lwork* required for optimum performance.

info (global)

= 0: the execution is successful.

< 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then *info* = $-(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

Application Notes

The matrix *Q* is represented as a product of elementary reflectors

$$Q = H(i_a) * H(i_a+1) * \dots * H(i_a+k-1),$$

where $k = \min(m, n)$.

Each *H*(*i*) has the form

$$H(i) = I - \tau_{ua} * v * v'$$

where *taua* is a real/complex scalar, and *v* is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ is stored on exit in $A(i_a+m-k+i-1, j_a:j_a+n-k+i-2)$, and *taua* in $\tau_{ua}[i_a+m-k+i-2]$. To form *Q* explicitly, use ScaLAPACK function [p?orgqr/p?ungrq](#). To use *Q* to update another matrix, use ScaLAPACK function [p?ormrq/p?unmrq](#).

The matrix *Z* is represented as a product of elementary reflectors

$$Z = H(j_b) * H(j_b+1) * \dots * H(j_b+k-1), \text{ where } k = \min(p, n).$$

Each *H*(*i*) has the form

$$H(i) = I - \tau_{ub} * v * v'$$

where *taub* is a real/complex scalar, and *v* is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:p)$ is stored on exit in $B(i_b+i:i_b+p-1, j_b+i-1)$, and *taub* in $\tau_{ub}[j_b+i-2]$. To form *Z* explicitly, use ScaLAPACK function [p?orgqr/p?ungqr](#). To use *Z* to update another matrix, use ScaLAPACK function [p?ormqr/p?unmqr](#).

Symmetric Eigenvalue Problems: ScaLAPACK Computational Routines

To solve a symmetric eigenproblem with ScaLAPACK, you usually need to reduce the matrix to real tridiagonal form *T* and then find the eigenvalues and eigenvectors of the tridiagonal matrix *T*. ScaLAPACK includes routines for reducing the matrix to a tridiagonal form by an orthogonal (or unitary) similarity transformation $A = QTQ^H$ as well as for solving tridiagonal symmetric eigenvalue problems. These routines are listed in [Table "Computational Routines for Solving Symmetric Eigenproblems"](#).

There are different routines for symmetric eigenproblems, depending on whether you need eigenvalues only or eigenvectors as well, and on the algorithm used (either the *QTQ* algorithm, or bisection followed by inverse iteration).

Computational Routines for Solving Symmetric Eigenproblems

| Operation | Dense symmetric/ Hermitian matrix | Orthogonal/unitary matrix | Symmetric tridiagonal matrix |
|--|--------------------------------------|------------------------------|------------------------------------|
| Reduce to tridiagonal form $A = QTQ^H$ | <code>p?sytrd/p?hetrd</code> | | |
| Multiply matrix after reduction | | <code>p?ormtr/p?unmtr</code> | |
| Find all eigenvalues and eigenvectors of a tridiagonal matrix T by a <i>QTQ</i> method | | | <code>steqr2*</code> |
| Find selected eigenvalues of a tridiagonal matrix T via bisection | | | <code>p?stebz</code> |
| Find selected eigenvectors of a tridiagonal matrix T by inverse iteration | | | <code>p?stein</code> |

* This routine is described as part of auxiliary ScaLAPACK routines.

p?syngst

Reduces a complex Hermitian-definite generalized eigenproblem to standard form.

Syntax

```
void pssyngst (const MKL_INT* ibtype, const char* uplo, const MKL_INT* n, float* a,
const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, const float* b, const
MKL_INT* ib, const MKL_INT* jb, const MKL_INT* descb, float* scale, float* work, const
MKL_INT* lwork, MKL_INT* info);
```

```
void pdsyngst (const MKL_INT* ibtype, const char* uplo, const MKL_INT* n, double* a,
const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, const double* b, const
MKL_INT* ib, const MKL_INT* jb, const MKL_INT* descb, double* scale, double* work,
const MKL_INT* lwork, MKL_INT* info);
```

Include Files

- `mkl_scalapack.h`

Description

`p?syngst` reduces a complex Hermitian-definite generalized eigenproblem to standard form.

`p?syngst` performs the same function as `p?hegst`, but is based on rank 2K updates, which are faster and more scalable than triangular solves (the basis of `p?syngst`).

`p?syngst` calls `p?hegst` when `uplo='U'`, hence `p?hengst` provides improved performance only when `uplo='L'`, `ibtype=1`.

`p?syngst` also calls `p?hegst` when insufficient workspace is provided, hence `p?syngst` provides improved performance only when `lwork >= 2 * NPO * NB + NQO * NB + NB * NB`

In the following `sub(A)` denotes $A(ia:ia+n-1, ja:ja+n-1)$ and `sub(B)` denotes $B(ib:ib+n-1, jb:jb+n-1)$.

If `ibtype = 1`, the problem is $sub(A) * x = \lambda * sub(B) * x$, and `sub(A)` is overwritten by $inv(U^H) * sub(A) * inv(U)$ or $inv(L) * sub(A) * inv(L^H)$

If `ibtype = 2` or `3`, the problem is $sub(A) * sub(B) * x = \lambda * x$ or $sub(B) * sub(A) * x = \lambda * x$, and `sub(A)` is overwritten by $U * sub(A) * U^H$ or $L^H * sub(A) * L$.

`sub(B)` must have been previously factorized as $U^H * U$ or $L * L^H$ by `p?potrf`.

Input Parameters

| | |
|---------------|---|
| <i>ibtype</i> | (global) = 1: compute $\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$ or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$; = 2 or 3: compute $U * \text{sub}(A) * U^H$ or $L^H * \text{sub}(A) * L$. |
| <i>uplo</i> | (global) = 'U': Upper triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as $U^H * U$; = 'L': Lower triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as $L * L^H$. |
| <i>n</i> | (global) The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$. $n \geq 0$. |
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$. On entry, this array contains the local pieces of the n -by- n Hermitian distributed matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. |
| <i>ia</i> | (global) A's global row index, which points to the beginning of the submatrix which is to be operated on. |
| <i>ja</i> | (global) A's global column index, which points to the beginning of the submatrix which is to be operated on. |
| <i>desca</i> | (global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix A. |
| <i>b</i> | (local) Pointer into the local memory to an array of size $lld_b * LOCC(jb+n-1)$. On entry, this array contains the local pieces of the triangular factor from the Cholesky factorization of $\text{sub}(B)$, as returned by <code>p?potrf</code> . |
| <i>ib</i> | (global) B's global row index, which points to the beginning of the submatrix which is to be operated on. |
| <i>jb</i> | (global) B's global column index, which points to the beginning of the submatrix which is to be operated on. |
| <i>descb</i> | (global and local) |

Array of size $dlen_$.
 The array descriptor for the distributed matrix B .

work (local)
 Array, size ($lwork$)

lwork (local or global)
 The size of the array *work*.
lwork is local input and must be at least $lwork \geq \text{MAX}(NB * (NPO + 1), 3 * NB)$
 When $ibtype = 1$ and $uplo = 'L'$, $p?syngst$ provides improved performance when $lwork \geq 2 * NPO * NB + NQ0 * NB + NB * NB$, where $NB = mb_a = nb_a$,
 $NPO = \text{numroc}(n, NB, 0, 0, NPROW)$,
 $NQ0 = \text{numroc}(n, NB, 0, 0, NPROW)$,
 numroc is a ScaLAPACK tool functions
 $MYROW, MYCOL, NPROW$ and $NPOL$ can be determined by calling the subroutine `blacs_gridinfo`.
 If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?erbla`.

Output Parameters

a On exit, if $info = 0$, the transformed matrix, stored in the same format as `sub(A)`.

scale (global)
 Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this routine. At present, *scale* is always returned as 1.0, it is returned here to allow for future enhancement.

work (local)
 Array, size ($lwork$)
 On exit, $work[0]$ returns the minimal and optimal $lwork$.

info (global)
 = 0: successful exit
 < 0: If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?syntrd

Reduces a real symmetric matrix to symmetric tridiagonal form.

Syntax

```
void pssytrd (const char* uplo, const MKL_INT* n, float* a, const MKL_INT* ia, const
MKL_INT* ja, const MKL_INT* desca, float* d, float* e, float* tau, float* work, const
MKL_INT* lwork, MKL_INT* info);
```

```
void pdsytrd (const char* uplo, const MKL_INT* n, double* a, const MKL_INT* ia, const
MKL_INT* ja, const MKL_INT* desca, double* d, double* e, double* tau, double* work,
const MKL_INT* lwork, MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

`p?sytrd` is a prototype version of `p?sytrd` which uses tailored codes (either the serial, `?sytrd`, or the parallel code, `p?sytrd`) when the workspace provided by the user is adequate.

`p?sytrd` reduces a real symmetric matrix $\text{sub}(A)$ to symmetric tridiagonal form T by an orthogonal similarity transformation:

$$Q' * \text{sub}(A) * Q = T, \text{ where } \text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1).$$

Features

`p?sytrd` is faster than `p?sytrd` on almost all matrices, particularly small ones (i.e. $n < 500 * \text{sqrt}(P)$), provided that enough workspace is available to use the tailored codes.

The tailored codes provide performance that is essentially independent of the input data layout.

The tailored codes place no restrictions on `ia`, `ja`, `MB` or `NB`. At present, `ia`, `ja`, `MB` and `NB` are restricted to those values allowed by `p?hetrd` to keep the interface simple (see the Application Notes section for more information about the restrictions).

Input Parameters

| | |
|-------------------|--|
| <code>uplo</code> | (global) |
| | Specifies whether the upper or lower triangular part of the symmetric matrix $\text{sub}(A)$ is stored: |
| | = 'U': Upper triangular |
| | = 'L': Lower triangular |
| <code>n</code> | (global) |
| | The number of rows and columns to be operated on, i.e. the order of the distributed submatrix $\text{sub}(A)$. $n \geq 0$. |
| <code>a</code> | (local) |
| | Pointer into the local memory to an array of size $ld_a * LOCc(\text{ja}+n-1)$. |
| | On entry, this array contains the local pieces of the symmetric distributed matrix $\text{sub}(A)$. If <code>uplo = 'U'</code> , the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <code>uplo = 'L'</code> , the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. |
| <code>ia</code> | (global) |

| | |
|--------------|---|
| | The row index in the global array <i>a</i> indicating the first row of sub(<i>A</i>). |
| <i>ja</i> | (global) The column index in the global array <i>a</i> indicating the first column of sub(<i>A</i>). |
| <i>desca</i> | (global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>work</i> | (local) Array, size (<i>lwork</i>) |
| <i>lwork</i> | (local or global) The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork \geq \text{MAX}(NB * (NP + 1), 3 * NB)$ For optimal performance, greater workspace is needed, i.e. $lwork \geq 2 * (ANB + 1) * (4 * NPS + 2) + (NPS + 4) * NPS$ $ANB = \text{pjlaenv}(ICTXT, 3, 'p?sytttrd', 'L', 0, 0, 0, 0)$ $ICTXT = \text{desca}(ctxt_)$ $SQNPC = \text{INT}(\text{sqrt}(\text{REAL}(NPROW * NPCOL)))$ <i>numroc</i> is a ScaLAPACK tool function. <i>pjlaenv</i> is a ScaLAPACK environmental inquiry function. <i>NPROW</i> and <i>NPCOL</i> can be determined by calling the subroutine <i>blacs_gridinfo</i> . |

Output Parameters

| | |
|----------|---|
| <i>a</i> | On exit, if <i>uplo</i> = 'U', the diagonal and first superdiagonal of sub(<i>A</i>) are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements above the first superdiagonal, with the array <i>tau</i> , represent the orthogonal matrix <i>Q</i> as a product of elementary reflectors; if <i>uplo</i> = 'L', the diagonal and first subdiagonal of sub(<i>A</i>) are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements below the first subdiagonal, with the array <i>tau</i> , represent the orthogonal matrix <i>Q</i> as a product of elementary reflectors. See Further Details . |
| <i>d</i> | (local) Array, size $\text{LOCc}(ja+n-1)$ The diagonal elements of the tridiagonal matrix <i>T</i> : $d(i) = A(i,i)$. <i>d</i> is tied to the distributed matrix <i>A</i> . |
| <i>e</i> | (local) Array, size $\text{LOCc}(ja+n-1)$ if <i>uplo</i> = 'U', $\text{LOCc}(ja+n-2)$ otherwise. The off-diagonal elements of the tridiagonal matrix <i>T</i> : $e(i) = A(i,i+1)$ if <i>uplo</i> = 'U', $e(i) = A(i+1,i)$ if <i>uplo</i> = 'L'. <i>e</i> is tied to the distributed matrix <i>A</i> . |

| | |
|-------------|---|
| <i>tau</i> | (local) Array, size $LOCc(ja+n-1)$. This array contains the scalar factors <i>tau</i> of the elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> . |
| <i>work</i> | (local) Array, size (<i>lwork</i>) On exit, <i>work</i> [0] returns the optimal <i>lwork</i> . |
| <i>info</i> | (global) = 0: successful exit < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = $-(i*100+j)$, if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$. |

Application Notes

If *uplo* = 'U', the matrix *Q* is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each *H*(*i*) has the form

$H(i) = I - \tau * v * v'$, where *tau* is a complex scalar, and *v* is a complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and *tau* in $\tau(ja+i-1)$.

If *uplo* = 'L', the matrix *Q* is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n-1).$$

Each *H*(*i*) has the form

$H(i) = I - \tau * v * v'$, where *tau* is a complex scalar, and *v* is a complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and *tau* in $\tau(ja+i-1)$.

The contents of sub(*A*) on exit are illustrated by the following examples with *n* = 5:

if *uplo* = 'U':

$$\begin{pmatrix} d & e & v2 & v3 & v4 \\ & d & e & v3 & v4 \\ & & d & e & v3 \\ & & & d & e \\ & & & & d \end{pmatrix}$$

if *uplo* = 'L':

$$\begin{pmatrix} d & & & & \\ e & d & & & \\ v1 & e & d & & \\ v1 & v2 & e & d & \\ v1 & v2 & v3 & e & d \end{pmatrix}$$

where *d* and *e* denote diagonal and off-diagonal elements of *T*, and *v_i* denotes an element of the vector defining *H*(*i*).

Alignment requirements

The distributed submatrix $\text{sub}(A)$ must verify some alignment properties, namely the following expression should be true:

($mb_a = nb_a$ and $IROFFA = ICOFFA$ and $IROFFA = 0$) with $IROFFA = \text{mod}(ia-1, mb_a)$, and $ICOFFA = \text{mod}(ja-1, nb_a)$.

p?sytrd

Reduces a symmetric matrix to real symmetric tridiagonal form by an orthogonal similarity transformation.

Syntax

```
void pssytrd (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *d , float *e , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdsytrd (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *d , double *e , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?sytrd` function reduces a real symmetric matrix $\text{sub}(A)$ to symmetric tridiagonal form T by an orthogonal similarity transformation:

$$Q^* \text{sub}(A) Q = T,$$

where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

| | |
|-------------------|---|
| <code>uplo</code> | (global) Specifies whether the upper or lower triangular part of the symmetric matrix $\text{sub}(A)$ is stored: If <code>uplo = 'U'</code> , upper triangular If <code>uplo = 'L'</code> , lower triangular |
| <code>n</code> | (global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$). |
| <code>a</code> | (local) Pointer into the local memory to an array of size <code>lld_a*LOCc(ja+n-1)</code> . On entry, this array contains the local pieces of the symmetric distributed matrix $\text{sub}(A)$. If <code>uplo = 'U'</code> , the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <code>uplo = 'L'</code> , the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. See <i>Application Notes</i> below. |

| | |
|---------------|--|
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>work</i> | (local) Workspace array of size <i>lwork</i> . |
| <i>lwork</i> | (local or global) size of <i>work</i> , must be at least: $lwork \geq \max(NB * (np + 1), 3 * NB)$, where $NB = mb_a = nb_a$, $np = \text{numroc}(n, NB, MYROW, iarow, NPROW)$, $iarow = \text{indxg2p}(ia, NB, MYROW, rsrc_a, NPROW)$. <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; <i>MYROW</i> , <i>MYCOL</i> , <i>NPROW</i> and <i>NPCOL</i> can be determined by calling the function <i>blacs_gridinfo</i> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i> . |

Output Parameters

| | |
|------------|--|
| <i>a</i> | On exit, if <i>uplo</i> = 'U', the diagonal and first superdiagonal of <i>sub(A)</i> are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements above the first superdiagonal, with the array <i>tau</i> , represent the orthogonal matrix <i>Q</i> as a product of elementary reflectors; if <i>uplo</i> = 'L', the diagonal and first subdiagonal of <i>sub(A)</i> are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements below the first subdiagonal, with the array <i>tau</i> , represent the orthogonal matrix <i>Q</i> as a product of elementary reflectors. See <i>Application Notes</i> below. |
| <i>d</i> | (local) Arrays of size $LOCc(ja+n-1)$. The diagonal elements of the tridiagonal matrix <i>T</i> : $d[i] = A(i+1, i+1), 0 \leq i < LOCc(ja+n-1)$. <i>d</i> is tied to the distributed matrix <i>A</i> . |
| <i>e</i> | (local) Arrays of size $LOCc(ja+n-1)$ if <i>uplo</i> = 'U', $LOCc(ja+n-2)$ otherwise. The off-diagonal elements of the tridiagonal matrix <i>T</i> : $e[i] = A(i+1, i+2), 0 \leq i < LOCc(ja+n-1)$ if <i>uplo</i> = 'U', $e[i] = A(i+2, i+1)$ if <i>uplo</i> = 'L'. <i>e</i> is tied to the distributed matrix <i>A</i> . |
| <i>tau</i> | (local) |

Arrays of size $LOCc(ja+n-1)$. This array contains the scalar factors of the elementary reflectors. tau is tied to the distributed matrix A .

$work[0]$

On exit $work[0]$ contains the minimum value of $lwork$ required for optimum performance.

$info$

(global)

= 0: the execution is successful.

< 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

If $uplo = 'U'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v',$$

where τ is a real scalar, and v is a real vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and τ in $tau[ja+i-2]$.

If $uplo = 'L'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v',$$

where τ is a real scalar, and v is a real vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and τ in $tau[ja+i-2]$.

The contents of $sub(A)$ on exit are illustrated by the following examples with $n = 5$:

If $uplo = 'U'$:

$$\begin{bmatrix} d & e & v2 & v3 & v4 \\ & d & e & v3 & v4 \\ & & d & e & v4 \\ & & & d & e \\ & & & & d \end{bmatrix}$$

If $uplo = 'L'$:

$$\begin{bmatrix} d & & & & \\ e & d & & & \\ v_1 & e & d & & \\ v_1 & v_2 & e & d & \\ v_1 & v_2 & v_3 & e & d \end{bmatrix}$$

where d and e denote diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

See Also

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

p?ormtr

Multiplies a general matrix by the orthogonal transformation matrix from a reduction to tridiagonal form determined by p?sytrd.

Syntax

```
void psormtr (char *side , char *uplo , char *trans , MKL_INT *m , MKL_INT *n , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork , MKL_INT *info );
void pdormtr (char *side , char *uplo , char *trans , MKL_INT *m , MKL_INT *n , double
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

This function overwrites the general real distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

| | | |
|----------------|---------------------|---------------------|
| | $side = 'L'$ | $side = 'R'$ |
| $trans = 'N':$ | $Q*\text{sub}(C)$ | $\text{sub}(C)*Q$ |
| $trans = 'T':$ | $Q^T*\text{sub}(C)$ | $\text{sub}(C)*Q^T$ |

where Q is a real orthogonal distributed matrix of order nq , with $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$.

Q is defined as the product of nq elementary reflectors, as returned by [p?sytrd](#).

If $uplo = 'U'$, $Q = H(nq-1) \dots H(2) H(1)$;

If $uplo = 'L'$, $Q = H(1) H(2) \dots H(nq-1)$.

Input Parameters

$side$ (global)
 $= 'L'$: Q or Q^T is applied from the left.

| | |
|---------------|--|
| | = 'R': Q or Q^T is applied from the right. |
| <i>trans</i> | (global) = 'N', no transpose, Q is applied. = 'T', transpose, Q^T is applied. |
| <i>uplo</i> | (global) = 'U': Upper triangle of $A(ia:*, ja:*)$ contains elementary reflectors from $p?sytrd$; = 'L': Lower triangle of $A(ia:*, ja:*)$ contains elementary reflectors from $p?sytrd$ |
| <i>m</i> | (global) The number of rows in the distributed matrix $sub(C)$ ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the distributed matrix $sub(C)$ ($n \geq 0$). |
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a * LOcc(ja+m-1)$ if $side = 'L'$, and $lld_a * LOcc(ja+n-1)$ if $side = 'R'$. Contains the vectors that define the elementary reflectors, as returned by $p?sytrd$. If $side='L'$, $lld_a \geq \max(1, LOCr(ia+m-1))$; If $side = 'R'$, $lld_a \geq \max(1, LOCr(ia+n-1))$. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <i>tau</i> | (local) Array of size of $ltau$ where if $side = 'L'$ and $uplo = 'U'$, $ltau = LOcc(m_a)$, if $side = 'L'$ and $uplo = 'L'$, $ltau = LOcc(ja+m-2)$, if $side = 'R'$ and $uplo = 'U'$, $ltau = LOcc(n_a)$, if $side = 'R'$ and $uplo = 'L'$, $ltau = LOcc(ja+n-2)$. $tau[i]$ must contain the scalar factor of the elementary reflector $H(i+1)$, as returned by $p?sytrd$ ($0 \leq i < ltau$). tau is tied to the distributed matrix A . |
| <i>c</i> | (local) Pointer into the local memory to an array of size $lld_c * LOcc(jc+n-1)$. Contains the local pieces of the distributed matrix $sub(C)$. |
| <i>ic, jc</i> | (global) The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C , respectively. |
| <i>desc</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix C . |

work (local)
Workspace array of size *lwork*.

lwork (local or global) size of *work*, must be at least:

```

if uplo = 'U',
  iaa= ia; jaa= ja+1, icc= ic; jcc= jc;
else uplo = 'L',
  iaa= ia+1, jaa= ja;
If side = 'L',
  icc= ic+1; jcc= jc;
else icc= ic; jcc= jc+1;
end if
end if
If side = 'L',
mi= m-1; ni= n
lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 + mpc0)*nb_a) + nb_a*nb_a
else
If side = 'R',
mi= m; ni = n-1;
lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 +
max(npa0+numroc(numroc(ni+icoffc, nb_a, 0, 0, NPCOL), nb_a,
0, 0, lcmq), mpc0))*nb_a)+ nb_a*nb_a
end if
where lcmq = lcm/NPCOL with lcm = ilcm(NPROW, NPCOL),
iroffa = mod(iaa-1, mb_a),
icoffa = mod(jaa-1, nb_a),
iarow = indxg2p(iaa, mb_a, MYROW, rsrc_a, NPROW),
npa0 = numroc(ni+iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(icc-1, mb_c),
icoffc = mod(jcc-1, nb_c),
icrow = indxg2p(icc, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jcc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`ilcm`, `indxcg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPOL` can be determined by calling the function `blacs_gridinfo`. If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|----------------------|--|
| <code>c</code> | Overwritten by the product $Q \cdot \text{sub}(C)$, or $Q' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q'$, or $\text{sub}(C) \cdot Q$. |
| <code>work[0]</code> | On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $\text{info} = -(i \cdot 100 + j)$; if the i -th argument is a scalar and had an illegal value, then $\text{info} = -i$. |

Description

`p?hengst` reduces a complex Hermitian-definite generalized eigenproblem to standard form.

`p?hengst` performs the same function as `p?hegst`, but is based on rank 2K updates, which are faster and more scalable than triangular solves (the basis of `p?hengst`).

`p?hengst` calls `p?hegst` when `uplo='U'`, hence `p?hengst` provides improved performance only when `uplo='L'` and `ibtype=1`.

`p?hengst` also calls `p?hegst` when insufficient workspace is provided, hence `p?hengst` provides improved performance only when `lwork` is sufficient (as described in the parameter descriptions).

In the following `sub(A)` denotes the submatrix $A(ia:ia+n-1, ja:ja+n-1)$ and `sub(B)` denotes the submatrix $B(ib:ib+n-1, jb:jb+n-1)$.

If `ibtype = 1`, the problem is $sub(A) * x = lambda * sub(B) * x$, and `sub(A)` is overwritten by $inv(U^H) * sub(A) * inv(U)$ or $inv(L) * sub(A) * inv(L^H)$

If `ibtype = 2` or `3`, the problem is $sub(A) * sub(B) * x = lambda * x$ or $sub(B) * sub(A) * x = lambda * x$, and `sub(A)` is overwritten by $U * sub(A) * U^H$ or $L^H * sub(A) * L$.

`sub(B)` must have been previously factorized as $U^H * U$ or $L * L^H$ by `p?potrf`.

Input Parameters

| | |
|---------------------|---|
| <code>ibtype</code> | (global) = 1: compute $inv(U^H) * sub(A) * inv(U)$ or $inv(L) * sub(A) * inv(L^H)$; = 2 or 3: compute $U * sub(A) * U^H$ or $L^H * sub(A) * L$. |
| <code>uplo</code> | (global) = 'U': Upper triangle of <code>sub(A)</code> is stored and <code>sub(B)</code> is factored as $U^H * U$; = 'L': Lower triangle of <code>sub(A)</code> is stored and <code>sub(B)</code> is factored as $L * L^H$. |
| <code>n</code> | (global) The order of the matrices <code>sub(A)</code> and <code>sub(B)</code> . $n \geq 0$. |
| <code>a</code> | (local) Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$. On entry, this array contains the local pieces of the n -by- n Hermitian distributed matrix <code>sub(A)</code> . If <code>uplo = 'U'</code> , the leading n -by- n upper triangular part of <code>sub(A)</code> contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <code>uplo = 'L'</code> , the leading n -by- n lower triangular part of <code>sub(A)</code> contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. |
| <code>ia</code> | (global) Global row index of matrix A , which points to the beginning of the submatrix on which to operate. |
| <code>ja</code> | (global) Global column index of matrix A , which points to the beginning of the submatrix on which to operate. |
| <code>desca</code> | (global and local) Array of size <code>dlen_</code> . The array descriptor for the distributed matrix A . |
| <code>b</code> | (local) Pointer into the local memory to an array of size $lld_b * LOCC(jb+n-1)$. |
| <code>ib</code> | (global) |

| | |
|--------------|---|
| | Global row index of matrix B , which points to the beginning of the submatrix on which to operate. |
| <i>jb</i> | (global) Global column index of matrix B , which points to the beginning of the submatrix on which to operate. |
| <i>descb</i> | (global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix B . |
| <i>work</i> | (local) Array, size (<i>lwork</i>) On exit, <i>work</i> (1) returns the minimal and optimal <i>lwork</i> . |
| <i>lwork</i> | (local) The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork \geq \text{MAX}(NB * (NPO + 1), 3 * NB)$. When <i>ibtype</i> = 1 and <i>uplo</i> = 'L', p?hengst provides improved performance when $lwork \geq 2 * NPO * NB + NQ0 * NB + NB * NB$, where $NB = mb_a = nb_a$, $NPO = \text{numroc}(n, NB, 0, 0, NPROW)$, $NQ0 = \text{numroc}(n, NB, 0, 0, NPROW)$, and <i>numroc</i> is a ScaLAPACK tool function. MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine <i>blacs_gridinfo</i> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>p?erbla</i> . |

Output Parameters

| | |
|--------------|---|
| <i>a</i> | On exit, if <i>info</i> = 0, the transformed matrix, stored in the same format as sub(A). |
| <i>scale</i> | (global) Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this routine. <i>scale</i> is always returned as 1.0. |
| <i>work</i> | On exit, <i>work</i> [0] returns the minimal and optimal <i>lwork</i> . |
| <i>info</i> | (global) = 0: successful exit < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . |

p?hentr

Reduces a complex Hermitian matrix to Hermitian tridiagonal form.

Syntax

```
void pchentrd (const char* uplo, const MKL_INT* n, MKL_Complex8* a, const MKL_INT* ia,
const MKL_INT* ja, const MKL_INT* desca, float* d, float* e, MKL_Complex8* tau,
MKL_Complex8* work, const MKL_INT* lwork, float* rwork, const MKL_INT* lrwork, MKL_INT*
info);
```

```
void pzchentrd (const char* uplo, const MKL_INT* n, MKL_Complex16* a, const MKL_INT* ia,
const MKL_INT* ja, const MKL_INT* desca, double* d, double* e, MKL_Complex16* tau,
MKL_Complex16* work, const MKL_INT* lwork, double* rwork, const MKL_INT* lrwork,
MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

p?hentr is a prototype version of p?hetrd which uses tailored codes (either the serial, ?hetrd, or the parallel code, p?hettrd) when adequate workspace is provided.

p?hentr reduces a complex Hermitian matrix $\text{sub}(A)$ to Hermitian tridiagonal form T by an unitary similarity transformation:

$$Q^* \text{sub}(A) Q = T, \text{ where } \text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1).$$

p?hentr is faster than p?hetrd on almost all matrices, particularly small ones (i.e. $n < 500 * \text{sqrt}(P)$), provided that enough workspace is available to use the tailored codes.

The tailored codes provide performance that is essentially independent of the input data layout.

The tailored codes place no restrictions on ia , ja , MB or NB. At present, ia , ja , MB and NB are restricted to those values allowed by p?hetrd to keep the interface simple (see the Application Notes section for more information about the restrictions).

Input Parameters

| | |
|-------------|--|
| <i>uplo</i> | (global) Specifies whether the upper or lower triangular part of the Hermitian matrix $\text{sub}(A)$ is stored: = 'U': Upper triangular = 'L': Lower triangular |
| <i>n</i> | (global) The number of rows and columns to be operated on, i.e. the order of the distributed submatrix $\text{sub}(A)$. $n \geq 0$. |
| <i>a</i> | (local) Pointer into the local memory to an array of size $\text{lld}_a * \text{LOCc}(\text{ja}+n-1)$. On entry, this array contains the local pieces of the Hermitian distributed matrix $\text{sub}(A)$. If $\text{uplo} = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly |

lower triangular part is not referenced. If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of sub(*A*) contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.

| | |
|---------------|---|
| <i>ia</i> | (global) The row index in the global array <i>a</i> indicating the first row of sub(<i>A</i>). |
| <i>ja</i> | (global) The column index in the global array <i>a</i> indicating the first column of sub(<i>A</i>). |
| <i>desca</i> | (global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>work</i> | (local) Array, size (<i>lwork</i>) |
| <i>lwork</i> | (local or global) The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork \geq \text{MAX}(NB * (NP + 1), 3 * NB)$. For optimal performance, greater workspace is needed: $lwork \geq 2 * (ANB + 1) * (4 * NPS + 2) + (NPS + 4) * NPS$ $ANB = \text{pjlaenv}(ICTXT, 3, 'p?hettrd', 'L', 0, 0, 0, 0)$ $ICTXT = \text{desca}(ctxt_)$ $SQNPC = \text{INT}(\text{sqrt}(\text{REAL}(NPROW * NPCOL)))$ $NPS = \text{MAX}(\text{numroc}(n, 1, 0, 0, SQNPC), 2 * ANB)$ <i>numroc</i> is a ScaLAPACK tool function. <i>pjlaenv</i> is a ScaLAPACK environmental inquiry function. <i>NPROW</i> and <i>NPCOL</i> can be determined by calling the subroutine <i>blacs_gridinfo</i> . |
| <i>rwork</i> | (local) Array, size (<i>lrwork</i>) |
| <i>lrwork</i> | (local or global) The size of the array <i>rwork</i> . <i>lrwork</i> is local input and must be at least $lrwork \geq 1$. For optimal performance, greater workspace is needed, i.e. $lrwork \geq \text{MAX}(2 * n)$ |

Output Parameters

| | |
|--------------|---|
| <i>a</i> | On exit, if <i>uplo</i> = 'U', the diagonal and first superdiagonal of sub(<i>A</i>) are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements above the first superdiagonal, with the array <i>tau</i> , represent the unitary matrix <i>Q</i> as a product of elementary reflectors; if <i>uplo</i> = 'L', the diagonal and first subdiagonal of sub(<i>A</i>) are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements below the first subdiagonal, with the array <i>tau</i> , represent the unitary matrix <i>Q</i> as a product of elementary reflectors. See Application Notes. |
| <i>d</i> | (local) Array, size LOCC(<i>ja+n-1</i>) The diagonal elements of the tridiagonal matrix <i>T</i> : $d[i - 1] = A(i,i)$. <i>d</i> is tied to the distributed matrix <i>A</i> . |
| <i>e</i> | (local) Array, size LOCC(<i>ja+n-1</i>) if <i>uplo</i> = 'U', LOCC(<i>ja+n-2</i>) otherwise. The off-diagonal elements of the tridiagonal matrix <i>T</i> : $e[i - 1] = A(i,i+1)$ if <i>uplo</i> = 'U', $e[i - 1] = A(i+1,i)$ if <i>uplo</i> = 'L'. <i>e</i> is tied to the distributed matrix <i>A</i> . |
| <i>tau</i> | (local) Array, size LOCC(<i>ja+n-1</i>). This array contains the scalar factors <i>tau</i> of the elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> . |
| <i>work</i> | On exit, <i>work</i> [0] returns the optimal <i>lwork</i> . |
| <i>rwork</i> | On exit, <i>rwork</i> [0] returns the optimal <i>lrwork</i> . |
| <i>info</i> | (global) = 0: successful exit < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = -(<i>j</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . |

Application Notes

If *uplo* = 'U', the matrix *Q* is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each *H*(*i*) has the form

$H(i) = I - \tau * v * v'$, where *tau* is a complex scalar, and *v* is a complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2,ja+i)$, and *tau* in $\tau(ja+i-1)$.

If *uplo* = 'L', the matrix *Q* is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n-1).$$

Each *H*(*i*) has the form

$H(i) = I - \tau * v * v'$, where τ is a complex scalar, and v is a complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and τ in $\tau(ja+i-1)$.

The contents of sub(A) on exit are illustrated by the following examples with $n = 5$:

if $uplo = 'U'$:

$$\begin{pmatrix} d & e & v2 & v3 & v4 \\ & d & e & v3 & v4 \\ & & d & e & v3 \\ & & & d & e \\ & & & & d \end{pmatrix}$$

if $uplo = 'L'$:

$$\begin{pmatrix} d & & & & \\ e & d & & & \\ v1 & e & d & & \\ v1 & v2 & e & d & \\ v1 & v2 & v3 & e & d \end{pmatrix}$$

where d and e denote diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

Alignment requirements

The distributed submatrix sub(A) must verify some alignment properties, namely the following expression should be true:

($mb_a = nb_a$ and $IROFFA = ICOFFA$ and $IROFFA = 0$) with $IROFFA = \text{mod}(ia-1, mb_a)$, and $ICOFFA = \text{mod}(ja-1, nb_a)$.

p?hetrd

Reduces a Hermitian matrix to Hermitian tridiagonal form by a unitary similarity transformation.

Syntax

```
void pchetrd (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *d , float *e , MKL_Complex8 *tau , MKL_Complex8 *work ,
MKL_INT *lwork , MKL_INT *info );
```

```
void pzhetrd (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *d , double *e , MKL_Complex16 *tau , MKL_Complex16 *work ,
MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?hetrd function reduces a complex Hermitian matrix sub(A) to Hermitian tridiagonal form T by a unitary similarity transformation:

$$Q^* \text{sub}(A) Q = T$$

where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

| | |
|---------------|--|
| <i>uplo</i> | (global) Specifies whether the upper or lower triangular part of the Hermitian matrix sub(A) is stored: If <i>uplo</i> = 'U', upper triangular If <i>uplo</i> = 'L', lower triangular |
| <i>n</i> | (global) The order of the distributed matrix sub(A) ($n \geq 0$). |
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a * LOCC(j_a + n - 1)$. On entry, this array contains the local pieces of the Hermitian distributed matrix sub(A). If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of sub(A) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of sub(A) contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. (see <i>Application Notes</i> below). |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A, respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A. |
| <i>work</i> | (local) Workspace array of size <i>lwork</i> . |
| <i>lwork</i> | (local or global) size of <i>work</i> , must be at least: $lwork \geq \max(NB * (np + 1), 3 * NB)$ where $NB = mb_a = nb_a$, $np = \text{numroc}(n, NB, MYROW, iarow, NPROW)$, $iarow = \text{indxg2p}(ia, NB, MYROW, rsrc_a, NPROW)$. <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function <i>blacs_gridinfo</i> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i> . |

Output Parameters

| | |
|----------|---|
| <i>a</i> | On exit, If <i>uplo</i> = 'U', the diagonal and first superdiagonal of sub(A) are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements above the first superdiagonal, with the array <i>tau</i> , represent |
|----------|---|

the unitary matrix Q as a product of elementary reflectors; if $uplo = 'L'$, the diagonal and first subdiagonal of $sub(A)$ are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements below the first subdiagonal, with the array tau , represent the unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

| | |
|-----------|--|
| d | (local) Arrays of size $LOCc(ja+n-1)$. The diagonal elements of the tridiagonal matrix T : $d[i] = A(i+1, i+1)$, $0 \leq i < LOCc(ja+n-1)$. d is tied to the distributed matrix A . |
| e | (local) Arrays of size $LOCc(ja+n-1)$ if $uplo = 'U'$; $LOCc(ja+n-2)$ - otherwise. The off-diagonal elements of the tridiagonal matrix T : $e[i] = A(i+1, i+2)$, $0 \leq i < LOCc(ja+n-1)$ if $uplo = 'U'$, $e[i] = A(i+2, i+1)$ if $uplo = 'L'$. e is tied to the distributed matrix A . |
| tau | (local) Array of size $LOCc(ja+n-1)$. This array contains the scalar factors of the elementary reflectors. tau is tied to the distributed matrix A . |
| $work[0]$ | On exit $work[0]$ contains the minimum value of $lwork$ required for optimum performance. |
| $info$ | (global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$. |

Application Notes

If $uplo = 'U'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) * \dots * H(2) * H(1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v',$$

where τ is a complex scalar, and v is a complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and τ in $tau[ja+i-2]$.

If $uplo = 'L'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(n-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v',$$

where τ is a complex scalar, and v is a complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and τ in $tau[ja+i-2]$.

The contents of $\text{sub}(A)$ on exit are illustrated by the following examples with $n = 5$:

If $\text{uplo} = 'U'$:

$$\begin{bmatrix} d & e & v2 & v3 & v4 \\ & d & e & v3 & v4 \\ & & d & e & v4 \\ & & & d & e \\ & & & & d \end{bmatrix}$$

If $\text{uplo} = 'L'$:

$$\begin{bmatrix} d & & & & \\ e & d & & & \\ v1 & e & d & & \\ v1 & v2 & e & d & \\ v1 & v2 & v3 & e & d \end{bmatrix}$$

where d and e denote diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

Description

This function overwrites the general complex distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

| | | |
|----------------|-----------------------|-----------------------|
| | $side = 'L'$ | $side = 'R'$ |
| $trans = 'N':$ | $Q * \text{sub}(C)$ | $\text{sub}(C) * Q$ |
| $trans = 'C':$ | $Q^H * \text{sub}(C)$ | $\text{sub}(C) * Q^H$ |

where Q is a complex unitary distributed matrix of order nq , with $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$.

Q is defined as the product of $nq-1$ elementary reflectors, as returned by [p?hetrd](#).

If $uplo = 'U'$, $Q = H(nq-1) \dots H(2) H(1)$;

If $uplo = 'L'$, $Q = H(1) H(2) \dots H(nq-1)$.

Input Parameters

| | |
|---------------|---|
| <i>side</i> | (global) $= 'L'$: Q or Q^H is applied from the left. $= 'R'$: Q or Q^H is applied from the right. |
| <i>trans</i> | (global) $= 'N'$, no transpose, Q is applied. $= 'C'$, conjugate transpose, Q^H is applied. |
| <i>uplo</i> | (global) $= 'U'$: Upper triangle of $A(ia:*, ja:*)$ contains elementary reflectors from p?hetrd ; $= 'L'$: Lower triangle of $A(ia:*, ja:*)$ contains elementary reflectors from p?hetrd |
| <i>m</i> | (global) The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$). |
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a * LOCc(ja+m-1)$ if $side = 'L'$, and $lld_a * LOCc(ja+n-1)$ if $side = 'R'$. Contains the vectors which define the elementary reflectors, as returned by p?hetrd . If $side = 'L'$, $lld_a \geq \max(1, LOCr(ia+m-1))$; If $side = 'R'$, $lld_a \geq \max(1, LOCr(ia+n-1))$. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <i>tau</i> | (local) |

Array of size of *ltau* where

```
If side = 'L' and uplo = 'U', ltau = LOCc(m_a),
if side = 'L' and uplo = 'L', ltau = LOCc(ja+m-2),
if side = 'R' and uplo = 'U', ltau = LOCc(n_a),
if side = 'R' and uplo = 'L', ltau = LOCc(ja+n-2).
```

tau[*i*] must contain the scalar factor of the elementary reflector $H(i+1)$, as returned by *p?hetrd* ($0 \leq j < ltau$). *tau* is tied to the distributed matrix *A*.

c

(local)

Pointer into the local memory to an array of size *lld_c***LOCc*(*jc+n-1*). Contains the local pieces of the distributed matrix sub (*C*).

ic, jc

(global) The row and column indices in the global matrix *C* indicating the first row and the first column of the submatrix *C*, respectively.

descc

(global and local) array of size *dlen_*. The array descriptor for the distributed matrix *C*.

work

(local)

Workspace array of size *lwork*.

lwork

(local or global) size of *work*, must be at least:

```
If uplo = 'U',
  iaa= ia; jaa= ja+1, icc= ic; jcc= jc;
else uplo = 'L',
  iaa= ia+1, jaa= ja;
If side = 'L',
  icc= ic+1; jcc= jc;
else icc= ic; jcc= jc+1;
end if
end if
If side = 'L',
  mi= m-1; ni= n
  lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 + mpc0)*nb_a) + nb_a*nb_a
else
  If side = 'R',
    mi= m; ni = n-1;
    lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 +
max(npa0+numroc(numroc(ni+icoffc, nb_a, 0, 0, NPCOL), nb_a,
0, 0, lcmq), mpc0))*nb_a) + nb_a*nb_a
end if
where lcmq = lcm/NPCOL with lcm = ilcm(NPROW, NPCOL),
```

```

iroffa = mod(iaa-1, mb_a),
icoffa = mod(jaa-1, nb_a),
iarow = indxg2p(iaa, mb_a, MYROW, rsrc_a, NPROW),
npa0 = numroc(ni+iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(icc-1, mb_c),
icoffc = mod(jcc-1, nb_c),
icrow = indxg2p(icc, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jcc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

NOTE

`mod(x, y)` is the integer remainder of x/y .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`. If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?erbla`.

Output Parameters

| | |
|----------------------|--|
| <code>c</code> | Overwritten by the product $Q \cdot \text{sub}(C)$, or $Q' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q'$, or $\text{sub}(C) \cdot Q$. |
| <code>work[0]</code> | On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info = -(i*100+j)</code> ; if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> . |

p?stebz

Computes the eigenvalues of a symmetric tridiagonal matrix by bisection.

Syntax

```
void psstebz (MKL_INT *ictxt , char *range , char *order , MKL_INT *n , float *vl ,
float *vu , MKL_INT *il , MKL_INT *iu , float *abstol , float *d , float *e , MKL_INT
*m , MKL_INT *nsplit , float *w , MKL_INT *iblock , MKL_INT *isplit , float *work ,
MKL_INT *lwork , MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );
```

```
void pdstebz (MKL_INT *ictxt , char *range , char *order , MKL_INT *n , double *vl ,
double *vu , MKL_INT *il , MKL_INT *iu , double *abstol , double *d , double *e ,
MKL_INT *m , MKL_INT *nsplit , double *w , MKL_INT *iblock , MKL_INT *isplit , double
*work , MKL_INT *lwork , MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?stebz` function computes the eigenvalues of a symmetric tridiagonal matrix in parallel. These may be all eigenvalues, all eigenvalues in the interval $[vl, vu]$, or the eigenvalues il through iu . A static partitioning of work is done at the beginning of `p?stebz` which results in all processes finding an (almost) equal number of eigenvalues.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

| | |
|---------------|---|
| <i>ictxt</i> | (global) The BLACS context handle. |
| <i>range</i> | (global) Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the function computes all eigenvalues. If <i>range</i> = 'V', the function computes eigenvalues in the interval $[vl, vu]$. If <i>range</i> = 'I', the function computes eigenvalues il through iu . |
| <i>order</i> | (global) Must be 'B' or 'E'. If <i>order</i> = 'B', the eigenvalues are to be ordered from smallest to largest within each split-off block. If <i>order</i> = 'E', the eigenvalues for the entire matrix are to be ordered from smallest to largest. |
| <i>n</i> | (global) The order of the tridiagonal matrix T ($n \geq 0$). |
| <i>vl, vu</i> | (global) |

If *range* = 'V', the function computes the lower and the upper bounds for the eigenvalues on the interval [*l*, *vu*].

If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, iu

(global)

Constraint: $1 \leq il \leq iu \leq n$.

If *range* = 'I', the index of the smallest eigenvalue is returned for *il* and of the largest eigenvalue for *iu* (assuming that the eigenvalues are in ascending order) must be returned.

If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol

(global)

The absolute tolerance to which each eigenvalue is required. An eigenvalue (or cluster) is considered to have converged if it lies in an interval of width *abstol*. If *abstol* ≤ 0, then the tolerance is taken as $ulp ||T||$, where *ulp* is the machine precision, and $||T||$ means the 1-norm of *T*

Eigenvalues will be computed most accurately when *abstol* is set to the underflow threshold `slamch('U')`, not 0. Note that if eigenvectors are desired later by inverse iteration (`p?stein`), *abstol* should be set to $2 * p?lamch('S')$.

d

(global)

Array of size *n*.

Contains *n* diagonal elements of the tridiagonal matrix *T*. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than $overflow^{(1/2)} * underflow^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.

e

(global)

Array of size *n* - 1.

Contains (*n*-1) off-diagonal elements of the tridiagonal matrix *T*. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than $overflow^{(1/2)} * underflow^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.

work

(local)

Array of size $\max(5n, 7)$. This is a workspace array.

lwork

(local) The size of the *work* array must be $\geq \max(5n, 7)$.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

iwork

(local) Array of size $\max(4n, 14)$. This is a workspace array.

liwork

(local) The size of the *iwork* array must $\geq \max(4n, 14, NPROCS)$.

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|----------|--|
| m | (global) The actual number of eigenvalues found. $0 \leq m \leq n$ |
| $nsplit$ | (global) The number of diagonal blocks detected in T . $1 \leq nsplit \leq n$ |
| w | (global) Array of size n . On exit, the first m elements of w contain the eigenvalues on all processes. |
| $iblock$ | (global) Array of size n . At each row/column j where $e[j-1]$ is zero or small, the matrix T is considered to split into a block diagonal matrix. On exit $iblock[j]$ specifies which block (from 1 to the number of blocks) the eigenvalue $w[j]$ belongs to. |

NOTE

In the (theoretically impossible) event that bisection does not converge for some or all eigenvalues, $info$ is set to 1 and the ones for which it did not are identified by a negative block number.

| | |
|----------|--|
| $isplit$ | (global) Array of size n . Contains the splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to $isplit[0]$, the second of rows/columns $isplit[0]+1$ through $isplit[1]$, and so on, and the $nsplit$ -th submatrix consists of rows/columns $isplit[nsplit-2]+1$ through $isplit[nsplit-1]=n$. (Only the first $nsplit$ elements are used, but since the $nsplit$ values are not known, n words must be reserved for $isplit$.) |
| $info$ | (global) If $info = 0$, the execution is successful. If $info < 0$, if $info = -i$, the i -th argument has an illegal value. If $info > 0$, some or all of the eigenvalues fail to converge or are not computed. If $info = 1$, bisection fails to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances. If $info = 2$, mismatch between the number of eigenvalues output and the number desired. |

If *info* = 3: *range*='I', and the Gershgorin interval initially used is incorrect. No eigenvalues are computed. Probable cause: the machine has a sloppy floating-point arithmetic. Increase the *fudge* parameter, recompile, and try again.

p?stedc

Computes all eigenvalues and eigenvectors of a symmetric tridiagonal matrix in parallel.

Syntax

```
void psstedc (const char* compz, const MKL_INT* n, float* d, float* e, float* q, const
MKL_INT* iq, const MKL_INT* jq, const MKL_INT* descq, float* work, MKL_INT* lwork,
MKL_INT* iwork, const MKL_INT* liwork, MKL_INT* info);
```

```
void pdstedc (const char* compz, const MKL_INT* n, double* d, double* e, double* q,
const MKL_INT* iq, const MKL_INT* jq, const MKL_INT* descq, double* work, MKL_INT*
lwork, MKL_INT* iwork, const MKL_INT* liwork, MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

p?stedc computes all eigenvalues and eigenvectors of a symmetric tridiagonal matrix in parallel, using the divide and conquer algorithm.

Input Parameters

| | |
|--------------|---|
| <i>compz</i> | = 'N': Compute eigenvalues only. (NOT IMPLEMENTED YET) = 'I': Compute eigenvectors of tridiagonal matrix also. = 'V': Compute eigenvectors of original dense symmetric matrix also. On entry, <i>Z</i> contains the orthogonal matrix used to reduce the original matrix to tridiagonal form. (NOT IMPLEMENTED YET) |
| <i>n</i> | (global) The order of the tridiagonal matrix <i>T</i> . $n \geq 0$. |
| <i>d</i> | (global) Array, size (<i>n</i>) On entry, the diagonal elements of the tridiagonal matrix. |
| <i>e</i> | (global) Array, size ($n-1$). On entry, the subdiagonal elements of the tridiagonal matrix. |
| <i>iq</i> | (global) |

| | |
|---------------|--|
| | Q's global row index, which points to the beginning of the submatrix which is to be operated on. |
| <i>jq</i> | (global) Q's global column index, which points to the beginning of the submatrix which is to be operated on. |
| <i>descq</i> | (global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix Q. |
| <i>work</i> | (local) Array, size (<i>lwork</i>) |
| <i>lwork</i> | (local) The size of the array <i>work</i> . $lwork = 6*n + 2*NP*NQ$ $NP = \text{numroc}(n, NB, MYROW, \text{DESCQ}(rsrc_), NPROW)$ $NQ = \text{numroc}(n, NB, MYCOL, \text{DESCQ}(csrc_), NPCOL)$ <i>numroc</i> is a ScaLAPACK tool function. If <i>lwork</i> = -1, the <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum size for the <i>work</i> array. The required workspace is returned as the first element of <i>work</i> and no error message is issued by <i>pxerbla</i> . |
| <i>iwork</i> | (local) Array, size (<i>liwork</i>) |
| <i>liwork</i> | The size of the array <i>iwork</i> . $liwork = 2 + 7*n + 8*NPCOL$ |

Output Parameters

| | |
|--------------|--|
| <i>d</i> | On exit, if <i>info</i> = 0, the eigenvalues in descending order. |
| <i>q</i> | (local) Array, local size (<i>lld_q</i> , $LOCc(jq+n-1)$) <i>q</i> contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. On output, <i>q</i> is distributed across the P processes in block cyclic format. |
| <i>work</i> | On output, <i>work</i> [0] returns the workspace needed. |
| <i>iwork</i> | On exit, if <i>liwork</i> > 0, <i>iwork</i> [0] returns the optimal <i>liwork</i> . |
| <i>info</i> | (global) = 0: successful exit. |

< 0: If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

> 0: The algorithm failed to compute the $info/(n+1)$ -th eigenvalue while working on the submatrix lying in global rows and columns $\text{mod}(info, n+1)$.

p?stein

Computes the eigenvectors of a tridiagonal matrix using inverse iteration.

Syntax

```

Include Files

- mkl_scalapack.h

Description

The `p?stein` function computes the eigenvectors of a symmetric tridiagonal matrix T corresponding to specified eigenvalues, by inverse iteration. `p?stein` does not orthogonalize vectors that are on different processes. The extent of orthogonalization is controlled by the input parameter `lwork`. Eigenvectors that are to be orthogonalized are computed by the same process. `p?stein` decides on the allocation of work among the processes and then calls `?stein2` (modified LAPACK function) on each individual process. If insufficient workspace is allocated, the expected orthogonalization may not be done.

NOTE

If the eigenvectors obtained are not orthogonal, increase `lwork` and run the code again.

$p = \text{NPROW} * \text{NPCOL}$ is the total number of processes.

Input Parameters

n (global) The order of the matrix T ($n \geq 0$).

| | |
|----------------|--|
| <i>m</i> | (global) The number of eigenvectors to be returned. |
| <i>d, e, w</i> | (global) Arrays: <i>d</i> of size <i>n</i> contains the diagonal elements of <i>T</i> . <i>e</i> of size <i>n-1</i> contains the off-diagonal elements of <i>T</i> . <i>w</i> of size <i>m</i> contains all the eigenvalues grouped by split-off block. The eigenvalues are supplied from smallest to largest within the block. (Here the output array <i>w</i> from <code>p?stebz</code> with order = 'B' is expected. The array should be replicated in all processes.) |
| <i>iblock</i> | (global) Array of size <i>n</i> . The submatrix indices associated with the corresponding eigenvalues in <i>w</i> : 1 for eigenvalues belonging to the first submatrix from the top, 2 for those belonging to the second submatrix, etc. (The output array <i>iblock</i> from <code>p?stebz</code> is expected here). |
| <i>isplit</i> | (global) Array of size <i>n</i> . The splitting points at which <i>T</i> breaks up into submatrices. The first submatrix consists of rows/columns 1 to <i>isplit</i> [0], the second of rows/columns <i>isplit</i> [0]+1 through <i>isplit</i> [1], and so on, and the <i>nsplit</i> -th submatrix consists of rows/columns <i>isplit</i> [<i>nsplit</i> -2]+1 through <i>isplit</i> [<i>nsplit</i> -1]= <i>n</i> . (The output array <i>isplit</i> from <code>p?stebz</code> is expected here.) |
| <i>orfac</i> | (global) <i>orfac</i> specifies which eigenvectors should be orthogonalized. Eigenvectors that correspond to eigenvalues within <i>orfac</i> * T of each other are to be orthogonalized. However, if the workspace is insufficient (see <i>lwork</i>), this tolerance may be decreased until all eigenvectors can be stored in one process. No orthogonalization is done if <i>orfac</i> is equal to zero. A default value of 1000 is used if <i>orfac</i> is negative. <i>orfac</i> should be identical on all processes |
| <i>iz, jz</i> | (global) The row and column indices in the global matrix <i>Z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively. |
| <i>descz</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> . |
| <i>work</i> | (local). Workspace array of size <i>lwork</i> . |
| <i>lwork</i> | (local) <i>lwork</i> controls the extent of orthogonalization which can be done. The number of eigenvectors for which storage is allocated on each process is $nvec = \text{floor}((lwork - \max(5*n, np00*mq00))/n)$. Eigenvectors corresponding to eigenvalue clusters of size $(nvec - \text{ceil}(m/p) + 1)$ are guaranteed to be orthogonal (the orthogonality is similar to that obtained from <code>?stein2</code>). |

NOTE

$lwork$ must be no smaller than $\max(5*n, np00*mq00) + \text{ceil}(m/p)*n$ and should have the same input value on all processes.

It is the minimum value of $lwork$ input on different processes that is significant.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

$iwork$ (local)
Workspace array of size $3n+p+1$.

$liwork$ (local) The size of the array $iwork$. It must be greater than $3*n+p+1$.
If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

z (local)
Array of size $descz[dlen_-1], n/NPCOL + NB$. z contains the computed eigenvectors associated with the specified eigenvalues. Any vector which fails to converge is set to its current iterate after MAXIT iterations (See ? [stein2](#)). On output, z is distributed across the p processes in block cyclic format.

$work$ On exit, $work[0]$ gives a lower bound on the workspace ($lwork$) that guarantees the user desired orthogonalization (see $orfac$). Note that this may overestimate the minimum workspace needed.

$iwork$ On exit, $iwork[0]$ contains the amount of integer workspace required.
On exit, the $iwork[1]$ through $iwork[p+1]$ indicate the eigenvectors computed by each process. Process i computes eigenvectors indexed $iwork[i+1]+1$ through $iwork[i+2]$.

$ifail$ (global) Array of size m . On normal exit, all elements of $ifail$ are zero. If one or more eigenvectors fail to converge after MAXIT iterations (as in ? [stein](#)), then $info > 0$ is returned. If $\text{mod}(info, m+1) > 0$, then for $i=1$ to $\text{mod}(info, m+1)$, the eigenvector corresponding to the eigenvalue $w[ifail[i-1]-1]$ failed to converge (w refers to the array of eigenvalues on output).

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

$iclustr$ (global) Array of size $2*p$.

This output array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be orthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*(2*I-1) to *iclustr*(2*I), *i* = 1 to *info*/(*m*+1), could not be orthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr* is a zero terminated array: *iclustr*[2*k-1] ≠ 0 and *iclustr*[2*k] = 0 if and only if *k* is the number of clusters.

gap

(global)

This output array contains the gap between eigenvalues whose eigenvectors could not be orthogonalized. The *info*/*m* output values in this array correspond to the *info*/(*m*+1) clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*-th cluster may be as high as $(O(n) * macheps) / gap[i-1]$.

info

(global)

If *info* = 0, the execution is successful.

If *info* < 0: If the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value, then *info* = -(*i**100+*j*),

If the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info* < 0: if *info* = -*i*, the *i*-th argument had an illegal value.

If *info* > 0: if mod(*info*, *m*+1) = *i*, then *i* eigenvectors failed to converge in MAXIT iterations. Their indices are stored in the array *ifail*. If *info*/(*m*+1) = *i*, then eigenvectors corresponding to *i* clusters of eigenvalues could not be orthogonalized due to insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

Nonsymmetric Eigenvalue Problems: ScaLAPACK Computational Routines

This section describes ScaLAPACK routines for solving nonsymmetric eigenvalue problems, computing the Schur factorization of general matrices, as well as performing a number of related computational tasks.

To solve a nonsymmetric eigenvalue problem with ScaLAPACK, you usually need to reduce the matrix to the upper Hessenberg form and then solve the eigenvalue problem with the Hessenberg matrix obtained.

[Table "Computational Routines for Solving Nonsymmetric Eigenproblems"](#) lists ScaLAPACK routines for reducing the matrix to the upper Hessenberg form by an orthogonal (or unitary) similarity transformation $A = QHQ^H$, as well as routines for solving eigenproblems with Hessenberg matrices, and multiplying the matrix after reduction.

Computational Routines for Solving Nonsymmetric Eigenproblems

| Operation performed | General matrix | Orthogonal/Unitary matrix | Hessenberg matrix |
|--|-------------------------|---|-------------------------|
| Reduce to Hessenberg form $A = QHQ^H$ | p?gehrd | | |
| Multiply the matrix after reduction | | p?ormhr / p?unmhr | |
| Find eigenvalues and Schur factorization | | | p?lahqr |

p?gehrd

Reduces a general matrix to upper Hessenberg form.

Syntax

```
void psgehrd (MKL_INT *n , MKL_INT *ilo , MKL_INT *ihi , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT
*info );
```

```
void pdgehrd (MKL_INT *n , MKL_INT *ilo , MKL_INT *ihi , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT
*info );
```

```
void pcgehrd (MKL_INT *n , MKL_INT *ilo , MKL_INT *ihi , MKL_Complex8 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pzgehrd (MKL_INT *n , MKL_INT *ilo , MKL_INT *ihi , MKL_Complex16 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work ,
MKL_INT *lwork , MKL_INT *info );
```

Description

The p?gehrd function reduces a real/complex general distributed matrix sub(A) to upper Hessenberg form H by an orthogonal or unitary similarity transformation

$$Q^* \text{sub}(A) Q = H,$$

where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

| | |
|------------|---|
| n | (global). The order of the distributed matrix sub(A) ($n \geq 0$). |
| ilo, ihi | (global). It is assumed that sub(A) is already upper triangular in rows $ia:ia+ilo-2$ and $ia+ihi:ia+n-1$ and columns $ja:ja+ilo-2$ and $ja+ihi:ja+n-1$. (See <i>Application Notes</i> below). If $n > 0$, $1 \leq ilo \leq ihi \leq n$; otherwise set $ilo = 1$, $ihi = n$. |
| a | (local) Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$. On entry, this array contains the local pieces of the n -by- n general distributed matrix sub(A) to be reduced. |
| ia, ja | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| $work$ | (local) Workspace array of size $lwork$. |

lwork (local or global) size of the array *work*. *lwork* is local input and must be at least

$$lwork \geq NB * NB + NB * \max(ihip+1, ihlp+inlq)$$

where $NB = mb_a = nb_a$,

$iroffa = \text{mod}(ia-1, NB)$,

$icoffa = \text{mod}(ja-1, NB)$,

$ioff = \text{mod}(ia+ilo-2, NB)$, $iarow = \text{indxg2p}(ia, NB, MYROW, rsrc_a, NPROW)$, $ihip = \text{numroc}(ihi+iroffa, NB, MYROW, iarow, NPROW)$,

$ilrow = \text{indxg2p}(ia+ilo-1, NB, MYROW, rsrc_a, NPROW)$,

$ihlp = \text{numroc}(ihi-ilo+ioff+1, NB, MYROW, ilrow, NPROW)$,

$ilcol = \text{indxg2p}(ja+ilo-1, NB, MYCOL, csrc_a, NPCOL)$,

$inlq = \text{numroc}(n-ilo+ioff+1, NB, MYCOL, ilcol, NPCOL)$,

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If $lwork = -1$, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a On exit, the upper triangle and the first subdiagonal of $\text{sub}(A)$ are overwritten with the upper Hessenberg matrix H , and the elements below the first subdiagonal, with the array *tau*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

tau (local).
Array of size at least $\max(ja+n-2)$.
The scalar factors of the elementary reflectors (see *Application Notes* below). Elements $ja:ja+ilo-2$ and $ja+ihi:ja+n-2$ of the global vector *tau* are set to zero. *tau* is tied to the distributed matrix A .

work[0] On exit *work*[0] contains the minimum value of *lwork* required for optimum performance.

info (global)
= 0: the execution is successful.
< 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of $(ihi-ilo)$ elementary reflectors

$$Q = H(ilo)*H(ilo+1)*...*H(ihi-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$, $v(i+1) = 1$ and $v(ihi+1:n) = 0$; $v(i+2:ihi)$ is stored on exit in $A(ia+ilo+i:ia+ihi-1, ja+ilo+i-2)$, and τ in $\tau[ja+ilo+i-3]$. The contents of A

$(ia:ia+n-1, ja:ja+n-1)$ are illustrated by the following example, with $n = 7$, $ilo = 2$ and $ihi = 6$:
on entry

$$\begin{bmatrix} a & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & & a & a & a & a & a \\ & & & a & a & a & a \\ & & & & a & a & a \\ & & & & & a & a \\ & & & & & & a \end{bmatrix}$$

on exit

$$\begin{bmatrix} a & a & a & h & h & h & a \\ & a & h & h & h & h & a \\ & & h & h & h & h & h \\ v2 & h & h & h & h & h & h \\ v2 & v3 & h & h & h & h & h \\ v2 & v3 & v4 & h & h & h & h \\ & & & & & & a \end{bmatrix}$$

where a denotes an element of the original matrix $\text{sub}(A)$, h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(ja+ilo+i-2)$.

p?ormhr

Multiplies a general matrix by the orthogonal transformation matrix from a reduction to Hessenberg form determined by p?gehrd.

Syntax

```
void psormhr (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *ilo ,
MKL_INT *ihi , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau ,
float *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork ,
MKL_INT *info );
```

```
void pdormhr (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *ilo ,
MKL_INT *ihi , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau ,
double *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT
*lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?ormhr function overwrites the general real distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

| | | |
|----------------|-----------------------|-----------------------|
| | $side = 'L'$ | $side = 'R'$ |
| $trans = 'N':$ | $Q * \text{sub}(C)$ | $\text{sub}(C) * Q$ |
| $trans = 'T':$ | $Q^T * \text{sub}(C)$ | $\text{sub}(C) * Q^T$ |

where Q is a real orthogonal distributed matrix of order nq , with $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$.

Q is defined as the product of $ihi-ilo$ elementary reflectors, as returned by p?gehrd.

$Q = H(ilo) H(ilo+1) \dots H(ihi-1)$.

Input Parameters

| | |
|------------|--|
| $side$ | (global) = 'L': Q or Q^T is applied from the left. = 'R': Q or Q^T is applied from the right. |
| $trans$ | (global) = 'N', no transpose, Q is applied. = 'T', transpose, Q^T is applied. |
| m | (global) The number of rows in the distributed matrix sub (C) ($m \geq 0$). |
| n | (global) The number of columns in he distributed matrix sub (C) ($n \geq 0$). |
| ilo, ihi | (global) ilo and ihi must have the same values as in the previous call of p?gehrd. Q is equal to the unit matrix except for the distributed submatrix $Q(ia+ilo:ia+ihi-1, ja+ilo:ja+ihi-1)$. |

If $side = 'L'$, $1 \leq ilo \leq ihi \leq \max(1, m)$;

If $side = 'R'$, $1 \leq ilo \leq ihi \leq \max(1, n)$;

ilo and ihi are relative indexes.

a

(local)

Pointer into the local memory to an array of size $lld_a * LOCC(ja+m-1)$ if $side = 'L'$, and $lld_a * LOCC(ja+n-1)$ if $side = 'R'$.

Contains the vectors which define the elementary reflectors, as returned by `p?gehrd`.

ia, ja

(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

$desca$

(global and local) array of size $dlen_$. The array descriptor for the distributed matrix A .

tau

(local)

Array of size $LOCC(ja+m-2)$ if $side = 'L'$, and $LOCC(ja+n-2)$ if $side = 'R'$.

$tau[j]$ contains the scalar factor of the elementary reflector $H(j+1)$ as returned by `p?gehrd` ($0 \leq j < \text{size}(tau)$). tau is tied to the distributed matrix A .

c

(local)

Pointer into the local memory to an array of size $lld_c * LOCC(jc+n-1)$.

Contains the local pieces of the distributed matrix $\text{sub}(C)$.

ic, jc

(global) The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C , respectively.

$descc$

(global and local) array of size $dlen_$. The array descriptor for the distributed matrix C .

$work$

(local)

Workspace array with size $lwork$.

$lwork$

(local or global)

The size of the array $work$.

$lwork$ must be at least $iaa = ia + ilo$; $jaa = ja + ilo - 1$;

If $side = 'L'$,

$mi = ihi - ilo$; $ni = n$; $icc = ic + ilo$; $jcc = jc$;

$lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + mpc0) * nb_a) + nb_a * nb_a$

else if $side = 'R'$,

$mi = m$; $ni = ihi - ilo$; $icc = ic$; $jcc = jc + ilo$;

$lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + \max(npa0 + \text{numroc}(\text{numroc}(ni + icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0)) * nb_a) + nb_a * nb_a$

end if

```

where  $lcmq = lcm/NPCOL$  with  $lcm = ilcm(NPROW, NPCOL)$ ,
 $iroffa = \text{mod}(iaa-1, mb\_a)$ ,
 $icoffa = \text{mod}(jaa-1, nb\_a)$ ,
 $iarow = \text{indxg2p}(iaa, mb\_a, MYROW, rsrc\_a, NPROW)$ ,
 $npa0 = \text{numroc}(ni+iroffa, mb\_a, MYROW, iarow, NPROW)$ ,
 $iroffc = \text{mod}(icc-1, mb\_c)$ ,  $icoffc = \text{mod}(jcc-1, nb\_c)$ ,
 $icrow = \text{indxg2p}(icc, mb\_c, MYROW, rsrc\_c, NPROW)$ ,
 $iccol = \text{indxg2p}(jcc, nb\_c, MYCOL, csrc\_c, NPCOL)$ ,
 $mpc0 = \text{numroc}(mi+iroffc, mb\_c, MYROW, icrow, NPROW)$ ,
 $nqc0 = \text{numroc}(ni+icoffc, nb\_c, MYCOL, iccol, NPCOL)$ ,

```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

$ilcm$, $indxg2p$ and $numroc$ are ScaLAPACK tool functions; $MYROW$, $MYCOL$, $NPROW$ and $NPCOL$ can be determined by calling the function `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?xerbla`.

Output Parameters

| | |
|----------------------|--|
| <code>c</code> | <code>sub(C)</code> is overwritten by $Q*\text{sub}(C)$, or $Q'*\text{sub}(C)$, or $\text{sub}(C)*Q'$, or $\text{sub}(C)*Q$. |
| <code>work[0]</code> | On exit <code>work[0]</code> contains the minimum value of $lwork$ required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$. |

Description

This function overwrites the general complex distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1,jc:jc+n-1)$ with

| | | |
|----------------|---------------------|---------------------|
| | $side = 'L'$ | $side = 'R'$ |
| $trans = 'N':$ | $Q*\text{sub}(C)$ | $\text{sub}(C)*Q$ |
| $trans = 'H':$ | $Q^H*\text{sub}(C)$ | $\text{sub}(C)*Q^H$ |

where Q is a complex unitary distributed matrix of order nq , with $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$.

Q is defined as the product of $ihi-ilo$ elementary reflectors, as returned by [p?gehrd](#).

$Q = H(ilo) H(ilo+1) \dots H(ihi-1)$.

Input Parameters

| | |
|------------|--|
| $side$ | (global) $= 'L'$: Q or Q^H is applied from the left. $= 'R'$: Q or Q^H is applied from the right. |
| $trans$ | (global) $= 'N'$, no transpose, Q is applied. $= 'C'$, conjugate transpose, Q^H is applied. |
| m | (global) The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$). |
| n | (global) The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$). |
| ilo, ihi | (global) These must be the same parameters ilo and ihi , respectively, as supplied to p?gehrd . Q is equal to the unit matrix except in the distributed submatrix $Q(ia+ilo:ia+ihi-1,ja+ilo:ja+ihi-1)$. If $side = 'L'$, then $1 \leq ilo \leq ihi \leq \max(1, m)$. If $side = 'R'$, then $1 \leq ilo \leq ihi \leq \max(1, n)$ ilo and ihi are relative indexes. |

| | |
|---------------|---|
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a*LOCc(ja+m-1)$ if $side = 'L'$, and $lld_a*LOCc(ja+n-1)$ if $side = 'R'$. Contains the vectors which define the elementary reflectors, as returned by <code>p?gehrd</code> . |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>tau</i> | (local) Array of size $LOCc(ja+m-2)$, if $side = 'L'$, and $LOCc(ja+n-2)$ if $side = 'R'$. <i>tau</i> [<i>j</i>] contains the scalar factor of the elementary reflector $H(j+1)$ as returned by <code>p?gehrd</code> ($0 \leq j < \text{size}(\text{tau})$). <i>tau</i> is tied to the distributed matrix <i>A</i> . |
| <i>c</i> | (local) Pointer into the local memory to an array of size $lld_c*LOCc(jc+n-1)$. Contains the local pieces of the distributed matrix sub(<i>C</i>). |
| <i>ic, jc</i> | (global) The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively. |
| <i>desc</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> . |
| <i>work</i> | (local) Workspace array with size <i>lwork</i> . |
| <i>lwork</i> | (local or global) The size of the array <i>work</i> . <i>lwork</i> must be at least $iaa = ia + ilo; jaa = ja + ilo - 1;$ If $side = 'L'$, $mi = ihi - ilo; ni = n; icc = ic + ilo; jcc = jc;$ $lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 + mpc0) * nb_a) + nb_a * nb_a$ else if $side = 'R'$, $mi = m; ni = ihi - ilo; icc = ic; jcc = jc + ilo;$ $lwork \geq \max((nb_a * (nb_a - 1)) / 2, (nqc0 +$ $\max(npa0 + \text{numroc}(\text{numroc}(ni + icoffc, nb_a, 0, 0, NPCOL), nb_a,$ $0, 0, lcmq), mpc0)) * nb_a) + nb_a * nb_a$ end if where $lcmq = lcm / NPCOL$ with $lcm = ilcm(NPROW, NPCOL),$ $iroffa = \text{mod}(iaa - 1, mb_a),$ $icoffa = \text{mod}(jaa - 1, nb_a),$ $iarow = \text{indxg2p}(iaa, mb_a, MYROW, rsrc_a, NPROW),$ |

```

npa0 = numroc(ni+iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(icc-1, mb_c),
icoffc = mod(jcc-1, nb_c),
icrow = indxg2p(icc, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jcc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

NOTE

`mod(x,y)` is the integer remainder of x/y .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|----------------------|---|
| <code>c</code> | C is overwritten by $Q^* \text{sub}(C)$ or $Q'^* \text{sub}(C)$ or $\text{sub}(C) * Q'$ or $\text{sub}(C) * Q$. |
| <code>work[0]</code> | On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <code>info = -(i*100+j)</code> ; if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info = -i</code> . |

Description

This is an auxiliary function used to find the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form from columns *ilo* and *ihi*.

Input Parameters

| | |
|-------------------|---|
| <i>wantt</i> | (global) If <i>wantt</i> ≠ 0, the full Schur form <i>T</i> is required; If <i>wantt</i> = 0, only eigenvalues are required. |
| <i>wantz</i> | (global) If <i>wantz</i> ≠ 0, the matrix of Schur vectors <i>Z</i> is required; If <i>wantz</i> = 0, Schur vectors are not required. |
| <i>n</i> | (global) The order of the Hessenberg matrix <i>A</i> (and <i>z</i> if <i>wantz</i> is non-zero). $n \geq 0$. |
| <i>ilo, ihi</i> | (global) It is assumed that <i>A</i> is already upper quasi-triangular in rows and columns <i>ihi</i> +1: <i>n</i> , and that $A(ilo, ilo-1) = 0$ (unless $ilo = 1$). <i>pdlahqr</i> works primarily with the Hessenberg submatrix in rows and columns <i>ilo</i> to <i>ihi</i> , but applies transformations to all of <i>H</i> if <i>wantt</i> is non-zero. $1 \leq ilo \leq \max(1, ihi)$; $ihiz \leq n$. |
| <i>a</i> | (global) Array, of size $lld_a * LOCC(n)$. On entry, the upper Hessenberg matrix <i>A</i> . |
| <i>desca</i> | (global and local) array of size <i>dlen</i> _· . The array descriptor for the distributed matrix <i>A</i> . |
| <i>iloz, ihiz</i> | (global) Specify the rows of the matrix <i>Z</i> to which transformations must be applied if <i>wantz</i> is non-zero. $1 \leq iloz \leq ilo$; $ihiz \leq ihiz \leq n$. |
| <i>z</i> | (global) Array. If <i>wantz</i> is non-zero, on entry <i>z</i> must contain the current matrix <i>Z</i> of transformations accumulated by <i>pdhseqr</i> . If <i>wantz</i> is zero, <i>z</i> is not referenced. |
| <i>descz</i> | (global and local) array of size <i>dlen</i> _· . The array descriptor for the distributed matrix <i>Z</i> . |
| <i>work</i> | (local) Workspace array with size <i>lwork</i> . |

lwork (local) The size of *work*. *lwork* is assumed big enough so that $lwork \geq 3*n + \max(2*\max(lld_z, lld_a) + 2*LOCq(n), 7*\text{ceil}(n/hbl) / lcm(NPROW, NPCOL))$.

If *lwork* = -1, then *work*[0] gets set to the above number and the code returns immediately.

iwork (global and local) array of size *ilwork*.

ilwork (local) This holds some of the *iblk* integer arrays.

Output Parameters

a On exit, if *wantt* is non-zero, *A* is upper quasi-triangular in rows and columns *ilo:ihi*, with any 2-by-2 or larger diagonal blocks not yet in standard form. If *wantt* is zero, the contents of *A* are unspecified on exit.

work[0] On exit *work*[0] contains the minimum value of *lwork* required for optimum performance.

wr, wi (global replicated output)

Arrays of size *n* each. The real and imaginary parts, respectively, of the computed eigenvalues *ilo* to *ihi* are stored in the corresponding elements of *wr* and *wi*. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of *wr* and *wi*, say the *i*-th and (*i* +1)-th, with $wi[i-1] > 0$ and $wi[i] < 0$. If *wantt* is zero, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *A*. *A* may be returned with larger diagonal blocks until the next release.

z On exit *z* has been updated; transformations are applied only to the submatrix *Z(ilo:ihiz, ilo:ihi)*.

info (global)

= 0: the execution is successful.

< 0: the parameter number - *info* is incorrect or inconsistent

> 0: p?lahqr failed to compute all the eigenvalues *ilo* to *ihi* in a total of $30*(ihi-ilo+1)$ iterations; if *info* = *i*, elements *i*+1: *ihi* of *wr* and *wi* contain the eigenvalues that have been successfully computed.

MKL_Complex16* work, double* rwork, MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

`pztrevc` computes some or all of the right and/or left eigenvectors of a complex upper triangular matrix T in parallel.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

$$T^*x = w^*x,$$

$$y^*T = w^*y'$$

where y' denotes the conjugate transpose of the vector y .

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of T , or the products Q^*X and/or Q^*Y , where Q is an input unitary matrix. If T was obtained from the Schur factorization of an original matrix $A = Q^*T^*Q'$, then Q^*X and Q^*Y are the matrices of right or left eigenvectors of A .

Input Parameters

| | |
|---------------|---|
| <i>side</i> | (global) = 'R': compute right eigenvectors only; = 'L': compute left eigenvectors only; = 'B': compute both right and left eigenvectors. |
| <i>howmny</i> | (global) = 'A': compute all right and/or left eigenvectors; = 'B': compute all right and/or left eigenvectors, and backtransform them using the input matrices supplied in <i>vr</i> and/or <i>vl</i> ; = 'S': compute selected right and/or left eigenvectors, specified by the logical array <i>select</i> . |
| <i>select</i> | (global) Array, size (<i>n</i>) If <i>howmny</i> = 'S', <i>select</i> specifies the eigenvectors to be computed. If <i>howmny</i> = 'A' or 'B', <i>select</i> is not referenced. To select the eigenvector corresponding to the j -th eigenvalue, <i>select</i> [$j - 1$] must be set to non-zero. |
| <i>n</i> | (global) The order of the matrix T . $n \geq 0$. |
| <i>t</i> | (local) Array, size $lld_t * LOCC(n)$. |

| | |
|---------------|---|
| | The upper triangular matrix T . T is modified, but restored on exit. |
| <i>desct</i> | (global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix T . |
| <i>v1</i> | (local) Array, size (<i>descv1</i> (<i>lld_</i>), <i>mm</i>) On entry, if <i>side</i> = 'L' or 'B' and <i>howmny</i> = 'B', <i>v1</i> must contain an n -by- n matrix Q (usually the unitary matrix Q of Schur vectors returned by ? hseqr). |
| <i>descv1</i> | (global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix VL . |
| <i>vr</i> | (local) Array, size <i>descvr</i> (<i>lld_</i>)* <i>mm</i> . On entry, if <i>side</i> = 'R' or 'B' and <i>howmny</i> = 'B', <i>vr</i> must contain an n -by- n matrix Q (usually the unitary matrix Q of Schur vectors returned by ? hseqr). |
| <i>descvr</i> | (global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix VR . |
| <i>mm</i> | (global) The number of columns in the arrays <i>v1</i> and/or <i>vr</i> . <i>mm</i> $\geq m$. |
| <i>work</i> | (local) Array, size (2* <i>desct</i> (<i>lld_</i>)) Additional workspace may be required if <i>p?lattr</i> s is updated to use <i>work</i> . |
| <i>rwork</i> | Array, size (<i>desct</i> (<i>lld_</i>)) |

Output Parameters

| | |
|-----------|---|
| <i>t</i> | The upper triangular matrix T . T is modified, but restored on exit. |
| <i>v1</i> | On exit, if <i>side</i> = 'L' or 'B', <i>v1</i> contains: if <i>howmny</i> = 'A', the matrix Y of left eigenvectors of T ; if <i>howmny</i> = 'B', the matrix $Q*Y$; if <i>howmny</i> = 'S', the left eigenvectors of T specified by <i>select</i> , stored consecutively in the columns of <i>v1</i> , in the same order as their eigenvalues. If <i>side</i> = 'R', <i>v1</i> is not referenced. |
| <i>vr</i> | On exit, if <i>side</i> = 'R' or 'B', <i>vr</i> contains: |

if *howmny* = 'A', the matrix *X* of right eigenvectors of *T*;
 if *howmny* = 'B', the matrix *Q***X*;
 if *howmny* = 'S', the right eigenvectors of *T* specified by *select*, stored consecutively in the columns of *vr*, in the same order as their eigenvalues. If *side* = 'L', *vr* is not referenced.

m (global)
 The number of columns in the arrays *vl* and/or *vr* actually used to store the eigenvectors. If *howmny* = 'A' or 'B', *m* is set to *n*. Each selected eigenvector occupies one column.

info (global)
 = 0: successful exit
 < 0: if *info* = -*i*, the *i*-th argument had an illegal value

Application Notes

The algorithm used in this program is basically backward (forward) substitution. Scaling should be used to make the code robust against possible overflow. But scaling has not yet been implemented in `p?lattr`s which is called by this routine to solve the triangular systems. `p?lattr`s just calls `p?trsv`.

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number (*x*,*y*) is taken to be $|x| + |y|$.

Singular Value Decomposition: ScaLAPACK Driver Routines

This section describes ScaLAPACK routines for computing the singular value decomposition (SVD) of a general *m*-by-*n* matrix *A* (see "Singular Value Decomposition" in LAPACK chapter).

To find the SVD of a general matrix *A*, this matrix is first reduced to a bidiagonal matrix *B* by a unitary (orthogonal) transformation, and then SVD of the bidiagonal matrix is computed. Note that the SVD of *B* is computed using the LAPACK routine `?bdsqr`.

Table "Computational Routines for Singular Value Decomposition (SVD)" lists ScaLAPACK computational routines for performing this decomposition.

Computational Routines for Singular Value Decomposition (SVD)

| Operation | General matrix | Orthogonal/unitary matrix |
|--|----------------------|------------------------------|
| Reduce <i>A</i> to a bidiagonal matrix | <code>p?gebrd</code> | |
| Multiply matrix after reduction | | <code>p?ormbr/p?unmbr</code> |

`p?gebrd`

Reduces a general matrix to bidiagonal form.

Syntax

```
void psgebrd (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *d , float *e , float *tauq , float *taup , float *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pdgebrd (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *d , double *e , double *tauq , double *taup , double *work ,
MKL_INT *lwork , MKL_INT *info );
```

```
void pcgebrd (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *d , float *e , MKL_Complex8 *tauq , MKL_Complex8 *taup ,
MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *info );

void pzgebrd (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *d , double *e , MKL_Complex16 *tauq , MKL_Complex16 *taup ,
MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?gebrd` function reduces a real/complex general m -by- n distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$ to upper or lower bidiagonal form B by an orthogonal/unitary transformation:

$$Q^* \text{sub}(A) P = B.$$

If $m \geq n$, B is upper bidiagonal; if $m < n$, B is lower bidiagonal.

Input Parameters

| | |
|---------------------|---|
| <code>m</code> | (global) The number of rows in the distributed matrix $\text{sub}(A)$ ($m \geq 0$). |
| <code>n</code> | (global) The number of columns in the distributed matrix $\text{sub}(A)$ ($n \geq 0$). |
| <code>a</code> | (local) Real pointer into the local memory to an array of size $\text{lld}_a * \text{LOCc}(\text{ja}+n-1)$. On entry, this array contains the distributed matrix $\text{sub}(A)$. |
| <code>ia, ja</code> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| <code>desca</code> | (global and local) array of size $\text{dlen}_$. The array descriptor for the distributed matrix A . |
| <code>work</code> | (local) Workspace array of size lwork . |
| <code>lwork</code> | (local or global) size of work , must be at least: $\text{lwork} \geq \text{nb} * (\text{mpa0} + \text{nqa0} + 1) + \text{nqa0}$ where $\text{nb} = \text{mb}_a = \text{nb}_a$, $\text{iroffa} = \text{mod}(\text{ia}-1, \text{nb})$, $\text{icoffa} = \text{mod}(\text{ja}-1, \text{nb})$, $\text{iarow} = \text{indxg2p}(\text{ia}, \text{nb}, \text{MYROW}, \text{rsrc}_a, \text{NPROW})$, $\text{iacol} = \text{indxg2p}(\text{ja}, \text{nb}, \text{MYCOL}, \text{csrc}_a, \text{NPCOL})$, $\text{mpa0} = \text{numroc}(m + \text{iroffa}, \text{nb}, \text{MYROW}, \text{iarow}, \text{NPROW})$, $\text{nqa0} = \text{numroc}(n + \text{icoffa}, \text{nb}, \text{MYCOL}, \text{iacol}, \text{NPCOL})$, |

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|-------------------------|--|
| <code>a</code> | On exit, if $m \geq n$, the diagonal and the first superdiagonal of $\text{sub}(A)$ are overwritten with the upper bidiagonal matrix B ; the elements below the diagonal, with the array <code>tauq</code> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array <code>taup</code> , represent the orthogonal matrix P as a product of elementary reflectors. If $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B ; the elements below the first subdiagonal, with the array <code>tauq</code> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array <code>taup</code> , represent the orthogonal matrix P as a product of elementary reflectors. See <i>Application Notes</i> below. |
| <code>d</code> | (local) Array of size <code>LOCc(ja+min(m,n)-1)</code> if $m \geq n$ and <code>LOCr(ia+min(m,n)-1)</code> otherwise. The distributed diagonal elements of the bidiagonal matrix B : $d[i] = A(i+1,i+1)$, $0 \leq i < \text{size}(d)$. <code>d</code> is tied to the distributed matrix A . |
| <code>e</code> | (local) Array of size <code>LOCr(ia+min(m,n)-1)</code> if $m \geq n$; <code>LOCc(ja+min(m,n)-2)</code> otherwise. The distributed off-diagonal elements of the bidiagonal distributed matrix B : If $m \geq n$, $e[i] = A(i+1,i+2)$ for $i = 0, 1, \dots, n-2$; if $m < n$, $e[i] = A(i+2,i+1)$ for $i = 0, 1, \dots, m-2$. <code>e</code> is tied to the distributed matrix A . |
| <code>tauq, taup</code> | (local) Arrays of size <code>LOCc(ja+min(m,n)-1)</code> for <code>tauq</code> and <code>LOCr(ia+min(m,n)-1)</code> for <code>taup</code> . Contain the scalar factors of the elementary reflectors that represent the orthogonal/unitary matrices Q and P , respectively. <code>tauq</code> and <code>taup</code> are tied to the distributed matrix A . See <i>Application Notes</i> below. |
| <code>work[0]</code> | On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info = -(i*100+j)</code> ; if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> . |

Application Notes

The matrices Q and P are represented as products of elementary reflectors:

If $m \geq n$,

$$Q = H(1)*H(2)*...*H(n), \text{ and } P = G(1)*G(2)*...*G(n-1).$$

Each $H(i)$ and $G(i)$ has the form:

$$H(i) = I - \tau u q^* v^* v' \text{ and } G(i) = I - \tau u p^* u^* u'$$

where $\tau u q$ and $\tau u p$ are real/complex scalars, and v and u are real/complex vectors;

$v(1:i-1) = 0$, $v(i) = 1$, and $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$;

$u(1:i) = 0$, $u(i+1) = 1$, and $u(i+2:n)$ is stored on exit in $A(ia+i-1, ja+i+1:ja+n-1)$;

$\tau u q$ is stored in $\tau u q[ja+i-2]$ and $\tau u p$ in $\tau u p[ia+i-2]$.

If $m < n$,

$$Q = H(1)*H(2)*...*H(m-1), \text{ and } P = G(1)*G(2)*...*G(m)$$

Each $H(i)$ and $G(i)$ has the form:

$$H(i) = I - \tau u q^* v^* v' \text{ and } G(i) = I - \tau u p^* u^* u'$$

here $\tau u q$ and $\tau u p$ are real/complex scalars, and v and u are real/complex vectors;

$v(1:i) = 0$, $v(i+1) = 1$, and $v(i+2:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$; $u(1:i-1) = 0$, $u(i) = 1$, and $u(i+1:n)$ is stored on exit in $A(ia+i-1, ja+i+1:ja+n-1)$;

$\tau u q$ is stored in $\tau u q[ja+i-2]$ and $\tau u p$ in $\tau u p[ia+i-2]$.

The contents of sub(A) on exit are illustrated by the following examples:

$m = 6$ and $n = 5$ ($m > n$):

$$\begin{bmatrix} d & e & u1 & u1 & u1 \\ v1 & d & e & u2 & u2 \\ v1 & v2 & d & e & u3 \\ v1 & v2 & v3 & d & e \\ v1 & v2 & v3 & v4 & d \\ v1 & v2 & v3 & v4 & v5 \end{bmatrix}$$

$m = 5$ and $n = 6$ ($m < n$):

$$\begin{bmatrix} d & u1 & u1 & u1 & u1 & u1 \\ e & d & u2 & u2 & u2 & u2 \\ v1 & e & d & u3 & u3 & u3 \\ v1 & v2 & e & d & u4 & u4 \\ v1 & v2 & v3 & e & d & u5 \end{bmatrix}$$

where d and e denote diagonal and off-diagonal elements of B , vi denotes an element of the vector defining $H(i)$, and ui an element of the vector defining $G(i)$.

See Also

Overview of [ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

p?ormbr

Multiplies a general matrix by one of the orthogonal matrices from a reduction to bidiagonal form determined by p?gebrd.

Syntax

```
void psormbr (char *vect , char *side , char *trans , MKL_INT *m , MKL_INT *n ,
MKL_INT *k , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau ,
float *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork ,
MKL_INT *info );
```

```
void pdormbr (char *vect , char *side , char *trans , MKL_INT *m , MKL_INT *n ,
MKL_INT *k , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau ,
double *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT
*lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

If $vect = 'Q'$, the `p?ormbr` function overwrites the general real distributed m -by- n matrix $sub(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

| | | |
|----------------|--------------|--------------|
| | $side = 'L'$ | $side = 'R'$ |
| $trans = 'N':$ | $Q sub(C)$ | $sub(C) Q$ |
| $trans = 'T':$ | $Q^T sub(C)$ | $sub(C) Q^T$ |

If $vect = 'P'$, the function overwrites $sub(C)$ with

| | | |
|----------------|--------------|--------------|
| | $side = 'L'$ | $side = 'R'$ |
| $trans = 'N':$ | $P sub(C)$ | $sub(C) P$ |
| $trans = 'T':$ | $P^T sub(C)$ | $sub(C) P^T$ |

Here Q and P^T are the orthogonal distributed matrices determined by `p?gebrd` when reducing a real distributed matrix $A(ia:*, ja:*)$ to bidiagonal form: $A(ia:*, ja:*) = Q*B*P^T$. Q and P^T are defined as products of elementary reflectors $H(i)$ and $G(i)$ respectively.

Let $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$. Therefore nq is the order of the orthogonal matrix Q or P^T that is applied.

If $vect = 'Q'$, $A(ia:*, ja:*)$ is assumed to have been an nq -by- k matrix:

If $nq \geq k$, $Q = H(1) H(2) \dots H(k)$;

If $nq < k$, $Q = H(1) H(2) \dots H(nq-1)$.

If $vect = 'P'$, $A(ia:*, ja:*)$ is assumed to have been a k -by- nq matrix:

If $k < nq$, $P = G(1) G(2) \dots G(k)$;

If $k \geq nq$, $P = G(1) G(2) \dots G(nq-1)$.

Input Parameters

| | |
|---------------|---|
| <i>vect</i> | (global) If <i>vect</i> = 'Q', then Q or Q^T is applied. If <i>vect</i> = 'P', then P or P^T is applied. |
| <i>side</i> | (global) If <i>side</i> = 'L', then Q or Q^T , P or P^T is applied from the left. If <i>side</i> = 'R', then Q or Q^T , P or P^T is applied from the right. |
| <i>trans</i> | (global) If <i>trans</i> = 'N', no transpose, Q or P is applied. If <i>trans</i> = 'T', then Q^T or P^T is applied. |
| <i>m</i> | (global) The number of rows in the distributed matrix sub (C). |
| <i>n</i> | (global) The number of columns in the distributed matrix sub (C). |
| <i>k</i> | (global) If <i>vect</i> = 'Q', the number of columns in the original distributed matrix reduced by <code>p?gebrd</code> ; If <i>vect</i> = 'P', the number of rows in the original distributed matrix reduced by <code>p?gebrd</code> . Constraints: $k \geq 0$. |
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a * LOCC(ja + \min(nq, k) - 1)$ if <i>vect</i> = 'Q', and $lld_a * LOCC(ja + nq - 1)$ if <i>vect</i> = 'P'. $nq = m$ if <i>side</i> = 'L', and $nq = n$ otherwise. The vectors that define the elementary reflectors $H(i)$ and $G(i)$, whose products determine the matrices Q and P , as returned by <code>p?gebrd</code> . If <i>vect</i> = 'Q', $lld_a \geq \max(1, LOCr(ia + nq - 1))$; If <i>vect</i> = 'P', $lld_a \geq \max(1, LOCr(ia + \min(nq, k) - 1))$. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A . |
| <i>tau</i> | (local) Array of size $LOCC(ja + \min(nq, k) - 1)$, if <i>vect</i> = 'Q', and $LOCr(ia + \min(nq, k) - 1)$, if <i>vect</i> = 'P'. <i>tau</i> [<i>i</i>] must contain the scalar factor of the elementary reflector $H(i+1)$ or $G(i+1)$ |

which determines Q or P , as returned by `pdgebrd` in its array argument `tauq` or `taup`. `tau` is tied to the distributed matrix A .

| | |
|---------------------|---|
| <code>c</code> | (local) Pointer into the local memory to an array of size <code>lld_c*LOCc(jc+n-1)</code> . Contains the local pieces of the distributed matrix sub (C). |
| <code>ic, jc</code> | (global) The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C , respectively. |
| <code>desc</code> | (global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix C . |
| <code>work</code> | (local) Workspace array of size <code>lwork</code> . |
| <code>lwork</code> | (local or global) size of <code>work</code> , must be at least: <pre> If side = 'L' nq = m; if ((vect = 'Q' and nq ≥ k) or (vect is not equal to 'Q' and nq > k)), iaa=ia; jaa=ja; mi=m; ni=n; icc=ic; jcc=jc; else iaa= ia+1; jaa=ja; mi=m-1; ni=n; icc=ic+1; jcc= jc; end if else If side = 'R', nq = n; if((vect = 'Q' and nq ≥ k) or (vect is not equal to 'Q' and nq > k)), iaa=ia; jaa=ja; mi=m; ni=n; icc=ic; jcc=jc; else iaa= ia; jaa= ja+1; mi= m; ni= n-1; icc= ic; jcc= jc+1; end if end if If vect = 'Q', If side = 'L', lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 + mpc0)*nb_a) + nb_a * nb_a else if side = 'R', lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 + max(npa0 + numroc(numroc(ni+icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0))*nb_a) + nb_a*nb_a end if else if vect is not equal to 'Q', if side = 'L', </pre> |

```

lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0 + max(mqa0 +
numroc(numroc(mi+iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0,
lcmp), nqc0))*mb_a) + mb_a*mb_a
else if side = 'R',
lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0 + nqc0)*mb_a) + mb_a*mb_a
end if
end if
where lcmp = lcm/NPROW, lcmq = lcm/NPCOL, with lcm =
ilcm(NPROW, NPCOL),
iroffa = mod(iaa-1, mb_a),
icoffa = mod(jaa-1, nb_a),
iarow = indxg2p(iaa, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(jaa, nb_a, MYCOL, csrc_a, NPCOL),
mqa0 = numroc(mi+icoffa, nb_a, MYCOL, iacol, NPCOL),
npa0 = numroc(ni+iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(icc-1, mb_c),
icoffc = mod(jcc-1, nb_c),
icrow = indxg2p(icc, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jcc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

NOTE

`mod(x, y)` is the integer remainder of x/y .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|----------------------|--|
| <code>c</code> | On exit, if <code>vect='Q'</code> , <code>sub(C)</code> is overwritten by $Q*\text{sub}(C)$, or $Q'*\text{sub}(C)$, or $\text{sub}(C)*Q'$, or $\text{sub}(C)*Q$; if <code>vect='P'</code> , <code>sub(C)</code> is overwritten by $P*\text{sub}(C)$, or $P'*\text{sub}(C)$, or $\text{sub}(C)*P'$, or $\text{sub}(C)*P$. |
| <code>work[0]</code> | On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. |

< 0 : if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?unmbr

Multiplies a general matrix by one of the unitary transformation matrices from a reduction to bidiagonal form determined by p?gebrd.

Syntax

```
void pcunmbr (char *vect , char *side , char *trans , MKL_INT *m , MKL_INT *n ,
MKL_INT *k , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
MKL_Complex8 *tau , MKL_Complex8 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc ,
MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pzunmbr (char *vect , char *side , char *trans , MKL_INT *m , MKL_INT *n ,
MKL_INT *k , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
MKL_Complex16 *tau , MKL_Complex16 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc ,
MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

If $vect = 'Q'$, the `p?unmbr` function overwrites the general complex distributed m -by- n matrix $sub(C) = C(ic:ic+m-1,jc:jc+n-1)$ with

| | | |
|----------------|--------------|--------------|
| | $side = 'L'$ | $side = 'R'$ |
| $trans = 'N':$ | $Q*sub(C)$ | $sub(C)*Q$ |
| $trans = 'C':$ | $Q^H*sub(C)$ | $sub(C)*Q^H$ |

If $vect = 'P'$, the function overwrites $sub(C)$ with

| | | |
|----------------|--------------|--------------|
| | $side = 'L'$ | $side = 'R'$ |
| $trans = 'N':$ | $P*sub(C)$ | $sub(C)*P$ |
| $trans = 'C':$ | $P^H*sub(C)$ | $sub(C)*P^H$ |

Here Q and P^H are the unitary distributed matrices determined by `p?gebrd` when reducing a complex distributed matrix $A(ia:*, ja:*)$ to bidiagonal form: $A(ia:*, ja:*) = Q*B*P^H$.

Q and P^H are defined as products of elementary reflectors $H(i)$ and $G(i)$ respectively.

Let $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$. Therefore nq is the order of the unitary matrix Q or P^H that is applied.

If $vect = 'Q'$, $A(ia:*, ja:*)$ is assumed to have been an nq -by- k matrix:

If $nq \geq k$, $Q = H(1) H(2) \dots H(k)$;

If $nq < k$, $Q = H(1) H(2) \dots H(nq-1)$.

If $vect = 'P'$, $A(ia:*, ja:*)$ is assumed to have been a k -by- nq matrix:

If $k < nq$, $P = G(1) G(2) \dots G(k)$;

If $k \geq nq$, $P = G(1) G(2) \dots G(nq-1)$.

Input Parameters

| | |
|---------------|---|
| <i>vect</i> | (global) If <i>vect</i> = 'Q', then Q or Q^H is applied. If <i>vect</i> = 'P', then P or P^H is applied. |
| <i>side</i> | (global) If <i>side</i> = 'L', then Q or Q^H , P or P^H is applied from the left. If <i>side</i> = 'R', then Q or Q^H , P or P^H is applied from the right. |
| <i>trans</i> | (global) If <i>trans</i> = 'N', no transpose, Q or P is applied. If <i>trans</i> = 'C', conjugate transpose, Q^H or P^H is applied. |
| <i>m</i> | (global) The number of rows in the distributed matrix sub (C) $m \geq 0$. |
| <i>n</i> | (global) The number of columns in the distributed matrix sub (C) $n \geq 0$. |
| <i>k</i> | (global) If <i>vect</i> = 'Q', the number of columns in the original distributed matrix reduced by <code>p?gebrd</code> ; If <i>vect</i> = 'P', the number of rows in the original distributed matrix reduced by <code>p?gebrd</code> . Constraints: $k \geq 0$. |
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a * LOCc(ja + \min(nq, k) - 1)$ if <i>vect</i> = 'Q', and $lld_a * LOCc(ja + nq - 1)$ if <i>vect</i> = 'P'. $nq = m$ if <i>side</i> = 'L', and $nq = n$ otherwise. The vectors that define the elementary reflectors $H(i)$ and $G(i)$, whose products determine the matrices Q and P , as returned by <code>p?gebrd</code> . If <i>vect</i> = 'Q', $lld_a \geq \max(1, LOCr(ia + nq - 1))$; If <i>vect</i> = 'P', $lld_a \geq \max(1, LOCr(ia + \min(nq, k) - 1))$. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A . |
| <i>tau</i> | (local) Array of size $LOCc(ja + \min(nq, k) - 1)$, if <i>vect</i> = 'Q', and $LOCr(ia + \min(nq, k) - 1)$, if <i>vect</i> = 'P'. <i>tau</i> [<i>i</i>] must contain the scalar factor of the elementary reflector $H(i+1)$ or $G(i+1)$, which determines Q or P , as returned by <code>p?gebrd</code> in its array argument <i>tauq</i> or <i>taup</i> . <i>tau</i> is tied to the distributed matrix A . |

| | |
|---------------|--|
| <i>c</i> | (local) Pointer into the local memory to an array of size $lld_c * LOCC(jc+n-1)$. Contains the local pieces of the distributed matrix sub (C). |
| <i>ic, jc</i> | (global) The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively. |
| <i>desc</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> . |
| <i>work</i> | (local) Workspace array of size <i>lwork</i> . |
| <i>lwork</i> | (local or global) size of <i>work</i> , must be at least: <pre> If <i>side</i> = 'L' <i>nq</i> = <i>m</i>; if ((<i>vect</i> = 'Q' and <i>nq</i> ≥ <i>k</i>) or (<i>vect</i> is not equal to 'Q' and <i>nq</i> > <i>k</i>)), <i>iaa</i> = <i>ia</i>; <i>jaa</i> = <i>ja</i>; <i>mi</i> = <i>m</i>; <i>ni</i> = <i>n</i>; <i>icc</i> = <i>ic</i>; <i>jcc</i> = <i>jc</i>; else <i>iaa</i> = <i>ia</i>+1; <i>jaa</i> = <i>ja</i>; <i>mi</i> = <i>m</i>-1; <i>ni</i> = <i>n</i>; <i>icc</i> = <i>ic</i>+1; <i>jcc</i> = <i>jc</i>; end if else If <i>side</i> = 'R', <i>nq</i> = <i>n</i>; if ((<i>vect</i> = 'Q' and <i>nq</i> ≥ <i>k</i>) or (<i>vect</i> is not equal to 'Q' and <i>nq</i> > <i>k</i>)), <i>iaa</i> = <i>ia</i>; <i>jaa</i> = <i>ja</i>; <i>mi</i> = <i>m</i>; <i>ni</i> = <i>n</i>; <i>icc</i> = <i>ic</i>; <i>jcc</i> = <i>jc</i>; else <i>iaa</i> = <i>ia</i>; <i>jaa</i> = <i>ja</i>+1; <i>mi</i> = <i>m</i>; <i>ni</i> = <i>n</i>-1; <i>icc</i> = <i>ic</i>; <i>jcc</i> = <i>jc</i>+1; end if end if If <i>vect</i> = 'Q', If <i>side</i> = 'L', <i>lwork</i> ≥ max((<i>nb_a</i>*(<i>nb_a</i>-1))/2, (<i>nqc</i>0+<i>mpc</i>0)*<i>nb_a</i>) + <i>nb_a</i>*<i>nb_a</i> else if <i>side</i> = 'R', <i>lwork</i> ≥ max((<i>nb_a</i>*(<i>nb_a</i>-1))/2, (<i>nqc</i>0 + max(<i>npa</i>0+numroc(numroc(<i>ni</i>+<i>icoffc</i>, <i>nb_a</i>, 0, 0, NPCOL), <i>nb_a</i>, 0, 0, <i>lcmq</i>), <i>mpc</i>0))*<i>nb_a</i>) + <i>nb_a</i>*<i>nb_a</i> end if else if <i>vect</i> is not equal to 'Q', if <i>side</i> = 'L', <i>lwork</i> ≥ max((<i>mb_a</i>*(<i>mb_a</i>-1))/2, (<i>mpc</i>0 + max(<i>mqa</i>0+numroc(numroc(<i>mi</i>+<i>iroffc</i>, <i>mb_a</i>, 0, 0, NPROW), <i>mb_a</i>, 0, 0, <i>lcmp</i>), <i>nqc</i>0))*<i>mb_a</i>) + <i>mb_a</i>*<i>mb_a</i> </pre> |

```

else if side = 'R',
  lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0 + nqc0)*mb_a) + mb_a*mb_a
end if
end if
where lcmp = lcm/NPROW, lcmq = lcm/NPCOL, with lcm =
  ilcm(NPROW, NPCOL),
irowfa = mod(iaa-1, mb_a),
icoffa = mod(jaa-1, nb_a),
iarow = indxg2p(iaa, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(jaa, nb_a, MYCOL, csrc_a, NPCOL),
mqa0 = numroc(mi+icoffa, nb_a, MYCOL, iacol, NPCOL),
npa0 = numroc(ni+irowfa, mb_a, MYROW, iarow, NPROW),
irowfc = mod(icc-1, mb_c),
icoffc = mod(jcc-1, nb_c),
icrow = indxg2p(icc, mb_c, MYROW, rsrc_c, NPROW),
icol = indxg2p(jcc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(mi+irowfc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(ni+icoffc, nb_c, MYCOL, icol, NPCOL),

```

NOTE

mod(*x*, *y*) is the integer remainder of *x*/*y*.

`indxg2p` and `numroc` are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function `blacs_gridinfo`.

If `lwork` = -1, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|----------------------|--|
| <code>c</code> | On exit, if <code>vect='Q'</code> , <code>sub(C)</code> is overwritten by <code>Q*sub(C)</code> , or <code>Q'*sub(C)</code> , or <code>sub(C)*Q'</code> , or <code>sub(C)*Q</code> ; if <code>vect='P'</code> , <code>sub(C)</code> is overwritten by <code>P*sub(C)</code> , or <code>P'*sub(C)</code> , or <code>sub(C)*P</code> , or <code>sub(C)*P'</code> . |
| <code>work[0]</code> | On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <code>info</code> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info</code> = - <i>i</i> . |

Generalized Symmetric-Definite Eigenvalue Problems: ScaLAPACK Computational Routines

This section describes ScaLAPACK routines that allow you to reduce the *generalized symmetric-definite eigenvalue problems* (see [Generalized Symmetric-Definite Eigenvalue Problems](#) in LAPACK chapters) to standard symmetric eigenvalue problem $Cy = \lambda y$, which you can solve by calling ScaLAPACK routines described earlier in this chapter (see [Symmetric Eigenproblems](#)).

Table "Computational Routines for Reducing Generalized Eigenproblems to Standard Problems" lists these routines.

Computational Routines for Reducing Generalized Eigenproblems to Standard Problems

| Operation | Real symmetric matrices | Complex Hermitian matrices |
|-----------------------------|-------------------------|----------------------------|
| Reduce to standard problems | p?sygst | p?hegst |

p?sygst

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form.

Syntax

```
void pssygst (MKL_INT *ibtype , char *uplo , MKL_INT *n , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb ,
float *scale , MKL_INT *info );

void pdsygst (MKL_INT *ibtype , char *uplo , MKL_INT *n , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT
*scale , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?sygst function reduces real symmetric-definite generalized eigenproblems to the standard form.

In the following sub(A) denotes $A(ia:ia+n-1, ja:ja+n-1)$ and sub(B) denotes $B(ib:ib+n-1, jb:jb+n-1)$.

If $ibtype = 1$, the problem is

$$\text{sub}(A)*x = \lambda*\text{sub}(B)*x,$$

and sub(A) is overwritten by $\text{inv}(U^T)*\text{sub}(A)*\text{inv}(U)$, or $\text{inv}(L)*\text{sub}(A)*\text{inv}(L^T)$.

If $ibtype = 2$ or 3 , the problem is

$$\text{sub}(A)*\text{sub}(B)*x = \lambda*x, \text{ or } \text{sub}(B)*\text{sub}(A)*x = \lambda*x,$$

and sub(A) is overwritten by $U*\text{sub}(A)*U^T$, or $L^T*\text{sub}(A)*L$.

sub(B) must have been previously factorized as U^T*U or $L*L^T$ by p?potrf.

Input Parameters

ibtype (global) Must be 1 or 2 or 3.

If $itype = 1$, compute $\text{inv}(U^T)*\text{sub}(A)*\text{inv}(U)$, or $\text{inv}(L)*\text{sub}(A)*\text{inv}(L^T)$;

| | |
|---------------|---|
| | If $itype = 2$ or 3 , compute $U*\text{sub}(A)*U^T$, or $L^T*\text{sub}(A)*L$. |
| <i>uplo</i> | (global) Must be 'U' or 'L'. If $uplo = 'U'$, the upper triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as U^T*U . If $uplo = 'L'$, the lower triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as $L*L^T$. |
| <i>n</i> | (global) The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$). |
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a*LOCc(ja+n-1)$. On entry, the array contains the local pieces of the n -by- n symmetric distributed matrix $\text{sub}(A)$. If $uplo = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <i>b</i> | (local) Pointer into the local memory to an array of size $lld_b*LOCc(jb+n-1)$. On entry, the array contains the local pieces of the triangular factor from the Cholesky factorization of $\text{sub}(B)$ as returned by <code>p?potrf</code> . |
| <i>ib, jb</i> | (global) The row and column indices in the global matrix B indicating the first row and the first column of the submatrix B , respectively. |
| <i>descb</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix B . |

Output Parameters

| | |
|--------------|---|
| <i>a</i> | On exit, if $info = 0$, the transformed matrix, stored in the same format as $\text{sub}(A)$. |
| <i>scale</i> | (global) Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this function. At present, <i>scale</i> is always returned as 1.0, it is returned here to allow for future enhancement. |
| <i>info</i> | (global) |

If $info = 0$, the execution is successful. If $info < 0$, if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?hegst

Reduces a Hermitian positive-definite generalized eigenvalue problem to the standard form.

Syntax

```
void pchegst (MKL_INT *ibtype , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , float *scale , MKL_INT *info );
```

```
void pzhegst (MKL_INT *ibtype , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , double *scale , MKL_INT *info );
```

Description

The `p?gesv` function computes the solution to a real or complex system of linear equations $\text{sub}(A) * X = \text{sub}(B)$, where $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ is an n -by- n distributed matrix and X and $\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1)$ are n -by- $nrhs$ distributed matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor $\text{sub}(A)$ as $\text{sub}(A) = P * L * U$, where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. L and U are stored in $\text{sub}(A)$. The factored form of $\text{sub}(A)$ is then used to solve the system of equations $\text{sub}(A) * X = \text{sub}(B)$.

Input Parameters

| | |
|---------------|---|
| <i>n</i> | (global) The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$). |
| <i>nrhs</i> | (global) The number of right hand sides, that is, the number of columns of the distributed submatrices B and X ($nrhs \geq 0$). |
| <i>a, b</i> | (local) Pointers into the local memory to arrays of local size <i>a</i> : $lld_a * LOCC(\text{ja} + n - 1)$ and <i>b</i> : $lld_b * LOCC(\text{jb} + nrhs - 1)$, respectively. On entry, the array <i>a</i> contains the local pieces of the n -by- n distributed matrix $\text{sub}(A)$ to be factored. On entry, the array <i>b</i> contains the right hand side distributed matrix $\text{sub}(B)$. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of $\text{sub}(A)$, respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A . |
| <i>ib, jb</i> | (global) The row and column indices in the global matrix B indicating the first row and the first column of $\text{sub}(B)$, respectively. |
| <i>descb</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix B . |

Output Parameters

| | |
|-------------|--|
| <i>a</i> | Overwritten by the factors L and U from the factorization $\text{sub}(A) = P * L * U$; the unit diagonal elements of L are not stored . |
| <i>b</i> | Overwritten by the solution distributed matrix X . |
| <i>ipiv</i> | (local) Array of size $LOCr(m_a) + mb_a$. This array contains the pivoting information. The (local) row <i>i</i> of the matrix was interchanged with the (global) row $ipiv[i - 1]$. This array is tied to the distributed matrix A . |
| <i>info</i> | (global) If $info=0$, the execution is successful. $info < 0$: |

If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

$info > 0$:

If $info = k$, $U(ia+k-1, ja+k-1)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

Description

The `p?gesvx` function uses the *LU* factorization to compute the solution to a real or complex system of linear equations $AX = B$, where A denotes the n -by- n submatrix $A(ia:ia+n-1, ja:ja+n-1)$, B denotes the n -by- $nrhs$ submatrix $B(ib:ib+n-1, jb:jb+nrhs-1)$ and X denotes the n -by- $nrhs$ submatrix $X(ix:ix+n-1, jx:jx+nrhs-1)$.

Error bounds on the solution and a condition estimate are also provided.

In the following description, af stands for the subarray of af from row iaf and column jaf to row $iaf+n-1$ and column $jaf+n-1$.

The function `p?gesvx` performs the following steps:

1. If $fact = 'E'$, real scaling factors R and C are computed to equilibrate the system:

$trans = 'N'$: $diag(R) * A * diag(C) * diag(C)^{-1} * X = diag(R) * B$

$trans = 'T'$: $(diag(R) * A * diag(C))^T * diag(R)^{-1} * X = diag(C) * B$

$trans = 'C'$: $(diag(R) * A * diag(C))^H * diag(R)^{-1} * X = diag(C) * B$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $diag(R) * A * diag(C)$ and B by $diag(R) * B$ (if $trans = 'N'$) or $diag(C) * B$ (if $trans = 'T'$ or $'C'$).

2. If $fact = 'N'$ or $'E'$, the *LU* decomposition is used to factor the matrix A (after equilibration if $fact = 'E'$) as $A = PLU$, where P is a permutation matrix, L is a unit lower triangular matrix, and U is upper triangular.
3. The factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than relative machine precision, steps 4 - 6 are skipped.
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $diag(C)$ (if $trans = 'N'$) or $diag(R)$ (if $trans = 'T'$ or $'C'$) so that it solves the original system before equilibration.

Input Parameters

| | |
|--------------------|--|
| <code>fact</code> | <p>(global) Must be $'F'$, $'N'$, or $'E'$.</p> <p>Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.</p> <p>If $fact = 'F'$ then, on entry, af and $ipiv$ contain the factored form of A. If $equed$ is not $'N'$, the matrix A has been equilibrated with scaling factors given by r and c. Arrays a, af, and $ipiv$ are not modified.</p> <p>If $fact = 'N'$, the matrix A is copied to af and factored.</p> <p>If $fact = 'E'$, the matrix A is equilibrated if necessary, then copied to af and factored.</p> |
| <code>trans</code> | <p>(global) Must be $'N'$, $'T'$, or $'C'$.</p> <p>Specifies the form of the system of equations:</p> <p>If $trans = 'N'$, the system has the form $A * X = B$ (No transpose);</p> <p>If $trans = 'T'$, the system has the form $A^T * X = B$ (Transpose);</p> <p>If $trans = 'C'$, the system has the form $A^H * X = B$ (Conjugate transpose);</p> |

| | |
|-----------------------|--|
| <i>n</i> | (global) The number of linear equations; the order of the submatrix A ($n \geq 0$). |
| <i>nrhs</i> | (global) The number of right hand sides; the number of columns of the distributed submatrices B and X ($nrhs \geq 0$). |
| <i>a, af, b, work</i> | (local) Pointers into the local memory to arrays of local size <i>a</i> : $lld_a * LOCC(ja + n - 1)$, <i>af</i> : $lld_af * LOCC(ja + n - 1)$, <i>b</i> : $lld_b * LOCC(jb + nrhs - 1)$, <i>work</i> : $lwork$. The array <i>a</i> contains the matrix A . If <i>fact</i> = 'F' and <i>equed</i> is not 'N', then A must have been equilibrated by the scaling factors in <i>r</i> and/or <i>c</i> . The array <i>af</i> is an input argument if <i>fact</i> = 'F'. In this case it contains on entry the factored form of the matrix A , that is, the factors L and U from the factorization $A = P * L * U$ as computed by <code>p?getrf</code> . If <i>equed</i> is not 'N', then <i>af</i> is the factored form of the equilibrated matrix A . The array <i>b</i> contains on entry the matrix B whose columns are the right-hand sides for the systems of equations. <i>work</i> is a workspace array. The size of <i>work</i> is (<i>lwork</i>). |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix $A(ia:ia+n-1, ja:ja+n-1)$, respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A . |
| <i>iaf, jaf</i> | (global) The row and column indices in the global matrix AF indicating the first row and the first column of the subarray <i>af</i> , respectively. |
| <i>descaf</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix AF . |
| <i>ib, jb</i> | (global) The row and column indices in the global matrix B indicating the first row and the first column of the submatrix $B(ib:ib+n-1, jb:jb+nrhs-1)$, respectively. |
| <i>descb</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix B . |
| <i>ipiv</i> | (local) Array of size $LOCr(m_a) + mb_a$. The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F'. On entry, it contains the pivot indices from the factorization $A = P * L * U$ as computed by <code>p?getrf</code> ; (local) row <i>i</i> of the matrix was interchanged with the (global) row <i>ipiv</i> [<i>i</i> - 1]. This array must be aligned with $A(ia:ia+n-1, *)$. |
| <i>equed</i> | (global) Must be 'N', 'R', 'C', or 'B'. <i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done: If <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N'); |

If *equed* = 'R', row equilibration was done, that is, *A* has been premultiplied by *diag(r)*;
 If *equed* = 'C', column equilibration was done, that is, *A* has been postmultiplied by *diag(c)*;
 If *equed* = 'B', both row and column equilibration was done; *A* has been replaced by *diag(r) * A * diag(c)*.

r, c

(local)

Arrays of size *LOCr(m_a)* and *LOCc(n_a)*, respectively.

The array *r* contains the row scale factors for *A*, and the array *c* contains the column scale factors for *A*. These arrays are input arguments if *fact* = 'F' only; otherwise they are output arguments. If *equed* = 'R' or 'B', *A* is multiplied on the left by *diag(r)*; if *equed* = 'N' or 'C', *r* is not accessed.

If *fact* = 'F' and *equed* = 'R' or 'B', each element of *r* must be positive.

If *equed* = 'C' or 'B', *A* is multiplied on the right by *diag(c)*; if *equed* = 'N' or 'R', *c* is not accessed.

If *fact* = 'F' and *equed* = 'C' or 'B', each element of *c* must be positive. Array *r* is replicated in every process column, and is aligned with the distributed matrix *A*. Array *c* is replicated in every process row, and is aligned with the distributed matrix *A*.

ix, jx

(global) The row and column indices in the global matrix *X* indicating the first row and the first column of the submatrix *X(ix:ix+n-1, jx:jx+nrhs-1)*, respectively.

descx

(global and local) array of size *dlen_*. The array descriptor for the distributed matrix *X*.

lwork

(local or global) The size of the array *work*; must be at least $\max(p?gecon(lwork), p?gerfs(lwork)) + LOCr(n_a)$.

iwork

(local, *psgesvx*/*pdgesvx* only). Workspace array. The size of *iwork* is (*liwork*).

liwork

(local, *psgesvx*/*pdgesvx* only). The size of the array *iwork*, must be at least *LOCr(n_a)*.

rwork

(local)

Workspace array, used in complex flavors only.

The size of *rwork* is (*lrwork*).

lrwork

(local or global, *pcgesvx*/*pzgesvx* only). The size of the array *rwork*; must be at least $2 * LOCc(n_a)$.

Output Parameters

x

(local)

Pointer into the local memory to an array of local size $l1d_x * LOCC(jx + nrhs - 1)$.

If $info = 0$, the array x contains the solution matrix X to the *original* system of equations. Note that A and B are modified on exit if $equed \neq 'N'$, and the solution to the *equilibrated* system is:

$diag(C)^{-1} * X$, if $trans = 'N'$ and $equed = 'C'$ or $'B'$; and
 $diag(R)^{-1} * X$, if $trans = 'T'$ or $'C'$ and $equed = 'R'$ or $'B'$.

a

Array a is not modified on exit if $fact = 'F'$ or $'N'$, or if $fact = 'E'$ and $equed = 'N'$.

If $equed \neq 'N'$, A is scaled on exit as follows:

$equed = 'R'$: $A = diag(R) * A$

$equed = 'C'$: $A = A * diag(c)$

$equed = 'B'$: $A = diag(R) * A * diag(c)$

af

If $fact = 'N'$ or $'E'$, then af is an output argument and on exit returns the factors L and U from the factorization $A = P * L * U$ of the original matrix A (if $fact = 'N'$) or of the equilibrated matrix A (if $fact = 'E'$). See the description of a for the form of the equilibrated matrix.

b

Overwritten by $diag(R) * B$ if $trans = 'N'$ and $equed = 'R'$ or $'B'$;

overwritten by $diag(c) * B$ if $trans = 'T'$ and $equed = 'C'$ or $'B'$; not changed if $equed = 'N'$.

r, c

These arrays are output arguments if $fact \neq 'F'$.

See the description of r, c in *Input Arguments* section.

$rcond$

(global).

An estimate of the reciprocal condition number of the matrix A after equilibration (if done). The function sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

$ferr, berr$

(local)

Arrays of size $LOCC(n_b)$ each. Contain the component-wise forward and relative backward errors, respectively, for each solution vector.

Arrays $ferr$ and $berr$ are both replicated in every process row, and are aligned with the matrices B and X .

$ipiv$

If $fact = 'N'$ or $'E'$, then $ipiv$ is an output argument and on exit contains the pivot indices from the factorization $A = P * L * U$ of the original matrix A (if $fact = 'N'$) or of the equilibrated matrix A (if $fact = 'E'$).

$equed$

If $fact \neq 'F'$, then $equed$ is an output argument. It specifies the form of equilibration that was done (see the description of $equed$ in *Input Arguments* section).

| | |
|-----------------------|--|
| <code>work[0]</code> | If <code>info=0</code> , on exit <code>work[0]</code> returns the minimum value of <code>lwork</code> required for optimum performance. |
| <code>iwork[0]</code> | If <code>info=0</code> , on exit <code>iwork[0]</code> returns the minimum value of <code>liwork</code> required for optimum performance. |
| <code>rwork[0]</code> | If <code>info=0</code> , on exit <code>rwork[0]</code> returns the minimum value of <code>lrwork</code> required for optimum performance. |
| <code>info</code> | If <code>info=0</code> , the execution is successful. <i>info</i> < 0: if the <i>i</i> th argument is an array and the <i>j</i> th entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . If <i>info</i> = <i>i</i> , and $i \leq n$, then $U(i,i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. If <i>info</i> = <i>i</i> , and $i = n + 1$, then U is nonsingular, but <i>rcond</i> is less than machine precision. The factorization has been completed, but the matrix is singular to working precision and the solution and error bounds have not been computed. |

Include Files

- `mkl_scalapack.h`

Description

The `p?gbsv` function computes the solution to a real or complex system of linear equations

$$\text{sub}(A) * X = \text{sub}(B),$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is an n -by- n real/complex general banded distributed matrix with bwl subdiagonals and bwu superdiagonals, and X and $\text{sub}(B) = B(ib:ib+n-1, 1:rhs)$ are n -by- $nrhs$ distributed matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor $\text{sub}(A)$ as $\text{sub}(A) = P^*L^*U^*Q$, where P and Q are permutation matrices, and L and U are banded lower and upper triangular matrices, respectively. The matrix Q represents reordering of columns for the sake of parallelism, while P represents reordering of rows for numerical stability using classic partial pivoting.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

| | |
|---------|---|
| n | (global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$). |
| bwl | (global) The number of subdiagonals within the band of A ($0 \leq bwl \leq n-1$). |
| bwu | (global) The number of superdiagonals within the band of A ($0 \leq bwu \leq n-1$). |
| $nrhs$ | (global) The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ($nrhs \geq 0$). |
| a, b | (local) Pointers into the local memory to arrays of local size a : $lld_a * LOCC(ja + n - 1)$ and b : $lld_b * LOCC(nrhs)$. On entry, the array a contains the local pieces of the global array A . On entry, the array b contains the right hand side distributed matrix $\text{sub}(B)$. |
| ja | (global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A). |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . If $desca[dtype_ - 1] = 501$, then $dlen_ \geq 7$; else if $desca[dtype_ - 1] = 1$, then $dlen_ \geq 9$. |
| ib | (global) The row index in the global matrix B indicating the first row of the matrix to be operated on (which may be either all of B or a submatrix of B). |
| $descb$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix B . If $descb[dtype_ - 1] = 502$, then $dlen_ \geq 7$; |

else if $descb[dtype_ -1] = 1$, then $dlen \geq 9$.

work

(local)

Workspace array of size *lwork*.

lwork

(local or global) The size of the array *work*, must be at least $lwork \geq (NB + bwu) * (bwl + bwu) + 6 * (bwl + bwu) * (bwl + 2 * bwu) + \max(nrhs * (NB + 2 * bwl + 4 * bwu), 1)$.

Output Parameters

a

On exit, contains details of the factorization. Note that the resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

b

On exit, this array contains the local pieces of the solution distributed matrix *X*.

ipiv

(local) array.

The size of *ipiv* must be at least $desca[NB - 1]$. This array contains pivot indices for local factorizations. You should not alter the contents between factorization and solve.

work[0]

On exit, *work*[0] contains the minimum value of *lwork* required for optimum performance.

info

If *info*=0, the execution is successful. *info* < 0:

If the *i*th argument is an array and the *j*-th entry had an illegal value, then $info = -(i * 100 + j)$; if the *i*th argument is a scalar and had an illegal value, then $info = -i$.

info > 0:

If $info = k \leq NPROCS$, the submatrix stored on processor *info* and factored locally was not nonsingular, and the factorization was not completed. If $info = k > NPROCS$, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

Description

The `p?dbsv` function solves the following system of linear equations:

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n real/complex banded diagonally dominant-like distributed matrix with bandwidth bwl , bwu .

Gaussian elimination without pivoting is used to factor a reordering of the matrix into LU .

Input Parameters

| | |
|--------|--|
| n | (global) The order of the distributed submatrix A , ($n \geq 0$). |
| bwl | (global) Number of subdiagonals. $0 \leq bwl \leq n-1$. |
| bwu | (global) Number of subdiagonals. $0 \leq bwu \leq n-1$. |
| $nrhs$ | (global) The number of right-hand sides; the number of columns of the distributed submatrix B , ($nrhs \geq 0$). |
| a | (local). Pointer into the local memory to an array with leading size $lld_a \geq (bwl + bwu + 1)$ (stored in $desca$). On entry, this array contains the local pieces of the distributed matrix. |
| ja | (global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A). |

| | |
|--------------|---|
| <i>desca</i> | (global and local) array of size <i>dlen</i> . If 1d type (<i>dtype_a</i> =501 or 502), <i>dlen</i> ≥ 7; If 2d type (<i>dtype_a</i> =1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>A</i> . Contains information of mapping of <i>A</i> to memory. |
| <i>b</i> | (local) Pointer into the local memory to an array of local lead size <i>lld_b</i> ≥ <i>nb</i> . On entry, this array contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$. |
| <i>ib</i> | (global) The row index in the global matrix <i>B</i> indicating the first row of the matrix to be operated on (which may be either all of <i>b</i> or a submatrix of <i>B</i>). |
| <i>descb</i> | (global and local) array of size <i>dlen</i> . If 1d type (<i>dtype_b</i> =502), <i>dlen</i> ≥ 7; If 2d type (<i>dtype_b</i> =1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>B</i> . Contains information of mapping of <i>B</i> to memory. |
| <i>work</i> | (local). Temporary workspace. This space may be overwritten in between calls to functions. <i>work</i> must be the size given in <i>lwork</i> . |
| <i>lwork</i> | (local or global) Size of user-input workspace <i>work</i> . If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i> [0] and an error code is returned. $lwork \geq nb(bw1+bwu) + 6\max(bw1, bwu) * \max(bw1, bwu) + \max(\max(bw1, bwu) nrhs, \max(bw1, bwu) * \max(bw1, bwu))$ |

Output Parameters

| | |
|-------------|---|
| <i>a</i> | On exit, this array contains information containing details of the factorization. Note that permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK. |
| <i>b</i> | On exit, this contains the local piece of the solutions distributed matrix <i>X</i> . |
| <i>work</i> | On exit, <i>work</i> [0] contains the minimal <i>lwork</i> . |
| <i>info</i> | (local) If <i>info</i> =0, the execution is successful. < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . > 0: If <i>info</i> = <i>k</i> < NPROCS, the submatrix stored on processor <i>info</i> and factored locally was not positive definite, and the factorization was not completed. |

If $info = k > NPROCS$, the submatrix stored on processor $info - NPROCS$ representing interactions with other processors was not positive definite, and the factorization was not completed.

Description

The function solves a system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n complex tridiagonal diagonally dominant-like distributed matrix.

Gaussian elimination without pivoting is used to factor a reordering of the matrix into LU .

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

| | |
|--------------|--|
| <i>n</i> | (global) The order of the distributed submatrix A ($n \geq 0$). |
| <i>nrhs</i> | The number of right hand sides; the number of columns of the distributed matrix B ($nrhs \geq 0$). |
| <i>d1</i> | (local). Pointer to local part of global vector storing the lower diagonal of the matrix. Globally, $d1[0]$ is not referenced, and $d1$ must be aligned with d . Must be of size $> desca[nb_ - 1]$. |
| <i>d</i> | (local). Pointer to local part of global vector storing the main diagonal of the matrix. |
| <i>du</i> | (local). Pointer to local part of global vector storing the upper diagonal of the matrix. Globally, $du[n - 1]$ is not referenced, and du must be aligned with d . |
| <i>ja</i> | (global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A). |
| <i>desca</i> | (global and local) array of size $dlen$. If 1d type ($dtype_a=501$ or 502), $dlen \geq 7$; If 2d type ($dtype_a=1$), $dlen \geq 9$. The array descriptor for the distributed matrix A . Contains information of mapping of A to memory. |
| <i>b</i> | (local) Pointer into the local memory to an array of local lead size $lld_b > nb$. On entry, this array contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$. |
| <i>ib</i> | (global) The row index in the global matrix B indicating the first row of the matrix to be operated on (which may be either all of b or a submatrix of B). |
| <i>descb</i> | (global and local) array of size $dlen$. If 1d type ($dtype_b=502$), $dlen \geq 7$; If 2d type ($dtype_b=1$), $dlen \geq 9$. The array descriptor for the distributed matrix B . Contains information of mapping of B to memory. |
| <i>work</i> | (local). |
| <i>lwork</i> | (local or global) Size of user-input workspace $work$. If $lwork$ is too small, the minimal acceptable size will be returned in $work[0]$ and an error code is returned. $lwork > (12*NPCOL+3*nb)+\max((10+2*\min(100, nrhs))*NPCOL+4*nrhs, 8*NPCOL)$ |

Output Parameters

| | |
|-------------|---|
| <i>dl</i> | On exit, this array contains information containing the * factors of the matrix. |
| <i>d</i> | On exit, this array contains information containing the * factors of the matrix. Must be of size $> \text{desca}[\text{nb}_- - 1]$. |
| <i>du</i> | On exit, this array contains information containing the * factors of the matrix. Must be of size $> \text{desca}[\text{nb}_- - 1]$. |
| <i>b</i> | On exit, this contains the local piece of the solutions distributed matrix <i>X</i> . |
| <i>work</i> | On exit, <i>work</i> [0] contains the minimal <i>lwork</i> . |
| <i>info</i> | <p>(local) If <i>info</i>=0, the execution is successful.</p> <p>< 0: If the <i>i</i>-th argument is an array and the <i>j</i>-entry had an illegal value, then $\text{info} = -(i*100+j)$, if the <i>i</i>-th argument is a scalar and had an illegal value, then $\text{info} = -i$.</p> <p>> 0: If $\text{info} = k < \text{NPROCS}$, the submatrix stored on processor <i>info</i> and factored locally was not positive definite, and the factorization was not completed.</p> <p>If $\text{info} = k > \text{NPROCS}$, the submatrix stored on processor $\text{info} - \text{NPROCS}$ representing interactions with other processors was not positive definite, and the factorization was not completed.</p> |

*descb , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?posv` function computes the solution to a real/complex system of linear equations

$$\text{sub}(A) * X = \text{sub}(B),$$

where $\text{sub}(A)$ denotes $A(ia:ia+n-1, ja:ja+n-1)$ and is an n -by- n symmetric/Hermitian distributed positive definite matrix and X and $\text{sub}(B)$ denoting $B(ib:ib+n-1, jb:jb+nrhs-1)$ are n -by- $nrhs$ distributed matrices. The Cholesky decomposition is used to factor $\text{sub}(A)$ as

$$\text{sub}(A) = U^T * U, \text{ if } \text{uplo} = 'U', \text{ or}$$

$$\text{sub}(A) = L * L^T, \text{ if } \text{uplo} = 'L',$$

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of $\text{sub}(A)$ is then used to solve the system of equations.

Input Parameters

| | |
|---------------|--|
| <i>uplo</i> | (global) Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of $\text{sub}(A)$ is stored. |
| <i>n</i> | (global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$). |
| <i>nrhs</i> | The number of right-hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ($nrhs \geq 0$). |
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$. On entry, this array contains the local pieces of the n -by- n symmetric distributed matrix $\text{sub}(A)$ to be factored. If $\text{uplo} = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If $\text{uplo} = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <i>b</i> | (local) Pointer into the local memory to an array of size $lld_b * LOCC(jb+nrhs-1)$. On entry, the local pieces of the right hand sides distributed matrix $\text{sub}(B)$. |
| <i>ib, jb</i> | (global) The row and column indices in the global matrix B indicating the first row and the first column of the submatrix B , respectively. |
| <i>descb</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix B . |

Output Parameters

| | |
|-------------|--|
| <i>a</i> | On exit, if <i>info</i> = 0, this array contains the local pieces of the factor <i>U</i> or <i>L</i> from the Cholesky factorization $\text{sub}(A) = U^H * U$, or $L * L^H$. |
| <i>b</i> | On exit, if <i>info</i> = 0, $\text{sub}(B)$ is overwritten by the solution distributed matrix <i>X</i> . |
| <i>info</i> | (global) If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> -1, had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . If <i>info</i> > 0: If <i>info</i> = <i>k</i> , the leading minor of order <i>k</i> , $A(\text{ia}:\text{ia}+\text{k}-1, \text{ja}:\text{ja}+\text{k}-1)$ is not positive definite, and the factorization could not be completed, and the solution has not been computed. |

Description

The `p?posvx` function uses the Cholesky factorization $A=U^T*U$ or $A=L*L^T$ to compute the solution to a real or complex system of linear equations

$$A(ia:ia+n-1, ja:ja+n-1)*X = B(ib:ib+n-1, jb:jb+nrhs-1),$$

where $A(ia:ia+n-1, ja:ja+n-1)$ is a n -by- n matrix and X and $B(ib:ib+n-1, jb:jb+nrhs-1)$ are n -by- $nrhs$ matrices.

Error bounds on the solution and a condition estimate are also provided.

In the following comments y denotes $Y(iy:iy+m-1, jy:jy+k-1)$, an m -by- k matrix where y can be a , af , b and x .

The function `p?posvx` performs the following steps:

1. If `fact = 'E'`, real scaling factors s are computed to equilibrate the system:

$$\text{diag}(sr)*A*\text{diag}(sc)*\text{inv}(\text{diag}(sc))*X = \text{diag}(sr)*B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(sr)*A*\text{diag}(sc)$ and B by $\text{diag}(sr)*B$.

2. If `fact = 'N'` or `'E'`, the Cholesky decomposition is used to factor the matrix A (after equilibration if `fact = 'E'`) as

$$A = U^T*U, \text{ if } \text{uplo} = 'U', \text{ or}$$

$$A = L*L^T, \text{ if } \text{uplo} = 'L',$$

where U is an upper triangular matrix and L is a lower triangular matrix.

3. The factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, steps 4-6 are skipped
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(sr)$ so that it solves the original system before equilibration.

Input Parameters

`fact` (global) Must be 'F', 'N', or 'E'.

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

If `fact = 'F'`: on entry, `af` contains the factored form of A . If `equed = 'Y'`, the matrix A has been equilibrated with scaling factors given by s . a and `af` will not be modified.

If `fact = 'N'`, the matrix A will be copied to `af` and factored.

If `fact = 'E'`, the matrix A will be equilibrated if necessary, then copied to `af` and factored.

| | |
|-----------------|--|
| <i>uplo</i> | (global) Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored. |
| <i>n</i> | (global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$). |
| <i>nrhs</i> | (global) The number of right-hand sides; the number of columns of the distributed submatrices B and X . ($nrhs \geq 0$). |
| <i>a</i> | (local) Pointer into the local memory to an array of local size $lld_a * LOCC(ja + n - 1)$. On entry, the symmetric/Hermitian matrix A , except if $fact = 'F'$ and $equed = 'Y'$, then A must contain the equilibrated matrix $\text{diag}(sr) * A * \text{diag}(sc)$. If $uplo = 'U'$, the leading n -by- n upper triangular part of A contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of A contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced. A is not modified if $fact = 'F'$ or 'N', or if $fact = 'E'$ and $equed = 'N'$ on exit. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <i>af</i> | (local) Pointer into the local memory to an array of local size $lld_af * LOCC(ja + n - 1)$. If $fact = 'F'$, then af is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$, in the same storage format as A . If $equed \neq 'N'$, then af is the factored form of the equilibrated matrix $\text{diag}(sr) * A * \text{diag}(sc)$. |
| <i>iaf, jaf</i> | (global) The row and column indices in the global matrix AF indicating the first row and the first column of the submatrix AF , respectively. |
| <i>descaf</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix AF . |
| <i>equed</i> | (global) Must be 'N' or 'Y'. $equed$ is an input argument if $fact = 'F'$. It specifies the form of equilibration that was done: If $equed = 'N'$, no equilibration was done (always true if $fact = 'N'$); If $equed = 'Y'$, equilibration was done and A has been replaced by $\text{diag}(sr) * A * \text{diag}(sc)$. |
| <i>sr</i> | (local) Array of size lld_a . |

The array *s* contains the scale factors for *A*. This array is an input argument if *fact* = 'F' only; otherwise it is an output argument.

If *equed* = 'N', *s* is not accessed.

If *fact* = 'F' and *equed* = 'Y', each element of *s* must be positive.

| | |
|---------------|---|
| <i>b</i> | (local) Pointer into the local memory to an array of local size $lld_b * LOCC(jb + nrhs - 1)$. On entry, the <i>n</i> -by- <i>nrhs</i> right-hand side matrix <i>B</i> . |
| <i>ib, jb</i> | (global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively. |
| <i>descb</i> | (global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> . |
| <i>x</i> | (local) Pointer into the local memory to an array of local size $lld_x * LOCC(jx + nrhs - 1)$. |
| <i>ix, jx</i> | (global) The row and column indices in the global matrix <i>X</i> indicating the first row and the first column of the submatrix <i>X</i> , respectively. |
| <i>descx</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>X</i> . |
| <i>work</i> | (local) Workspace array of size <i>lwork</i> . |
| <i>lwork</i> | (local or global) The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork = \max(p?pocon(lwork), p?porfs(lwork)) + LOCr(n_a)$. $lwork = 3 * desca[lld_ - 1]$. If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i> . |
| <i>iwork</i> | (local) Workspace array of size <i>liwork</i> . |
| <i>liwork</i> | (local or global) The size of the array <i>iwork</i> . <i>liwork</i> is local input and must be at least $liwork = desca[lld_ - 1]$ $liwork = LOCr(n_a)$. If <i>liwork</i> = -1, then <i>liwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i> . |

Output Parameters

| | |
|--------------|---|
| <i>a</i> | On exit, if <i>fact</i> = 'E' and <i>equed</i> = 'Y', <i>a</i> is overwritten by $\text{diag}(sr) * a * \text{diag}(sc)$. |
| <i>af</i> | If <i>fact</i> = 'N', then <i>af</i> is an output argument and on exit returns the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ of the original matrix <i>A</i> . If <i>fact</i> = 'E', then <i>af</i> is an output argument and on exit returns the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ of the equilibrated matrix <i>A</i> (see the description of <i>A</i> for the form of the equilibrated matrix). |
| <i>equed</i> | If <i>fact</i> ≠ 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section). |
| <i>sr</i> | This array is an output argument if <i>fact</i> ≠ 'F'. See the description of <i>sr</i> in <i>Input Arguments</i> section. |
| <i>sc</i> | This array is an output argument if <i>fact</i> ≠ 'F'. See the description of <i>sc</i> in <i>Input Arguments</i> section. |
| <i>b</i> | On exit, if <i>equed</i> = 'N', <i>b</i> is not modified; if <i>trans</i> = 'N' and <i>equed</i> = 'R' or 'B', <i>b</i> is overwritten by $\text{diag}(r) * b$; if <i>trans</i> = 'T' or 'C' and <i>equed</i> = 'C' or 'B', <i>b</i> is overwritten by $\text{diag}(c) * b$. |
| <i>x</i> | (local) If <i>info</i> = 0 the <i>n</i> -by- <i>nrhs</i> solution matrix <i>X</i> to the original system of equations. Note that <i>A</i> and <i>B</i> are modified on exit if <i>equed</i> ≠ 'N', and the solution to the equilibrated system is $\text{inv}(\text{diag}(sc)) * X$ if <i>trans</i> = 'N' and <i>equed</i> = 'C' or 'B', or $\text{inv}(\text{diag}(sr)) * X$ if <i>trans</i> = 'T' or 'C' and <i>equed</i> = 'R' or 'B'. |
| <i>rcond</i> | (global) An estimate of the reciprocal condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision (in particular, if <i>rcond</i> =0), the matrix is singular to working precision. This condition is indicated by a return code of <i>info</i> > 0. |
| <i>ferr</i> | Arrays of size at least $\max(LOC, n_b)$. The estimated forward error bounds for each solution vector <i>X</i> (<i>j</i>) (the <i>j</i> -th column of the solution matrix <i>X</i>). If <i>xtrue</i> is the true solution, <i>ferr</i> [<i>j</i> - 1] bounds the magnitude of the largest entry in $(X(j) - xtrue)$ divided by the magnitude of the largest entry in <i>X</i> (<i>j</i>). The quality of the error bound depends on the quality of the estimate of $\text{norm}(\text{inv}(A))$ computed in the code; if the estimate of $\text{norm}(\text{inv}(A))$ is accurate, the error bound is guaranteed. |
| <i>berr</i> | (local) |

Arrays of size at least $\max(LOC, n_b)$. The componentwise relative backward error of each solution vector $X(j)$ (the smallest relative change in any entry of A or B that makes $X(j)$ an exact solution).

`work[0]`

(local) On exit, `work[0]` returns the minimal and optimal `liwork`.

`info`

(global)

If `info=0`, the execution is successful.

< 0: if `info = -i`, the i -th argument had an illegal value

> 0: if `info = i`, and $i \leq n$: if `info = i`, the leading minor of order i of a is not positive definite, so the factorization could not be completed, and the solution and error bounds could not be computed.

= $n+1$: `rcond` is less than machine precision. The factorization has been completed, but the matrix is singular to working precision, and the solution and error bounds have not been computed.

MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?pbsv` function solves a system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n real/complex banded symmetric positive definite distributed matrix with bandwidth `bw`.

Cholesky factorization is used to factor a reordering of the matrix into $L * L'$.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

| | |
|--------------|--|
| <i>uplo</i> | (global) Must be 'U' or 'L'. Indicates whether the upper or lower triangular of <i>A</i> is stored. If <i>uplo</i> = 'U', the upper triangular <i>A</i> is stored If <i>uplo</i> = 'L', the lower triangular of <i>A</i> is stored. |
| <i>n</i> | (global) The order of the distributed matrix <i>A</i> ($n \geq 0$). |
| <i>bw</i> | (global) The number of subdiagonals in <i>L</i> or <i>U</i> . $0 \leq bw \leq n-1$. |
| <i>nrhs</i> | (global) The number of right-hand sides; the number of columns in <i>B</i> ($nrhs \geq 0$). |
| <i>a</i> | (local). Pointer into the local memory to an array with leading size $lld_a \geq (bw+1)$ (stored in <i>desca</i>). On entry, this array contains the local pieces of the distributed matrix $sub(A)$ to be factored. |
| <i>ja</i> | (global) The index in the global matrix <i>A</i> indicating the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>). |
| <i>desca</i> | (global and local) array of size <i>dlen</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>b</i> | (local) Pointer into the local memory to an array of local lead size $lld_b \geq nb$. On entry, this array contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$. |
| <i>ib</i> | (global) The row index in the global matrix <i>B</i> indicating the first row of the matrix to be operated on (which may be either all of <i>b</i> or a submatrix of <i>B</i>). |
| <i>descb</i> | (global and local) array of size <i>dlen</i> . If 1D type ($dtype_b = 502$), $dlen \geq 7$; If 2D type ($dtype_b = 1$), $dlen \geq 9$. The array descriptor for the distributed matrix <i>B</i> . Contains information of mapping of <i>B</i> to memory. |

| | |
|--------------|--|
| <i>work</i> | (local). Temporary workspace. This space may be overwritten in between calls to functions. <i>work</i> must be the size given in <i>lwork</i> . |
| <i>lwork</i> | (local or global) Size of user-input workspace <i>work</i> . If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i> [0] and an error code is returned. $lwork \geq (nb+2*bw)*bw + \max((bw*nrhs), bw*bw)$ |

Output Parameters

| | |
|-------------|---|
| <i>a</i> | On exit, this array contains information containing details of the factorization. Note that permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK. |
| <i>b</i> | On exit, contains the local piece of the solutions distributed matrix X. |
| <i>work</i> | On exit, <i>work</i> [0] contains the minimal <i>lwork</i> . |
| <i>info</i> | (global) If <i>info</i> =0, the execution is successful. < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = $-(i*100+j)$, if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$. > 0: If <i>info</i> = $k \leq NPROCS$, the submatrix stored on processor <i>info</i> and factored locally was not positive definite, and the factorization was not completed. If <i>info</i> = $k > NPROCS$, the submatrix stored on processor <i>info</i> -NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed. |

Notice revision #20110804

Input Parameters

| | |
|---------|--|
| n | (global) The order of matrix A ($n \geq 0$). |
| $nrhs$ | (global) The number of right-hand sides; the number of columns of the distributed submatrix B ($nrhs \geq 0$). |
| d | (local) Pointer to local part of global vector storing the main diagonal of the matrix. |
| e | (local) Pointer to local part of global vector storing the upper diagonal of the matrix. Globally, $du(n)$ is not referenced, and du must be aligned with d . |
| ja | (global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A). |
| $desca$ | (global and local) array of size $dlen$. If 1d type ($dtype_a=501$ or 502), $dlen \geq 7$; If 2d type ($dtype_a=1$), $dlen \geq 9$. The array descriptor for the distributed matrix A . Contains information of mapping of A to memory. |
| b | (local) Pointer into the local memory to an array of local lead size $lld_b \geq nb$. On entry, this array contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$. |

| | |
|--------------|--|
| <i>ib</i> | (global) The row index in the global matrix <i>B</i> indicating the first row of the matrix to be operated on (which may be either all of <i>b</i> or a submatrix of <i>B</i>). |
| <i>descb</i> | (global and local) array of size <i>dlen</i> . If 1d type (<i>dtype_b</i> = 502), <i>dlen</i> ≥ 7; If 2d type (<i>dtype_b</i> = 1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>B</i> . Contains information of mapping of <i>B</i> to memory. |
| <i>work</i> | (local). Temporary workspace. This space may be overwritten in between calls to functions. <i>work</i> must be the size given in <i>lwork</i> . |
| <i>lwork</i> | (local or global) Size of user-input workspace <i>work</i> . If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i> [0] and an error code is returned. $lwork > (12 * NPCOL + 3 * nb) + \max((10 + 2 * \min(100, nrhs)) * NPCOL + 4 * nrhs, 8 * NPCOL)$. |

Output Parameters

| | |
|-------------|--|
| <i>d</i> | On exit, this array contains information containing the factors of the matrix. Must be of size greater than or equal to <i>desca</i> [<i>nb</i> - 1]. |
| <i>e</i> | On exit, this array contains information containing the factors of the matrix. Must be of size greater than or equal to <i>desca</i> [<i>nb</i> - 1]. |
| <i>b</i> | On exit, this contains the local piece of the solutions distributed matrix <i>X</i> . |
| <i>work</i> | On exit, <i>work</i> [0] contains the minimal <i>lwork</i> . |
| <i>info</i> | (local) If <i>info</i> =0, the execution is successful. < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . > 0: If <i>info</i> = <i>k</i> ≤ NPROCS, the submatrix stored on processor <i>info</i> and factored locally was not positive definite, and the factorization was not completed. If <i>info</i> = <i>k</i> > NPROCS, the submatrix stored on processor <i>info</i> -NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed. |

*jb , MKL_INT *descb , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?gels` function solves overdetermined or underdetermined real/ complex linear systems involving an m -by- n matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$, or its transpose/ conjugate-transpose, using a QTQ or LQ factorization of $\text{sub}(A)$. It is assumed that $\text{sub}(A)$ has full rank.

The following options are provided:

1. If $\text{trans} = 'N'$ and $m \geq n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem

$$\text{minimize } ||\text{sub}(B) - \text{sub}(A) * X||$$

2. If $\text{trans} = 'N'$ and $m < n$: find the minimum norm solution of an underdetermined system $\text{sub}(A) * X = \text{sub}(B)$.
3. If $\text{trans} = 'T'$ and $m \geq n$: find the minimum norm solution of an undetermined system $\text{sub}(A)^T * X = \text{sub}(B)$.
4. If $\text{trans} = 'T'$ and $m < n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem

$$\text{minimize } ||\text{sub}(B) - \text{sub}(A)^T * X||,$$

where $\text{sub}(B)$ denotes $B(\text{ib}:\text{ib}+m-1, \text{jb}:\text{jb}+nrhs-1)$ when $\text{trans} = 'N'$ and $B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1)$ otherwise. Several right hand side vectors b and solution vectors x can be handled in a single call; when $\text{trans} = 'N'$, the solution vectors are stored as the columns of the n -by- $nrhs$ right hand side matrix $\text{sub}(B)$ and the m -by- $nrhs$ right hand side matrix $\text{sub}(B)$ otherwise.

Input Parameters

| | |
|--------------|---|
| <i>trans</i> | (global) Must be 'N', or 'T'. If $\text{trans} = 'N'$, the linear system involves matrix $\text{sub}(A)$; If $\text{trans} = 'T'$, the linear system involves the transposed matrix A^T (for real flavors only). |
| <i>m</i> | (global) The number of rows in the distributed matrix $\text{sub}(A)$ ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the distributed matrix $\text{sub}(A)$ ($n \geq 0$). |

| | |
|---------------|--|
| <i>nrhs</i> | (global) The number of right-hand sides; the number of columns in the distributed submatrices $\text{sub}(B)$ and X . ($nrhs \geq 0$). |
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$. On entry, contains the m -by- n matrix A . |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <i>b</i> | (local) Pointer into the local memory to an array of local size $lld_b * LOCC(jb + nrhs - 1)$. On entry, this array contains the local pieces of the distributed matrix B of right-hand side vectors, stored columnwise; $\text{sub}(B)$ is m -by- $nrhs$ if $trans = 'N'$, and n -by- $nrhs$ otherwise. |
| <i>ib, jb</i> | (global) The row and column indices in the global matrix B indicating the first row and the first column of the submatrix B , respectively. |
| <i>descb</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix B . |
| <i>work</i> | (local) Workspace array with size $lwork$. |
| <i>lwork</i> | (local or global) . The size of the array $work/lwork$ is local input and must be at least $lwork \geq ltau + \max(lwf, lws)$, where if $m > n$, then $ltau = \text{numroc}(ja + \min(m, n) - 1, nb_a, MYCOL, csrc_a, NPCOL),$ $lwf = nb_a * (mpa0 + nqa0 + nb_a)$ $lws = \max((nb_a * (nb_a - 1)) / 2, (nrhsqb0 + mpb0) * nb_a) + nb_a * nb_a$ else $ltau = \text{numroc}(ia + \min(m, n) - 1, mb_a, MYROW, rsrc_a, NPROW),$ $lwf = mb_a * (mpa0 + nqa0 + mb_a)$ $lws = \max((mb_a * (mb_a - 1)) / 2, (npb0 + \max(nqa0 + \text{numroc}(\text{numroc}(n + iroffb, mb_a, 0, 0, NPROW), mb_a, 0, 0, lcmp), nrhsqb0)) * mb_a) + mb_a * mb_a$ end if, where $lcmp = lcm / NPROW$ with $lcm = \text{ilcm}(NPROW, NPCOL)$, $iroffa = \text{mod}(ia - 1, mb_a),$ $icoffa = \text{mod}(ja - 1, nb_a),$ $iarow = \text{indxg2p}(ia, mb_a, MYROW, rsrc_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb_a, MYROW, rsrc_a, NPROW)$ |

```

mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow, NPROW),
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol, NPCOL),
iroffb = mod(ib-1, mb_b),
icoffb = mod(jb-1, nb_b),
ibrow = indxg2p(ib, mb_b, MYROW, rsrc_b, NPROW),
ibcol = indxg2p(jb, nb_b, MYCOL, csrc_b, NPCOL),
mpb0 = numroc(m+iroffb, mb_b, MYROW, icrow, NPROW),
nqb0 = numroc(n+icoffb, nb_b, MYCOL, ibcol, NPCOL),

```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW`, and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|----------------------|---|
| <code>a</code> | On exit, If $m \geq n$, <code>sub(A)</code> is overwritten by the details of its <i>QR</i> factorization as returned by <code>p?geqrf</code> ; if $m < n$, <code>sub(A)</code> is overwritten by details of its <i>LQ</i> factorization as returned by <code>p?gelqf</code> . |
| <code>b</code> | On exit, <code>sub(B)</code> is overwritten by the solution vectors, stored columnwise: if <code>trans = 'N'</code> and $m \geq n$, rows 1 to n of <code>sub(B)</code> contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements $n+1$ to m in that column; If <code>trans = 'N'</code> and $m < n$, rows 1 to n of <code>sub(B)</code> contain the minimum norm solution vectors; If <code>trans = 'T'</code> and $m \geq n$, rows 1 to m of <code>sub(B)</code> contain the minimum norm solution vectors; if <code>trans = 'T'</code> and $m < n$, rows 1 to m of <code>sub(B)</code> contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements $m+1$ to n in that column. |
| <code>work[0]</code> | On exit, <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance. |
| <code>info</code> | (global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then <code>info = - (i* 100+j)</code> , if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> . |

p?syev

Computes selected eigenvalues and eigenvectors of a symmetric matrix.

Syntax

```
void pssyev (char *jobz , char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *w , float *z , MKL_INT *iz , MKL_INT *jz , MKL_INT *descz , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdsyev (char *jobz , char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *w , double *z , MKL_INT *iz , MKL_INT *jz , MKL_INT *descz , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?syev` function computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A by calling the recommended sequence of ScaLAPACK functions.

In its present form, the function assumes a homogeneous system and makes no checks for consistency of the eigenvalues or eigenvectors across the different processes. Because of this, it is possible that a heterogeneous system may return incorrect results without any error messages.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

| | |
|-------------|--|
| <i>jobz</i> | (global) Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed. |
| <i>uplo</i> | (global) Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: If <i>uplo</i> = 'U', a stores the upper triangular part of A . If <i>uplo</i> = 'L', a stores the lower triangular part of A . |
| <i>n</i> | (global) The number of rows and columns of the matrix A ($n \geq 0$). |
| <i>a</i> | (local) Block cyclic array of global size $n*n$ and local size $lld_a*LOCc(ja+n-1)$. On entry, the symmetric matrix A . If <i>uplo</i> = 'U', only the upper triangular part of A is used to define the elements of the symmetric matrix. |

If *uplo* = 'L', only the lower triangular part of *A* is used to define the elements of the symmetric matrix.

ia, ja

(global) The row and column indices in the global matrix *A* indicating the first row and the first column of the submatrix *A*, respectively.

desca

(global and local) array of size *dlen_*. The array descriptor for the distributed matrix *A*.

iz, jz

(global) The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz

(global and local) array of size *dlen_*. The array descriptor for the distributed matrix *Z*.

work

(local)

Array of size *lwork*.

lwork

(local) See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N'), then $lwork \geq 5*n + sizesytrd + 1$,

where *sizesytrd* is the workspace for *p?sytrd* and is $\max(NB*(np + 1), 3*NB)$.

If eigenvectors are requested (*jobz* = 'V') then the amount of workspace required to guarantee that all eigenvectors are computed is:

$$qrmem = 2*n-2$$

$$lwmin = 5*n + n*ldc + \max(sizemqrleft, qrmem) + 1$$

Variable definitions:

$$nb = desca[mb_ - 1] = desca[nb_ - 1] = descz[mb_ - 1] = descz[nb_ - 1];$$

$$nn = \max(n, nb, 2);$$

$$desca[rsrc_ - 1] = desca[rsrc_ - 1] = descz[rsrc_ - 1] = descz[csrc_ - 1] = 0$$

$$np = \text{numroc}(nn, nb, 0, 0, \text{NPROW})$$

$$nq = \text{numroc}(\max(n, nb, 2), nb, 0, 0, \text{NPCOL})$$

$$nrc = \text{numroc}(n, nb, \text{myprowc}, 0, \text{NPROCS})$$

$$ldc = \max(1, nrc)$$

sizemqrleft is the workspace for *p?ormtr* when its *side* argument is 'L'.

myprowc is defined when a new context is created as follows:

```
call blacs_get(desca[ctxt_ - 1], 0, contextc)
```

```
call blacs_gridinit(contextc, 'R', NPROCS, 1)
```

```
call blacs_gridinfo(contextc, nprowc, npcoldc, myprowc, mypcoldc)
```

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?xerbla`.

Output Parameters

| | |
|----------------------|--|
| <code>a</code> | On exit, the lower triangle (if $uplo='L'$) or the upper triangle (if $uplo='U'$) of A , including the diagonal, is destroyed. |
| <code>w</code> | (global). Array of size n . On normal exit, the first m entries contain the selected eigenvalues in ascending order. |
| <code>z</code> | (local). Array, global size $n*n$, local size $lld_z*LOCc(jz+n-1)$. If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If $jobz = 'N'$, then z is not referenced. |
| <code>work[0]</code> | On output, <code>work[0]</code> returns the workspace needed to guarantee completion. If the input parameters are incorrect, <code>work[0]</code> may also be incorrect. If $jobz = 'N'$ <code>work[0]</code> = minimal (optimal) amount of workspace If $jobz = 'V'$ <code>work[0]</code> = minimal workspace required to generate all the eigenvectors. |
| <code>info</code> | (global) If $info = 0$, the execution is successful. If $info < 0$: If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$. If $info > 0$: If $info=1$ through n , the i -th eigenvalue did not converge in <code>?steqr2</code> after a total of $30n$ iterations. If $info= n+1$, then <code>p?syev</code> has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from <code>p?syev</code> cannot be guaranteed. |

Description

The `p?syevd` function computes all eigenvalues and eigenvectors of a real symmetric matrix A by using a divide and conquer algorithm.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

| | |
|---------------|--|
| <i>jobz</i> | (global) Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed. |
| <i>uplo</i> | (global) Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: If <i>uplo</i> = 'U', a stores the upper triangular part of A . If <i>uplo</i> = 'L', a stores the lower triangular part of A . |
| <i>n</i> | (global) The number of rows and columns of the matrix A ($n \geq 0$). |
| <i>a</i> | (local). Block cyclic array of global size $n*n$ and local size $lld_a*LOCc(ja+n-1)$. On entry, the symmetric matrix A . If <i>uplo</i> = 'U', only the upper triangular part of A is used to define the elements of the symmetric matrix. If <i>uplo</i> = 'L', only the lower triangular part of A is used to define the elements of the symmetric matrix. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . If <i>desca</i> [<i>ctxt_</i> - 1] is incorrect, <code>p?syevd</code> cannot guarantee correct error reporting. |

| | |
|---------------|---|
| <i>iz, jz</i> | (global) The row and column indices in the global matrix <i>Z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively. |
| <i>descz</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> . <i>descz[ctxt_ - 1]</i> must equal <i>desca[ctxt_ - 1]</i> . |
| <i>work</i> | (local). Array of size <i>lwork</i> . |
| <i>lwork</i> | (local) The size of the array <i>work</i> . If eigenvalues are requested: $lwork \geq \max(1+6*n + 2*np*nq, trilwmin) + 2*n$ with $trilwmin = 3*n + \max(nb*(np + 1), 3*nb)$ $np = \text{numroc}(n, nb, myrow, iarow, NPROW)$ $nq = \text{numroc}(n, nb, mycol, iacol, NPCOL)$ If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by <i>pxerbla</i> . |
| <i>iwork</i> | (local) Workspace array of size <i>liwork</i> . |
| <i>liwork</i> | (local) , size of <i>iwork</i> . $liwork = 7*n + 8*npcol + 2.$ |

Output Parameters

| | |
|------------------|---|
| <i>a</i> | On exit, the lower triangle (if <i>uplo</i> = 'L'), or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten. |
| <i>w</i> | (global). Array of size <i>n</i> . If <i>info</i> = 0, <i>w</i> contains the eigenvalues in the ascending order. |
| <i>z</i> | (local). Array, global size (<i>n, n</i>), local size $lld_z*LOCc(jz+n-1)$. The <i>z</i> parameter contains the orthonormal eigenvectors of the matrix <i>A</i> . |
| <i>work</i> [0] | On exit, returns adequate workspace to allow optimal performance. |
| <i>iwork</i> [0] | (local). On exit, if <i>liwork</i> > 0, <i>iwork</i> [0] returns the optimal <i>liwork</i> . |
| <i>info</i> | (global) If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0: |

If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$. If the i -th argument is a scalar and had an illegal value, then $info = -i$.

If $info > 0$:

The algorithm failed to compute the $info/(n+1)$ -th eigenvalue while working on the submatrix lying in global rows and columns $\text{mod}(info, n+1)$.

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

```

Include Files

- mkl_scalapack.h

Description

`p?syevr` computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A distributed in 2D blockcyclic format by calling the recommended sequence of ScaLAPACK functions.

First, the matrix A is reduced to real symmetric tridiagonal form. Then, the eigenproblem is solved using the parallel MRRR algorithm. Last, if eigenvectors have been computed, a backtransformation is done.

Upon successful completion, each processor stores a copy of all computed eigenvalues in w . The eigenvector matrix z is stored in 2D block-cyclic format distributed over all processors.

Note that subsets of eigenvalues/vectors can be selected by specifying a range of values or a range of indices for the desired eigenvalues.

Notice revision #20110804

Input Parameters

| | |
|--------------|---|
| <i>jobz</i> | (global) Specifies whether or not to compute the eigenvectors: = 'N': Compute eigenvalues only. = 'V': Compute eigenvalues and eigenvectors. |
| <i>range</i> | (global) = 'A': all eigenvalues will be found. = 'V': all eigenvalues in the interval $[vl, vu]$ will be found. = 'I': the il -th through iu -th eigenvalues will be found. |
| <i>uplo</i> | (global) Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: = 'U': Upper triangular = 'L': Lower triangular |
| <i>n</i> | (global) The number of rows and columns of the matrix a . $n \geq 0$ |
| <i>a</i> | Block cyclic array of global size $n * n$, local size $lld_a * LOC_c(ja+n-1)$. This array contains the local pieces of the symmetric distributed matrix A . If $uplo = 'U'$, only the upper triangular part of a is used to define the elements of the symmetric matrix. If $uplo = 'L'$, only the lower triangular part of a is used to define the elements of the symmetric matrix. On exit, the lower triangle (if $uplo='L'$) or the upper triangle (if $uplo='U'$) of a , including the diagonal, is destroyed. |
| <i>ia</i> | (global) Global row index in the global matrix A that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix. |
| <i>ja</i> | (global) Global column index in the global matrix A that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix. |
| <i>desca</i> | (global and local) array of size $dlen_ = 9$. |

| | |
|---------|---|
| | The array descriptor for the distributed matrix a . |
| vl | (global) If $range='V'$, the lower bound of the interval to be searched for eigenvalues. Not referenced if $range = 'A'$ or $'I'$. |
| vu | (global) If $range='V'$, the upper bound of the interval to be searched for eigenvalues. Not referenced if $range = 'A'$ or $'I'$. |
| il | (global) If $range='I'$, the index (from smallest to largest) of the smallest eigenvalue to be returned. $il \geq 1$. Not referenced if $range = 'A'$. |
| iu | (global) If $range='I'$, the index (from smallest to largest) of the largest eigenvalue to be returned. $\min(il, n) \leq iu \leq n$. Not referenced if $range = 'A'$. |
| iz | (global) Global row index in the global matrix Z that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix. |
| jz | (global) Global column index in the global matrix Z that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix. |
| $descz$ | array of size $dlen_$. The array descriptor for the distributed matrix z . The context $descz[ctxt_ - 1]$ must equal $desca[ctxt_ - 1]$. Also note the array alignment requirements specified below. |
| $work$ | (local workspace) array of size $lwork$ |
| $lwork$ | (local) Size of $work$, must be at least 3. See below for definitions of variables used to define $lwork$. If no eigenvectors are requested ($jobz = 'N'$) then $lwork \geq 2 + 5*n + \max(12 * nn, neig * (np0 + 1))$ If eigenvectors are requested ($jobz = 'V'$) then the amount of workspace required is: $lwork \geq 2 + 5*n + \max(18*nn, np0 * mq0 + 2 * neig * neig) + (2 + \text{iceil}(neig, nprow*npcol)) * nn$ Variable definitions: |

$neig$ = number of eigenvectors requested

$nb = desca[mb_ - 1] = desca(nb_) = descz[mb_ - 1] = descz(nb_)$

$nn = \max(n, neig, 2)$

$desca[rsrc_ - 1] = desca[csrc_nb_ - 1] = descz[rsrc_ - 1] = descz[csrc_ - 1] = 0$

$np0 = \text{numroc}(nn, neig, 0, 0, nprow)$

$mq0 = \text{numroc}(\max(neig, neig, 2), neig, 0, 0, npcol)$

$\text{ceil}(x, y)$ is a ScaLAPACK function returning $\text{ceil}(x/y)$, and $nprow$ and $npcol$ can be determined by calling the function `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pxerbla`.

$liwork$

(local)

size of $iwork$

Let $nnp = \max(n, nprow*npcol + 1, 4)$. Then:

$liwork \geq 12*nnp + 2*n$ when the eigenvectors are desired

$liwork \geq 10*nnp + 2*n$ when only the eigenvalues have to be computed

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

OUTPUT Parameters

m

(global)

Total number of eigenvalues found. $0 \leq m \leq n$.

nz

(global)

Total number of eigenvectors computed. $0 \leq nz \leq m$.

The number of columns of z that are filled.

If $jobz \neq 'V'$, nz is not referenced.

If $jobz = 'V'$, $nz = m$

w

(global) array of size n

Upon successful exit, the first m entries contain the selected eigenvalues in ascending order.

z

Block-cyclic array, global size $n*n$, local size $lld_z*LOC_c(jz+n-1)$.

On exit, contains local pieces of distributed matrix Z .

| | |
|--------------|--|
| <i>work</i> | On return, <i>work</i> [0] contains the optimal amount of workspace required for efficient execution. If <i>jobz</i> ='N' <i>work</i> [0] = optimal amount of workspace required to compute the eigenvalues. If <i>jobz</i> ='V' <i>work</i> [0] = optimal amount of workspace required to compute eigenvalues and eigenvectors. |
| <i>iwork</i> | (local workspace) array On return, <i>iwork</i> [0] contains the amount of integer workspace required. |
| <i>info</i> | (global) = 0: successful exit < 0: If the <i>i</i> -th argument is an array and the <i>j</i> th-entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . |

Application Notes

The distributed submatrices $a(ia:*, ja:*)$ and $z(iz:iz+m-1, jz:jz+n-1)$ must satisfy the following alignment properties:

1. Identical (quadratic) dimension: $desca[m_ - 1] = descz[m_ - 1] = desca[n_ - 1] = descz[n_ - 1]$
2. Quadratic conformal blocking: $desca[mb_ - 1] = desca[nb_ - 1] = descz[mb_ - 1] = descz[nb_ - 1]$,
 $desca[rsrc_ - 1] = descz[rsrc_ - 1]$
3. $\text{mod}(ia-1, mb_a) = \text{mod}(iz-1, mb_z) = 0$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

Notice revision #20110804

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

| | |
|---------|---|
| $jobz$ | (global) Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If $jobz = 'N'$, then only eigenvalues are computed. If $jobz = 'V'$, then eigenvalues and eigenvectors are computed. |
| $range$ | (global) Must be 'A', 'V', or 'I'. If $range = 'A'$, all eigenvalues will be found. If $range = 'V'$, all eigenvalues in the half-open interval $[vl, vu]$ will be found. If $range = 'I'$, the eigenvalues with indices il through iu will be found. |
| $uplo$ | (global) Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: If $uplo = 'U'$, a stores the upper triangular part of A . If $uplo = 'L'$, a stores the lower triangular part of A . |
| n | (global) The number of rows and columns of the matrix A ($n \geq 0$). |
| a | (local). Block cyclic array of global size $n*n$ and local size $lld_a*LOCc(ja+n-1)$. On entry, the symmetric matrix A . If $uplo = 'U'$, only the upper triangular part of A is used to define the elements of the symmetric matrix. |

| | |
|---------------|--|
| | If <i>uplo</i> = 'L', only the lower triangular part of <i>A</i> is used to define the elements of the symmetric matrix. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>vl, vu</i> | (global) If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; $vl \leq vu$. Not referenced if <i>range</i> = 'A' or 'I'. |
| <i>il, iu</i> | (global) If <i>range</i> = 'I', the indices of the smallest and largest eigenvalues to be returned. Constraints: $il \geq 1$ $\min(il, n) \leq iu \leq n$ Not referenced if <i>range</i> = 'A' or 'V'. |
| <i>abstol</i> | (global). If <i>jobz</i> ='V', setting <i>abstol</i> to <code>p?lamch(context, 'U')</code> yields the most orthogonal eigenvectors. The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + eps * \max(a , b)$, where <i>eps</i> is the machine precision. If <i>abstol</i> is less than or equal to zero, then $eps * \text{norm}(T)$ will be used in its place, where $\text{norm}(T)$ is the 1-norm of the tridiagonal matrix obtained by reducing <i>A</i> to tridiagonal form. Eigenvalues will be computed most accurately when <i>abstol</i> is set to twice the underflow threshold $2 * p?lamch('S')$ not zero. If this function returns with $(\text{mod}(\text{info}, 2) \neq 0)$ or $(\text{mod}(\text{info}/8, 2) \neq 0)$, indicating that some eigenvalues or eigenvectors did not converge, try setting <i>abstol</i> to $2 * p?lamch('S')$. |
| <i>orfac</i> | (global). Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol = orfac * \text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see <i>lwork</i>), <i>tol</i> may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if <i>orfac</i> equals zero. A default value of 1.0e-3 is used if <i>orfac</i> is negative. <i>orfac</i> should be identical on all processes. |
| <i>iz, jz</i> | (global) The row and column indices in the global matrix <i>Z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively. |
| <i>descz</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> . <code>descz[ctxt_ - 1]</code> must equal <code>desca[ctxt_ - 1]</code> . |

work (local)
 Array of size *lwork*.

lwork (local) The size of the array *work*.
 See below for definitions of variables used to define *lwork*.
 If no eigenvectors are requested (*jobz* = 'N'), then $lwork \geq 5*n + \max(5*nn, NB*(np0 + 1))$.
 If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:
 $lwork \geq 5*n + \max(5*nn, np0*mq0 + 2*NB*NB) + \text{iceil}(neig, NPROW*NPCOL)*nn$
 The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following to *lwork*:
 $(clustersize-1)*n$,
 where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:
 $\{w[k - 1], \dots, w[k+clustersize-2] | w[j] \leq w[j-1]\} + orfac*2*norm(A)$,
 where
neig = number of eigenvectors requested
 $nb = desca[mb_ - 1] = desca[nb_ - 1] = descz[mb_ - 1] = descz[nb_ - 1]$;
 $nn = \max(n, nb, 2)$;
 $desca[rsrc_ - 1] = desca[nb_ - 1] = descz[rsrc_ - 1] = descz[csrc_ - 1] = 0$;
 $np0 = \text{numroc}(nn, nb, 0, 0, NPROW)$;
 $mq0 = \text{numroc}(\max(neig, nb, 2), nb, 0, 0, NPCOL)$
iceil(*x*, *y*) is a ScaLAPACK function returning ceiling(*x*/*y*)
 If *lwork* is too small to guarantee orthogonality, *p?syevx* attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.
 If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned.
 Note that when *range*='V', number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if *lwork* is large enough to compute the eigenvalues, *p?sygvx* computes the eigenvalues and as many eigenvectors as possible.
Relationship between workspace, orthogonality & performance:
 Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:
 $lwork \geq \max(lwork, 5*n + nsytrd_lwopt)$,

where *lwork*, as defined previously, depends upon the number of eigenvectors requested, and

```
nsytrd_lwopt = n + 2*(anb+1)*(4*nps+2) + (nps + 3)*nps;
```

```
anb = pjlaenv(desca[ctxt_ - 1], 3, 'p?sytrd', 'L', 0, 0, 0, 0);
```

```
sqnpc = int(sqrt(dble(NPROW * NPCOL)));
```

```
nps = max(numroc(n, 1, 0, 0, sqnpc), 2*anb);
```

numroc is a ScaLAPACK tool functions;

pjlaenv is a ScaLAPACK environmental inquiry function

MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.

For large *n*, no extra workspace is needed, however the biggest boost in performance comes for small *n*, so it is wise to provide the extra workspace (typically less than a megabyte per process).

If *clustersize* > $n/\sqrt{\text{NPROW}*\text{NPCOL}}$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is, *clustersize* = *n*-1) *p?stein* will perform no better than *?stein* on single processor.

For *clustersize* = $n/\sqrt{\text{NPROW}*\text{NPCOL}}$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For *clustersize* > $n/\sqrt{\text{NPROW}*\text{NPCOL}}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by *pxerbla*.

iwork

(local) Workspace array.

liwork

(local) , size of *iwork*. $liwork \geq 6*nnp$

Where: $nnp = \max(n, \text{NPROW}*\text{NPCOL} + 1, 4)$

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

a

On exit, the lower triangle (if *uplo* = 'L') or the upper triangle (if *uplo* = 'U') of *A*, including the diagonal, is overwritten.

m

(global) The total number of eigenvalues found; $0 \leq m \leq n$.

nz

(global) Total number of eigenvectors computed. $0 \leq nz \leq m$.

The number of columns of z that are filled.

If $jobz \neq 'V'$, nz is not referenced.

If $jobz = 'V'$, $nz = m$ unless the user supplies insufficient space and $p?syevx$ is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in z ($m \leq descz[n_ - 1]$) and sufficient workspace to compute them. (See $lwork$). $p?syevx$ is always able to detect insufficient space without computation unless $range = 'V'$.

w

(global).

Array of size n . The first m elements contain the selected eigenvalues in ascending order.

z

(local).

Array, global size $n*n$, local size $lld_z*LOCc(jz+n-1)$.

If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.

If $jobz = 'N'$, then z is not referenced.

$work[0]$

On exit, returns workspace adequate workspace to allow optimal performance.

$iwork[0]$

On return, $iwork[0]$ contains the amount of integer workspace required.

$ifail$

(global).

Array of size n .

If $jobz = 'V'$, then on normal exit, the first m elements of $ifail$ are zero. If $(\text{mod}(\text{info}, 2) \neq 0)$ on exit, then $ifail$ contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then $ifail$ is not referenced.

$iclustr$

(global) Array of size $(2*NPROW*NPCOL)$

This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see $lwork$, $orfac$ and $info$). Eigenvectors corresponding to clusters of eigenvalues indexed $iclustr(2*i-1)$ to $iclustr(2*i)$, could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. $iclustr$ is a zero terminated array. $iclustr[2*k - 1] \neq 0$ and $iclustr[2*k] = 0$ if and only if k is the number of clusters.

$iclustr$ is not referenced if $jobz = 'N'$.

gap

(global)

Array of size $NPROW*NPCOL$

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*th cluster may be as high as $(C*n) / \text{gap}[i - 1]$ where *C* is a small constant.

info

(global)

If *info* = 0, the execution is successful.If *info* < 0:If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = $-(i*100+j)$, if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.If *info* > 0: if $(\text{mod}(\text{info}, 2) \neq 0)$, then one or more eigenvectors failed to converge. Their indices are stored in *ifail*. Ensure $\text{abstol} = 2.0 * p * \text{lamch}('U')$.If $(\text{mod}(\text{info}/2, 2) \neq 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.If $(\text{mod}(\text{info}/4, 2) \neq 0)$, then space limit prevented *p?syevxf* from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.If $(\text{mod}(\text{info}/8, 2) \neq 0)$, then *p?stebz* failed to compute eigenvalues. Ensure $\text{abstol} = 2.0 * p * \text{lamch}('U')$.**NOTE** $\text{mod}(x, y)$ is the integer remainder of x/y .**See Also**

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

p?heev

Computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix.

Syntax

```
void pcheev (char *jobz , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *w , MKL_Complex8 *z , MKL_INT *iz , MKL_INT
*jz , MKL_INT *descz , MKL_Complex8 *work , MKL_INT *lwork , float *rwork , MKL_INT
*lrwork , MKL_INT *info );
```

```
void pzheev (char *jobz , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *w , MKL_Complex16 *z , MKL_INT *iz , MKL_INT
*jz , MKL_INT *descz , MKL_Complex16 *work , MKL_INT *lwork , double *rwork , MKL_INT
*lrwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?heev` function computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A by calling the recommended sequence of ScaLAPACK functions. The function assumes a homogeneous system and makes spot checks of the consistency of the eigenvalues across the different processes. A heterogeneous system may return incorrect results without any error messages.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

| | |
|----------|--|
| $jobz$ | (global) Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If $jobz = 'N'$, then only eigenvalues are computed. If $jobz = 'V'$, then eigenvalues and eigenvectors are computed. |
| $uplo$ | (global) Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: If $uplo = 'U'$, a stores the upper triangular part of A . If $uplo = 'L'$, a stores the lower triangular part of A . |
| n | (global) The number of rows and columns of the matrix A ($n \geq 0$). |
| a | (local). Block cyclic array of global size $n*n$ and local size $lld_a*LOCc(ja+n-1)$. On entry, the Hermitian matrix A . If $uplo = 'U'$, only the upper triangular part of A is used to define the elements of the Hermitian matrix. If $uplo = 'L'$, only the lower triangular part of A is used to define the elements of the Hermitian matrix. |
| ia, ja | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . If $desca[ctxt_ - 1]$ is incorrect, <code>p?heev</code> cannot guarantee correct error reporting. |
| iz, jz | (global) The row and column indices in the global matrix Z indicating the first row and the first column of the submatrix Z , respectively. |
| $descz$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix Z . $descz[ctxt_ - 1]$ must equal $desca[ctxt_ - 1]$. |
| $work$ | (local). Array of size $lwork$. |
| $lwork$ | (local) The size of the array $work$. If only eigenvalues are requested ($jobz = 'N'$): |

$$lwork \geq \max(nb*(np0 + 1), 3) + 3*n$$

If eigenvectors are requested ($jobz = 'V'$), then the amount of workspace required:

$$lwork \geq (np0+nq0+nb)*nb + 3*n + n^2$$

with $nb = desca[mb_ - 1] = desca[nb_ - 1] = nb = descz[mb_ - 1] = descz[nb_ - 1]$

$$np0 = \text{numroc}(nn, nb, 0, 0, \text{NPROW}).$$

$$nq0 = \text{numroc}(\max(n, nb, 2), nb, 0, 0, \text{NPCOL}).$$

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by `pxerbla`.

rwork

(local).

Workspace array of size *lrwork*.*lrwork*(local) The size of the array *rwork*.See below for definitions of variables used to define *lrwork*.If no eigenvectors are requested ($jobz = 'N'$), then $lrwork \geq 2*n$.If eigenvectors are requested ($jobz = 'V'$), then $lrwork \geq 2*n + 2*n-2$.

If $lrwork = -1$, then $lrwork$ is global input and a workspace query is assumed; the function only calculates the minimum size required for the *rwork* array. The required workspace is returned as the first element of *rwork*, and no error message is issued by `pxerbla`.

Output Parameters

a

On exit, the lower triangle (if $uplo = 'L'$), or the upper triangle (if $uplo = 'U'$) of *A*, including the diagonal, is overwritten.

w

(global).

Array of size n . The first m elements contain the selected eigenvalues in ascending order.

z

(local).

Array, global size $n*n$, local size $lld_z*LOCc(jz+n-1)$.

If $jobz = 'V'$, then on normal exit the first m columns of *z* contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If $jobz = 'N'$, then *z* is not referenced.

work[0]

On exit, returns adequate workspace to allow optimal performance.

If $jobz = 'N'$, then *work[0]* = minimal workspace only for eigenvalues.

If `jobz = 'V'`, then `work[0]` = minimal workspace required to generate all the eigenvectors.

`rwork[0]`

(local)

On output, `rwork[0]` returns workspace required to guarantee completion.

`info`

(global)

If `info = 0`, the execution is successful.

If `info < 0`:

If the i -th argument is an array and the j -entry had an illegal value, then `info = -(i*100+j)`. If the i -th argument is a scalar and had an illegal value, then `info = -i`.

If `info > 0`:

If `info = 1` through n , the i -th eigenvalue did not converge in `?stegr2` after a total of $30*n$ iterations.

If `info = n+1`, then `p?heev` detected heterogeneity, and the accuracy of the results cannot be guaranteed.

Description

The `p?heevd` function computes all eigenvalues and eigenvectors of a complex Hermitian matrix A by using a divide and conquer algorithm.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

| | |
|---------------|---|
| <i>jobz</i> | (global) Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed. |
| <i>uplo</i> | (global) Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is stored: If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> . |
| <i>n</i> | (global) The number of rows and columns of the matrix <i>A</i> ($n \geq 0$). |
| <i>a</i> | (local). Block cyclic array of global size $n*n$ and local size $lld_a*LOCc(ja+n-1)$. On entry, the Hermitian matrix <i>A</i> . If <i>uplo</i> = 'U', only the upper triangular part of <i>A</i> is used to define the elements of the Hermitian matrix. If <i>uplo</i> = 'L', only the lower triangular part of <i>A</i> is used to define the elements of the Hermitian matrix. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>desca</i> [<i>ctxt_</i> - 1] is incorrect, p?heevd cannot guarantee correct error reporting. |
| <i>iz, jz</i> | (global) The row and column indices in the global matrix <i>Z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively. |
| <i>descz</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> . <i>descz</i> [<i>ctxt_</i> - 1] must equal <i>desca</i> [<i>ctxt_</i> - 1]. |
| <i>work</i> | (local). Array of size <i>lwork</i> . |
| <i>lwork</i> | (local) The size of the array <i>work</i> . If eigenvalues are requested: $lwork = n + (nb0 + mq0 + nb)*nb$ with $np0 = \text{numroc}(\max(n, nb, 2), nb, 0, 0, \text{NPROW})$ $mq0 = \text{numroc}(\max(n, nb, 2), nb, 0, 0, \text{NPCOL})$ If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by p?xerbla. |
| <i>rwork</i> | (local). |

lwork Workspace array of size *lwork*.
 (local) The size of the array *rwork*.
 $lwork \geq 1 + 9*n + 3*np*nq$,
 with $np = \text{numroc}(n, nb, myrow, iarow, NPROW)$
 $nq = \text{numroc}(n, nb, mycol, iacol, NPCOL)$

iwork (local) Workspace array of size *liwork*.

liwork (local) , size of *iwork*.
 $liwork = 7*n + 8*npcol + 2$.

Output Parameters

a On exit, the lower triangle (if *uplo* = 'L'), or the upper triangle (if *uplo* = 'U') of *A*, including the diagonal, is overwritten.

w (global).
 Array of size *n*. If *info* = 0, *w* contains the eigenvalues in the ascending order.

z (local).
 Array, global size $n*n$, local size $lld_z*LOCc(jz+n-1)$.
 The *z* parameter contains the orthonormal eigenvectors of the matrix *A*.

work[0] On exit, returns adequate workspace to allow optimal performance.

rwork[0] (local)
 On output, *rwork*[0] returns workspace required to guarantee completion.

iwork[0] (local).
 On return, *iwork*[0] contains the amount of integer workspace required.

info (global)
 If *info* = 0, the execution is successful.
 If *info* < 0:
 If the *i*-th argument is an array and the *j*-entry had an illegal value, then $info = -(i*100+j)$. If the *i*-th argument is a scalar and had an illegal value, then $info = -i$.
 If *info* > 0:
 If *info* = 1 through *n*, the *i*-th eigenvalue did not converge.

```

Include Files

- mkl_scalapack.h

Description

p?heevr computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A distributed in 2D blockcyclic format by calling the recommended sequence of ScaLAPACK functions.

First, the matrix A is reduced to complex Hermitian tridiagonal form. Then, the eigenproblem is solved using the parallel MRRR algorithm. Last, if eigenvectors have been computed, a backtransformation is done.

Upon successful completion, each processor stores a copy of all computed eigenvalues in w . The eigenvector matrix Z is stored in 2D block-cyclic format distributed over all processors.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

jobz (global)
Specifies whether or not to compute the eigenvectors:
= 'N': Compute eigenvalues only.
= 'V': Compute eigenvalues and eigenvectors.

range (global)
= 'A': all eigenvalues will be found.

| | |
|--------------|---|
| | <p>= 'V': all eigenvalues in the interval $[v_l, v_u]$ will be found.</p> <p>= 'I': the i_l-th through i_u-th eigenvalues will be found.</p> |
| <i>uplo</i> | <p>(global)</p> <p>Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is stored:</p> <p>= 'U': Upper triangular</p> <p>= 'L': Lower triangular</p> |
| <i>n</i> | <p>(global)</p> <p>The number of rows and columns of the matrix <i>A</i>. $n \geq 0$</p> |
| <i>a</i> | <p>Block-cyclic array, global size $n * n$), local size $lld_a * LOC_c(ja+n-1)$</p> <p>Contains the local pieces of the Hermitian distributed matrix <i>A</i>. If <i>uplo</i> = 'U', only the upper triangular part of <i>a</i> is used to define the elements of the Hermitian matrix. If <i>uplo</i> = 'L', only the lower triangular part of <i>a</i> is used to define the elements of the Hermitian matrix.</p> |
| <i>ia</i> | <p>(global)</p> <p>Global row index in the global matrix <i>A</i> that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.</p> |
| <i>ja</i> | <p>(global)</p> <p>Global column index in the global matrix <i>A</i> that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.</p> |
| <i>desca</i> | <p>(global and local) array of size <i>dlen_</i>. (The ScaLAPACK descriptor length is <i>dlen_</i> = 9.)</p> <p>The array descriptor for the distributed matrix <i>a</i>. The descriptor stores details about the 2D block-cyclic storage, see the notes below. If <i>desca</i> is incorrect, <i>p?heevr</i> cannot work correctly.</p> <p>Also note the array alignment requirements specified below</p> |
| <i>v_l</i> | <p>(global)</p> <p>If <i>range</i>='V', the lower bound of the interval to be searched for eigenvalues. Not referenced if <i>range</i> = 'A' or 'I'.</p> |
| <i>v_u</i> | <p>(global)</p> <p>If <i>range</i>='V', the upper bound of the interval to be searched for eigenvalues. Not referenced if <i>range</i> = 'A' or 'I'.</p> |
| <i>i_l</i> | <p>(global)</p> <p>If <i>range</i>='I', the index (from smallest to largest) of the smallest eigenvalue to be returned. $i_l \geq 1$.</p> <p>Not referenced if <i>range</i> = 'A'.</p> |
| <i>i_u</i> | <p>(global)</p> |

If *range*='I', the index (from smallest to largest) of the largest eigenvalue to be returned. $\min(il,n) \leq iu \leq n$.

Not referenced if *range* = 'A'.

iz

(global)

Global row index in the global matrix *Z* that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

jz

(global)

Global column index in the global matrix *Z* that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

descz

(global and local) array of size *dlen_*.

The array descriptor for the distributed matrix *z*. *descz*[*ctxt_* - 1] must equal *desca*[*ctxt_* - 1]

work

(local workspace) array of size *lwork*

lwork

(local)

Size of *work* array, must be at least 3.

If only eigenvalues are requested:

$$lwork \geq n + \max(nb * (np00 + 1), nb * 3)$$

If eigenvectors are requested:

$$lwork \geq n + (np00 + mq00 + nb) * nb$$

For definitions of *np00* and *mq00*, see *lrwork*.

For optimal performance, greater workspace is needed, i.e.

$$lwork \geq \max(lwork, nhetr_d_lwork)$$

Where *lwork* is as defined above, and

$$nhetr_d_lwork = n + 2*(an_b+1)*(4*nps+2) + (nps + 1) * nps$$

$$ictxt = desca[ctxt_ - 1]$$

$$an_b = p_jlaenv(ictxt, 3, 'PCHETTRD', 'L', 0, 0, 0, 0)$$

$$sqnpc = \text{sqrt}(\text{real}(nprow * npc col))$$

$$nps = \max(\text{numroc}(n, 1, 0, 0, sqnpc), 2*an_b)$$

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

rwork

(local workspace) array of size *lrwork*

lrwork

(local)

Size of *rwork*, must be at least 3.

See below for definitions of variables used to define *lrwork*.

If no eigenvectors are requested (*jobz* = 'N') then

$$lwork \geq 2 + 5 * n + \max(12 * n, nb * (np00 + 1))$$

If eigenvectors are requested (*jobz* = 'V') then the amount of workspace required is:

$$lwork \geq 2 + 5 * n + \max(18 * n, np00 * mq00 + 2 * nb * nb) + (2 + \text{iceil}(neig, nprow * npc0l)) * n$$

NOTE

iceil(*x*, *y*) is the ceiling of *x/y*.

Variable definitions:

neig = number of eigenvectors requested

nb = *desca*[*mb_* - 1] = *desca*[*nb_* - 1] = *descz*[*mb_* - 1] = *descz*[*nb_* - 1]

nn = $\max(n, nb, 2)$

desca[*rsrc_* - 1] = *desca*[*csrc_* - 1] = *descz*[*rsrc_* - 1] = *descz*[*csrc_* - 1] = 0

np00 = *numroc*(*nn*, *nb*, 0, 0, *nprow*)

mq00 = *numroc*($\max(neig, nb, 2)$, *nb*, 0, 0, *npcol*)

iceil(*x*, *y*) is a ScaLAPACK function returning *ceiling(x/y)*, and *nprow* and *npcol* can be determined by calling the function *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by *pxerbla*

iwork (local workspace) array of size *liwork*

liwork (local)

size of *iwork*

Let *nnp* = $\max(n, nprow * npc0l + 1, 4)$. Then:

liwork $\geq 12 * nnp + 2 * n$ when the eigenvectors are desired

liwork $\geq 10 * nnp + 2 * n$ when only the eigenvalues have to be computed

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*

OUTPUT Parameters

a The lower triangle (if *uplo*='L') or the upper triangle (if *uplo*='U') of *a*, including the diagonal, is destroyed.

m (global)

| | |
|--------------|---|
| | Total number of eigenvalues found. $0 \leq m \leq n$. |
| <i>nz</i> | (global) Total number of eigenvectors computed. $0 \leq nz \leq m$. The number of columns of <i>z</i> that are filled. If <i>jobz</i> ≠ 'V', <i>nz</i> is not referenced. If <i>jobz</i> = 'V', <i>nz</i> = <i>m</i> |
| <i>w</i> | (global) array of size <i>n</i> On normal exit, the first <i>m</i> entries contain the selected eigenvalues in ascending order. |
| <i>z</i> | (local) array, global size $n * n$, local size $lld_z * LOC_c(jz+n-1)$ If <i>jobz</i> = 'V', then on normal exit the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If <i>jobz</i> = 'N', then <i>z</i> is not referenced. |
| <i>work</i> | <i>work</i> [0] returns workspace adequate workspace to allow optimal performance. |
| <i>rwork</i> | On return, <i>rwork</i> [0] contains the optimal amount of workspace required for efficient execution. if <i>jobz</i> ='N' <i>rwork</i> [0] = optimal amount of workspace required to compute the eigenvalues. if <i>jobz</i> ='V' <i>rwork</i> [0] = optimal amount of workspace required to compute eigenvalues and eigenvectors. |
| <i>iwork</i> | On return, <i>iwork</i> [0] contains the amount of integer workspace required. |
| <i>info</i> | (global) = 0: successful exit < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = $-(i*100+j)$, if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$. |

Application Notes

The distributed submatrices $a(ia:*, ja:*)$ and $z(iz:iz+m-1, jz:jz+n-1)$ must satisfy the following alignment properties:

1. Identical (quadratic) dimension: $desca[m_ - 1] = descz[m_ - 1] = desca[n_ - 1] = descz[n_ - 1]$
2. Quadratic conformal blocking: $desca[mb_ - 1] = desca[nb_ - 1] = descz[mb_ - 1] = descz[nb_ - 1]$,
 $desca[rsrc_ - 1] = descz[rsrc_ - 1]$
3. $\text{mod}(ia-1, mb_a) = \text{mod}(iz-1, mb_z) = 0$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

Include Files

- mkl_scalapack.h

Description

The p?heevx function computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A by calling the recommended sequence of ScaLAPACK functions. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

$jobz$ (global) Must be 'N' or 'V'.

Specifies if it is necessary to compute the eigenvectors:

If $jobz = 'N'$, then only eigenvalues are computed.

| | |
|---------------|---|
| | If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed. |
| <i>range</i> | (global) Must be 'A', 'V', or 'I'. If <i>range</i> = 'A', all eigenvalues will be found. If <i>range</i> = 'V', all eigenvalues in the half-open interval [<i>vl</i> , <i>vu</i>] will be found. If <i>range</i> = 'I', the eigenvalues with indices <i>il</i> through <i>iu</i> will be found. |
| <i>uplo</i> | (global) Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is stored: If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> . |
| <i>n</i> | (global) The number of rows and columns of the matrix <i>A</i> ($n \geq 0$). |
| <i>a</i> | (local). Block cyclic array of global size $n*n$ and local size $lld_a*LOCc(ja+n-1)$. On entry, the Hermitian matrix <i>A</i> . If <i>uplo</i> = 'U', only the upper triangular part of <i>A</i> is used to define the elements of the Hermitian matrix. If <i>uplo</i> = 'L', only the lower triangular part of <i>A</i> is used to define the elements of the Hermitian matrix. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>desca</i> [<i>ctxt_</i> - 1] is incorrect, p?heevx cannot guarantee correct error reporting. |
| <i>vl, vu</i> | (global) If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; not referenced if <i>range</i> = 'A' or 'I'. |
| <i>il, iu</i> | (global) If <i>range</i> = 'I', the indices of the smallest and largest eigenvalues to be returned. Constraints: $il \geq 1; \min(il, n) \leq iu \leq n$. Not referenced if <i>range</i> = 'A' or 'V'. |
| <i>abstol</i> | (global). If <i>jobz</i> ='V', setting <i>abstol</i> to <code>p?lamch(context, 'U')</code> yields the most orthogonal eigenvectors. |

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + eps * \max(|a|, |b|)$, where eps is the machine precision. If $abstol$ is less than or equal to zero, then $eps * \text{norm}(T)$ will be used in its place, where $\text{norm}(T)$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues are computed most accurately when $abstol$ is set to twice the underflow threshold $2 * \text{p?lamch}('S')$, not zero. If this function returns with $((\text{mod}(\text{info}, 2) \neq 0) . \text{or.} (\text{mod}(\text{info}/8, 2) \neq 0))$, indicating that some eigenvalues or eigenvectors did not converge, try setting $abstol$ to $2 * \text{p?lamch}('S')$.

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

orfac

(global).

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol = orfac * \text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see *lwork*), *tol* may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of 1.0e-3 is used if *orfac* is negative.

orfac should be identical on all processes.

iz, jz

(global) The row and column indices in the global matrix Z indicating the first row and the first column of the submatrix Z , respectively.

descz

(global and local) array of size *dlen_*. The array descriptor for the distributed matrix Z . $\text{descz}[\text{ctxt}_ - 1]$ must equal $\text{desca}[\text{ctxt}_ - 1]$.

work

(local).

Array of size *lwork*.

lwork

(local) The size of the array *work*.

If only eigenvalues are requested:

$$lwork \geq n + \max(nb * (np0 + 1), 3)$$

If eigenvectors are requested:

$$lwork \geq n + (np0 + mq0 + nb) * nb$$

with $nq0 = \text{numroc}(nn, nb, 0, 0, \text{NPCOL})$.

$$lwork \geq 5 * n + \max(5 * nn, np0 * mq0 + 2 * nb * nb) + \text{iceil}(neig, \text{NPROW} * \text{NPCOL}) * nn$$

For optimal performance, greater workspace is needed, that is

$$lwork \geq \max(lwork, \text{nhetrd_lwork})$$

where *lwork* is as defined above, and $\text{nhetrd_lwork} = n + 2 * (anb + 1) * (4 * nps + 2) + (nps + 1) * nps$

$$ictxt = \text{desca}[\text{ctxt}_ - 1]$$

```

anb = pjlavenv(ictxt, 3, 'pchettrd', 'L', 0, 0, 0, 0)
sqnpc = sqrt(dble(NPROW * NPCOL))
nps = max(numroc(n, 1, 0, 0, sqnpc), 2*anb)

```

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pxerbla`.

rwork

(local)

Workspace array of size $lwork$.*lwork*(local) The size of the array *work*.See below for definitions of variables used to define $lwork$.If no eigenvectors are requested ($jobz = 'N'$), then $lwork \geq 5*nn+4*n$.If eigenvectors are requested ($jobz = 'V'$), then the amount of workspace required to guarantee that all eigenvectors are computed is:
$$lwork \geq 4*n + \max(5*nn, np0*mq0+2*nb*nb) + \text{iceil}(neig, \text{NPROW}*NPCOL)*nn$$

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and $orfac$ is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following values to $lwork$:

$$(clustersize-1)*n,$$

where $clustersize$ is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

$$\{w[k-1], \dots, w[k+clustersize-2] | w[j] \leq w[j-1] + orfac*2*norm(A)\}.$$

Variable definitions:

 $neig$ = number of eigenvectors requested;
$$nb = desca[mb_ - 1] = desca[nb_ - 1] = descz[mb_ - 1] = descz[nb_ - 1];$$

$$nn = \max(n, NB, 2);$$

$$desca[rsrc_ - 1] = desca[nb_ - 1] = descz[rsrc_ - 1] = descz[csrc_ - 1] = 0;$$

$$np0 = \text{numroc}(nn, nb, 0, 0, \text{NPROW});$$

$$mq0 = \text{numroc}(\max(neig, nb, 2), nb, 0, 0, \text{NPCOL});$$

$$\text{iceil}(x, y)$$
 is a ScaLAPACK function returning $\text{ceiling}(x/y)$
When $lwork$ is too small:

If $lwork$ is too small to guarantee orthogonality, `p?heevx` attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues. If $lwork$ is too small to compute all the eigenvectors requested, no computation is performed and $info = -23$ is returned. Note that when $range = 'V'$, `p?heevx` does not know how many eigenvectors are requested

until the eigenvalues are computed. Therefore, when `range='V'` and as long as `lwork` is large enough to allow `p?heevx` to compute the eigenvalues, `p?heevx` will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality and performance:

If $clustersize \geq n/\sqrt{NPROW * NPCOL}$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is, $clustersize = n-1$) `p?stein` will perform no better than `?stein` on 1 processor.

For $clustersize = n/\sqrt{NPROW * NPCOL}$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For $clustersize > n/\sqrt{NPROW * NPCOL}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `p?xerbla`.

`iwork` (local) Workspace array.

`liwork` (local), size of `iwork`.

$$liwork \geq 6 * nnp$$

Where: $nnp = \max(n, NPROW * NPCOL + 1, 4)$

If `liwork = -1`, then `liwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?xerbla`.

Output Parameters

`a` On exit, the lower triangle (if `uplo = 'L'`), or the upper triangle (if `uplo = 'U'`) of A , including the diagonal, is overwritten.

`m` (global) The total number of eigenvalues found; $0 \leq m \leq n$.

`nz` (global) Total number of eigenvectors computed. $0 \leq nz \leq m$.

The number of columns of z that are filled.

If `jobz ≠ 'V'`, `nz` is not referenced.

If `jobz = 'V'`, `nz = m` unless the user supplies insufficient space and `p?heevx` is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in z ($m \leq descz[n_ - 1]$) and sufficient workspace to compute them. (See `lwork`). `p?heevx` is always able to detect insufficient space without computation unless `range='V'`.

`w` (global).

| | |
|------------|--|
| | <p>Array of size n. The first m elements contain the selected eigenvalues in ascending order.</p> |
| z | <p>(local).</p> <p>Array, global size $n*n$, local size $lld_z*LOCc(jz+n-1)$.</p> <p>If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i>.</p> <p>If $jobz = 'N'$, then z is not referenced.</p> |
| $work[0]$ | <p>On exit, returns adequate workspace to allow optimal performance.</p> |
| $rwork$ | <p>(local).</p> <p>Array of size $lwork$. On return, $rwork[0]$ contains the optimal amount of workspace required for efficient execution.</p> <p>If $jobz='N'$ $rwork[0]$ = optimal amount of workspace required to compute eigenvalues efficiently.</p> <p>If $jobz='V'$ $rwork[0]$ = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.</p> <p>If $range='V'$, it is assumed that all eigenvectors may be required.</p> |
| $iwork[0]$ | <p>(local)</p> <p>On return, $iwork[0]$ contains the amount of integer workspace required.</p> |
| $ifail$ | <p>(global)</p> <p>Array of size n.</p> <p>If $jobz = 'V'$, then on normal exit, the first m elements of $ifail$ are zero. If $(\text{mod}(\text{info}, 2) \neq 0)$ on exit, then $ifail$ contains the indices of the eigenvectors that failed to converge.</p> <p>If $jobz = 'N'$, then $ifail$ is not referenced.</p> |
| $iclustr$ | <p>(global)</p> <p>Array of size $2*NPROW*NPCOL$.</p> <p>This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see <i>lwork</i>, <i>orfac</i> and <i>info</i>). Eigenvectors corresponding to clusters of eigenvalues indexed $iclustr[2*i - 2]$ to $iclustr[2*i - 1]$, could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. $iclustr$ is a zero terminated array. ($iclustr[2*k - 1] \neq 0$ and $iclustr[2*k] = 0$) if and only if k is the number of clusters. $iclustr$ is not referenced if $jobz = 'N'$.</p> |
| gap | <p>(global)</p> <p>Array of size $(NPROW*NPCOL)$</p> |

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*-th cluster may be as high as $(C*n)/gap(i)$ where *C* is a small constant.

info

(global)

If *info* = 0, the execution is successful.

If *info* < 0:

If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = $-(i*100+j)$. If the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

If *info* > 0:

If $(\text{mod}(\text{info}, 2) \neq 0)$, then one or more eigenvectors failed to converge. Their indices are stored in *ifail*. Ensure $\text{abstol} = 2.0 * p?lamch('U')$

If $(\text{mod}(\text{info}/2, 2) \neq 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If $(\text{mod}(\text{info}/4, 2) \neq 0)$, then space limit prevented *p?syevx* from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If $(\text{mod}(\text{info}/8, 2) \neq 0)$, then *p?stebz* failed to compute eigenvalues. Ensure $\text{abstol} = 2.0 * p?lamch('U')$.

Description

The `p?gesvd` function computes the singular value decomposition (SVD) of an m -by- n matrix A , optionally computing the left and/or right singular vectors. The SVD is written

$$A = U \Sigma V^T,$$

where Σ is an m -by- n matrix that is zero except for its $\min(m, n)$ diagonal elements, U is an m -by- m orthogonal matrix, and V is an n -by- n orthogonal matrix. The diagonal elements of Σ are the singular values of A and the columns of U and V are the corresponding right and left singular vectors, respectively. The singular values are returned in array s in decreasing order and only the first $\min(m, n)$ columns of U and rows of $vt = V^T$ are computed.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

mp = number of local rows in A and U

nq = number of local columns in A and VT

$size$ = $\min(m, n)$

$sizeq$ = number of local columns in U

$sizep$ = number of local rows in VT

$jobu$ (global) Specifies options for computing all or part of the matrix U .
 If $jobu = 'V'$, the first $size$ columns of U (the left singular vectors) are returned in the array u ;
 If $jobu = 'N'$, no columns of U (no left singular vectors) are computed.

$jobvt$ (global)
 Specifies options for computing all or part of the matrix V^T .
 If $jobvt = 'V'$, the first $size$ rows of V^T (the right singular vectors) are returned in the array vt ;
 If $jobvt = 'N'$, no rows of V^T (no right singular vectors) are computed.

| | |
|-----------------|---|
| <i>m</i> | (global) The number of rows of the matrix A ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in A ($n \geq 0$). |
| <i>a</i> | (local). Block cyclic array, global size (m, n) , local size (mp, nq) . |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A . |
| <i>iu, ju</i> | (global) The row and column indices in the global matrix U indicating the first row and the first column of the submatrix U , respectively. |
| <i>descu</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix U . |
| <i>ivt, jvt</i> | (global) The row and column indices in the global matrix VT indicating the first row and the first column of the submatrix VT , respectively. |
| <i>descvt</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix VT . |
| <i>work</i> | (local). Workspace array of size <i>lwork</i> |
| <i>lwork</i> | (local) The size of the array <i>work</i> ; $lwork > 2 + 6 * sizeb + \max(watobd, wbdtosvd)$, where $sizeb = \max(m, n)$, and <i>watobd</i> and <i>wbdtosvd</i> refer, respectively, to the workspace required to bidiagonalize the matrix A and to go from the bidiagonal matrix to the singular value decomposition $USVT$. For <i>watobd</i> , the following holds: $watobd = \max(\max(wp?lange, wp?gebrd), \max(wp?lared2d, wp?lared1d))$, where <i>wp?lange</i> , <i>wp?lared1d</i> , <i>wp?lared2d</i> , <i>wp?gebrd</i> are the workspaces required respectively for the subprograms <i>p?lange</i> , <i>p?lared1d</i> , <i>p?lared2d</i> , <i>p?gebrd</i> . Using the standard notation $mp = \text{numroc}(m, mb, \text{MYROW}, \text{desca}[\text{ctxt}_ - 1], \text{NPROW})$, $nq = \text{numroc}(n, nb, \text{MYCOL}, \text{desca}[\text{lld}_ - 1], \text{NPCOL})$, the workspaces required for the above subprograms are $wp?lange = mp$, $wp?lared1d = nq0$, $wp?lared2d = mp0$, $wp?gebrd = nb * (mp + nq + 1) + nq$, where <i>nq0</i> and <i>mp0</i> refer, respectively, to the values obtained at <code>MYCOL = 0</code> and <code>MYROW = 0</code> . In general, the upper limit for the workspace is given by a workspace required on processor (0,0): |

$$w_{atobd} \leq nb * (mp0 + nq0 + 1) + nq0.$$

In case of a homogeneous process grid this upper limit can be used as an estimate of the minimum workspace for every processor.

For *wbdtosvd*, the following holds:

$$wbdtosvd = size * (wantu * nru + wantvt * ncv) + \max(w?bdsqr, \max(wantu * wp?ormbrqln, wantvt * wp?ormbrprt)),$$

where

$wantu(wantvt) = 1$, if left/right singular vectors are wanted, and $wantu(wantvt) = 0$, otherwise. $w?bdsqr$, $wp?ormbrqln$, and $wp?ormbrprt$ refer respectively to the workspace required for the subprograms $?bdsqr$, $p?ormbr(qln)$, and $p?ormbr(prt)$, where qln and prt are the values of the arguments *vect*, *side*, and *trans* in the call to $p?ormbr$. nru is equal to the local number of rows of the matrix U when distributed 1-dimensional "column" of processes. Analogously, ncv is equal to the local number of columns of the matrix VT when distributed across 1-dimensional "row" of processes. Calling the LAPACK procedure $?bdsqr$ requires

$$w?bdsqr = \max(1, 2 * size + (2 * size - 4) * \max(wantu, wantvt))$$

on every processor. Finally,

$$wp?ormbrqln = \max((nb * (nb - 1)) / 2, (sizeq + mp) * nb) + nb * nb,$$

$$wp?ormbrprt = \max((mb * (mb - 1)) / 2, (sizep + nq) * mb) + mb * mb,$$

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum size for the work array. The required workspace is returned as the first element of *work* and no error message is issued by `pxerbla`.

rwork

Workspace array of size $1 + 4 * sizeb$. Not used for `psgesvd` and `pdgesvd`.

Output Parameters

a

On exit, the contents of *a* are destroyed.

s

(global).

Array of size *size*.

Contains the singular values of A sorted so that $s(i) \geq s(i+1)$.

u

(local).

local size $mp * sizeq$, global size $m * size$)

If $jobu = 'V'$, *u* contains the first $\min(m, n)$ columns of U .

If $jobu = 'N'$ or $'O'$, *u* is not referenced.

vt

(local).

local size (*sizep*, *nq*), global size (*size*, *n*)

If $jobvt = 'V'$, *vt* contains the first *size* rows of V^T if $jobu = 'N'$, *vt* is not referenced.

| | |
|--------------|--|
| <i>work</i> | On exit, if <i>info</i> = 0, then <i>work</i> [0] returns the required minimal size of <i>lwork</i> . |
| <i>rwork</i> | On exit, if <i>info</i> = 0, then <i>rwork</i> [0] returns the required size of <i>rwork</i> . |
| <i>info</i> | (global) If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, If <i>info</i> = - <i>i</i> , the <i>i</i> th parameter had an illegal value. If <i>info</i> > 0 <i>i</i> , then if ?bdsqr did not converge, If <i>info</i> = min(<i>m</i> , <i>n</i>) + 1, then p?gesvd has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from p?gesvd cannot be guaranteed. |

Description

The p?sygvx function computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x, \text{sub}(A) \text{ sub}(B) * x = \lambda * x, \text{ or } \text{sub}(B) * \text{sub}(A) * x = \lambda * x.$$

Here *x* denotes eigen vectors, λ (*lambda*) denotes eigenvalues, *sub*(*A*) denoting *A*(*ia:ia+n-1, ja:ja+n-1*) is assumed to symmetric, and *sub*(*B*) denoting *B*(*ib:ib+n-1, jb:jb+n-1*) is also positive definite.

Notice revision #20110804

Input Parameters

| | |
|---------------|---|
| <i>ibtype</i> | (global) Must be 1 or 2 or 3. Specifies the problem type to be solved: If <i>ibtype</i> = 1, the problem type is $\text{sub}(A) * x = \text{lambda} * \text{sub}(B) * x$; If <i>ibtype</i> = 2, the problem type is $\text{sub}(A) * \text{sub}(B) * x = \text{lambda} * x$; If <i>ibtype</i> = 3, the problem type is $\text{sub}(B) * \text{sub}(A) * x = \text{lambda} * x$. |
| <i>jobz</i> | (global) Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors. |
| <i>range</i> | (global) Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the function computes all eigenvalues. If <i>range</i> = 'V', the function computes eigenvalues in the interval: [<i>vl</i> , <i>vu</i>] If <i>range</i> = 'I', the function computes eigenvalues with indices <i>il</i> through <i>iu</i> . |
| <i>uplo</i> | (global) Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of $\text{sub}(A)$ and $\text{sub}(B)$; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of $\text{sub}(A)$ and $\text{sub}(B)$. |
| <i>n</i> | (global) The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$, $n \geq 0$. |
| <i>a</i> | (local) Pointer into the local memory to an array of size $\text{lld_a} * \text{LOCc}(j_{a+n-1})$. On entry, this array contains the local pieces of the <i>n</i> -by- <i>n</i> symmetric distributed matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix. |

| | |
|---------------|--|
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>desca[ctxt_ - 1]</i> is incorrect, <i>p?sygvx</i> cannot guarantee correct error reporting. |
| <i>b</i> | (local). Pointer into the local memory to an array of size <i>lld_b*LOCc(jb+n-1)</i> . On entry, this array contains the local pieces of the <i>n</i> -by- <i>n</i> symmetric distributed matrix sub(<i>B</i>). If <i>uplo = 'U'</i> , the leading <i>n</i> -by- <i>n</i> upper triangular part of sub(<i>B</i>) contains the upper triangular part of the matrix. If <i>uplo = 'L'</i> , the leading <i>n</i> -by- <i>n</i> lower triangular part of sub(<i>A</i>) contains the lower triangular part of the matrix. |
| <i>ib, jb</i> | (global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively. |
| <i>descb</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> . <i>descb[ctxt_ - 1]</i> must be equal to <i>desca[ctxt_ - 1]</i> . |
| <i>vl, vu</i> | (global) If <i>range = 'V'</i> , the lower and upper bounds of the interval to be searched for eigenvalues. If <i>range = 'A'</i> or <i>'I'</i> , <i>vl</i> and <i>vu</i> are not referenced. |
| <i>il, iu</i> | (global) If <i>range = 'I'</i> , the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $il \geq 1, \min(il, n) \leq iu \leq n$ If <i>range = 'A'</i> or <i>'V'</i> , <i>il</i> and <i>iu</i> are not referenced. |
| <i>abstol</i> | (global) If <i>jobz='V'</i> , setting <i>abstol</i> to <i>p?lamch(context, 'U')</i> yields the most orthogonal eigenvectors. The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + eps * \max(a , b),$ where <i>eps</i> is the machine precision. If <i>abstol</i> is less than or equal to zero, then <i>eps*norm(T)</i> will be used in its place, where <i>norm(T)</i> is the 1-norm of the tridiagonal matrix obtained by reducing <i>A</i> to tridiagonal form. Eigenvalues will be computed most accurately when <i>abstol</i> is set to twice the underflow threshold <i>2*p?lamch('S')</i> not zero. If this function returns with $((\text{mod}(\text{info}, 2) \neq 0) \text{ or } (\text{mod}(\text{info}/8, 2) \neq 0))$, indicating that some eigenvalues or eigenvectors did not converge, try setting <i>abstol</i> to <i>2*p?lamch('S')</i> . |

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

| | |
|---------------|---|
| <i>orfac</i> | (global). Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $\text{tol} = \text{orfac} * \text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see <i>lwork</i>), <i>tol</i> may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if <i>orfac</i> equals zero. A default value of $1.0\text{e-}3$ is used if <i>orfac</i> is negative. <i>orfac</i> should be identical on all processes. |
| <i>iz, jz</i> | (global) The row and column indices in the global matrix <i>Z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively. |
| <i>descz</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> . <i>descz</i> [<i>ctxt_</i> - 1] must equal <i>desca</i> [<i>ctxt_</i> - 1]. |
| <i>work</i> | (local) Workspace array of size <i>lwork</i> |
| <i>lwork</i> | (local) Size of the array <i>work</i> . See below for definitions of variables used to define <i>lwork</i> . If no eigenvectors are requested (<i>jobz</i> = 'N'), then $\text{lwork} \geq 5 * n + \max(5 * nn, \text{NB} * (\text{np0} + 1))$. If eigenvectors are requested (<i>jobz</i> = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is: $\text{lwork} \geq 5 * n + \max(5 * nn, \text{np0} * \text{mq0} + 2 * \text{nb} * \text{nb}) + \text{iceil}(\text{neig}, \text{NPROW} * \text{NPCOL}) * nn$ The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and <i>orfac</i> is too small. If you want to guarantee orthogonality at the cost of potentially poor performance you should add the following to <i>lwork</i> : $(\text{clustersize} - 1) * n,$ where <i>clustersize</i> is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues: $\{w[k - 1], \dots, w[k + \text{clustersize} - 2] \mid w[j] \leq w[j - 1] + \text{orfac} * 2 * \text{norm}(A)\}$ Variable definitions: <i>neig</i> = number of eigenvectors requested, $\text{nb} = \text{desca}[\text{mb}_ - 1] = \text{desca}[\text{nb}_ - 1] = \text{descz}[\text{mb}_ - 1] = \text{descz}[\text{nb}_ - 1],$ $\text{nn} = \max(n, \text{nb}, 2),$ $\text{desca}[\text{rsrc}_ - 1] = \text{desca}[\text{nb}_ - 1] = \text{descz}[\text{rsrc}_ - 1] = \text{descz}[\text{csrc}_ - 1] = 0,$ |

$np0 = \text{numroc}(nn, nb, 0, 0, \text{NPROW}),$

$mq0 = \text{numroc}(\max(neig, nb, 2), nb, 0, 0, \text{NPCOL})$

$\text{iceil}(x, y)$ is a ScaLAPACK function returning $\text{ceiling}(x/y)$

If $lwork$ is too small to guarantee orthogonality, $p?syevx$ attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If $lwork$ is too small to compute all the eigenvectors requested, no computation is performed and $info = -23$ is returned.

Note that when $range = 'V'$, number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if $lwork$ is large enough to compute the eigenvalues, $p?sygvx$ computes the eigenvalues and as many eigenvectors as possible.

Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

$lwork \geq \max(lwork, 5*n + nsytrd_lwopt, nsygst_lwopt),$ where

$lwork$, as defined previously, depends upon the number of eigenvectors requested, and

$nsytrd_lwopt = n + 2*(anb+1)*(4*nps+2) + (nps+3)*nps$

$nsygst_lwopt = 2*np0*nb + nq0*nb + nb*nb$

$anb = \text{pjlaenv}(\text{desca}[\text{ctxt}_ - 1], 3, p?\text{sytrd} \text{ ', 'L', 0, 0, 0, 0})$

$sqnpc = \text{int}(\text{sqrt}(\text{dble}(\text{NPROW} * \text{NPCOL})))$

$nps = \max(\text{numroc}(n, 1, 0, 0, sqnpc), 2*anb)$

$\text{NB} = \text{desca}[\text{mb}_ - 1]$

$np0 = \text{numroc}(n, nb, 0, 0, \text{NPROW})$

$nq0 = \text{numroc}(n, nb, 0, 0, \text{NPCOL})$

numroc is a ScaLAPACK tool functions;

pjlaenv is a ScaLAPACK environmental inquiry function

$\text{MYROW}, \text{MYCOL}, \text{NPROW}$ and NPCOL can be determined by calling the function blacs_gridinfo .

For large n , no extra workspace is needed, however the biggest boost in performance comes for small n , so it is wise to provide the extra workspace (typically less than a Megabyte per process).

If $clustersize \geq n/\text{sqrt}(\text{NPROW}*\text{NPCOL})$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is, $clustersize = n-1$) $p?\text{stein}$ will perform no better than $?\text{stein}$ on a single processor.

For $clustersize = n/\text{sqrt}(\text{NPROW}*\text{NPCOL})$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For $clustersize > n/\sqrt{NPROW * NPCOL}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pxerbla`.

iwork (local) Workspace array.

liwork (local) , size of *iwork*.

$liwork \geq 6 * nnp$

Where:

$nnp = \max(n, NPROW * NPCOL + 1, 4)$

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a On exit,
If $jobz = 'V'$, and if $info = 0$, sub(A) contains the distributed matrix Z of eigenvectors. The eigenvectors are normalized as follows:

for $ibtype = 1$ or 2 , $Z^T * \text{sub}(B) * Z = I$;

for $ibtype = 3$, $Z^T * \text{inv}(\text{sub}(B)) * Z = I$.

If $jobz = 'N'$, then on exit the upper triangle (if $uplo = 'U'$) or the lower triangle (if $uplo = 'L'$) of sub(A), including the diagonal, is destroyed.

b On exit, if $info \leq n$, the part of sub(B) containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $\text{sub}(B) = U^T * U$ or $\text{sub}(B) = L * L^T$.

m (global) The total number of eigenvalues found, $0 \leq m \leq n$.

nz (global)

Total number of eigenvectors computed. $0 \leq nz \leq m$. The number of columns of z that are filled.

If $jobz \neq 'V'$, *nz* is not referenced.

If $jobz = 'V'$, $nz = m$ unless the user supplies insufficient space and `p?sygvx` is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in z ($m \leq \text{descz}(n_)$) and sufficient workspace to compute them. (See *lwork* below.) `p?sygvx` is always able to detect insufficient space without computation unless $range = 'V'$.

w (global)

Array of size n . On normal exit, the first m entries contain the selected eigenvalues in ascending order.

z

(local).

global size $n*n$, local size $lld_z*LOCc(jz+n-1)$.

If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If $jobz = 'N'$, then z is not referenced.

work

If $jobz='N'$ $work[0]$ = optimal amount of workspace required to compute eigenvalues efficiently

If $jobz = 'V'$ $work[0]$ = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.

If $range='V'$, it is assumed that all eigenvectors may be required.

ifail

(global)

Array of size n .

ifail provides additional information when $info \neq 0$

If $(mod(info/16,2) \neq 0)$ then $ifail[0]$ indicates the order of the smallest minor which is not positive definite. If $(mod(info,2) \neq 0)$ on exit, then *ifail* contains the indices of the eigenvectors that failed to converge.

If neither of the above error conditions hold and $jobz = 'V'$, then the first m elements of *ifail* are set to zero.

iclustr

(global)

Array of size $(2*NPROW*NPCOL)$. This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed $iclustr[2*i - 2]$ to $iclustr[2*i - 1]$, could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr* is a zero terminated array.

$(iclustr[2*k - 1] \neq 0$.and. $iclustr[2*k]=0)$ if and only if k is the number of clusters *iclustr* is not referenced if $jobz = 'N'$.

gap

(global)

Array of size $NPROW*NPCOL$. This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the i -th cluster may be as high as $(C*n)/gap[i - 1]$, where C is a small constant.

info

(global)

If $info = 0$, the execution is successful.

If $info < 0$: the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

If $info > 0$:

If $(\text{mod}(info, 2) \neq 0)$, then one or more eigenvectors failed to converge. Their indices are stored in *ifail*.

If $(\text{mod}(info, 2, 2) \neq 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If $(\text{mod}(info/4, 2) \neq 0)$, then space limit prevented $p?sygvx$ from computing all of the eigenvectors between vl and vu . The number of eigenvectors computed is returned in *nz*.

If $(\text{mod}(info/8, 2) \neq 0)$, then $p?stebz$ failed to compute eigenvalues.

If $(\text{mod}(info/16, 2) \neq 0)$, then B was not positive definite. *ifail(1)* indicates the order of the smallest minor which is not positive definite.

Description

The $p?hegvx$ function computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x, \quad \text{sub}(A) * \text{sub}(B) * x = \lambda * x, \quad \text{or} \quad \text{sub}(B) * \text{sub}(A) * x = \lambda * x.$$

Here $\text{sub}(A)$ denoting $A(ia:ia+n-1, ja:ja+n-1)$ and $\text{sub}(B)$ are assumed to be Hermitian and $\text{sub}(B)$ denoting $B(ib:ib+n-1, jb:jb+n-1)$ is also positive definite.

Notice revision #20110804

Input Parameters

| | |
|---------------|--|
| <i>ibtype</i> | (global) Must be 1 or 2 or 3. Specifies the problem type to be solved: If <i>ibtype</i> = 1, the problem type is $\text{sub}(A) * x = \text{lambda} * \text{sub}(B) * x;$ If <i>ibtype</i> = 2, the problem type is $\text{sub}(A) * \text{sub}(B) * x = \text{lambda} * x;$ If <i>ibtype</i> = 3, the problem type is $\text{sub}(B) * \text{sub}(A) * x = \text{lambda} * x.$ |
| <i>jobz</i> | (global) Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors. |
| <i>range</i> | (global) Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the function computes all eigenvalues. If <i>range</i> = 'V', the function computes eigenvalues in the interval: [<i>v1</i> , <i>vu</i>] If <i>range</i> = 'I', the function computes eigenvalues with indices <i>il</i> through <i>iu</i> . |
| <i>uplo</i> | (global) Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of $\text{sub}(A)$ and $\text{sub}(B)$; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of $\text{sub}(A)$ and $\text{sub}(B)$. |
| <i>n</i> | (global) The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$). |
| <i>a</i> | (local) |

Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$. On entry, this array contains the local pieces of the n -by- n Hermitian distributed matrix $sub(A)$. If $uplo = 'U'$, the leading n -by- n upper triangular part of $sub(A)$ contains the upper triangular part of the matrix. If $uplo = 'L'$, the leading n -by- n lower triangular part of $sub(A)$ contains the lower triangular part of the matrix.

ia, ja

(global)

The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

desca(global and local) array of size $dlen_$.

The array descriptor for the distributed matrix A . If $desca[ctxt_ - 1]$ is incorrect, `p?hegvx` cannot guarantee correct error reporting.

b

(local).

Pointer into the local memory to an array of size $lld_b * LOCC(jb+n-1)$. On entry, this array contains the local pieces of the n -by- n Hermitian distributed matrix $sub(B)$.

If $uplo = 'U'$, the leading n -by- n upper triangular part of $sub(B)$ contains the upper triangular part of the matrix.

If $uplo = 'L'$, the leading n -by- n lower triangular part of $sub(B)$ contains the lower triangular part of the matrix.

ib, jb

(global)

The row and column indices in the global matrix B indicating the first row and the first column of the submatrix B , respectively.

descb(global and local) array of size $dlen_$.

The array descriptor for the distributed matrix B . $descb[ctxt_ - 1]$ must be equal to $desca[ctxt_ - 1]$.

vl, vu

(global)

If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.

If $range = 'A'$ or $'I'$, vl and vu are not referenced.

il, iu

(global)

If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $il \geq 1$, $\min(il, n) \leq iu \leq n$

If $range = 'A'$ or $'V'$, il and iu are not referenced.

abstol

(global)

If $jobz = 'V'$, setting $abstol$ to `p?lamch(context, 'U')` yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to

$abstol + eps * \max(|a|, |b|)$,

where eps is the machine precision. If $abstol$ is less than or equal to zero, then $eps * \text{norm}(T)$ will be used in its place, where $\text{norm}(T)$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when $abstol$ is set to twice the underflow threshold $2 * p?lamch('S')$ not zero. If this function returns with $((\text{mod}(\text{info}, 2) \neq 0) .or. * (\text{mod}(\text{info}/8, 2) \neq 0))$, indicating that some eigenvalues or eigenvectors did not converge, try setting $abstol$ to $2 * p?lamch('S')$.

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

orfac

(global).

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol = orfac * \text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see *lwork*), tol may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of 1.0E-3 is used if *orfac* is negative. *orfac* should be identical on all processes.

iz, jz

(global) The row and column indices in the global matrix Z indicating the first row and the first column of the submatrix Z , respectively.

descz

(global and local) array of size $dlen_$. The array descriptor for the distributed matrix Z . $descz[ctxt_ - 1]$ must equal $desca[ctxt_ - 1]$.

work

(local)

Workspace array of size *lwork*

lwork

(local).

The size of the array *work*.

If only eigenvalues are requested:

$$lwork \geq n + \max(NB * (np0 + 1), 3)$$

If eigenvectors are requested:

$$lwork \geq n + (np0 + mq0 + NB) * NB$$

with $nq0 = \text{numroc}(nn, NB, 0, 0, NPCOL)$.

For optimal performance, greater workspace is needed, that is

$$lwork \geq \max(lwork, n, nhetrd_lwopt, nhegst_lwopt)$$

where *lwork* is as defined above, and

$$nhetrd_lwork = 2 * (anb + 1) * (4 * nps + 2) + (nps + 1) * nps;$$

$$nhegst_lwopt = 2 * np0 * nb + nq0 * nb + nb * nb$$

$$nb = desca[mb_ - 1]$$

$$np0 = \text{numroc}(n, nb, 0, 0, NPROW)$$

```

ng0 = numroc(n, nb, 0, 0, NPCOL)
ictxt = desca[ctxt_ - 1]
anb = pjlenv(ictxt, 3, 'p?hettrd', 'L', 0, 0, 0, 0)
sqnpc = sqrt(dble(NPROW * NPCOL))
nps = max(numroc(n, 1, 0, 0, sqnpc), 2*anb)

```

numroc is a ScaLAPACK tool functions;

pjlenv is a ScaLAPACK environmental inquiry function MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by p_xerbla.

rwork

(local)

Workspace array of size *lwork*.

lwork

(local) The size of the array *rwork*.

See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N'), then $lwork \geq 5*nn+4*n$

If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

$$lwork \geq 4*n + \max(5*nn, np0*mq0) + \text{iceil}(neig, NPROW*NPCOL)*nn$$

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following value to *lwork*:

$$(clustersize-1)*n,$$

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

$$\{w[k-1], \dots, w[k+clustersize-2] \mid |w[j]-w[j-1]| \leq orfac*2*norm(A)\}$$

Variable definitions:

neig = number of eigenvectors requested;

$$nb = desca[mb_ - 1] = desca[nb_ - 1] = descz[mb_ - 1] = descz[nb_ - 1];$$

$$nn = \max(n, nb, 2);$$

$$desca[rsrc_ - 1] = desca[nb_ - 1] = descz[rsrc_ - 1] = descz[csrc_ - 1] = 0;$$

$$np0 = \text{numroc}(nn, nb, 0, 0, NPROW);$$

$$mq0 = \text{numroc}(\max(neig, nb, 2), nb, 0, 0, NPCOL);$$

iceil(*x*, *y*) is a ScaLAPACK function returning ceiling(*x*/*y*).

When *lwork* is too small:

If *lwork* is too small to guarantee orthogonality, `p?hegvx` attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -25 is returned. Note that when *range*='V', `p?hegvx` does not know how many eigenvectors are requested until the eigenvalues are computed. Therefore, when *range*='V' and as long as *lwork* is large enough to allow `p?hegvx` to compute the eigenvalues, `p?hegvx` will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality & performance:

If $clustersize > n/\sqrt{NPROW*NPCOL}$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is, $clustersize = n-1$) `p?stein` will perform no better than `?stein` on 1 processor.

For $clustersize = n/\sqrt{NPROW*NPCOL}$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For $clustersize > n/\sqrt{NPROW*NPCOL}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pxerbla`.

iwork (local) Workspace array.

liwork (local) , size of *iwork*.

$liwork \geq 6 * nnp$

Where: $nnp = \max(n, NPROW*NPCOL + 1, 4)$

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a On exit, if *jobz* = 'V', then if *info* = 0, sub(A) contains the distributed matrix *Z* of eigenvectors.

The eigenvectors are normalized as follows:

If *ibtype* = 1 or 2, then $Z^H * \text{sub}(B) * Z = i$;

If *ibtype* = 3, then $Z^H * \text{inv}(\text{sub}(B)) * Z = i$.

If *jobz* = 'N', then on exit the upper triangle (if *uplo*='U') or the lower triangle (if *uplo*='L') of sub(A), including the diagonal, is destroyed.

| | |
|--------------|--|
| <i>b</i> | On exit, if $info \leq n$, the part of $sub(B)$ containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $sub(B) = U^H * U$, or $sub(B) = L * L^H$. |
| <i>m</i> | (global) The total number of eigenvalues found, $0 \leq m \leq n$. |
| <i>nz</i> | (global) Total number of eigenvectors computed. $0 < nz < m$. The number of columns of z that are filled. If $jobz \neq 'V'$, nz is not referenced. If $jobz = 'V'$, $nz = m$ unless the user supplies insufficient space and <code>p?hegvx</code> is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in z ($m \leq descz[n_ - 1]$) and sufficient workspace to compute them. (See <i>lwork</i> below.) The function <code>p?hegvx</code> is always able to detect insufficient space without computation unless $range = 'V'$. |
| <i>w</i> | (global) Array of size n . On normal exit, the first m entries contain the selected eigenvalues in ascending order. |
| <i>z</i> | (local). global size $n * n$, local size $lld_z * LOcc(jz+n-1)$. If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i> . If $jobz = 'N'$, then z is not referenced. |
| <i>work</i> | On exit, $work[0]$ returns the optimal amount of workspace. |
| <i>rwork</i> | On exit, $rwork[0]$ contains the amount of workspace required for optimal efficiency If $jobz = 'N'$ $rwork[0] =$ optimal amount of workspace required to compute eigenvalues efficiently If $jobz = 'V'$ $rwork[0] =$ optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality. If $range = 'V'$, it is assumed that all eigenvectors may be required when computing optimal workspace. |
| <i>ifail</i> | (global) Array of size n . <i>ifail</i> provides additional information when $info \neq 0$ If $(mod(info/16,2) \neq 0)$, then $ifail[0]$ indicates the order of the smallest minor which is not positive definite. If $(mod(info,2) \neq 0)$ on exit, then $ifail[0]$ contains the indices of the eigenvectors that failed to converge. |

If neither of the above error conditions are held, and $jobz = 'V'$, then the first m elements of $ifail$ are set to zero.

iclustr

(global)

Array of size $(2*NPROW*NPCOL)$. This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed $iclustr(2*i-1)$ to $iclustr(2*i)$, could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal.

iclustr() is a zero terminated array. ($iclustr(2*k) \neq 0$ and $iclustr(2*k+1)=0$) if and only if k is the number of clusters.

iclustr is not referenced if $jobz = 'N'$.

gap

(global)

Array of size $NPROW*NPCOL$.

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the i -th cluster may be as high as $(C*n)/gap(i)$, where C is a small constant.

info

(global)

If $info = 0$, the execution is successful.

If $info < 0$: the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

If $info > 0$:

If $(\text{mod}(info, 2) \neq 0)$, then one or more eigenvectors failed to converge. Their indices are stored in *ifail*.

If $(\text{mod}(info, 2, 2) \neq 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If $(\text{mod}(info/4, 2) \neq 0)$, then space limit prevented `p?sygvx` from computing all of the eigenvectors between vl and vu . The number of eigenvectors computed is returned in *nz*.

If $(\text{mod}(info/8, 2) \neq 0)$, then `p?stebz` failed to compute eigenvalues.

If $(\text{mod}(info/16, 2) \neq 0)$, then B was not positive definite. *ifail(1)* indicates the order of the smallest minor which is not positive definite.

ScaLAPACK Auxiliary Routines

ScaLAPACK Auxiliary Routines

| Routine Name | Data Types | Description |
|-------------------------|-------------------------|---|
| <code>b?laapp</code> | <code>s, d</code> | Multiplies a matrix with an orthogonal matrix. |
| <code>b?laexc</code> | <code>s, d</code> | Swaps adjacent diagonal blocks of a real upper quasi-triangular matrix in Schur canonical form, by an orthogonal similarity transformation. |
| <code>b?trexc</code> | <code>s, d</code> | Reorders the Schur factorization of a general matrix. |
| <code>p?lacgv</code> | <code>c, z</code> | Conjugates a complex vector. |
| <code>p?max1</code> | <code>c, z</code> | Finds the index of the element whose real part has maximum absolute value (similar to the Level 1 PBLAS <code>p?amax</code> , but using the absolute value to the real part). |
| <code>pmpcol</code> | <code>s, d</code> | <i>Finds the collaborators of a process.</i> |
| <code>pmpim2</code> | <code>s, d</code> | Computes the eigenpair range assignments for all processes. |
| <code>?combamax1</code> | <code>c, z</code> | Finds the element with maximum real part absolute value and its corresponding global index. |
| <code>p?sum1</code> | <code>sc, dz</code> | Forms the 1-norm of a complex vector similar to Level 1 PBLAS <code>p?asum</code> , but using the true absolute value. |
| <code>p?dbtrsv</code> | <code>s, d, c, z</code> | Computes an <i>LU</i> factorization of a general tridiagonal matrix with no pivoting. The routine is called by <code>p?dbtrs</code> . |
| <code>p?dttrsv</code> | <code>s, d, c, z</code> | Computes an <i>LU</i> factorization of a general band matrix, using partial pivoting with row interchanges. The routine is called by <code>p?dttrs</code> . |
| <code>p?gebal</code> | <code>s, d</code> | Balances a general real matrix. |
| <code>p?gebd2</code> | <code>s, d, c, z</code> | Reduces a general rectangular matrix to real bidiagonal form by an orthogonal/unitary transformation (unblocked algorithm). |
| <code>p?gehd2</code> | <code>s, d, c, z</code> | Reduces a general matrix to upper Hessenberg form by an orthogonal/unitary similarity transformation (unblocked algorithm). |
| <code>p?gelq2</code> | <code>s, d, c, z</code> | Computes an <i>LQ</i> factorization of a general rectangular matrix (unblocked algorithm). |
| <code>p?geql2</code> | <code>s, d, c, z</code> | Computes a <i>QL</i> factorization of a general rectangular matrix (unblocked algorithm). |
| <code>p?geqr2</code> | <code>s, d, c, z</code> | Computes a <i>QR</i> factorization of a general rectangular matrix (unblocked algorithm). |
| <code>p?gerq2</code> | <code>s, d, c, z</code> | Computes an <i>RQ</i> factorization of a general rectangular matrix (unblocked algorithm). |
| <code>p?getf2</code> | <code>s, d, c, z</code> | Computes an <i>LU</i> factorization of a general matrix, using partial pivoting with row interchanges (local blocked algorithm). |
| <code>p?labrd</code> | <code>s, d, c, z</code> | Reduces the first <i>nb</i> rows and columns of a general rectangular matrix <i>A</i> to real bidiagonal form by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of <i>A</i> . |

| Routine Name | Data Types | Description |
|-------------------------------|------------------------------|--|
| <code>p?lacon</code> | <code>s, d, c, z</code> | Estimates the 1-norm of a square matrix, using the reverse communication for evaluating matrix-vector products. |
| <code>p?laconsb</code> | <code>s, d</code> | Looks for two consecutive small subdiagonal elements. |
| <code>p?lacr2</code> | <code>s, d, c, z</code> | Copies all or part of a distributed matrix to another distributed matrix. |
| <code>p?lacr3</code> | <code>s, d</code> | Copies from a global parallel array into a local replicated array or vice versa. |
| <code>p?lacpy</code> | <code>s, d, c, z</code> | Copies all or part of one two-dimensional array to another. |
| <code>p?laevswp</code> | <code>s, d, c, z</code> | Moves the eigenvectors from where they are computed to ScaLAPACK standard block cyclic array. |
| <code>p?lahrd</code> | <code>s, d, c, z</code> | Reduces the first nb columns of a general rectangular matrix A so that elements below the k^{th} subdiagonal are zero, by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A. |
| <code>p?laiect</code> | <code>s, d, c, z</code> | Exploits IEEE arithmetic to accelerate the computations of eigenvalues. |
| <code>p?lamve</code> | <code>s, d</code> | Copies all or part of one two-dimensional distributed array to another. |
| <code>p?lange</code> | <code>s, d, c, z</code> | Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a general rectangular matrix. |
| <code>p?lanhs</code> | <code>s, d, c, z</code> | Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of an upper Hessenberg matrix. |
| <code>p?lansy, p?lanhe</code> | <code>s, d, c, z/c, z</code> | Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a real symmetric or complex Hermitian matrix. |
| <code>p?lantr</code> | <code>s, d, c, z</code> | Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a triangular matrix. |
| <code>p?lapiv</code> | <code>s, d, c, z</code> | Applies a permutation matrix to a general distributed matrix, resulting in row or column pivoting. |
| <code>p?laqge</code> | <code>s, d, c, z</code> | Scales a general rectangular matrix, using row and column scaling factors computed by <code>p?geequ</code> . |
| <code>p?laqr0</code> | <code>s, d</code> | Computes the eigenvalues of a Hessenberg matrix and optionally returns the matrices from the Schur decomposition. |
| <code>p?laqr1</code> | <code>s, d</code> | Sets a scalar multiple of the first column of the product of a 2-by-2 or 3-by-3 matrix and specified shifts. |
| <code>p?laqr2</code> | <code>s, d</code> | Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation). |

| Routine Name | Data Types | Description |
|------------------------|-------------------------|--|
| <code>p?laqr3</code> | <code>s, d</code> | Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation). |
| <code>p?laqr4</code> | <code>s, d</code> | Computes the eigenvalues of a Hessenberg matrix, and optionally computes the matrices from the Schur decomposition. |
| <code>p?laqr5</code> | <code>s, d</code> | Performs a single small-bulge multi-shift QR sweep. |
| <code>p?laqsy</code> | <code>s, d, c, z</code> | Scales a symmetric/Hermitian matrix, using scaling factors computed by <code>p?poequ</code> . |
| <code>p?lared1d</code> | <code>s, d</code> | Redistributes an array assuming that the input array <i>bycol</i> is distributed across rows and that all process columns contain the same copy of <i>bycol</i> . |
| <code>p?lared2d</code> | <code>s, d</code> | Redistributes an array assuming that the input array <i>byrow</i> is distributed across columns and that all process rows contain the same copy of <i>byrow</i> . |
| <code>p?larf</code> | <code>s, d, c, z</code> | Applies an elementary reflector to a general rectangular matrix. |
| <code>p?larfb</code> | <code>s, d, c, z</code> | Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix. |
| <code>p?larfc</code> | <code>c, z</code> | Applies the conjugate transpose of an elementary reflector to a general matrix. |
| <code>p?larfg</code> | <code>s, d, c, z</code> | Generates an elementary reflector (Householder matrix). |
| <code>p?larft</code> | <code>s, d, c, z</code> | Forms the triangular vector T of a block reflector $H=I-VTV^H$ |
| <code>p?larz</code> | <code>s, d, c, z</code> | Applies an elementary reflector as returned by <code>p?tzzrf</code> to a general matrix. |
| <code>p?larzb</code> | <code>s, d, c, z</code> | Applies a block reflector or its transpose/conjugate-transpose as returned by <code>p?tzzrf</code> to a general matrix. |
| <code>p?larzc</code> | <code>c, z</code> | Applies (multiplies by) the conjugate transpose of an elementary reflector as returned by <code>p?tzzrf</code> to a general matrix. |
| <code>p?larzt</code> | <code>s, d, c, z</code> | Forms the triangular factor T of a block reflector $H=I-VTV^H$ as returned by <code>p?tzzrf</code> . |
| <code>p?lascl</code> | <code>s, d, c, z</code> | Multiplies a general rectangular matrix by a real scalar defined as C_{to}/C_{from} . |
| <code>p?laset</code> | <code>s, d, c, z</code> | Initializes the off-diagonal elements of a matrix to α and the diagonal elements to β . |
| <code>p?lasmsub</code> | <code>s, d</code> | Looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero. |
| <code>p?lassq</code> | <code>s, d, c, z</code> | Updates a sum of squares represented in scaled form. |
| <code>p?laswp</code> | <code>s, d, c, z</code> | Performs a series of row interchanges on a general rectangular matrix. |
| <code>p?latra</code> | <code>s, d, c, z</code> | Computes the trace of a general square distributed matrix. |

| Routine Name | Data Types | Description |
|---------------------------------|---------------------|--|
| p?latrd | <i>s, d, c, z</i> | Reduces the first <i>nb</i> rows and columns of a symmetric/Hermitian matrix <i>A</i> to real tridiagonal form by an orthogonal/unitary similarity transformation. |
| p?latrz | <i>s, d, c, z</i> | Reduces an upper trapezoidal matrix to upper triangular form by means of orthogonal/unitary transformations. |
| p?lauu2 | <i>s, d, c, z</i> | Computes the product UU^H or $L^H L$, where <i>U</i> and <i>L</i> are upper or lower triangular matrices (local unblocked algorithm). |
| p?lauum | <i>s, d, c, z</i> | Computes the product UU^H or $L^H L$, where <i>U</i> and <i>L</i> are upper or lower triangular matrices. |
| p?lawil | <i>s, d</i> | Forms the Wilkinson transform. |
| p?org2l/p?ung2l | <i>s, d, c, z</i> | Generates all or part of the orthogonal/unitary matrix <i>Q</i> from a <i>QL</i> factorization determined by p?geqlf (unblocked algorithm). |
| p?org2r/p?ung2r | <i>s, d, c, z</i> | Generates all or part of the orthogonal/unitary matrix <i>Q</i> from a <i>QR</i> factorization determined by p?geqrf (unblocked algorithm). |
| p?orgl2/p?ungl2 | <i>s, d, c, z</i> | Generates all or part of the orthogonal/unitary matrix <i>Q</i> from an <i>LQ</i> factorization determined by p?gelqf (unblocked algorithm). |
| p?orgr2/p?ungr2 | <i>s, d, c, z</i> | Generates all or part of the orthogonal/unitary matrix <i>Q</i> from an <i>RQ</i> factorization determined by p?gerqf (unblocked algorithm). |
| p?orm2l/p?unm2l | <i>s, d, c, z</i> | Multiplies a general matrix by the orthogonal/unitary matrix from a <i>QL</i> factorization determined by p?geqlf (unblocked algorithm). |
| p?orm2r/p?unm2r | <i>s, d, c, z</i> | Multiplies a general matrix by the orthogonal/unitary matrix from a <i>QR</i> factorization determined by p?geqrf (unblocked algorithm). |
| p?orml2/p?unml2 | <i>s, d, c, z</i> | Multiplies a general matrix by the orthogonal/unitary matrix from an <i>LQ</i> factorization determined by p?gelqf (unblocked algorithm). |
| p?ormr2/p?unmr2 | <i>s, d, c, z</i> | Multiplies a general matrix by the orthogonal/unitary matrix from an <i>RQ</i> factorization determined by p?gerqf (unblocked algorithm). |
| p?pbtrsv | <i>s, d, c, z</i> | Solves a single triangular linear system via <code>frontsolve</code> or <code>backsolve</code> where the triangular matrix is a factor of a banded matrix computed by p?pbtrf . |
| p?pttrsv | <i>s, d, c, z</i> | Solves a single triangular linear system via <code>frontsolve</code> or <code>backsolve</code> where the triangular matrix is a factor of a tridiagonal matrix computed by p?pttrf . |
| p?potf2 | <i>s, d, c, z</i> | Computes the Cholesky factorization of a symmetric/Hermitian positive definite matrix (local unblocked algorithm). |
| p?rot | <i>s, d</i> | Applies a planar rotation to two distributed vectors. |
| p?rscl | <i>s, d, cs, zd</i> | Multiplies a vector by the reciprocal of a real scalar. |
| p?sygs2/p?hegs2 | <i>s, d, c, z</i> | Reduces a symmetric/Hermitian positive-definite generalized eigenproblem to standard form, using the factorization results obtained from p?potrf (local unblocked algorithm). |
| p?syt2/p?hetd2 | <i>s, d, c, z</i> | Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (local unblocked algorithm). |

| Routine Name | Data Types | Description |
|-----------------------|-------------------------|--|
| <code>p?trord</code> | <code>s, d</code> | Reorders the Schur factorization of a general matrix. |
| <code>p?trsen</code> | <code>s, d</code> | Reorders the Schur factorization of a matrix and (optionally) computes the reciprocal condition numbers and invariant subspace for the selected cluster of eigenvalues. |
| <code>p?trti2</code> | <code>s, d, c, z</code> | Computes the inverse of a triangular matrix (local unblocked algorithm). |
| <code>?lamsh</code> | <code>s, d</code> | Sends multiple shifts through a small (single node) matrix to maximize the number of bulges that can be sent through. |
| <code>?laqr6</code> | <code>s, d</code> | Performs a single small-bulge multi-shift QR sweep collecting the transformations. |
| <code>?lar1va</code> | <code>s, d</code> | <i>Computes scaled eigenvector corresponding to given eigenvalue.</i> |
| <code>?laref</code> | <code>s, d</code> | Applies Householder reflectors to matrices on either their rows or columns. |
| <code>?larrb2</code> | <code>s, d</code> | Provides limited bisection to locate eigenvalues for more accuracy. |
| <code>?larrd2</code> | <code>s, d</code> | Computes the eigenvalues of a symmetric tridiagonal matrix to suitable accuracy. |
| <code>?larre2</code> | <code>s, d</code> | Given a tridiagonal matrix, sets small off-diagonal elements to zero and for each unreduced block, finds base representations and eigenvalues. |
| <code>?larre2a</code> | <code>s, d</code> | <i>Given a tridiagonal matrix, sets small off-diagonal elements to zero and for each unreduced block, finds base representations and eigenvalues.</i> |
| <code>?larrf2</code> | <code>s, d</code> | Finds a new relatively robust representation such that at least one of the eigenvalues is relatively isolated. |
| <code>?larrv2</code> | <code>s, d</code> | Computes the eigenvectors of the tridiagonal matrix $T = L*D*L^T$ given L, D and the eigenvalues of $L*D*L^T$. |
| <code>?lasorte</code> | <code>s, d</code> | Sorts eigenpairs by real and complex data types. |
| <code>?lasrt2</code> | <code>s, d</code> | Sorts numbers in increasing or decreasing order. |
| <code>?stegr2</code> | <code>s, d</code> | Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix. |
| <code>?stegr2a</code> | <code>s, d</code> | Computes selected eigenvalues and initial representations needed for eigenvector computations. |
| <code>?stegr2b</code> | <code>s, d</code> | From eigenvalues and initial representations computes the selected eigenvalues and eigenvectors of the real symmetric tridiagonal matrix in parallel on multiple processors. |
| <code>?stein2</code> | <code>s, d</code> | Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix, using inverse iteration. |
| <code>?dbtff2</code> | <code>s, d, c, z</code> | Computes an LU factorization of a general band matrix with no pivoting (local unblocked algorithm). |
| <code>?dbtrf</code> | <code>s, d, c, z</code> | Computes an LU factorization of a general band matrix with no pivoting (local blocked algorithm). |

| Routine Name | Data Types | Description |
|-----------------------|-------------------------|---|
| <code>?dttrf</code> | <code>s, d, c, z</code> | Computes an <i>LU</i> factorization of a general tridiagonal matrix with no pivoting (local blocked algorithm). |
| <code>?dttrsv</code> | <code>s, d, c, z</code> | Solves a general tridiagonal system of linear equations using the <i>LU</i> factorization computed by <code>?dttrf</code> . |
| <code>?pttrsv</code> | <code>s, d, c, z</code> | Solves a symmetric (Hermitian) positive-definite tridiagonal system of linear equations, using the <i>LDL^H</i> factorization computed by <code>?pttrf</code> . |
| <code>?steqr2</code> | <code>s, d</code> | Computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit <i>QL</i> or <i>QR</i> method. |
| <code>?trmvt</code> | <code>s, d, c, z</code> | Performs matrix-vector operations. |
| <code>pilaenv</code> | NA | Returns the positive integer value of the logical blocking size. |
| <code>pilaenvx</code> | NA | Called from the ScaLAPACK routines to choose problem-dependent parameters for the local environment. |
| <code>pjlaenv</code> | NA | Called from the ScaLAPACK symmetric and Hermitian tailored eigen-routines to choose problem-dependent parameters for the local environment. |

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

p?lacgv

Conjugates a complex vector.

Syntax

```
void pclacgv (MKL_INT *n , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx );
```

```
void pzlacgv (MKL_INT *n , MKL_Complex16 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?lacgv` function conjugates a complex vector $\text{sub}(X)$ of length n , where $\text{sub}(X)$ denotes $X(ix, jx:jx+n-1)$ if `incx = m_x`, and $X(ix:ix+n-1, jx)$ if `incx = 1`.

Input Parameters

| | |
|--------------|---|
| <i>n</i> | (global) The length of the distributed vector $\text{sub}(X)$. |
| <i>x</i> | (local). Pointer into the local memory to an array of size $\text{lld}_x * \text{LOCc}(n_x)$. On entry the vector to be conjugated $x[i] = X(ix+(j_x-1)*m_x+i*incx)$, $0 \leq i < n$. |
| <i>ix</i> | (global) The row index in the global matrix X indicating the first row of $\text{sub}(X)$. |
| <i>jx</i> | (global) The column index in the global matrix X indicating the first column of $\text{sub}(X)$. |
| <i>descx</i> | (global and local) Array of size $\text{dlen}_x=9$. The array descriptor for the distributed matrix X . |
| <i>incx</i> | (global) The global increment for the elements of X . Only two values of <i>incx</i> are supported in this version, namely 1 and m_x . <i>incx</i> must not be zero. |

Output Parameters

| | |
|----------|--|
| <i>x</i> | (local). On exit, the local pieces of conjugated distributed vector $\text{sub}(X)$. |
|----------|--|

p?max1

Finds the index of the element whose real part has maximum absolute value (similar to the Level 1 PBLAS $p?amax$, but using the absolute value to the real part).

Syntax

```
void pcmax1 (MKL_INT *n , MKL_Complex8 *amax , MKL_INT *indx , MKL_Complex8 *x ,
MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx );

void pzmax1 (MKL_INT *n , MKL_Complex16 *amax , MKL_INT *indx , MKL_Complex16 *x ,
MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?max1` function computes the global index of the maximum element in absolute value of a distributed vector $\text{sub}(X)$. The global index is returned in *indx* and the value is returned in *amax*, where $\text{sub}(X)$ denotes $X(ix:ix+n-1, jx)$ if $incx = 1$, $X(ix, jx:jx+n-1)$ if $incx = m_x$.

Input Parameters

| | |
|--------------|--|
| <i>n</i> | (global). The number of components of the distributed vector $\text{sub}(X)$. $n \geq 0$. |
| <i>x</i> | (local) Pointer into the local memory to an array of size $\text{lld}_x * \text{LOCc}(j_x+n-1)$. On entry this array contains the local pieces of the distributed vector $\text{sub}(X)$. |
| <i>ix</i> | (global) The row index in the global matrix X indicating the first row of $\text{sub}(X)$. |
| <i>jx</i> | (global) The column index in the global matrix X indicating the first column of $\text{sub}(X)$. |
| <i>descx</i> | (global and local) Array of size $dlen_$. The array descriptor for the distributed matrix X . |
| <i>incx</i> | (global).The global increment for the elements of X . Only two values of <i>incx</i> are supported in this version, namely 1 and m_x . <i>incx</i> must not be zero. |

Output Parameters

| | |
|-------------|--|
| <i>amax</i> | (global output).The absolute value of the largest entry of the distributed vector $\text{sub}(X)$ only in the scope of $\text{sub}(X)$. |
| <i>indx</i> | (global output).The global index of the element of the distributed vector $\text{sub}(X)$ whose real part has maximum absolute value. |

pilaver

Returns the ScaLAPACK version.

Syntax

```
void pilaver (MKL_INT* vers_major, MKL_INT* vers_minor, MKL_INT* vers_patch);
```

Include Files

- `mkl_scalapack.h`

Description

This function returns the ScaLAPACK version.

Output Parameters

| | |
|-------------------|--|
| <i>vers_major</i> | Return the ScaLAPACK major version. |
| <i>vers_minor</i> | Return the ScaLAPACK minor version from the major version. |
| <i>vers_patch</i> | Return the ScaLAPACK patch version from the minor version. |

pmpcol

Finds the collaborators of a process.

Syntax

```
void pmpcol(MKL_INT* myproc, MKL_INT* nprocs, MKL_INT* iil, MKL_INT* needil, MKL_INT*
neediu, MKL_INT* pmyils, MKL_INT* pmyius, MKL_INT* colbrt, MKL_INT* frstcl, MKL_INT*
lastcl);
```

Include Files

- mkl_scalapack.h

Description

Using the output from [pmpim2](#) and given the information on eigenvalue clusters, `pmpcol` finds the collaborators of `myproc`.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

| | |
|---------------------|--|
| <code>myproc</code> | The processor number, $0 \leq myproc < nprocs$. |
| <code>nprocs</code> | The total number of processors available. |
| <code>iil</code> | The index of the leftmost eigenvalue in the eigenvalue cluster. |
| <code>needil</code> | The leftmost position in the eigenvalue cluster needed by <code>myproc</code> . |
| <code>neediu</code> | The rightmost position in the eigenvalue cluster needed by <code>myproc</code> . |
| <code>pmyils</code> | array For each processor p , $0 < p \leq nprocs$, <code>pmyils[p-1]</code> is the index of the first eigenvalue in the eigenvalue cluster to be computed. <code>pmyils[p-1]</code> equals zero if p stays idle. |
| <code>pmyius</code> | array For each processor p , <code>pmyius[p-1]</code> is the index of the last eigenvalue in the eigenvalue cluster to be computed. <code>pmyius[p-1]</code> equals zero if p stays idle. |

OUTPUT Parameters

| | |
|-----------------------|---|
| <i>colbrt</i> | Non-zero if <i>myproc</i> collaborates. |
| <i>frstcl, lastcl</i> | First and last collaborator of <i>myproc</i> . <i>myproc</i> collaborates with: <i>frstcl, ..., myproc-1, myproc+1, ...,lastcl</i> If <i>myproc</i> = <i>frstcl</i> , there are no collaborators on the left. If <i>myproc</i> = <i>lastcl</i> , there are no collaborators on the right. If <i>frstcl</i> = 0 and <i>lastcl</i> = <i>nprocs-1</i> , then <i>myproc</i> collaborates with everybody |

pmpim2

Computes the eigenpair range assignments for all processes.

Syntax

```
void pmpim2(MKL_INT* il, MKL_INT* iu, MKL_INT* nprocs, MKL_INT* pmyils, MKL_INT* pmyius);
```

Include Files

- `mkl_scalapack.h`

Description

`pmpim2` is the scheduling function. It computes for all processors the eigenpair range assignments.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

| | |
|---------------|---|
| <i>il, iu</i> | The range of eigenpairs to be computed. |
| <i>nprocs</i> | The total number of processors available. |

Output Parameters

| | |
|---------------|-------|
| <i>pmyils</i> | array |
|---------------|-------|

For each processor p , $pmyils[p-1]$ is the index of the first eigenvalue in a cluster to be computed.

$pmyils[p-1]$ equals zero if p stays idle.

$pmyius$

array

For each processor p , $pmyius[p-1]$ is the index of the last eigenvalue in a cluster to be computed.

$pmyius[p-1]$ equals zero if p stays idle.

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

?combamax1

Finds the element with maximum real part absolute value and its corresponding global index.

Syntax

```
void ccombamax1 (MKL_Complex8 *v1 , MKL_Complex8 *v2 );
void zcombamax1 (MKL_Complex16 *v1 , MKL_Complex16 *v2 );
```

Include Files

- `mk1_scalapack.h`

Description

The `?combamax1` function finds the element having maximum real part absolute value as well as its corresponding global index.

Input Parameters

| | |
|------|---|
| $v1$ | (local) Array of size 2. The first maximum absolute value element and its global index. $v1[0]=amax$, $v1[1]=indx$. |
| $v2$ | (local) Array of size 2. The second maximum absolute value element and its global index. $v2[0]=amax$, $v2[1]=indx$. |

Output Parameters

| | |
|------|---|
| $v1$ | (local). The first maximum absolute value element and its global index. $v1[0]=amax$, $v1[1]=indx$. |
|------|---|

See Also

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

p?sum1

Forms the 1-norm of a complex vector similar to Level 1 PBLAS `p?asum`, but using the true absolute value.

Syntax

```
void pscsum1 (MKL_INT *n , float *asum , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
```

```
void pdzsum1 (MKL_INT *n , double *asum , MKL_Complex16 *x , MKL_INT *ix , MKL_INT
*jx , MKL_INT *descx , MKL_INT *incx );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?sum1` function returns the sum of absolute values of a complex distributed vector `sub(x)` in `asum`, where `sub(x)` denotes $X(ix:ix+n-1, jx:jx)$, if `incx = 1`, $X(ix:ix, jx:jx+n-1)$, if `incx = m_x`.

Based on `p?asum` from the Level 1 PBLAS. The change is to use the 'genuine' absolute value.

Input Parameters

| | |
|--------------------|--|
| <code>n</code> | (global). The number of components of the distributed vector <code>sub(x)</code> . $n \geq 0$. |
| <code>x</code> | (local) Pointer into the local memory to an array of size <code>lld_x * LOCc(jx+n-1)</code> . This array contains the local pieces of the distributed vector <code>sub(x)</code> . |
| <code>ix</code> | (global) The row index in the global matrix X indicating the first row of <code>sub(X)</code> . |
| <code>jx</code> | (global) The column index in the global matrix X indicating the first column of <code>sub(X)</code> . |
| <code>descx</code> | (local) Array of size <code>dlen_ = 9</code> . The array descriptor for the distributed matrix X . |
| <code>incx</code> | (global) The global increment for the elements of X . Only two values of <code>incx</code> are supported in this version, namely 1 and <code>m_x</code> . |

Output Parameters

| | |
|-------------------|--|
| <code>asum</code> | (local) The sum of absolute values of the distributed vector <code>sub(X)</code> only in its scope. |
|-------------------|--|

p?dbtrsv

Computes an LU factorization of a general triangular matrix with no pivoting. The function is called by p?dbtrs.

Syntax

```
void psdbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , float *a , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib ,
MKL_INT *descb , float *af , MKL_INT *laf , float *work , MKL_INT *lwork , MKL_INT
*info );
```

```
void pddbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , double *a , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib ,
MKL_INT *descb , double *af , MKL_INT *laf , double *work , MKL_INT *lwork , MKL_INT
*info );
```

```
void pcdbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , MKL_Complex8 *a , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b ,
MKL_INT *ib , MKL_INT *descb , MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8 *work ,
MKL_INT *lwork , MKL_INT *info );
```

```
void pzdbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , MKL_Complex16 *a , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b ,
MKL_INT *ib , MKL_INT *descb , MKL_Complex16 *af , MKL_INT *laf , MKL_Complex16
*work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?dbtrsv function solves a banded triangular system of linear equations

$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs)$ or

$A(1:n, ja:ja+n-1)^T * X = B(ib:ib+n-1, 1:nrhs)$ (for real flavors); $A(1:n, ja:ja+n-1)^H * X = B(ib:ib+n-1, 1:nrhs)$ (for complex flavors),

where $A(1:n, ja:ja+n-1)$ is a banded triangular matrix factor produced by the Gaussian elimination code of p?dbtrf and is stored in $A(1:n, ja:ja+n-1)$ and af . The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to $uplo$, and the choice of solving $A(1:n, ja:ja+n-1)$ or $A(1:n, ja:ja+n-1)^T$ is dictated by the user by the parameter $trans$.

The function p?dbtrf must be called first.

Input Parameters

| | |
|---------|--|
| $uplo$ | (global) If $uplo = 'U'$, the upper triangle of $A(1:n, ja:ja+n-1)$ is stored, if $uplo = 'L'$, the lower triangle of $A(1:n, ja:ja+n-1)$ is stored. |
| $trans$ | (global) If $trans = 'N'$, solve with $A(1:n, ja:ja+n-1)$, if $trans = 'C'$, solve with conjugate transpose $A(1:n, ja:ja+n-1)$. |

| | |
|--------------|---|
| <i>n</i> | (global) The order of the distributed submatrix <i>A</i> ; ($n \geq 0$). |
| <i>bwl</i> | (global) Number of subdiagonals. $0 \leq bwl \leq n-1$. |
| <i>bwu</i> | (global) Number of subdiagonals. $0 \leq bwu \leq n-1$. |
| <i>nrhs</i> | (global) The number of right-hand sides; the number of columns of the distributed submatrix <i>B</i> ($nrhs \geq 0$). |
| <i>a</i> | (local). Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$, where $lld_a \geq (bwl+bwu+1)$. On entry, this array contains the local pieces of the <i>n</i> -by- <i>n</i> unsymmetric banded distributed Cholesky factor <i>L</i> or L^T , represented in global <i>A</i> as $A(1:n, ja:ja+n-1)$. This local portion is stored in the packed banded format used in LAPACK. See the <i>Application Notes</i> below and the ScaLAPACK manual for more detail on the format of distributed matrices. |
| <i>ja</i> | (global) The index in the global matrix <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>). |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . if 1d type ($dtype_a = 501$ or 502), $dlen \geq 7$; if 2d type ($dtype_a = 1$), $dlen \geq 9$. The array descriptor for the distributed matrix <i>A</i> . Contains information of mapping of <i>A</i> to memory. |
| <i>b</i> | (local) Pointer into the local memory to an array of local lead dimension $lld_b \geq nb$. On entry, this array contains the local pieces of the right-hand sides $B(ib:ib+n-1, 1:nrhs)$. |
| <i>ib</i> | (global) The row index in the global matrix <i>B</i> that points to the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i>). |
| <i>descb</i> | (global and local) array of size <i>dlen_</i> . if 1d type ($dtype_b = 502$), $dlen \geq 7$; if 2d type ($dtype_b = 1$), $dlen \geq 9$. The array descriptor for the distributed matrix <i>B</i> . Contains information of mapping <i>B</i> to memory. |
| <i>laf</i> | (local) Size of user-input auxiliary fill-in space <i>af</i> . $laf \geq nb * (bwl+bwu) + 6 * \max(bwl, bwu) * \max(bwl, bwu)$. If <i>laf</i> is not large enough, an error code is returned and the minimum acceptable size will be returned in $af[0]$. |
| <i>work</i> | (local). Temporary workspace. This space may be overwritten in between function calls. <i>work</i> must be the size given in <i>lwork</i> . |

lwork (local or global)
 Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work[0]* and an error code is returned.
 $lwork \geq \max(bwl, bwu) * nrhs.$

Output Parameters

a (local).
 This local portion is stored in the packed banded format used in LAPACK. Please see the ScaLAPACK manual for more detail on the format of distributed matrices.

b On exit, this contains the local piece of the solutions distributed matrix *X*.

af (local).
 auxiliary fill-in space. The fill-in space is created in a call to the factorization function *p?dbtrf* and is stored in *af*. If a linear system is to be solved using *p?dbtrf* after the factorization function, *af* must not be altered after the factorization.

work On exit, *work[0]* contains the minimal *lwork*.

info (local).
 If *info* = 0, the execution is successful.
 < 0: If the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value, then *info* = - (*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?dttrsv

Computes an LU factorization of a general band matrix, using partial pivoting with row interchanges. The function is called by p?dttrs.

Syntax

```
void psdttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , float *dl ,
float *d , float *du , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT
*descb , float *af , MKL_INT *laf , float *work , MKL_INT *lwork , MKL_INT *info );

void pddttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , double *dl ,
double *d , double *du , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib ,
MKL_INT *descb , double *af , MKL_INT *laf , double *work , MKL_INT *lwork , MKL_INT
*info );

void pcdttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex8
*d , MKL_Complex8 *d , MKL_Complex8 *du , MKL_INT *ja , MKL_INT *desca , MKL_Complex8
*b , MKL_INT *ib , MKL_INT *descb , MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8
*work , MKL_INT *lwork , MKL_INT *info );
```

```
void pzdttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex16
*d1 , MKL_Complex16 *d , MKL_Complex16 *du , MKL_INT *ja , MKL_INT *desca ,
MKL_Complex16 *b , MKL_INT *ib , MKL_INT *descb , MKL_Complex16 *af , MKL_INT *laf ,
MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The pzdttrsv function solves a tridiagonal triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs) \text{ or}$$

$$A(1:n, ja:ja+n-1)^T * X = B(ib:ib+n-1, 1:nrhs) \text{ for real flavors; } A(1:n, ja:ja+n-1)^H * X = B(ib:ib+n-1, 1:nrhs) \text{ for complex flavors,}$$

where $A(1:n, ja:ja+n-1)$ is a tridiagonal matrix factor produced by the Gaussian elimination code of pzdttrf and is stored in $A(1:n, ja:ja+n-1)$ and af .

The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to *uplo*, and the choice of solving $A(1:n, ja:ja+n-1)$ or $A(1:n, ja:ja+n-1)^T$ is dictated by the user by the parameter *trans*.

The function pzdttrf must be called first.

Input Parameters

| | |
|--------------|--|
| <i>uplo</i> | (global) If <i>uplo</i> ='U', the upper triangle of $A(1:n, ja:ja+n-1)$ is stored, if <i>uplo</i> = 'L', the lower triangle of $A(1:n, ja:ja+n-1)$ is stored. |
| <i>trans</i> | (global) If <i>trans</i> = 'N', solve with $A(1:n, ja:ja+n-1)$, if <i>trans</i> = 'C', solve with conjugate transpose $A(1:n, ja:ja+n-1)$. |
| <i>n</i> | (global) The order of the distributed submatrix A; ($n \geq 0$). |
| <i>nrhs</i> | (global) The number of right-hand sides; the number of columns of the distributed submatrix $B(ib:ib+n-1, 1:nrhs)$. ($nrhs \geq 0$). |
| <i>d1</i> | (local). Pointer to local part of global vector storing the lower diagonal of the matrix. Globally, $d1[0]$ is not referenced, and <i>d1</i> must be aligned with <i>d</i> . Must be of size $\geq nb_a$. |
| <i>d</i> | (local). Pointer to local part of global vector storing the main diagonal of the matrix. |
| <i>du</i> | (local). Pointer to local part of global vector storing the upper diagonal of the matrix. |

| | |
|--------------|---|
| | Globally, $du[n-1]$ is not referenced, and du must be aligned with d . |
| <i>ja</i> | (global) The index in the global matrix A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A). |
| <i>desca</i> | (global and local) array of size $dlen_$. if 1d type ($dtype_a = 501$ or 502), $dlen \geq 7$; if 2d type ($dtype_a = 1$), $dlen \geq 9$. The array descriptor for the distributed matrix A . Contains information of mapping of A to memory. |
| <i>b</i> | (local) Pointer into the local memory to an array of local lead dimension $lld_b \geq nb$. On entry, this array contains the local pieces of the right-hand sides $B(ib:ib+n-1, 1:nrhs)$. |
| <i>ib</i> | (global) The row index in the global matrix B that points to the first row of the matrix to be operated on (which may be either all of B or a submatrix of B). |
| <i>descb</i> | (global and local) array of size $dlen_$. if 1d type ($dtype_b = 502$), $dlen \geq 7$; if 2d type ($dtype_b = 1$), $dlen \geq 9$. The array descriptor for the distributed matrix B . Contains information of mapping B to memory. |
| <i>laf</i> | (local). Size of user-input auxiliary fill-in space af . $laf \geq 2*(nb+2)$. If laf is not large enough, an error code is returned and the minimum acceptable size will be returned in $af[0]$. |
| <i>work</i> | (local). Temporary workspace. This space may be overwritten in between function calls. $work$ must be the size given in $lwork$. |
| <i>lwork</i> | (local or global) Size of user-input workspace $work$. If $lwork$ is too small, the minimal acceptable size will be returned in $work[0]$ and an error code is returned. $lwork \geq 10*npcol+4*nrhs$. |

Output Parameters

| | |
|-----------|---|
| <i>d1</i> | (local). On exit, this array contains information containing the factors of the matrix. |
| <i>d</i> | On exit, this array contains information containing the factors of the matrix. Must be of size $\geq nb_a$. |

| | |
|-------------|---|
| <i>b</i> | On exit, this contains the local piece of the solutions distributed matrix X. |
| <i>af</i> | (local). Auxiliary fill-in space. The fill-in space is created in a call to the factorization function <code>p?dttrf</code> and is stored in <i>af</i> . If a linear system is to be solved using <code>p?dttrs</code> after the factorization function, <i>af</i> must not be altered after the factorization. |
| <i>work</i> | On exit, <code>work[0]</code> contains the minimal <i>lwork</i> . |
| <i>info</i> | (local). If <i>info</i> =0, the execution is successful. if <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> -1, had an illegal value, then <i>info</i> = - (<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . |

p?gebal

Balances a general real matrix.

Syntax

```
void psgebal(char* job, MKL_INT* n, float* a, MKL_INT* desca, MKL_INT* ilo, MKL_INT*
ihi, float* scale, MKL_INT* info);
```

```
void pdgebal(char* job, MKL_INT* n, double* a, MKL_INT* desca, MKL_INT* ilo, MKL_INT*
ihi, double* scale, MKL_INT* info);
```

Include Files

- `mkl_scalapack.h`

Description

`p?gebal` balances a general real matrix *A*. This involves, first, permuting *A* by a similarity transformation to isolate eigenvalues in the first 1 to *ilo*-1 and last *ihi*+1 to *n* elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns *ilo* to *ihi* to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

Input Parameters

| | |
|------------|---|
| <i>job</i> | (global) Specifies the operations to be performed on <i>a</i> : = 'N': none: simply set <i>ilo</i> = 1, <i>ihi</i> = <i>n</i> , <i>scale</i> [<i>i</i>] = 1.0 for <i>i</i> = 0,..., <i>n</i> -1; = 'P': permute only; = 'S': scale only; = 'B': both permute and scale. |
|------------|---|

| | |
|---------|---|
| n | (global) The order of the matrix A ($n \geq 0$). |
| a | (local) Pointer into the local memory to an array of size $lld_a * LOC_c(n)$ This array contains the local pieces of global input matrix A . |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |

OUTPUT Parameters

| | |
|------------|---|
| a | On exit, a is overwritten by the balanced matrix A . If $job = 'N'$, a is not referenced. See Notes for further details. |
| ilo, ihi | (global) ilo and ihi are set to integers such that on exit matrix elements $A(i,j)$ are zero if $i > j$ and $j = 1, \dots, ilo-1$ or $i = ihi+1, \dots, n$. If $job = 'N'$ or $'S'$, $ilo = 1$ and $ihi = n$. |
| $scale$ | (global) array of size n . Details of the permutations and scaling factors applied to a . If pj is the index of the row and column interchanged with row and column j and dj is the scaling factor applied to row and column j , then $scale[j-1] = pj$ for $j = 1, \dots, ilo-1$ $scale[j-1] = dj$ for $j = ilo, \dots, ihi$ The order in which the interchanges are made is n to $ihi+1$, then 1 to $ilo-1$. |
| $info$ | (global) = 0: successful exit. < 0: if $info = -i$, the i -th argument had an illegal value. |

Application Notes

The permutations consist of row and column interchanges which put the matrix in the form

$$PAP = \begin{pmatrix} T_1 & X & Y \\ \mathbf{0} & B & Z \\ \mathbf{0} & \mathbf{0} & T_2 \end{pmatrix}$$

where T_1 and T_2 are upper triangular matrices whose eigenvalues lie along the diagonal. The column indices ilo and ihi mark the starting and ending columns of the submatrix B . Balancing consists of applying a diagonal similarity transformation $D^{-1}BD$ to make the 1-norms of each row of B and its corresponding column nearly equal. The output matrix is

$$\begin{pmatrix} T_1 & XD & Y \\ 0 & D^{-1}BD & D^{-1}Z \\ 0 & 0 & T_2 \end{pmatrix}$$

Information about the permutations P and the diagonal matrix D is returned in the vector *scale*.

p?gebd2

Reduces a general rectangular matrix to real bidiagonal form by an orthogonal/unitary transformation (unblocked algorithm).

Syntax

```
void psgebd2 (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *d , float *e , float *tauq , float *taup , float *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pdgebd2 (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *d , double *e , double *tauq , double *taup , double *work ,
MKL_INT *lwork , MKL_INT *info );
```

```
void pcgebd2 (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *d , float *e , MKL_Complex8 *tauq , MKL_Complex8 *taup ,
MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pzgebd2 (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *d , double *e , MKL_Complex16 *tauq , MKL_Complex16 *taup ,
MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?gebd2 function reduces a real/complex general m -by- n distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$ to upper or lower bidiagonal form B by an orthogonal/unitary transformation:

$$Q^* \text{sub}(A) P = B.$$

If $m \geq n$, B is the upper bidiagonal; if $m < n$, B is the lower bidiagonal.

Input Parameters

- | | |
|-----|--|
| m | (global) The number of rows of the distributed matrix $\text{sub}(A)$. ($m \geq 0$). |
| n | (global) |

| | |
|---------------|---|
| | The number of columns in the distributed matrix $\text{sub}(A)$. ($n \geq 0$). |
| <i>a</i> | (local). Pointer into the local memory to an array of size $lld_a * LOC_c(ja+n-1)$. On entry, this array contains the local pieces of the general distributed matrix $\text{sub}(A)$. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively. |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <i>work</i> | (local). This is a workspace array of size <i>lwork</i> . |
| <i>lwork</i> | (local or global) The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork \geq \max(mpa0, nqa0)$, where $nb = mb_a = nb_a$, $irowfa = \text{mod}(ia-1, nb)$, $iarow = \text{indxg2p}(ia, nb, myrow, rsrc_a, nprow)$, $iacol = \text{indxg2p}(ja, nb, mycol, csrc_a, npcot)$, $mpa0 = \text{numroc}(m+irowfa, nb, myrow, iarow, nprow)$, $nqa0 = \text{numroc}(n+icoffa, nb, mycol, iacol, npcot)$. indxg2p and numroc are ScaLAPACK tool functions; <i>myrow</i> , <i>mycol</i> , <i>nprow</i> , and <i>npcol</i> can be determined by calling the function <code>blacs_gridinfo</code> . If $lwork = -1$, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> . |

Output Parameters

| | |
|----------|---|
| <i>a</i> | (local). On exit, if $m \geq n$, the diagonal and the first superdiagonal of $\text{sub}(A)$ are overwritten with the upper bidiagonal matrix B ; the elements below the diagonal, with the array <i>tauq</i> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array <i>taup</i> , represent the orthogonal matrix P as a product of elementary reflectors. If $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B ; the elements below the first subdiagonal, with the array <i>tauq</i> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array <i>taup</i> , represent the orthogonal matrix P as a product of elementary reflectors. See <i>Applications Notes</i> below. |
| <i>d</i> | (local) |

Array of size $LOCc(ja+\min(m,n)-1)$ if $m \geq n$; $LOCr(ia+\min(m,n)-1)$ otherwise. The distributed diagonal elements of the bidiagonal matrix B : $d[i] = A(i+1,i+1)$, $i=0, 1, \dots, \text{size}(d) - 1$. d is tied to the distributed matrix A .

e

(local)

Array of size $LOCc(ja+\min(m,n)-1)$ if $m \geq n$; $LOCr(ia+\min(m,n)-2)$ otherwise. The distributed diagonal elements of the bidiagonal matrix B :
if $m \geq n$, $e[i] = A(i+1,i+2)$ for $i = 0, 1, \dots, n-2$;
if $m < n$, $e[i] = A(i+2,i+1)$ for $i = 0, 1, \dots, m-2$. e is tied to the distributed matrix A .

tauq

(local).

Array of size $LOCc(ja+\min(m,n)-1)$. The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Q . *tauq* is tied to the distributed matrix A .

taup

(local).

Array of size $LOCr(ia+\min(m,n)-1)$. The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix P . *taup* is tied to the distributed matrix A .

work

On exit, *work*[0] returns the minimal and optimal *lwork*.

info

(local)

If *info* = 0, the execution is successful.

if *info* < 0: If the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value, then *info* = - (*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

The matrices Q and P are represented as products of elementary reflectors:

If $m \geq n$,

$$Q = H(1)*H(2)*\dots*H(n), \text{ and } P = G(1)*G(2)*\dots*G(n-1)$$

Each $H(i)$ and $G(i)$ has the form:

$$H(i) = I - \tau_{uq} * v * v', \text{ and } G(i) = I - \tau_{up} * u * u',$$

where τ_{uq} and τ_{up} are real/complex scalars, and v and u are real/complex vectors. $v(1:i-1) = 0$, $v(i) = 1$, and $v(i+1:m)$ is stored on exit in

$$A(ia+i-ia+m-1, ja+i-1);$$

$$u(1:i) = 0, u(i+1) = 1, \text{ and } u(i+2:n) \text{ is stored on exit in } A(ia+i-1, ja+i+1:ja+n-1);$$

τ_{uq} is stored in $\tau_{uq}[ja+i-2]$ and τ_{up} in $\tau_{up}[ia+i-2]$.

If $m < n$,

$$v(1:i) = 0, v(i+1) = 1, \text{ and } v(i+2:m) \text{ is stored on exit in } A(ia+i+1: ia+m-1, ja+i-1);$$

$$u(1:i-1) = 0, u(i) = 1, \text{ and } u(i+1:n) \text{ is stored on exit in } A(ia+i-1, ja+i:ja+n-1);$$

τ_{uq} is stored in $\tau_{uq}[ja+i-2]$ and τ_{up} in $\tau_{up}[ia+i-2]$.

The contents of $\text{sub}(A)$ on exit are illustrated by the following examples:

$$\begin{array}{l}
 m = 6 \text{ and } n = 5 (m > n) : \\
 \begin{bmatrix} d & e & u1 & u1 & u1 \\ v1 & d & e & u2 & u2 \\ v1 & v2 & d & e & u3 \\ v1 & v2 & v3 & d & e \\ v1 & v2 & v3 & v4 & d \\ v1 & v2 & v3 & v4 & v5 \end{bmatrix}
 \end{array}
 \qquad
 \begin{array}{l}
 m = 5 \text{ and } n = 6 (m < n) : \\
 \begin{bmatrix} d & u1 & u1 & u1 & u1 & u1 \\ e & d & u2 & u2 & u2 & u2 \\ v1 & e & d & u3 & u3 & u3 \\ v1 & v2 & e & d & u4 & u4 \\ v1 & v2 & v3 & e & d & u5 \end{bmatrix}
 \end{array}$$

where d and e denote diagonal and off-diagonal elements of B , v_i denotes an element of the vector defining $H(i)$, and u_i an element of the vector defining $G(i)$.

*lwork , MKL_INT *info );
```

```
void pzgehd2 (MKL_INT *n , MKL_INT *ilo , MKL_INT *ihi , MKL_Complex16 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work ,
MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?gehd2` function reduces a real/complex general distributed matrix $\text{sub}(A)$ to upper Hessenberg form H by an orthogonal/unitary similarity transformation: $Q^* \text{sub}(A) Q = H$, where $\text{sub}(A) = A(\text{ia}+\text{n}-1 : \text{ia}+\text{n}-1, \text{ja}+\text{n}-1 : \text{ja}+\text{n}-1)$.

Input Parameters

`n` (global) The order of the distributed submatrix A . ($n \geq 0$).

`ilo, ihi` (global) It is assumed that the matrix $\text{sub}(A)$ is already upper triangular in rows $\text{ia}:\text{ia}+\text{ilo}-2$ and $\text{ia}+\text{ihi}:\text{ia}+\text{n}-1$ and columns $\text{ja}:\text{ja}+\text{jlo}-2$ and $\text{ja}+\text{jhi}:\text{ja}+\text{n}-1$. See *Application Notes* for further information.

If $n \geq 0$, $1 \leq ilo \leq ihi \leq n$; otherwise set $ilo = 1$, $ihi = n$.

a (local).
Pointer into the local memory to an array of size $lld_a * LOC_c(ja+n-1)$.

On entry, this array contains the local pieces of the n -by- n general distributed matrix $sub(A)$ to be reduced.

ia, ja (global) The row and column indices in the global matrix A indicating the first row and the first column of $sub(A)$, respectively.

desca (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A .

work (local).
This is a workspace array of size *lwork*.

lwork (local or global)
The size of the array *work*.
lwork is local input and must be at least $lwork \geq nb + \max(npa0, nb)$, where $nb = mb_a = nb_a$, $irow = \text{mod}(ia-1, nb)$, $iarow = \text{indxg2p}(ia, nb, myrow, rsrc_a, nprow)$, $npa0 = \text{numroc}(ihi + irow, nb, myrow, iarow, nprow)$.

indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *ncol* can be determined by calling the function `blacs_gridinfo`.

If $lwork = -1$, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a (local). On exit, the upper triangle and the first subdiagonal of $sub(A)$ are overwritten with the upper Hessenberg matrix H , and the elements below the first subdiagonal, with the array *tau*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors. (see *Application Notes* below).

tau (local).
Array of size $LOC_c(ja+n-2)$ The scalar factors of the elementary reflectors (see *Application Notes* below). Elements $ja:ja+ilo-2$ and $ja+ihi:ja+n-2$ of the global vector *tau* are set to zero. *tau* is tied to the distributed matrix A .

work On exit, *work*[0] returns the minimal and optimal *lwork*.

info (local)
If $info = 0$, the execution is successful.
if $info < 0$: If the i -th argument is an array and the j -th entry, indexed $j-1$, had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of (*ihi-ilo*) elementary reflectors

$$Q = H(ilo) * H(ilo+1) * \dots * H(ihi-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v',$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$, $v(i+1) = 1$ and $v(ihi+1:n) = 0$; $v(i+2:ihi)$ is stored on exit in $A(ia+ilo+i:i+ihi-1, ia+ilo+i-2)$, and τ in $\tau[ja+ilo+i-3]$.

The contents of $A(ia:ia+n-1, ja:ja+n-1)$ are illustrated by the following example, with $n = 7$, $ilo = 2$ and $ihi = 6$:

| on entry | on exit |
|---|---|
| $\begin{bmatrix} a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ & & & & & & a \end{bmatrix}$ | $\begin{bmatrix} a & a & h & h & h & h & a \\ a & h & h & h & h & h & a \\ h & h & h & h & h & h & h \\ v2 & h & h & h & h & h & h \\ v2 & v3 & h & h & h & h & h \\ v2 & v3 & v4 & h & h & h & h \\ & & & & & & a \end{bmatrix}$ |

where a denotes an element of the original matrix $\text{sub}(A)$, h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(ja+ilo+i-2)$.

Computes an LQ factorization of a general rectangular matrix (unblocked algorithm).

Syntax

```
void psgelq2 (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdgelq2 (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pcgelq2 (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pzgelq2 (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `pxerbla` function computes an LQ factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1) = L*Q$.

Input Parameters

| | |
|---------------------|--|
| <code>m</code> | (global) The number of rows of the distributed matrix $\text{sub}(A)$. ($m \geq 0$). |
| <code>n</code> | (global) The number of columns of the distributed matrix $\text{sub}(A)$. ($n \geq 0$). |
| <code>a</code> | (local). Pointer into the local memory to an array of size $\text{lld}_a * \text{LOCc}(\text{ja}+n-1)$. On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ which is to be factored. |
| <code>ia, ja</code> | (global) The row and column indices in the global matrix A indicating the first row and the first column of $\text{sub}(A)$, respectively. |
| <code>desca</code> | (global and local) array of size $\text{dlen}_$. The array descriptor for the distributed matrix A . |
| <code>work</code> | (local). This is a workspace array of size lwork . |
| <code>lwork</code> | (local or global) The size of the array work . lwork is local input and must be at least $\text{lwork} \geq nq0 + \max(1, mp0)$, where $\text{iroff} = \text{mod}(\text{ia}-1, \text{mb}_a)$, $\text{icoff} = \text{mod}(\text{ja}-1, \text{nb}_a)$, $\text{iarow} = \text{indxg2p}(\text{ia}, \text{mb}_a, \text{myrow}, \text{rsrc}_a, \text{nprow})$, $\text{iacol} = \text{indxg2p}(\text{ja}, \text{nb}_a, \text{mycol}, \text{csrc}_a, \text{npcol})$, $\text{mp0} = \text{numroc}(m+\text{iroff}, \text{mb}_a, \text{myrow}, \text{iarow}, \text{nprow})$, $\text{nq0} = \text{numroc}(n+\text{icoff}, \text{nb}_a, \text{mycol}, \text{iacol}, \text{npcol})$, indxg2p and numroc are ScaLAPACK tool functions; myrow , mycol , nprow , and npcol can be determined by calling the function <code>blacs_gridinfo</code> . If $\text{lwork} = -1$, then lwork is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> . |

Output Parameters

| | |
|----------------|----------|
| <code>a</code> | (local). |
|----------------|----------|

On exit, the elements on and below the diagonal of sub(A) contain the m by $\min(m,n)$ lower trapezoidal matrix L (L is lower triangular if $m \leq n$); the elements above the diagonal, with the array τ , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

τ (local).
 Array of size $LOCr(ia+\min(m, n)-1)$. This array contains the scalar factors of the elementary reflectors. τ is tied to the distributed matrix A .

$work$ On exit, $work[0]$ returns the minimal and optimal $lwork$.

$info$ (local) If $info = 0$, the execution is successful. if $info < 0$: If the i -th argument is an array and the j -th entry, indexed $j-1$, had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$Q = H(ia+k-1) * H(ia+k-2) * \dots * H(ia)$ for real flavors, $Q = (H(ia+k-1))^{H*} (H(ia+k-2))^{H} \dots (H(ia))^{H}$ for complex flavors,

where $k = \min(m,n)$.

Each $H(i)$ has the form

$H(i) = I - \tau * v * v'$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1: i-1) = 0$ and $v(i) = 1$; $v(i+1: n)$ (for real flavors) or $\text{conjg}(v(i+1: n))$ (for complex flavors) is stored on exit in $A(ia+i-1, ja+i: ja+n-1)$, and τ in $\tau[ia+i-2]$.

```

Include Files

- `mkl_scalapack.h`

Description

The `p?geql2` function computes a QL factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q * L$.

Input Parameters

| | |
|---------------------|---|
| <code>m</code> | (global) The number of rows in the distributed matrix $\text{sub}(A)$. ($m \geq 0$). |
| <code>n</code> | (global) The number of columns in the distributed matrix $\text{sub}(A)$. ($n \geq 0$). |
| <code>a</code> | (local). Pointer into the local memory to an array of size $lld_a * LOC_c(ja+n-1)$. On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ which is to be factored. |
| <code>ia, ja</code> | (global) The row and column indices in the global matrix A indicating the first row and the first column of $\text{sub}(A)$, respectively. |
| <code>desca</code> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <code>work</code> | (local). This is a workspace array of size $lwork$. |
| <code>lwork</code> | (local or global) The size of the array $work$. $lwork$ is local input and must be at least $lwork \geq mp0 + \max(1, nq0)$, where $iroff = \text{mod}(ia-1, mb_a)$, $icoff = \text{mod}(ja-1, nb_a)$, $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$, $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcot)$, $mp0 = \text{numroc}(m+iroff, mb_a, myrow, iarow, nprow)$, $nq0 = \text{numroc}(n+icoff, nb_a, mycol, iacol, npcot)$, indxg2p and numroc are ScaLAPACK tool functions; $myrow$, $mycol$, $nprow$, and $npcot$ can be determined by calling the function <code>blacs_gridinfo</code> . If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> . |

Output Parameters

| | |
|----------------|----------|
| <code>a</code> | (local). |
|----------------|----------|

On exit,

if $m \geq n$, the lower triangle of the distributed submatrix $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the n -by- n lower triangular matrix L ;

if $m \leq n$, the elements on and below the $(n-m)$ -th superdiagonal contain the m -by- n lower trapezoidal matrix L ; the remaining elements, with the array τ , represent the orthogonal/ unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

τ

(local).

Array of size $LOCc(ja+n-1)$. This array contains the scalar factors of the elementary reflectors. τ is tied to the distributed matrix A .

$work$

On exit, $work[0]$ returns the minimal and optimal $lwork$.

$info$

(local).

If $info = 0$, the execution is successful. if $info < 0$: If the i -th argument is an array and the j -th entry, indexed $j-1$, had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja+k-1) * \dots * H(ja+1) * H(ja), \text{ where } k = \min(m, n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(m-k+i+1:m) = 0$ and $v(m-k+i) = 1$; $v(1:m-k+i-1)$ is stored on exit in $A(ia:ia+m-k+i-2, ja+n-k+i-1)$, and τ in $\tau[ja+n-k+i-2]$.

p?geqr2

Computes a QR factorization of a general rectangular matrix (unblocked algorithm).

Syntax

```
void psgeqr2 (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdgeqr2 (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pcgeqr2 (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pzgeqr2 (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?geqr2` function computes a QR factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q^*R$.

Input Parameters

| | |
|---------------------|---|
| <code>m</code> | (global) The number of rows in the distributed matrix $\text{sub}(A)$. ($m \geq 0$). |
| <code>n</code> | (global) The number of columns in the distributed matrix $\text{sub}(A)$. ($n \geq 0$). |
| <code>a</code> | (local). Pointer into the local memory to an array of size $lld_a * LOC_c(ja+n-1)$. On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ which is to be factored. |
| <code>ia, ja</code> | (global) The row and column indices in the global matrix A indicating the first row and the first column of $\text{sub}(A)$, respectively. |
| <code>desca</code> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <code>work</code> | (local). This is a workspace array of size $lwork$. |
| <code>lwork</code> | (local or global) The size of the array $work$. $lwork$ is local input and must be at least $lwork \geq mp0 + \max(1, nq0)$, where $iroff = \text{mod}(ia-1, mb_a)$, $icoff = \text{mod}(ja-1, nb_a)$, $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$, $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcot)$, $mp0 = \text{numroc}(m+iroff, mb_a, myrow, iarow, nprow)$, $nq0 = \text{numroc}(n+icoff, nb_a, mycol, iacol, npcot)$. indxg2p and numroc are ScaLAPACK tool functions; $myrow$, $mycol$, $nprow$, and $npcol$ can be determined by calling the function <code>blacs_gridinfo</code> . If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> . |

Output Parameters

| | |
|----------------|----------|
| <code>a</code> | (local). |
|----------------|----------|

On exit, the elements on and above the diagonal of sub(A) contain the $\min(m,n)$ by n upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array τ , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

τ (local).
 Array of size $LOCc(ja+\min(m,n)-1)$. This array contains the scalar factors of the elementary reflectors. τ is tied to the distributed matrix A .

$work$ On exit, $work[0]$ returns the minimal and optimal $lwork$.

$info$ (local)
 If $info = 0$, the execution is successful. if $info < 0$:
 If the i -th argument is an array and the j -th entry, indexed $j-1$, had an illegal value, then $info = -(i*100+j)$,
 if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja) * H(ja+1) * \dots * H(ja+k-1), \text{ where } k = \min(m,n).$$

Each $H(i)$ has the form

$$H(j) = I - \tau * v * v',$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$, and τ in $\tau[ja+i-2]$.

Description

The `p?gerq2` function computes an RQ factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = R*Q$.

Input Parameters

| | |
|---------------|---|
| <i>m</i> | (global) The number of rows in the distributed matrix $\text{sub}(A)$. ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the distributed matrix $\text{sub}(A)$. ($n \geq 0$). |
| <i>a</i> | (local). Pointer into the local memory to an array of size $lld_a * LOC_c(ja+n-1)$. On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ which is to be factored. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of $\text{sub}(A)$, respectively. |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <i>work</i> | (local). This is a workspace array of size $lwork$. |
| <i>lwork</i> | (local or global) The size of the array $work$. $lwork$ is local input and must be at least $lwork \geq nq0 + \max(1, mp0)$, where $iroff = \text{mod}(ia-1, mb_a), \quad icoff = \text{mod}(ja-1, nb_a),$ $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow),$ $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcot), \quad mp0 = \text{numroc}(m+iroff, mb_a, myrow, iarow, nprow),$ $nq0 = \text{numroc}(n+icoff, nb_a, mycol, iacol, npcot),$ indxg2p and numroc are ScaLAPACK tool functions; $myrow$, $mycol$, $nprow$, and $npcol$ can be determined by calling the function <code>blacs_gridinfo</code> . If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> . |

Output Parameters

| | |
|----------|----------------------|
| <i>a</i> | (local). On exit, |
|----------|----------------------|

if $m \leq n$, the upper triangle of $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the m -by- m upper triangular matrix R ;

if $m \geq n$, the elements on and above the $(m-n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix R ; the remaining elements, with the array τ , represent the orthogonal/ unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

τ (local).

Array of size $LOCr(ia+m-1)$. This array contains the scalar factors of the elementary reflectors. τ is tied to the distributed matrix A .

$work$ On exit, $work[0]$ returns the minimal and optimal $lwork$.

$info$ (local)

If $info = 0$, the execution is successful.

if $info < 0$: If the i -th argument is an array and the j -th entry, indexed $j-1$, had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$Q = H(ia) * H(ia+1) * \dots * H(ia+k-1)$ for real flavors,

$Q = (H(ia))^H * (H(ia+1))^H * \dots * (H(ia+k-1))^H$ for complex flavors,

where $k = \min(m, n)$.

Each $H(i)$ has the form

$H(i) = I - \tau * v * v'$,

where τ is a real/complex scalar, and v is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ for real flavors or $\text{conjg}(v(1:n-k+i-1))$ for complex flavors is stored on exit in $A(ia+m-k+i-1, ja:ja+n-k+i-2)$, and τ in $\tau[ia+m-k+i-2]$.

MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
```

```
void pcgetf2 (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
```

```
void pzgetf2 (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `pzgetf2` function computes an LU factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ using partial pivoting with row interchanges.

The factorization has the form $\text{sub}(A) = P * L * U$, where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$). This is the right-looking Parallel Level 2 BLAS version of the algorithm.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

| | |
|----------|---|
| m | (global) The number of rows in the distributed matrix $\text{sub}(A)$. ($m \geq 0$). |
| n | (global) The number of columns in the distributed matrix $\text{sub}(A)$. ($nb_a - \text{mod}(ja-1, nb_a) \geq n \geq 0$). |
| a | (local). Pointer into the local memory to an array of size $lld_a * LOC_c(ja+n-1)$. On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$. |
| ia, ja | (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively. |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |

Output Parameters

| | |
|--------|--|
| $ipiv$ | (local) Array of size $(LOC_r(m_a) + mb_a)$. This array contains the pivoting information. $ipiv[i] \rightarrow$ The global row that local row $(i + 1)$ was swapped with, $i = 0, 1, \dots, LOC_r(m_a) + mb_a - 1$. This array is tied to the distributed matrix A . |
|--------|--|

info (local).

If *info* = 0: successful exit.

If *info* < 0:

- if the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value, then *info* = $-(i*100+j)$,
- if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

If *info* > 0: If *info* = *k*, the matrix element $U(ia+k-1, ja+k-1)$ is exactly zero. The factorization has been completed, but the factor *U* is exactly singular, and division by zero will occur if it is used to solve a system of equations.

 double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , double *y , MKL_INT *iy ,
 MKL_INT *jy , MKL_INT *descy , double *work );
```

```
void pclabrd (MKL_INT *m , MKL_INT *n , MKL_INT *nb , MKL_Complex8 *a , MKL_INT *ia ,
 MKL_INT *ja , MKL_INT *desca , float *d , float *e , MKL_Complex8 *tauq , MKL_Complex8
 *taup , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_Complex8
 *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_Complex8 *work );
```

```
void pzlabrd (MKL_INT *m , MKL_INT *n , MKL_INT *nb , MKL_Complex16 *a , MKL_INT *ia ,
 MKL_INT *ja , MKL_INT *desca , double *d , double *e , MKL_Complex16 *tauq ,
 MKL_Complex16 *taup , MKL_Complex16 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
 MKL_Complex16 *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_Complex16 *work );
```

Include Files

- mkl_scalapack.h

Description

The p?labrd function reduces the first *nb* rows and columns of a real/complex general *m*-by-*n* distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ to upper or lower bidiagonal form by an orthogonal/unitary transformation $Q^* A P$, and returns the matrices *X* and *Y* necessary to apply the transformation to the unreduced part of $\text{sub}(A)$.

If $m \geq n$, $\text{sub}(A)$ is reduced to upper bidiagonal form; if $m < n$, $\text{sub}(A)$ is reduced to lower bidiagonal form.

This is an auxiliary function called by `p?gebrd`.

Input Parameters

| | |
|---------------|---|
| <i>m</i> | (global) The number of rows in the distributed matrix $\text{sub}(A)$. ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the distributed matrix $\text{sub}(A)$. ($n \geq 0$). |
| <i>nb</i> | (global) The number of leading rows and columns of $\text{sub}(A)$ to be reduced. |
| <i>a</i> | (local). Pointer into the local memory to an array of size $lld_a * LOC_c(ja+n-1)$. On entry, this array contains the local pieces of the general distributed matrix $\text{sub}(A)$. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A . |
| <i>ix, jx</i> | (global) The row and column indices in the global matrix X indicating the first row and the first column of the matrix $\text{sub}(X)$, respectively. |
| <i>descx</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix X . |
| <i>iy, jy</i> | (global) The row and column indices in the global matrix Y indicating the first row and the first column of the matrix $\text{sub}(Y)$, respectively. |
| <i>descy</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix Y . |
| <i>work</i> | (local). Workspace array of size <i>lwork</i> . $lwork \geq nb_a + nq$, with $nq = \text{numroc}(n + \text{mod}(ia-1, nb_y), nb_y, mycol, iacol, npc1)$ $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npc1)$ <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; <i>myrow</i> , <i>mycol</i> , <i>nrow</i> , and <i>npc1</i> can be determined by calling the function <code>blacs_gridinfo</code> . |

Output Parameters

| | |
|----------|--|
| <i>a</i> | (local) On exit, the first <i>nb</i> rows and columns of the matrix are overwritten; the rest of the distributed matrix $\text{sub}(A)$ is unchanged. |
|----------|--|

If $m \geq n$, elements on and below the diagonal in the first nb columns, with the array $tauq$, represent the orthogonal/unitary matrix Q as a product of elementary reflectors; and elements above the diagonal in the first nb rows, with the array $taup$, represent the orthogonal/unitary matrix P as a product of elementary reflectors.

If $m < n$, elements below the diagonal in the first nb columns, with the array $tauq$, represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and elements on and above the diagonal in the first nb rows, with the array $taup$, represent the orthogonal/unitary matrix P as a product of elementary reflectors. See *Application Notes* below.

 d

(local).

Array of size $LOCr(ia+\min(m,n)-1)$ if $m \geq n$; $LOCc(ja+\min(m,n)-1)$ otherwise. The distributed diagonal elements of the bidiagonal distributed matrix B :

$$d[i] = A(ia+i, ja+i), i = 0, 1, \dots, \text{size}(d)-1$$

d is tied to the distributed matrix A .

 e

(local).

Array of size $LOCr(ia+\min(m,n)-1)$ if $m \geq n$; $LOCc(ja+\min(m,n)-2)$ otherwise. The distributed off-diagonal elements of the bidiagonal distributed matrix B :

$$\text{if } m \geq n, e[i] = A(ia+i, ja+i+1) \text{ for } i = 0, 1, \dots, n-2;$$

$$\text{if } m < n, e[i] = A(ia+i+1, ja+i) \text{ for } i = 0, 1, \dots, m-2.$$

e is tied to the distributed matrix A .

 $tauq, taup$

(local).

Array size $LOCc(ja+\min(m,n)-1)$ for $tauq$, size $LOCr(ia+\min(m,n)-1)$ for $taup$. The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Q for $tauq$, P for $taup$. $tauq$ and $taup$ are tied to the distributed matrix A . See *Application Notes* below.

 x

(local)

Pointer into the local memory to an array of size $lld_x * nb$. On exit, the local pieces of the distributed m -by- nb matrix $X(ix:ix+m-1, jx:jx+nb-1)$ required to update the unreduced part of $\text{sub}(A)$.

 y

(local).

Pointer into the local memory to an array of size $lld_y * nb$. On exit, the local pieces of the distributed n -by- nb matrix $Y(iy:iy+n-1, jy:jy+nb-1)$ required to update the unreduced part of $\text{sub}(A)$.

Application Notes

The matrices Q and P are represented as products of elementary reflectors:

$$Q = H(1) * H(2) * \dots * H(nb), \text{ and } P = G(1) * G(2) * \dots * G(nb)$$

Each $H(i)$ and $G(i)$ has the form:

$$H(i) = I - tauq * v * v', \text{ and } G(i) = I - taup * u * u',$$

where τ_{uq} and τ_{up} are real/complex scalars, and v and u are real/complex vectors.

If $m \geq n$, $v(1:i-1) = 0$, $v(i) = 1$, and $v(i:m)$ is stored on exit in

$A(ia+i-1:ia+m-1, ja+i-1)$; $u(1:i) = 0$, $u(i+1:n) = 1$, and $u(i+1:n)$ is stored on exit in $A(ia+i-1, ja+i:ja+n-1)$; τ_{uq} is stored in $\tau_{uq}[ja+i-2]$ and τ_{up} in $\tau_{up}[ia+i-2]$.

If $m < n$, $v(1:i) = 0$, $v(i+1:n) = 1$, and $v(i+1:m)$ is stored on exit in

$A(ia+i+1:ia+m-1, ja+i-1)$; $u(1:i-1) = 0$, $u(i) = 1$, and $u(i:n)$ is stored on exit in $A(ia+i-1, ja+i:ja+n-1)$; τ_{uq} is stored in $\tau_{uq}[ja+i-2]$ and τ_{up} in $\tau_{up}[ia+i-2]$. The elements of the vectors v and u together form the m -by- nb matrix V and the nb -by- n matrix U' which are necessary, with X and Y , to apply the transformation to the unreduced part of the matrix, using a block update of the form: $\text{sub}(A) := \text{sub}(A) - V*Y' - X*U'$. The contents of $\text{sub}(A)$ on exit are illustrated by the following examples with $nb = 2$:

$$\begin{array}{l}
 m = 6 \text{ and } n = 5 (m > n): \\
 \begin{bmatrix} 1 & 1 & u1 & u1 & u1 \\ v1 & 1 & 1 & u2 & u2 \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \end{bmatrix} \\
 \\
 m = 5 \text{ and } n = 6 (m < n): \\
 \begin{bmatrix} 1 & u1 & u1 & u1 & u1 & u1 \\ 1 & 1 & u2 & u2 & u2 & u2 \\ v1 & 1 & a & a & a & a \\ v1 & v2 & a & a & a & a \\ v1 & v2 & a & a & a & a \end{bmatrix}
 \end{array}$$

where a denotes an element of the original matrix which is unchanged, v_i denotes an element of the vector defining $H(i)$, and u_i an element of the vector defining $G(i)$.

p?lacon

Estimates the 1-norm of a square matrix, using the reverse communication for evaluating matrix-vector products.

Syntax

```
void pslacon (MKL_INT *n , float *v , MKL_INT *iv , MKL_INT *jv , MKL_INT *descv ,
float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *isgn , float *est ,
MKL_INT *kase );
```

```
void pdlacon (MKL_INT *n , double *v , MKL_INT *iv , MKL_INT *jv , MKL_INT *descv ,
double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *isgn , double *est ,
MKL_INT *kase );
```

```
void pclacon (MKL_INT *n , MKL_Complex8 *v , MKL_INT *iv , MKL_INT *jv , MKL_INT
*descv , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , float *est ,
MKL_INT *kase );
```

```
void pzlacon (MKL_INT *n , MKL_Complex16 *v , MKL_INT *iv , MKL_INT *jv , MKL_INT
*descv , MKL_Complex16 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , double *est ,
MKL_INT *kase );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?lacon` function estimates the 1-norm of a square, real/unitary distributed matrix A . Reverse communication is used for evaluating matrix-vector products. x and v are aligned with the distributed matrix A , this information is implicitly contained within iv , ix , $descv$, and $descx$.

Input Parameters

| | |
|----------|---|
| n | (global) The length of the distributed vectors v and x . $n \geq 0$. |
| v | (local). Pointer into the local memory to an array of size $LOCr(n+\text{mod}(iv-1, mb_v))$. On the final return, $v = a*w$, where $est = \text{norm}(v)/\text{norm}(w)$ (w is not returned). |
| iv, jv | (global) The row and column indices in the global matrix V indicating the first row and the first column of the submatrix V , respectively. |
| $descv$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix V . |
| x | (local). Pointer into the local memory to an array of size $LOCr(n+\text{mod}(ix-1, mb_x))$. |
| ix, jx | (global) The row and column indices in the global matrix X indicating the first row and the first column of the submatrix X , respectively. |
| $descx$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix X . |
| $isgn$ | (local). Array of size $LOCr(n+\text{mod}(ix-1, mb_x))$. $isgn$ is aligned with x and v . |
| $kase$ | (local). On the initial call to <code>p?lacon</code> , $kase$ should be 0. |

Output Parameters

| | |
|--------|---|
| x | (local). On an intermediate return, X should be overwritten by $A*X$, if $kase=1$, $A'*X$, if $kase=2$, <code>p?lacon</code> must be re-called with all the other parameters unchanged. |
| est | (global). |
| $kase$ | (local) On an intermediate return, $kase$ is 1 or 2, indicating whether X should be overwritten by $A*X$, or $A'*X$. On the final return from <code>p?lacon</code> , $kase$ is again 0. |

p?laconsb

Looks for two consecutive small subdiagonal elements.

Syntax

```
void pslaconsb (const float *a, const MKL_INT *desca, const MKL_INT *i, const MKL_INT *l, MKL_INT *m, const float *h44, const float *h33, const float *h43h34, float *buf, const MKL_INT *lwork );
```

```
void pdlaconsb (const double *a, const MKL_INT *desca, const MKL_INT *i, const MKL_INT *l, MKL_INT *m, const double *h44, const double *h33, const double *h43h34, double *buf, const MKL_INT *lwork );
```

```
void pclaconsb (const MKL_Complex8 *a , const MKL_INT *desca , const MKL_INT *i , const MKL_INT *l , MKL_INT *m , const MKL_Complex8 *h44 , const MKL_Complex8 *h33 , const MKL_Complex8 *h43h34 , MKL_Complex8 *buf , const MKL_INT *lwork );
```

```
void pzlaconsb (const MKL_Complex16 *a , const MKL_INT *desca , const MKL_INT *i , const MKL_INT *l , MKL_INT *m , const MKL_Complex16 *h44 , const MKL_Complex16 *h33 , const MKL_Complex16 *h43h34 , MKL_Complex16 *buf , const MKL_INT *lwork );
```

Include Files

- mkl_scalapack.h

Description

The p?laconsb function looks for two consecutive small subdiagonal elements by analyzing the effect of starting a double shift *QR* iteration given by *h44*, *h33*, and *h43h34* to see if this process makes a subdiagonal negligible.

Input Parameters

| | |
|---|--|
| <i>a</i> | (local) Array of size $lld_a * LOCc(n_a)$. On entry, the Hessenberg matrix whose tridiagonal part is being scanned. Unchanged on exit. |
| <i>desca</i> | (global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>i</i> | (global) The global location of the bottom of the unreduced submatrix of <i>A</i> . Unchanged on exit. |
| <i>l</i> | (global) The global location of the top of the unreduced submatrix of <i>A</i> . Unchanged on exit. |
| <i>h44</i> , <i>h33</i> , <i>h43h34</i> | (global). These three values are for the double shift <i>QR</i> iteration. |
| <i>lwork</i> | (local) |

This must be at least $7 * \text{ceil}(\text{ceil}((i-1)/mb_a) / \text{lcm}(nprow, npc1))$. Here lcm is the least common multiple and $nprow * npc1$ is the logical grid size.

Output Parameters

m (global). On exit, this yields the starting location of the QR double shift. This will satisfy:
 $i \leq m \leq i-2$.

buf (local).
 Array of size *lwork*.

p?lacp2

Copies all or part of a distributed matrix to another distributed matrix.

Syntax

```
void pslacp2 (char *uplo , MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
void pdlacp2 (char *uplo , MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
void pclacp2 (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
void pzlacp2 (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
```

Include Files

- mkl_scalapack.h

Description

The p?lacp2 function copies all or part of a distributed matrix *A* to another distributed matrix *B*. No communication is performed, p?lacp2 performs a local copy $\text{sub}(A) := \text{sub}(B)$, where $\text{sub}(A)$ denotes $A(ia:ia+m-1, a:ja+n-1)$ and $\text{sub}(B)$ denotes $B(ib:ib+m-1, jb:jb+n-1)$.

p?lacp2 requires that only dimension of the matrix operands is distributed.

Input Parameters

uplo (global) Specifies the part of the distributed matrix $\text{sub}(A)$ to be copied:
 = 'U': Upper triangular part is copied; the strictly lower triangular part of $\text{sub}(A)$ is not referenced;

= 'L': Lower triangular part is copied; the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

Otherwise: all of the matrix $\text{sub}(A)$ is copied.

| | |
|---------------|--|
| <i>m</i> | (global) The number of rows in the distributed matrix $\text{sub}(A)$. ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the distributed matrix $\text{sub}(A)$. ($n \geq 0$). |
| <i>a</i> | (local). Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$. On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of $\text{sub}(A)$, respectively. |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <i>ib, jb</i> | (global) The row and column indices in the global matrix B indicating the first row and the first column of $\text{sub}(B)$, respectively. |
| <i>descb</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix B . |

Output Parameters

| | |
|----------|--|
| <i>b</i> | (local). Pointer into the local memory to an array of size $lld_b * LOCC(jb+n-1)$. This array contains on exit the local pieces of the distributed matrix $\text{sub}(B)$ set as follows: if $uplo = 'U'$, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $1 \leq i \leq m$, $1 \leq j \leq n$; if $uplo = 'L'$, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $j \leq i \leq m$, $1 \leq j \leq n$; otherwise, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $1 \leq i \leq m$, $1 \leq j \leq n$. |
|----------|--|

p?lcp3

Copies from a global parallel array into a local replicated array or vice versa.

Syntax

```
void pslcp3 (const MKL_INT *m, const MKL_INT *i, float *a, const MKL_INT *desca, float *b, const MKL_INT *ldb, const MKL_INT *ii, const MKL_INT *jj, const MKL_INT *rev );
```

```

void pdlacp3 (const MKL_INT *m, const MKL_INT *i, double *a, const MKL_INT *desca,
double *b, const MKL_INT *ldb, const MKL_INT *ii, const MKL_INT *jj, const MKL_INT
*rev );

void pclacp3 (const MKL_INT *m, const MKL_INT *i, MKL_Complex8 *a, const MKL_INT
*desca, MKL_Complex8 *b, const MKL_INT *ldb, const MKL_INT *ii, const MKL_INT *jj,
const MKL_INT *rev);

void pzlacp3 (const MKL_INT *m, const MKL_INT *i, MKL_Complex16 *a, const MKL_INT
*desca, MKL_Complex16 *b, const MKL_INT *ldb, const MKL_INT *ii, const MKL_INT *jj,
const MKL_INT *rev);

```

Include Files

- mkl_scalapack.h

Description

This is an auxiliary function that copies from a global parallel array into a local replicated array or vice versa. Note that the entire submatrix that is copied gets placed on one node or more. The receiving node can be specified precisely, or all nodes can receive, or just one row or column of nodes.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

| | |
|--------------|--|
| <i>m</i> | (global) <i>m</i> is the order of the square submatrix that is copied. <i>m</i> ≥ 0. Unchanged on exit. |
| <i>i</i> | (global) The matrix element $A(i, i)$ is the global location that the copying starts from. Unchanged on exit. |
| <i>a</i> | (local) Array of size $lld_a * LOCc(n_a)$. On entry, the parallel matrix to be copied into or from. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>b</i> | (local) Array of size $ldb * LOCc(m)$. If <i>rev</i> = 0, this is the global portion of the matrix $A(i:i+m-1, i:i+m-1)$. If <i>rev</i> = 1, this is unchanged on exit. |
| <i>ldb</i> | (local) |

The leading dimension of B .

ii, jj

(global) By using rev 0 and 1, data can be sent out and returned again. If $rev = 0$, then ii is destination row index and jj is destination column index for the node(s) receiving the replicated matrix B . If $ii \geq 0, jj \geq 0$, then node (ii, jj) receives the data. If $ii = -1, jj \geq 0$, then all rows in column jj receive the data. If $ii \geq 0, jj = -1$, then all cols in row ii receive the data. If $ii = -1, jj = -1$, then all nodes receive the data. If $rev \neq 0$, then ii is the source row index for the node(s) sending the replicated B .

rev

(global) Use $rev = 0$ to send global matrix A into locally replicated matrix B (on node (ii, jj)). Use $rev \neq 0$ to send locally replicated B from node (ii, jj) to its owner (which changes depending on its location in A) into the global A .

Output Parameters

a

On exit, if $rev = 1$, the copied data. Unchanged on exit if $rev = 0$.

b

If $rev = 1$, this is unchanged on exit.

p?lacpy

Copies all or part of one two-dimensional array to another.

Syntax

```
void pslacpy (char *uplo , MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
```

```
void pdlacpy (char *uplo , MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
```

```
void pclacpy (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
```

```
void pzlacpy (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?lacpy` function copies all or part of a distributed matrix A to another distributed matrix B . No communication is performed, `p?lacpy` performs a local copy $\text{sub}(B) := \text{sub}(A)$, where $\text{sub}(A)$ denotes $A(ia:ia+m-1, ja:ja+n-1)$ and $\text{sub}(B)$ denotes $B(ib:ib+m-1, jb:jb+n-1)$.

Input Parameters

| | |
|---------------|--|
| <i>uplo</i> | (global) Specifies the part of the distributed matrix $\text{sub}(A)$ to be copied: = 'U': Upper triangular part; the strictly lower triangular part of $\text{sub}(A)$ is not referenced; = 'L': Lower triangular part; the strictly upper triangular part of $\text{sub}(A)$ is not referenced. Otherwise: all of the matrix $\text{sub}(A)$ is copied. |
| <i>m</i> | (global) The number of rows in the distributed matrix $\text{sub}(A)$. ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the distributed matrix $\text{sub}(A)$. ($n \geq 0$). |
| <i>a</i> | (local). Pointer into the local memory to an array of size $lld_a * LOCc(ja+n-1)$. On entry, this array contains the local pieces of the distributed matrix $\text{sub}(A)$. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively. |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <i>ib, jb</i> | (global) The row and column indices in the global matrix B indicating the first row and the first column of $\text{sub}(B)$ respectively. |
| <i>descb</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix B . |

Output Parameters

| | |
|----------|--|
| <i>b</i> | (local). Pointer into the local memory to an array of size $lld_b * LOCc(jb+n-1)$. This array contains on exit the local pieces of the distributed matrix $\text{sub}(B)$ set as follows: if $uplo = 'U'$, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $1 \leq j \leq n$; if $uplo = 'L'$, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $j \leq m$, $1 \leq j \leq n$; otherwise, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $1 \leq j \leq m$, $1 \leq j \leq n$. |
|----------|--|

p?laevswp

Moves the eigenvectors from where they are computed to ScaLAPACK standard block cyclic array.

Syntax

```
void pslaevswp (MKL_INT *n , float *zin , MKL_INT *ldzi , float *z , MKL_INT *iz ,
MKL_INT *jz , MKL_INT *descz , MKL_INT *nvs , MKL_INT *key , float *work , MKL_INT
*lwork );
```

```
void pdlaevswp (MKL_INT *n , double *zin , MKL_INT *ldzi , double *z , MKL_INT *iz ,
MKL_INT *jz , MKL_INT *descz , MKL_INT *nvs , MKL_INT *key , double *work , MKL_INT
*lwork );
```

```
void pclaevswp (MKL_INT *n , float *zin , MKL_INT *ldzi , MKL_Complex8 *z , MKL_INT
*iz , MKL_INT *jz , MKL_INT *descz , MKL_INT *nvs , MKL_INT *key , float *rwork ,
MKL_INT *lrwork );
```

```
void pzlaevswp (MKL_INT *n , double *zin , MKL_INT *ldzi , MKL_Complex16 *z , MKL_INT
*iz , MKL_INT *jz , MKL_INT *descz , MKL_INT *nvs , MKL_INT *key , double *rwork ,
MKL_INT *lrwork );
```

Include Files

- mkl_scalapack.h

Description

The `p?laevswp` function moves the eigenvectors (potentially unsorted) from where they are computed, to a ScaLAPACK standard block cyclic array, sorted so that the corresponding eigenvalues are sorted.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

| | |
|---------------|---|
| <i>n</i> | (global) The order of the matrix <i>A</i> . $n \geq 0$. |
| <i>zin</i> | (local). Array of size $ldzi * nvs[iam+1]$. The eigenvectors on input. <i>iam</i> is a process rank from $[0, nprocs)$ interval. Each eigenvector resides entirely in one process. Each process holds a contiguous set of $nvs[iam+1]$ eigenvectors. The global number of the first eigenvector that the process holds is: ((sum for $i=[0, iam]$ of $nvs[i]$)+1). |
| <i>ldzi</i> | (local) The leading dimension of the <i>zin</i> array. |
| <i>iz, jz</i> | (global) The row and column indices in the global matrix <i>Z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively. |
| <i>descz</i> | (global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> . |
| <i>nvs</i> | (global) Array of size $nprocs+1$ $nvs[i]$ = number of eigenvectors held by processes $[0, i)$ $nvs[0]$ = number of eigenvectors held by processes $[0, 0) = 0$ |

| | |
|---------------|--|
| | $nvs[nprocs]$ = number of eigenvectors held by $[0, nprocs)$ = total number of eigenvectors. |
| <i>key</i> | (global) Array of size n . Indicates the actual index (after sorting) for each of the eigenvectors. |
| <i>rwork</i> | (local). Array of size $lrwork$. |
| <i>lrwork</i> | (local) Size of <i>work</i> . |

Output Parameters

| | |
|----------|---|
| <i>z</i> | (local). Array of global size $n * n$ and of local size $lld_z * nq$. The eigenvectors on output. The eigenvectors are distributed in a block cyclic manner in both dimensions, with a block size of nb . |
|----------|---|

p?lahrd

Reduces the first nb columns of a general rectangular matrix A so that elements below the k -th subdiagonal are zero, by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A .

Syntax

```
void pslahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , float *a , MKL_INT *ia , MKL_INT
 *ja , MKL_INT *desca , float *tau , float *t , float *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , float *work );
```

```
void pdlahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *tau , double *t , double *y , MKL_INT *iy ,
MKL_INT *jy , MKL_INT *descy , double *work );
```

```
void pclahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *t , MKL_Complex8 *y ,
MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_Complex8 *work );
```

```
void pzlahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *t , MKL_Complex16
*y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_Complex16 *work );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?lahrd` function reduces the first nb columns of a real general n -by- $(n-k+1)$ distributed matrix $A(ia:ia+n-1, ja:ja+n-k)$ so that elements below the k -th subdiagonal are zero. The reduction is performed by an orthogonal/unitary similarity transformation Q^*A*Q . The function returns the matrices V and T which determine Q as a block reflector $I-V*T*V'$, and also the matrix $Y = A*V*T$.

This is an auxiliary function called by `p?gehrd`. In the following comments $sub(A)$ denotes $A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

| | |
|----------|---|
| n | (global) The order of the distributed matrix $sub(A)$. $n \geq 0$. |
| k | (global) The offset for the reduction. Elements below the k -th subdiagonal in the first nb columns are reduced to zero. |
| nb | (global) The number of columns to be reduced. |
| a | (local). Pointer into the local memory to an array of size $lld_a * LOCc(ja+n-k)$. On entry, this array contains the local pieces of the n -by- $(n-k+1)$ general distributed matrix $A(ia:ia+n-1, ja:ja+n-k)$. |
| ia, ja | (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $sub(A)$, respectively. |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| iy, jy | (global) The row and column indices in the global matrix Y indicating the first row and the first column of the matrix $sub(Y)$, respectively. |
| $descy$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix Y . |
| $work$ | (local). Array of size nb . |

Output Parameters

| | |
|-------|---|
| a | (local). On exit, the elements on and above the k -th subdiagonal in the first nb columns are overwritten with the corresponding elements of the reduced distributed matrix; the elements below the k -th subdiagonal, with the array tau , represent the matrix Q as a product of elementary reflectors. The other columns of the matrix $A(ia:ia+n-1, ja:ja+n-k)$ are unchanged. (See <i>Application Notes</i> below.) |
| tau | (local) |

Array of size $LOCc(j_{a+n-2})$. The scalar factors of the elementary reflectors (see *Application Notes* below). τ is tied to the distributed matrix A .

t (local)
Array of size $nb_a * nb_a$. The upper triangular matrix T .

y (local).
Pointer into the local memory to an array of size $lld_y * nb_a$. On exit, this array contains the local pieces of the n -by- nb distributed matrix Y . $lld_y \geq LOCr(i_{a+n-1})$.

Application Notes

The matrix Q is represented as a product of nb elementary reflectors

$$Q = H(1) * H(2) * \dots * H(nb).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v',$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i+k-1) = 0$, $v(i+k) = 1$; $v(i+k+1:n)$ is stored on exit in $A(i_{a+i+k}:i_{a+n-1}, j_{a+i-1})$, and τ in $\tau[j_{a+i-2}]$.

The elements of the vectors v together form the $(n-k+1)$ -by- nb matrix V which is needed, with T and Y , to apply the transformation to the unreduced part of the matrix, using an update of the form: $A(i_{a:i_{a+n-1}}, j_{a:j_{a+n-k}}) := (I - V * T * V') * (A(i_{a:i_{a+n-1}}, j_{a:j_{a+n-k}}) - Y * V')$. The contents of $A(i_{a:i_{a+n-1}}, j_{a:j_{a+n-k}})$ on exit are illustrated by the following example with $n = 7$, $k = 3$, and $nb = 2$:

$$\begin{bmatrix} a & h & a & a & a \\ a & h & a & a & a \\ a & h & a & a & a \\ h & h & a & a & a \\ v1 & h & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix $A(i_{a:i_{a+n-1}}, j_{a:j_{a+n-k}})$, h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(i)$.

p?laiect

Exploits IEEE arithmetic to accelerate the computations of eigenvalues.

Syntax

```
void pslaiect (float *sigma , MKL_INT *n , float *d , MKL_INT *count );
void pdlaiectb (float *sigma , MKL_INT *n , float *d , MKL_INT *count );
void pdlaiectl (float *sigma , MKL_INT *n , float *d , MKL_INT *count );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?laiect` function computes the number of negative eigenvalues of $(A - \sigma I)$. This implementation of the Sturm Sequence loop exploits IEEE arithmetic and has no conditionals in the innermost loop. The signbit for real function `pslaiect` is assumed to be bit 32. Double-precision functions `pdlaiectb` and `pdlaiectl` differ in the order of the double precision word storage and, consequently, in the signbit location. For `pdlaiectb`, the double precision word is stored in the big-endian word order and the signbit is assumed to be bit 32. For `pdlaiectl`, the double precision word is stored in the little-endian word order and the signbit is assumed to be bit 64.

This is a ScaLAPACK internal function and arguments are not checked for unreasonable values.

Input Parameters

| | |
|--------------|--|
| <i>sigma</i> | The shift. <code>p?laiect</code> finds the number of eigenvalues less than equal to <i>sigma</i> . |
| <i>n</i> | The order of the tridiagonal matrix <i>T</i> . $n \geq 1$. |
| <i>d</i> | Array of size $2n-1$. On entry, this array contains the diagonals and the squares of the off-diagonal elements of the tridiagonal matrix <i>T</i> . These elements are assumed to be interleaved in memory for better cache performance. The diagonal entries of <i>T</i> are in the entries $d[0], d[2], \dots, d[2n-2]$, while the squares of the off-diagonal entries are $d[1], d[3], \dots, d[2n-3]$. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than $overflow^{(1/2)} * underflow^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that. |

Output Parameters

| | |
|----------|---|
| <i>n</i> | The count of the number of eigenvalues of <i>T</i> less than or equal to <i>sigma</i> . |
|----------|---|

p?lamve

Copies all or part of one two-dimensional distributed array to another.

Syntax

```
void pslamve(char* uplo, MKL_INT* m, MKL_INT* n, float* a, MKL_INT* ia, MKL_INT* ja,
MKL_INT* desca, float* b, MKL_INT* ib, MKL_INT* jb, MKL_INT* descb, float* dwork);
void pdlamve(char* uplo, MKL_INT* m, MKL_INT* n, double* a, MKL_INT* ia, MKL_INT* ja,
MKL_INT* desca, double* b, MKL_INT* ib, MKL_INT* jb, MKL_INT* descb, double* dwork);
```

Include Files

- `mkl_scalapack.h`

Description

`p?lamve` copies all or part of a distributed matrix A to another distributed matrix B . There is no alignment assumptions at all except that A and B are of the same size.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

| | |
|--------------|--|
| <i>uplo</i> | (global) Specifies the part of the distributed matrix $\text{sub}(A)$ to be copied: = 'U': Upper triangular part is copied; the strictly lower triangular part of $\text{sub}(A)$ is not referenced; = 'L': Lower triangular part is copied; the strictly upper triangular part of $\text{sub}(A)$ is not referenced; Otherwise: All of the matrix $\text{sub}(A)$ is copied. |
| <i>m</i> | (global) The number of rows to be operated on, which is the number of rows of the distributed matrix $\text{sub}(A)$. $m \geq 0$. |
| <i>n</i> | (global) The number of columns to be operated on, which is the number of columns of the distributed matrix $\text{sub}(A)$. $n \geq 0$. |
| <i>a</i> | (local) pointer into the local memory to an array of size $lld_a * LOC_c(ja + n - 1)$. This array contains the local pieces of the distributed matrix $\text{sub}(A)$ to be copied from. |
| <i>ia</i> | (global) The row index in the global matrix A indicating the first row of $\text{sub}(A)$. |
| <i>ja</i> | (global) The column index in the global matrix A indicating the first column of $\text{sub}(A)$. |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <i>ib</i> | (global) The row index in the global matrix B indicating the first row of $\text{sub}(B)$. |

| | |
|--------------|--|
| <i>jb</i> | (global) The column index in the global matrix <i>B</i> indicating the first column of sub(<i>B</i>). |
| <i>descb</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> . |
| <i>dwork</i> | (local workspace) array If <i>uplo</i> = 'U' or <i>uplo</i> = 'L' and number of processors > 1, the length of <i>dwork</i> is at least as large as the length of <i>b</i> . Otherwise, <i>dwork</i> is not referenced. |

OUTPUT Parameters

| | |
|----------|--|
| <i>b</i> | (local) pointer into the local memory to an array of size <i>lld_b</i> * <i>LOC_c(jb + n - 1)</i> . This array contains on exit the local pieces of the distributed matrix sub(<i>B</i>). |
|----------|--|

p?lange

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a general rectangular matrix.

Syntax

```
float pslange (char *norm , MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *work );
double pdlange (char *norm , MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *work );
float pclange (char *norm , MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *work );
double pzlange (char *norm , MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *work );
```

Include Files

- mkl_scalapack.h

Description

The p?lange function returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$.

Input Parameters

| | |
|-------------|---|
| <i>norm</i> | (global) Specifies what value is returned by the function: = 'M' or 'm': $\text{val} = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix <i>A</i> , it s not a matrix norm. |
|-------------|---|

| | |
|---------------|--|
| | = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), |
| | = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), |
| | = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares). |
| <i>m</i> | (global) The number of rows in the distributed matrix sub(A). When $m = 0$, <i>p?</i> <i>lange</i> is set to zero. $m \geq 0$. |
| <i>n</i> | (global) The number of columns in the distributed matrix sub(A). When $n = 0$, <i>p?</i> <i>lange</i> is set to zero. $n \geq 0$. |
| <i>a</i> | (local). Pointer into the local memory to an array of size $lld_a * LOCc(ja+n-1)$ containing the local pieces of the distributed matrix sub(A). |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix sub(A), respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A . |
| <i>work</i> | (local). Array size <i>lwork</i> . $lwork \geq 0$ if <i>norm</i> = 'M' or 'm' (not referenced), $nq0$ if <i>norm</i> = '1', 'O' or 'o', $mp0$ if <i>norm</i> = 'I' or 'i', 0 if <i>norm</i> = 'F', 'f', 'E' or 'e' (not referenced), where $irow = \text{mod}(ia-1, mb_a)$, $icol = \text{mod}(ja-1, nb_a)$, $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$, $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcot)$, $mp0 = \text{numroc}(m+irow, mb_a, myrow, iarow, nprow)$, $nq0 = \text{numroc}(n+icol, nb_a, mycol, icol, npcot)$, <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; <i>myrow</i> , <i>mycol</i> , <i>nprow</i> , and <i>npcol</i> can be determined by calling the function <i>blacs_gridinfo</i> . |

Output Parameters

val The value returned by the function.

See Also

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lanhs

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of an upper Hessenberg matrix.

Syntax

```
float pslanhs (char *norm , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *work );
```

```
double pdlanhs (char *norm , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *work );
```

```
float pclanhs (char *norm , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *work );
```

```
double pzlanhs (char *norm , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *work );
```

Include Files

- mkl_scalapack.h

Description

The p?lanhs function returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an upper Hessenberg distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$.

Input Parameters

| | |
|---------------|--|
| <i>norm</i> | Specifies the value to be returned by the function: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix <i>A</i> . = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix <i>A</i> (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix <i>A</i> (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix <i>A</i> (square root of sum of squares). |
| <i>n</i> | (global) The number of columns in the distributed matrix sub(<i>A</i>). When $n = 0$, p?lanhs is set to zero. $n \geq 0$. |
| <i>a</i> | (local). Pointer into the local memory to an array of size $lld_a * LOCC(\text{ja}+n-1)$ containing the local pieces of the distributed matrix sub(<i>A</i>). |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix sub(<i>A</i>), respectively. |

desca (global and local) array of size *dlen_*. The array descriptor for the distributed matrix A.

work (local).
 Array of size *lwork*.
lwork \geq 0 if *norm* = 'M' or 'm' (not referenced),
*nq*0 if *norm* = '1', 'O' or 'o',
*mp*0 if *norm* = 'I' or 'i',
 0 if *norm* = 'F', 'f', 'E' or 'e' (not referenced),
 where
iroffa = mod(*ia*-1, *mb_a*), *icoffa* = mod(*ja*-1, *nb_a*),
iarow = indxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nrow*),
iacol = indxg2p(*ja*, *nb_a*, *mycol*, *csrc_a*, *ncol*),
mp0 = numroc(*m*+*iroffa*, *mb_a*, *myrow*, *iarow*, *nrow*),
nq0 = numroc(*n*+*icoffa*, *nb_a*, *mycol*, *iacol*, *ncol*),
 indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *imycol*, *nrow*,
 and *ncol* can be determined by calling the function `blacs_gridinfo`.

Output Parameters

val The value returned by the function.

See Also

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lansy, p?lanhe

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a real symmetric or a complex Hermitian matrix.

Syntax

```
float pslansy (char *norm , char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT
 *ja , MKL_INT *desca , float *work );

double pdlansy (char *norm , char *uplo , MKL_INT *n , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *work );

float pclansy (char *norm , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *work );

double pzlansy (char *norm , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *work );

float pplanhe (char *norm , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *work );

double pzlanhe (char *norm , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *work );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?lansy` and `p?lanhe` functions return the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$.

Input Parameters

| | |
|---------------|---|
| <i>norm</i> | <p>(global) Specifies what value is returned by the function:</p> <ul style="list-style-type: none"> = 'M' or 'm': $\text{val} = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix <i>A</i>, it s not a matrix norm. = '1' or 'O' or 'o': $\text{val} = \text{norm1}(A)$, 1-norm of the matrix <i>A</i> (maximum column sum), = 'I' or 'i': $\text{val} = \text{normI}(A)$, infinity norm of the matrix <i>A</i> (maximum row sum), = 'F', 'f', 'E' or 'e': $\text{val} = \text{normF}(A)$, Frobenius norm of the matrix <i>A</i> (square root of sum of squares). |
| <i>uplo</i> | <p>(global) Specifies whether the upper or lower triangular part of the symmetric matrix $\text{sub}(A)$ is to be referenced.</p> <ul style="list-style-type: none"> = 'U': Upper triangular part of $\text{sub}(A)$ is referenced, = 'L': Lower triangular part of $\text{sub}(A)$ is referenced. |
| <i>n</i> | <p>(global)</p> <p>The number of columns in the distributed matrix $\text{sub}(A)$. When $n = 0$, <code>p?lansy</code> is set to zero. $n \geq 0$.</p> |
| <i>a</i> | <p>(local).</p> <p>Pointer into the local memory to an array of size $\text{lld}_a * \text{LOCc}(\text{ja}+n-1)$ containing the local pieces of the distributed matrix $\text{sub}(A)$.</p> <p>If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of $\text{sub}(A)$ contains the upper triangular matrix whose norm is to be computed, and the strictly lower triangular part of this matrix is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of $\text{sub}(A)$ contains the lower triangular matrix whose norm is to be computed, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.</p> |
| <i>ia, ja</i> | <p>(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.</p> |
| <i>desca</i> | <p>(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>A</i>.</p> |
| <i>work</i> | <p>(local).</p> <p>Array of size <i>lwork</i>.</p> <p>$\text{lwork} \geq 0$ if <i>norm</i> = 'M' or 'm' (not referenced),</p> <p>$2 * nq0 + mp0 + ldw$ if <i>norm</i> = '1', 'O' or 'o', 'I' or 'i',</p> |

where ldw is given by:

```
if( nprow≠npcol ) then
  ldw = mb_a*iceil(iceil(np0,mb_a), (lcm/nprow))
else
  ldw = 0
end if
```

0 if $norm = 'F', 'f', 'E' \text{ or } 'e'$ (not referenced),

where lcm is the least common multiple of $nprow$ and $npcol$, $lcm = ilcm(nprow, npcol)$ and $iceil(x,y)$ is a ScaLAPACK function that returns ceiling (x/y) .

```
iroffa = mod(ia-1, mb_a), icoffa = mod(ja-1, nb_a),
```

```
iarow = indxg2p(ia, mb_a, myrow, rsrc_a, nprow),
```

```
iacol = indxg2p(ja, nb_a, mycol, csrc_a, npcol),
```

```
mp0 = numroc(m+iroffa, mb_a, myrow, iarow, nprow),
```

```
nq0 = numroc(n+icoffa, nb_a, mycol, iacol, npcol),
```

$ilcm$, $iceil$, $indxg2p$, and $numroc$ are ScaLAPACK tool functions; $myrow$, $mycol$, $nprow$, and $npcol$ can be determined by calling the function `blacs_gridinfo`.

Output Parameters

val The value returned by the function.

See Also

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lantr

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a triangular matrix.

Syntax

```
float pslantr (char *norm , char *uplo , char *diag , MKL_INT *m , MKL_INT *n , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *work );
```

```
double pdlantr (char *norm , char *uplo , char *diag , MKL_INT *m , MKL_INT *n ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *work );
```

```
float pclantr (char *norm , char *uplo , char *diag , MKL_INT *m , MKL_INT *n ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *work );
```

```
double pzlantr (char *norm , char *uplo , char *diag , MKL_INT *m , MKL_INT *n ,
MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *work );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?lantr` function returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$.

Input Parameters

| | |
|---------------|--|
| <i>norm</i> | (global) Specifies what value is returned by the function: = 'M' or 'm': $\text{val} = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A , it is not a matrix norm. = '1' or 'O' or 'o': $\text{val} = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $\text{val} = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $\text{val} = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares). |
| <i>uplo</i> | (global) Specifies whether the upper or lower triangular part of the symmetric matrix $\text{sub}(A)$ is to be referenced. = 'U': Upper trapezoidal, = 'L': Lower trapezoidal. Note that $\text{sub}(A)$ is triangular instead of trapezoidal if $m = n$. |
| <i>diag</i> | (global) Specifies whether the distributed matrix $\text{sub}(A)$ has unit diagonal. = 'N': Non-unit diagonal. = 'U': Unit diagonal. |
| <i>m</i> | (global) The number of rows in the distributed matrix $\text{sub}(A)$. When $m = 0$, <code>p?lantr</code> is set to zero. $m \geq 0$. |
| <i>n</i> | (global) The number of columns in the distributed matrix $\text{sub}(A)$. When $n = 0$, <code>p?lantr</code> is set to zero. $n \geq 0$. |
| <i>a</i> | (local). Pointer into the local memory to an array of size $\text{lld_a} * \text{LOCc}(\text{ja}+n-1)$ containing the local pieces of the distributed matrix $\text{sub}(A)$. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively. |
| <i>desca</i> | (global and local) array of size dlen_ . The array descriptor for the distributed matrix A . |

work (local).
 Array size *lwork*.
 $lwork \geq 0$ if *norm* = 'M' or 'm' (not referenced),
 $nq0$ if *norm* = '1', 'O' or 'o',
 $mp0$ if *norm* = 'I' or 'i',
 0 if *norm* = 'F', 'f', 'E' or 'e' (not referenced),
 $irowfa = \text{mod}(ia-1, mb_a)$, $icoffa = \text{mod}(ja-1, nb_a)$,
 $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$,
 $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcot)$,
 $mp0 = \text{numroc}(m+irowfa, mb_a, myrow, iarow, nprow)$,
 $nq0 = \text{numroc}(n+icoffa, nb_a, mycol, iacol, npcot)$,
 indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*,
 and *npcot* can be determined by calling the function `blacs_gridinfo`.

Output Parameters

val The value returned by the function.

See Also

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lapiv

Applies a permutation matrix to a general distributed matrix, resulting in row or column pivoting.

Syntax

```
void pslapiv (char *direc , char *rowcol , char *pivroc , MKL_INT *m , MKL_INT *n ,

Description

The `p?lapiv` function applies either P (permutation matrix indicated by $ipiv$) or $inv(P)$ to a general m -by- n distributed matrix $sub(A) = A(ia:ia+m-1, ja:ja+n-1)$, resulting in row or column pivoting. The pivot vector may be distributed across a process row or a column. The pivot vector should be aligned with the distributed matrix A . This function will transpose the pivot vector, if necessary.

For example, if the row pivots should be applied to the columns of $sub(A)$, pass `rowcol='C'` and `pivroc='C'`.

Input Parameters

| | |
|---------------------|--|
| <code>direc</code> | (global) Specifies in which order the permutation is applied: = 'F' (Forward): Applies pivots forward from top of matrix. Computes $P * sub(A)$. = 'B' (Backward): Applies pivots backward from bottom of matrix. Computes $inv(P) * sub(A)$. |
| <code>rowcol</code> | (global) Specifies if the rows or columns are to be permuted: = 'R': Rows will be permuted, = 'C': Columns will be permuted. |
| <code>pivroc</code> | (global) Specifies whether $ipiv$ is distributed over a process row or column: = 'R': $ipiv$ is distributed over a process row, = 'C': $ipiv$ is distributed over a process column. |
| <code>m</code> | (global) The number of rows in the distributed matrix $sub(A)$. When $m = 0$, <code>p?lapiv</code> is set to zero. $m \geq 0$. |
| <code>n</code> | (global) The number of columns in the distributed matrix $sub(A)$. When $n = 0$, <code>p?lapiv</code> is set to zero. $n \geq 0$. |
| <code>a</code> | (local). Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$ containing the local pieces of the distributed matrix $sub(A)$. |
| <code>ia, ja</code> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $sub(A)$, respectively. |
| <code>desca</code> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <code>ipiv</code> | (local) Array of size $lipiv$; |

```

when rowcol='R' or 'r':
  lipiv≥LOCr(ia+m-1) + mb_a if pivroc='C' or 'c',
  lipiv≥LOCc(m + mod(jp-1, nb_p)) if pivroc='R' or 'r', and,
when rowcol='C' or 'c':
  lipiv≥LOCr(n + mod(ip-1, mb_p)) if pivroc='C' or 'c',
  lipiv≥LOCc(ja+n-1) + nb_a if pivroc='R' or 'r'.

```

This array contains the pivoting information. $ipiv(i)$ is the global row (column), local row (column) i was swapped with. When $rowcol='R'$ or $'r'$ and $pivroc='C'$ or $'c'$, or $rowcol='C'$ or $'c'$ and $pivroc='R'$ or $'r'$, the last piece of this array of size mb_a (resp. nb_a) is used as workspace. In those cases, this array is tied to the distributed matrix A .

ip, jp (global) The row and column indices in the global matrix P indicating the first row and the first column of the matrix sub(P), respectively.

$descip$ (global and local) array of size $dlen_$. The array descriptor for the distributed vector $ipiv$.

$iwork$ (local).

Array of size ldw , where ldw is equal to the workspace necessary for transposition, and the storage of the transposed $ipiv$:

Let lcm be the least common multiple of $npro$ and $npcol$.

```

if( *rowcol == 'r' && *pivroc == 'r') {
  if( npro == npc ) {
    ldw = LOCr( n_p + (*jp-1)%nb_p ) + nb_p;
  } else {
    ldw = LOCr( n_p + (*jp-1)%nb_p ) +
    nb_p * ceil( ceil(LOCc(n_p)/nb_p) / (lcm/npc) );
  }
} else if( *rowcol == 'c' && *pivroc == 'c') {
  if( npro == npc ) {
    ldw = LOCc( m_p + (*ip-1)%mb_p ) + mb_p;
  } else {
    ldw = LOCc( m_p + (*ip-1)%mb_p ) +
    mb_p *ceil(ceil(LOCr(m_p)/mb_p) / (lcm/npro) );
  }
} else {
  // iwork is not referenced.

```

Output Parameters

a (local).
On exit, the local pieces of the permuted distributed submatrix.

p?lapv2

Applies a permutation to an m -by- n distributed matrix.

Syntax

```
void pslapv2 (const char* direc, const char* rowcol, const MKL_INT* m, const MKL_INT*
n, float* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, const
MKL_INT* ipiv, const MKL_INT* ip, const MKL_INT* jp, const MKL_INT* descip);
```

```
void pdlapv2 (const char* direc, const char* rowcol, const MKL_INT* m, const MKL_INT*
n, double* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, const
MKL_INT* ipiv, const MKL_INT* ip, const MKL_INT* jp, const MKL_INT* descip);
```

```
void pclapv2 (const char* direc, const char* rowcol, const MKL_INT* m, const MKL_INT*
n, MKL_Complex8* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, const
MKL_INT* ipiv, const MKL_INT* ip, const MKL_INT* jp, const MKL_INT* descip);
```

```
void pzlapv2 (const char* direc, const char* rowcol, const MKL_INT* m, const MKL_INT*
n, MKL_Complex16* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT* desca, const
MKL_INT* ipiv, const MKL_INT* ip, const MKL_INT* jp, const MKL_INT* descip);
```

Include Files

- mkl_scalapack.h

Description

`p?lapv2` applies either P (permutation matrix indicated by `ipiv`) or $\text{inv}(P)$ to an m -by- n distributed matrix $\text{sub}(A)$ denoting $A(ia:ia+m-1, ja:ja+n-1)$, resulting in row or column pivoting. The pivot vector should be aligned with the distributed matrix A . For pivoting the rows of $\text{sub}(A)$, `ipiv` should be distributed along a process column and replicated over all process rows. Similarly, `ipiv` should be distributed along a process row and replicated over all process columns for column pivoting.

Input Parameters

| | |
|---------------------|---|
| <code>direc</code> | (global) Specifies in which order the permutation is applied: = 'F' (Forward) Applies pivots Forward from top of matrix. Computes $P * \text{sub}(A)$; = 'B' (Backward) Applies pivots Backward from bottom of matrix. Computes $\text{inv}(P) * \text{sub}(A)$. |
| <code>rowcol</code> | (global) Specifies if the rows or columns are to be permuted: = 'R' Rows will be permuted, = 'C' Columns will be permuted. |
| <code>m</code> | (global) The number of rows to be operated on, i.e. the number of rows of the distributed submatrix $\text{sub}(A)$. $m \geq 0$. |
| <code>n</code> | (global) The number of columns to be operated on, i.e. the number of columns of the distributed submatrix $\text{sub}(A)$. $n \geq 0$. |
| <code>a</code> | Pointer into local memory to an array of size $lld_a * LOCC(ja+n-1)$. |

On entry, this local array contains the local pieces of the distributed matrix sub(*A*) to which the row or columns interchanges will be applied.

| | |
|---------------|--|
| <i>ia</i> | (global) The row index in the global array <i>a</i> indicating the first row of sub(<i>A</i>). |
| <i>ja</i> | (global) The column index in the global array <i>a</i> indicating the first column of sub(<i>A</i>). |
| <i>desca</i> | (global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>ipiv</i> | Array, size $\geq \text{LOCr}(m_a) + mb_a$ if <i>rowcol</i> = 'R', $\text{LOCc}(n_a) + nb_a$ otherwise. It contains the pivoting information. <i>ipiv</i> [<i>i</i> - 1] is the global row (column), local row (column) <i>i</i> was swapped with. The last piece of the array of size <i>mb_a</i> or <i>nb_a</i> is used as workspace. <i>ipiv</i> is tied to the distributed matrix <i>A</i> . |
| <i>ip</i> | (global) The global row index of <i>ipiv</i> , which points to the beginning of the submatrix on which to operate. |
| <i>jp</i> | (global) The global column index of <i>ipiv</i> , which points to the beginning of the submatrix on which to operate. |
| <i>descip</i> | (global and local) Array of size 8. The array descriptor for the distributed matrix <i>ipiv</i> . |

Output Parameters

| | |
|----------|---|
| <i>a</i> | On exit, this array contains the local pieces of the permuted distributed matrix. |
|----------|---|

p?laqge

Scales a general rectangular matrix, using row and column scaling factors computed by p?geequ.

Syntax

```
void pslaqge (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *r , float *c , float *rowcnd , float *colcnd , float *amax , char
*equed );
```

```
void pdlaqge (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *r , double *c , double *rowcnd , double *colcnd , double
*amax , char *equed );
```

```
void pclaqge (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *r , float *c , float *rowcnd , float *colcnd , float *amax ,
char *equed );
```

```
void pzlaqge (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *r , double *c , double *rowcnd , double *colcnd , double
*amax , char *equed );
```

Include Files

- mkl_scalapack.h

Description

The `p?laqge` function equilibrates a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ using the row and scaling factors in the vectors r and c computed by `p?geequ`.

Input Parameters

| | |
|----------|---|
| m | (global) The number of rows in the distributed matrix $\text{sub}(A)$. ($m \geq 0$). |
| n | (global) The number of columns in the distributed matrix $\text{sub}(A)$. ($n \geq 0$). |
| a | (local). Pointer into the local memory to an array of size $lld_a * LOCc(ja+n-1)$. On entry, this array contains the distributed matrix $\text{sub}(A)$. |
| ia, ja | (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively. |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| r | (local). Array of size $LOCr(m_a)$. The row scale factors for $\text{sub}(A)$. r is aligned with the distributed matrix A , and replicated across every process column. r is tied to the distributed matrix A . |
| c | (local). Array of size $LOCc(n_a)$. The row scale factors for $\text{sub}(A)$. c is aligned with the distributed matrix A , and replicated across every process column. c is tied to the distributed matrix A . |
| $rowcnd$ | (local). The global ratio of the smallest $r[i]$ to the largest $r[i]$, $ia-1 \leq i \leq ia+m-2$. |
| $colcnd$ | (local). The global ratio of the smallest $c[i]$ to the largest $c[i]$, $ia-1 \leq i \leq ia+n-2$. |
| $amax$ | (global). Absolute value of largest distributed submatrix entry. |

Output Parameters

| | |
|--------------|--|
| <i>a</i> | (local). On exit, the equilibrated distributed matrix. See <i>equed</i> for the form of the equilibrated distributed submatrix. |
| <i>equed</i> | (global) Specifies the form of equilibration that was done. = 'N': No equilibration = 'R': Row equilibration, that is, sub(<i>A</i>) has been pre-multiplied by $\text{diag}(r[ia-1:ia+m-2])$, = 'C': column equilibration, that is, sub(<i>A</i>) has been post-multiplied by $\text{diag}(c[ja-1:ja+n-2])$, = 'B': Both row and column equilibration, that is, sub(<i>A</i>) has been replaced by $\text{diag}(r[ia-1:ia+m-2]) * \text{sub}(A) * \text{diag}(c[ja-1:ja+n-2])$. |

p?laqr0

Computes the eigenvalues of a Hessenberg matrix and optionally returns the matrices from the Schur decomposition.

Syntax

```
void pslaqr0(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* n, MKL_INT* ilo, MKL_INT* ihi,
float* h, MKL_INT* desch, float* wr, float* wi, MKL_INT* iloz, MKL_INT* ihiz, float*
z, MKL_INT* descz, float* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork,
MKL_INT* info, MKL_INT* recllevel);
```

```
void pdlaqr0(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* n, MKL_INT* ilo, MKL_INT* ihi,
double* h, MKL_INT* desch, double* wr, double* wi, MKL_INT* iloz, MKL_INT* ihiz,
double* z, MKL_INT* descz, double* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT*
liwork, MKL_INT* info, MKL_INT* recllevel);
```

Include Files

- mkl_scalapack.h

Description

p?laqr0 computes the eigenvalues of a Hessenberg matrix *H* and, optionally, the matrices *T* and *Z* from the Schur decomposition $H = Z * T * Z^T$, where *T* is an upper quasi-triangular matrix (the Schur form), and *Z* is the orthogonal matrix of Schur vectors.

Optionally *Z* may be postmultiplied into an input orthogonal matrix *Q* so that this function can give the Schur factorization of a matrix *A* which has been reduced to the Hessenberg form *H* by the orthogonal matrix *Q*: $A = Q * H * Q^T = (QZ) * T * (QZ)^T$.

Input Parameters

| | |
|-------------------|---|
| <i>wantt</i> | (global) Non-zero : the full Schur form T is required; Zero : only eigenvalues are required. |
| <i>wantz</i> | (global) Non-zero : the matrix of Schur vectors Z is required; Zero: Schur vectors are not required. |
| <i>n</i> | (global) The order of the Hessenberg matrix H (and Z if <i>wantz</i> is non-zero). $n \geq 0$. |
| <i>ilo, ihi</i> | (global) It is assumed that the matrix H is already upper triangular in rows and columns $1:ilo-1$ and $ihi+1:n$. <i>ilo</i> and <i>ihi</i> are normally set by a previous call to <code>p?gebal</code> , and then passed to <code>p?gehrd</code> when the matrix output by <i>ihi</i> is reduced to Hessenberg form. Otherwise <i>ilo</i> and <i>ihi</i> should be set to 1 and n , respectively. If $n > 0$, then $1 \leq ilo \leq ihi \leq n$. If $n = 0$, then $ilo = 1$ and $ihi = 0$. |
| <i>h</i> | (global) array of size $lld_h * LOC_c(n)$ The upper Hessenberg matrix H . |
| <i>desch</i> | (global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix H . |
| <i>iloz, ihiz</i> | Specify the rows of the matrix Z to which transformations must be applied if <i>wantz</i> is non-zero, $1 \leq iloz \leq ilo; ihi \leq ihiz \leq n$. |
| <i>z</i> | Array of size $lld_z * LOC_c(n)$. If <i>wantz</i> is non-zero, contains the matrix Z . If <i>wantz</i> equals zero, <i>z</i> is not referenced. |
| <i>descz</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix Z . |
| <i>work</i> | (local workspace) array of size <i>lwork</i> |
| <i>lwork</i> | (local) The length of the workspace array <i>work</i> . |
| <i>iwork</i> | (local workspace) array of size <i>liwork</i> |
| <i>liwork</i> | (local) The length of the workspace array <i>iwork</i> . |
| <i>recllevel</i> | (local) |

Level of recursion. *recllevel* = 0 must hold on entry.

OUTPUT Parameters

| | |
|------------------|--|
| <i>h</i> | On exit, if <i>wantt</i> is non-zero, the matrix <i>H</i> is upper quasi-triangular in rows and columns <i>ilo:ihi</i> , with 1-by-1 and 2-by-2 blocks on the main diagonal. The 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with $H(i,i) = H(i+1,i+1)$ and $H(i+1,i)*H(i,i+1) < 0$. If <i>info</i> = 0 and <i>wantt</i> equals zero, the contents of <i>h</i> are unspecified on exit. |
| <i>wr, wi</i> | The real and imaginary parts, respectively, of the computed eigenvalues <i>ilo</i> to <i>ihi</i> are stored in the corresponding elements of <i>wr</i> and <i>wi</i> . If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of <i>wr</i> and <i>wi</i> , say the <i>i</i> -th and (<i>i</i> +1)th, with $wi[i-1] > 0$ and $wi[i] < 0$. If <i>wantt</i> is non-zero, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in <i>h</i> . |
| <i>z</i> | Updated matrix with transformations applied only to the submatrix $Z(ilo:ihi,ilo:ihi)$. If COMPZ = 'I', on exit, if <i>info</i> = 0, <i>z</i> contains the orthogonal matrix <i>Z</i> of the Schur vectors of <i>H</i> . If <i>wantz</i> is non-zero, then $Z(ilo:ihi,iloz:ihiz)$ is replaced by $Z(ilo:ihi,iloz:ihiz)*U$, when <i>U</i> is the orthogonal/unitary Schur factor of $H(ilo:ihi,ilo:ihi)$. If <i>wantz</i> equals zero, then <i>z</i> is not defined. |
| <i>work</i> [0] | On exit, if <i>info</i> = 0, <i>work</i> [0] returns the optimal <i>lwork</i> . |
| <i>iwork</i> [0] | On exit, if <i>info</i> = 0, <i>iwork</i> [0] returns the optimal <i>liwork</i> . |
| <i>info</i> | > 0: if <i>info</i> = <i>i</i> , then the function failed to compute all the eigenvalues. Elements 0: <i>ilo</i> -2 and <i>i</i> : <i>n</i> -1 of <i>wr</i> and <i>wi</i> contain those eigenvalues which have been successfully computed. > 0: if <i>wantt</i> equals zero, then the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns <i>ilo</i> through <i>ihi</i> of the final output value of <i>H</i> . > 0: if <i>wantt</i> is non-zero, then (initial value of <i>H</i>)* <i>U</i> = <i>U</i> *(final value of <i>H</i>), where <i>U</i> is an orthogonal/unitary matrix. The final value of <i>H</i> is upper Hessenberg and quasi-triangular/triangular in rows and columns <i>info</i> +1 through <i>ihi</i> . > 0: if <i>wantz</i> is non-zero, then (final value of $Z(ilo:ihi,iloz:ihiz)$)=(initial value of $Z(ilo:ihi,iloz:ihiz)$)* <i>U</i> , where <i>U</i> is the orthogonal/unitary matrix in the previous expression (regardless of the value of <i>wantt</i>). > 0: if <i>wantz</i> equals zero, then <i>z</i> is not accessed. |

p?laqr1

Sets a scalar multiple of the first column of the product of a 2-by-2 or 3-by-3 matrix and specified shifts.

Syntax

```
void pslaqr1(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* n, MKL_INT* ilo, MKL_INT* ihi,
float* a, MKL_INT* desca, float* wr, float* wi, MKL_INT* iloz, MKL_INT* ihiz, float*
z, MKL_INT* descz, float* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* ilwork,
MKL_INT* info);
```

```
void pdlaqr1(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* n, MKL_INT* ilo, MKL_INT* ihi,
double* a, MKL_INT* desca, double* wr, double* wi, MKL_INT* iloz, MKL_INT* ihiz,
double* z, MKL_INT* descz, double* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT*
ilwork, MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

p?laqr1 is an auxiliary function used to find the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form from columns *ilo* to *ihi*.

This is a modified version of p?lahqr from ScaLAPACK version 1.7.3. The following modifications were made:

- Workspace query functionality was added.
- Aggressive early deflation is implemented.
- Aggressive deflation (looking for two consecutive small subdiagonal elements by PSLACONS) is abandoned.
- The returned Schur form is now in canonical form, i.e., the returned 2-by-2 blocks really correspond to complex conjugate pairs of eigenvalues.
- For some reason, the original version of p?lahqr sometimes did not read out the converged eigenvalues correctly. This is now fixed.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

wantt (global)
 Non-zero : the full Schur form *T* is required;
 Zero: only eigenvalues are required.

| | |
|-------------------|---|
| <i>wantz</i> | Non-zero : the matrix of Schur vectors Z is required; Zero: Schur vectors are not required. |
| <i>n</i> | (global) The order of the Hessenberg matrix A (and Z if <i>wantz</i> is non-zero). $n \geq 0$. |
| <i>ilo, ihi</i> | (global) It is assumed that the matrix A is already upper quasi-triangular in rows and columns $ihi+1:n$, and that $A(ilo,ilo-1) = 0$ (unless $ilo = 1$). <i>p?laqr1</i> works primarily with the Hessenberg submatrix in rows and columns ilo to ihi , but applies transformations to all of H if <i>wantt</i> is non-zero. $1 \leq ilo \leq \max(1, ihi)$; $ihi \leq n$. |
| <i>a</i> | (global) array of size $lld_a * LOC_c(n)$ On entry, the upper Hessenberg matrix A . |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <i>iloz, ihiz</i> | (global) Specify the rows of the matrix Z to which transformations must be applied if <i>wantz</i> is non-zero. $1 \leq iloz \leq ilo$; $ihi \leq ihiz \leq n$. |
| <i>z</i> | (global) array of size $lld_z * LOC_c(n)$. If <i>wantz</i> is non-zero, on entry z must contain the current matrix Z of transformations accumulated by <i>p?hseqr</i> . If <i>wantz</i> is zero, z is not referenced. |
| <i>descz</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix Z . |
| <i>work</i> | (local output) array of size $lwork$ |
| <i>lwork</i> | (local) The size of the work array ($lwork \geq 1$). If $lwork = -1$, then a workspace query is assumed. |
| <i>iwork</i> | (global and local) array of size $ilwork$ This holds the some of the IBLK integer arrays. |
| <i>ilwork</i> | (local) The size of the <i>iwork</i> array ($ilwork \geq 3$). |

OUTPUT Parameters

| | |
|-----------------|---|
| <i>a</i> | If <i>wantt</i> is non-zero, the matrix <i>A</i> is upper quasi-triangular in rows and columns <i>ilo:ihi</i> , with any 2-by-2 or larger diagonal blocks not yet in standard form. If <i>wantt</i> equals zero, the contents of <i>a</i> are unspecified on exit. |
| <i>wr, wi</i> | (global replicated) array of size <i>n</i> The real and imaginary parts, respectively, of the computed eigenvalues <i>ilo</i> to <i>ihi</i> are stored in the corresponding elements of <i>wr</i> and <i>wi</i> . If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of <i>wr</i> and <i>wi</i> , say the <i>i</i> -th and (<i>i</i> +1)th, with <i>wi</i> [<i>i</i> -1] > 0 and <i>wi</i> [<i>i</i>] < 0. If <i>wantt</i> is non-zero, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in <i>a</i> . <i>a</i> may be returned with larger diagonal blocks until the next release. |
| <i>z</i> | On exit <i>z</i> is updated; transformations are applied only to the submatrix <i>Z</i> (<i>iloz:ihiz,ilo:ihi</i>). If <i>wantz</i> equals zero, <i>z</i> is not referenced. |
| <i>work</i> [0] | On exit, if <i>info</i> = 0, <i>work</i> [0] returns the optimal <i>lwork</i> . |
| <i>info</i> | (global) < 0: parameter number <i>-info</i> incorrect or inconsistent = 0: successful exit > 0: <i>p?laqr1</i> failed to compute all the eigenvalues <i>ilo</i> to <i>ihi</i> in a total of 30*(<i>ihi-ilo</i> +1) iterations; if <i>info</i> = <i>i</i> , elements <i>i:ihi-1</i> of <i>wr</i> and <i>wi</i> contain those eigenvalues which have been successfully computed. |

Application Notes

This algorithm is very similar to *p?ahqr*. Unlike *p?lahqr*, instead of sending one double shift through the largest unreduced submatrix, this algorithm sends multiple double shifts and spaces them apart so that there can be parallelism across several processor row/columns. Another critical difference is that this algorithm aggregates multiple transforms together in order to apply them in a block fashion.

Current Notes and/or Restrictions:

- This code requires the distributed block size to be square and at least six (6); unlike simpler codes like LU, this algorithm is extremely sensitive to block size. Unwise choices of too small a block size can lead to bad performance.
- This code requires *a* and *z* to be distributed identically and have identical contexts.
- This release currently does not have a function for resolving the Schur blocks into regular 2x2 form after this code is completed. Because of this, a significant performance impact is required while the deflation is done by sometimes a single column of processors.
- This code does not currently block the initial transforms so that none of the rows or columns for any bulge are completed until all are started. To offset pipeline start-up it is recommended that at least 2*LCM(NPROW,NPCOL) bulges are used (if possible)
- The maximum number of bulges currently supported is fixed at 32. In future versions this will be limited only by the incoming *work* array.
- The matrix *A* must be in upper Hessenberg form. If elements below the subdiagonal are nonzero, the resulting transforms may be nonsimilar. This is also true with the LAPACK function.
- For this release, it is assumed *rsrc_*=*csrc_*=0

- Currently, all the eigenvalues are distributed to all the nodes. Future releases will probably distribute the eigenvalues by the column partitioning.
- The internals of this function are subject to change.

Description

p?laqr2 accepts as input an upper Hessenberg matrix A and performs an orthogonal similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output A is overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal similarity transformation of A . It is to be hoped that the final version of A has many zero subdiagonal entries.

This function handles small deflation windows which is affordable by one processor. Normally, it is called by [p?laqr1](#). All the inputs are assumed to be valid without checking.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

`wantt` (global)

| | |
|-------------------|--|
| | <p>If <i>wantt</i> is non-zero, then the Hessenberg matrix <i>A</i> is fully updated so that the quasi-triangular Schur factor may be computed (in cooperation with the calling function).</p> <p>If <i>wantt</i> equals zero, then only enough of <i>A</i> is updated to preserve the eigenvalues.</p> |
| <i>wantz</i> | <p>(global)</p> <p>If <i>wantz</i> is non-zero, then the orthogonal matrix <i>Z</i> is updated so that the orthogonal Schur factor may be computed (in cooperation with the calling function).</p> <p>If <i>wantz</i> equals zero, then <i>z</i> is not referenced.</p> |
| <i>n</i> | <p>(global)</p> <p>The order of the matrix <i>A</i> and (if <i>wantz</i> is non-zero) the order of the orthogonal matrix <i>Z</i>.</p> |
| <i>ktop, kbot</i> | <p>(global)</p> <p>It is assumed without a check that either $kbot = n$ or $A(kbot+1, kbot)=0$. <i>kbot</i> and <i>ktop</i> together determine an isolated block along the diagonal of the Hessenberg matrix. However, $A(ktop, ktop-1)=0$ is not essentially necessary if <i>wantt</i> is non-zero .</p> |
| <i>nw</i> | <p>(global)</p> <p>Deflation window size. $1 \leq nw \leq (kbot-ktop+1)$. Normally $nw \geq 3$ if <i>p?laqr2</i> is called by <i>p?laqr1</i>.</p> |
| <i>a</i> | <p>(local) array of size $lld_a * LOC_c(n)$</p> <p>The initial <i>n</i>-by-<i>n</i> section of <i>a</i> stores the Hessenberg matrix undergoing aggressive early deflation.</p> |
| <i>desca</i> | <p>(global and local) array of size <i>dlen_</i>.</p> <p>The array descriptor for the distributed matrix <i>A</i>.</p> |
| <i>iloz, ihiz</i> | <p>(global)</p> <p>Specify the rows of the matrix <i>Z</i> to which transformations must be applied if <i>wantz</i> is non-zero. $1 \leq iloz \leq ihiz \leq n$.</p> |
| <i>z</i> | <p>Array of size $lld_z * LOC_c(n)$</p> <p>If <i>wantz</i> is non-zero, then on output, the orthogonal similarity transformation mentioned above has been accumulated into the matrix $Z(iloz:ihiz, kbot:ktop)$, stored in <i>z</i>, from the right.</p> <p>If <i>wantz</i> is zero, then <i>z</i> is unreferenced.</p> |
| <i>descz</i> | <p>(global and local) array of size <i>dlen_</i>.</p> <p>The array descriptor for the distributed matrix <i>Z</i>.</p> |
| <i>t</i> | <p>(local workspace) array of size $ldt * nw$.</p> |

| | |
|---------------|---|
| <i>ldt</i> | (local) The leading dimension of the array <i>t</i> . $ldt \geq nw$. |
| <i>v</i> | (local workspace) array of size $ldv * nw$. |
| <i>ldv</i> | (local) The leading dimension of the array <i>v</i> . $ldv \geq nw$. |
| <i>wr, wi</i> | (local workspace) array of size <i>kbot</i> . |
| <i>work</i> | (local workspace) array of size <i>lwork</i> . |
| <i>lwork</i> | (local) <i>work(lwork)</i> is a local array and <i>lwork</i> is assumed big enough so that $lwork \geq nw * nw$. |

OUTPUT Parameters

| | |
|---------------|---|
| <i>a</i> | On output <i>a</i> has been transformed by an orthogonal similarity transformation, perturbed, and returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries. |
| <i>z</i> | |
| <i>ns</i> | (global) The number of unconverged (that is, approximate) eigenvalues returned in <i>sr</i> and <i>si</i> that may be used as shifts by the calling function. |
| <i>nd</i> | (global) The number of converged eigenvalues uncovered by this function. |
| <i>sr, si</i> | (global) array of size <i>kbot</i> On output, the real and imaginary parts of approximate eigenvalues that may be used for shifts are stored in <i>sr</i> [<i>kbot-nd-ns</i>] through <i>sr</i> [<i>kbot-nd-1</i>] and <i>si</i> [<i>kbot-nd-ns</i>] through <i>si</i> [<i>kbot-nd-1</i>], respectively. On processor #0, the real and imaginary parts of converged eigenvalues are stored in <i>sr</i> [<i>kbot-nd</i>] through <i>sr</i> [<i>kbot-1</i>] and <i>si</i> [<i>kbot-nd</i>] through <i>si</i> [<i>kbot-1</i>], respectively. On other processors, these entries are set to zero. |

Description

This function accepts as input an upper Hessenberg matrix H and performs an orthogonal similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output H is overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal similarity transformation of H . It is to be hoped that the final version of H has many zero subdiagonal entries.

Input Parameters

| | | |
|--------------|-----------|--|
| <i>wantt</i> | (global) | If <i>wantt</i> is non-zero, then the Hessenberg matrix H is fully updated so that the quasi-triangular Schur factor may be computed (in cooperation with the calling function). If <i>wantt</i> equals zero, then only enough of H is updated to preserve the eigenvalues. |
| <i>wantz</i> | (global) | If <i>wantz</i> is non-zero, then the orthogonal matrix Z is updated so that the orthogonal Schur factor may be computed (in cooperation with the calling function). If <i>wantz</i> equals zero, then z is not referenced. |
| <i>n</i> | (global) | The order of the matrix H and (if <i>wantz</i> is non-zero), the order of the orthogonal matrix Z . |
| <i>ktop</i> | (global) | It is assumed that either $ktop = 1$ or $H(ktop,ktop-1)=0$. <i>kbot</i> and <i>ktop</i> together determine an isolated block along the diagonal of the Hessenberg matrix. |
| <i>kbot</i> | (global) | It is assumed without a check that either $kbot = n$ or $H(kbot+1,kbot)=0$. <i>kbot</i> and <i>ktop</i> together determine an isolated block along the diagonal of the Hessenberg matrix. |

| | |
|-------------------|---|
| <i>nw</i> | (global) Deflation window size. $1 \leq nw \leq (kbot-ktop+1)$. |
| <i>h</i> | (local) array of size $lld_h * LOC_c(n)$ The initial n -by- n section of H stores the Hessenberg matrix undergoing aggressive early deflation. |
| <i>desch</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix H . |
| <i>iloz, ihiz</i> | (global) Specify the rows of the matrix Z to which transformations must be applied if <i>wantz</i> is non-zero. $1 \leq iloz \leq ihiz \leq n$. |
| <i>z</i> | Array of size $lld_z * LOC_c(n)$ If <i>wantz</i> is non-zero, then on output, the orthogonal similarity transformation mentioned above has been accumulated into the matrix $Z(iloz:ihiz,kbot:ktop)$ from the right. If <i>wantz</i> is zero, then <i>z</i> is unreferenced. |
| <i>descz</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix Z . |
| <i>v</i> | (global workspace) array of size $lld_v * LOC_c(nw)$ An nw -by- nw distributed work array. |
| <i>descv</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix V . |
| <i>nh</i> | The number of columns of t . $nh \geq nw$. |
| <i>t</i> | (global workspace) array of size $lld_t * LOC_c(nh)$ |
| <i>desct</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix T . |
| <i>nv</i> | (global) The number of rows of work array wv available for workspace. $nv \geq nw$. |
| <i>wv</i> | (global workspace) array of size $lld_w * LOC_c(nw)$ |
| <i>descw</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix wv . |
| <i>work</i> | (local workspace) array of size $lwork$. |
| <i>lwork</i> | (local) The size of the work array <i>work</i> ($lwork \geq 1$). $lwork = 2*nw$ suffices, but greater efficiency may result from larger values of <i>lwork</i> . |

If $lwork = -1$, then a workspace query is assumed; `p?laqr3` only estimates the optimal workspace size for the given values of n , nw , $ktop$ and $kbot$. The estimate is returned in $work[0]$. No error message related to $lwork$ is issued by `xerbla`. Neither h nor z are accessed.

$iwork$ (local workspace) array of size $liwork$

$liwork$ (local)
 The length of the workspace array $iwork$ ($liwork \geq 1$).
 If $liwork = -1$, then a workspace query is assumed.

OUTPUT Parameters

h On output h has been transformed by an orthogonal similarity transformation, perturbed, and the returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.

z IF $wantz$ is non-zero, then on output, the orthogonal similarity transformation mentioned above has been accumulated into the matrix $Z(i_{loz}:i_{hiz}, kbot:ktop)$ from the right.
 If $wantz$ is zero, then z is unreferenced.

ns (global)
 The number of unconverged (that is, approximate) eigenvalues returned in sr and si that may be used as shifts by the calling function.

nd (global)
 The number of converged eigenvalues uncovered by this function.

sr, si (global) array of size $kbot$. The real and imaginary parts of approximate eigenvalues that may be used for shifts are stored in $sr[kbot-nd-ns]$ through $sr[kbot-nd-1]$ and $si[kbot-nd-ns]$ through $si[kbot-nd-1]$, respectively. The real and imaginary parts of converged eigenvalues are stored in $sr[kbot-nd]$ through $sr[kbot-1]$ and $si[kbot-nd]$ through $si[kbot-1]$, respectively.

$work[0]$ On exit, if $info = 0$, $work[0]$ returns the optimal $lwork$

$iwork[0]$ On exit, if $info = 0$, $iwork[0]$ returns the optimal $liwork$

p?laqr5

Performs a single small-bulge multi-shift QR sweep.

Syntax

```
void pslaqr5(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* kacc22, MKL_INT* n, MKL_INT*
ktop, MKL_INT* kbot, MKL_INT* nshfts, float* sr, float* si, float* h, MKL_INT* desch,
MKL_INT* iloz, MKL_INT* ihiz, float* z, MKL_INT* descz, float* work, MKL_INT* lwork,
MKL_INT* iwork, MKL_INT* liwork);
```

```
void pdlaqr5(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* kacc22, MKL_INT* n, MKL_INT*
ktop, MKL_INT* kbot, MKL_INT* nshfts, double* sr, double* si, double* h, MKL_INT*
desch, MKL_INT* iloz, MKL_INT* ihiz, double* z, MKL_INT* descz, double* work, MKL_INT*
lwork, MKL_INT* iwork, MKL_INT* liwork);
```

Include Files

- mkl_scalapack.h

Description

This auxiliary function called by [p?laqr0](#) performs a single small-bulge multi-shift QR sweep by chasing separated groups of bulges along the main block diagonal of a Hessenberg matrix H .

Input Parameters

| | |
|-------------------|--|
| <i>wantt</i> | (global) scalar <i>wantt</i> is non-zero if the quasi-triangular Schur factor is being computed. <i>wantt</i> is set to zero otherwise. |
| <i>wantz</i> | (global) scalar <i>wantz</i> is non-zero if the orthogonal Schur factor is being computed. <i>wantz</i> is set to zero otherwise. |
| <i>kacc22</i> | (global) Value 0, 1, or 2. Specifies the computation mode of far-from-diagonal orthogonal updates. = 0: p?laqr5 does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries. = 1: p?laqr5 accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries. = 2: p?laqr5 accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies. |
| <i>n</i> | (global) scalar The order of the Hessenberg matrix H and, if <i>wantz</i> is non-zero, the order of the orthogonal matrix Z . |
| <i>ktop, kbot</i> | (global) scalar These are the first and last rows and columns of an isolated diagonal block upon which the QR sweep is to be applied. It is assumed without a check that either $ktop = 1$ or $H(ktop,ktop-1) = 0$ and either $kbot = n$ or $H(kbot+1,kbot) = 0$. |
| <i>nshfts</i> | (global) scalar |

| | |
|-------------------|--|
| | <i>nshfts</i> gives the number of simultaneous shifts. <i>nshfts</i> must be positive and even. |
| <i>sr, si</i> | (global) Array of size <i>nshfts</i> <i>sr</i> contains the real parts and <i>si</i> contains the imaginary parts of the <i>nshfts</i> shifts of origin that define the multi-shift QR sweep. |
| <i>h</i> | (local) Array of size <i>lld_h</i> * <i>LOC_c(n)</i> On input <i>h</i> contains a Hessenberg matrix <i>H</i> . |
| <i>desch</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>H</i> . |
| <i>iloz, ihiz</i> | (global) Specify the rows of the matrix <i>Z</i> to which transformations must be applied if <i>wantzis</i> non-zero. $1 \leq iloz \leq ihiz \leq n$ |
| <i>z</i> | (local) array of size <i>lld_z</i> * <i>LOC_c(n)</i> If <i>wantzis</i> non-zero, then the QR Sweep orthogonal similarity transformation is accumulated into the matrix <i>Z</i> (<i>iloz:ihiz,kbot:ktop</i>) from the right. If <i>wantzequals</i> zero, then <i>z</i> is unreferenced. |
| <i>descz</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> . |
| <i>work</i> | (local workspace) array of size <i>lwork</i> |
| <i>lwork</i> | (local) The size of the <i>work</i> array (<i>lwork</i> ≥ 1). If <i>lwork</i> = -1, then a workspace query is assumed. |
| <i>iwork</i> | (local workspace) array of size <i>liwork</i> |
| <i>liwork</i> | (local) The size of the <i>iwork</i> array (<i>liwork</i> ≥ 1). If <i>liwork</i> = -1, then a workspace query is assumed. |

Output Parameters

| | |
|------------------|---|
| <i>h</i> | A multi-shift QR sweep with shifts $sr(j) + i * si(j)$ is applied to the isolated diagonal block in rows and columns <i>ktop</i> through <i>kbot</i> of the matrix <i>H</i> . |
| <i>z</i> | If <i>wantzis</i> non-zero, <i>z</i> is updated with transformations applied only to the submatrix <i>Z</i> (<i>iloz:ihiz,kbot:ktop</i>). |
| <i>work</i> [0] | On exit, if <i>info</i> = 0, <i>work</i> [0] returns the optimal <i>lwork</i> . |
| <i>iwork</i> [0] | On exit, if <i>info</i> = 0, <i>iwork</i> [0] returns the optimal <i>liwork</i> . |

p?laqsy

Scales a symmetric/Hermitian matrix, using scaling factors computed by p?poequ.

Syntax

```
void pslaqsy (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *sr , float *sc , float *scond , float *amax , char *equed );
```

```
void pdlaqsy (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *sr , double *sc , double *scond , double *amax , char
*equed );
```

```
void pclaqsy (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *sr , float *sc , float *scond , float *amax , char *equed );
```

```
void pzlaqsy (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *sr , double *sc , double *scond , double *amax , char
*equed );
```

Include Files

- mkl_scalapack.h

Description

The p?laqsy function equilibrates a symmetric distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the scaling factors in the vectors *sr* and *sc*. The scaling factors are computed by p?poequ.

Input Parameters

| | |
|-------------|--|
| <i>uplo</i> | (global) Specifies the upper or lower triangular part of the symmetric distributed matrix $\text{sub}(A)$ is to be referenced: = 'U': Upper triangular part; = 'L': Lower triangular part. |
| <i>n</i> | (global) The order of the distributed matrix $\text{sub}(A)$. $n \geq 0$. |
| <i>a</i> | (local). Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$. On entry, this array contains the local pieces of the distributed matrix $\text{sub}(A)$. On entry, the local pieces of the distributed symmetric matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced. |

| | |
|---------------|--|
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix sub(<i>A</i>), respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>sr</i> | (local) Array of size <i>LOCr(m_a)</i> . The scale factors for the matrix <i>A(ia:ia+m-1, ja:ja+n-1)</i> . <i>sr</i> is aligned with the distributed matrix <i>A</i> , and replicated across every process column. <i>sr</i> is tied to the distributed matrix <i>A</i> . |
| <i>sc</i> | (local) Array of size <i>LOCc(m_a)</i> . The scale factors for the matrix <i>A(ia:ia+m-1, ja:ja+n-1)</i> . <i>sc</i> is aligned with the distributed matrix <i>A</i> , and replicated across every process column. <i>sc</i> is tied to the distributed matrix <i>A</i> . |
| <i>scond</i> | (global). Ratio of the smallest <i>sr[i]</i> (respectively <i>sc[j]</i>) to the largest <i>sr[i]</i> (respectively <i>sc[j]</i>), with $ia - 1 \leq i < ia + n - 1$ and $ja - 1 \leq j < ja + n - 1$. |
| <i>amax</i> | (global). Absolute value of largest distributed submatrix entry. |

Output Parameters

| | |
|--------------|---|
| <i>a</i> | On exit, if <i>equed</i> = 'Y', the equilibrated matrix: $\text{diag}(sr_{ia}, \dots, sr_{ia+n-1}) * \text{sub}(A) * \text{diag}(sc_{ja}, \dots, sc_{ja+n-1})$. |
| <i>equed</i> | (global). Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, that is, sub(<i>A</i>) has been replaced by: $\text{diag}(sr_{ia}, \dots, sr_{ia+n-1}) * \text{sub}(A) * \text{diag}(sc_{ja}, \dots, sc_{ja+n-1})$. |

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lared1d

Redistributes an array assuming that the input array, bycol, is distributed across rows and that all process columns contain the same copy of bycol.

Syntax

```
void pslared1d (MKL_INT *n , MKL_INT *ia , MKL_INT *ja , MKL_INT *desc , float *bycol ,
float *byall , float *work , MKL_INT *lwork );
```

```
void pdlared1d (MKL_INT *n , MKL_INT *ia , MKL_INT *ja , MKL_INT *desc , double
*bycol , double *byall , double *work , MKL_INT *lwork );
```

Include Files

- mkl_scalapack.h

Description

The `pdlared1d` function redistributes a 1D array. It assumes that the input array `bycol` is distributed across rows and that all process column contain the same copy of `bycol`. The output array `byall` is identical on all processes and contains the entire array.

Input Parameters

`np` = Number of local rows in `bycol()`

| | |
|---------------------|--|
| <code>n</code> | (global) The number of elements to be redistributed. $n \geq 0$. |
| <code>ia, ja</code> | (global) <code>ia, ja</code> must be equal to 1. |
| <code>desc</code> | (local) array of size 9. A 2D array descriptor, which describes <code>bycol</code> . |
| <code>bycol</code> | (local). Distributed block cyclic array of global size <code>n</code> and of local size <code>np</code> . <code>bycol</code> is distributed across the process rows. All process columns are assumed to contain the same value. |
| <code>work</code> | (local). size <code>lwork</code> . Used to hold the buffers sent from one process to another. |
| <code>lwork</code> | (local) The size of the <code>work</code> array. $lwork \geq \text{numroc}(n, \text{desc}[\text{nb}_], 0, 0, \text{npcol})$. |

Output Parameters

| | |
|--------------------|---|
| <code>byall</code> | (global). Global size <code>n</code> , local size <code>n</code> . <code>byall</code> is exactly duplicated on all processes. It contains the same values as <code>bycol</code> , but it is replicated across all processes rather than being distributed. |
|--------------------|---|

p?lared2d

Redistributes an array assuming that the input array `byrow` is distributed across columns and that all process rows contain the same copy of `byrow`.

Syntax

```
void pslared2d (MKL_INT *n , MKL_INT *ia , MKL_INT *ja , MKL_INT *desc , float *byrow ,
float *byall , float *work , MKL_INT *lwork );
```

```
void pdlared2d (MKL_INT *n , MKL_INT *ia , MKL_INT *ja , MKL_INT *desc , double
*byrow , double *byall , double *work , MKL_INT *lwork );
```

Include Files

- mkl_scalapack.h

Description

The `pdlared2d` function redistributes a 1D array. It assumes that the input array `byrow` is distributed across columns and that all process rows contain the same copy of `byrow`. The output array `byall` will be identical on all processes and will contain the entire array.

Input Parameters

`np` = Number of local rows in `byrow()`

| | |
|---------------------|--|
| <code>n</code> | (global) The number of elements to be redistributed. $n \geq 0$. |
| <code>ia, ja</code> | (global) <code>ia, ja</code> must be equal to 1. |
| <code>desc</code> | (local) array of size <code>dlen_</code> . A 2D array descriptor, which describes <code>byrow</code> . |
| <code>byrow</code> | (local). Distributed block cyclic array of global size <code>n</code> and of local size <code>np</code> . <code>byrow</code> is distributed across the process columns. All process rows are assumed to contain the same value. |
| <code>work</code> | (local). size <code>lwork</code> . Used to hold the buffers sent from one process to another. |
| <code>lwork</code> | (local) The size of the <code>work</code> array. $lwork \geq \text{numroc}(n, \text{desc}[nb_], 0, 0, \text{npcol})$. |

Output Parameters

| | |
|--------------------|---|
| <code>byall</code> | (global). Global size <code>n</code> , local size <code>n</code> . <code>byall</code> is exactly duplicated on all processes. It contains the same values as <code>byrow</code> , but it is replicated across all processes rather than being distributed. |
|--------------------|---|

Description

The `p?larf` function applies a real/complex elementary reflector Q (or Q^T) to a real/complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = I - \tau * v * v',$$

where τ is a real/complex scalar and v is a real/complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Input Parameters

| | |
|---------------|--|
| <i>side</i> | (global). = 'L': form $Q * \text{sub}(C)$, = 'R': form $\text{sub}(C) * Q$, $Q = Q^T$. |
| <i>m</i> | (global) The number of rows in the distributed submatrix $\text{sub}(A)$. ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the distributed submatrix $\text{sub}(A)$. ($n \geq 0$). |
| <i>v</i> | (local). Pointer into the local memory to an array of size $lld_v * LOCC(n_v)$, containing the local pieces of the global distributed matrix V representing the Householder transformation Q , $V(iv:iv+m-1, jv)$ if $side = 'L'$ and $incv = 1$, $V(iv, jv:jv+m-1)$ if $side = 'L'$ and $incv = m_v$, $V(iv:iv+n-1, jv)$ if $side = 'R'$ and $incv = 1$, $V(iv, jv:jv+n-1)$ if $side = 'R'$ and $incv = m_v$. The array v is the representation of Q . v is not used if $\tau = 0$. |
| <i>iv, jv</i> | (global) The row and column indices in the global matrix V indicating the first row and the first column of the matrix $\text{sub}(V)$, respectively. |

| | |
|---------------|--|
| <i>descv</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>V</i> . |
| <i>incv</i> | (global) The global increment for the elements of <i>V</i> . Only two values of <i>incv</i> are supported in this version, namely 1 and <i>m_v</i> . <i>incv</i> must not be zero. |
| <i>tau</i> | (local). Array of size <i>LOCc(jv)</i> if <i>incv</i> = 1, and <i>LOCr(iv)</i> otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix <i>V</i> . |
| <i>c</i> | (local). Pointer into the local memory to an array of size <i>lld_c</i> * <i>LOCc(jc+n-1)</i> , containing the local pieces of sub(<i>C</i>). |
| <i>ic, jc</i> | (global) The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the matrix sub(<i>C</i>), respectively. |
| <i>descC</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> . |
| <i>work</i> | (local). Array of size <i>lwork</i> . If <i>incv</i> = 1, if <i>side</i> = 'L', if <i>ivcol</i> = <i>iccol</i> , <i>lwork</i> ≥ <i>nqc0</i> else <i>lwork</i> ≥ <i>mpc0</i> + max(1, <i>nqc0</i>) end if else if <i>side</i> = 'R', <i>lwork</i> ≥ <i>nqc0</i> + max(max(1, <i>mpc0</i>), numroc(numroc(<i>n</i> + <i>icoffc</i> , <i>nb_v</i> , 0, 0, <i>npcol</i>), <i>nb_v</i> , 0, 0, <i>lcmq</i>)) end if else if <i>incv</i> = <i>m_v</i> , if <i>side</i> = 'L', <i>lwork</i> ≥ <i>mpc0</i> + max(max(1, <i>nqc0</i>), numroc(numroc(<i>m</i> + <i>iroffc</i> , <i>mb_v</i> , 0, 0, <i>nprow</i>), <i>mb_v</i> , 0, 0, <i>lcmp</i>)) else if <i>side</i> = 'R', if <i>ivrow</i> = <i>icrow</i> , <i>lwork</i> ≥ <i>mpc0</i> |

```

        else
             $lwork \geq nqc0 + \max(1, mpc0)$ 
        end if
    end if
end if,

```

where lcm is the least common multiple of $nrow$ and $ncol$ and $lcm = ilcm(nrow, ncol)$, $lcmp = lcm/nrow$, $lcmq = lcm/ncol$,
 $iroffc = \text{mod}(ic-1, mb_c)$, $icoffc = \text{mod}(jc-1, nb_c)$,
 $icrow = \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nrow)$,
 $iccol = \text{indxg2p}(jc, nb_c, mycol, csrc_c, ncol)$,
 $mpc0 = \text{numroc}(m+iroffc, mb_c, myrow, icrow, nrow)$,
 $nqc0 = \text{numroc}(n+icoffc, nb_c, mycol, iccol, ncol)$,
 $ilcm$, indxg2p , and numroc are ScaLAPACK tool functions; $myrow$, $mycol$, $nrow$, and $ncol$ can be determined by calling the function `blacs_gridinfo`.

Output Parameters

`c` (local).
 On exit, `sub(C)` is overwritten by the $Q \cdot \text{sub}(C)$ if `side = 'L'`,
 or `sub(C) * Q` if `side = 'R'`.

Description

The `p?larfb` function applies a real/complex block reflector Q or its transpose Q^T /conjugate transpose Q^H to a real/complex distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ from the left or the right.

Input Parameters

| | |
|---------------------|---|
| <code>side</code> | (global) if <code>side = 'L'</code> : apply Q or Q^T for real flavors (Q^H for complex flavors) from the Left; if <code>side = 'R'</code> : apply Q or Q^T for real flavors (Q^H for complex flavors) from the Right. |
| <code>trans</code> | (global) if <code>trans = 'N'</code> : no transpose, apply Q ; for real flavors, if <code>trans='T'</code> : transpose, apply Q^T for complex flavors, if <code>trans = 'C'</code> : conjugate transpose, apply Q^H ; |
| <code>direct</code> | (global) Indicates how Q is formed from a product of elementary reflectors. if <code>direct = 'F'</code> : $Q = H(1)*H(2)*\dots*H(k)$ (Forward) if <code>direct = 'B'</code> : $Q = H(k)*\dots*H(2)*H(1)$ (Backward) |
| <code>storev</code> | (global) Indicates how the vectors that define the elementary reflectors are stored: if <code>storev = 'C'</code> : Columnwise if <code>storev = 'R'</code> : Rowwise. |
| <code>m</code> | (global) The number of rows in the distributed matrix $\text{sub}(C)$. ($m \geq 0$). |
| <code>n</code> | (global) The number of columns in the distributed matrix $\text{sub}(C)$. ($n \geq 0$). |
| <code>k</code> | (global) The order of the matrix T . |
| <code>v</code> | (local). Pointer into the local memory to an array of size <code>lld_v * LOCc(jv+k-1)</code> if <code>storev = 'C'</code> , <code>lld_v * LOCc(jv+m-1)</code> if <code>storev = 'R'</code> and <code>side = 'L'</code> , <code>lld_v * LOCc(jv+n-1)</code> if <code>storev = 'R'</code> and <code>side = 'R'</code> . It contains the local pieces of the distributed vectors V representing the Householder transformation. if <code>storev = 'C'</code> and <code>side = 'L'</code> , <code>lld_v</code> \geq <code>max(1, LOCr(iv+m-1))</code> ; |

```

if storev = 'C' and side = 'R', lld_v ≥ max(1, LOCr(iv+n-1));
if storev = 'R', lld_v ≥ LOCr(jv+k-1).

```

iv, jv (global)
The row and column indices in the global matrix V indicating the first row and the first column of the matrix sub(V), respectively.

descv (global and local) array of size $dlen_$. The array descriptor for the distributed matrix V .

c (local).
Pointer into the local memory to an array of size $lld_c * LOCc(jc+n-1)$, containing the local pieces of sub(C).

ic, jc (global) The row and column indices in the global matrix C indicating the first row and the first column of the matrix sub(C), respectively.

desc (global and local) array of size $dlen_$. The array descriptor for the distributed matrix C .

work (local).
Workspace array of size $lwork$.
If $storev = 'C'$,
if $side = 'L'$,
 $lwork \geq (nqc0 + mpc0) * k$
else if $side = 'R'$,
 $lwork \geq (nqc0 + \max(npv0 + \text{numroc}(\text{numroc}(n + icoffc, nb_v, 0, 0, npc0), nb_v, 0, 0, lcmq), mpc0)) * k$
end if
else if $storev = 'R'$,
if $side = 'L'$,
 $lwork \geq (mpc0 + \max(mqv0 + \text{numroc}(\text{numroc}(m + iroffv, mb_v, 0, 0, nprow), mb_v, 0, 0, lcmp), nqc0)) * k$
else if $side = 'R'$,
 $lwork \geq (mpc0 + nqc0) * k$
end if
end if,
where
 $lcmq = lcm / npc0$ with $lcm = iclm(nprow, npc0)$,
 $iroffv = \text{mod}(iv-1, mb_v)$, $icoffv = \text{mod}(jv-1, nb_v)$,
 $ivrow = \text{indxg2p}(iv, mb_v, myrow, rsrc_v, nprow)$,

```

ivcol = indxg2p( jv, nb_v, mycol, csrc_v, npcov ),

iccol = indxg2p( jc, nb_c, mycol, csrc_c, npcov ),
MpC0 = numroc( m+iroffc, mb_c, myrow, icrow, nprow ),
NpC0 = numroc( n+icoffc, mb_c, myrow, icrow, nprow ),
NqC0 = numroc( n+icoffc, nb_c, mycol, iccol, npcov ),
ilcm, indxg2p, and numroc are ScaLAPACK tool functions; myrow, mycol,
nprow, and npcov can be determined by calling the function
blacs_gridinfo.

```

Output Parameters

t (local).
 Array of size $mb_v * mb_vif$ *storev* = 'R', and $nb_v * nb_vif$ *storev* = 'C'. The triangular matrix *t* is the representation of the block reflector.

c (local).
 On exit, sub(C) is overwritten by the $Q * sub(C)$, or $Q' * sub(C)$, or $sub(C) * Q$, or $sub(C) * Q'$. *Q'* is transpose (conjugate transpose) of *Q*.

p?larfg

Generates an elementary reflector (Householder matrix).

Syntax

```
void pslarfg (MKL_INT *n , float *alpha , MKL_INT *iax , MKL_INT *jax , float *x ,
MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , float *tau );
```

```
void pdlarfg (MKL_INT *n , double *alpha , MKL_INT *iax , MKL_INT *jax , double *x ,
MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , double *tau );
```

```
void pclarfg (MKL_INT *n , MKL_Complex8 *alpha , MKL_INT *iax , MKL_INT *jax ,
MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx ,
MKL_Complex8 *tau );
```

```
void pzlarfg (MKL_INT *n , MKL_Complex16 *alpha , MKL_INT *iax , MKL_INT *jax ,
MKL_Complex16 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx ,
MKL_Complex16 *tau );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?larfg` function generates a real/complex elementary reflector H of order n , such that

$$H * \text{sub}(X) = H * \begin{pmatrix} x(iax, jax) \\ x \end{pmatrix} = \begin{pmatrix} alpha \\ 0 \end{pmatrix}, \quad H^H * H = I,$$

where $alpha$ is a scalar (a real scalar - for complex flavors), and `sub(X)` is an $(n-1)$ -element real/complex distributed vector $X(ix:ix+n-2, jx)$ if `incx = 1` and $X(ix, jx:jx+n-2)$ if `incx = m_x`. H is represented in the form

$$H = I - tau * \begin{pmatrix} 1 \\ v \end{pmatrix} * (1 \ v')$$

where τ is a real/complex scalar and v is a real/complex $(n-1)$ -element vector. Note that H is not Hermitian.

If the elements of $\text{sub}(X)$ are all zero (and $X(iax, jax)$ is real for complex flavors), then $\tau = 0$ and H is taken to be the unit matrix.

Otherwise $1 \leq \text{real}(\tau) \leq 2$ and $\text{abs}(\tau-1) \leq 1$.

Input Parameters

| | | |
|------------|--------------------|--|
| n | (global) | The global order of the elementary reflector. $n \geq 0$. |
| iax, jax | (global) | The global row and column indices of $X(iax, jax)$ in the global matrix X . |
| x | (local). | Pointer into the local memory to an array of size $lld_x * LOCc(n_x)$. This array contains the local pieces of the distributed vector $\text{sub}(X)$. Before entry, the incremented array $\text{sub}(X)$ must contain vector x . |
| ix, jx | (global) | The row and column indices in the global matrix X indicating the first row and the first column of $\text{sub}(X)$, respectively. |
| $descx$ | (global and local) | Array of size $dlen_$. The array descriptor for the distributed matrix X . |
| $incx$ | (global) | The global increment for the elements of x . Only two values of $incx$ are supported in this version, namely 1 and m_x . $incx$ must not be zero. |

Output Parameters

| | | |
|----------|----------|--|
| α | (local) | On exit, α is computed in the process scope having the vector $\text{sub}(X)$. |
| x | (local). | On exit, it is overwritten with the vector v . |
| τ | (local). | Array of size $LOCc(jx)$ if $incx = 1$, and $LOCr(ix)$ otherwise. This array contains the Householder scalars related to the Householder vectors. τ is tied to the distributed matrix X . |

*t , MKL_Complex16 *work );
```

Include Files

- mkl_scalapack.h

Description

The p?larft function forms the triangular factor T of a real/complex block reflector H of order n , which is defined as a product of k elementary reflectors.

If $direct = 'F'$, $H = H(1)*H(2) \dots *H(k)$, and T is upper triangular;

If $direct = 'B'$, $H = H(k)* \dots *H(2)*H(1)$, and T is lower triangular.

If $storev = 'C'$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th column of the distributed matrix V , and

$$H = I - V^* T^* V'$$

If $storev = 'R'$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th row of the distributed matrix V , and

$$H = I - V' * T^* V.$$

Input Parameters

| | |
|---------------|--|
| <i>direct</i> | (global) |
| | Specifies the order in which the elementary reflectors are multiplied to form the block reflector: |
| | if $direct = 'F'$: $H = H(1)*H(2)* \dots *H(k)$ (forward) |
| | if $direct = 'B'$: $H = H(k)* \dots *H(2)*H(1)$ (backward). |
| <i>storev</i> | (global) |
| | Specifies how the vectors that define the elementary reflectors are stored (See <i>Application Notes</i> below): |
| | if $storev = 'C'$: columnwise; |
| | if $storev = 'R'$: rowwise. |

| | |
|----------|---|
| n | (global) The order of the block reflector H . $n \geq 0$. |
| k | (global) The order of the triangular factor T , is equal to the number of elementary reflectors. $1 \leq k \leq mb_v$ ($= nb_v$). |
| v | Pointer into the local memory to an array of local size $LOCr(iv+n-1) * LOCc(jv+k-1)$ if $storev = 'C'$, and $LOCr(iv+k-1) * LOCc(jv+n-1)$ if $storev = 'R'$. The distributed matrix V contains the Householder vectors. (See <i>Application Notes</i> below). |
| iv, jv | (global) The row and column indices in the global matrix V indicating the first row and the first column of the matrix $sub(V)$, respectively. |
| $descv$ | (local) array of size $dlen_$. The array descriptor for the distributed matrix V . |
| tau | (local) Array of size $LOCr(iv+k-1)$ if $incv = m_v$, and $LOCc(jv+k-1)$ otherwise. This array contains the Householder scalars related to the Householder vectors. tau is tied to the distributed matrix V . |
| $work$ | (local). Workspace array of size $k*(k-1)/2$. |

Output Parameters

| | |
|-----|---|
| v | |
| t | (local) Array of size $nb_v * nb_v$ if $storev = 'C'$, and $mb_v * mb_v$ otherwise. It contains the k -by- k triangular factor of the block reflector associated with v . If $direct = 'F'$, t is upper triangular; if $direct = 'B'$, t is lower triangular. |

Application Notes

The shape of the matrix V and the storage of the vectors that define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

direct = 'F' and *storev* = 'C' :

$$V(iv : iv + n - 1, \\ jv : jv + k - 1) = \begin{bmatrix} 1 & & & & \\ v1 & 1 & & & \\ v1 & v2 & 1 & & \\ v1 & v2 & v3 & & \\ v1 & v2 & v3 & & \end{bmatrix}$$

direct = 'F' and *storev* = 'R' :

$$V(iv : iv + k - 1, \\ jv : jv + n - 1) = \begin{bmatrix} 1 & v1 & v1 & v1 & v1 \\ & 1 & v2 & v2 & v2 \\ & & 1 & v3 & v3 \end{bmatrix}$$

direct = 'B' and *storev* = 'C' :

$$V(iv : iv + n - 1, \\ jv : jv + k - 1) = \begin{bmatrix} v1 & v2 & v3 \\ v1 & v2 & v3 \\ 1 & v2 & v3 \\ & 1 & v3 \\ & & 1 \end{bmatrix}$$

direct = 'B' and *storev* = 'R' :

$$V(iv : iv + k - 1, \\ jv : jv + n - 1) = \begin{bmatrix} v1 & v1 & 1 \\ v2 & v2 & v2 & 1 \\ v3 & v3 & v3 & v3 & 1 \end{bmatrix}$$

Description

The `p?larz` function applies a real/complex elementary reflector Q (or Q^T) to a real/complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = I - \tau * v * v',$$

where τ is a real/complex scalar and v is a real/complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Q is a product of k elementary reflectors as returned by `p?tzzrf`.

Input Parameters

| | |
|---------------|--|
| <i>side</i> | (global) if <i>side</i> = 'L': form $Q \cdot \text{sub}(C)$, if <i>side</i> = 'R': form $\text{sub}(C) \cdot Q$, $Q = Q^T$ (for real flavors). |
| <i>m</i> | (global) The number of rows in the distributed matrix $\text{sub}(C)$. ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the distributed matrix $\text{sub}(C)$. ($n \geq 0$). |
| <i>l</i> | (global) The columns of the distributed matrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. If <i>side</i> = 'L', $m \geq l \geq 0$, if <i>side</i> = 'R', $n \geq l \geq 0$. |
| <i>v</i> | (local). Pointer into the local memory to an array of size $ld_v * LOcc(n_v)$ containing the local pieces of the global distributed matrix V representing the Householder transformation Q , $V(iv:iv+1-1, jv)$ if <i>side</i> = 'L' and <i>incv</i> = 1, $V(iv, jv:jv+1-1)$ if <i>side</i> = 'L' and <i>incv</i> = m_v , $V(iv:iv+1-1, jv)$ if <i>side</i> = 'R' and <i>incv</i> = 1, $V(iv, jv:jv+1-1)$ if <i>side</i> = 'R' and <i>incv</i> = m_v . The vector v in the representation of Q . v is not used if $\tau = 0$. |
| <i>iv, jv</i> | (global) The row and column indices in the global distributed matrix V indicating the first row and the first column of the matrix $\text{sub}(V)$, respectively. |
| <i>descv</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix V . |
| <i>incv</i> | (global) The global increment for the elements of V . Only two values of <i>incv</i> are supported in this version, namely 1 and m_v . <i>incv</i> must not be zero. |
| <i>tau</i> | (local) Array of size $LOcc(jv)$ if <i>incv</i> = 1, and $LOCr(iv)$ otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix V . |
| <i>c</i> | (local). |

Pointer into the local memory to an array of size $lld_c * LOCC(jc+n-1)$, containing the local pieces of sub(C).

ic, jc

(global)

The row and column indices in the global matrix C indicating the first row and the first column of the matrix sub(C), respectively.

desc

(global and local) array of size *dlen_*. The array descriptor for the distributed matrix C.

work

(local).

Array of size *lwork*

If *incv* = 1,

if *side* = 'L' ,

if *ivcol* = *iccol*,

$lwork \geq NqC0$

else

$lwork \geq MpC0 + \max(1, NqC0)$

end if

else if *side* = 'R' ,

$lwork \geq NqC0 + \max(\max(1, MpC0), \text{numroc}(\text{numroc}(n+icoffc,nb_v, 0,0,npcol),nb_v,0,0,lcmq))$

end if

else if *incv* = *m_v*,

if *side* = 'L' ,

$lwork \geq MpC0 + \max(\max(1, NqC0), \text{numroc}(\text{numroc}(m+iroffc,mb_v, 0,0,nprow),mb_v,0,0,lcmp))$

else if *side* = 'R' ,

if *ivrow* = *icrow*,

$lwork \geq MpC0$

else

$lwork \geq NqC0 + \max(1, MpC0)$

end if

end if

end if.

Here *lcm* is the least common multiple of *nprow* and *npcol* and

$lcm = \text{ilcm}(nprow, npcol)$, $lcmp = lcm / nprow$,

$lcmq = lcm / npcpl$,

$iroffc = \text{mod}(ic-1, mb_c)$, $icoffc = \text{mod}(jc-1, nb_c)$,

$icrow = \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprow)$,

$iccol = \text{indxg2p}(jc, nb_c, mycol, csrc_c, npcpl)$,

```

mpc0 = numroc( m+iroffc, mb_c, myrow, icrow, nprow ),
nqc0 = numroc( n+icoffc, nb_c, mycol, iccol, npc0l ),
ilcm, indxcg2p, and numroc are ScaLAPACK tool functions; myrow, mycol,
nprow, and npc0l can be determined by calling the function
blacs_gridinfo.

```

Output Parameters

c (local).
On exit, sub(C) is overwritten by the $Q^* \text{sub}(C)$ if *side* = 'L', or $\text{sub}(C) * Q$ if *side* = 'R'.

MKL_INT *descc , MKL_Complex8 *work );

void pzlarzb (char *side , char *trans , char *direct , char *storev , MKL_INT *m ,
MKL_INT *n , MKL_INT *k , MKL_INT *l , MKL_Complex16 *v , MKL_INT *iv , MKL_INT *jv ,
MKL_INT *descv , MKL_Complex16 *t , MKL_Complex16 *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc , MKL_Complex16 *work );

```

Include Files

- mkl_scalapack.h

Description

The p?larzb function applies a real/complex block reflector Q or its transpose Q^T (conjugate transpose Q^H for complex flavors) to a real/complex distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ from the left or the right.

Q is a product of k elementary reflectors as returned by p?tzzrf.

Currently, only *storev* = 'R' and *direct* = 'B' are supported.

Input Parameters

| | |
|---------------|--|
| <i>side</i> | (global) if <i>side</i> = 'L': apply Q or Q^T (Q^H for complex flavors) from the Left; if <i>side</i> = 'R': apply Q or Q^T (Q^H for complex flavors) from the Right. |
| <i>trans</i> | (global) if <i>trans</i> = 'N': No transpose, apply Q ; If <i>trans</i> ='T': Transpose, apply Q^T (real flavors); If <i>trans</i> ='C': Conjugate transpose, apply Q^H (complex flavors). |
| <i>direct</i> | (global) Indicates how H is formed from a product of elementary reflectors. if <i>direct</i> = 'F': $H = H(1)*H(2)*\dots*H(k)$ - forward (not supported) ; if <i>direct</i> = 'B': $H = H(k)*\dots*H(2)*H(1)$ - backward. |
| <i>storev</i> | (global) Indicates how the vectors that define the elementary reflectors are stored: if <i>storev</i> = 'C': columnwise (not supported). if <i>storev</i> = 'R': rowwise. |
| <i>m</i> | (global) The number of rows in the distributed submatrix sub(C). ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the distributed submatrix sub(C). ($n \geq 0$). |
| <i>k</i> | (global) The order of the matrix T . (= the number of elementary reflectors whose product defines the block reflector). |
| <i>l</i> | (global) The columns of the distributed submatrix sub(A) containing the meaningful part of the Householder reflectors. If <i>side</i> = 'L', $m \geq l \geq 0$, if <i>side</i> = 'R', $n \geq l \geq 0$. |
| <i>v</i> | (local). Pointer into the local memory to an array of size $lld_v * LOCC(jv+m-1)$ if <i>side</i> = 'L', $lld_v * LOCC(jv+m-1)$ if <i>side</i> = 'R'. It contains the local pieces of the distributed vectors V representing the Householder transformation as returned by <code>p?tzrzf</code> . $lld_v \geq LOCr(iv+k-1)$. |
| <i>iv, jv</i> | (global) |

The row and column indices in the global matrix V indicating the first row and the first column of the submatrix $\text{sub}(V)$, respectively.

descv (global and local) array of size *dlen_*. The array descriptor for the distributed matrix V .

t (local)
Array of size $mb_v * mb_v$.
The lower triangular matrix T in the representation of the block reflector.

c (local).
Pointer into the local memory to an array of size $lld_c * LOCc(jc+n-1)$.
On entry, the m -by- n distributed matrix $\text{sub}(C)$.

ic, jc (global)
The row and column indices in the global matrix C indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.

desc (global and local) array of size *dlen_*. The array descriptor for the distributed matrix C .

work (local).
Array of size *lwork*.

```

If storev = 'C' ,
    if side = 'L' ,
        lwork ≥ (nqc0 + mpc0) * k
    else if side = 'R' ,
        lwork ≥ (nqc0 + max(npv0 + numroc(numroc(n+icoffc, nb_v, 0, 0,
            npcol),
                nb_v, 0, 0, lcmq), mpc0)) * k
    end if
else if storev = 'R' ,
    if side = 'L' ,
        lwork ≥ (mpc0 + max(mqv0 + numroc(numroc(m+iroffc, mb_v, 0, 0,
            nprw),
                mb_v, 0, 0, lcmp), nqc0)) * k
    else if side = 'R' ,
        lwork ≥ (mpc0 + nqc0) * k
    end if
end if.

```

Here $lcmq = lcm/npcol$ with $lcm = iclm(nprw, npcol)$,
 $iroffv = \text{mod}(iv-1, mb_v)$, $icoffv = \text{mod}(jv-1, nb_v)$,
 $ivrow = \text{indxg2p}(iv, mb_v, myrow, rsrc_v, nprw)$,

```

ivcol = indxg2p(jv, nb_v, mycol, csrc_v, npc0l),
mqv0 = numroc(m+icoffv, nb_v, mycol, ivcol, npc0l),
npv0 = numroc(n+iroffv, mb_v, myrow, ivrow, nprow),
iroffc = mod(ic-1, mb_c), icoffc= mod(jc-1, nb_c),
icrow= indxg2p(ic, mb_c, myrow, rsrc_c, nprow),
iccol= indxg2p(jc, nb_c, mycol, csrc_c, npc0l),
mpc0 = numroc(m+iroffc, mb_c, myrow, icrow, nprow),
npc0 = numroc(n+icoffc, mb_c, myrow, icrow, nprow),
nqc0 = numroc(n+icoffc, nb_c, mycol, iccol, npc0l),
ilcm, indxg2p, and numroc are ScaLAPACK tool functions; myrow, mycol,
nprow, and npc0l can be determined by calling the function
blacs_gridinfo.

```

Output Parameters

c (local).
 On exit, $\text{sub}(C)$ is overwritten by the $Q \cdot \text{sub}(C)$, or $Q' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q$, or $\text{sub}(C) \cdot Q'$, where Q' is the transpose (conjugate transpose) of Q .

- mkl_scalapack.h

Description

The `p?larzc` function applies a complex elementary reflector Q^H to a complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = I - \tau \cdot v \cdot v',$$

where τ is a complex scalar and v is a complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Q is a product of k elementary reflectors as returned by `p?tzrzf`.

Input Parameters

| | |
|---------------|--|
| <i>side</i> | (global) if <i>side</i> = 'L': form $Q^H * \text{sub}(C)$; if <i>side</i> = 'R': form $\text{sub}(C) * Q^H$. |
| <i>m</i> | (global) The number of rows in the distributed matrix $\text{sub}(C)$. ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the distributed matrix $\text{sub}(C)$. ($n \geq 0$). |
| <i>l</i> | (global) The columns of the distributed matrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. If <i>side</i> = 'L', $m \geq l \geq 0$, if <i>side</i> = 'R', $n \geq l \geq 0$. |
| <i>v</i> | (local). Pointer into the local memory to an array of size $lld_v * LOCC(n_v)$ containing the local pieces of the global distributed matrix V representing the Householder transformation Q , $V(iv:iv+1-1, jv)$ if <i>side</i> = 'L' and <i>incv</i> = 1, $V(iv, jv:jv+1-1)$ if <i>side</i> = 'L' and <i>incv</i> = m_v , $V(iv:iv+1-1, jv)$ if <i>side</i> = 'R' and <i>incv</i> = 1, $V(iv, jv:jv+1-1)$ if <i>side</i> = 'R' and <i>incv</i> = m_v . The vector v in the representation of Q . v is not used if <i>tau</i> = 0. |
| <i>iv, jv</i> | (global) The row and column indices in the global matrix V indicating the first row and the first column of the matrix $\text{sub}(V)$, respectively. |
| <i>descv</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix V . |
| <i>incv</i> | (global) The global increment for the elements of V . Only two values of <i>incv</i> are supported in this version, namely 1 and m_v . <i>incv</i> must not be zero. |
| <i>tau</i> | (local) Array of size $LOCC(jv)$ if <i>incv</i> = 1, and $LOCr(iv)$ otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix V . |
| <i>c</i> | (local). |

Pointer into the local memory to an array of size $lld_c * LOCC(jc+n-1)$, containing the local pieces of sub(C).

ic, jc

(global)

The row and column indices in the global matrix C indicating the first row and the first column of the matrix sub(C), respectively.

desc

(global and local) array of size $dlen_$. The array descriptor for the distributed matrix C .

work

(local).

```

If incv = 1,
  if side = 'L' ,
    if ivcol = iccol,
      lwork ≥ nqc0
    else
      lwork ≥ mpc0 + max(1, nqc0)
    end if
  else if side = 'R' ,
    lwork ≥ nqc0 + max(max(1, mpc0), numroc(numroc(n+icoffc, nb_v, 0,
0, npcol),
      nb_v, 0, 0, lcmq)) end if
else if incv = m_v,
  if side = 'L' ,
    lwork ≥ mpc0 + max(max(1, nqc0), numroc(numroc(m+iroffc, mb_v, 0,
0, nprow),
      mb_v, 0, 0, lcmp))
  else if side = 'R',
    if ivrow = icrow,
      lwork ≥ mpc0
    else
      lwork ≥ nqc0 + max(1, mpc0)
    end if
  end if
end if
end if

```

Here lcm is the least common multiple of $nprow$ and $npcol$;

$lcm = ilcm(nprow, npcol)$, $lcmp = lcm/nprow$, $lcmq = lcm/npcol$,

$iroffc = mod(ic-1, mb_c)$, $icoffc = mod(jc-1, nb_c)$,

$icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nprow)$,

$iccol = indxg2p(jc, nb_c, mycol, csrc_c, npcol)$,

$mpc0 = numroc(m+iroffc, mb_c, myrow, icrow, nprow)$,

$nqc0 = numroc(n+icoffc, nb_c, mycol, iccol, npcol)$,

$ilcm$, $indxg2p$, and $numroc$ are ScaLAPACK tool functions;

$myrow$, $mycol$, $nprow$, and $npcol$ can be determined by calling the function `blacs_gridinfo`.

Output Parameters

c

(local).

On exit, $\text{sub}(C)$ is overwritten by the $Q^H * \text{sub}(C)$ if $\text{side} = 'L'$, or $\text{sub}(C) * Q^H$ if $\text{side} = 'R'$.

*t , MKL_Complex16 *work );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?larzt` function forms the triangular factor T of a real/complex block reflector H of order greater than n , which is defined as a product of k elementary reflectors as returned by [p?tzrzf](#).

If $\text{direct} = 'F'$, $H = H(1) * H(2) * \dots * H(k)$, and T is upper triangular;

If $\text{direct} = 'B'$, $H = H(k) * \dots * H(2) * H(1)$, and T is lower triangular.

If $\text{storev} = 'C'$, the vector which defines the elementary reflector $H(i)$, is stored in the i -th column of the array v , and

$$H = I - v * t * v^H.$$

If $\text{storev} = 'R'$, the vector, which defines the elementary reflector $H(i)$, is stored in the i -th row of the array v , and

$$H = I - v^H * t * v.$$

Currently, only $\text{storev} = 'R'$ and $\text{direct} = 'B'$ are supported.

Input Parameters

| | |
|---------------------|--|
| <code>direct</code> | (global) Specifies the order in which the elementary reflectors are multiplied to form the block reflector: if $\text{direct} = 'F'$: $H = H(1) * H(2) * \dots * H(k)$ (Forward, not supported) |
|---------------------|--|

| | |
|---------------|--|
| | if <i>direct</i> = 'B': $H = H(k) * \dots * H(2) * H(1)$ (Backward). |
| <i>storev</i> | (global) Specifies how the vectors which defines the elementary reflectors are stored: if <i>storev</i> = 'C': columnwise (not supported); if <i>storev</i> = 'R': rowwise. |
| <i>n</i> | (global) The order of the block reflector H . $n \geq 0$. |
| <i>k</i> | (global) The order of the triangular factor T (= the number of elementary reflectors). $1 \leq k \leq mb_v (= nb_v)$. |
| <i>v</i> | Pointer into the local memory to an array of local size $LOCr(iv+k-1) * LOCc(jv+n-1)$. The distributed matrix V contains the Householder vectors. See <i>Application Notes</i> below. |
| <i>iv, jv</i> | (global) The row and column indices in the global matrix V indicating the first row and the first column of the matrix $sub(V)$, respectively. |
| <i>descv</i> | (local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix V . |
| <i>tau</i> | (local) Array of size $LOCr(iv+k-1)$ if <i>incv</i> = <i>m_v</i> , and $LOCc(jv+k-1)$ otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix V . |
| <i>work</i> | (local). Workspace array of size $(k * (k-1) / 2)$. |

Output Parameters

| | |
|----------|---|
| <i>v</i> | |
| <i>t</i> | (local) Array of size $mb_v * mb_v$. It contains the k -by- k triangular factor of the block reflector associated with v . t is lower triangular. |

Application Notes

The shape of the matrix V and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

direct='F' and storev='C'

$$\begin{matrix}
 \begin{bmatrix} v1 & v2 & v3 \\ v1 & v2 & v3 \end{bmatrix} \\
 v = \begin{matrix} . & . & . \\ . & . & . \\ 1 & . & . \\ & 1 & . \\ & & 1 \end{matrix}
 \end{matrix}$$

direct='F' and storev='R':

$$\begin{bmatrix} \overbrace{v1 \ v1 \ v1 \ v1 \ v1}^{\times} \ . \ . \ . \ . \ . \ 1 \\ v2 \ v2 \ v2 \ v2 \ v2 \ . \ . \ . \ 1 \\ v3 \ v3 \ v3 \ v3 \ v3 \ . \ . \ 1 \end{bmatrix}$$

direct='B' and storev='C':

$$\begin{matrix}
 1 \\
 . \ 1 \\
 . \ . \ 1 \\
 . \ . \ . \\
 v = \begin{matrix} . \ . \ . \\ v1 \ v2 \ v3 \end{matrix}
 \end{matrix}$$

direct='B' and storev='R':

$$\begin{bmatrix} 1 \ . \ . \ . \ . \ \overbrace{v1 \ v1 \ v1 \ v1 \ v1}^{\times} \\ . \ 1 \ . \ . \ . \ v2 \ v2 \ v2 \ v2 \ v2 \\ . \ . \ 1 \ . \ . \ v3 \ v3 \ v3 \ v3 \ v3 \end{bmatrix}$$

p?lascl

Multiplies a general rectangular matrix by a real scalar defined as C_{to}/C_{from} .

Syntax

```
void pslascl (char *type , float *cfrom , float *cto , MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```

void pdlascl (char *type , double *cfrom , double *cto , MKL_INT *m , MKL_INT *n ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );

void pclascl (char *type , float *cfrom , float *cto , MKL_INT *m , MKL_INT *n ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );

void pzlascl (char *type , double *cfrom , double *cto , MKL_INT *m , MKL_INT *n ,
MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );

```

Include Files

- mkl_scalapack.h

Description

The `p?lascl` function multiplies the m -by- n real/complex distributed matrix $\text{sub}(A)$ denoting $A(ia:ia+m-1, ja:ja+n-1)$ by the real/complex scalar $cto/cfrom$. This is done without over/underflow as long as the final result $cto*A(i,j)/cfrom$ does not over/underflow. `type` specifies that $\text{sub}(A)$ may be full, upper triangular, lower triangular or upper Hessenberg.

Input Parameters

| | |
|-------------------------|---|
| <code>type</code> | (global) <code>type</code> indicates the storage type of the input distributed matrix. if <code>type = 'G'</code> : $\text{sub}(A)$ is a full matrix, if <code>type = 'L'</code> : $\text{sub}(A)$ is a lower triangular matrix, if <code>type = 'U'</code> : $\text{sub}(A)$ is an upper triangular matrix, if <code>type = 'H'</code> : $\text{sub}(A)$ is an upper Hessenberg matrix. |
| <code>cfrom, cto</code> | (global) The distributed matrix $\text{sub}(A)$ is multiplied by $cto/cfrom$. $A(i,j)$ is computed without over/underflow if the final result $cto*A(i,j)/cfrom$ can be represented without over/underflow. <code>cfrom</code> must be nonzero. |
| <code>m</code> | (global) The number of rows in the distributed matrix $\text{sub}(A)$. ($m \geq 0$). |
| <code>n</code> | (global) The number of columns in the distributed matrix $\text{sub}(A)$. ($n \geq 0$). |
| <code>a</code> | (local input/local output) Pointer into the local memory to an array of size $lld_a * LOCc(ja+n-1)$. This array contains the local pieces of the distributed matrix $\text{sub}(A)$. |
| <code>ia, ja</code> | (global) The column and row indices in the global matrix A indicating the first row and column of the matrix $\text{sub}(A)$, respectively. |
| <code>desca</code> | (global and local) Array of size $dlen_$. The array descriptor for the distributed matrix A . |

Output Parameters

| | |
|-------------|---|
| <i>a</i> | (local). On exit, this array contains the local pieces of the distributed matrix multiplied by <i>cto/cfrom</i> . |
| <i>info</i> | (local) if <i>info</i> = 0: the execution is successful. if <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> -1, had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . |

p?lase2

Initializes an m-by-n distributed matrix.

Syntax

```
void pslase2 (const char* uplo, const MKL_INT* m, const MKL_INT* n, const float* alpha,
const float* beta, float* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT*
desca);
```

```
void pdlase2 (const char* uplo, const MKL_INT* m, const MKL_INT* n, const double*
alpha, const double* beta, double* a, const MKL_INT* ia, const MKL_INT* ja, const
MKL_INT* desca);
```

```
void pclase2 (const char* uplo, const MKL_INT* m, const MKL_INT* n, const MKL_Complex8*
alpha, const MKL_Complex8* beta, MKL_Complex8* a, const MKL_INT* ia, const MKL_INT*
ja, const MKL_INT* desca);
```

```
void pzlase2 (const char* uplo, const MKL_INT* m, const MKL_INT* n, const
MKL_Complex16* alpha, const MKL_Complex16* beta, MKL_Complex16* a, const MKL_INT* ia,
const MKL_INT* ja, const MKL_INT* desca);
```

Include Files

- mkl_scalapack.h

Description

p?lase2 initializes an *m*-by-*n* distributed matrix sub(*A*) denoting $A(ia:ia+m-1,ja:ja+n-1)$ to *beta* on the diagonal and *alpha* on the off-diagonals. p?lase2 requires that only the dimension of the matrix operand is distributed.

Input Parameters

| | |
|-------------|---|
| <i>uplo</i> | (global) Specifies the part of the distributed matrix sub(<i>A</i>) to be set: = 'U': Upper triangular part is set; the strictly lower triangular part of sub(<i>A</i>) is not changed; |
|-------------|---|

= 'L': Lower triangular part is set; the strictly upper triangular part of $\text{sub}(A)$ is not changed;

Otherwise: All of the matrix $\text{sub}(A)$ is set.

| | |
|--------------|---|
| <i>m</i> | (global) The number of rows to be operated on i.e the number of rows of the distributed submatrix $\text{sub}(A)$. $m \geq 0$. |
| <i>n</i> | (global) The number of columns to be operated on i.e the number of columns of the distributed submatrix $\text{sub}(A)$. $n \geq 0$. |
| <i>alpha</i> | (global) The constant to which the off-diagonal elements are to be set. |
| <i>beta</i> | (global) The constant to which the diagonal elements are to be set. |
| <i>ia</i> | (global) The row index in the global array <i>a</i> indicating the first row of $\text{sub}(A)$. |
| <i>ja</i> | (global) The column index in the global array <i>a</i> indicating the first column of $\text{sub}(A)$. |
| <i>desca</i> | (global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |

Output Parameters

| | |
|----------|--|
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$. This array contains the local pieces of the distributed matrix $\text{sub}(A)$ to be set. On exit, the leading <i>m</i> -by- <i>n</i> submatrix $\text{sub}(A)$ is set as follows: if <i>uplo</i> = 'U', $A(ia+i-1, ja+j-1) = alpha, 1 \leq i \leq j-1, 1 \leq j \leq n$, if <i>uplo</i> = 'L', $A(ia+i-1, ja+j-1) = alpha, j+1 \leq i \leq m, 1 \leq j \leq n$, otherwise, $A(ia+i-1, ja+j-1) = alpha, 1 \leq i \leq m, 1 \leq j \leq n, ia+i \neq ja+j$, and, for all <i>uplo</i> , $A(ia+i-1, ja+i-1) = beta, 1 \leq i \leq \min(m, n)$. |
|----------|--|

p?laset

Initializes the offdiagonal elements of a matrix to *alpha* and the diagonal elements to *beta*.

Syntax

```
void pslaset (char *uplo , MKL_INT *m , MKL_INT *n , float *alpha , float *beta ,
float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );

void pdlaset (char *uplo , MKL_INT *m , MKL_INT *n , double *alpha , double *beta ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );

void pclaset (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex8 *alpha , MKL_Complex8
*beta , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );

void pzaset (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex16 *alpha ,
MKL_Complex16 *beta , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

Include Files

- mkl_scalapack.h

Description

The `p?laset` function initializes an m -by- n distributed matrix $\text{sub}(A)$ denoting $A(ia:ia+m-1, ja:ja+n-1)$ to β on the diagonal and α on the offdiagonals.

Input Parameters

| | |
|--------------|---|
| <i>uplo</i> | (global) Specifies the part of the distributed matrix $\text{sub}(A)$ to be set: if <i>uplo</i> = 'U': upper triangular part; the strictly lower triangular part of $\text{sub}(A)$ is not changed; if <i>uplo</i> = 'L': lower triangular part; the strictly upper triangular part of $\text{sub}(A)$ is not changed. Otherwise: all of the matrix $\text{sub}(A)$ is set. |
| <i>m</i> | (global) The number of rows in the distributed matrix $\text{sub}(A)$. ($m \geq 0$). |
| <i>n</i> | (global) The number of columns in the distributed matrix $\text{sub}(A)$. ($n \geq 0$). |
| <i>alpha</i> | (global). The constant to which the offdiagonal elements are to be set. |
| <i>beta</i> | (global). The constant to which the diagonal elements are to be set. |

Output Parameters

| | |
|----------|--|
| <i>a</i> | (local). Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$. This array contains the local pieces of the distributed matrix $\text{sub}(A)$ to be set. On exit, the leading m -by- n matrix $\text{sub}(A)$ is set as follows: if <i>uplo</i> = 'U', $A(ia+i-1, ja+j-1) = \alpha, 1 \leq i \leq m-1, 1 \leq j \leq n$, if <i>uplo</i> = 'L', $A(ia+i-1, ja+j-1) = \alpha, j+1 \leq i \leq m, 1 \leq j \leq n$, |
|----------|--|

otherwise, $A(i_a+i-1, j_a+j-1) = \alpha$, $1 \leq i \leq m$, $1 \leq j \leq n$, $i_a+i \neq j_a+j$, and, for all $uplo$, $A(i_a+i-1, j_a+i-1) = \beta$, $1 \leq j \leq \min(m, n)$.

ia, ja

(global)

The column and row indices in the distributed matrix A indicating the first row and column of the matrix sub(A), respectively.

desca

(global and local)

Array of size *dlen_*. The array descriptor for the distributed matrix A .

See Also

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lasmsub

Looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero.

Syntax

```
void pslasmsub (const float *a, const MKL_INT *desca, const MKL_INT *i, const MKL_INT *l, MKL_INT *k, const float *smlnum, float *buf, const MKL_INT *lwork );
```

```
void pdlasmsub (const double *a, const MKL_INT *desca, const MKL_INT *i, const MKL_INT *l, MKL_INT *k, const double *smlnum, double *buf, const MKL_INT *lwork );
```

```
void pclasmsub (const MKL_Complex8 *a , const MKL_INT *desca , const MKL_INT *i , const MKL_INT *l , MKL_INT *k , const float *smlnum , MKL_Complex8 *buf , const MKL_INT *lwork );
```

```
void pzlasmsub (const MKL_Complex16 *a , const MKL_INT *desca , const MKL_INT *i , const MKL_INT *l , MKL_INT *k , const double *smlnum , MKL_Complex16 *buf , const MKL_INT *lwork );
```

Include Files

- mkl_scalapack.h

Description

The p?lasmsubfunction looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero. This function performs a global maximum and must be called by all processes.

Input Parameters

a

(local)

Array of size $lld_a * LOCC(n_a)$.

On entry, the Hessenberg matrix whose tridiagonal part is being scanned. Unchanged on exit.

desca

(global and local)

Array of size *dlen_*. The array descriptor for the distributed matrix A .

i

(global)

| | |
|----------|--|
| | The global location of the bottom of the unreduced submatrix of A . Unchanged on exit. |
| l | (global) The global location of the top of the unreduced submatrix of A . Unchanged on exit. |
| $smlnum$ | (global) On entry, a "small number" for the given matrix. Unchanged on exit. The machine-dependent constants for the stopping criterion. |
| $lwork$ | (local) This must be at least $2 * \text{ceil}(\text{ceil}((i-1)/mb_a) / \text{lcm}(nprow, npcol))$. Here lcm is least common multiple and $nprow \times npcold$ is the logical grid size. |

Output Parameters

| | |
|-------|--|
| k | (global) On exit, this yields the bottom portion of the unreduced submatrix. This will satisfy: $l \leq k \leq i-1$. |
| buf | (local). Array of size $lwork$. |

Application Notes

This routine parallelizes the code from `?lahqr` that looks for a single small subdiagonal element.

See Also

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lasrt

Sorts the numbers in an array and the corresponding vectors in increasing order.

Syntax

```
void pslasrt (const char* id, const MKL_INT* n, float* d, const float* q, const
MKL_INT* iq, const MKL_INT* jq, const MKL_INT* descq, float* work, const MKL_INT*
lwork, MKL_INT* iwork, const MKL_INT* liwork, MKL_INT* info);
```

```
void pdlasrt (const char* id, const MKL_INT* n, double* d, const double* q, const
MKL_INT* iq, const MKL_INT* jq, const MKL_INT* descq, double* work, const MKL_INT*
lwork, MKL_INT* iwork, const MKL_INT* liwork, MKL_INT* info);
```

Include Files

- `mkl_scalapack.h`

Description

`p?lasrt` sorts the numbers in d and the corresponding vectors in q in increasing order.

Input Parameters

| | |
|---------------|---|
| <i>id</i> | (global) = 'I': sort <i>d</i> in increasing order; = 'D': sort <i>d</i> in decreasing order. (NOT IMPLEMENTED YET) |
| <i>n</i> | (global) The number of columns to be operated on i.e the number of columns of the distributed submatrix sub(<i>Q</i>). $n \geq 0$. |
| <i>d</i> | (global) Array, size (<i>n</i>) |
| <i>q</i> | (local) Pointer into the local memory to an array of size $lld_q * LOCc(jq+n-1)$. This array contains the local pieces of the distributed matrix sub(<i>A</i>) to be copied from. |
| <i>iq</i> | (global) The row index in the global array <i>A</i> indicating the first row of sub(<i>Q</i>). |
| <i>jq</i> | (global) The column index in the global array <i>A</i> indicating the first column of sub(<i>Q</i>). |
| <i>descq</i> | (global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>work</i> | (local) Array, size (<i>lwork</i>) |
| <i>lwork</i> | (local) The size of the array <i>work</i> . $lwork = \text{MAX}(n, NP * (NB + NQ))$, where $NP = \text{numroc}(n, NB, MYROW, IAROW, NPROW)$, $NQ = \text{numroc}(n, NB, MYCOL, DESCQ(csrc_), NPCOL)$. <i>numroc</i> is a ScaLAPACK tool function. |
| <i>iwork</i> | (local) Array, size (<i>liwork</i>) |
| <i>liwork</i> | (local) The size of the array <i>iwork</i> . $liwork = n + 2 * NB + 2 * NPCOL$ |

Output Parameters

| | |
|----------|--|
| <i>d</i> | On exit, the numbers in <i>d</i> are sorted in increasing order. |
|----------|--|

info (global)
 = 0: successful exit
 < 0: If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?lassq

Updates a sum of squares represented in scaled form.

Syntax

```
void plassq (MKL_INT *n , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , float *scale , float *sumsq );
```

```
void pdlassq (MKL_INT *n , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , double *scale , double *sumsq );
```

```
void pclassq (MKL_INT *n , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , float *scale , float *sumsq );
```

```
void pzlassq (MKL_INT *n , MKL_Complex16 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , double *scale , double *sumsq );
```

Include Files

- mkl_scalapack.h

Description

The p?lassq function returns the values *scl* and *sumsq* such that

$$scl^2 * sumsq = x_1^2 + \dots + x_n^2 + scale^2 * sumsq,$$

where

$x_i = \text{sub}(X) = X(ix + (jx-1)*m_x + (i-1)*incx)$ for plassq/pdlassq ,

$x_i = \text{sub}(X) = \text{abs}(X(ix + (jx-1)*m_x + (i-1)*incx))$ for pclassq/pzlassq.

For real functions plassq/pdlassq the value of *sumsq* is assumed to be non-negative and *scl* returns the value

$$scl = \max(scale, \text{abs}(x_i)).$$

For complex functions pclassq/pzlassq the value of *sumsq* is assumed to be at least unity and the value of *ssq* will then satisfy

$$1.0 \leq ssq \leq sumsq + 2n$$

Value *scale* is assumed to be non-negative and *scl* returns the value

$$scl = \max_i \left(scale, \text{abs}(\text{real}(x_i)), \text{abs}(\text{aimag}(x_i)) \right)$$

For all functions p?lassq values *scale* and *sumsq* must be supplied in *scale* and *sumsq* respectively, and *scale* and *sumsq* are overwritten by *scl* and *ssq* respectively.

All functions p?lassq make only one pass through the vector sub(*X*).

Input Parameters

| | |
|--------------|--|
| <i>n</i> | (global) The length of the distributed vector $\text{sub}(x)$. |
| <i>x</i> | The array that stores the vector for which a scaled sum of squares is computed: $x[ix + (jx-1)*m_x + i*incx], 0 \leq i < n.$ |
| <i>ix</i> | (global) The row index in the global matrix X indicating the first row of $\text{sub}(X)$. |
| <i>jx</i> | (global) The column index in the global matrix X indicating the first column of $\text{sub}(X)$. |
| <i>descx</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix X . |
| <i>incx</i> | (global) The global increment for the elements of X . Only two values of <i>incx</i> are supported in this version, namely 1 and <i>m_x</i> . The argument <i>incx</i> must not equal zero. |
| <i>scale</i> | (local). On entry, the value <i>scale</i> in the equation above. |
| <i>sumsq</i> | (local) On entry, the value <i>sumsq</i> in the equation above. |

Output Parameters

| | |
|--------------|--|
| <i>scale</i> | (local). On exit, <i>scale</i> is overwritten with <i>scl</i> , the scaling factor for the sum of squares. |
| <i>sumsq</i> | (local). On exit, <i>sumsq</i> is overwritten with the value <i>sumsq</i> , the basic sum of squares from which <i>scl</i> has been factored out. |

See Also

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

p?laswp

Performs a series of row interchanges on a general rectangular matrix.

Syntax

```
void pslaswp (char *direc , char *rowcol , MKL_INT *n , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *k1 , MKL_INT *k2 , MKL_INT *ipiv );
```

```
void pdlaswp (char *direc , char *rowcol , MKL_INT *n , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *k1 , MKL_INT *k2 , MKL_INT *ipiv );

void pclaswp (char *direc , char *rowcol , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *k1 , MKL_INT *k2 , MKL_INT *ipiv );

void pzlaswp (char *direc , char *rowcol , MKL_INT *n , MKL_Complex16 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *k1 , MKL_INT *k2 , MKL_INT *ipiv );
```

Include Files

- mkl_scalapack.h

Description

The `p?laswp` function performs a series of row or column interchanges on the distributed matrix $\text{sub}(A)=A(ia:ia+n-1, ja:ja+n-1)$. One interchange is initiated for each of rows or columns $k1$ through $k2$ of $\text{sub}(A)$. This function assumes that the pivoting information has already been broadcast along the process row or column. Also note that this function will only work for $k1-k2$ being in the same mb (or nb) block. If you want to pivot a full matrix, use `p?lapiv`.

Input Parameters

| | |
|---------------|---|
| <i>direc</i> | (global) Specifies in which order the permutation is applied: = 'F' - forward, = 'B' - backward. |
| <i>rowcol</i> | (global) Specifies if the rows or columns are permuted: = 'R' - rows, = 'C' - columns. |
| <i>n</i> | (global) If <i>rowcol</i> ='R', the length of the rows of the distributed matrix $A(*, ja:ja+n-1)$ to be permuted; If <i>rowcol</i> ='C', the length of the columns of the distributed matrix $A(ia:ia+n-1, *)$ to be permuted; |
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a * LOCc(n_a)$. On entry, this array contains the local pieces of the distributed matrix to which the row/columns interchanges will be applied. |
| <i>ia</i> | (global) The row index in the global matrix A indicating the first row of $\text{sub}(A)$. |
| <i>ja</i> | (global) The column index in the global matrix A indicating the first column of $\text{sub}(A)$. |
| <i>desca</i> | (global and local) array of size $dlen_$. |

| | |
|--------|--|
| | The array descriptor for the distributed matrix A . |
| $k1$ | (global) The first element of $ipiv$ for which a row or column interchange will be done. |
| $k2$ | (global) The last element of $ipiv$ for which a row or column interchange will be done. |
| $ipiv$ | (local) Array of size $LOCr(m_a)+mb_a$ for row pivoting and $LOCr(n_a)+nb_a$ for column pivoting. This array is tied to the matrix A , $ipiv[k]=l$ implies rows (or columns) $k+1$ and l are to be interchanged, $k = 0, 1, \dots, \text{size}(ipiv) - 1$. |

Output Parameters

| | |
|-----|--|
| A | (local) On exit, the permuted distributed matrix. |
|-----|--|

p?latra

Computes the trace of a general square distributed matrix.

Syntax

```
float pslatra (MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
double pdlatra (MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
void pclatra (MKL_Complex8 * , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
void pzlatra (MKL_Complex16 * , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

Include Files

- `mkl_scalapack.h`

Description

This function computes the trace of an n -by- n distributed matrix $\text{sub}(A)$ denoting $A(ia:ia+n-1, ja:ja+n-1)$. The result is left on every process of the grid.

Input Parameters

| | |
|-----|---|
| n | (global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$. $n \geq 0$. |
| a | (local). |

Pointer into the local memory to an array of size $lld_a * LOCc(ja+n-1)$ containing the local pieces of the distributed matrix, the trace of which is to be computed.

ia, ja (global) The row and column indices respectively in the global matrix A indicating the first row and the first column of the matrix $sub(A)$, respectively.

desca (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A .

Output Parameters

val The value returned by the function.

p?latrd

Reduces the first nb rows and columns of a symmetric/Hermitian matrix A to real tridiagonal form by an orthogonal/unitary similarity transformation.

Syntax

```
void pslatrd (char *uplo , MKL_INT *n , MKL_INT *nb , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *d , float *e , float *tau , float *w , MKL_INT *iw , MKL_INT *jw , MKL_INT *descw , float *work );
```

```
void pdlatrd (char *uplo , MKL_INT *n , MKL_INT *nb , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *d , double *e , double *tau , double *w , MKL_INT *iw , MKL_INT *jw , MKL_INT *descw , double *work );
```

```
void pclatrd (char *uplo , MKL_INT *n , MKL_INT *nb , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *d , float *e , MKL_Complex8 *tau , MKL_Complex8 *w , MKL_INT *iw , MKL_INT *jw , MKL_INT *descw , MKL_Complex8 *work );
```

```
void pzlatrd (char *uplo , MKL_INT *n , MKL_INT *nb , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *d , double *e , MKL_Complex16 *tau , MKL_Complex16 *w , MKL_INT *iw , MKL_INT *jw , MKL_INT *descw , MKL_Complex16 *work );
```

Include Files

- mkl_scalapack.h

Description

The `p?latrd` function reduces nb rows and columns of a real symmetric or complex Hermitian matrix $sub(A) = A(ia:ia+n-1, ja:ja+n-1)$ to symmetric/complex tridiagonal form by an orthogonal/unitary similarity transformation $Q'^*sub(A)Q$, and returns the matrices V and W , which are needed to apply the transformation to the unreduced part of $sub(A)$.

If $uplo = U$, `p?latrd` reduces the last nb rows and columns of a matrix, of which the upper triangle is supplied;

if $uplo = L$, `p?latrd` reduces the first nb rows and columns of a matrix, of which the lower triangle is supplied.

This is an auxiliary function called by `p?sytrd/p?hetrd`.

Input Parameters

| | | |
|--------------|--------------------|--|
| <i>uplo</i> | (global) | Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored: = 'U': Upper triangular = L: Lower triangular. |
| <i>n</i> | (global) | The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$. $n \geq 0$. |
| <i>nb</i> | (global) | The number of rows and columns to be reduced. |
| <i>a</i> | | Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$. On entry, this array contains the local pieces of the symmetric/Hermitian distributed matrix $\text{sub}(A)$. If $uplo = U$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If $uplo = L$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. |
| <i>ia</i> | (global) | The row index in the global matrix A indicating the first row of $\text{sub}(A)$. |
| <i>ja</i> | (global) | The column index in the global matrix A indicating the first column of $\text{sub}(A)$. |
| <i>desca</i> | (global and local) | array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <i>iw</i> | (global) | The row index in the global matrix W indicating the first row of $\text{sub}(W)$. |
| <i>jwt</i> | (global) | The column index in the global matrix W indicating the first column of $\text{sub}(W)$. |
| <i>descw</i> | (global and local) | array of size $dlen_$. The array descriptor for the distributed matrix W . |
| <i>work</i> | (local) | Workspace array of size nb_a . |

Output Parameters

| | |
|------------|---|
| <i>a</i> | (local) On exit, if <i>uplo</i> = 'U', the last <i>nb</i> columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of sub(<i>A</i>); the elements above the diagonal with the array <i>tau</i> represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors; if <i>uplo</i> = 'L', the first <i>nb</i> columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of sub(<i>A</i>); the elements below the diagonal with the array <i>tau</i> represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors. |
| <i>d</i> | (local) Array of size $LOCc(ja+n-1)$. The diagonal elements of the tridiagonal matrix <i>T</i> : $d[i] = A(i+1,i+1)$, $i = 0, 1, \dots, LOCc(ja+n-1)-1$. <i>d</i> is tied to the distributed matrix <i>A</i> . |
| <i>e</i> | (local) Array of size $LOCc(ja+n-1)$ if <i>uplo</i> = 'U', $LOCc(ja+n-2)$ otherwise. The off-diagonal elements of the tridiagonal matrix <i>T</i> : $e[i] = A(i+1, i+2)$ if <i>uplo</i> = 'U', $e[i] = A(i+2, i+1)$ if <i>uplo</i> = 'L', $i = 0, 1, \dots, LOCc(ja+n-1)-1$. <i>e</i> is tied to the distributed matrix <i>A</i> . |
| <i>tau</i> | (local) Array of size $LOCc(ja+n-1)$. This array contains the scalar factors of the elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> . |
| <i>w</i> | (local) Pointer into the local memory to an array of size $lld_w * nb_w$. This array contains the local pieces of the <i>n</i> -by- <i>nb_w</i> matrix <i>w</i> required to update the unreduced part of sub(<i>A</i>). |

Application Notes

If *uplo* = 'U', the matrix *Q* is represented as a product of elementary reflectors

$$Q = H(n) * H(n-1) * \dots * H(n-nb+1)$$

Each *H(i)* has the form

$$H(i) = I - tau * v * v^T,$$

where *tau* is a real/complex scalar, and *v* is a real/complex vector with $v(i:n) = 0$ and $v(i-1) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-1, ja+i)$, and *tau* in $tau[ja+i-2]$.

If *uplo* = 'L', the matrix *Q* is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(nb)$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v^T,$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and τ in $\tau[ja+i-2]$.

The elements of the vectors v together form the n -by- nb matrix V which is needed, with W , to apply the transformation to the unreduced part of the matrix, using a symmetric/Hermitian rank- $2k$ update of the form:

$$\text{sub}(A) := \text{sub}(A) - v w^T - w v^T.$$

The contents of a on exit are illustrated by the following examples with

$n = 5$ and $nb = 2$:

| | |
|---|---|
| if $uplo='U'$: | if $uplo='L'$: |
| $\begin{bmatrix} a & a & a & v_4 & v_5 \\ & a & a & v_4 & v_5 \\ & & a & 1 & v_5 \\ & & & d & 1 \\ & & & & d \end{bmatrix}$ | $\begin{bmatrix} d & & & & \\ 1 & d & & & \\ v_1 & 1 & a & & \\ v_1 & v_2 & a & a & \\ v_1 & v_2 & a & a & a \end{bmatrix}$ |

where d denotes a diagonal element of the reduced matrix, a denotes an element of the original matrix that is unchanged, and v_i denotes an element of the vector defining $H(i)$.

MKL_Complex16 *work );
```

Include Files

- mkl_scalapack.h

Description

The `p?latrs` function solves a triangular system of equations $Ax = sb$, $A^T x = sb$ or $A^H x = sb$, where s is a scale factor set to prevent overflow. The description of the function will be extended in the future releases.

Input Parameters

| | |
|---------------|--|
| <i>uplo</i> | Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular |
| <i>trans</i> | Specifies the operation applied to Ax . = 'N': Solve $Ax = s*b$ (no transpose) = 'T': Solve $A^T x = s*b$ (transpose) = 'C': Solve $A^H x = s*b$ (conjugate transpose), where s - is a scale factor |
| <i>diag</i> | Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular |
| <i>normin</i> | Specifies whether <i>cnorm</i> has been set or not. = 'Y': <i>cnorm</i> contains the column norms on entry; = 'N': <i>cnorm</i> is not set on entry. On exit, the norms will be computed and stored in <i>cnorm</i> . |
| <i>n</i> | The order of the matrix A . $n \geq 0$ |
| <i>a</i> | Array of size $lda * n$. Contains the triangular matrix A . If <i>uplo</i> = U, the leading n -by- n upper triangular part of the array <i>a</i> contains the upper triangular matrix, and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of the array <i>a</i> contains the lower triangular matrix, and the strictly upper triangular part of <i>a</i> is not referenced. If <i>diag</i> = 'U', the diagonal elements of <i>a</i> are also not referenced and are assumed to be 1. |

| | |
|---------------|--|
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |
| <i>x</i> | Array of size <i>n</i> . On entry, the right hand side <i>b</i> of the triangular system. |
| <i>ix</i> | (global).The row index in the global matrix <i>X</i> indicating the first row of sub(<i>x</i>). |
| <i>jx</i> | (global) The column index in the global matrix <i>X</i> indicating the first column of sub(<i>X</i>). |
| <i>descx</i> | (global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>X</i> . |
| <i>cnorm</i> | Array of size <i>n</i> . If <i>normin</i> = 'Y', <i>cnorm</i> is an input argument and <i>cnorm</i> [<i>j</i>] contains the norm of the off-diagonal part of the (<i>j</i> +1)-th column of the matrix <i>A</i> , <i>j</i> =0, 1, ..., <i>n</i> -1. If <i>trans</i> = 'N', <i>cnorm</i> [<i>j</i>] must be greater than or equal to the infinity-norm, and if <i>trans</i> = 'T' or 'C', <i>cnorm</i> [<i>j</i>] must be greater than or equal to the 1-norm. |
| <i>work</i> | (local). Temporary workspace. |

Output Parameters

| | |
|--------------|--|
| <i>X</i> | On exit, <i>x</i> is overwritten by the solution vector <i>x</i> . |
| <i>scale</i> | Array of size <i>lda</i> * <i>n</i> . The scaling factor <i>s</i> for the triangular system as described above. If <i>scale</i> = 0, the matrix <i>A</i> is singular or badly scaled, and the vector <i>x</i> is an exact or approximate solution to $Ax = 0$. |
| <i>cnorm</i> | If <i>normin</i> = 'N', <i>cnorm</i> is an output argument and <i>cnorm</i> [<i>j</i>] returns the 1-norm of the off-diagonal part of the (<i>j</i> +1)-th column of <i>A</i> , <i>j</i> =0, 1, ..., <i>n</i> -1. |

p?latrz

Reduces an upper trapezoidal matrix to upper triangular form by means of orthogonal/unitary transformations.

Syntax

```
void pslatz (MKL_INT *m , MKL_INT *n , MKL_INT *l , float *a , MKL_INT *ia , MKL_INT
 *ja , MKL_INT *desca , float *tau , float *work );

void pdlatrz (MKL_INT *m , MKL_INT *n , MKL_INT *l , double *a , MKL_INT *ia , MKL_INT
 *ja , MKL_INT *desca , double *tau , double *work );
```

```
void pclatrz (MKL_INT *m , MKL_INT *n , MKL_INT *l , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work );

void pzlatrz (MKL_INT *m , MKL_INT *n , MKL_INT *l , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work );
```

Include Files

- mkl_scalapack.h

Description

The `p?latrz` function reduces the m -by- n ($m \leq n$) real/complex upper trapezoidal matrix $\text{sub}(A) = [A(ia:ia+m-1, ja:ja+m-1)A(ia:ia+m-1, ja+n-l:ja+n-1)]$ to upper triangular form by means of orthogonal/unitary transformations.

The upper trapezoidal matrix $\text{sub}(A)$ is factored as

$$\text{sub}(A) = (R \ 0) * Z,$$

where Z is an n -by- n orthogonal/unitary matrix and R is an m -by- m upper triangular matrix.

Input Parameters

| | |
|---------|---|
| m | (global) The number of rows in the distributed matrix $\text{sub}(A)$. $m \geq 0$. |
| n | (global) The number of columns in the distributed matrix $\text{sub}(A)$. $n \geq 0$. |
| l | (global) The number of columns of the distributed matrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. $l > 0$. |
| a | (local) Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$. On entry, the local pieces of the m -by- n distributed matrix $\text{sub}(A)$, which is to be factored. |
| ia | (global) The row index in the global matrix A indicating the first row of $\text{sub}(A)$. |
| ja | (global) The column index in the global matrix A indicating the first column of $\text{sub}(A)$. |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| $work$ | (local) Workspace array of size $lwork$. $lwork \geq nq0 + \max(1, mp0)$, where $iroff = \text{mod}(ia-1, mb_a)$, $icoff = \text{mod}(ja-1, nb_a)$, |

```

iarow = indxg2p(ia, mb_a, myrow, rsrc_a, nrow),
iacol = indxg2p(ja, nb_a, mycol, csrc_a, ncol),
mp0 = numroc(m+iroff, mb_a, myrow, iarow, nrow),
nq0 = numroc(n+icoff, nb_a, mycol, iacol, ncol),
numroc, indxg2p, and numroc are ScaLAPACK tool functions; myrow,
mycol, nrow, and ncol can be determined by calling the function
blacs_gridinfo.

```

Output Parameters

| | |
|------------|---|
| <i>a</i> | On exit, the leading m -by- m upper triangular part of $\text{sub}(A)$ contains the upper triangular matrix R , and elements $n-l+1$ to n of the first m rows of $\text{sub}(A)$, with the array tau , represent the orthogonal/unitary matrix Z as a product of m elementary reflectors. |
| <i>tau</i> | (local) Array of size $\text{LOCr}(ja+m-1)$. This array contains the scalar factors of the elementary reflectors. tau is tied to the distributed matrix A . |

Application Notes

The factorization is obtained by Householder's method. The k -th transformation matrix, $Z(k)$, which is used (or, in case of complex functions, whose conjugate transpose is used) to introduce zeros into the $(m - k + 1)$ -th row of $\text{sub}(A)$, is given in the form

$$Z(k) = \begin{bmatrix} I & 0 \\ 0 & T(k) \end{bmatrix},$$

where

$$T(k) = I - \mathit{tau} * u(k) * u(k)', \quad u(k) = \begin{bmatrix} I \\ 0 \\ z(k) \end{bmatrix}$$

tau is a scalar and $z(k)$ is an $(n-m)$ -element vector. tau and $z(k)$ are chosen to annihilate the elements of the k -th row of $\text{sub}(A)$. The scalar tau is returned in the k -th element of tau , indexed $k-1$, and the vector $u(k)$ in the k -th row of $\text{sub}(A)$, such that the elements of $z(k)$ are in $A(k, m+1), \dots, A(k, n)$. The elements of R are returned in the upper triangular part of $\text{sub}(A)$.

Z is given by

$$Z = Z(1) Z(2) \dots Z(m).$$

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lauu2

Computes the product $U*U'$ or $L'*L$, where U and L are upper or lower triangular matrices (local unblocked algorithm).

Syntax

```
void pslauu2 (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

```
void pdlauu2 (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

```
void pclauu2 (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

```
void pzlauu2 (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

Include Files

- mkl_scalapack.h

Description

The p?lauu2 function computes the product $U*U'$ or $L'*L$, where the triangular factor U or L is stored in the upper or lower triangular part of the distributed matrix

$sub(A) = A(ia:ia+n-1, ja:ja+n-1)$.

If *uplo* = 'U' or 'u', then the upper triangle of the result is stored, overwriting the factor U in $sub(A)$.

If *uplo* = 'L' or 'l', then the lower triangle of the result is stored, overwriting the factor L in $sub(A)$.

This is the unblocked form of the algorithm, calling [BLAS Level 2 Routines](#). No communication is performed by this function, the matrix to operate on should be strictly local to one process.

Input Parameters

| | |
|-------------|---|
| <i>uplo</i> | (global) Specifies whether the triangular factor stored in the <i>matrix</i> $sub(A)$ is upper or lower triangular: = U: upper triangular = L: lower triangular. |
| <i>n</i> | (global) The number of rows and columns to be operated on, that is, the order of the triangular factor U or L . $n \geq 0$. |
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$. On entry, the local pieces of the triangular factor U or L . |
| <i>ia</i> | (global) The row index in the global matrix A indicating the first row of $sub(A)$. |
| <i>ja</i> | (global) |

The column index in the global matrix A indicating the first column of $\text{sub}(A)$.

desca (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A .

Output Parameters

a (local)
On exit, if $uplo = 'U'$, the upper triangle of the distributed matrix $\text{sub}(A)$ is overwritten with the upper triangle of the product $U*U'$; if $uplo = 'L'$, the lower triangle of $\text{sub}(A)$ is overwritten with the lower triangle of the product $L'*L$.

See Also

p?lauum

*Computes the product $U*U'$ or $L'*L$, where U and L are upper or lower triangular matrices.*

Syntax

```
void pslauum (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

```
void pdlauum (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

```
void pclauum (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

```
void pzlauum (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?lauum` function computes the product $U*U'$ or $L'*L$, where the triangular factor U or L is stored in the upper or lower triangular part of the matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

If $uplo = 'U'$ or $'u'$, then the upper triangle of the result is stored, overwriting the factor U in $\text{sub}(A)$. If $uplo = 'L'$ or $'l'$, then the lower triangle of the result is stored, overwriting the factor L in $\text{sub}(A)$.

This is the blocked form of the algorithm, calling Level 3 PBLAS.

Input Parameters

uplo (global)
Specifies whether the triangular factor stored in the matrix $\text{sub}(A)$ is upper or lower triangular:
= $'U'$: upper triangular

= 'L': lower triangular.

| | | |
|--------------|---|--|
| <i>n</i> | (global) | The number of rows and columns to be operated on, that is, the order of the triangular factor <i>U</i> or <i>L</i> . $n \geq 0$. |
| <i>a</i> | (local) | Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$. On entry, the local pieces of the triangular factor <i>U</i> or <i>L</i> . |
| <i>ia</i> | (global) | The row index in the global matrix <i>A</i> indicating the first row of sub(<i>A</i>). |
| <i>ja</i> | (global) | The column index in the global matrix <i>A</i> indicating the first column of sub(<i>A</i>). |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . | The array descriptor for the distributed matrix <i>A</i> . |

Output Parameters

| | | |
|----------|---------|---|
| <i>a</i> | (local) | On exit, if <i>uplo</i> = 'U', the upper triangle of the distributed matrix sub(<i>A</i>) is overwritten with the upper triangle of the product $U*U'$; if <i>uplo</i> = 'L', the lower triangle of sub(<i>A</i>) is overwritten with the lower triangle of the product $L'*L$. |

```

Include Files

- `mkl_scalapack.h`

Description

The `p?lawil` function gets the transform given by `h44`, `h33`, and `h43h34` into `v` starting at row `m`.

Input Parameters

| | |
|---------------------|--|
| <code>ii</code> | (global) Number of the process row which owns the matrix element $A(m+2, m+2)$. |
| <code>jj</code> | (global) Number of the process column which owns the matrix element $A(m+2, m+2)$. |
| <code>m</code> | (global) On entry, the location from where the transform starts (row <code>m</code>). Unchanged on exit. |
| <code>a</code> | (local) Array of size <code>lld_a*LOCc(n_a)</code> . On entry, the Hessenberg matrix. Unchanged on exit. |
| <code>desca</code> | (global and local) Array of size <code>dlen_</code> . The array descriptor for the distributed matrix <code>A</code> . Unchanged on exit. |
| <code>h43h34</code> | (global) These three values are for the double shift <code>QR</code> iteration. Unchanged on exit. |

Output Parameters

| | |
|----------------|--|
| <code>v</code> | (global) Array of size 3 that contains the transform on output. |
|----------------|--|

[p?org2l/p?ung2l](#)

Generates all or part of the orthogonal/unitary matrix `Q` from a `QL` factorization determined by `p?geqlf` (unblocked algorithm).

Syntax

```
void psorg2l (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdorg2l (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pcung21 (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );

void pzung21 (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT
*lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?org21/p?ung21` function generates an m -by- n real/complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m :

$Q = H(k)*...*H(2)*H(1)$ as returned by `p?geqlf`.

Input Parameters

| | |
|---------|---|
| m | (global) The number of rows in the distributed submatrix Q . $m \geq 0$. |
| n | (global) The number of columns in the distributed submatrix Q . $m \geq n \geq 0$. |
| k | (global) The number of elementary reflectors whose product defines the matrix Q . $n \geq k \geq 0$. |
| a | Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$. On entry, the j -th column of the matrix stored in a must contain the vector that defines the elementary reflector $H(j)$, $ja+n-k \leq j \leq ja+n-k$, as returned by <code>p?geqlf</code> in the k columns of its <i>distributed matrix</i> argument $A(ia:*, ja+n-k:ja+n-1)$. |
| ia | (global) The row index in the global matrix A indicating the first row of sub(A). |
| ja | (global) The column index in the global matrix A indicating the first column of sub(A). |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| tau | (local) Array of size $LOCC(ja+n-1)$. $tau[j]$ contains the scalar factor of the elementary reflector $H(j+1)$, $j = 0, 1, \dots, LOCC(ja+n-1)-1$, as returned by <code>p?geqlf</code> . |
| $work$ | (local) |

Workspace array of size *lwork*.

lwork (local or global)
The size of the array *work*.
lwork is local input and must be at least $lwork \geq mpa0 + \max(1, nqa0)$, where

```

iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, myrow, rsrc_a, nprow),
iacol = indxg2p(ja, nb_a, mycol, csrc_a, npcot),
mpa0 = numroc(m+iroffa, mb_a, myrow, iarow, nprow),
nqa0 = numroc(n+icoffa, nb_a, mycol, iacol, npcot).

```

`indxg2p` and `numroc` are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the function `blacs_gridinfo`.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a On exit, this array contains the local pieces of the *m*-by-*n* distributed matrix *Q*.

work On exit, *work*[0] returns the minimal and optimal *lwork*.

info (local).
= 0: successful exit
< 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value,
then *info* = - (*i**100 + *j*),
if the *i*-th argument is a scalar and had an illegal value,
then *info* = -*i*.

Description

The p?orm2l/p?unm2l function overwrites the general real/complex m -by- n distributed matrix sub (C)= $C(ic:ic+m-1,jc:jc+n-1)$ with

$Q*\text{sub}(C)$ if $side = 'L'$ and $trans = 'N'$, or

$Q^T*\text{sub}(C) / Q^H*\text{sub}(C)$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$\text{sub}(C)*Q$ if $side = 'R'$ and $trans = 'N'$, or

$\text{sub}(C)*Q^T / \text{sub}(C)*Q^H$ if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(k)*\dots*H(2)*H(1)$ as returned by p?geqlf . Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

| | |
|--------------|---|
| <i>side</i> | (global) |
| | = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left, |
| | = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right. |
| <i>trans</i> | (global) |

| | |
|--------------|---|
| | <p>= 'N': apply Q (no transpose)</p> <p>= 'T': apply Q^T (transpose, for real flavors)</p> <p>= 'C': apply Q^H (conjugate transpose, for complex flavors)</p> |
| <i>m</i> | <p>(global)</p> <p>The number of rows in the distributed matrix $\text{sub}(C)$. $m \geq 0$.</p> |
| <i>n</i> | <p>(global)</p> <p>The number of columns in the distributed matrix $\text{sub}(C)$. $n \geq 0$.</p> |
| <i>k</i> | <p>(global)</p> <p>The number of elementary reflectors whose product defines the matrix Q.</p> <p>If $\text{side} = \text{'L'}$, $m \geq k \geq 0$;</p> <p>if $\text{side} = \text{'R'}$, $n \geq k \geq 0$.</p> |
| <i>a</i> | <p>(local)</p> <p>Pointer into the local memory to an array of size $\text{lld}_a * \text{LOCc}(ja+k-1)$.</p> <p>On entry, the j-th row of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?geqlf in the k columns of its distributed matrix argument $A(\text{ia} : *, ja : ja+k-1)$. The argument $A(\text{ia} : *, ja : ja+k-1)$ is modified by the function but restored on exit.</p> <p>If $\text{side} = \text{'L'}$, $\text{lld}_a \geq \max(1, \text{LOCr}(\text{ia}+m-1))$,</p> <p>if $\text{side} = \text{'R'}$, $\text{lld}_a \geq \max(1, \text{LOCr}(\text{ia}+n-1))$.</p> |
| <i>ia</i> | <p>(global)</p> <p>The row index in the global matrix A indicating the first row of $\text{sub}(A)$.</p> |
| <i>ja</i> | <p>(global)</p> <p>The column index in the global matrix A indicating the first column of $\text{sub}(A)$.</p> |
| <i>desca</i> | <p>(global and local) array of size $dlen_$. The array descriptor for the distributed matrix A.</p> |
| <i>tau</i> | <p>(local)</p> <p>Array of size $\text{LOCc}(ja+n-1)$. $\text{tau}[j]$ contains the scalar factor of the elementary reflector $H(j+1)$, $j = 0, 1, \dots, \text{LOCc}(ja+n-1)-1$, as returned by p?geqlf. This array is tied to the distributed matrix A.</p> |
| <i>c</i> | <p>(local)</p> <p>Pointer into the local memory to an array of size $\text{lld}_c * \text{LOCc}(jc+n-1)$. On entry, the local pieces of the distributed matrix $\text{sub}(C)$.</p> |
| <i>ic</i> | <p>(global)</p> <p>The row index in the global matrix C indicating the first row of $\text{sub}(C)$.</p> |
| <i>jc</i> | <p>(global)</p> |

The column index in the global matrix C indicating the first column of $\text{sub}(C)$.

desc (global and local) array of size *dlen_*. The array descriptor for the distributed matrix C .

work (local)
Workspace array of size *lwork*.
On exit, *work*(1) returns the minimal and optimal *lwork*.

lwork (local or global)
The size of the array *work*.
lwork is local input and must be at least
if *side* = 'L', $lwork \geq mpc0 + \max(1, nqc0)$,
if *side* = 'R', $lwork \geq nqc0 + \max(\max(1, mpc0), \text{numroc}(\text{numroc}(n + icoffc, nb_a, 0, 0, npc0), nb_a, 0, 0, lcmq))$,

where

$$lcmq = lcm / npc0,$$

$$lcm = iclm(nprow, npc0),$$

$$iroffc = \text{mod}(ic-1, mb_c),$$

$$icoffc = \text{mod}(jc-1, nb_c),$$

$$icrow = \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprow),$$

$$iccol = \text{indxg2p}(jc, nb_c, mycol, csrc_c, npc0),$$

$$Mqc0 = \text{numroc}(m + icoffc, nb_c, mycol, icrow, nprow),$$

$$Npc0 = \text{numroc}(n + iroffc, mb_c, myrow, iccol, npc0),$$

iclm, *indxg2p*, and *numroc* are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npc0* can be determined by calling the function *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

c On exit, *c* is overwritten by $Q * \text{sub}(C)$, or $Q^T * \text{sub}(C) / Q^H * \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$

work On exit, *work*[0] returns the minimal and optimal *lwork*.

info (local)
= 0: successful exit
< 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value,
then *info* = - (*i**100 + *j*),

if the i -th argument is a scalar and had an illegal value,
then $info = -i$.

NOTE

The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If $side = 'L'$, ($mb_a == mb_c$ && $iroffa == iroffc$ && $iarow == icrow$)

If $side = 'R'$, ($mb_a == nb_c$ && $iroffa == iroffc$).

Description

The `p?orm2r/p?unm2r` function overwrites the general real/complex m -by- n distributed matrix sub (C)= $C(ic:ic+m-1, jc:jc+n-1)$ with

$Q*\text{sub}(C)$ if $side = 'L'$ and $trans = 'N'$, or

$Q^T*\text{sub}(C)$ / $Q^H*\text{sub}(C)$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$\text{sub}(C)*Q$ if $side = 'R'$ and $trans = 'N'$, or

$\text{sub}(C)*Q^T$ / $\text{sub}(C)*Q^H$ if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$ as returned by `p?geqrf`. Q is of order m if `side = 'L'` and of order n if `side = 'R'`.

Input Parameters

| | |
|--------------------|---|
| <code>side</code> | (global) = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left, = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right. |
| <code>trans</code> | (global) = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors) |
| <code>m</code> | (global) The number of rows in the distributed matrix <code>sub(C)</code> . $m \geq 0$. |
| <code>n</code> | (global) The number of columns in the distributed matrix <code>sub(C)</code> . $n \geq 0$. |
| <code>k</code> | (global) The number of elementary reflectors whose product defines the matrix Q . If <code>side = 'L'</code> , $m \geq k \geq 0$; if <code>side = 'R'</code> , $n \geq k \geq 0$. |
| <code>a</code> | (local) Pointer into the local memory to an array of size <code>lld_a * LOCC(ja+k-1)</code> . On entry, the j -th column of the matrix stored in <code>a</code> must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by <code>p?geqrf</code> in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. The argument $A(ia:*, ja:ja+k-1)$ is modified by the function but restored on exit. If <code>side = 'L'</code> , <code>lld_a</code> \geq <code>max(1, LOCr(ia+m-1))</code> , if <code>side = 'R'</code> , <code>lld_a</code> \geq <code>max(1, LOCr(ia+n-1))</code> . |
| <code>ia</code> | (global) The row index in the global matrix A indicating the first row of <code>sub(A)</code> . |
| <code>ja</code> | (global) The column index in the global matrix A indicating the first column of <code>sub(A)</code> . |
| <code>desca</code> | (global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix A . |
| <code>tau</code> | (local) |

Array of size $LOCc(ja+k-1) \cdot \tau[j]$ contains the scalar factor of the elementary reflector $H(j+1)$, $j = 0, 1, \dots, LOCc(ja+k-1)-1$, as returned by [p?geqrf](#). This array is tied to the distributed matrix A .

| | |
|--------------|--|
| <i>c</i> | (local) Pointer into the local memory to an array of size $lld_c * LOCc(jc+n-1)$. On entry, the local pieces of the distributed matrix sub (C). |
| <i>ic</i> | (global) The row index in the global matrix C indicating the first row of sub(C). |
| <i>jc</i> | (global) The column index in the global matrix C indicating the first column of sub(C). |
| <i>desc</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix C . |
| <i>work</i> | (local) Workspace array of size $lwork$. |
| <i>lwork</i> | (local or global) The size of the array $work$. <i>lwork</i> is local input and must be at least if $side = 'L'$, $lwork \geq mpc0 + \max(1, nqc0)$, if $side = 'R'$, $lwork \geq nqc0 + \max(\max(1, mpc0), \text{numroc}(\text{numroc}(n + icoffc, nb_a, 0, 0, npc0), nb_a, 0, 0, lcmq))$, where $lcmq = lcm/npcol$, $lcm = iclm(nprow, npc0)$, $iroffc = \text{mod}(ic-1, mb_c)$, $icoffc = \text{mod}(jc-1, nb_c)$, $icrow = \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprow)$, $iccol = \text{indxg2p}(jc, nb_c, mycol, csrc_c, npc0)$, $Mqc0 = \text{numroc}(m+icoffc, nb_c, mycol, icrow, nprow)$, $Npc0 = \text{numroc}(n+iroffc, mb_c, myrow, iccol, npc0)$, $iclm$, $indxg2p$ and numroc are ScaLAPACK tool functions; $myrow$, $mycol$, $nprow$, and $npc0$ can be determined by calling the function <code>blacs_gridinfo</code> . If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla . |

Output Parameters

| | |
|-------------|--|
| <i>c</i> | On exit, <i>c</i> is overwritten by $Q \cdot \text{sub}(C)$, or $Q^T \cdot \text{sub}(C) / Q^H \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q$, or $\text{sub}(C) \cdot Q^T / \text{sub}(C) \cdot Q^H$ |
| <i>work</i> | On exit, <i>work</i> [0] returns the minimal and optimal <i>lwork</i> . |
| <i>info</i> | (local) = 0: successful exit < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> -1, had an illegal value, then <i>info</i> = - (<i>i</i> *100 + <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . |

NOTE

The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If *side* = 'L', (*mb_a* == *mb_c*) && (*irowfa* == *irowfc*) && (*iarow* == *icrow*).

If *side* = 'R', (*mb_a* == *nb_c*) && (*irowfa* == *irowfc*).

Description

The `p?orml2/p?unml2` function overwrites the general real/complex m -by- n distributed matrix sub(C)= $C(ic:ic+m-1, jc:jc+n-1)$ with

$Q*\text{sub}(C)$ if $side = 'L'$ and $trans = 'N'$, or

$Q^T*\text{sub}(C) / Q^H*\text{sub}(C)$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$\text{sub}(C)*Q$ if $side = 'R'$ and $trans = 'N'$, or

$\text{sub}(C)*Q^T / \text{sub}(C)*Q^H$ if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$ (for real flavors)

$Q = (H(k))^H * \dots * (H(2))^H * (H(1))^H$ (for complex flavors)

as returned by `p?gelqf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

| | |
|--------------|---|
| <i>side</i> | (global) = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left, = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right. |
| <i>trans</i> | (global) = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors) |
| <i>m</i> | (global) The number of rows in the distributed matrix sub(C). $m \geq 0$. |
| <i>n</i> | (global) The number of columns in the distributed matrix sub(C). $n \geq 0$. |
| <i>k</i> | (global) The number of elementary reflectors whose product defines the matrix Q . If $side = 'L'$, $m \geq k \geq 0$; if $side = 'R'$, $n \geq k \geq 0$. |
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a * LOCC(ja+m-1)$ if $side='L'$, $lld_a * LOCC(ja+n-1)$ if $side='R'$, |

where $lld_a \geq \max(1, LOCr(ia+k-1))$.

On entry, the i -th row of the matrix stored in a must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by `p?gelqf` in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. The argument $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit.

| | |
|--------------------|---|
| <code>ia</code> | (global) The row index in the global matrix A indicating the first row of $sub(A)$. |
| <code>ja</code> | (global) The column index in the global matrix A indicating the first column of $sub(A)$. |
| <code>desca</code> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <code>tau</code> | (local) Array of size $LOCc(ia+k-1)$. $tau[i]$ contains the scalar factor of the elementary reflector $H(i+1)$, $i = 0, 1, \dots, LOCc(ja+k-1)-1$, as returned by <code>p?gelqf</code> . This array is tied to the distributed matrix A . |
| <code>c</code> | (local) Pointer into the local memory to an array of size $lld_c * LOCc(jc+n-1)$. On entry, the local pieces of the distributed matrix $sub(C)$. |
| <code>ic</code> | (global) The row index in the global matrix C indicating the first row of $sub(C)$. |
| <code>jc</code> | (global) The column index in the global matrix C indicating the first column of $sub(C)$. |
| <code>descc</code> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix C . |
| <code>work</code> | (local) Workspace array of size $lwork$. |
| <code>lwork</code> | (local or global) The size of the array $work$. |

$lwork$ is local input and must be at least

if $side = 'L'$, $lwork \geq mqc0 + \max(\max(1, npc0), \text{numroc}(\text{numroc}(m + icoffc, mb_a, 0, 0, nprow), mb_a, 0, 0, lcm)),$

if $side = 'R'$, $lwork \geq npc0 + \max(1, mqc0),$

where

$lcmp = lcm / nprow,$

$lcm = iclm(nprow, npc0),$

```

iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nprow),
iccol = indxg2p(jc, nb_c, mycol, csrc_c, npc1),
Mpc0 = numroc(m+icoffc, mb_c, mycol, icrow, nprow),
Nqc0 = numroc(n+iroffc, nb_c, myrow, iccol, npc1),
ilcm, indxg2p and numroc are ScaLAPACK tool functions; myrow, mycol,
nprow, and npc1 can be determined by calling the function
blacs_gridinfo.

```

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

| | |
|--------|---|
| c | On exit, c is overwritten by $Q*\text{sub}(C)$, or $Q^T*\text{sub}(C)$ / $Q^H*\text{sub}(C)$, or $\text{sub}(C)*Q$, or $\text{sub}(C)*Q^T$ / $\text{sub}(C)*Q^H$ |
| $work$ | On exit, $work[0]$ returns the minimal and optimal $lwork$. |
| $info$ | (local) = 0: successful exit < 0: if the i -th argument is an array and the j -th entry, indexed $j-1$, had an illegal value, then $info = -(i*100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$. |

NOTE

The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If $side = 'L'$, $(nb_a == mb_c \ \&\& \ icoffa == iroffc)$

If $side = 'R'$, $(nb_a == nb_c \ \&\& \ icoffa == icoffc \ \&\& \ iacol == iccol)$.

Description

The `p?ormr2/p?unmr2` function overwrites the general real/complex m -by- n distributed matrix sub $(C)=C(ic:ic+m-1, jc:jc+n-1)$ with

Q *sub(C) if `side = 'L'` and `trans = 'N'`, or

Q^T *sub(C) / Q^H *sub(C) if `side = 'L'` and `trans = 'T'` (for real flavors) or `trans = 'C'` (for complex flavors), or

sub(C)* Q if `side = 'R'` and `trans = 'N'`, or

sub(C)* Q^T / sub(C)* Q^H if `side = 'R'` and `trans = 'T'` (for real flavors) or `trans = 'C'` (for complex flavors).

where Q is a real orthogonal or complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(1)*H(2)*...*H(k)$ (for real flavors)

$Q = (H(1))^H*(H(2))^H*...*(H(k))^H$ (for complex flavors)

as returned by `p?gerqf`. Q is of order m if `side = 'L'` and of order n if `side = 'R'`.

Input Parameters

| | |
|--------------------|---|
| <code>side</code> | (global) |
| | = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left, |
| | = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right. |
| <code>trans</code> | (global) |
| | = 'N': apply Q (no transpose) |
| | = 'T': apply Q^T (transpose, for real flavors) |
| | = 'C': apply Q^H (conjugate transpose, for complex flavors) |

| | |
|--------------|--|
| <i>m</i> | (global) The number of rows in the distributed matrix $\text{sub}(C)$. $m \geq 0$. |
| <i>n</i> | (global) The number of columns in the distributed matrix $\text{sub}(C)$. $n \geq 0$. |
| <i>k</i> | (global) The number of elementary reflectors whose product defines the matrix Q . If $\text{side} = 'L', m \geq k \geq 0$; if $\text{side} = 'R', n \geq k \geq 0$. |
| <i>a</i> | (local) Pointer into the local memory to an array of size $\text{lld}_a * \text{LOCc}(ja+m-1)$ if $\text{side}='L'$, $\text{lld}_a * \text{LOCc}(ja+n-1)$ if $\text{side}='R'$, where $\text{lld}_a \geq \max(1, \text{LOCr}(ia+k-1))$. On entry, the i -th row of the matrix stored in a must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gerqf in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. The argument $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit. |
| <i>ia</i> | (global) The row index in the global matrix A indicating the first row of $\text{sub}(A)$. |
| <i>ja</i> | (global) The column index in the global matrix A indicating the first column of $\text{sub}(A)$. |
| <i>desca</i> | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . |
| <i>tau</i> | (local) Array of size $\text{LOCc}(ia+k-1)$. $\text{tau}[j]$ contains the scalar factor of the elementary reflector $H(j+1)$, $j = 0, 1, \dots, \text{LOCc}(ja+k-1)-1$, as returned by p?gerqf . This array is tied to the distributed matrix A . |
| <i>c</i> | (local) Pointer into the local memory to an array of size $\text{lld}_c * \text{LOCc}(jc+n-1)$. On entry, the local pieces of the distributed matrix $\text{sub}(C)$. |
| <i>ic</i> | (global) The row index in the global matrix C indicating the first row of $\text{sub}(C)$. |
| <i>jc</i> | (global) |

The column index in the global matrix C indicating the first column of $\text{sub}(C)$.

desc

(global and local) array of size *dlen_*. The array descriptor for the distributed matrix C .

work

(local)

Workspace array of size *lwork*.

lwork

where $lcmp = lcm/nprow,$

$lcm = iclm(nprow, npc0),$

$iroffc = \text{mod}(ic-1, mb_c),$

$icoffc = \text{mod}(jc-1, nb_c),$

$icrow = \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprow),$

$iccol = \text{indxg2p}(jc, nb_c, mycol, csrc_c, npc0),$

$Mpc0 = \text{numroc}(m + iroffc, mb_c, myrow, icrow, nprow),$

$Nqc0 = \text{numroc}(n + icoffc, nb_c, mycol, iccol, npc0),$

iclm, *indxg2p* and *numroc* are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npc0* can be determined by calling the function *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

c

On exit, *c* is overwritten by $Q * \text{sub}(C)$, or $Q^T * \text{sub}(C) / Q^H * \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$

work

On exit, *work*[0] returns the minimal and optimal *lwork*.

info

(local)

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value,

then $info = -(i * 100 + j),$

if the *i*-th argument is a scalar and had an illegal value,

then $info = -i.$

NOTE

The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If $side = 'L'$, $(nb_a == mb_c) \ \&\& \ (icoffa == iroffc)$.

If $side = 'R'$, $(nb_a == nb_c) \ \&\& \ (icoffa == icoffc) \ \&\& \ (iacol == iccol)$.

p?pbtrsv

Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a banded matrix computed by p?pbtrf.

Syntax

```
void pspbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bw , MKL_INT *nrhs ,
float *a , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *descb ,
float *af , MKL_INT *laf , float *work , MKL_INT *lwork , MKL_INT *info );

void pdpbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bw , MKL_INT *nrhs ,
double *a , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *descb ,
double *af , MKL_INT *laf , double *work , MKL_INT *lwork , MKL_INT *info );

void pcpbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bw , MKL_INT *nrhs ,
MKL_Complex8 *a , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib ,
MKL_INT *descb , MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );

void pzpbttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bw , MKL_INT *nrhs ,
MKL_Complex16 *a , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib ,
MKL_INT *descb , MKL_Complex16 *af , MKL_INT *laf , MKL_Complex16 *work , MKL_INT
*lwork , MKL_INT *info );
```

Description

The p?pbtrsv function solves a banded triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(jb:jb+n-1, 1:nrhs)$$

or

$$A(1:n, ja:ja+n-1)^T * X = B(jb:jb+n-1, 1:nrhs) \text{ for real flavors,}$$

$$A(1:n, ja:ja+n-1)^H * X = B(jb:jb+n-1, 1:nrhs) \text{ for complex flavors,}$$

where $A(1:n, ja:ja+n-1)$ is a banded triangular matrix factor produced by the Cholesky factorization code p?pbtrf and is stored in $A(1:n, ja:ja+n-1)$ and af . The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to $uplo$.

The function p?pbtrf must be called first.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

| | |
|--------------|---|
| <i>uplo</i> | (global) Must be 'U' or 'L'. If <i>uplo</i> = 'U', upper triangle of $A(1:n, ja:ja+n-1)$ is stored; If <i>uplo</i> = 'L', lower triangle of $A(1:n, ja:ja+n-1)$ is stored. |
| <i>trans</i> | (global) Must be 'N' or 'T' or 'C'. If <i>trans</i> = 'N', solve with $A(1:n, ja:ja+n-1)$; If <i>trans</i> = 'T' or 'C' for real flavors, solve with $A(1:n, ja:ja+n-1)^T$. If <i>trans</i> = 'C' for complex flavors, solve with conjugate transpose $(A(1:n, ja:ja+n-1))^H$. |
| <i>n</i> | (global) The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$. $n \geq 0$. |
| <i>bw</i> | (global) The number of subdiagonals in 'L' or 'U', $0 \leq bw \leq n-1$. |
| <i>nrhs</i> | (global) The number of right hand sides; the number of columns of the distributed submatrix $B(jb:jb+n-1, 1:nrhs)$; $nrhs \geq 0$. |
| <i>a</i> | (local) Pointer into the local memory to an array with the first size $lld_a \geq (bw + 1)$, stored in <i>desca</i> . On entry, this array contains the local pieces of the n -by- n symmetric banded distributed Cholesky factor L or $L^T * A(1:n, ja:ja+n-1)$. This local portion is stored in the packed banded format used in LAPACK. See the <i>Application Notes</i> below and the ScaLAPACK manual for more detail on the format of distributed matrices. |
| <i>ja</i> | (global) The index in the global in the global matrix A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A). |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A . |

If 1D type ($dtype_a = 501$), then $dlen \geq 7$;

If 2D type ($dtype_a = 1$), then $dlen \geq 9$.

Contains information on mapping of A to memory. (See ScaLAPACK manual for full description and options.)

b (local)

Pointer into the local memory to an array of local lead size $lld_b \geq nb$.

On entry, this array contains the local pieces of the right hand sides $B(jb:jb+n-1, 1:nrhs)$.

ib (global) The row index in the global matrix B that points to the first row of the matrix to be operated on (which may be either all of B or a submatrix of B).

descb (global and local) array of size $dlen_$. The array descriptor for the distributed matrix B .

If 1D type ($dtype_b = 502$), then $dlen \geq 7$;

If 2D type ($dtype_b = 1$), then $dlen \geq 9$.

Contains information on mapping of B to memory. Please, see ScaLAPACK manual for full description and options.

laf (local)

The size of user-input auxiliary fill-in space af . Must be $laf \geq (nb + 2*bw)*bw$. If laf is not large enough, an error code will be returned and the minimum acceptable size will be returned in $af[0]$.

work (local)

The array $work$ is a temporary workspace array of size $lwork$. This space may be overwritten in between function calls.

lwork (local or global) The size of the user-input workspace $work$, must be at least $lwork \geq bw*nrhs$. If $lwork$ is too small, the minimal acceptable size will be returned in $work[0]$ and an error code is returned.

Output Parameters

af (local)

The array af is of size laf . It contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function [p?pbtrf](#) and is stored in af . If a linear system is to be solved using [p?pbtrs](#) after the factorization function, af must not be altered after the factorization.

b On exit, this array contains the local piece of the solutions distributed matrix X .

work[0] On exit, $work[0]$ contains the minimum value of $lwork$.

info (local)

= 0: successful exit

< 0: if the i -th argument is an array and the j -th entry, indexed $j-1$, had an illegal value,
 then $info = - (i*100 + j)$,
 if the i -th argument is a scalar and had an illegal value,
 then $info = -i$.

Application Notes

If the factorization function and the solve function are to be called separately to solve various sets of right-hand sides using the same coefficient matrix, the auxiliary space af must not be altered between calls to the factorization function and the solve function.

The best algorithm for solving banded and tridiagonal linear systems depends on a variety of parameters, especially the bandwidth. Currently, only algorithms designed for the case $N/P \gg bw$ are implemented. These algorithms go by many names, including Divide and Conquer, Partitioning, domain decomposition-type, etc.

The Divide and Conquer algorithm assumes the matrix is narrowly banded compared with the number of equations. In this situation, it is best to distribute the input matrix A one-dimensionally, with columns atomic and rows divided amongst the processes. The basic algorithm divides the banded matrix up into P pieces with one stored on each processor, and then proceeds in 2 phases for the factorization or 3 for the solution of a linear system.

- 1. Local Phase :** The individual pieces are factored independently and in parallel. These factors are applied to the matrix creating fill-in, which is stored in a non-inspectable way in auxiliary space af . Mathematically, this is equivalent to reordering the matrix A as PAP^T and then factoring the principal leading submatrix of size equal to the sum of the sizes of the matrices factored on each processor. The factors of these submatrices overwrite the corresponding parts of A in memory.
- 2. Reduced System Phase :** A small ($bw*(P-1)$) system is formed representing interaction of the larger blocks and is stored (as are its factors) in the space af . A parallel Block Cyclic Reduction algorithm is used. For a linear system, a parallel front solve followed by an analogous backsolve, both using the structure of the factored matrix, are performed.
- 3. Back Substitution Phase:** For a linear system, a local backsubstitution is performed on each processor in parallel.

p?pttrsv

Solves a single triangular linear system via `frontsolve` or `backsolve` where the triangular matrix is a factor of a tridiagonal matrix computed by `p?pttrf`.

Syntax

```
void pspttrsv (char *uplo , MKL_INT *n , MKL_INT *nrhs , float *d , float *e , MKL_INT
*ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *descb , float *af , MKL_INT
*laf , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdpttrsv (char *uplo , MKL_INT *n , MKL_INT *nrhs , double *d , double *e ,
MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *descb , double *af ,
MKL_INT *laf , double *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pcpttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , float *d ,
MKL_Complex8 *e , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib ,
MKL_INT *descb , MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pzpttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , double *d ,
MKL_Complex16 *e , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib ,
MKL_INT *descb , MKL_Complex16 *af , MKL_INT *laf , MKL_Complex16 *work , MKL_INT
*lwork , MKL_INT *info );
```

Include Files

Description

The `p?pttrsv` function solves a tridiagonal triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(jb:jb+n-1, 1:nrhs)$$

or

$$A(1:n, ja:ja+n-1)^T * X = B(jb:jb+n-1, 1:nrhs) \text{ for real flavors,}$$

$$A(1:n, ja:ja+n-1)^H * X = B(jb:jb+n-1, 1:nrhs) \text{ for complex flavors,}$$

where $A(1:n, ja:ja+n-1)$ is a tridiagonal triangular matrix factor produced by the Cholesky factorization code `p?pttrf` and is stored in $A(1:n, ja:ja+n-1)$ and af . The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to `uplo`.

The function `p?pttrf` must be called first.

Input Parameters

| | |
|--------------------|---|
| <code>uplo</code> | (global) Must be 'U' or 'L'. If <code>uplo = 'U'</code> , upper triangle of $A(1:n, ja:ja+n-1)$ is stored; If <code>uplo = 'L'</code> , lower triangle of $A(1:n, ja:ja+n-1)$ is stored. |
| <code>trans</code> | (global) Must be 'N' or 'C'. If <code>trans = 'N'</code> , solve with $A(1:n, ja:ja+n-1)$; If <code>trans = 'C'</code> (for complex flavors), solve with conjugate transpose $(A(1:n, ja:ja+n-1))^H$. |
| <code>n</code> | (global) The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$. $n \geq 0$. |
| <code>nrhs</code> | (global) The number of right hand sides; the number of columns of the distributed submatrix $B(jb:jb+n-1, 1:nrhs)$; $nrhs \geq 0$. |
| <code>d</code> | (local) Pointer to the local part of the global vector storing the main diagonal of the matrix; must be of size $\geq nb_a$. |
| <code>e</code> | (local) |

| | |
|--------------|---|
| | <p>Pointer to the local part of the global vector du storing the upper diagonal of the matrix; must be of size $\geq nb_a$. Globally, $du(n)$ is not referenced, and du must be aligned with d.</p> |
| <i>ja</i> | <p>(global) The index in the global matrix A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).</p> |
| <i>desca</i> | <p>(global and local) array of size $dlen_$. The array descriptor for the distributed matrix A.</p> <p>If 1D type ($dtype_a = 501$ or 502), then $dlen \geq 7$;</p> <p>If 2D type ($dtype_a = 1$), then $dlen \geq 9$.</p> <p>Contains information on mapping of A to memory. See ScaLAPACK manual for full description and options.</p> |
| <i>b</i> | <p>(local)</p> <p>Pointer into the local memory to an array of local lead size $lld_b \geq nb$.</p> <p>On entry, this array contains the local pieces of the right hand sides $B(jb:jb+n-1, 1:nrhs)$.</p> |

p?potf2

Computes the Cholesky factorization of a symmetric/Hermitian positive definite matrix (local unblocked algorithm).

Syntax

```
void pspotf2 (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *info );

void pdpotf2 (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *info );

void pcpotf2 (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *info );

void pzpotf2 (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?potf2` function computes the Cholesky factorization of a real symmetric or complex Hermitian positive definite distributed matrix sub (*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1).

The factorization has the form

sub(*A*) = *U***U*, if *uplo* = 'U', or sub(*A*) = *L***L'*, if *uplo* = 'L',

where *U* is an upper triangular matrix, *L* is lower triangular. *X'* denotes transpose (conjugate transpose) of *X*.

Input Parameters

| | |
|---------------|---|
| <i>uplo</i> | (global) Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix <i>A</i> is stored. = 'U': upper triangle of sub (<i>A</i>) is stored; = 'L': lower triangle of sub (<i>A</i>) is stored. |
| <i>n</i> | (global) The number of rows and columns to be operated on, that is, the order of the distributed matrix sub (<i>A</i>). $n \geq 0$. |
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$ containing the local pieces of the <i>n</i> -by- <i>n</i> symmetric distributed matrix sub(<i>A</i>) to be factored. If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of sub(<i>A</i>) contains the upper triangular matrix and the strictly lower triangular part of this matrix is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of sub(<i>A</i>) contains the lower triangular matrix and the strictly upper triangular part of sub(<i>A</i>) is not referenced. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the sub(<i>A</i>), respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . |

Output Parameters

| | |
|-------------|--|
| <i>a</i> | (local) On exit, if <i>uplo</i> = 'U', the upper triangular part of the distributed matrix contains the Cholesky factor <i>U</i> ; if <i>uplo</i> = 'L', the lower triangular part of the distributed matrix contains the Cholesky factor <i>L</i> . |
| <i>info</i> | (local) = 0: successful exit < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> -1, had an illegal value, then <i>info</i> = - (<i>i</i> *100 + <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . |

> 0 : if $info = k$, the leading minor of order k is not positive definite, and the factorization could not be completed.

p?rot

Applies a planar rotation to two distributed vectors.

Syntax

```
void psrot(MKL_INT* n, float* x, MKL_INT* ix, MKL_INT* jx, MKL_INT* descx, MKL_INT*
incx, float* y, MKL_INT* iy, MKL_INT* jy, MKL_INT* descy, MKL_INT* incy, float* cs,
float* sn, float* work, MKL_INT* lwork, MKL_INT* info);
```

```
void pdrot(MKL_INT* n, double* x, MKL_INT* ix, MKL_INT* jx, MKL_INT* descx, MKL_INT*
incx, double* y, MKL_INT* iy, MKL_INT* jy, MKL_INT* descy, MKL_INT* incy, double* cs,
double* sn, double* work, MKL_INT* lwork, MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

p?rot applies a planar rotation defined by cs and sn to the two distributed vectors $sub(x)$ and $sub(y)$.

Input Parameters

| | |
|---------|--|
| n | (global) The number of elements to operate on when applying the planar rotation to x and y ($n \geq 0$). |
| x | (local) array of size $((j_x-1)*m_x + ix + (n-1)*abs(incx))$ This array contains the entries of the distributed vector $sub(x)$. |
| ix | (global) The global row index of the submatrix of the distributed matrix x to operate on. If $incx = 1$, then it is required that $ix = iy$. $1 \leq ix \leq m_x$. |
| jx | (global) The global column index of the submatrix of the distributed matrix x to operate on. If $incx = m_x$, then it is required that $jx = jy$. $1 \leq ix \leq n_x$. |
| $descx$ | (global and local) array of size 9 The array descriptor of the distributed matrix x . |
| $incx$ | (global) The global increment for the elements of x . Only two values of $incx$ are supported in this version, namely 1 and m_x . Moreover, it must hold that $incx = m_x$ if $incy = m_y$ and that $incx = 1$ if $incy = 1$. |

| | |
|---------------|--|
| <i>y</i> | (local) array of size $((jy-1)*m_y + iy + (n-1)*abs(incy))$ This array contains the entries of the distributed vector <code>sub(y)</code> . |
| <i>iy</i> | (global) The global row index of the submatrix of the distributed matrix <i>y</i> to operate on. If <i>incy</i> = 1, then it is required that <i>iy</i> = <i>ix</i> . $1 \leq iy \leq m_y$. |
| <i>jy</i> | (global) The global column index of the submatrix of the distributed matrix <i>y</i> to operate on. If <i>incy</i> = <i>m_x</i> , then it is required that <i>jy</i> = <i>jx</i> . $1 \leq jy \leq m_y$. |
| <i>descy</i> | (global and local) array of size 9 The array descriptor of the distributed matrix <i>y</i> . |
| <i>incy</i> | (global) The global increment for the elements of <i>y</i> . Only two values of <i>incy</i> are supported in this version, namely 1 and <i>m_y</i> . Moreover, it must hold that <i>incy</i> = <i>m_y</i> if <i>incx</i> = <i>m_x</i> and that <i>incy</i> = 1 if <i>incx</i> = 1. |
| <i>cs, sn</i> | (global) The parameters defining the properties of the planar rotation. It must hold that $0 \leq cs, sn \leq 1$ and that $sn^2 + cs^2 = 1$. The latter is hardly checked in finite precision arithmetics. |
| <i>work</i> | (local workspace) array of size <i>lwork</i> |
| <i>lwork</i> | (local) The length of the workspace array <i>work</i> . If <i>incx</i> = 1 and <i>incy</i> = 1, then <i>lwork</i> = $2*m_x$ If <i>lwork</i> = -1, then a workspace query is assumed; the function only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by pxerbla . |

OUTPUT Parameters

| | |
|-----------------|--|
| <i>x</i> | |
| <i>y</i> | |
| <i>work</i> [0] | On exit, if <i>info</i> = 0, <i>work</i> [0] returns the optimal <i>lwork</i> |
| <i>info</i> | (global) = 0: successful exit < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value. If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> -1, had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . |

MKL_INT *descx , MKL_INT *incx );
```

Include Files

- mkl_scalapack.h

Description

The p?rscl function multiplies an n -element real/complex vector $\text{sub}(X)$ by the real scalar $1/a$. This is done without overflow or underflow as long as the final result $\text{sub}(X)/a$ does not overflow or underflow.

$\text{sub}(X)$ denotes $X(ix:ix+n-1, jx:jx)$, if $incx = 1$,

and $X(ix:ix, jx:jx+n-1)$, if $incx = m_x$.

Input Parameters

| | |
|---------|---|
| n | (global) The number of components of the distributed vector $\text{sub}(X)$. $n \geq 0$. |
| sa | The scalar a that is used to divide each component of the vector $\text{sub}(X)$. This parameter must be ≥ 0 . |
| sx | Array containing the local pieces of a distributed matrix of size of at least $((jx-1)*m_x + ix + (n-1)*abs(incx))$. This array contains the entries of the distributed vector $\text{sub}(X)$. |
| ix | (global) The row index of the submatrix of the distributed matrix X to operate on. |
| jx | (global) The column index of the submatrix of the distributed matrix X to operate on. |
| $descx$ | (global and local) Array of size 9. The array descriptor for the distributed matrix X . |
| $incx$ | (global) |

The increment for the elements of X . This version supports only two values of $incx$, namely 1 and m_x .

Output Parameters

sx On exit, the result x/a .

Include Files

- mkl_scalapack.h

Description

The p?sygs2/p?hegs2 function reduces a real symmetric-definite or a complex Hermitian positive-definite generalized eigenproblem to standard form.

Here $\text{sub}(A)$ denotes $A(ia:ia+n-1, ja:ja+n-1)$, and $\text{sub}(B)$ denotes $B(ib:ib+n-1, jb:jb+n-1)$.

If $ibtype = 1$, the problem is

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x$$

and $\text{sub}(A)$ is overwritten by

$\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$ or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$ - for real flavors, and

$\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$ or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$ - for complex flavors.

If $ibtype = 2$ or 3 , the problem is

$$\text{sub}(A) * \text{sub}(B) x = \lambda * x \text{ or } \text{sub}(B) * \text{sub}(A) x = \lambda * x$$

and $\text{sub}(A)$ is overwritten by

$U^* \text{sub}(A) * U^T$ or $L^* * T^* \text{sub}(A) * L^-$ for real flavors and

$U^* \text{sub}(A) * U^H$ or $L^* * H^* \text{sub}(A) * L^-$ for complex flavors.

The matrix $\text{sub}(B)$ must have been previously factorized as $U^T * U$ or $L^* L^T$ (for real flavors), or as $U^H * U$ or $L^* L^H$ (for complex flavors) by [p?potrf](#).

Input Parameters

| | |
|---------------|---|
| <i>ibtype</i> | (global) = 1: compute $\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$ for real functions, and $\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$ for complex functions; = 2 or 3: compute $U^* \text{sub}(A) * U^T$, or $L^T * \text{sub}(A) * L$ for real functions, and $U^* \text{sub}(A) * U^H$ or $L^H * \text{sub}(A) * L$ for complex functions. |
| <i>uplo</i> | (global) Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored, and how $\text{sub}(B)$ is factorized. = 'U': Upper triangular of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factorized as $U^T * U$ (for real functions) or as $U^H * U$ (for complex functions). = 'L': Lower triangular of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factorized as $L^* L^T$ (for real functions) or as $L^* L^H$ (for complex functions) |
| <i>n</i> | (global) The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$. $n \geq 0$. |
| <i>a</i> | (local) Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$. On entry, this array contains the local pieces of the n -by- n symmetric/Hermitian distributed matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced. |
| <i>ia, ja</i> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the $\text{sub}(A)$, respectively. |
| <i>desca</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A . |
| <i>B</i> | (local) Pointer into the local memory to an array of size $lld_b * LOCC(jb+n-1)$. |

On entry, this array contains the local pieces of the triangular factor from the Cholesky factorization of $\text{sub}(B)$ as returned by `p?potrf`.

ib, jb

(global)

The row and column indices in the global matrix B indicating the first row and the first column of the $\text{sub}(B)$, respectively.

descb

(global and local) array of size *dlen_*. The array descriptor for the distributed matrix B .

Output Parameters

a

(local)

On exit, if *info* = 0, the transformed matrix is stored in the same format as $\text{sub}(A)$.

info

= 0: successful exit.

< 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value,

then *info* = - (*i**100+ *j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (local unblocked algorithm).

Syntax

```
void pssytd2 (char *uplo, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *d, float *e, float *tau, float *work, MKL_INT *lwork, MKL_INT *info);
```

```
void pdsytd2 (char *uplo, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *d, double *e, double *tau, double *work, MKL_INT *lwork, MKL_INT *info);
```

```
void pchetd2 (char *uplo, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, float *d, float *e, MKL_Complex8 *tau, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);
```

```
void pzhetd2 (char *uplo, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT *desca, double *d, double *e, MKL_Complex16 *tau, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);
```

Include Files

- `mkl_scalapack.h`

Description

The `p?sytd2/p?hetd2` function reduces a real symmetric/complex Hermitian matrix $\text{sub}(A)$ to symmetric/Hermitian tridiagonal form T by an orthogonal/unitary similarity transformation:

$$Q^* \text{sub}(A) Q = T, \text{ where } \text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1).$$

Input Parameters

| | |
|---------------------|---|
| <code>uplo</code> | (global) Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored: = 'U': upper triangular = 'L': lower triangular |
| <code>n</code> | (global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$. $n \geq 0$. |
| <code>a</code> | (local) Pointer into the local memory to an array of size $lld_a * LOC_c(\text{ja}+n-1)$. On entry, this array contains the local pieces of the n -by- n symmetric/Hermitian distributed matrix $\text{sub}(A)$. If <code>uplo = 'U'</code> , the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced. If <code>uplo = 'L'</code> , the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced. |
| <code>ia, ja</code> | (global) The row and column indices in the global matrix A indicating the first row and the first column of the $\text{sub}(A)$, respectively. |
| <code>desca</code> | (global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix A . |
| <code>work</code> | (local) The array <code>work</code> is a temporary workspace array of size <code>lwork</code> . |

Output Parameters

| | |
|----------------|---|
| <code>a</code> | On exit, if <code>uplo = 'U'</code> , the diagonal and first superdiagonal of $\text{sub}(A)$ are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements above the first superdiagonal, with the array <code>tau</code> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors; if <code>uplo = 'L'</code> , the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements below the first subdiagonal, with the array <code>tau</code> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors. See the <i>Application Notes</i> below. |
|----------------|---|

| | |
|----------------|---|
| <i>d</i> | (local) Array of size $LOCc(ja+n-1)$. The diagonal elements of the tridiagonal matrix T : $d[i] = A(i+1,i+1)$, where $i=0,1, \dots, LOCc(ja+n-1) - 1$; d is tied to the distributed matrix A . |
| <i>e</i> | (local) Array of size $LOCc(ja+n-1)$, if $uplo = 'U'$, $LOCc(ja+n-2)$ otherwise. The off-diagonal elements of the tridiagonal matrix T : $e[i] = A(i+1,i+2)$ if $uplo = 'U'$, $e[i] = A(i+2,i+1)$ if $uplo = 'L'$, where $i=0,1, \dots, LOCc(ja+n-1) - 1$. e is tied to the distributed matrix A . |
| <i>tau</i> | (local) Array of size $LOCc(ja+n-1)$. The scalar factors of the elementary reflectors. tau is tied to the distributed matrix A . |
| <i>work[0]</i> | On exit, <i>work[0]</i> returns the minimal and optimal value of <i>lwork</i> . |
| <i>lwork</i> | (local or global) The size of the workspace array <i>work</i> . $lwork$ is local input and must be at least $lwork \geq 3n$. If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla . |
| <i>info</i> | (local) = 0: successful exit < 0: if the i -th argument, indexed $i-1$, is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$. |

Application Notes

If $uplo = 'U'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) * \dots * H(2) * H(1)$$

Each $H(i)$ has the form

$$H(i) = I - tau * v * v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and τ in $\tau[ja+i-2]$.

If $uplo = 'L'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1)*H(2)*\dots*H(n-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau*v*v',$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and τ in $\tau[ja+i-2]$.

The contents of sub (A) on exit are illustrated by the following examples with $n = 5$:

$$\begin{array}{l} \text{if } uplo='U': \\ \left[\begin{array}{ccccc} d & e & v_2 & v_3 & v_4 \\ & d & e & v_3 & v_4 \\ & & d & e & v_4 \\ & & & d & e \\ & & & & d \end{array} \right] \end{array} \qquad \begin{array}{l} \text{if } uplo='L': \\ \left[\begin{array}{ccccc} d & & & & \\ e & d & & & \\ v_1 & e & d & & \\ v_1 & v_2 & e & d & \\ v_1 & v_2 & v_3 & e & d \end{array} \right] \end{array}$$

where d and e denotes diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

NOTE

The distributed matrix sub(A) must verify some alignment properties, namely the following expression should be true:

$$(mb_a == nb_a \ \&\& \ iroffa == icoffa) \text{ where } iroffa = \text{mod}(ia - 1, mb_a) \text{ and } icoffa = \text{mod}(ja - 1, nb_a).$$

p?trord

Reorders the Schur factorization of a general matrix.

Syntax

```
void pstrord( char* compq, MKL_INT* select, MKL_INT* para, MKL_INT* n, float* t,
MKL_INT* it, MKL_INT* jt, MKL_INT* desct, float* q, MKL_INT* iq, MKL_INT* jq, MKL_INT*
descq, float* wr, float* wi, MKL_INT* m, float* work, MKL_INT* lwork, MKL_INT* iwork,
MKL_INT* liwork, MKL_INT* info);
```

```
void pdtrord(char* compq, MKL_INT* select, MKL_INT* para, MKL_INT* n, double* t,
MKL_INT* it, MKL_INT* jt, MKL_INT* desct, double* q, MKL_INT* iq, MKL_INT* jq,
MKL_INT* descq, double* wr, double* wi, MKL_INT* m, double* work, MKL_INT* lwork,
MKL_INT* iwork, MKL_INT* liwork, MKL_INT* info);
```

Include Files

- `mkl_scalapack.h`

Description

`p?trord` reorders the real Schur factorization of a real matrix $A = Q^*T^*Q^T$, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T , and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

T must be in Schur form (as returned by `p?lahqr`), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks.

This function uses a delay and accumulate procedure for performing the off-diagonal updates.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

| | |
|----------------------|---|
| <code>compq</code> | (global) = 'V': update the matrix q of Schur vectors; = 'N': do not update q . |
| <code>select</code> | (global) array of size n <i>select</i> specifies the eigenvalues in the selected cluster. To select a real eigenvalue $w(j)$, <i>select</i> [$j-1$] must be set to 1. To select a complex conjugate pair of eigenvalues $w(j)$ and $w(j+1)$, corresponding to a 2-by-2 diagonal block, either <i>select</i> [$j-1$] or <i>select</i> [j] or both must be set to 1; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded. |
| <code>para</code> | (global) Block parameters: |
| <code>para[0]</code> | maximum number of concurrent computational windows allowed in the algorithm; $0 < para[0] \leq \min(nprow, npcot)$ must hold; |
| <code>para[1]</code> | number of eigenvalues in each window; $0 < para[1] < para[2]$ must hold; |
| <code>para[2]</code> | window size; $para[1] < para[2] < mb_t$ must hold; |

| | |
|-----------------|---|
| <i>para</i> [3] | minimal percentage of FLOPS required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations; $0 \leq \textit{para}[3] \leq 100$ must hold; |
| <i>para</i> [4] | width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form; $0 < \textit{para}[4] \leq \textit{mb_t}$ must hold. |
| <i>para</i> [5] | the maximum number of eigenvalues moved together over a process border; in practice, this will be approximately half of the cross border window size; $0 < \textit{para}[5] \leq \textit{para}[1]$ must hold. |
| <i>n</i> | (global) The order of the globally distributed matrix <i>t</i> . $n \geq 0$. |
| <i>t</i> | (local) array of size $\textit{lld_t} * \textit{LOC}_c(n)$. The local pieces of the global distributed upper quasi-triangular matrix <i>T</i> , in Schur form. |
| <i>it, jt</i> | (global) The row and column index in the global matrix <i>T</i> indicating the first column of <i>T</i> . $it = jt = 1$ must hold (see Application Notes). |
| <i>desct</i> | (global and local) array of size $\textit{dlen_}$. The array descriptor for the global distributed matrix <i>T</i> . |
| <i>q</i> | (local) array of size $\textit{lld_q} * \textit{LOC}_c(n)$. On entry, if $\textit{compq} = 'V'$, the local pieces of the global distributed matrix <i>Q</i> of Schur vectors. If $\textit{compq} = 'N'$, <i>q</i> is not referenced. |
| <i>iq, jq</i> | (global) The column index in the global matrix <i>Q</i> indicating the first column of <i>Q</i> . $iq = jq = 1$ must hold (see Application Notes). |
| <i>descq</i> | (global and local) array of size $\textit{dlen_}$. The array descriptor for the global distributed matrix <i>Q</i> . |
| <i>work</i> | (local workspace) array of size \textit{lwork} |
| <i>lwork</i> | (local) The size of the array <i>work</i> . If $\textit{lwork} = -1$, then a workspace query is assumed; the function only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by pxerbla . |

iwork (local workspace) array of size *liwork*

liwork (local)
 The size of the array *iwork*.
 If *liwork* = -1, then a workspace query is assumed; the function only calculates the optimal size of the *iwork* array, returns this value as the first entry of the *iwork* array, and no error message related to *liwork* is issued by `pxerbla`

OUTPUT Parameters

select (global) array of size *n*
 The (partial) reordering is displayed.

t On exit, *t* is overwritten by the local pieces of the reordered matrix *T*, again in Schur form, with the selected eigenvalues in the globally leading diagonal blocks.

q On exit, if *compq* = 'V', *q* has been postmultiplied by the global orthogonal transformation matrix which reorders *t*; the leading *m* columns of *q* form an orthonormal basis for the specified invariant subspace.
 If *compq* = 'N', *q* is not referenced.

wr, wi (global) array of size *n*
 The real and imaginary parts, respectively, of the reordered eigenvalues of the matrix *T*. The eigenvalues are in principle stored in the same order as on the diagonal of *T*, with $wr[i] = T(i+1,i+1)$ and, if $T(i:i+1,i:i+1)$ is a 2-by-2 diagonal block, $wi[i-1] > 0$ and $wi[i] = -wi[i-1]$.
 Note also that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

m (global)
 The size of the specified invariant subspace.
 $0 \leq m \leq n$.

work[0] On exit, if *info* = 0, *work*[0] returns the optimal *lwork*.

iwork[0] On exit, if *info* = 0, *iwork*[0] returns the optimal *liwork*.

info (global)
 = 0: successful exit
 < 0: if *info* = -*i*, the *i*-th argument had an illegal value. If the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value, then *info* = -(*i**1000+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.
 > 0: here we have several possibilities

- Reordering of *t* failed because some eigenvalues are too close to separate (the problem is very ill-conditioned);

t may have been partially reordered, and wr and wi contain the eigenvalues in the same order as in t .

On exit, $info = \{\text{the index of } t \text{ where the swap failed (indexing starts at 1)}\}$.

- A 2-by-2 block to be reordered split into two 1-by-1 blocks and the second block failed to swap with an adjacent block.

On exit, $info = \{\text{the index of } t \text{ where the swap failed}\}$.

- If $info = n+1$, there is no valid BLACS context (see the BLACS documentation for details).

Application Notes

The following alignment requirements must hold:

- $mb_t = nb_t = mb_q = nb_q$
- $rsrc_t = rsrc_q$
- $csrc_t = csrc_q$

All matrices must be blocked by a block factor larger than or equal to two (3). This is to simplify reordering across processor borders in the presence of 2-by-2 blocks.

This algorithm cannot work on submatrices of t and q , i.e., $it = jt = iq = jq = 1$ must hold. This is however no limitation since [p?lahqr](#) does not compute Schur forms of submatrices anyway.

Parallel execution recommendations:

- Use a square grid, if possible, for maximum performance. The block parameters in $para$ should be kept well below the data distribution block size.
- In general, the parallel algorithm strives to perform as much work as possible without crossing the block borders on the main block diagonal.

See Also

Input Parameters

| | |
|---------------|--|
| <i>job</i> | (global) Specifies whether condition numbers are required for the cluster of eigenvalues (<i>s</i>) or the invariant subspace (<i>sep</i>): = 'N': no condition numbers are required; = 'E': only the condition number for the cluster of eigenvalues is computed (<i>s</i>); = 'V': only the condition number for the invariant subspace is computed (<i>sep</i>); = 'B': condition numbers for both the cluster and the invariant subspace are computed (<i>s</i> and <i>sep</i>). |
| <i>compq</i> | (global) = 'V': update the matrix <i>q</i> of Schur vectors; = 'N': do not update <i>q</i> . |
| <i>select</i> | (global) array of size <i>n</i> <i>select</i> specifies the eigenvalues in the selected cluster. To select a real eigenvalue $w(j)$, <i>select</i> [<i>j</i> -1] must be set to a non-zero number. To select a complex conjugate pair of eigenvalues $w(j)$ and $w(j+1)$, corresponding to a 2-by-2 diagonal block, either <i>select</i> [<i>j</i> -1] or <i>select</i> [<i>j</i>] or both must be set to a non-zero number; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded. |
| <i>para</i> | (global) Block parameters: |

| | |
|-----------------|---|
| <i>para</i> [0] | maximum number of concurrent computational windows allowed in the algorithm; $0 < para[0] \leq \min(NPROW, NPCOL)$ must hold; |
| <i>para</i> [1] | number of eigenvalues in each window; $0 < para[1] < para[2]$ must hold; |
| <i>para</i> [2] | window size; $para[1] < para[2] < mb_t$ must hold; |
| <i>para</i> [3] | minimal percentage of flops required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations; $0 \leq para[3] \leq 100$ must hold; |
| <i>para</i> [4] | width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form; $0 < para[4] \leq mb_t$ must hold. |
| <i>para</i> [5] | the maximum number of eigenvalues moved together over a process border; in practice, this will be approximately half of the cross border window size $0 < para[5] \leq para[1]$ must hold; |
| <i>n</i> | (global) The order of the globally distributed matrix <i>t</i> . $n \geq 0$. |
| <i>t</i> | (local) array of size $lld_t * LOC_c(n)$. The local pieces of the global distributed upper quasi-triangular matrix <i>T</i> , in Schur form. |
| <i>it, jt</i> | (global) The row and column index in the global matrix <i>T</i> indicating the first column of <i>T</i> . $it = jt = 1$ must hold (see Application Notes). |
| <i>desct</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the global distributed matrix <i>T</i> . |
| <i>q</i> | (local) array of size $lld_q * LOC_c(n)$. On entry, if <i>compq</i> = 'V', the local pieces of the global distributed matrix <i>Q</i> of Schur vectors. If <i>compq</i> = 'N', <i>q</i> is not referenced. |
| <i>iq, jq</i> | (global) The column index in the global matrix <i>Q</i> indicating the first column of <i>Q</i> . $iq = jq = 1$ must hold (see Application Notes). |
| <i>descq</i> | (global and local) array of size <i>dlen_</i> . The array descriptor for the global distributed matrix <i>Q</i> . |

| | |
|---------------|--|
| <i>work</i> | (local workspace) array of size <i>lwork</i> |
| <i>lwork</i> | (local) The size of the array <i>work</i> . If <i>lwork</i> = -1, then a workspace query is assumed; the function only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by pxerbla . |
| <i>iwork</i> | (local workspace) array of size <i>liwork</i> |
| <i>liwork</i> | (local) The size of the array <i>iwork</i> . If <i>liwork</i> = -1, then a workspace query is assumed; the function only calculates the optimal size of the <i>iwork</i> array, returns this value as the first entry of the <i>iwork</i> array, and no error message related to <i>liwork</i> is issued by pxerbla . |

OUTPUT Parameters

| | |
|---------------|---|
| <i>t</i> | <i>t</i> is overwritten by the local pieces of the reordered matrix <i>T</i> , again in Schur form, with the selected eigenvalues in the globally leading diagonal blocks. |
| <i>q</i> | On exit, if <i>compq</i> = 'V', <i>q</i> has been postmultiplied by the global orthogonal transformation matrix which reorders <i>t</i> ; the leading <i>m</i> columns of <i>q</i> form an orthonormal basis for the specified invariant subspace. If <i>compq</i> = 'N', <i>q</i> is not referenced. |
| <i>wr, wi</i> | (global) array of size <i>n</i> The real and imaginary parts, respectively, of the reordered eigenvalues of the matrix <i>T</i> . The eigenvalues are in principle stored in the same order as on the diagonal of <i>T</i> , with <i>wr</i> [<i>j</i>] = <i>T</i> (<i>i</i> +1, <i>i</i> +1) and, if <i>T</i> (<i>i</i> : <i>i</i> +1, <i>i</i> : <i>i</i> +1) is a 2-by-2 diagonal block, <i>wi</i> [<i>j</i> -1] > 0 and <i>wi</i> [<i>j</i>] = - <i>wi</i> [<i>j</i> -1]. Note also that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering. |
| <i>m</i> | (global) The size of the specified invariant subspace. $0 \leq m \leq n$. |
| <i>s</i> | (global) If <i>job</i> = 'E' or 'B', <i>s</i> is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues. <i>s</i> cannot underestimate the true reciprocal condition number by more than a factor of \sqrt{n} . If <i>m</i> = 0 or <i>n</i> , <i>s</i> = 1. If <i>job</i> = 'N' or 'V', <i>s</i> is not referenced. |
| <i>sep</i> | (global) |

If $job = 'V'$ or $'B'$, sep is the estimated reciprocal condition number of the specified invariant subspace. If

$m = 0$ or n , $sep = \text{norm}(t)$.

If $job = 'N'$ or $'E'$, sep is not referenced.

$work[0]$ On exit, if $info = 0$, $work[0]$ returns the optimal $lwork$.

$iwork[0]$ On exit, if $info = 0$, $iwork[0]$ returns the optimal $liwork$.

$info$ (global)

= 0: successful exit

< 0: if $info = -i$, the i -th argument had an illegal value.

If the i -th argument is an array and the j -th entry, indexed $j-1$, had an illegal value, then $info = -(i*1000+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

> 0: here we have several possibilities

- Reordering of t failed because some eigenvalues are too close to separate (the problem is very ill-conditioned); t may have been partially reordered, and wr and wi contain the eigenvalues in the same order as in t .

On exit, $info = \{\text{the index of } t \text{ where the swap failed (indexing starts at 1)}\}$.

- A 2-by-2 block to be reordered split into two 1-by-1 blocks and the second block failed to swap with an adjacent block.

On exit, $info = \{\text{the index of } t \text{ where the swap failed}\}$.

- If $info = n+1$, there is no valid BLACS context (see the BLACS documentation for details).

Application Notes

The following alignment requirements must hold:

- $mb_t = nb_t = mb_q = nb_q$
- $rsrc_t = rsrc_q$
- $csrc_t = csrc_q$

All matrices must be blocked by a block factor larger than or equal to two (3). This to simplify reordering across processor borders in the presence of 2-by-2 blocks.

This algorithm cannot work on submatrices of t and q , i.e., $it = jt = iq = jq = 1$ must hold. This is however no limitation since [p?lahqr](#) does not compute Schur forms of submatrices anyway.

For parallel execution, use a square grid, if possible, for maximum performance. The block parameters in $para$ should be kept well below the data distribution block size.

In general, the parallel algorithm strives to perform as much work as possible without crossing the block borders on the main block diagonal.

p?trti2

Computes the inverse of a triangular matrix (local unblocked algorithm).

Syntax

```
void pstrti2 (char *uplo , char *diag , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
void pdtrti2 (char *uplo , char *diag , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
void pctrti2 (char *uplo , char *diag , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
void pztrti2 (char *uplo , char *diag , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?trti2 function computes the inverse of a real/complex upper or lower triangular block matrix sub (A) = $A(ia:ia+n-1, ja:ja+n-1)$.

This matrix should be contained in one and only one process memory space (local operation).

Input Parameters

| | |
|-------------|--|
| <i>uplo</i> | (global) Specifies whether the matrix sub (A) is upper or lower triangular. = 'U': sub (A) is upper triangular = 'L': sub (A) is lower triangular. |
| <i>diag</i> | (global) Specifies whether or not the matrix A is unit triangular. = 'N': sub (A) is non-unit triangular = 'U': sub (A) is unit triangular. |
| <i>n</i> | (global) The number of rows and columns to be operated on, i.e., the order of the distributed submatrix sub (A). $n \geq 0$. |
| <i>a</i> | (local) Pointer into the local memory to an array, size $lld_a * LOCC(ja+n-1)$. On entry, this array contains the local pieces of the triangular matrix sub(A). If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of the matrix sub(A) contains the upper triangular part of the matrix, and the strictly lower triangular part of sub(A) is not referenced. |

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of the matrix sub(*A*) contains the lower triangular part of the matrix, and the strictly upper triangular part of sub(*A*) is not referenced. If *diag* = 'U', the diagonal elements of sub(*A*) are not referenced either and are assumed to be 1.

ia, ja

(global)

The row and column indices in the global matrix *A* indicating the first row and the first column of the sub(*A*), respectively.

desca

(global and local) array of size *dlen_*. The array descriptor for the distributed matrix *A*.

Output Parameters

a

On exit, the (triangular) inverse of the original matrix, in the same storage format.

info

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value,

then *info* = - (*i**100+*j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

See Also

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

?lahqr2

Updates the eigenvalues and Schur decomposition.

Syntax

```
void clahqr2 (const MKL_INT* wantt, const MKL_INT* wantz, const MKL_INT* n, const
MKL_INT* ilo, const MKL_INT* ihi, MKL_Complex8* h, const MKL_INT* ldh, MKL_Complex8*
w, const MKL_INT* iloz, const MKL_INT* ihiz, MKL_Complex8* z, const MKL_INT* ldz,
MKL_INT* info);
```

```
void zlahqr2 (const MKL_INT* wantt, const MKL_INT* wantz, const MKL_INT* n, const
MKL_INT* ilo, const MKL_INT* ihi, MKL_Complex16* h, const MKL_INT* ldh, MKL_Complex16*
w, const MKL_INT* iloz, const MKL_INT* ihiz, MKL_Complex16* z, const MKL_INT* ldz,
MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

?lahqr2 is an auxiliary routine called by ?hseqr to update the eigenvalues and Schur decomposition already computed by ?hseqr, by dealing with the Hessenberg submatrix in rows and columns *ilo* to *ihi*. This version of ?lahqr (not the standard LAPACK version) uses a double-shift algorithm (like LAPACK's ?lahqr). Unlike the standard LAPACK convention, this does not assume the subdiagonal is real, nor does it work to preserve this quality if given.

Input Parameters

| | |
|-------------------|--|
| <i>wantt</i> | <p>≠ 0: the full Schur form <i>T</i> is required; = 0: only eigenvalues are required.</p> |
| <i>wantz</i> | <p>≠ 0: the matrix of Schur vectors <i>Z</i> is required; = 0: Schur vectors are not required.</p> |
| <i>n</i> | The order of the matrix <i>H</i> . $n \geq 0$. |
| <i>ilo, ihi</i> | <p>It is assumed that the matrix <i>H</i> is upper triangular in rows and columns <i>ihi</i> + 1 : <i>n</i>, and that matrix element $H(i_{lo}, i_{lo}-1) = 0$ (unless $i_{lo} = 1$). ?lahqr works primarily with the Hessenberg submatrix in rows and columns <i>ilo</i> to <i>ihi</i>, but applies transformations to all of <i>h</i> if <i>wantt</i> is nonzero. $1 \leq i_{lo} \leq \max(1, i_{hi}); i_{hi} \leq n$.</p> |
| <i>h</i> | <p>Array, size $ldh * n$. On entry, the upper Hessenberg matrix <i>H</i>.</p> |
| <i>ldh</i> | The leading dimension of the array <i>h</i> . $ldh \geq \max(1, n)$. |
| <i>iloz, ihiz</i> | <p>Specify the rows of <i>Z</i> to which transformations must be applied if <i>wantz</i> ≠ 0. $1 \leq i_{loz} \leq i_{lo}; i_{hi} \leq i_{hiz} \leq n$.</p> |
| <i>z</i> | <p>Array, size $ldz * n$. If <i>wantz</i> ≠ 0, on entry <i>z</i> must contain the current matrix <i>Z</i> of transformations. If <i>wantz</i> = 0, <i>z</i> is not referenced.</p> |
| <i>ldz</i> | The leading dimension of the array <i>z</i> . $ldz \geq \max(1, n)$. |

Output Parameters

| | |
|----------|---|
| <i>h</i> | On exit, if <i>wantt</i> ≠ 0, <i>h</i> is upper triangular in rows and columns <i>ilo</i> : <i>ihi</i> . If <i>wantt</i> = 0, the contents of <i>h</i> are unspecified on exit. |
| <i>w</i> | <p>Array, size (<i>n</i>) The computed eigenvalues <i>ilo</i> to <i>ihi</i> are stored in the corresponding elements of <i>w</i>. If <i>wantt</i> ≠ 0, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in <i>h</i>, with $w[i] = H(i, i)$.</p> |

z If *wantz* ≠ 0, on exit *z* has been updated; transformations are applied only to the submatrix $Z(i_{loz}:i_{hiz}, i_{lo}:i_{hi})$. If *wantz* = 0, *z* is not referenced.

info = 0: successful exit
 > 0: if *info* = *i*, ?lahqr failed to compute all the eigenvalues *ilo* to *ihi* in a total of $30*(i_{hi}-i_{lo}+1)$ iterations; elements $w[i:i_{hi} - 1]$ contain those eigenvalues which have been successfully computed.

?lamsh

Sends multiple shifts through a small (single node) matrix to maximize the number of bulges that can be sent through.

Syntax

```
void slamsh (float *s, const MKL_INT *lds, MKL_INT *nbulge, const MKL_INT *jblk, float
*h, const MKL_INT *ldh, const MKL_INT *n, const float *ulp );

void dlamsh (double *s, const MKL_INT *lds, MKL_INT *nbulge, const MKL_INT *jblk,
double *h, const MKL_INT *ldh, const MKL_INT *n, const double *ulp );

void clamsh (MKL_Complex8 *s , const MKL_INT *lds , MKL_INT *nbulge , const MKL_INT
*jblk , MKL_Complex8 *h , const MKL_INT *ldh , const MKL_INT *n , const float *ulp );

void zlamsh (MKL_Complex16 *s , const MKL_INT *lds , MKL_INT *nbulge , const MKL_INT
*jblk , MKL_Complex16 *h , const MKL_INT *ldh , const MKL_INT *n , const double *ulp );
```

Include Files

- mkl_scalapack.h

Description

The ?lamsh function sends multiple shifts through a small (single node) matrix to see how small consecutive subdiagonal elements are modified by subsequent shifts in an effort to maximize the number of bulges that can be sent through. The function should only be called when there are multiple shifts/bulges (*nbulge* > 1) and the first shift is starting in the middle of an unreduced Hessenberg matrix because of two or more small consecutive subdiagonal elements.

Input Parameters

s (local)
 Array of size $lds*2*jblk$.
 On entry, the matrix of shifts. Only the 2x2 diagonal of *s* is referenced. It is assumed that *s* has *jblk* double shifts (size 2).

lds (local)
 On entry, the leading dimension of *S*; unchanged on exit. $1 < nbulge \leq jblk \leq lds/2$.

nbulge (local)
 On entry, the number of bulges to send through *h* (>1). *nbulge* should be less than the maximum determined (*jblk*). $1 < nbulge \leq jblk \leq lds/2$.

| | |
|-------------|---|
| <i>jblk</i> | (local) On entry, the number of double shifts determined for <i>S</i> ; unchanged on exit. |
| <i>h</i> | (local) Array of size $ldh*n$. On entry, the local matrix to apply the shifts on. <i>h</i> should be aligned so that the starting row is 2. |
| <i>ldh</i> | (local) On entry, the leading dimension of <i>H</i> ; unchanged on exit. |
| <i>n</i> | (local) On entry, the size of <i>H</i> . If all the bulges are expected to go through, <i>n</i> should be at least $4nbulge+2$. Otherwise, <i>nbulge</i> may be reduced by this function. |
| <i>ulp</i> | (local) On entry, machine precision. Unchanged on exit. |

Output Parameters

| | |
|---------------|---|
| <i>s</i> | On exit, the data is rearranged in the best order for applying. |
| <i>nbulge</i> | On exit, the maximum number of bulges that can be sent through. |
| <i>h</i> | On exit, the data is destroyed. |

See Also

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

?lapst

Sorts the numbers in increasing or decreasing order.

Syntax

```
void slapst (const char* id, const MKL_INT* n, const float* d, MKL_INT* indx, MKL_INT* info);
```

```
void dlapst (const char* id, const MKL_INT* n, const double* d, MKL_INT* indx, MKL_INT* info);
```

Include Files

- `mkl_scalapack.h`

Description

?lapst is a modified version of the LAPACK routine ?lasrt.

Define a permutation *indx* that sorts the numbers in *d* in increasing order (if *id* = 'I') or in decreasing order (if *id* = 'D').

Use Quick Sort, reverting to Insertion sort on arrays of size ≤ 20 . Dimension of STACK limits *n* to about 2^{32} .

Input Parameters

| | |
|-----------|--|
| <i>id</i> | = 'I': sort <i>d</i> in increasing order; = 'D': sort <i>d</i> in decreasing order. |
| <i>n</i> | The length of the array <i>d</i> . |
| <i>d</i> | Array, size (<i>n</i>) The array to be sorted. |

Output Parameters

| | |
|-------------|---|
| <i>indx</i> | Array, size (<i>n</i>). The permutation which sorts the array <i>d</i> . |
| <i>info</i> | = 0: successful exit < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value |

?laqr6

Performs a single small-bulge multi-shift QR sweep collecting the transformations.

Syntax

```
void slaqr6(char* job, MKL_INT* wantt, MKL_INT* wantz, MKL_INT* kacc22, MKL_INT* n,
MKL_INT* ktop, MKL_INT* kbot, MKL_INT* nshfts, float* sr, float* si, float* h,
MKL_INT* ldh, MKL_INT* iloz, MKL_INT* ihiz, float* z, MKL_INT* ldz, float* v, MKL_INT*
ldv, float* u, MKL_INT* ldu, MKL_INT* nv, float* wv, MKL_INT* ldwv, MKL_INT* nh,
float* wh, MKL_INT* ldwh);
```

```
void dlaqr6(char* job, MKL_INT* wantt, MKL_INT* wantz, MKL_INT* kacc22, MKL_INT* n,
MKL_INT* ktop, MKL_INT* kbot, MKL_INT* nshfts, double* sr, double* si, double* h,
MKL_INT* ldh, MKL_INT* iloz, MKL_INT* ihiz, double* z, MKL_INT* ldz, double* v,
MKL_INT* ldv, double* u, MKL_INT* ldu, MKL_INT* nv, double* wv, MKL_INT* ldwv,
MKL_INT* nh, double* wh, MKL_INT* ldwh);
```

Include Files

- mkl_scalapack.h

Description

This auxiliary function performs a single small-bulge multi-shift QR sweep, moving the chain of bulges from top to bottom in the submatrix $H(k_{top}:k_{bot}, k_{top}:k_{bot})$, collecting the transformations in the matrix *V* or accumulating the transformations in the matrix *Z* (see below).

This is a modified version of ?laqr5 from LAPACK 3.1.

Input Parameters

job Set the kind of *job* to do in ?laqr6, as follows:

| | |
|-------------------|--|
| | <p><i>job</i> = 'I': Introduce and chase bulges in submatrix</p> <p><i>job</i> = 'C': Chase bulges from top to bottom of submatrix</p> <p><i>job</i> = 'O': Chase bulges off submatrix</p> |
| <i>wantt</i> | <i>wantt</i> is non-zero if the quasi-triangular Schur factor is being computed. <i>wantt</i> is set to zero otherwise. |
| <i>wantz</i> | <i>wantz</i> is non-zero if the orthogonal Schur factor is being computed. <i>wantz</i> is set to zero otherwise. |
| <i>kacc22</i> | Specifies the computation mode of far-from-diagonal orthogonal updates. <ul style="list-style-type: none"> = 0: ?laqr6 does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries. = 1: ?laqr6 accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries. = 2: ?laqr6 accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies. |
| <i>n</i> | <i>n</i> is the order of the Hessenberg matrix <i>H</i> upon which this function operates. |
| <i>ktop, kbot</i> | These are the first and last rows and columns of an isolated diagonal block upon which the QR sweep is to be applied. It is assumed without a check that either $ktop = 1$ or $H(ktop,ktop-1) = 0$ and either $kbot = n$ or $H(kbot+1,kbot) = 0$. |
| <i>nshfts</i> | <i>nshfts</i> gives the number of simultaneous shifts. <i>nshfts</i> must be positive and even. |
| <i>sr, si</i> | Array of size <i>nshfts</i> <i>sr</i> contains the real parts and <i>si</i> contains the imaginary parts of the <i>nshfts</i> shifts of origin that define the multi-shift QR sweep. |
| <i>h</i> | Array of size $ldh * n$ On input <i>h</i> contains a Hessenberg matrix <i>H</i> . |
| <i>ldh</i> | <i>ldh</i> is the leading dimension of <i>H</i> just as declared in the calling function. $ldh \geq \max(1,n)$. |
| <i>iloz, ihiz</i> | Specify the rows of the matrix <i>Z</i> to which transformations must be applied if <i>wantz</i> is non-zero. $1 \leq iloz \leq ihiz \leq n$ |
| <i>z</i> | Array of size $ldz * ktop$ If <i>wantz</i> is non-zero, then the QR sweep orthogonal similarity transformation is accumulated into the matrix $Z(iloz:ihiz,kbot:ktop)$, stored in the array <i>z</i> , from the right. If <i>wantz</i> equals zero, then <i>z</i> is unreferenced. |

| | |
|-------------|---|
| <i>ldz</i> | <i>ldz</i> is the leading dimension of <i>z</i> just as declared in the calling function. <i>ldz</i> ≥ <i>n</i> . |
| <i>v</i> | (workspace) array of size <i>ldv</i> * <i>nshfts</i> /2 |
| <i>ldv</i> | <i>ldv</i> is the leading dimension of <i>v</i> as declared in the calling function. <i>ldv</i> ≥ 3. |
| <i>u</i> | (workspace) array of size <i>ldu</i> * (3* <i>nshfts</i> -3) |
| <i>ldu</i> | <i>ldu</i> is the leading dimension of <i>u</i> just as declared in the calling function. <i>ldu</i> ≥ 3* <i>nshfts</i> -3. |
| <i>nh</i> | <i>nh</i> is the number of columns in array <i>wh</i> available for workspace. <i>nh</i> ≥ 1 is required for usage of this workspace, otherwise the updates of the far-from-diagonal elements will be updated without level 3 BLAS. |
| <i>wh</i> | (workspace) array of size <i>ldwh</i> * <i>nh</i> |
| <i>ldwh</i> | Leading dimension of <i>wh</i> just as declared in the calling function. <i>ldwh</i> ≥ 3* <i>nshfts</i> -3. |
| <i>nv</i> | <i>nv</i> is the number of rows in <i>wv</i> available for workspace. <i>nv</i> ≥ 1 is required for usage of this workspace, otherwise the updates of the far-from-diagonal elements will be updated without level 3 BLAS. |
| <i>wv</i> | (workspace) array of size <i>ldwv</i> * 3* <i>nshfts</i> |
| <i>ldwv</i> | scalar <i>ldwv</i> is the leading dimension of <i>wv</i> as declared in the in the calling function. <i>ldwv</i> ≥ <i>nv</i> . |

OUTPUT Parameters

| | |
|----------|--|
| <i>h</i> | A multi-shift QR sweep with shifts $sr[j]+i*si[j]$ is applied to the isolated diagonal block in matrix rows and columns <i>ktop</i> through <i>kbot</i> . |
| <i>z</i> | If <i>wantzis</i> non-zero, then the QR sweep orthogonal/unitary similarity transformation is accumulated into the matrix $Z(i_{loz}:i_{hiz},k_{bot}:k_{top})$ from the right. If <i>wantze</i> equals zero, then <i>z</i> is unreferenced. |

Application Notes

Notes

Based on contributions by Karen Braman and Ralph Byers, Department of Mathematics, University of Kansas, USA Robert Granat, Department of Computing Science and HPC2N, Umea University, Sweden

?slar1va

Computes scaled eigenvector corresponding to given eigenvalue.

Syntax

```
void slar1va(MKL_INT* n, MKL_INT* b1, MKL_INT* bn, float* lambda, float* d, float* l,
float* ld, float* lld, float* pivmin, float* gaptol, float* z, MKL_INT* wantnc,
MKL_INT* negcnt, float* ztz, float* mingma, MKL_INT* r, MKL_INT* isuppz, float*
nrminv, float* resid, float* rqcrr, float* work);
```

```
void dlar1va(MKL_INT* n, MKL_INT* b1, MKL_INT* bn, double* lambda, double* d, double*
l, double* ld, double* lld, double* pivmin, double* gaptol, double* z, MKL_INT*
wantnc, MKL_INT* negcnt, double* ztz, double* mingma, MKL_INT* r, MKL_INT* isuppz,
double* nrminv, double* resid, double* rqcrr, double* work);
```

Include Files

- mkl_scalapack.h

Description

?slar1va computes the (scaled) r -th column of the inverse of the submatrix in rows $b1$ through bn of the tridiagonal matrix $LDL^T - \lambda I$. When λ is close to an eigenvalue, the computed vector is an accurate eigenvector. Usually, r corresponds to the index where the eigenvector is largest in magnitude. The following steps accomplish this computation :

1. Stationary qd transform, $LDL^T - \lambda I = L_+ D_+ L_+^T$,
2. Progressive qd transform, $LDL^T - \lambda I = U \cdot D \cdot U^T$,
3. Computation of the diagonal elements of the inverse of $LDL^T - \lambda I$ by combining the above transforms, and choosing r as the index where the diagonal of the inverse is (one of the) largest in magnitude.
4. Computation of the (scaled) r -th column of the inverse using the twisted factorization obtained by combining the top part of the stationary and the bottom part of the progressive transform.

Input Parameters

| | |
|----------|--|
| n | The order of the matrix LDL^T . |
| $b1$ | First index of the submatrix of LDL^T . |
| bn | Last index of the submatrix of LDL^T . |
| $lambda$ | The shift λ . In order to compute an accurate eigenvector, $lambda$ should be a good approximation to an eigenvalue of LDL^T . |
| l | Array of size $n-1$ The $(n-1)$ subdiagonal elements of the unit bidiagonal matrix L , in elements 0 to $n-2$. |
| d | Array of size n The n diagonal elements of the diagonal matrix D . |
| ld | Array of size $n-1$ The $n-1$ elements $l[i]*d[i]$, $i=0, \dots, n-2$. |

| | |
|---------------|---|
| <i>lld</i> | Array of size $n-1$ The $n-1$ elements $l[i]*l[i]*d[i]$, $i=0,\dots,n-2$. |
| <i>pivmin</i> | The minimum pivot in the Sturm sequence. |
| <i>gaptol</i> | Tolerance that indicates when eigenvector entries are negligible with respect to their contribution to the residual. |
| <i>z</i> | Array of size n On input, all entries of z must be set to 0. |
| <i>wantnc</i> | Specifies whether <i>negcnt</i> has to be computed. |
| <i>r</i> | The twist index for the twisted factorization used to compute z . On input, $0 \leq r \leq n$. If r is input as 0, r is set to the index where $(LDL^T - \sigma I)^{-1}$ is largest in magnitude. If $1 \leq r \leq n$, r is unchanged. Ideally, r designates the position of the maximum entry in the eigenvector. |
| <i>work</i> | (Workspace) array of size $4*n$ |

OUTPUT Parameters

| | |
|---------------|---|
| <i>z</i> | On output, z contains the (scaled) r -th column of the inverse. The scaling is such that $z[r-1]$ equals 1. |
| <i>negcnt</i> | If <i>wantnc</i> is non-zero then <i>negcnt</i> = the number of pivots $< pivmin$ in the matrix factorization LDL^T , and <i>negcnt</i> = -1 otherwise. |
| <i>ztz</i> | The square of the 2-norm of z . |
| <i>mingma</i> | The reciprocal of the largest (in magnitude) diagonal element of the inverse of $LDL^T - \sigma I$. |
| <i>r</i> | On output, r contains the twist index used to compute z . |
| <i>isuppz</i> | array of size 2 The support of the vector in z , i.e., the vector z is non-zero only in elements <i>isuppz</i> [0] and <i>isuppz</i> [1]. |
| <i>nrminv</i> | $nrminv = 1/\text{SQRT}(ztz)$ |
| <i>resid</i> | The residual of the FP vector. $resid = \text{ABS}(mingma)/\text{SQRT}(ztz)$ |
| <i>rqcorr</i> | The Rayleigh Quotient correction to <i>lambda</i> . |

```

Include Files

- mkl_scalapack.h

Description

?laref applies one or several Householder reflectors of size 3 to one or two matrices (if column is specified) on either their rows or columns.

Input Parameters

| | |
|-------------|---|
| <i>type</i> | (local) If 'R': Apply reflectors to the rows of the matrix (apply from left) Otherwise: Apply reflectors to the columns of the matrix Unchanged on exit. |
| <i>a</i> | (local) Array, $lld_a * LOCc(ja+n-1)$ On entry, the matrix to receive the reflections. |
| <i>lda</i> | (local) |

| | |
|---------------|---|
| | On entry, the leading dimension of a . Unchanged on exit. |
| <i>wantz</i> | (local) If $wantz \neq 0$, then apply any column reflections to z as well. If $wantz = 0$, then do no additional work on z . |
| z | (local) Array, $ldz * ncols$, where the value $ncols$ depends on other arguments. If $wantz \neq 0$ and $type \neq 'R'$ then $ncols = icoll + 3 * (lihiz - liloz + 1)$. Otherwise, $ncols$ is unused. On entry, the second matrix to receive column reflections. This is changed only if $wantz$ is set. |
| <i>ldz</i> | (local) On entry, the leading dimension of z . Unchanged on exit. |
| <i>block</i> | (local) If nonzero, then apply several reflectors at once and read their data from the <i>vecs</i> array. If zero, apply the single reflector given by $v2, v3, t1, t2$, and $t3$. |
| <i>irowl</i> | (local) On entry, the local row element of a . |
| <i>icoll</i> | (local) On entry, the local column element of a . |
| <i>istart</i> | (local) Specifies the "number" of the first reflector. This is used as an index into <i>vecs</i> if <i>block</i> is set. <i>istart</i> is ignored if <i>block</i> is zero. |
| <i>istop</i> | (local) Specifies the "number" of the last reflector. This is used as an index into <i>vecs</i> if <i>block</i> is set. <i>istop</i> is ignored if <i>block</i> is zero. |
| <i>itmpl</i> | (local) Starting range into a . For rows, this is the local first column. For columns, this is the local first row. |
| <i>itmp2</i> | (local) Ending range into a . For rows, this is the local last column. For columns, this is the local last row. |

| | | |
|---------------------------|---------|---|
| <i>liloz, lihiz</i> | (local) | These serve the same purpose as <i>itmp1, itmp2</i> but for <i>z</i> when <i>wantz</i> is set. |
| <i>vecs</i> | (local) | Array of size 3*N (matrix size) This holds the size 3 reflectors one after another and this is only accessed when <i>block</i> is nonzero |
| <i>v2, v3, t1, t2, t3</i> | (local) | This holds information on a single size 3 Householder reflector and is read when <i>block</i> is zero, and overwritten when <i>block</i> is nonzero |

Output Parameters

| | |
|---------------------------|--|
| <i>a</i> | The updated matrix on exit. |
| <i>z</i> | This is changed only if <i>wantz</i> is set. |
| <i>irow1</i> | Undefined on output. |
| <i>icol1</i> | Undefined on output. |
| <i>v2, v3, t1, t2, t3</i> | Overwritten when <i>block</i> is nonzero. |

?larrb2

Provides limited bisection to locate eigenvalues for more accuracy.

Syntax

```
void slarrb2(MKL_INT* n, float* d, float* lld, MKL_INT* ifirst, MKL_INT* ilast, float*
rtol1, float* rtol2, MKL_INT* offset, float* w, float* wgap, float* werr, float* work,
MKL_INT* iwork, float* pivmin, float* lgpvmn, float* lgspdm, MKL_INT* twist, MKL_INT*
info);
```

```
void dlarrb2(MKL_INT* n, double* d, double* lld, MKL_INT* ifirst, MKL_INT* ilast,
double* rtol1, double* rtol2, MKL_INT* offset, double* w, double* wgap, double* werr,
double* work, MKL_INT* iwork, double* pivmin, double* lgpvmn, double* lgspdm, MKL_INT*
twist, MKL_INT* info);
```

Include Files

- `mkl_scalapack.h`

Description

Given the relatively robust representation (RRR) LDL^T , ?larrb2 does "limited" bisection to refine the eigenvalues of LDL^T with indices in a given range to more accuracy. Initial guesses for these eigenvalues are input in *w*, the corresponding estimate of the error in these guesses and their gaps are input in *werr* and *wgap*, respectively. During bisection, intervals [*left*, *right*] are maintained by storing their mid-points and semi-widths in the arrays *w* and *werr* respectively. The range of indices is specified by the *ifirst*, *ilast*, and *offset* parameters, as explained in [Input Parameters](#).

NOTE

There are very few minor differences between `larrb` from LAPACK and this current function `?larrb2`. The most important reason for creating this nearly identical copy is profiling: in the ScaLAPACK MRRR algorithm, eigenvalue computation using `?larrb2` is used for refinement in the construction of the representation tree, as opposed to the initial computation of the eigenvalues for the root RRR which uses `?larrb`. When profiling, this allows an easy quantification of refinement work vs. computing eigenvalues of the root.

Input Parameters

| | |
|---------------------|--|
| <i>n</i> | The order of the matrix. |
| <i>d</i> | Array of size <i>n</i> . The <i>n</i> diagonal elements of the diagonal matrix <i>D</i> . |
| <i>lld</i> | Array of size <i>n</i> -1. The (<i>n</i> -1) elements $l_{i+1} * l_{i+1} * d[i]$, $i=0, \dots, n-2$. |
| <i>ifirst</i> | The index of the first eigenvalue to be computed. |
| <i>ilast</i> | The index of the last eigenvalue to be computed. |
| <i>rtol1, rtol2</i> | Tolerance for the convergence of the bisection intervals. An interval [<i>left</i> , <i>right</i>] has converged if $right - left < \max(rtol1 * gap, rtol2 * \max(left , right))$ where <i>gap</i> is the (estimated) distance to the nearest eigenvalue. |
| <i>offset</i> | Offset for the arrays <i>w</i> , <i>wgap</i> and <i>werr</i> , i.e., the elements indexed <i>ifirst</i> - <i>offset</i> - 1 through <i>ilast</i> - <i>offset</i> - 1 of these arrays are to be used. |
| <i>w</i> | Array of size <i>n</i> On input, $w[ifirst - offset - 1]$ through $w[ilast - offset - 1]$ are estimates of the eigenvalues of LDL^T indexed <i>ifirst</i> through <i>ilast</i> . |
| <i>wgap</i> | Array of size <i>n</i> -1. On input, the (estimated) gaps between consecutive eigenvalues of LDL^T , i.e., $wgap[I - offset - 1]$ is the gap between eigenvalues <i>I</i> and <i>I</i> + 1. Note that if <i>ifirst</i> = <i>ilast</i> then $wgap[ifirst - offset - 1]$ must be set to zero. |
| <i>werr</i> | Array of size <i>n</i> . On input, $werr[ifirst - offset - 1]$ through $werr[ilast - offset - 1]$ are the errors in the estimates of the corresponding elements in <i>w</i> . |
| <i>work</i> | (workspace) array of size $4*n$. Workspace. |
| <i>iwork</i> | (workspace) array of size $2*n$. Workspace. |

| | |
|---------------|--|
| <i>pivmin</i> | The minimum pivot in the Sturm sequence. |
| <i>lgpvmn</i> | Logarithm of <i>pivmin</i> , precomputed. |
| <i>lgspdm</i> | Logarithm of the spectral diameter, precomputed. |
| <i>twist</i> | The twist index for the twisted factorization that is used for the <i>negcount</i> . <i>twist</i> = <i>n</i> : Compute <i>negcount</i> from $LDL^T - \lambda I = L_+ D_+ L_+^T$ <i>twist</i> = 1: Compute <i>negcount</i> from $LDL^T - \lambda I = U_+ D_+ U_+^T$ <i>twist</i> = <i>r</i> , $1 < r < n$: Compute <i>negcount</i> from $LDL^T - \lambda I = N_r A_r N_r^T$ |

OUTPUT Parameters

| | |
|-------------|--|
| <i>w</i> | On output, the eigenvalue estimates in <i>w</i> are refined. |
| <i>wgap</i> | On output, the eigenvalue gaps in <i>wgap</i> are refined. |
| <i>werr</i> | On output, the errors in <i>werr</i> are refined. |
| <i>info</i> | Error flag. |

?larrd2

Computes the eigenvalues of a symmetric tridiagonal matrix to suitable accuracy.

Syntax

```
void slarrd2(char* range, char* order, MKL_INT* n, float* vl, float* vu, MKL_INT* il,
MKL_INT* iu, float* gers, float* reltol, float* d, float* e, float* e2, float* pivmin,
MKL_INT* nsplit, MKL_INT* isplit, MKL_INT* m, float* w, float* werr, float* wl, float*
wu, MKL_INT* iblock, MKL_INT* indexw, float* work, MKL_INT* iwork, MKL_INT* dol,
MKL_INT* dou, MKL_INT* info);
```

```
void dlarrd2(char* range, char* order, MKL_INT* n, double* vl, double* vu, MKL_INT*
il, MKL_INT* iu, double* gers, double* reltol, double* d, double* e, double* e2,
double* pivmin, MKL_INT* nsplit, MKL_INT* isplit, MKL_INT* m, double* w, double* werr,
double* wl, double* wu, MKL_INT* iblock, MKL_INT* indexw, double* work, MKL_INT*
iwork, MKL_INT* dol, MKL_INT* dou, MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

?larrd2 computes the eigenvalues of a symmetric tridiagonal matrix *T* to limited initial accuracy. This is an auxiliary code to be called from [larre2a](#).

`?larrd2` has been created using the LAPACK code `larrd` which itself stems from `stebz`. The motivation for creating `?larrd2` is efficiency: When computing eigenvalues in parallel and the input tridiagonal matrix splits into blocks, `?larrd2` can skip over blocks which contain none of the eigenvalues from DOL to DOU for which the processor responsible. In extreme cases (such as large matrices consisting of many blocks of small size like 2x2), the gain can be substantial.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

| | |
|-----------------|---|
| <i>range</i> | <p>= 'A': ("All") all eigenvalues will be found.</p> <p>= 'V': ("Value") all eigenvalues in the half-open interval $(v_l, v_u]$ will be found.</p> <p>= 'I': ("Index") eigenvalues of the entire matrix with the indices in a given range will be found.</p> |
| <i>order</i> | <p>= 'B': ("By Block") the eigenvalues will be grouped by split-off block (see <i>iblock</i>, <i>isplit</i>) and ordered from smallest to largest within the block.</p> <p>= 'E': ("Entire matrix") the eigenvalues for the entire matrix will be ordered from smallest to largest.</p> |
| <i>n</i> | The order of the tridiagonal matrix T . $n \geq 0$. |
| <i>v_l, v_u</i> | <p>If <i>range</i>='V', the lower and upper bounds of the interval to be searched for eigenvalues. Eigenvalues less than or equal to v_l, or greater than v_u, will not be returned. $v_l < v_u$.</p> <p>Not referenced if <i>range</i> = 'A' or 'I'.</p> |
| <i>il, iu</i> | <p>If <i>range</i>='I', the indices (in ascending order) of the smallest eigenvalue, to be returned in $w[il-1]$, and largest eigenvalue, to be returned in $w[iu-1]$.</p> <p>$1 \leq il \leq iu \leq n$, if $n > 0$; $il = 1$ and $iu = 0$ if $n = 0$.</p> <p>Not referenced if <i>range</i> = 'A' or 'V'.</p> |
| <i>gers</i> | <p>Array of size $2*n$</p> <p>The n Gerschgorin intervals (the i-th Gerschgorin interval is $(gers[2*i-2], gers[2*i-1])$).</p> |
| <i>reltol</i> | The minimum relative width of an interval. When an interval is narrower than <i>reltol</i> times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. Note: this should always be at least $\text{radix} * \text{machine epsilon}$. |

| | |
|-----------------|--|
| <i>d</i> | Array of size n The n diagonal elements of the tridiagonal matrix T . |
| <i>e</i> | Array of size $n-1$ The $(n-1)$ off-diagonal elements of the tridiagonal matrix T . |
| <i>e2</i> | Array of size $n-1$ The $(n-1)$ squared off-diagonal elements of the tridiagonal matrix T . |
| <i>pivmin</i> | The minimum pivot allowed in the sturm sequence for T . |
| <i>nsplit</i> | The number of diagonal blocks in the matrix T . $1 \leq nsplit \leq n$. |
| <i>isplit</i> | Array of size n The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to <i>isplit</i> [0], the second of rows/columns <i>isplit</i> [0]+1 through <i>isplit</i> [1], etc., and the <i>nsplit</i> -th submatrix consists of rows/columns <i>isplit</i> [<i>nsplit</i> -2]+1 through <i>isplit</i> [<i>nsplit</i> -1]= n . (Only the first <i>nsplit</i> elements will actually be used, but since the user cannot know a priori what value <i>nsplit</i> will have, n words must be reserved for <i>isplit</i> .) |
| <i>work</i> | (workspace) Array of size $4*n$ |
| <i>iwork</i> | (workspace) Array of size $3*n$ |
| <i>dol, dou</i> | Specifying an index range <i>dol</i> : <i>dou</i> allows the user to work on only a selected part of the representation tree. Otherwise, the setting <i>dol</i> =1, <i>dou</i> = n should be applied. Note that <i>dol</i> and <i>dou</i> refer to the order in which the eigenvalues are stored in W . |

OUTPUT Parameters

| | |
|-------------|---|
| <i>m</i> | The actual number of eigenvalues found. $0 \leq m \leq n$. (See also the description of <i>info</i> =2,3.) |
| <i>w</i> | Array of size n On exit, the first m elements of <i>w</i> will contain the eigenvalue approximations. ?larrd2 computes an interval $I_j = (a_j, b_j]$ that includes eigenvalue j . The eigenvalue approximation is given as the interval midpoint $w[j-1] = (a_j + b_j)/2$. The corresponding error is bounded by $werr[j-1] = \text{abs}(a_j - b_j)/2$. |
| <i>werr</i> | Array of size n The error bound on the corresponding eigenvalue approximation in <i>w</i> . |

| | |
|---------------|---|
| <i>wl, wu</i> | <p>The interval $(wl, wu]$ contains all the wanted eigenvalues.</p> <p>If <i>range</i>='V', then $wl=v_l$ and $wu=v_u$.</p> <p>If <i>range</i>='A', then <i>wl</i> and <i>wu</i> are the global Gerschgorin bounds on the spectrum.</p> <p>If <i>range</i>='I', then <i>wl</i> and <i>wu</i> are computed by SLAEBZ from the index range specified.</p> |
| <i>iblock</i> | <p>Array of size <i>n</i></p> <p>At each row/column <i>j</i> where $e[j-1]$ is zero or small, the matrix <i>T</i> is considered to split into a block diagonal matrix. On exit, if <i>info</i> = 0, <i>iblock</i>[<i>i</i>] specifies to which block (from 0 to the number of blocks minus one) the eigenvalue $w[i]$ belongs. (<i>?larre2</i> may use the remaining <i>n-m</i> elements as workspace.)</p> |
| <i>indexw</i> | <p>Array of size <i>n</i></p> <p>The indices of the eigenvalues within each block (submatrix); for example, <i>indexw</i>[<i>i</i>] = <i>j</i> and <i>iblock</i>[<i>i</i>] = <i>k</i> imply that the (<i>i</i>+1)-th eigenvalue $w[i]$ is the <i>j</i>-th eigenvalue in block <i>k</i>.</p> |
| <i>info</i> | <p>= 0: successful exit</p> <p>< 0: if <i>info</i> = -<i>i</i>, the <i>i</i>-th argument had an illegal value</p> <p>> 0: some or all of the eigenvalues failed to converge or were not computed:</p> <ul style="list-style-type: none"> • =1 or 3: Bisection failed to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances. • =2 or 3: <i>range</i>='I' only: Not all of the eigenvalues <i>il:iu</i> were found. • = 4: <i>range</i>='I', and the Gershgorin interval initially used was too small. No eigenvalues were computed. |

pivmin, double* work, MKL_INT* iwork, MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

To find the desired eigenvalues of a given real symmetric tridiagonal matrix T , `?larre2` sets, via `?larra`, "small" off-diagonal elements to zero. For each block T_i , it finds

- a suitable shift at one end of the block's spectrum,
- the root RRR, $T_i - \sigma_i I = L_i D_i L_i^T$, and
- eigenvalues of each $L_i D_i L_i^T$.

The representations and eigenvalues found are then returned to `?stegr2` to compute the eigenvectors T .

`?larre2` is more suitable for parallel computation than the original LAPACK code for computing the root RRR and its eigenvalues. When computing eigenvalues in parallel and the input tridiagonal matrix splits into blocks, `?larre2` can skip over blocks which contain none of the eigenvalues from `dol` to `dou` for which the processor is responsible. In extreme cases (such as large matrices consisting of many blocks of small size, e.g. 2x2), the gain can be substantial.

Notice revision #20110804

Input Parameters

| | |
|---------------------|---|
| <code>range</code> | <p>= 'A': ("All") all eigenvalues will be found.</p> <p>= 'V': ("Value") all eigenvalues in the half-open interval $(vl, vu]$ will be found.</p> <p>= 'I': ("Index") eigenvalues of the entire matrix with the indices in a given range will be found.</p> |
| <code>n</code> | The order of the matrix. $n > 0$. |
| <code>vl, vu</code> | <p>If <code>range='V'</code>, the lower and upper bounds for the eigenvalues.</p> <p>Eigenvalues less than or equal to <code>vl</code>, or greater than <code>vu</code>, will not be returned. $vl < vu$.</p> |
| <code>il, iu</code> | If <code>range='I'</code> , the indices (in ascending order) of the smallest eigenvalue, to be returned in <code>w[il-1]</code> , and largest eigenvalue, to be returned in <code>w[iu-1]</code> . |

| | |
|---------------------|---|
| | $1 \leq i_l \leq i_u \leq n.$ |
| <i>d</i> | Array of size <i>n</i> The <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i> . |
| <i>e</i> | Array of size <i>n</i> The first (<i>n</i> -1) entries contain the subdiagonal elements of the tridiagonal matrix <i>T</i> ; <i>e</i> [<i>n</i> -1] need not be set. |
| <i>e2</i> | Array of size <i>n</i> The first (<i>n</i> -1) entries contain the squares of the subdiagonal elements of the tridiagonal matrix <i>T</i> ; <i>e2</i> [<i>n</i> -1] need not be set. |
| <i>rtol1, rtol2</i> | Parameters for bisection. An interval [<i>left, right</i>] has converged if $right-left < \max(rtol1*gap, rtol2*\max(left , right))$ |
| <i>spltol</i> | The threshold for splitting. |
| <i>dol, dou</i> | Specifying an index range <i>dol:dou</i> allows the user to work on only a selected part of the representation tree. Otherwise, the setting <i>dol</i> =1, <i>dou</i> = <i>n</i> should be applied. Note that <i>dol</i> and <i>dou</i> refer to the order in which the eigenvalues are stored in <i>w</i> . |
| <i>work</i> | Workspace array of size $6*n$ |
| <i>iwork</i> | Workspace array of size $5*n$ |

OUTPUT Parameters

| | |
|---------------|---|
| <i>vl, vu</i> | If <i>range</i> ='I' or 'A', <i>vl</i> and <i>vu</i> contain bounds on the desired part of the spectrum. |
| <i>d</i> | The <i>n</i> diagonal elements of the diagonal matrices <i>D_i</i> . |
| <i>e</i> | <i>e</i> contains the subdiagonal elements of the unit bidiagonal matrices <i>L_i</i> . The entries <i>e</i> [<i>isplit</i> [<i>i</i>]], $0 \leq i < nsplit$, contain the base points σ_{i+1} on output. |
| <i>e2</i> | The entries <i>e2</i> [<i>isplit</i> [<i>i</i>]], $0 \leq i < nsplit$, are set to zero. |
| <i>nsplit</i> | The number of blocks <i>T</i> splits into. $1 \leq nsplit \leq n$. |
| <i>isplit</i> | Array of size <i>n</i> The splitting points, at which <i>T</i> breaks up into blocks. The first block consists of rows/columns 1 to <i>isplit</i> [0], the second of rows/columns <i>isplit</i> [0]+1 through <i>isplit</i> [1], etc., and the <i>nsplit</i> -th block consists of rows/columns <i>isplit</i> [<i>nsplit</i> -2]+1 through <i>isplit</i> [<i>nsplit</i> -1]= <i>n</i> . |
| <i>m</i> | The total number of eigenvalues (of all $L_i D_i L_i^T$) found. |

| | |
|---------------|---|
| <i>w</i> | <p>Array of size n</p> <p>The first m elements contain the eigenvalues. The eigenvalues of each of the blocks, $L_i D_i L_i^T$, are sorted in ascending order (<code>?larre2</code> may use the remaining $n-m$ elements as workspace).</p> <p>Note that immediately after exiting this function, only the eigenvalues in w with indices in range $dol-1:dou-1$ might rely on this processor when the eigenvalue computation is done in parallel.</p> |
| <i>werr</i> | <p>Array of size n</p> <p>The error bound on the corresponding eigenvalue in w.</p> <p>Note that immediately after exiting this function, only the uncertainties in $werr$ with indices in range $dol-1:dou-1$ might rely on this processor when the eigenvalue computation is done in parallel.</p> |
| <i>wgap</i> | <p>Array of size n</p> <p>The separation from the right neighbor eigenvalue in w.</p> <p>The gap is only with respect to the eigenvalues of the same block as each block has its own representation tree.</p> <p>Exception: at the right end of a block we store the left gap</p> <p>Note that immediately after exiting this function, only the gaps in $wgap$ with indices in range $dol-1:dou-1$ might rely on this processor when the eigenvalue computation is done in parallel.</p> |
| <i>iblock</i> | <p>Array of size n</p> <p>The indices of the blocks (submatrices) associated with the corresponding eigenvalues in w; $iblock[i]=1$ if eigenvalue $w[i]$ belongs to the first block from the top, $iblock[i]=2$ if $w[i]$ belongs to the second block, and so on.</p> |
| <i>indexw</i> | <p>Array of size n</p> <p>The indices of the eigenvalues within each block (submatrix); for example, $indexw[i]=10$ and $iblock[i]=2$ imply that the $(i+1)$-th eigenvalue $w[i]$ is the 10th eigenvalue in block 2.</p> |
| <i>gers</i> | <p>Array of size $2*n$</p> <p>The n Gerschgorin intervals (the i-th Gerschgorin interval is $(gers[2*i-2], gers[2*i-1])$).</p> |
| <i>pivmin</i> | <p>The minimum pivot in the sturm sequence for T.</p> |
| <i>info</i> | <p>= 0: successful exit</p> <p>> 0: A problem occurred in <code>?larre2</code>.</p> <p>< 0: One of the called functions signaled an internal problem.</p> <p>Needs inspection of the corresponding parameter <i>info</i> for further information.</p> <p>=-1: Problem in <code>?larrd</code>.</p> <p>=-2: Not enough internal iterations to find the base representation.</p> |

Description

To find the desired eigenvalues of a given real symmetric tridiagonal matrix T , ?larre2a sets any "small" off-diagonal elements to zero, and for each unreduced block T_i , it finds

- a suitable shift at one end of the block's spectrum,
- the base representation, $T_i - \sigma_i I = L_i D_i L_i^T$, and
- eigenvalues of each $L_i D_i L_i^T$.

NOTE

The algorithm obtains a crude picture of all the wanted eigenvalues (as selected by *range*). However, to reduce work and improve scalability, only the eigenvalues *dol* to *dou* are refined. Furthermore, if the matrix splits into blocks, RRRs for blocks that do not contain eigenvalues from *dol* to *dou* are skipped. The DQDS algorithm (function ?lasq2) is not used, unlike in the sequential case. Instead, eigenvalues are computed in parallel to some figures using bisection.

Notice revision #20110804

Input Parameters

| | |
|---------------------|--|
| <i>range</i> | <p>= 'A': ("All") all eigenvalues will be found.</p> <p>= 'V': ("Value") all eigenvalues in the half-open interval $(v_l, v_u]$ will be found.</p> <p>= 'I': ("Index") eigenvalues of the entire matrix with the indices in a given range will be found.</p> |
| <i>n</i> | The order of the matrix. $n > 0$. |
| <i>v_l, v_u</i> | <p>If <i>range</i>='V', the lower and upper bounds for the eigenvalues. Eigenvalues less than or equal to v_l, or greater than v_u, will not be returned. $v_l < v_u$.</p> <p>If <i>range</i>='I' or 'A', <code>?larre2a</code> computes bounds on the desired part of the spectrum.</p> |
| <i>il, iu</i> | <p>If <i>range</i>='I', the indices (in ascending order) of the smallest eigenvalue, to be returned in $w[il-1]$, and largest eigenvalue, to be returned in $w[iu-1]$.</p> <p>$1 \leq il \leq iu \leq n$.</p> |
| <i>d</i> | <p>Array of size n</p> <p>On entry, the n diagonal elements of the tridiagonal matrix T.</p> |
| <i>e</i> | <p>Array of size n</p> <p>The first $(n-1)$ entries contain the subdiagonal elements of the tridiagonal matrix T; $e[n-1]$ need not be set.</p> |
| <i>e2</i> | <p>Array of size n</p> <p>The first $(n-1)$ entries contain the squares of the subdiagonal elements of the tridiagonal matrix T; $e2[n-1]$ need not be set.</p> |
| <i>rtol1, rtol2</i> | <p>Parameters for bisection.</p> <p>An interval $[left, right]$ has converged if $right - left < \max(rtol1*gap, rtol2*\max(left , right))$</p> |
| <i>spltol</i> | The threshold for splitting. |
| <i>dol, dou</i> | <p>If the user wants to work on only a selected part of the representation tree, he can specify an index range $dol:dou$.</p> <p>Otherwise, the setting $dol=1, dou=n$ should be applied.</p> |

Note that *dol* and *dou* refer to the order in which the eigenvalues are stored in *w*.

| | |
|---------------|--|
| <i>work</i> | Workspace array of size $6*n$ |
| <i>iwork</i> | Workspace array of size $5*n$ |
| <i>minrgp</i> | The minimum relative gap threshold to decide whether an eigenvalue or a cluster boundary is reached. |

OUTPUT Parameters

| | |
|-----------------------|--|
| <i>vl, vu</i> | <p>If <i>range</i>='V', the lower and upper bounds for the eigenvalues. Eigenvalues less than or equal to <i>vl</i>, or greater than <i>vu</i>, are not returned. $vl < vu$.</p> <p>If <i>range</i>='I' or <i>range</i>='A', <i>?larre2a</i> computes bounds on the desired part of the spectrum.</p> |
| <i>d</i> | The n diagonal elements of the diagonal matrices D_j . |
| <i>e</i> | <i>e</i> contains the subdiagonal elements of the unit bidiagonal matrices L_j . The entries $e[isplit[i]]$, $0 \leq i < nsplit$, contain the base points σ_{i+1} on output. |
| <i>e2</i> | The entries $e2[isplit[i]]$, $0 \leq i < nsplit$ have been set to zero. |
| <i>nsplit</i> | The number of blocks <i>T</i> splits into. $1 \leq nsplit \leq n$. |
| <i>isplit</i> | <p>Array of size n</p> <p>The splitting points, at which <i>T</i> breaks up into blocks.</p> <p>The first block consists of rows/columns 1 to $isplit[0]$, the second of rows/columns $isplit[0]+1$ through $isplit[1]$, etc., and the <i>nsplit</i>-th block consists of rows/columns $isplit[nsplit-2]+1$ through $isplit[nsplit-1]=n$.</p> |
| <i>m</i> | The total number of eigenvalues (of all $L_j D_j L_j^T$) found. |
| <i>needil, neediu</i> | The indices of the leftmost and rightmost eigenvalues of the root node RRR which are needed to accurately compute the relevant part of the representation tree. |
| <i>w</i> | <p>Array of size n</p> <p>The first m elements contain the eigenvalues. The eigenvalues of each of the blocks, $L_j D_j L_j^T$, are sorted in ascending order (<i>?larre2a</i> may use the remaining $n-m$ elements as workspace).</p> <p>Note that immediately after exiting this function, only the eigenvalues in <i>w</i> with indices in range $dol-1:dou-1$ rely on this processor because the eigenvalue computation is done in parallel.</p> |
| <i>werr</i> | <p>Array of size n</p> <p>The error bound on the corresponding eigenvalue in <i>w</i>.</p> |

Note that immediately after exiting this function, only the uncertainties in w_{err} with indices in range $dol-1:dou-1$ are reliable on this processor because the eigenvalue computation is done in parallel.

wgap

Array of size n

The separation from the right neighbor eigenvalue in w . The gap is only with respect to the eigenvalues of the same block as each block has its own representation tree.

Exception: at the right end of a block we store the left gap

Note that immediately after exiting this function, only the gaps in $wgap$ with indices in range $dol-1:dou-1$ are reliable on this processor because the eigenvalue computation is done in parallel.

iblock

Array of size n

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in w ; $iblock[i]=1$ if eigenvalue $w[i]$ belongs to the first block from the top, $iblock[i]=2$ if $w[i]$ belongs to the second block, and so on.

indexw

Array of size n

The indices of the eigenvalues within each block (submatrix); for example, $indexw[i]=10$ and $iblock[i]=2$ imply that the $(i+1)$ -th eigenvalue $w[i]$ is the 10th eigenvalue in block 2.

gers

Array of size $2*n$

The n Gerschgorin intervals (the i -th Gerschgorin interval is $(gers[2*i-2], gers[2*i-1])$).

pivmin

The minimum pivot in the sturm sequence for T .

info

= 0: successful exit

> 0: A problem occurred in `?larre2a`.

< 0: One of the called functions signaled an internal problem. Needs inspection of the corresponding parameter *info* for further information.

=-1: Problem in `?larrd2`.

=-2: Not enough internal iterations to find base representation.

=-3: Problem in `?larrb2` when computing the refined root representation.

=-4: Problem in `?larrb2` when performing bisection on the desired part of the spectrum.

= -9 Problem: $m < dou-dol+1$, that is the code found fewer eigenvalues than it was supposed to.

?larrf2

Finds a new relatively robust representation such that at least one of the eigenvalues is relatively isolated.

Syntax

```
void slarrf2(MKL_INT* n, float* d, float* l, float* ld, MKL_INT* clstrt, MKL_INT*
clend, MKL_INT* clmid1, MKL_INT* clmid2, float* w, float* wgap, float* werr, MKL_INT*
trymid, float* spdiam, float* clgapl, float* clgapr, float* pivmin, float* sigma,
float* dplus, float* lplus, float* work, MKL_INT* info);
```

```
void dlarrf2(MKL_INT* n, double* d, double* l, double* ld, MKL_INT* clstrt, MKL_INT*
clend, MKL_INT* clmid1, MKL_INT* clmid2, double* w, double* wgap, double* werr,
MKL_INT* trymid, double* spdiam, double* clgapl, double* clgapr, double* pivmin,
double* sigma, double* dplus, double* lplus, double* work, MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

Given the initial representation LDL^T and its cluster of close eigenvalues (in a relative measure), defined by the indices of the first and last eigenvalues in the cluster, `?larrf2` finds a new relatively robust representation $LDL^T - \sigma I = L_+ D_+ L_+^T$ such that at least one of the eigenvalues of $L_+ D_+ L_+^T$ is relatively isolated.

This is an enhanced version of `?larrf` that also tries shifts in the middle of the cluster, should there be a large gap, in order to break large clusters into at least two pieces.

Input Parameters

| | |
|-----------------------|--|
| <i>n</i> | The order of the matrix (subblock, if the matrix was split). |
| <i>d</i> | Array of size <i>n</i> The <i>n</i> diagonal elements of the diagonal matrix <i>D</i> . |
| <i>l</i> | Array of size <i>n</i> -1 The (<i>n</i> -1) subdiagonal elements of the unit bidiagonal matrix <i>L</i> . |
| <i>ld</i> | Array of size <i>n</i> -1 The (<i>n</i> -1) elements $l[i]*d[i]$. |
| <i>clstrt</i> | The index of the first eigenvalue in the cluster. |
| <i>clend</i> | The index of the last eigenvalue in the cluster. |
| <i>clmid1, clmid2</i> | The index of a middle eigenvalue pair with large gap. |
| <i>w</i> | Array of size $\geq (clend-clstrt+1)$ The eigenvalue approximations of LDL^T in ascending order. $w[clstrt - 1]$ through $w[clend - 1]$ form the cluster of relatively close eigenvalues. |
| <i>wgap</i> | Array of size $\geq (clend-clstrt+1)$ The separation from the right neighbor eigenvalue in <i>w</i> . |
| <i>werr</i> | Array of size $\geq (clend-clstrt+1)$ <i>werr</i> contains the semiwidth of the uncertainty interval of the corresponding eigenvalue approximation in <i>w</i> . |

| | |
|-----------------------|---|
| <i>spdiam</i> | Estimate of the spectral diameter obtained from the Gerschgorin intervals |
| <i>clgapl, clgapr</i> | Absolute gap on each end of the cluster. Set by the calling function to protect against shifts too close to eigenvalues outside the cluster. |
| <i>pivmin</i> | The minimum pivot allowed in the Sturm sequence. |
| <i>work</i> | Workspace array of size $2*n$ |

OUTPUT Parameters

| | |
|--------------|--|
| <i>wgap</i> | Contains refined values of its input approximations. Very small gaps are unchanged. |
| <i>sigma</i> | The shift (σ) used to form $L_+D_+L_+^T$. |
| <i>dplus</i> | Array of size n The n diagonal elements of the diagonal matrix D_+ . |
| <i>lplus</i> | Array of size $n-1$ The first $(n-1)$ elements of <i>lplus</i> contain the subdiagonal elements of the unit bidiagonal matrix L_+ . |

```

Include Files

- `mkl_scalapack.h`

Description

?larrv2 computes the eigenvectors of the tridiagonal matrix $T = LDL^T$ given L , D and approximations to the eigenvalues of LDL^T . The input eigenvalues should have been computed by [larre2a](#) or by previous calls to ?larrv2.

The major difference between the parallel and the sequential construction of the representation tree is that in the parallel case, not all eigenvalues of a given cluster might be computed locally. Other processors might "own" and refine part of an eigenvalue cluster. This is crucial for scalability. Thus there might be communication necessary before the current level of the representation tree can be parsed.

Please note:

- The calling sequence has two additional integer parameters, dol and dou , that should satisfy $m \geq dou \geq dol \geq 1$. These parameters are only relevant when both eigenvalues and eigenvectors are computed (`stegr2b` parameter `jobz = 'V'`). ?larrv2 only computes the eigenvectors corresponding to eigenvalues dol through dou in w . (That is, instead of computing the eigenvectors belonging to $w[0]$ through $w[m-1]$, only the eigenvectors belonging to eigenvalues $w[dol - 1]$ through $w[dou - 1]$ are computed. In this case, only the eigenvalues $dol:dou$ are guaranteed to be accurately refined to all figures by Rayleigh-Quotient iteration.
- The additional arguments `vstart`, `finish`, `ndepth`, `parity`, `zoffset` are included as a thread-safe implementation equivalent to save variables. These variables store details about the local representation tree which is computed layerwise. For scalability reasons, eigenvalues belonging to the locally relevant representation tree might be computed on other processors. These need to be communicated before the inspection of the RRRs can proceed on any given layer. Note that only when the variable `finish` is non-zero, the computation has ended. All eigenpairs between dol and dou have been computed. m is set to $dou - dol + 1$.
- ?larrv2 needs more workspace in z than the sequential `slarrv`. It is used to store the conformal embedding of the local representation tree.

Notice revision #20110804

Input Parameters

| | |
|----------|--|
| n | The order of the matrix. $n \geq 0$. |
| vl, vu | Lower and upper bounds of the interval that contains the desired eigenvalues. $vl < vu$. Needed to compute gaps on the left or right end of the extremal eigenvalues in the desired range. vu is currently not used but kept as parameter in case needed. |
| d | Array of size n The n diagonal elements of the diagonal matrix d . On exit, d is overwritten. |
| l | Array of size n |

The $(n-1)$ subdiagonal elements of the unit bidiagonal matrix L are in elements 0 to $n-2$ of l (if the matrix is not split.) At the end of each block is stored the corresponding shift as given by `?larre`. On exit, l is overwritten.

| | |
|-----------------------------|---|
| <code>pivmin</code> | The minimum pivot allowed in the sturm sequence. |
| <code>isplit</code> | <p>Array of size n</p> <p>The splitting points, at which the matrix T breaks up into blocks. The first block consists of rows/columns 1 to <code>isplit[0]</code>, the second of rows/columns <code>isplit[0] + 1</code> through <code>isplit[1]</code>, etc.</p> |
| <code>m</code> | The total number of input eigenvalues. $0 \leq m \leq n$. |
| <code>dol, dou</code> | <p>If you want to compute only selected eigenvectors from all the eigenvalues supplied, you can specify an index range <code>dol:dou</code>. Or else the setting <code>dol=1, dou=m</code> should be applied. Note that <code>dol</code> and <code>dou</code> refer to the order in which the eigenvalues are stored in w. If you want to compute only selected eigenpairs, the columns <code>dol-1</code> to <code>dou+1</code> of the eigenvector space Z contain the computed eigenvectors. All other columns of Z are set to zero.</p> <p>If <code>dol > 1</code>, then <code>Z(:,dol-1-zoffset)</code> is used.</p> <p>If <code>dou < m</code>, then <code>Z(:,dou+1-zoffset)</code> is used.</p> |
| <code>needil, neediu</code> | <p>Describe which are the left and right outermost eigenvalues that still need to be included in the computation. These indices indicate whether eigenvalues from other processors are needed to correctly compute the conformally embedded representation tree.</p> <p>When <code>dol ≤ needil ≤ neediu ≤ dou</code>, all required eigenvalues are local to the processor and no communication is required to compute its part of the representation tree.</p> |
| <code>minrgp</code> | The minimum relative gap threshold to decide whether an eigenvalue or a cluster boundary is reached. |
| <code>rtol1, rtol2</code> | Parameters for bisection. An interval <code>[left,right]</code> has converged if <code>right-left < max(rtol1*gap, rtol2*max(left , right))</code> |
| <code>w</code> | <p>Array of size n</p> <p>The first m elements of w contain the approximate eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array w from <code>?stegr2a</code> is expected here.) Furthermore, they are with respect to the shift of the corresponding root representation for their block.</p> |
| <code>werr</code> | <p>Array of size n</p> <p>The first m elements contain the semiwidth of the uncertainty interval of the corresponding eigenvalue in w.</p> |
| <code>wgap</code> | Array of size n |

| | |
|----------------|---|
| | The separation from the right neighbor eigenvalue in w . |
| <i>iblock</i> | Array of size n The indices of the blocks (submatrices) associated with the corresponding eigenvalues in w ; <i>iblock</i> [i]=1 if eigenvalue w [i] belongs to the first block from the top, <i>iblock</i> [i]=2 if w [i] belongs to the second block, and so on. |
| <i>indexw</i> | Array of size n The indices of the eigenvalues within each block (submatrix). For example: <i>indexw</i> [i]= 10 and <i>iblock</i> [i]=2 imply that the ($i+1$)-th eigenvalue w [i] is the 10th eigenvalue in block 2. |
| <i>gers</i> | Array of size $2*n$ The n Gerschgorin intervals (the i -th Gerschgorin interval is (<i>gers</i> [$2*i-2$], <i>gers</i> [$2*i-1$])). The Gerschgorin intervals should be computed from the original unshifted matrix. Not used but kept as parameter for possible future use. |
| <i>sdiam</i> | Array of size n The spectral diameters for all unreduced blocks. |
| <i>ldz</i> | The leading dimension of the array z . $ldz \geq 1$, and if <i>stegr2b</i> parameter <i>jobz</i> = 'V', $ldz \geq \max(1, n)$. |
| <i>work</i> | (workspace) array of size $12*n$ |
| <i>iwork</i> | (workspace) Array of size $7*n$ |
| <i>vstart</i> | Non-zero on initialization, set to zero afterwards. |
| <i>finish</i> | A flag that indicates whether all eigenpairs have been computed. |
| <i>maxcls</i> | The largest cluster worked on by this processor in the representation tree. |
| <i>ndepth</i> | The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated. |
| <i>parity</i> | An internal parameter needed for the storage of the clusters on the current level of the representation tree. |
| <i>zoffset</i> | Offset for storing the eigenpairs when z is distributed in 1D-cyclic fashion. |

OUTPUT Parameters

| | |
|-----------------------|---|
| <i>needil, neediu</i> | |
| w | Unshifted eigenvalues for which eigenvectors have already been computed. |
| <i>werr</i> | Contains refined values of its input approximations. |
| <i>wgap</i> | Contains refined values of its input approximations. Very small gaps are changed. |
| z | Array of size $ldz * \max(1, m)$ |

If *info* = 0, the first *m* columns of the matrix *Z*, stored in the array *z*, contain the orthonormal eigenvectors of the matrix *T* corresponding to the input eigenvalues, with the *i*-th column of *Z* holding the eigenvector associated with *w*[*i* - 1].

In the distributed version, only a subset of columns is accessed, see *dol*, *dou*, and *zoffset*.

isuppz

Array of size $2 * \max(1, m)$

The support of the eigenvectors in *z*, i.e., the indices indicating the non-zero elements in *z*. The *i*-th eigenvector is non-zero only in elements *isuppz*[$2 * i - 2$] through *isuppz*[$2 * i - 1$].

vstart

Non-zero on initialization, set to zero afterwards.

finish

A flag that indicates whether all eigenpairs have been computed.

maxcls

The largest cluster worked on by this processor in the representation tree.

ndepth

The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.

parity

An internal parameter needed for the storage of the clusters on the current level of the representation tree.

info

= 0: successful exit

> 0: A problem occurred in ?*larrv2*.

< 0: One of the called functions signaled an internal problem.

Needs inspection of the corresponding parameter *info* for further information.

== -1: Problem in ?*larrb2* when refining a child's eigenvalues.

== -2: Problem in ?*larrf2* when computing the RRR of a child. When a child is inside a tight cluster, it can be difficult to find an RRR. A partial remedy from the user's point of view is to make the parameter *minrgp* smaller and recompile. However, as the orthogonality of the computed vectors is proportional to $1 / \text{minrgp}$, be aware that decreasing *minrgp* might be reduce precision.

== -3: Problem in ?*larrb2* when refining a single eigenvalue after the Rayleigh correction was rejected.

= 5: The Rayleigh Quotient Iteration failed to converge to full accuracy.

?*lasorte*

Sorts eigenpairs by real and complex data types.

Syntax

```
void slasorte (float *s , MKL_INT *lds , MKL_INT *j , float *out , MKL_INT *info );
```

```
void dlasorte (double *s , MKL_INT *lds , MKL_INT *j , double *out , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `?lasorte` function sorts eigenpairs so that real eigenpairs are together and complex eigenpairs are together. This helps to employ 2x2 shifts easily since every second subdiagonal is guaranteed to be zero. This function does no parallel work and makes no calls.

Optimization Notice

Notice revision #20110804

Input Parameters

| | |
|-------------|---|
| <i>s</i> | (local) Array of size <i>lds</i> . On entry, a matrix already in Schur form. |
| <i>lds</i> | (local) On entry, the leading dimension of the array <i>s</i> ; unchanged on exit. |
| <i>j</i> | (local) On entry, the order of the matrix <i>S</i> ; unchanged on exit. |
| <i>out</i> | (local) Array of size $2*j$. The work buffer required by the function. |
| <i>info</i> | (local) Set, if the input matrix had an odd number of real eigenvalues and things could not be paired or if the input matrix <i>S</i> was not originally in Schur form. 0 indicates successful completion. |

Output Parameters

| | |
|------------|---|
| <i>s</i> | On exit, the diagonal blocks of <i>S</i> have been rewritten to pair the eigenvalues. The resulting matrix is no longer similar to the input. |
| <i>out</i> | Work buffer. |

See Also

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

?lasrt2

Sorts numbers in increasing or decreasing order.

Syntax

```
void slasrt2 (char *id , MKL_INT *n , float *d , MKL_INT *key , MKL_INT *info );
void dlasrt2 (char *id , MKL_INT *n , double *d , MKL_INT *key , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The ?lasrt2 function is modified LAPACK function ?lasrt, which sorts the numbers in *d* in increasing order (if *id* = 'I') or in decreasing order (if *id* = 'D'). It uses Quick Sort, reverting to Insertion Sort on arrays of size ≤ 20 . The size of *STACK* limits *n* to about 2^{32} .

Input Parameters

| | |
|------------|---|
| <i>id</i> | = 'I': sort <i>d</i> in increasing order; = 'D': sort <i>d</i> in decreasing order. |
| <i>n</i> | The length of the array <i>d</i> . |
| <i>d</i> | Array of size <i>n</i> . On entry, the array to be sorted. |
| <i>key</i> | Array of size <i>n</i> . On entry, <i>key</i> contains a key to each of the entries in <i>d</i> . Typically, $key[i] = i+1$ for all $i = 0, \dots, n-1$. |

Output Parameters

| | |
|-------------|--|
| <i>d</i> | On exit, <i>d</i> has been sorted into increasing order ($d[0] \leq \dots \leq d[n - 1]$) or into decreasing order ($d[0] \geq \dots \geq d[n - 1]$), depending on <i>id</i> . |
| <i>info</i> | = 0: successful exit < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value. |
| <i>key</i> | On exit, <i>key</i> is permuted in exactly the same manner as <i>d</i> was permuted from input to output. Therefore, if $key[i] = i+1$ for all $i = 0, \dots, n-1$ on input, $d[i]$ on output equals $d[key[i]-1]$ on input. |

?stegr2

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

Syntax

```
void sstegr2(char* jobz, char* range, MKL_INT* n, float* d, float* e, float* vl,
float* vu, MKL_INT* il, MKL_INT* iu, MKL_INT* m, float* w, float* z, MKL_INT* ldz,
MKL_INT* nzc, MKL_INT* isuppz, float* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT*
liwork, MKL_INT* dol, MKL_INT* dou, MKL_INT* zoffset, MKL_INT* info);
```

```
void dstegr2(char* jobz, char* range, MKL_INT* n, double* d, double* e, double* vl,
double* vu, MKL_INT* il, MKL_INT* iu, MKL_INT* m, double* w, double* z, MKL_INT* ldz,
MKL_INT* nzc, MKL_INT* isuppz, double* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT*
liwork, MKL_INT* dol, MKL_INT* dou, MKL_INT* zoffset, MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

?stegr2 computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T . It is invoked in the ScaLAPACK MRRR driver `p?syevr` and the corresponding Hermitian version either when only eigenvalues are to be computed, or when only a single processor is used (the sequential-like case).

?stegr2 has been adapted from LAPACK's ?stegr. Please note the following crucial changes.

1. The calling sequence has two additional integer parameters, dol and dou , that should satisfy $m \geq dou \geq dol \geq 1$. ?stegr2 only computes the eigenpairs corresponding to eigenvalues dol through dou in w , indexed $dol-1$ through $dou-1$. (That is, instead of computing the eigenpairs belonging to $w[0]$ through $w[m-1]$, only the eigenvectors belonging to eigenvalues $w[dol-1]$ through $w[dou-1]$ are computed. In this case, only the eigenvalues dol through dou are guaranteed to be fully accurate.
2. m is *not* the number of eigenvalues specified by $range$, but is $m = dou - dol + 1$. This concerns the case where only eigenvalues are computed, but on more than one processor. Thus, in this case m refers to the number of eigenvalues computed on this processor.
3. The arrays w and z might not contain all the wanted eigenpairs locally, instead this information is distributed over other processors.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

- $jobz$ = 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

| | |
|---------------|--|
| <i>range</i> | <p>= 'A': all eigenvalues will be found.</p> <p>= 'V': all eigenvalues in the half-open interval $(vl, vu]$ will be found.</p> <p>= 'I': eigenvalues of the entire matrix with the indices in a given range will be found.</p> |
| <i>n</i> | The order of the matrix. $n \geq 0$. |
| <i>d</i> | <p>Array of size n</p> <p>On entry, the n diagonal elements of the tridiagonal matrix T. Overwritten on exit.</p> |
| <i>e</i> | <p>Array of size n</p> <p>On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix T in elements 0 to $n-2$ of e. $e[n-1]$ need not be set on input, but is used internally as workspace. Overwritten on exit.</p> |
| <i>vl</i> | |
| <i>vu</i> | <p>If $range='V'$, the lower and upper bounds of the interval to be searched for eigenvalues. $vl < vu$.</p> <p>Not referenced if $range = 'A'$ or 'I'.</p> |
| <i>il, iu</i> | <p>If $range='I'$, the indices (in ascending order) of the smallest eigenvalue, to be returned in $w[il-1]$, and largest eigenvalue, to be returned in $w[iu-1]$.</p> <p>$1 \leq il \leq iu \leq n$, if $n > 0$.</p> <p>Not referenced if $range = 'A'$ or 'V'.</p> |
| <i>ldz</i> | The leading dimension of the array z . $ldz \geq 1$, and if $jobz = 'V'$, then $ldz \geq \max(1, n)$. |
| <i>nzc</i> | <p>The number of eigenvectors to be held in the array z, storing the matrix Z.</p> <p>If $range = 'A'$, then $nzc \geq \max(1, n)$.</p> <p>If $range = 'V'$, then $nzc \geq$ the number of eigenvalues in $(vl, vu]$.</p> <p>If $range = 'I'$, then $nzc \geq iu - il + 1$.</p> <p>If $nzc = -1$, then a workspace query is assumed; the function calculates the number of columns of the matrix Z that are needed to hold the eigenvectors. This value is returned as the first entry of the z array, and no error message related to nzc is issued.</p> |
| <i>lwork</i> | <p>The size of the array $work$. $lwork \geq \max(1, 18*n)$</p> <p>if $jobz = 'V'$, and $lwork \geq \max(1, 12*n)$ if $jobz = 'N'$. If $lwork = -1$, then a workspace query is assumed; the function only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued.</p> |
| <i>liwork</i> | The size of the array $iwork$. $liwork \geq \max(1, 10*n)$ if the eigenvectors are desired, and $liwork \geq \max(1, 8*n)$ if only the eigenvalues are to be computed. |

If $liwork = -1$, then a workspace query is assumed; the function only calculates the optimal size of the $iwork$ array, returns this value as the first entry of the $iwork$ array, and no error message related to $liwork$ is issued.

dol, dou

From the eigenvalues $w[0]$ through $w[m-1]$, only eigenvectors $Z(:,dol)$ to $Z(:,dou)$ are computed.

If $dol > 1$, then $Z(:,dol-1-zoffset)$ is used and overwritten.

If $dou < m$, then $Z(:,dou+1-zoffset)$ is used and overwritten.

$zoffset$

Offset for storing the eigenpairs when z is distributed in 1D-cyclic fashion

OUTPUT Parameters

m

Globally summed over all processors, m equals the total number of eigenvalues found. $0 \leq m \leq n$. If $range = 'A'$, $m = n$, and if $range = 'I'$, $m = iu - il + 1$. The local output equals $m = dou - dol + 1$.

w

Array of size n

The first m elements contain the selected eigenvalues in ascending order. Note that immediately after exiting this function, only the eigenvalues indexed $dol-1$ through $dou-1$ are reliable on this processor because the eigenvalue computation is done in parallel. Other processors will hold reliable information on other parts of the w array. This information is communicated in the ScaLAPACK driver.

z

Array of size $ldz * \max(1,m)$.

If $jobz = 'V'$, and if $info = 0$, then the first m columns of the matrix Z stored in z contain some of the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i -th column of Z holding the eigenvector associated with $w[i-1]$.

If $jobz = 'N'$, then z is not referenced.

Note: the user must ensure that at least $\max(1,m)$ columns of the matrix are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and can be computed with a workspace query by setting $nzc = -1$, see below.

$isuppz$

array of size $2 * \max(1,m)$

The support of the eigenvectors in z , i.e., the indices indicating the nonzero elements in z . The i -th computed eigenvector is nonzero only in elements $isuppz[2*i-2]$ through $isuppz[2*i-1]$. This is relevant in the case when the matrix is split. $isuppz$ is only set if $n > 2$.

$work$

On exit, if $info = 0$, $work[0]$ returns the optimal (and minimal) $lwork$.

$iwork$

On exit, if $info = 0$, $iwork[0]$ returns the optimal $liwork$.

$info$

On exit, $info$

= 0: successful exit

other: if $info = -i$, the i -th argument had an illegal value

if *info* = 10X, internal error in ?larre2,

if *info* = 20X, internal error in ?larrv.

Here, the digit X = ABS(*iinfo*) < 10, where *iinfo* is the nonzero error code returned by ?larre2 or ?larrv, respectively.

?stegr2a

Computes selected eigenvalues and initial representations needed for eigenvector computations.

Syntax

```
void sstegr2a(char* jobz, char* range, MKL_INT* n, float* d, float* e, float* vl,
float* vu, MKL_INT* il, MKL_INT* iu, MKL_INT* m, float* w, float* z, MKL_INT* ldz,
MKL_INT* nzc, float* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT*
dol, MKL_INT* dou, MKL_INT* needil, MKL_INT* neediu, MKL_INT* inderr, MKL_INT* nsplit,
float* pivmin, float* scale, float* wl, float* wu, MKL_INT* info);
```

```
void dstegr2a(char* jobz, char* range, MKL_INT* n, double* d, double* e, double* vl,
double* vu, MKL_INT* il, MKL_INT* iu, MKL_INT* m, double* w, double* z, MKL_INT* ldz,
MKL_INT* nzc, double* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT*
dol, MKL_INT* dou, MKL_INT* needil, MKL_INT* neediu, MKL_INT* inderr, MKL_INT* nsplit,
double* pivmin, double* scale, double* wl, double* wu, MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

?stegr2a computes selected eigenvalues and initial representations needed for eigenvector computations in ?stegr2b. It is invoked in the ScaLAPACK MRRR driver p?syevr and the corresponding Hermitian version when both eigenvalues and eigenvectors are computed in parallel on multiple processors. For this case, ?stegr2a implements the first part of the MRRR algorithm, parallel eigenvalue computation and finding the root RRR. At the end of ?stegr2a, other processors might have a part of the spectrum that is needed to continue the computation locally. Once this eigenvalue information has been received by the processor, the computation can then proceed by calling the second part of the parallel MRRR algorithm, ?stegr2b.

Please note:

- The calling sequence has two additional integer parameters, (compared to LAPACK's [stegr](#)), these are *dol* and *dou* and should satisfy $m \geq dou \geq dol \geq 1$. These parameters are only relevant for the case *jobz* = 'V'.

Globally invoked over all processors, ?stegr2a computes all the eigenvalues specified by *range*.

?stegr2a locally only computes the eigenvalues corresponding to eigenvalues *dol* through *dou* in *w*, indexed *dol*-1 through *dou*-1. (That is, instead of computing the eigenvectors belonging to $w[[0]$ through $w[[m-1]$, only the eigenvectors belonging to eigenvalues $w[[dol-1]$ through $w[[dou-1]$ are computed. In this case, only the eigenvalues *dol* through *dou* are guaranteed to be fully accurate.

- *m* is not the number of eigenvalues specified by *range*, but it is $m = dou - dol + 1$. Instead, *m* refers to the number of eigenvalues computed on this processor.
- While no eigenvectors are computed in ?stegr2a itself (this is done later in ?stegr2b), the interface

If $jobz = 'V'$ then, depending on $range$ and $dol, dou, ?stegr2a$ might need more workspace in z than the original $?stegr$. In particular, the arrays w and z might not contain all the wanted eigenpairs locally, instead this information is distributed over other processors.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

| | |
|----------|---|
| $jobz$ | <p>= 'N': Compute eigenvalues only;</p> <p>= 'V': Compute eigenvalues and eigenvectors.</p> |
| $range$ | <p>= 'A': all eigenvalues will be found.</p> <p>= 'V': all eigenvalues in the half-open interval $(vl, vu]$ will be found.</p> <p>= 'I': eigenvalues of the entire matrix with the indices in a given range will be found.</p> |
| n | The order of the matrix. $n \geq 0$. |
| d | <p>Array of size n</p> <p>The n diagonal elements of the tridiagonal matrix T. Overwritten on exit.</p> |
| e | <p>Array of size n</p> <p>On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix T in elements 0 to $n-2$ of e. $e[n-1]$ need not be set on input, but is used internally as workspace. Overwritten on exit.</p> |
| vl, vu | <p>If $range='V'$, the lower and upper bounds of the interval to be searched for eigenvalues. $vl < vu$.</p> <p>Not referenced if $range = 'A'$ or 'I'.</p> |
| il, iu | <p>If $range='I'$, the indices (in ascending order) of the smallest eigenvalue, to be returned in $w[il-1]$, and largest eigenvalue, to be returned in $w[iu-1]$. $1 \leq il \leq iu \leq n$, if $n > 0$.</p> <p>Not referenced if $range = 'A'$ or 'V'.</p> |
| ldz | The leading dimension of the array z . $ldz \geq 1$, and if $jobz = 'V'$, then $ldz \geq \max(1, n)$. |
| nzc | <p>The number of eigenvectors to be held in the array z.</p> <p>If $range = 'A'$, then $nzc \geq \max(1, n)$.</p> <p>If $range = 'V'$, then $nzc \geq$ the number of eigenvalues in $(vl, vu]$.</p> |

If $range = 'I'$, then $nzc \geq iu - il + 1$.

If $nzc = -1$, then a workspace query is assumed; the function calculates the number of columns of the matrix stored in array z that are needed to hold the eigenvectors. This value is returned as the first entry of the z array, and no error message related to nzc is issued.

$lwork$

The size of the array $work$. $lwork \geq \max(1, 18 * n)$ if $jobz = 'V'$, and $lwork \geq \max(1, 12 * n)$ if $jobz = 'N'$.

If $lwork = -1$, then a workspace query is assumed; the function only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued.

$liwork$

The size of the array $iwork$. $liwork \geq \max(1, 10 * n)$ if the eigenvectors are desired, and $liwork \geq \max(1, 8 * n)$ if only the eigenvalues are to be computed.

If $liwork = -1$, then a workspace query is assumed; the function only calculates the optimal size of the $iwork$ array, returns this value as the first entry of the $iwork$ array, and no error message related to $liwork$ is issued.

dol, dou

From all the eigenvalues $w[0]$ through $w[m-1]$, only eigenvalues $w[dol-1]$ through $w[dou-1]$ are computed.

OUTPUT Parameters

m

Globally summed over all processors, m equals the total number of eigenvalues found. $0 \leq m \leq n$.

If $range = 'A'$, $m = n$, and if $range = 'I'$, $m = iu - il + 1$.

The local output equals $m = dou - dol + 1$.

w

Array of size n

The first m elements contain approximations to the selected eigenvalues in ascending order. Note that immediately after exiting this function, only the eigenvalues indexed $dol-1$ through $dou-1$ are reliable on this processor because the eigenvalue computation is done in parallel. The other entries are very crude preliminary approximations. Other processors hold reliable information on these other parts of the w array.

This information is communicated in the ScaLAPACK driver.

z

Array of size $ldz * \max(1, m)$.

?stegr2a does not compute eigenvectors, this is done in ?stegr2b. The argument z as well as all related other arguments only appear to keep the interface consistent and to signal to the user that this function is meant to be used when eigenvectors are computed.

$work$

On exit, if $info = 0$, $work[0]$ returns the optimal (and minimal) $lwork$.

$iwork$

On exit, if $info = 0$, $iwork[0]$ returns the optimal $liwork$.

| | |
|-----------------------|---|
| <i>needil, neediu</i> | The indices of the leftmost and rightmost eigenvalues needed to accurately compute the relevant part of the representation tree. This information can be used to find out which processors have the relevant eigenvalue information needed so that it can be communicated. |
| <i>inderr</i> | <i>inderr</i> points to the place in the work space where the eigenvalue uncertainties (errors) are stored. |
| <i>nsplit</i> | The number of blocks into which T splits. $1 \leq nsplit \leq n$. |
| <i>pivmin</i> | The minimum pivot in the sturm sequence for T . |
| <i>scale</i> | The scaling factor for the tridiagonal T . |
| <i>wl, wu</i> | The interval $(wl, wu]$ contains all the wanted eigenvalues. It is either given by the user or computed in ?larre2a . |
| <i>info</i> | On exit, <i>info</i> = 0: successful exit other: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value if <i>info</i> = 10 <i>x</i> , internal error in ?larre2a , Here, the digit $x = \text{abs}(iinfo) < 10$, where <i>iinfo</i> is the nonzero error code returned by ?larre2a . |

See Also

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

?stegr2b

From eigenvalues and initial representations computes the selected eigenvalues and eigenvectors of the real symmetric tridiagonal matrix in parallel on multiple processors.

Syntax

```
void sstegr2b(char* jobz, MKL_INT* n, float* d, float* e, MKL_INT* m, float* w, float* z, MKL_INT* ldz, MKL_INT* nzc, MKL_INT* isuppz, float* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT* dol, MKL_INT* dou, MKL_INT* needil, MKL_INT* neediu, MKL_INT* indwlc, float* pivmin, float* scale, float* wl, float* wu, MKL_INT* vstart, MKL_INT* finish, MKL_INT* maxcls, MKL_INT* ndepth, MKL_INT* parity, MKL_INT* zoffset, MKL_INT* info);
```

```
void dstegr2b(char* jobz, MKL_INT* n, double* d, double* e, MKL_INT* m, double* w, double* z, MKL_INT* ldz, MKL_INT* nzc, MKL_INT* isuppz, double* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT* dol, MKL_INT* dou, MKL_INT* needil, MKL_INT* neediu, MKL_INT* indwlc, double* pivmin, double* scale, double* wl, double* wu, MKL_INT* vstart, MKL_INT* finish, MKL_INT* maxcls, MKL_INT* ndepth, MKL_INT* parity, MKL_INT* zoffset, MKL_INT* info);
```

Include Files

- `mkl_scalapack.h`

Description

?stegr2b should only be called after a call to ?stegr2a. From eigenvalues and initial representations computed by ?stegr2a, ?stegr2b computes the selected eigenvalues and eigenvectors of the real symmetric tridiagonal matrix in parallel on multiple processors. It is potentially invoked multiple times on a given processor because the locally relevant representation tree might depend on spectral information that is "owned" by other processors and might need to be communicated.

Please note:

- The calling sequence has two additional integer parameters, *dol* and *dou*, that should satisfy $m \geq dou \geq dol \geq 1$. These parameters are only relevant for the case *jobz* = 'V'. ?stegr2b only computes the eigenvectors corresponding to eigenvalues *dol* through *dou* in *w*, indexed *dol*-1 through *dou*-1. (That is, instead of computing the eigenvectors belonging to $w[0]$ through $w[m-1]$, only the eigenvectors belonging to eigenvalues $w[dol-1]$ through $w[dou-1]$ are computed. In this case, only the eigenvalues *dol* through *dou* are guaranteed to be accurately refined to all figures by Rayleigh-Quotient iteration.
- The additional arguments *vstart*, *finish*, *ndepth*, *parity*, *zoffset* are included as a thread-safe implementation equivalent to save variables. These variables store details about the local representation tree which is computed layerwise. For scalability reasons, eigenvalues belonging to the locally relevant representation tree might be computed on other processors. These need to be communicated before the inspection of the RRRs can proceed on any given layer. Note that only when the variable *finish* is non-zero, the computation has ended. All eigenpairs between *dol* and *dou* have been computed. *m* is set to $dou - dol + 1$.
- ?stegr2b needs more workspace in *z* than the sequential ?stegr. It is used to store the conformal embedding of the local representation tree.

| | |
|-------------|---|
| <i>jobz</i> | = 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors. |
| <i>n</i> | The order of the matrix. $n \geq 0$. |
| <i>d</i> | Array of size <i>n</i> The <i>n</i> diagonal elements of the tridiagonal matrix T. Overwritten on exit. |
| <i>e</i> | Array of size <i>n</i> The (<i>n</i> -1) subdiagonal elements of the tridiagonal matrix T in elements 0 to <i>n</i> -2 of <i>e</i> . $e[n-1]$ need not be set on input, but is used internally as workspace. Overwritten on exit. |
| <i>m</i> | The total number of eigenvalues found in ?stegr2a. $0 \leq m \leq n$. |

| | |
|-----------------------|--|
| <i>w</i> | <p>Array of size n</p> <p>The first m elements contain approximations to the selected eigenvalues in ascending order. Note that only the eigenvalues from the locally relevant part of the representation tree, that is all the clusters that include eigenvalues from dol through dou, are reliable on this processor. (It does not need to know about any others anyway.)</p> |
| <i>ldz</i> | <p>The leading dimension of the array z. $ldz \geq 1$, and if $jobz = 'V'$, then $ldz \geq \max(1, n)$.</p> |
| <i>nzc</i> | <p>The number of eigenvectors to be held in the array z, storing the matrix Z.</p> |
| <i>lwork</i> | <p>The size of the array $work$. $lwork \geq \max(1, 18 * n)$ if $jobz = 'V'$, and $lwork \geq \max(1, 12 * n)$ if $jobz = 'N'$.</p> <p>If $lwork = -1$, then a workspace query is assumed; the function only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued.</p> |
| <i>liwork</i> | <p>The size of the array $iwork$. $liwork \geq \max(1, 10 * n)$ if the eigenvectors are desired, and $liwork \geq \max(1, 8 * n)$ if only the eigenvalues are to be computed.</p> <p>If $liwork = -1$, then a workspace query is assumed; the function only calculates the optimal size of the $iwork$ array, returns this value as the first entry of the $iwork$ array, and no error message related to $liwork$ is issued.</p> |
| <i>dol, dou</i> | <p>From the eigenvalues $w[0]$ through $w[m-1]$, only eigenvectors $Z(:, dol)$ to $Z(:, dou)$ are computed.</p> <p>If $dol > 1$, then $Z(:, dol-1-zoffset)$ is used and overwritten.</p> <p>If $dou < m$, then $Z(:, dou+1-zoffset)$ is used and overwritten.</p> |
| <i>needil, neediu</i> | <p>Describes which are the left and right outermost eigenvalues still to be computed. Initially computed by ?larre2a, modified in the course of the algorithm.</p> |
| <i>pivmin</i> | <p>The minimum pivot in the sturm sequence for T.</p> |
| <i>scale</i> | <p>The scaling factor for T. Used for unscaling the eigenvalues at the very end of the algorithm.</p> |
| <i>wl, wu</i> | <p>The interval $(wl, wu]$ contains all the wanted eigenvalues.</p> |
| <i>vstart</i> | <p>Non-zero on initialization, set to zero afterwards.</p> |
| <i>finish</i> | <p>Indicates whether all eigenpairs have been computed.</p> |
| <i>maxcls</i> | <p>The largest cluster worked on by this processor in the representation tree.</p> |
| <i>ndepth</i> | <p>The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.</p> |
| <i>parity</i> | <p>An internal parameter needed for the storage of the clusters on the current level of the representation tree.</p> |

zoffset Offset for storing the eigenpairs when *z* is distributed in 1D-cyclic fashion.

OUTPUT Parameters

z Array of size $ldz * \max(1,m)$

If *jobz* = 'V', and if *info* = 0, then a subset of the first *m* columns of the matrix *Z*, stored in *z*, contain the orthonormal eigenvectors of the matrix *T* corresponding to the selected eigenvalues, with the *i*-th column of *Z* holding the eigenvector associated with *w*[*i*-1].

See *dol*, *dou* for more information.

isuppz array of size $2 * \max(1,m)$.

The support of the eigenvectors in *z*, i.e., the indices indicating the nonzero elements in *z*. The *i*-th computed eigenvector is nonzero only in elements *isuppz*[$2*i-2$] through *isuppz*[$2*i-1$]. This is relevant in the case when the matrix is split. *isuppz* is only set if *n*>2.

work On exit, if *info* = 0, *work*[0] returns the optimal (and minimal) *lwork*.

iwork On exit, if *info* = 0, *iwork*[0] returns the optimal *liwork*.

needil, *neediu* Modified in the course of the algorithm.

indwlc Pointer into the workspace location where the local eigenvalue representations are stored. ("Local eigenvalues" are those relative to the individual shifts of the RRRs.)

vstart Non-zero on initialization, set to zero afterwards.

finish Indicates whether all eigenpairs have been computed

maxcls The largest cluster worked on by this processor in the representation tree.

ndepth The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.

parity An internal parameter needed for the storage of the clusters on the current level of the representation tree.

info On exit, *info*

= 0: successful exit

other: if *info* = -*i*, the *i*-th argument had an illegal value

if *info* = 20*x*, internal error in ?*larrv2*.

Here, the digit *x* = $\text{abs}(iinfo) < 10$, where *iinfo* is the nonzero error code returned by ?*larrv2*

?stein2

Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix, using inverse iteration.

Syntax

```
void sstein2 (MKL_INT *n , float *d , float *e , MKL_INT *m , float *w , MKL_INT
*iblock , MKL_INT *isplit , float *orfac , float *z , MKL_INT *ldz , float *work ,
MKL_INT *iwork , MKL_INT *ifail , MKL_INT *info );

void dstein2 (MKL_INT *n , double *d , double *e , MKL_INT *m , double *w , MKL_INT
*iblock , MKL_INT *isplit , double *orfac , double *z , MKL_INT *ldz , double *work ,
MKL_INT *iwork , MKL_INT *ifail , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The ?stein2 function is a modified LAPACK function ?stein. It computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter *maxits* (currently set to 5).

Input Parameters

| | |
|-----------|--|
| n | The order of the matrix T ($n \geq 0$). |
| m | The number of eigenvectors to be found ($0 \leq m \leq n$). |
| d, e, w | <p>Arrays:</p> <p>d, of size n. The n diagonal elements of the tridiagonal matrix T.</p> <p>e, of size n.</p> <p>The $(n-1)$ subdiagonal elements of the tridiagonal matrix T, in elements 1 to $n-1$. $e[n-1]$ need not be set.</p> <p>w, of size n.</p> <p>The first m elements of w contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array w from ?stebz with ORDER = 'B' is expected here).</p> <p>The size of w must be at least $\max(1, n)$.</p> |
| $iblock$ | <p>Array of size n.</p> <p>The submatrix indices associated with the corresponding eigenvalues in w;</p> <p>$iblock[j] = 1$, if eigenvalue $w[j]$ belongs to the first submatrix from the top,</p> <p>$iblock[j] = 2$, if eigenvalue $w[j]$ belongs to the second submatrix, etc. (The output array $iblock$ from ?stebz is expected here).</p> |

| | |
|---------------|--|
| <i>isplit</i> | Array of size n . The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to <i>isplit</i> [0], the second submatrix consists of rows/columns <i>isplit</i> [0]+1 through <i>isplit</i> [1], etc. (The output array <i>isplit</i> from <i>?stebz</i> is expected here). |
| <i>orfac</i> | <i>orfac</i> specifies which eigenvectors should be orthogonalized. Eigenvectors that correspond to eigenvalues which are within $orfac * T $ of each other are to be orthogonalized. |
| <i>ldz</i> | The leading dimension of the output array z ; $ldz \geq \max(1, n)$. |
| <i>work</i> | Workspace array of size $5n$. |
| <i>iwork</i> | Workspace array of size n . |

Output Parameters

| | |
|--------------|--|
| <i>z</i> | Array of size $ldz * m$. The computed eigenvectors. The eigenvector associated with the eigenvalue $w[i]$ is stored in the $(i+1)$ -th column of the matrix Z represented by z , $i=0, \dots, m-1$. Any vector that fails to converge is set to its current iterate after <i>maxits</i> iterations. |
| <i>ifail</i> | Array of size m . On normal exit, all elements of <i>ifail</i> are zero. If one or more eigenvectors fail to converge after <i>maxits</i> iterations, then their indices are stored in the array <i>ifail</i> . |
| <i>info</i> | <i>info</i> = 0, the exit is successful. <i>info</i> < 0: if <i>info</i> = $-i$, the i -th had an illegal value. <i>info</i> > 0: if <i>info</i> = i , then i eigenvectors failed to converge in <i>maxits</i> iterations. Their indices are stored in the array <i>ifail</i> . |

?dbtf2

Computes an LU factorization of a general band matrix with no pivoting (local unblocked algorithm).

Syntax

```
void sdbtf2 (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , float *ab , MKL_INT *ldab , MKL_INT *info );
void ddbtf2 (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , double *ab , MKL_INT *ldab , MKL_INT *info );
void cdbtf2 (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , MKL_Complex8 *ab , MKL_INT *ldab , MKL_INT *info );
```

```
void zdbtf2 (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , MKL_Complex16 *ab ,
MKL_INT *ldab , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `zdbtf2` function computes an LU factorization of a general real/complex m -by- n band matrix A without using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling [BLAS Routines and Functions](#).

Input Parameters

| | |
|--------|--|
| m | The number of rows of the matrix A ($m \geq 0$). |
| n | The number of columns in A ($n \geq 0$). |
| kl | The number of sub-diagonals within the band of A ($kl \geq 0$). |
| ku | The number of super-diagonals within the band of A ($ku \geq 0$). |
| ab | Array of size $ldab * n$. The matrix A in band storage, in rows $kl+1$ to $2kl+ku+1$; rows 1 to kl of the matrix need not be set. The j -th column of A is stored in the array ab as follows: $ab[kl+ku+i-j+(j-1)*ldab] = A(i,j)$ for $\max(1, j-ku) \leq j \leq \min(m, j+kl)$. |
| $ldab$ | The leading dimension of the array ab . ($ldab \geq 2kl + ku + 1$) |

Output Parameters

| | |
|--------|--|
| ab | On exit, details of the factorization: U is stored as an upper triangular band matrix with $kl+ku$ superdiagonals in rows 1 to $kl+ku+1$, and the multipliers used during the factorization are stored in rows $kl+ku+2$ to $2*kl+ku+1$. See the <i>Application Notes</i> below for further details. |
| $info$ | = 0: successful exit < 0: if $info = -i$, the i -th argument had an illegal value, > 0: if $info = +i$, the matrix element $U(i,i)$ is 0. The factorization has been completed, but the factor U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations. |

Application Notes

The band storage scheme is illustrated by the following example, when $m = n = 6$, $kl = 2$, $ku = 1$:

| on entry | on exit |
|--|--|
| $\begin{bmatrix} * & a_{12} & a_{23} & a_{34} & a_{45} & a_{56} \\ a_{11} & a_{22} & a_{33} & a_{44} & a_{55} & a_{66} \\ a_{21} & a_{32} & a_{43} & a_{54} & a_{65} & * \\ a_{31} & a_{42} & a_{53} & a_{64} & * & * \end{bmatrix}$ | $\begin{bmatrix} * & u_{12} & u_{23} & u_{34} & u_{45} & u_{56} \\ u_{11} & u_{22} & u_{33} & u_{44} & u_{55} & u_{66} \\ m_{21} & m_{32} & m_{43} & m_{54} & m_{65} & * \\ m_{31} & m_{42} & m_{53} & m_{64} & * & * \end{bmatrix}$ |

The function does not use array elements marked *; elements marked + need not be set on entry, but the function requires them to store elements of U , because of fill-in resulting from the row interchanges.

?dbtrf

Computes an LU factorization of a general band matrix with no pivoting (local blocked algorithm).

Syntax

```
void sdbtrf (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , float *ab , MKL_INT *ldab , MKL_INT *info );
```

```
void ddbtrf (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , double *ab , MKL_INT *ldab , MKL_INT *info );
```

```
void cdbtrf (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , MKL_Complex8 *ab , MKL_INT *ldab , MKL_INT *info );
```

```
void zdbtrf (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , MKL_Complex16 *ab , MKL_INT *ldab , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

This function computes an LU factorization of a real m -by- n band matrix A without using partial pivoting or row interchanges.

This is the blocked version of the algorithm, calling [BLAS Routines and Functions](#).

Input Parameters

| | |
|------|---|
| m | The number of rows of the matrix A ($m \geq 0$). |
| n | The number of columns in A ($n \geq 0$). |
| kl | The number of sub-diagonals within the band of A ($kl \geq 0$). |
| ku | The number of super-diagonals within the band of A ($ku \geq 0$). |
| ab | Array of size $ldab * n$. |

The matrix A in band storage, in rows $kl+1$ to $2kl+ku+1$; rows 1 to kl need not be set. The j -th column of A is stored in the array ab as follows: $ab[kl+ku+i-j+(j-1)*ldab] = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(m, j+kl)$.

$ldab$

The leading dimension of the array ab .

($ldab \geq 2kl + ku + 1$)

Output Parameters

ab

On exit, details of the factorization: U is stored as an upper triangular band matrix with $kl+ku$ superdiagonals in rows 1 to $kl+ku+1$, and the multipliers used during the factorization are stored in rows $kl+ku+2$ to $2*kl+ku+1$. See the *Application Notes* below for further details.

$info$

= 0: successful exit

< 0: if $info = -i$, the i -th argument had an illegal value,

> 0: if $info = +i$, the matrix element $U(i,i)$ is 0. The factorization has been completed, but the factor U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

Application Notes

The band storage scheme is illustrated by the following example, when $m = n = 6$, $kl = 2$, $ku = 1$:

| on entry | on exit |
|--|--|
| $\begin{bmatrix} * & a_{12} & a_{23} & a_{34} & a_{45} & a_{56} \\ a_{11} & a_{22} & a_{33} & a_{44} & a_{55} & a_{66} \\ a_{21} & a_{32} & a_{43} & a_{54} & a_{65} & * \\ a_{31} & a_{42} & a_{53} & a_{64} & * & * \end{bmatrix}$ | $\begin{bmatrix} * & u_{12} & u_{23} & u_{34} & u_{45} & u_{56} \\ u_{11} & u_{22} & u_{33} & u_{44} & u_{55} & u_{66} \\ m_{21} & m_{32} & m_{43} & m_{54} & m_{65} & * \\ m_{31} & m_{42} & m_{53} & m_{64} & * & * \end{bmatrix}$ |

The function does not use array elements marked *.

```
void cdttrf (MKL_INT *n , MKL_Complex8 *dl , MKL_Complex8 *d , MKL_Complex8 *du , MKL_INT *info );
```

```
void zdttrf (MKL_INT *n , MKL_Complex16 *dl , MKL_Complex16 *d , MKL_Complex16 *du , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `?dtttrf` function computes an LU factorization of a real or complex tridiagonal matrix A using elimination without partial pivoting.

The factorization has the form $A = L*U$, where L is a product of unit lower bidiagonal matrices and U is upper triangular with nonzeros only in the main diagonal and first superdiagonal.

Input Parameters

| | |
|-------------|--|
| n | The order of the matrix A ($n \geq 0$). |
| dl, d, du | Arrays containing elements of A . The array dl of size $(n-1)$ contains the sub-diagonal elements of A . The array d of size n contains the diagonal elements of A . The array du of size $(n-1)$ contains the super-diagonal elements of A . |

Output Parameters

| | |
|--------|---|
| dl | Overwritten by the $(n-1)$ multipliers that define the matrix L from the LU factorization of A . |
| d | Overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A . |
| du | Overwritten by the $(n-1)$ elements of the first super-diagonal of U . |
| $info$ | = 0: successful exit < 0: if $info = -i$, the i -th argument had an illegal value, > 0: if $info = i$, the matrix element $U(i,i)$ is exactly 0. The factorization has been completed, but the factor U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations. |

See Also

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

?dtttrsv

Solves a general tridiagonal system of linear equations using the LU factorization computed by `?dtttrf`.

Syntax

```
void sdttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , float *dl ,
float *d , float *du , float *b , MKL_INT *ldb , MKL_INT *info );
```

```
void ddttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , double *dl ,
double *d , double *du , double *b , MKL_INT *ldb , MKL_INT *info );
```

```

void cdtttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex8
*d1 , MKL_Complex8 *d , MKL_Complex8 *du , MKL_Complex8 *b , MKL_INT *ldb , MKL_INT
*info );

void zdtttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex16
*d1 , MKL_Complex16 *d , MKL_Complex16 *du , MKL_Complex16 *b , MKL_INT *ldb , MKL_INT
*info );

```

Include Files

- mkl_scalapack.h

Description

The `cdtttrsv` function solves one of the following systems of linear equations:

$$L * X = B, L^T * X = B, \text{ or } L^H * X = B,$$

$$U * X = B, U^T * X = B, \text{ or } U^H * X = B$$

with factors of the tridiagonal matrix A from the LU factorization computed by `cdttrf`.

Input Parameters

| | |
|------------------|---|
| <i>uplo</i> | Specifies whether to solve with L or U . |
| <i>trans</i> | Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $A * X = B$ is solved for X (no transpose). If <i>trans</i> = 'T', then $A^T * X = B$ is solved for X (transpose). If <i>trans</i> = 'C', then $A^H * X = B$ is solved for X (conjugate transpose). |
| <i>n</i> | The order of the matrix A ($n \geq 0$). |
| <i>nrhs</i> | The number of right-hand sides, that is, the number of columns in the matrix B ($nrhs \geq 0$). |
| <i>d1,d,du,b</i> | The array <i>d1</i> of size $(n - 1)$ contains the $(n - 1)$ multipliers that define the matrix L from the LU factorization of A . The array <i>d</i> of size n contains n diagonal elements of the upper triangular matrix U from the LU factorization of A . The array <i>du</i> of size $(n - 1)$ contains the $(n - 1)$ elements of the first super-diagonal of U . On entry, the array <i>b</i> of size $ldb * nrhs$ contains the right-hand side of matrix B . |
| <i>ldb</i> | The leading dimension of the array <i>b</i> ; $ldb \geq \max(1, n)$. |

Output Parameters

| | |
|-------------|--|
| <i>b</i> | Overwritten by the solution matrix X . |
| <i>info</i> | If <i>info</i> =0, the execution is successful. If <i>info</i> = $-i$, the i -th parameter had an illegal value. |

See Also

Overview of ScaLAPACK Routines for details of ScaLAPACK array descriptor structures and related notations.

?pttrsv

Solves a symmetric (Hermitian) positive-definite tridiagonal system of linear equations, using the L^*D*L^H factorization computed by `?pttrf`.

Syntax

```
void spttrsv (char *trans , MKL_INT *n , MKL_INT *nrhs , float *d , float *e , float *b , MKL_INT *ldb , MKL_INT *info );
```

```
void dpttrsv (char *trans , MKL_INT *n , MKL_INT *nrhs , double *d , double *e , double *b , MKL_INT *ldb , MKL_INT *info );
```

```
void cpttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , float *d , MKL_Complex8 *e , MKL_Complex8 *b , MKL_INT *ldb , MKL_INT *info );
```

```
void zpttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , double *d , MKL_Complex16 *e , MKL_Complex16 *b , MKL_INT *ldb , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `?pttrsv` function solves one of the triangular systems:

$L^T * X = B$, or $L * X = B$ for real flavors,

or

$L * X = B$, or $L^H * X = B$,

$U * X = B$, or $U^H * X = B$ for complex flavors,

where L (or U for complex flavors) is the Cholesky factor of a Hermitian positive-definite tridiagonal matrix A such that

$A = L^*D*L^H$ (computed by `spttrf/dpttrf`)

or

$A = U^H * D * U$ or $A = L^*D*L^H$ (computed by `cpttrf/zpttrf`).

Input Parameters

| | |
|--------------------|--|
| <code>uplo</code> | Must be 'U' or 'L'. Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and the form of the factorization: If <code>uplo = 'U'</code> , e is the superdiagonal of U , and $A = U^H * D * U$ or $A = L^*D*L^H$; if <code>uplo = 'L'</code> , e is the subdiagonal of L , and $A = L^*D*L^H$. The two forms are equivalent, if A is real. |
| <code>trans</code> | Specifies the form of the system of equations: |

| | |
|--------|---|
| | for real flavors: if $trans = 'N'$: $L^*X = B$ (no transpose) if $trans = 'T'$: $L^T * X = B$ (transpose) for complex flavors: if $trans = 'N'$: $U^*X = B$ or $L^*X = B$ (no transpose) if $trans = 'C'$: $U^H * X = B$ or $L^H * X = B$ (conjugate transpose). |
| n | The order of the tridiagonal matrix A . $n \geq 0$. |
| $nrhs$ | The number of right hand sides, that is, the number of columns of the matrix B . $nrhs \geq 0$. |
| d | array of size n . The n diagonal elements of the diagonal matrix D from the factorization computed by ?pttrf . |
| e | array of size $(n-1)$. The $(n-1)$ off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by ?pttrf . See <i>uplo</i> . |
| b | array of size $ldb * nrhs$. On entry, the right hand side matrix B . |
| ldb | The leading dimension of the array b . $ldb \geq \max(1, n)$. |

Output Parameters

| | |
|--------|--|
| b | On exit, the solution matrix X . |
| $info$ | = 0: successful exit < 0: if $info = -i$, the i -th argument had an illegal value. |

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

?steqr2

Computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method.

Syntax

```
void ssteqr2 (char *compz , MKL_INT *n , float *d , float *e , float *z , MKL_INT
*ldz , MKL_INT *nr , float *work , MKL_INT *info );
void dsteqr2 (char *compz , MKL_INT *n , double *d , double *e , double *z , MKL_INT
*ldz , MKL_INT *nr , double *work , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `?steqr2` function is a modified version of LAPACK function `?steqr`. The `?steqr2` function computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. `?steqr2` is modified from `?steqr` to allow each ScaLAPACK process running `?steqr2` to perform updates on a distributed matrix Q . Proper usage of `?steqr2` can be gleaned from examination of ScaLAPACK function `p?syeval`.

Input Parameters

| | |
|-------------------------|--|
| <code>compz</code> | <p>Must be 'N' or 'I'.</p> <p>If <code>compz = 'N'</code>, the function computes eigenvalues only. If <code>compz = 'I'</code>, the function computes the eigenvalues and eigenvectors of the tridiagonal matrix T.</p> <p>z must be initialized to the identity matrix by <code>p?laset</code> or <code>?laset</code> prior to entering this function.</p> |
| <code>n</code> | The order of the matrix T ($n \geq 0$). |
| <code>d, e, work</code> | <p>Arrays:</p> <p>d contains the diagonal elements of T. The size of d must be at least $\max(1, n)$.</p> <p>e contains the $(n-1)$ subdiagonal elements of T. The size of e must be at least $\max(1, n-1)$.</p> <p>$work$ is a workspace array. The size of $work$ is $\max(1, 2*n-2)$. If <code>compz = 'N'</code>, then $work$ is not referenced.</p> |
| <code>z</code> | <p>(local)</p> <p>Array of global size $n * n$ and of local size $ldz * nr$.</p> <p>If <code>compz = 'V'</code>, then z contains the orthogonal matrix used in the reduction to tridiagonal form.</p> |
| <code>ldz</code> | <p>The leading dimension of the array z. Constraints:</p> <p>$ldz \geq 1$,</p> <p>$ldz \geq \max(1, n)$, if eigenvectors are desired.</p> |
| <code>nr</code> | <p>$nr = \max(1, \text{numroc}(n, nb, myprow, 0, nprocs))$.</p> <p>If <code>compz = 'N'</code>, then nr is not referenced.</p> |

Output Parameters

| | |
|----------------|--|
| <code>d</code> | <p>On exit, the eigenvalues in ascending order, if <code>info = 0</code>.</p> <p>See also <code>info</code>.</p> |
| <code>e</code> | On exit, e has been destroyed. |
| <code>z</code> | On exit, if <code>info = 0</code> , then, |

if `compz = 'V'`, `z` contains the orthonormal eigenvectors of the original symmetric matrix, and if `compz = 'I'`, `z` contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If `compz = 'N'`, then `z` is not referenced.

`info`

`info = 0`, the exit is successful.

`info < 0`: if `info = -i`, the `i`-th had an illegal value.

`info > 0`: the algorithm has failed to find all the eigenvalues in a total of $30n$ iterations;

if `info = i`, then `i` elements of `e` have not converged to zero; on exit, `d` and `e` contain the elements of a symmetric tridiagonal matrix, which is orthogonally similar to the original matrix.

?trmvt

Performs matrix-vector operations.

Syntax

```
void strmvt (const char* uplo, const MKL_INT* n, const float* t, const MKL_INT* ldt,
float* x, const MKL_INT* incx, const float* y, const MKL_INT* incy, float* w, const
MKL_INT* incw, const float* z, const MKL_INT* incz);
```

```
void dtrmvt (const char* uplo, const MKL_INT* n, const double* t, const MKL_INT* ldt,
double* x, const MKL_INT* incx, const double* y, const MKL_INT* incy, double* w, const
MKL_INT* incw, const double* z, const MKL_INT* incz);
```

```
void ctrmvt (const char* uplo, const MKL_INT* n, const MKL_Complex8* t, const MKL_INT*
ldt, MKL_Complex8* x, const MKL_INT* incx, const MKL_Complex8* y, const MKL_INT* incy,
MKL_Complex8* w, const MKL_INT* incw, const MKL_Complex8* z, const MKL_INT* incz);
```

```
void ztrmvt (const char* uplo, const MKL_INT* n, const MKL_Complex16* t, const MKL_INT*
ldt, MKL_Complex16* x, const MKL_INT* incx, const MKL_Complex16* y, const MKL_INT*
incy, MKL_Complex16* w, const MKL_INT* incw, const MKL_Complex16* z, const MKL_INT*
incz);
```

Include Files

- `mkl_scalapack.h`

Description

?trmvt performs the matrix-vector operations as follows:

strmvt and dtrmvt: $x := T^* y$, and $w := T^* z$

ctrmvt and ztrmvt: $x := \text{conjg}(T^*) y$, and $w := T^* z$,

where `x` is an `n` element vector and `T` is an `n`-by-`n` upper or lower triangular matrix.

Input Parameters

| | |
|-------------|--|
| <i>uplo</i> | <p>On entry, <i>uplo</i> specifies whether the matrix is an upper or lower triangular matrix as follows:</p> <p><i>uplo</i> = 'U' or 'u' <i>A</i> is an upper triangular matrix.</p> <p><i>uplo</i> = 'L' or 'l' <i>A</i> is a lower triangular matrix.</p> <p>Unchanged on exit.</p> |
| <i>n</i> | <p>On entry, <i>n</i> specifies the order of the matrix <i>A</i>. <i>n</i> must be at least zero.</p> <p>Unchanged on exit.</p> |
| <i>t</i> | <p>Array of size (<i>ldt</i>, <i>n</i>).</p> <p>Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i>-by-<i>n</i> upper triangular part of the array <i>t</i> must contain the upper triangular matrix and the strictly lower triangular part of <i>t</i> is not referenced.</p> <p>Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i>-by-<i>n</i> lower triangular part of the array <i>t</i> must contain the lower triangular matrix and the strictly upper triangular part of <i>t</i> is not referenced.</p> |
| <i>ldt</i> | <p>On entry, <i>lda</i> specifies the first dimension of <i>A</i> as declared in the calling (sub) program. <i>lda</i> must be at least max(1, <i>n</i>).</p> <p>Unchanged on exit.</p> |
| <i>incx</i> | <p>On entry, <i>incx</i> specifies the increment for the elements of <i>x</i>. <i>incx</i> must not be zero.</p> <p>Unchanged on exit.</p> |
| <i>y</i> | <p>Array of size at least (1 + (<i>n</i> - 1) * abs(<i>incy</i>)).</p> <p>Before entry, the incremented array <i>y</i> must contain the <i>n</i> element vector <i>y</i>.</p> <p>Unchanged on exit.</p> |
| <i>incy</i> | <p>On entry, <i>incy</i> specifies the increment for the elements of <i>y</i>. <i>incy</i> must not be zero.</p> <p>Unchanged on exit.</p> |
| <i>incw</i> | <p>On entry, <i>incw</i> specifies the increment for the elements of <i>w</i>. <i>incw</i> must not be zero.</p> <p>Unchanged on exit.</p> |
| <i>z</i> | <p>Array of size at least (1 + (<i>n</i> - 1) * abs(<i>incz</i>)).</p> <p>Before entry, the incremented array <i>z</i> must contain the <i>n</i> element vector <i>z</i>.</p> <p>Unchanged on exit.</p> |
| <i>incz</i> | <p>On entry, <i>incz</i> specifies the increment for the elements of <i>z</i>. <i>incz</i> must not be zero.</p> |

Unchanged on exit.

Output Parameters

| | |
|----------|---|
| <i>t</i> | <p>Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i>-by-<i>n</i> upper triangular part of the array <i>t</i> must contain the upper triangular matrix and the strictly lower triangular part of <i>t</i> is not referenced.</p> <p>Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i>-by-<i>n</i> lower triangular part of the array <i>t</i> must contain the lower triangular matrix and the strictly upper triangular part of <i>t</i> is not referenced.</p> |
| <i>x</i> | <p>Array of size at least $(1 + (n - 1) * \text{abs}(incx))$.</p> <p>On exit, $x = T * y$.</p> |
| <i>w</i> | <p>Array of size at least $(1 + (n - 1) * \text{abs}(incw))$.</p> <p>On exit, $w = T * z$.</p> |

pilaenv

Returns the positive integer value of the logical blocking size.

Syntax

```
MKL_INT pilaenv (const MKL_INT *ictxt , const char *prec);
```

Include Files

- mkl_pblas.h

Description

`pilaenv` returns the positive integer value of the logical blocking size. This value is machine and precision specific. This version provides a logical blocking size which should give good though not optimal performance on many of the currently available distributed-memory concurrent computers. You are encouraged to modify this subroutine to set this tuning parameter for your particular machine.

Input Parameters

| | |
|--------------|---|
| <i>ictxt</i> | <p>On entry, <i>ictxt</i> specifies the BLACS context handle, indicating the global context of the operation. The context itself is global, but the value of <i>ictxt</i> is local.</p> |
| <i>prec</i> | <p>On input, <i>prec</i> specifies the precision for which the logical block size should be returned as follows:</p> <p><i>prec</i> = 'S' or 's' single precision real, <i>prec</i> = 'D' or 'd' double precision real, <i>prec</i> = 'C' or 'c' single precision complex, <i>prec</i> = 'Z' or 'z' double precision complex, <i>prec</i> = 'I' or 'i' integer.</p> |

Application Notes

Before modifying this routine to tune the library performance on your system, be aware of the following:

1. The value this function returns must be strictly larger than zero,
2. If you are planning to link your program with different instances of the library (for example, on a heterogeneous machine), you *must* compile each instance of the library with exactly the same version of this routine for obvious interoperability reasons.

pilaenvx

Called from the ScaLAPACK routines to choose problem-dependent parameters for the local environment.

Syntax

```
MKL_INT pilaenvx (const MKL_INT* ictxt, const MKL_INT* ispec, const char* name, const
char* opts, const MKL_INT* n1, const MKL_INT* n2, const MKL_INT* n3, const MKL_INT*
```

Include Files

- mkl.h

Description

`pilaenvx` is called from the ScaLAPACK routines to choose problem-dependent parameters for the local environment. See `ispec` for a description of the parameters. This version provides a set of parameters which should give good, though not optimal, performance on many of the currently available computers. You are encouraged to modify this subroutine to set the tuning parameters for your particular machine using the option and problem size information in the arguments.

Input Parameters

| | |
|--------------------|---|
| <code>ictxt</code> | (local input) On entry, <code>ictxt</code> specifies the BLACS context handle, indicating the global context of the operation. The context itself is global, but the value of <code>ictxt</code> is local. |
| <code>ispec</code> | (global input) Specifies the parameter to be returned as the value of <code>pilaenvx</code> . = 1: the optimal blocksize; if this value is 1, an unblocked algorithm will give the best performance (unlikely). = 2: the minimum block size for which the block routine should be used; if the usable block size is less than this value, an unblocked routine should be used. = 3: the crossover point (in a block routine, for N less than this value, an unblocked routine should be used). = 4: the number of shifts, used in the nonsymmetric eigenvalue routines (DEPRECATED). = 5: the minimum column dimension for blocking to be used; rectangular blocks must have dimension at least k by m , where k is given by <code>pilaenvx(2, ...)</code> and m by <code>pilaenvx(5, ...)</code> . = 6: the crossover point for the SVD (when reducing an m by n matrix to bidiagonal form, if $\max(m,n)/\min(m,n)$ exceeds this value, a QR factorization is used first to reduce the matrix to a triangular form). |

- = 7: the number of processors.
- = 8: the crossover point for the multishift QR method for nonsymmetric eigenvalue problems (DEPRECATED).
- = 9: maximum size of the subproblems at the bottom of the computation tree in the divide-and-conquer algorithm (used by `?gelsd` and `?gesdd`).
- =10: IEEE NaN arithmetic can be trusted not to trap.
- =11: infinity arithmetic can be trusted not to trap.

12 <= *ispec* <= 16:

`p?hseqr` or one of its subroutines, see `piparmq` for detailed explanation.

17 <= *ispec* <= 22:

Parameters for `pb?trord/p?hseqr` (not all), as follows:

- =17: maximum number of concurrent computational windows;
- =18: number of eigenvalues/bulges in each window;
- =19: computational window size;
- =20: minimal percentage of FLOPS required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations;
- =21: width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form;
- =22: the maximum number of eigenvalues moved together over a process border;
- =23: the number of processors involved in Aggressive Early Deflation (AED);
- =99: Maximum iteration chunksize in OpenMP parallelization.

name

(global input)

The name of the calling subroutine, in either upper case or lower case.

opts

(global input) The character options to the subroutine name, concatenated into a single character string. For example, *uplo* = 'U', *trans* = 'T', and *diag* = 'N' for a triangular routine would be specified as *opts* = 'UTN'.

n1, *n2*, *n3*, and *n4*

(global input) Problem dimensions for the subroutine name; these may not all be required.

Output Parameters

result

(global output)

>= 0: the value of the parameter specified by *ispec*.

< 0: if *pilaenvx* = -*k*, the *k*-th argument had an illegal value.

Application Notes

The following conventions have been used when calling `ilaenv` from the LAPACK routines:

1. *opts* is a concatenation of all of the character options to subroutine name, in the same order that they appear in the argument list for name, even if they are not used in determining the value of the parameter specified by *ispec*.
2. The problem dimensions *n1*, *n2*, *n3*, and *n4* are specified in the order that they appear in the argument list for *name*. *n1* is used first, *n2* second, and so on, and unused problem dimensions are passed a value of -1.
3. The parameter value returned by `ilaenv` is checked for validity in the calling subroutine. For example, `ilaenv` is used to retrieve the optimal block size for `strtri` as follows:

```
NB = ilaenv( 1, 'STRTRI', UPLO // DIAG, N, -1, -1, -1 );
if( NB<=1 ) {
    NB = MAX( 1, N );
}
```

The same conventions hold for this ScaLAPACK-style variant.

pjlaenv

Called from the ScaLAPACK symmetric and Hermitian tailored eigen-routines to choose problem-dependent parameters for the local environment.

Syntax

```
MKL_INT pjlaenv (const MKL_INT* ictxt, const MKL_INT* ispec, const char* name, const
char* opts, const MKL_INT* n1, const MKL_INT* n2, const MKL_INT* n3, const MKL_INT*
n4);
```

Include Files

- `mkl.h`

Description

`pjlaenv` is called from the ScaLAPACK symmetric and Hermitian tailored eigen-routines to choose problem-dependent parameters for the local environment. See *ispec* for a description of the parameters. This version provides a set of parameters which should give good, though not optimal, performance on many of the currently available computers. You are encouraged to modify this subroutine to set the tuning parameters for your particular machine using the option and problem size information in the arguments.

Input Parameters

ispec (global input) Specifies the parameter to be returned as the value of `pjlaenv`.

= 1: the data layout blocksize;

= 2: the panel blocking factor;

= 3: the algorithmic blocking factor;

= 4: execution path control;

= 5: maximum size for direct call to the LAPACK routine.

name (global input) The name of the calling subroutine, in either upper case or lower case.

| | |
|---|---|
| <i>opts</i> | (global input) The character options to the subroutine name, concatenated into a single character string. For example, <i>uplo</i> = 'U', <i>trans</i> = 'T', and <i>diag</i> = 'N' for a triangular routine would be specified as <i>opts</i> = 'UTN'. |
| <i>n1</i> , <i>n2</i> , <i>n3</i> , and <i>n4</i> | (global input) Problem dimensions for the subroutine name; these may not all be required. At present, only <i>n1</i> is used, and it (<i>n1</i>) is used only for 'TTRD'. |

Output Parameters

| | |
|---------------|--|
| <i>result</i> | (global or local output) ≥ 0 : the value of the parameter specified by <i>ispec</i> . < 0 : if <i>pjlaenv</i> = $-k$, the k -th argument had an illegal value. Most parameters set via a call to <i>pjlaenv</i> must be identical on all processors and hence <i>pjlaenv</i> will return the same value to all procesors (i.e. global output). However some, in particular, the panel blocking factor can be different on each processor and hence <i>pjlaenv</i> can return different values on different processors (i.e. local output). |
|---------------|--|

Application Notes

The following conventions have been used when calling *pjlaenv* from the ScaLAPACK routines:

- opts* is a concatenation of all of the character options to subroutine name, in the same order that they appear in the argument list for name, even if they are not used in determining the value of the parameter specified by *ispec*.
- The problem dimensions *n1*, *n2*, *n3*, and *n4* are specified in the order that they appear in the argument list for name. *n1* is used first, *n2* second, and so on, and unused problem dimensions are passed a value of -1.
 - The parameter value returned by *pjlaenv* is checked for validity in the calling subroutine. For example, *pjlaenv* is used to retrieve the optimal blocksize for *STRTRI* as follows:

```
NB = pjlaenv( 1, 'STRTRI', UPLO // DIAG, N, -1, -1, -1 );
IF( NB>=1 ) {
    NB = MAX( 1, N );
}
```

pjlaenv is patterned after *ilaenv* and keeps the same interface in anticipation of future needs, even though *pjlaenv* is only sparsely used at present in ScaLAPACK. Most ScaLAPACK codes use the input data layout blocking factor as the algorithmic blocking factor - hence there is no need or opportunity to set the algorithmic or data decomposition blocking factor. *pXYytevx.f* and *pXYytgvx.f* and *pXYyttrd.f* are the only codes which call *pjlaenv*. *pXYytevx.f* and *pXYytgvx.f* redistribute the data to the best data layout for each transformation. *pXYyttrd.f* uses a data layout blocking factor of 1.

ScaLAPACK Utility Functions and Routines

This section describes ScaLAPACK utility functions and routines. Summary information about these routines is given in the following table:

ScaLAPACK Utility Functions and Routines

| Routine Name | Data Types | Description |
|--------------------------|------------|---|
| <code>p?labad</code> | s,d | Returns the square root of the underflow and overflow thresholds if the exponent-range is very large. |
| <code>p?lachkieee</code> | s,d | Performs a simple check for the features of the IEEE standard. |

| Routine Name | Data Types | Description |
|-----------------------|-------------------|---|
| <code>p?lamch</code> | <code>s, d</code> | Determines machine parameters for floating-point arithmetic. |
| <code>p?lasnbt</code> | <code>s, d</code> | Computes the position of the sign bit of a floating-point number. |

See Also

`pxerbla` Error handling routine called by ScaLAPACK routines.

p?labad

Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.

Syntax

```
void pslabad (MKL_INT *ictxt , float *small , float *large );
void pdlabad (MKL_INT *ictxt , double *small , double *large );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?labad` function takes as input the values computed by `p?lamch` for underflow and overflow, and returns the square root of each of these values if the log of `large` is sufficiently large. This function is intended to identify machines with a large exponent range, such as the Crays, and redefine the underflow and overflow limits to be the square roots of the values computed by `p?lamch`. This function is needed because `p?lamch` does not compensate for poor arithmetic in the upper half of the exponent range, as is found on a Cray.

In addition, this function performs a global minimization and maximization on these values, to support heterogeneous computing networks.

Input Parameters

| | |
|--------------------|---|
| <code>ictxt</code> | (global) The BLACS context handle in which the computation takes place. |
| <code>small</code> | (local). On entry, the underflow threshold as computed by <code>p?lamch</code> . |
| <code>large</code> | (local). On entry, the overflow threshold as computed by <code>p?lamch</code> . |

Output Parameters

| | |
|--------------------|---|
| <code>small</code> | (local). On exit, if $\log_{10}(\text{large})$ is sufficiently large, the square root of <code>small</code> , otherwise unchanged. |
| <code>large</code> | (local). On exit, if $\log_{10}(\text{large})$ is sufficiently large, the square root of <code>large</code> , otherwise unchanged. |

See Also

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lachskeee

Performs a simple check for the features of the IEEE standard.

Syntax

```
void pslachskeee (MKL_INT *isieee , float *rmax , float *rmin );  
void pdlachskeee (MKL_INT *isieee , float *rmax , float *rmin );
```

Include Files

- mkl_scalapack.h

Description

The p?lachskeee function performs a simple check to make sure that the features of the IEEE standard are implemented. In some implementations, p?lachskeee may not return.

This is a ScaLAPACK internal function and arguments are not checked for unreasonable values.

Input Parameters

| | |
|-------------|---|
| <i>rmax</i> | (local). The overflow threshold (= ?lamch ('O')). |
| <i>rmin</i> | (local). The underflow threshold (= ?lamch ('U')). |

Output Parameters

| | |
|---------------|--|
| <i>isieee</i> | (local). On exit, <i>isieee</i> = 1 implies that all the features of the IEEE standard that we rely on are implemented. On exit, <i>isieee</i> = 0 implies that some the features of the IEEE standard that we rely on are missing. |
|---------------|--|

See Also

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lamch

Determines machine parameters for floating-point arithmetic.

Syntax

```
float pslamch (MKL_INT *ictxt , char *cmach );  
double pdlamch (MKL_INT *ictxt , char *cmach );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?lamch` function determines single precision machine parameters.

Input Parameters

`ictxt` (global). The BLACS context handle in which the computation takes place.

`cmach` (global)
Specifies the value to be returned by `p?lamch`:

- = 'E' or 'e', `p?lamch := eps`
- = 'S' or 's', `p?lamch := sfmin`
- = 'B' or 'b', `p?lamch := base`
- = 'P' or 'p', `p?lamch := eps*base`
- = 'N' or 'n', `p?lamch := t`
- = 'R' or 'r', `p?lamch := rnd`
- = 'M' or 'm', `p?lamch := emin`
- = 'U' or 'u', `p?lamch := rmin`
- = 'L' or 'l', `p?lamch := emax`
- = 'O' or 'o', `p?lamch := rmax,`

where

- `eps` = relative machine precision
- `sfmin` = safe minimum, such that $1/sfmin$ does not overflow
- `base` = base of the machine
- `prec` = `eps*base`
- `t` = number of (base) digits in the mantissa
- `rnd` = 1.0 when rounding occurs in addition, 0.0 otherwise
- `emin` = minimum exponent before (gradual) underflow
- `rmin` = underflow threshold - $base^{(emin-1)}$
- `emax` = largest exponent before overflow
- `rmax` = overflow threshold - $(base^{emax}) * (1-eps)$

Output Parameters

`val` Value returned by the function.

See Also

[Overview of ScaLAPACK Routines](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lasnbt

Computes the position of the sign bit of a floating-point number.

Syntax

```
void pslasnbt (MKL_INT *ieflag );
void pdlasnbt (MKL_INT *ieflag );
```

Include Files

- mkl_scalapack.h

Description

The p?lasnbt function finds the position of the signbit of a single/double precision floating point number. This function assumes IEEE arithmetic, and hence, tests only the 32-nd bit (for single precision) or 32-nd and 64-th bits (for double precision) as a possibility for the signbit. `sizeof(int)` is assumed equal to 4 bytes.

If a compile time flag (`NO_IEEE`) indicates that the machine does not have IEEE arithmetic, `ieflag = 0` is returned.

Output Parameters

ieflag This flag indicates the position of the signbit of any single/double precision floating point number.

ieflag = 0, if the compile time flag `NO_IEEE` indicates that the machine does not have IEEE arithmetic, or if `sizeof(int)` is different from 4 bytes.

ieflag = 1 indicates that the signbit is the 32-nd bit for a single precision function.

In the case of a double precision function:

ieflag = 1 indicates that the signbit is the 32-nd bit (Big Endian).

ieflag = 2 indicates that the signbit is the 64-th bit (Little Endian).

ScaLAPACK Redistribution/Copy Routines

This section describes ScaLAPACK redistribution/copy routines. Summary information about these routines is given in the following table:

ScaLAPACK Redistribution/Copy Routines

| Routine Name | Data Types | Description |
|--------------|---------------|--|
| p?gemr2d | s, d, c, z, i | Copies a submatrix from one general rectangular matrix to another. |
| p?trmr2d | s, d, c, z, i | Copies a submatrix from one trapezoidal matrix to another. |

See Also

[pxerbla](#) Error handling routine called by ScaLAPACK routines.

p?gemr2d

Copies a submatrix from one general rectangular matrix to another.

Syntax

```
void psgemr2d (MKL_INT *m, MKL_INT *n, float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , MKL_INT *ictxt );

void pdgemr2d (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , MKL_INT
*ictxt );

void pcgemr2d (MKL_INT *m , MKL_INT *n MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb ,
MKL_INT *ictxt );

void pzgemr2d (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb ,
MKL_INT *ictxt );

void pigemr2d (MKL_INT *m , MKL_INT *n , MKL_INT *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , MKL_INT
*ictxt );
```

Include Files

- mkl_scalapack.h

Description

The p?gemr2d function copies the indicated matrix or submatrix of A to the indicated matrix or submatrix of B . It provides a truly general copy from any block cyclicly-distributed matrix or submatrix to any other block cyclicly-distributed matrix or submatrix. With p?trmr2d, these functions are the only ones in the ScaLAPACK library which provide inter-context operations: they can take a matrix or submatrix A in context A (distributed over process grid A) and copy it to a matrix or submatrix B in context B (distributed over process grid B).

There does not need to be a relationship between the two operand matrices or submatrices other than their global size and the fact that they are both legal block cyclicly-distributed matrices or submatrices. This means that they can, for example, be distributed across different process grids, have varying block sizes and differing matrix starting points, or be contained in different sized distributed matrices.

Take care when context A is disjoint from context B . The general rules for which parameters need to be set are:

- All calling processes must have the correct m and n .
- Processes in context A must correctly define all parameters describing A .
- Processes in context B must correctly define all parameters describing B .
- Processes which are not members of context A must pass $ctxt_a = -1$ and need not set other parameters describing A .
- Processes which are not members of context B must pass $ctxt_b = -1$ and need not set other parameters describing B .

Because of its generality, p?gemr2d can be used for many operations not usually associated with copy functions. For instance, it can be used to take a matrix on one process and distribute it across a process grid, or the reverse. If a supercomputer is grouped into a virtual parallel machine with a workstation, for instance, this function can be used to move the matrix from the workstation to the supercomputer and back.

In ScaLAPACK, it is called to copy matrices from a two-dimensional process grid to a one-dimensional process grid. It can be used to redistribute matrices so that distributions providing maximal performance can be used by various component libraries, as well.

Note that this function requires an array descriptor with $dtype_ = 1$.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

| | |
|----------|--|
| m | (global) The number of rows of matrix A to be copied ($m \geq 0$). |
| n | (global) The number of columns of matrix A to be copied ($n \geq 0$). |
| a | (local) Pointer into the local memory to array of size $lld_a * LOCC(ja+n-1)$ containing the source matrix A . |
| ia, ja | (global) The row and column indices in the array A indicating the first row and the first column, respectively, of the submatrix of A to copy. $1 \leq ia \leq total_rows_in_a - m + 1$, $1 \leq ja \leq total_columns_in_a - n + 1$. |
| $desca$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix A . Only $dtype_a = 1$ is supported, so $dlen_ = 9$. If the calling process is not part of the context of A , $ctxt_a$ must be equal to -1. |
| ib, jb | (global) The row and column indices in the array B indicating the first row and the first column, respectively, of the submatrix B to which to copy the matrix. $1 \leq ib \leq total_rows_in_b - m + 1$, $1 \leq jb \leq total_columns_in_b - n + 1$. |
| $descb$ | (global and local) array of size $dlen_$. The array descriptor for the distributed matrix B . Only $dtype_b = 1$ is supported, so $dlen_ = 9$. If the calling process is not part of the context of B , $ctxt_b$ must be equal to -1. |
| $ictxt$ | (global). The context encompassing at least the union of all processes in context A and context B . All processes in the context $ictxt$ must call this function, even if they do not own a piece of either matrix. |

Output Parameters

b Pointer into the local memory to array of size $lld_b * LOCC(jb+n-1)$.
Overwritten by the submatrix from *A*.

MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , MKL_INT *ictxt );
```

```
void pitrmr2d (char *uplo , char *diag , MKL_INT *m , MKL_INT *n , MKL_INT *a ,
MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , MKL_INT *ictxt );
```

Include Files

- mkl_scalapack.h

Description

The `p?trmr2d` function copies the indicated matrix or submatrix of *A* to the indicated matrix or submatrix of *B*. It provides a truly general copy from any block cyclicly-distributed matrix or submatrix to any other block cyclicly-distributed matrix or submatrix. With `p?gemr2d`, these functions are the only ones in the ScaLAPACK library which provide inter-context operations: they can take a matrix or submatrix *A* in context *A* (distributed over process grid *A*) and copy it to a matrix or submatrix *B* in context *B* (distributed over process grid *B*).

The `p?trmr2d` function assumes the matrix or submatrix to be trapezoidal. Only the upper or lower part is copied, and the other part is unchanged.

There does not need to be a relationship between the two operand matrices or submatrices other than their global size and the fact that they are both legal block cyclicly-distributed matrices or submatrices. This means that they can, for example, be distributed across different process grids, have varying block sizes and differing matrix starting points, or be contained in different sized distributed matrices.

Take care when context *A* is disjoint from context *B*. The general rules for which parameters need to be set are:

- All calling processes must have the correct m and n .
- Processes in context A must correctly define all parameters describing A .
- Processes in context B must correctly define all parameters describing B .
- Processes which are not members of context A must pass $ctxt_a = -1$ and need not set other parameters describing A .
- Processes which are not members of context B must pass $ctxt_b = -1$ and need not set other parameters describing B .

Because of its generality, `p?trmr2d` can be used for many operations not usually associated with copy functions. For instance, it can be used to take a matrix on one process and distribute it across a process grid, or the reverse. If a supercomputer is grouped into a virtual parallel machine with a workstation, for instance, this function can be used to move the matrix from the workstation to the supercomputer and back. In ScaLAPACK, it is called to copy matrices from a two-dimensional process grid to a one-dimensional process grid. It can be used to redistribute matrices so that distributions providing maximal performance can be used by various component libraries, as well.

Note that this function requires an array descriptor with $dtype_ = 1$.

Optimization Notice

Sparse Solver Routines

Intel® Math Kernel Library (Intel® MKL) provides user-callable sparse solver software to solve real or complex, symmetric, structurally symmetric or nonsymmetric, positive definite, indefinite or Hermitian square sparse linear system of algebraic equations.

The terms and concepts required to understand the use of the Intel MKL sparse solver routines are discussed in the [Appendix A "Linear Solvers Basics"](#). If you are familiar with linear sparse solvers and sparse matrix storage schemes, you can skip these sections and go directly to the interface descriptions.

This chapter describes

- the direct sparse solver based on PARDISO* which is referred to here as [Intel MKL PARDISO](#);
- the alternative interface for the direct sparse solver which is referred to here as the [DSS interface](#);
- [iterative sparse solvers \(ISS\)](#) based on the reverse communication interface (RCI);
- and [two preconditioners](#) based on the incomplete LU factorization technique.

Intel MKL PARDISO - Parallel Direct Sparse Solver Interface

This section describes the interface to the shared-memory multiprocessing parallel direct sparse solver known as the Intel MKL PARDISO solver.

The Intel MKL PARDISO package is a high-performance, robust, memory efficient, and easy to use software package for solving large sparse linear systems of equations on shared memory multiprocessors. The solver uses a combination of left- and right-looking Level-3 BLAS supernode techniques [[Schenk00-2](#)]. To improve sequential and parallel sparse numerical factorization performance, the algorithms are based on a Level-3 BLAS update and pipelining parallelism is used with a combination of left- and right-looking supernode techniques [[Schenk00](#), [Schenk01](#), [Schenk02](#), [Schenk03](#)]. The parallel pivoting methods allow complete supernode pivoting to compromise numerical stability and scalability during the factorization process. For sufficiently large problem sizes, numerical experiments demonstrate that the scalability of the parallel algorithm is nearly independent of the shared-memory multiprocessing architecture.

The following table lists the names of the Intel MKL PARDISO routines and describes their general use.

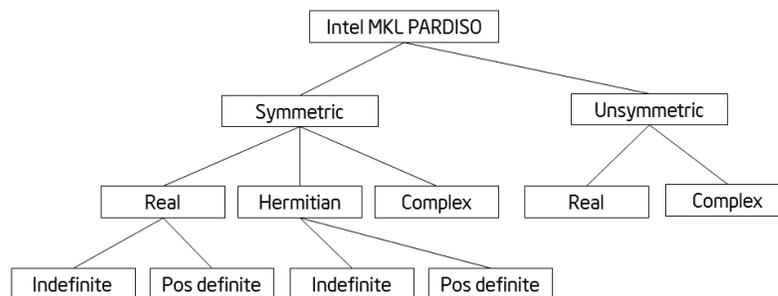

Intel MKL PARDISO Routines

| Routine | Description |
|--------------------------------|---|
| <code>pardisoinit</code> | Initializes Intel MKL PARDISO with default parameters depending on the matrix type. |
| <code>pardiso</code> | Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides. |
| <code>pardiso_64</code> | Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides, 64-bit integer version. |
| <code>pardiso_getenv</code> | Retrieves additional values from the Intel MKL PARDISO handle. |
| <code>pardiso_setenv</code> | Sets additional values in the Intel MKL PARDISO handle. |
| <code>mkl_pardiso_pivot</code> | Replaces routine which handles Intel MKL PARDISO pivots with user-defined routine. |
| <code>pardiso_getdiag</code> | Returns diagonal elements of initial and factorized matrix. |

| Routine | Description |
|--|--|
| <code>pardiso_handle_store</code> | Store internal structures from <code>pardiso</code> to a file. |
| <code>pardiso_handle_restore</code> | Restore <code>pardiso</code> internal structures from a file. |
| <code>pardiso_handle_delete</code> | Delete files with <code>pardiso</code> internal structure data. |
| <code>pardiso_handle_store_64</code> | Store internal structures from <code>pardiso_64</code> to a file. |
| <code>pardiso_handle_restore_64</code> | Restore <code>pardiso_64</code> internal structures from a file. |
| <code>pardiso_handle_delete_64</code> | Delete files with <code>pardiso_64</code> internal structure data. |

The Intel MKL PARDISO solver supports a wide range of real and complex sparse matrix types (see [the figure below](#)).

Sparse Matrices That Can Be Solved with the Intel MKL PARDISO Solver

The Intel MKL PARDISO solver performs four tasks:

- analysis and symbolic factorization
- numerical factorization
- forward and backward substitution including iterative refinement
- termination to release all internal solver memory.

You can find code examples that use Intel MKL PARDISO routines to solve systems of linear equations in the `examples` folder of the Intel MKL installation directory:

- `examples/solverc/source`

Supported Matrix Types

The analysis steps performed by Intel MKL PARDISO depend on the structure of the input matrix A .

Symmetric Matrices

The solver first computes a symmetric fill-in reducing permutation P based on either the minimum degree algorithm [Liu85] or the nested dissection algorithm from the METIS package [Karypis98] (both included with Intel MKL), followed by the parallel left-right looking numerical Cholesky factorization [Schenk00-2] of $PAP^T = LL^T$ for symmetric positive-definite matrices, or $PAP^T = LDL^T$ for symmetric indefinite matrices. The solver uses diagonal pivoting, or 1x1 and 2x2 Bunch-Kaufman pivoting for symmetric indefinite matrices. An approximation of X is found by forward and backward substitution and optional iterative refinement.

Whenever numerically acceptable 1x1 and 2x2 pivots cannot be found within the diagonal supernode block, the coefficient matrix is perturbed. One or two passes of iterative refinement may be required to correct the effect of the perturbations. This restricting notion of pivoting with iterative refinement is effective for highly indefinite symmetric systems. Furthermore, for a large set of matrices from different applications areas, this method is as accurate as a direct factorization method that uses complete sparse pivoting techniques [Schenk04].

Another method of improving the pivoting accuracy is to use symmetric weighted matching algorithms. These algorithms identify large entries in the coefficient matrix A that, if permuted close to the diagonal, permit the factorization process to identify more acceptable pivots and proceed with fewer pivot perturbations. These algorithms are based on maximum weighted matchings and improve the quality of the factor in a complementary way to the alternative of using more complete pivoting techniques.

The inertia is also computed for real symmetric indefinite matrices.

Structurally Symmetric Matrices

The solver first computes a symmetric fill-in reducing permutation P followed by the parallel numerical factorization of $PAP^T = QLU^T$. The solver uses partial pivoting in the supernodes and an approximation of X is found by forward and backward substitution and optional iterative refinement.

Nonsymmetric Matrices

The solver first computes a nonsymmetric permutation P_{MPS} and scaling matrices D_r and D_c with the aim of placing large entries on the diagonal to enhance reliability of the numerical factorization process [Duff99]. In the next step the solver computes a fill-in reducing permutation P based on the matrix $P_{MPS}A + (P_{MPS}A)^T$ followed by the parallel numerical factorization

$$QLUR = PP_{MPS}D_rAD_cP$$

with supernode pivoting matrices Q and R . When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99]. The magnitude of the potential pivot is tested against a constant threshold of

$$\alpha = \text{eps} * ||A2||_{\text{inf}}$$

where eps is the machine precision, $A2 = P * P_{MPS} * D_r * A * D_c * P$, and $||A2||_{\text{inf}}$ is the infinity norm of A . Any tiny pivots encountered during elimination are set to the sign $(1_{IT}) * \text{eps} * ||A2||_{\text{inf}}$, which trades off some numerical stability for the ability to keep pivots from getting too small. Although many failures could render the factorization well-defined but essentially useless, in practice the diagonal elements are rarely modified for a large class of matrices. The result of this pivoting approach is that the factorization is, in general, not exact and iterative refinement may be needed.

Sparse Data Storage

Intel MKL PARDISO stores sparse data in several formats:

- CSR3: The 3-array variation of the compressed sparse row format described in [Three Array Variation of CSR Format](#).
- BSR3: The three-array variation of the block compressed sparse row format described in [Three Array Variation of BSR Format](#). Use `iparm[36]` to specify the block size.
- VBSR: Variable BSR format. Intel MKL PARDISO analyzes the matrix provided in CSR3 format and converts it into an internal structure which can improve performance for matrices with a block structure. Use `iparm[36] = -t` ($0 < t \leq 100$) to specify use of internal VBSR format and to set the degree of similarity required to combine elements of the matrix. For example, if you set `iparm[36] = -80`, two rows of the input matrix are combined when their non-zero patterns are 80% or more similar.

NOTE

Intel MKL only supports VBSR format for real and symmetric positive definite or indefinite matrices ($mtype = 2$ or $mtype = -2$).

For all storage formats, the Intel MKL PARDISO parameter ja is used for the *columns* array, ia is used for *rowIndex*, and a is used for *values*. The algorithms in Intel MKL PARDISO require column indices ja to be in increasing order per row and that the diagonal element in each row be present for any structurally symmetric matrix. For symmetric or nonsymmetric matrices the diagonal elements which are equal to zero are not necessary.

CAUTION

Intel MKL PARDISO column indices ja must be in increasing order per row. You can validate the sparse matrix structure with the matrix checker ([iparm\[26\]](#))

NOTE

While the presence of zero diagonal elements for symmetric matrices is not required, you should explicitly set zero diagonal elements for symmetric matrices. Otherwise, Intel MKL PARDISO creates internal copies of arrays ia , ja , and a full of diagonal elements, which require additional memory and computational time. However, the memory and time required the diagonal elements in internal arrays is usually not significant compared to the memory and the time required to factor and solve the matrix.

Storage of Matrices

By default, Intel MKL PARDISO stores matrices in RAM. However, you can specify that Intel MKL PARDISO store matrices on disk by setting [iparm\[59\]](#). This is referred to as in-core (IC) and out-of-core (OOC), respectively.

OOC parameters can be set in a configuration file. You can set the path to this file and its name using environmental variables `MKL_PARDISO_OOC_CFG_PATH` and `MKL_PARDISO_OOC_CFG_FILE_NAME`.

These variables specify the path and filename as follows:

`<MKL_PARDISO_OOC_CFG_PATH>/<MKL_PARDISO_OOC_CFG_FILE_NAME>` for Linux* OS and macOS*, and
`<MKL_PARDISO_OOC_CFG_PATH>\<MKL_PARDISO_OOC_CFG_FILE_NAME>` for Windows* OS.

By default, the name of the file is `pardiso_ooc.cfg` and it is placed in the current directory.

All temporary data files can be deleted or stored when the calculations are completed in accordance with the value of the environmental variable `MKL_PARDISO_OOC_KEEP_FILE`. If it is not set or if it is set to 1, then all files are deleted. If it is set to 0, then all files are stored.

By default, the OOC version of Intel MKL PARDISO uses the current directory for storing data, and all work arrays associated with the matrix factors are stored in files named `ooc_temp` with different extensions. These default values can be changed by using the environmental variable `MKL_PARDISO_OOC_PATH`.

To set the environmental variables `MKL_PARDISO_OOC_MAX_CORE_SIZE`, `MKL_PARDISO_OOC_MAX_SWAP_SIZE`, `MKL_PARDISO_OOC_KEEP_FILE`, and `MKL_PARDISO_OOC_PATH`, create the configuration file with the following lines:

```
MKL_PARDISO_OOC_PATH = <path>\ooc_file
MKL_PARDISO_OOC_MAX_CORE_SIZE = N
MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

where $\langle path \rangle$ is the directory for storing data, ooc_file is the file name without any extension, N is the maximum size of RAM in megabytes available for Intel MKL PARDISO (default value is 2000 MB), K is the maximum swap size in megabytes available for Intel MKL PARDISO (default value is 0 MB). Do not set $N+K$ greater than the size of the RAM plus the size of the swap. Be sure to allow enough free memory for the operating system and any other processes which are necessary.

CAUTION

The maximum length of the path lines in the configuration files is 1000 characters.

Alternatively the environment variables can be set via command line.

For Linux* OS and macOS*:

```
export MKL_PARDISO_OOC_PATH = <path>/ooc_file
export MKL_PARDISO_OOC_MAX_CORE_SIZE = N
export MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
export MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

For Windows* OS:

```
set MKL_PARDISO_OOC_PATH = <path>\ooc_file
set MKL_PARDISO_OOC_MAX_CORE_SIZE = N
set MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
set MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

NOTE

The values specified in a command line have higher priorities: if a variable is changed in the configuration file and in the command line, OOC version of Intel MKL PARDISO uses only the value defined in the command line.

Direct-Iterative Preconditioning for Nonsymmetric Linear Systems

The solver uses a combination of direct and iterative methods [Sonn89] to accelerate the linear solution process for transient simulation. Most applications of sparse solvers require solutions of systems with gradually changing values of the nonzero coefficient matrix, but with an identical sparsity pattern. In these applications, the analysis phase of the solvers has to be performed only once and the numerical factorizations are the important time-consuming steps during the simulation. Intel MKL PARDISO uses a numerical factorization and applies the factors in a preconditioned Krylow-Subspace iteration. If the iteration does not converge, the solver automatically switches back to the numerical factorization. This method can be applied to nonsymmetric matrices in Intel MKL PARDISO. You can select the method using the $iparm[3]$ input parameter. The $iparm[19]$ parameter returns the error status after running Intel MKL PARDISO.

Single and Double Precision Computations

Intel MKL PARDISO solves tasks using single or double precision. Each precision has its benefits and drawbacks. Double precision variables have more digits to store value, so the solver uses more memory for keeping data. But this mode solves matrices with better accuracy, which is especially important for input matrices with large condition numbers.

Single precision variables have fewer digits to store values, so the solver uses less memory than in the double precision mode. Additionally this mode usually takes less time. But as computations are made less precisely, only some systems of equations can be solved accurately enough using single precision.

Separate Forward and Backward Substitution

The solver execution step (see $parameter_{phase} = 33$ below) can be divided into two or three separate substitutions: forward, backward, and possible diagonal. This separation can be explained by the examples of solving systems with different matrix types.

A real symmetric positive definite matrix A ($mtype = 2$) is factored by Intel MKL PARDISO as $A = L^*L^T$. In this case the solution of the system $A*x=b$ can be found as sequence of substitutions: $L*y=b$ (forward substitution, $phase = 331$) and $L^T*x=y$ (backward substitution, $phase = 333$).

A real nonsymmetric matrix A ($mtype = 11$) is factored by Intel MKL PARDISO as $A = L*U$. In this case the solution of the system $A*x=b$ can be found by the following sequence: $L*y=b$ (forward substitution, $phase = 331$) and $U*x=y$ (backward substitution, $phase = 333$).

Solving a system with a real symmetric indefinite matrix A ($mtype = -2$) is slightly different from the cases above. Intel MKL PARDISO factors this matrix as $A=LDL^T$, and the solution of the system $A*x=b$ can be calculated as the following sequence of substitutions: $L*y=b$ (forward substitution, $phase = 331$), $D*v=y$ (diagonal substitution, $phase = 332$), and finally $L^T*x=v$ (backward substitution, $phase = 333$). Diagonal substitution makes sense only for symmetric indefinite matrices ($mtype = -2, -4, 6$). For matrices of other types a solution can be found as described in the first two examples.

CAUTION

The number of refinement steps (`iparm[7]`) must be set to zero if a solution is calculated with separate substitutions ($phase = 331, 332, 333$), otherwise Intel MKL PARDISO produces the wrong result.

NOTE

Different pivoting (`iparm[20]`) produces different LDL^T factorization. Therefore results of forward, diagonal and backward substitutions with diagonal pivoting can differ from results of the same steps with Bunch-Kaufman pivoting. Of course, the final results of sequential execution of forward, diagonal and backward substitution are equal to the results of the full solving step ($phase=33$) regardless of the pivoting used.

Callback Function for Pivoting Control

In-core Intel MKL PARDISO allows you to control pivoting with a callback routine, `mkl_pardiso_pivot`. You can then use the `pardiso_getdiag` routine to access the diagonal elements. Set `iparm[55]` to 1 in order to use the callback functionality.

pardiso

Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.

Syntax

```
void pardiso (_MKL_DSS_HANDLE_t pt, const MKL_INT *maxfct, const MKL_INT *mnum, const
MKL_INT *mtype, const MKL_INT *phase, const MKL_INT *n, const void *a, const MKL_INT
*ia, const MKL_INT *ja, MKL_INT *perm, const MKL_INT *nrhs, MKL_INT *iparm, const
MKL_INT *msglvl, void *b, void *x, MKL_INT *error);
```

Include Files

- `mkl.h`

Description

The routine `pardiso` calculates the solution of a set of sparse linear equations

$$A*X = B$$

with single or multiple right-hand sides, using a parallel LU , LDL , or LL^T factorization, where A is an n -by- n matrix, and X and B are n -by- $nrhs$ vectors or matrices.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

pt Array with size of 64.
Handle to internal data structure. The entries must be set to zero prior to the first call to `pardiso`. Unique for factorization.

CAUTION

After the first call to `pardiso` do not directly modify *pt*, as that could cause a serious memory leak.

Use the `pardiso_handle_store` or `pardiso_handle_store_64` routine to store the content of *pt* to a file. Restore the contents of *pt* from the file using `pardiso_handle_restore` or `pardiso_handle_restore_64`. Use `pardiso_handle_store` and `pardiso_handle_restore` with `pardiso`, and `pardiso_handle_store_64` and `pardiso_handle_restore_64` with `pardiso_64`.

maxfct Maximum number of factors with identical sparsity structure that must be kept in memory at the same time. In most applications this value is equal to 1. It is possible to store several different factorizations with the same nonzero structure at the same time in the internal data structure management of the solver.

`pardiso` can process several matrices with an identical matrix sparsity pattern and it can store the factors of these matrices at the same time. Matrices with a different sparsity structure can be kept in memory with different memory address pointers *pt*.

mnum Indicates the actual matrix for the solution phase. With this scalar you can define which matrix to factorize. The value must be: $1 \leq mnum \leq maxfct$.
In most applications this value is 1.

mtype Defines the matrix type, which influences the pivoting method. The Intel MKL PARDISO solver supports the following matrices:

| | |
|----|---|
| 1 | real and structurally symmetric |
| 2 | real and symmetric positive definite |
| -2 | real and symmetric indefinite |
| 3 | complex and structurally symmetric |
| 4 | complex and Hermitian positive definite |
| -4 | complex and Hermitian indefinite |
| 6 | complex and symmetric |
| 11 | real and nonsymmetric |
| 13 | complex and nonsymmetric |

phase

Controls the execution of the solver. Usually it is a two- or three-digit integer. The first digit indicates the starting phase of execution and the second digit indicates the ending phase. Intel MKL PARDISO has the following phases of execution:

- Phase 1: Fill-reduction analysis and symbolic factorization
- Phase 2: Numerical factorization
- Phase 3: Forward and Backward solve including optional iterative refinement

This phase can be divided into two or three separate substitutions: forward, backward, and diagonal (see [Separate Forward and Backward Substitution](#)).

- Memory release phase (*phase*= 0 or *phase*= -1)

If a previous call to the routine has computed information from previous phases, execution may start at any phase. The *phase* parameter can have the following values:

| <i>phase</i> | Solver Execution Steps |
|--------------|--|
| 11 | Analysis |
| 12 | Analysis, numerical factorization |
| 13 | Analysis, numerical factorization, solve, iterative refinement |
| 22 | Numerical factorization |
| 23 | Numerical factorization, solve, iterative refinement |
| 33 | Solve, iterative refinement |
| 331 | like <i>phase</i> =33, but only forward substitution |
| 332 | like <i>phase</i> =33, but only diagonal substitution (if available) |
| 333 | like <i>phase</i> =33, but only backward substitution |

| <i>phase</i> | Solver Execution Steps |
|--------------|---|
| 0 | Release internal memory for L and U matrix number <i>mnum</i> |
| -1 | Release all internal memory for all matrices |

If $iparm[35] = 0$, phases 331, 332, and 333 perform this decomposition:

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{12} & L_{22} \end{bmatrix} \begin{bmatrix} D_{11} & 0 \\ 0 & D_{22} \end{bmatrix} \begin{bmatrix} U_{11} & U_{21} \\ 0 & U_{22} \end{bmatrix}$$

If $iparm[35] = 2$, phases 331, 332, and 333 perform a different decomposition:

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{12} & I \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & S \end{bmatrix} \begin{bmatrix} U_{11} & U_{21} \\ 0 & I \end{bmatrix}$$

You can supply a custom implementation for phase 332 instead of calling `pardiso`. For example, it can be implemented with dense LAPACK functionality. Custom implementation also allows you to substitute the matrix S with your own.

NOTE

For very large Schur complement matrices use LAPACK functionality to compute the Schur complement vector instead of the Intel MKL PARDISO phase 332 implementation.

n Number of equations in the sparse linear systems of equations $A^*X = B$.
Constraint: $n > 0$.

a Array. Contains the non-zero elements of the coefficient matrix A corresponding to the indices in ja . The coefficient matrix can be either real or complex. The matrix must be stored in the three-array variant of the compressed sparse row (CSR3) or in the three-array variant of the block compressed sparse row (BSR3) format, and the matrix must be stored with increasing values of ja for each row.

For CSR3 format, the size of a is the same as that of ja . Refer to the *values* array description in [Three Array Variation of CSR Format](#) for more details.

For BSR3 format the size of a is the size of ja multiplied by the square of the block size. Refer to the *values* array description in [Three Array Variation of BSR Format](#) for more details.

NOTE

If you set $iparm[36]$ to a negative value, Intel MKL PARDISO converts the data from CSR3 format to an internal variable BSR (VBSR) format. See [Sparse Data Storage](#).

ia Array, size $(n+1)$.

For CSR3 format, $ia[i]$ ($i < n$) points to the first column index of row i in the array ja . That is, $ia[i]$ gives the index of the element in array a that contains the first non-zero element from row i of A . The last element $ia[n]$ is taken to be equal to the number of non-zero elements in A , plus one. Refer to *rowIndex* array description in [Three Array Variation of CSR Format](#) for more details.

For BSR3 format, $ia[i]$ ($i < n$) points to the first column index of row i in the array ja . That is, $ia[i]$ gives the index of the element in array a that contains the first non-zero block from row i of A . The last element $ia[n]$ is taken to be equal to the number of non-zero blocks in A , plus one. Refer to *rowIndex* array description in [Three Array Variation of BSR Format](#) for more details.

The array ia is accessed in all phases of the solution process.

Indexing of ia is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter $iparm[34]$.

ja

For CSR3 format, array ja contains column indices of the sparse matrix A . It is important that the indices are in increasing order per row. For structurally symmetric matrices it is assumed that all diagonal elements are stored (even if they are zeros) in the list of non-zero elements in a and ja . For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in [Three Array Variation of CSR Format](#).

For BSR3 format, array ja contains column indices of the sparse matrix A . It is important that the indices are in increasing order per row. For structurally symmetric matrices it is assumed that all diagonal blocks are stored (even if they are zeros) in the list of non-zero blocks in a and ja . For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in [Three Array Variation of BSR Format](#).

The array ja is accessed in all phases of the solution process.

Indexing of ja is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter $iparm[34]$.

$perm$

Array, size (n). Depending on the value of $iparm[4]$ and $iparm[30]$, either holds the permutation vector of size n or specifies elements used for computing a partial solution.

- If $iparm[4] = 1$, $iparm[30] = 0$, and $iparm[35] = 0$, $perm$ specifies the fill-in reducing ordering to the solver. Let A be the original matrix and $C = P^*A^*P^T$ be the permuted matrix. Row (column) i of C is the $perm[i]$ row (column) of A . The array $perm$ is also used to return the permutation vector calculated during fill-in reducing ordering stage.

NOTE

Be aware that setting $iparm[4] = 1$ prevents use of a parallel algorithm for the solve step.

- If $iparm[4] = 2$, $iparm[30] = 0$, and $iparm[35] = 0$, the permutation vector computed in phase 11 is returned in the $perm$ array.

- If $iparm[4] = 0$, $iparm[30] > 0$, and $iparm[35] = 0$, $perm$ specifies elements of the right-hand side to use or of the solution to compute for a partial solution.
- If $iparm[4] = 0$, $iparm[30] = 0$, and $iparm[35] > 0$, $perm$ specifies elements for a Schur complement.

See [iparm\[4\]](#) and [iparm\[30\]](#) for more details.

Indexing of $perm$ is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter [iparm\[34\]](#).

| | |
|---------------|--|
| <i>nrhs</i> | Number of right-hand sides that need to be solved for. |
| <i>iparm</i> | Array, size (64). This array is used to pass various parameters to Intel MKL PARDISO and to return some useful information after execution of the solver. See pardiso iparm Parameter for more details about the <i>iparm</i> parameters. |
| <i>msglvl</i> | Message level information. If $msglvl = 0$ then <code>pardiso</code> generates no output, if $msglvl = 1$ the solver prints statistical information to the screen. |
| <i>b</i> | Array, size ($n*nrhs$). On entry, contains the right-hand side vector/matrix B , which is placed in memory contiguously. The $b[+k*nrhs]$ element must hold the i -th component of k -th right-hand side vector. Note that b is only accessed in the solution phase. |

Output Parameters

(See also [Intel MKL PARDISO Parameters in Tabular Form.](#))

| | |
|--------------|---|
| <i>pt</i> | Handle to internal data structure. |
| <i>perm</i> | See the Input Parameter description of the <i>perm</i> array. |
| <i>iparm</i> | On output, some <i>iparm</i> values report information such as the numbers of non-zero elements in the factors. See pardiso iparm Parameter for more details about the <i>iparm</i> parameters. |
| <i>b</i> | On output, the array is replaced with the solution if $iparm[5] = 1$. |
| <i>x</i> | Array, size ($n*nrhs$). If $iparm[5] = 0$ it contains solution vector/matrix X , which is placed contiguously in memory. The $x[i + k*n]$ element must hold the i -th component of the k -th solution vector. Note that x is only accessed in the solution phase. |
| <i>error</i> | The error indicator according to the below table: |

| error | Information |
|--------------|--------------------|
| 0 | no error |
| -1 | input inconsistent |
| -2 | not enough memory |

| error | Information |
|--------------|---|
| -3 | reordering problem |
| -4 | zero pivot, numerical factorization or iterative refinement problem |
| -5 | unclassified (internal) error |
| -6 | reordering failed (matrix types 11 and 13 only) |
| -7 | diagonal matrix is singular |
| -8 | 32-bit integer overflow problem |
| -9 | not enough memory for OOC |
| -10 | error opening OOC files |
| -11 | read/write error with OOC files |
| -12 | (pardiso_64 only) pardiso_64 called from 32-bit library |

pardisoinit

Initialize Intel MKL PARDISO with default parameters in accordance with the matrix type.

Syntax

```
void pardisoinit (_MKL_DSS_HANDLE_t pt, const MKL_INT *mtype, MKL_INT *iparm );
```

Include Files

- mkl.h

Description

This function initializes Intel MKL PARDISO internal address pointer *pt* with zero values (as needed for the very first call of *pardiso*) and sets default *iparm* values in accordance with the matrix type. Intel MKL supplies the *pardisoinit* routine to be compatible with PARDISO 3.2 or lower.

NOTE

An alternative way to set default *iparm* values is to call *pardiso* in the analysis phase with *iparm(1)=0*. In this case you must initialize the internal address pointer *pt* with zero values manually.

NOTE

The *pardisoinit* routine initializes only the in-core version of Intel MKL PARDISO. Switching on the out-of core version of Intel MKL PARDISO as well as changing default *iparm* values can be done after the call to *pardisoinit* but before the first call to *pardiso*.

Input Parameters

| | |
|--------------|--|
| <i>perm</i> | Ignored. |
| <i>mtype</i> | This scalar value defines the matrix type. Based on this value <code>pardisoinit</code> sets default values for the <i>iparm</i> array. Refer to the section Intel MKL PARDISO Parameters in Tabular Form for more details about the default values of Intel MKL PARDISO |

Output Parameters

| | |
|-----------|--|
| <i>pt</i> | Array with a dimension of 64. Solver internal data address pointer. These addresses are passed to the solver, and all related internal memory management is organized through this array. The <code>pardisoinit</code> routine nullifies the array <i>pt</i> . |
|-----------|--|

NOTE

It is very important that the pointer *pt* is initialized with zero before the first call of Intel MKL PARDISO. After that first call you should never modify the pointer, because it could cause a serious memory leak or a crash.

| | |
|--------------|---|
| <i>iparm</i> | Array with a dimension of 64. This array is used to pass various parameters to Intel MKL PARDISO and to return some useful information after execution of the solver. The <code>pardisoinit</code> routine fills-in the <i>iparm</i> array with the default values. Refer to the section Intel MKL PARDISO Parameters in Tabular Form for more details about the default values of Intel MKL PARDISO. |
|--------------|---|

pardiso_64

Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides, 64-bit integer version.

Syntax

```
void pardiso_64 (_MKL_DSS_HANDLE_t pt, const long long int *maxfct, const long long int *mnum, const long long int *mtype, const long long int *phase, const long long int *n, const void *a, const long long int *ia, const long long int *ja, long long int *perm, const long long int *nrhs, long long int *iparm, const long long int *msglvl, void *b, void *x, long long int *error);
```

Include Files

- `mkl.h`

Description

`pardiso_64` is an alternative ILP64 (64-bit integer) version of the `pardiso` routine (see [Description](#) section for more details). The interface of `pardiso_64` is the same as the interface of `pardiso`, but it accepts and returns all integer data as `long long int`.

Use `pardiso_64` when `pardiso` for solving large matrices (with the number of non-zero elements on the order of 500 million or more). You can use it together with the usual LP64 interfaces for the rest of Intel MKL functionality. In other words, if you use 64-bit integer version (`pardiso_64`), you do not need to re-link your applications with ILP64 libraries. Take into account that `pardiso_64` may perform slower than regular `pardiso` on the reordering and symbolic factorization phase.

NOTE

`pardiso_64` is supported only in the 64-bit libraries. If `pardiso_64` is called from the 32-bit libraries, it returns `error = -12`.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

The input parameters of `pardiso_64` are the same as the input parameters of `pardiso`, but `pardiso_64` accepts all integer data as `long long int`.

Output Parameters

The output parameters of `pardiso_64` are the same as the [output parameters of `pardiso`](#), but `pardiso_64` returns all integer data as `long long int`.

`pardiso_getenv`, `pardiso_setenv`

Retrieves additional values from or sets additional values in the Intel MKL PARDISO handle.

Syntax

```
MKL_INT pardiso_getenv (const _MKL_DSS_HANDLE_t handle, const enum PARDISO_ENV_PARAM *param, char *value);
```

```
MKL_INT pardiso_setenv (_MKL_DSS_HANDLE_t handle , const enum PARDISO_ENV_PARAM *param, const char *value);
```

Include Files

- `mkl.h`

Description

These functions operate with the Intel MKL PARDISO handle. The `pardiso_getenv` routine retrieves additional values from the Intel MKL PARDISO handle, and `pardiso_setenv` sets specified values in the Intel MKL PARDISO handle.

These functions enable retrieving and setting the name of the Intel MKL PARDISO OOC file.

To retrieve the Intel MKL PARDISO OOC file name, you can apply this function to any properly-created handle.

To set the Intel MKL PARDISO OOC file name in the handle you must call the function before the reordering stage. This is because the OOC file name is stored in the handle after the reordering stage and it is not changed during further computations.

NOTE

A 1024-byte internal buffer is used inside Intel MKL PARDISO for storing the OOC file name. Allocate a 1024-byte buffer for passing to the `pardiso_getenv` function as the `value` parameter.

Input Parameters

| | |
|---------------------|---|
| <code>handle</code> | Intel MKL PARDISO handle for which to set and from which to retrieve information. (See DSS Interface Description for structure description) |
| <code>param</code> | Specifies the required parameter. The only value is <code>PARDISO_OCC_FILE_NAME</code> , defined in the corresponding include file. |
| <code>value</code> | Input parameter for <code>pardiso_setenv</code> . Contains the name of the OOC file that must be used in the handle. |

Output Parameters

| | |
|---------------------|--|
| <code>handle</code> | Output parameter for <code>pardiso_setenv</code> . Data object of the <code>MKL_DSS_HANDLE</code> type (see DSS Interface Description). |
| <code>value</code> | Output parameter for <code>pardiso_getenv</code> . Contains the name of the OOC file which must be used in the handle. |

mkl_pardiso_pivot

Replaces routine which handles Intel MKL PARDISO pivots with user-defined routine.

Syntax

```
void mkl_pardiso_pivot (const void *ai, void *bi, const void *eps);
```

Include Files

- `mkl.h`

Description

The `mkl_pardiso_pivot` routine allows you to handle diagonal elements which arise during numerical factorization that are zero or near zero. By default, Intel MKL PARDISO determines that a diagonal element `bi` is a pivot if `bi < eps`, and if so, replaces it with `eps`. But you can provide your own routine to modify the resulting factorized matrix in case there are small elements on the diagonal during the factorization step.

NOTE

To use this routine, you must set `iparm[55]` to 1 before the main `pardiso` loop.

Input Parameters

| | |
|-----------------|--|
| <code>ai</code> | Diagonal element of initial matrix corresponding to pivot element. |
| <code>bi</code> | Diagonal element of factorized matrix that could be chosen as a pivot element. |

eps Scalar to compare with diagonal of factorized matrix. On input equal to parameter described by *iparm[9]*.

Output Parameters

bi In case element is chosen as a pivot, value with which to replace the pivot.

pardiso_getdiag

Returns diagonal elements of initial and factorized matrix.

Syntax

```
void pardiso_getdiag (const _MKL_DSS_HANDLE_t pt, void *df, void *da, const MKL_INT *mnum, MKL_INT *error);
```

Include Files

- mkl.h

Description

This routine returns the diagonal elements of the initial and factorized matrix for a real or Hermitian matrix.

NOTE

In order to use this routine, you must set *iparm[55]* to 1 before the main *pardiso* loop.

Input Parameters

pt Array with a size of 64. Handle to internal data structure for the Intel MKL PARDISO solver. The entries must be set to zero prior to the first call to *pardiso*. Unique for factorization.

mnum Indicates the actual matrix for the solution phase of the Intel MKL PARDISO solver. With this scalar you can define the diagonal elements of the factorized matrix that you want to obtain. The value must be: 1 $\leq mnum \leq maxfct$. In most applications this value is 1.

Output Parameters

df Array with a dimension of *n*. Contains diagonal elements of the factorized matrix after factorization.

NOTE

Elements of *df* correspond to diagonal elements of matrix *L* computed during phase 22. Because during phase 22 Intel MKL PARDISO makes additional permutations to improve stability, it is possible that array *df* is not in line with the *perm* array computed during phase 11.

da Array with a dimension of *n*. Contains diagonal elements of the initial matrix.

NOTE

Elements of *da* correspond to diagonal elements of matrix *L* computed during phase 22. Because during phase 22 Intel MKL PARDISO makes additional permutations to improve stability, it is possible that array *da* is not in line with the *perm* array computed during phase 11.

error The error indicator.

| error | Information |
|--------------|--|
| 0 | no error |
| -1 | Diagonal information not turned on before <code>pardiso</code> main loop (<code>iparm[55]=0</code>). |

pardiso_handle_store

Store internal structures from `pardiso` to a file.

Syntax

```
void pardiso_handle_store (_MKL_DSS_HANDLE_t pt, const char *dirname, MKL_INT *error);
```

Include Files

- `mkl.h`

Description

This function stores Intel MKL PARDISO structures to a file, allowing you to store Intel MKL PARDISO internal structures between the stages of the `pardiso` routine. The `pardiso_handle_restore` routine can restore the Intel MKL PARDISO internal structures from the file.

Input Parameters

| | |
|----------------|--|
| <i>pt</i> | Array with a size of 64. Handle to internal data structure. |
| <i>dirname</i> | String containing the name of the directory to which to write the files with the content of the internal structures. Use an empty string ("") to specify the current directory. The routine creates a file named <code>handle.pds</code> in the directory. |

Output Parameters

| <i>pt</i> | Handle to internal data structure. |
|--------------|------------------------------------|
| <i>error</i> | The error indicator. |
| error | Information |
| 0 | No error. |
| -2 | Not enough memory. |
| -10 | Cannot open file for writing. |

| error | Information |
|--------------|------------------------------|
| -11 | Error while writing to file. |
| -13 | Wrong file format. |

pardiso_handle_restore

Restore pardiso internal structures from a file.

Syntax

```
void pardiso_handle_restore (_MKL_DSS_HANDLE_t pt, const char *dirname, MKL_INT *error);
```

Include Files

- mkl.h

Description

This function restores Intel MKL PARDISO structures from a file. This allows you to restore Intel MKL PARDISO internal structures stored by `pardiso_handle_store` after a phase of the `pardiso` routine and continue execution of the next phase.

Input Parameters

dirname String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

Output Parameters

pt Array with a dimension of 64. Handle to internal data structure.

error The error indicator.

| error | Information |
|--------------|--------------------------------|
| 0 | No error. |
| -2 | Not enough memory. |
| -10 | Cannot open file for reading. |
| -11 | Error while reading from file. |
| -13 | Wrong file format. |

pardiso_handle_delete

Delete files with pardiso internal structure data.

Syntax

```
void pardiso_handle_delete (const char *dirname, MKL_INT *error);
```

Include Files

- `mkl.h`

Description

This function deletes files generated with `pardiso_handle_store` that contain Intel MKL PARDISO internal structures.

Input Parameters

dirname String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

Output Parameters

error The error indicator.

| error | Information |
|--------------|----------------------|
| 0 | No error. |
| -10 | Cannot delete files. |

`pardiso_handle_store_64`

Store internal structures from `pardiso_64` to a file.

Syntax

```
void pardiso_handle_store_64 (_MKL_DSS_HANDLE_t pt, const char *dirname, MKL_INT *error);
```

Include Files

- `mkl.h`

Description

This function stores Intel MKL PARDISO structures to a file, allowing you to store Intel MKL PARDISO internal structures between the stages of the `pardiso_64` routine. The `pardiso_handle_restore_64` routine can restore the Intel MKL PARDISO internal structures from the file.

Input Parameters

pt Array with a dimension of 64. Handle to internal data structure.

dirname String containing the name of the directory to which to write the files with the content of the internal structures. Use an empty string ("") to specify the current directory. The routine creates a file named `handle.pds` in the directory.

Output Parameters

pt Handle to internal data structure.

error The error indicator.

| error | Information |
|--------------|--|
| 0 | No error. |
| -2 | Not enough memory. |
| -10 | Cannot open file for writing. |
| -11 | Error while writing to file. |
| -12 | Not supported in 32-bit library - routine is only supported in 64-bit libraries. |
| -13 | Wrong file format. |

pardiso_handle_restore_64

Restore pardiso_64 internal structures from a file.

Syntax

```
void pardiso_handle_restore_64 (_MKL_DSS_HANDLE_t pt, const char *dirname, MKL_INT *error);
```

Include Files

- mkl.h

Description

This function restores Intel MKL PARDISO structures from a file. This allows you to restore Intel MKL PARDISO internal structures stored by `pardiso_handle_store_64` after a phase of the `pardiso_64` routine and continue execution of the next phase.

Input Parameters

dirname String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

Input Parameters

pt Array with a dimension of 64. Handle to internal data structure.

error The error indicator.

| error | Information |
|--------------|--------------------------------|
| 0 | No error. |
| -2 | Not enough memory. |
| -10 | Cannot open file for reading. |
| -11 | Error while reading from file. |
| -13 | Wrong file format. |

pardiso_handle_delete_64

Syntax

Delete files with `pardiso_64` internal structure data.

```
void pardiso_handle_delete_64 (const char *dirname, MKL_INT *error);
```

Include Files

- `mkl.h`

Description

This function deletes files generated with `pardiso_handle_store_64` that contain Intel MKL PARDISO internal structures.

Input Parameters

dirname String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

Output Parameters

error The error indicator.

| error | Information |
|--------------|--|
| 0 | No error. |
| -10 | Cannot delete files. |
| -12 | Not supported in 32-bit library - routine is only supported in 64-bit libraries. |

Intel MKL PARDISO Parameters in Tabular Form

The following table lists all parameters of Intel MKL PARDISO and gives their brief descriptions.

| Parameter | Type | Description | Values | Comments | In/Out |
|---------------|----------|--|---------------------|---|--------|
| <i>pt</i> | void* | Solver internal data address pointer | 0 | Must be initialized with zeros and never be modified later | in/out |
| <i>maxfct</i> | MKL_INT* | Maximal number of factors in memory | >0 | Generally used value is 1 | in |
| <i>mnum</i> | MKL_INT* | The number of matrix (from 1 to <i>maxfct</i>) to solve | [1: <i>maxfct</i>] | Generally used value is 1 | in |
| <i>mtype</i> | MKL_INT* | Matrix type | 1 2 | Real and structurally symmetric Real and symmetric positive definite | in |

| Parameter | Type | Description | Values | Comments | In/Out |
|--------------|----------|---|--------|---|--------|
| | | | -2 | Real and symmetric indefinite | |
| | | | 3 | Complex and structurally symmetric | |
| | | | 4 | Complex and Hermitian positive definite | |
| | | | -4 | Complex and Hermitian indefinite | |
| | | | 6 | Complex and symmetric matrix | |
| | | | 11 | Real and nonsymmetric matrix | |
| | | | 13 | Complex and nonsymmetric matrix | |
| <i>phase</i> | MKL_INT* | Controls the execution of the solver For <i>iparm</i> [35] > 0, phases 331, 332, and 333 perform a different decomposition. See the <i>phase</i> parameter of pardiso for details. | 11 | Analysis | in |
| | | | 12 | Analysis, numerical factorization | |
| | | | 13 | Analysis, numerical factorization, solve | |
| | | | 22 | Numerical factorization | |
| | | | 23 | Numerical factorization, solve | |
| | | | 33 | Solve, iterative refinement | |
| | | | 331 | <i>phase</i> =33, but only forward substitution | |
| | | | 332 | <i>phase</i> =33, but only diagonal substitution | |
| | | | 333 | <i>phase</i> =33, but only backward substitution | |
| | | | 0 | Release internal memory for L and U of the matrix number <i>mnum</i> | |
| | | | -1 | Release all internal memory for all matrices | |
| <i>n</i> | MKL_INT* | Number of equations in the sparse linear system $A*X = B$ | >0 | | in |
| <i>a</i> | void* | Contains the non-zero elements of the coefficient matrix <i>A</i> | * | The size of <i>a</i> is the same as that of <i>ja</i> , and the coefficient matrix can be either real or complex. The matrix must be stored in the 3-array variation of | in |

| Parameter | Type | Description | Values | Comments | In/Out |
|--------------------------|----------|---|--------|---|--------|
| <i>ia</i> [<i>n</i>] | MKL_INT* | <i>rowIndex</i> array in CSR3 format | >=0 | <p>compressed sparse row (CSR3) format with increasing values of <i>ja</i> for each row</p> <p><i>ia</i>[<i>i</i>] gives the index of the element in array <i>a</i> that contains the first non-zero element from row <i>i</i> of <i>A</i>. The last element <i>ia</i>(<i>n</i>) is taken to be equal to the number of non-zero elements in <i>A</i>.</p> <p>Note: <i>iparm</i>[34] indicates whether row/column indexing starts from 1 or 0.</p> | in |
| <i>ja</i> | MKL_INT* | <i>columns</i> array in CSR3 format | >=0 | <p>The column indices for each row of <i>A</i> must be sorted in increasing order. For structurally symmetric matrices zero diagonal elements must be stored in <i>a</i> and <i>ja</i>. Zero diagonal elements should be stored for symmetric matrices, although they are not required. For symmetric matrices, the solver needs only the upper triangular part of the system.</p> <p>Note: <i>iparm</i>[34] indicates whether row/column indexing starts from 1 or 0.</p> | in |
| <i>perm</i> [<i>n</i>] | MKL_INT* | Holds the permutation vector of size <i>n</i> or specifies elements used for computing a partial solution | >=0 | <p>You can apply your own fill-in reducing ordering (<i>iparm</i>[4] = 1) or return the permutation from the solver (<i>iparm</i>[4] = 2).</p> <p>Let $C = P^* A^* P^T$ be the permuted matrix. Row (column) <i>i</i> of <i>C</i> is the <i>perm</i>(<i>i</i>) row (column) of <i>A</i>. The numbering of the array must describe a permutation.</p> <p>To specify elements for a partial solution, set <i>iparm</i>[4] = 0, <i>iparm</i>[30] > 0, and <i>iparm</i>[35] = 0.</p> | in/out |

| Parameter | Type | Description | Values | Comments | In/Out |
|------------------|----------|---|----------|---|--------|
| | | | | <p>To specify elements for a Schur complement, set $iparm[4] = 0$, $iparm[30] = 0$, and $iparm[35] > 0$.</p> <p>Note: $iparm[34]$ indicates whether row/column indexing starts from 1 or 0.</p> | |
| <i>nrhs</i> | MKL_INT* | Number of right-hand sides that need to be solved for | ≥ 0 | <p>Generally used value is 1</p> <p>To obtain better Intel MKL PARDISO performance, during the numerical factorization phase you can provide the maximum number of right-hand sides, which can be used further during the solving phase.</p> | in |
| <i>iparm[64]</i> | MKL_INT* | This array is used to pass various parameters to Intel MKL PARDISO and to return some useful information after execution of the solver (see pardiso iparm Parameter for more details) | * | If $iparm[0]=0$, Intel MKL PARDISO fills $iparm[1]$ through $iparm[63]$ with default values and uses them. | in/out |
| <i>msglvl</i> | MKL_INT* | Message level information | 0 1 | <p>Intel MKL PARDISO generates no output</p> <p>Intel MKL PARDISO prints statistical information</p> | in |
| <i>b[n*nrhs]</i> | void* | Right-hand side vectors | * | <p>On entry, contains the right-hand side vector/matrix B, which is placed contiguously in memory. The $b[i+k*n]$ element must hold the i-th component of k-th right-hand side vector. Note that b is only accessed in the solution phase.</p> <p>On output, the array is replaced with the solution if $iparm[5]=1$.</p> | in/out |
| <i>x[n*nrhs]</i> | void* | Solution vectors | * | <p>On output, if $iparm[5]=0$, contains solution vector/matrix X which is placed contiguously in memory. The $x[i+k*n]$ element</p> | out |

| Parameter | Type | Description | Values | Comments | In/Out |
|--------------|----------|-----------------|--------|---|--------|
| | | | | must hold the i -th component of k -th solution vector. Note that x is only accessed in the solution phase. | |
| <i>error</i> | MKL_INT* | Error indicator | 0 | No error | out |
| | | | -1 | Input inconsistent | |
| | | | -2 | Not enough memory | |
| | | | -3 | Reordering problem | |
| | | | -4 | Zero pivot, numerical factorization or iterative refinement problem | |
| | | | -5 | Unclassified (internal) error | |
| | | | -6 | Reordering failed (matrix types 11 and 13 only) | |
| | | | -7 | Diagonal matrix is singular | |
| | | | -8 | 32-bit integer overflow problem | |
| | | | -9 | Not enough memory for OOC | |
| | | | -10 | Problems with opening OOC temporary files | |
| | | | -11 | Read/write problems with the OOC data file | |

¹⁾ See description of PARDISO_DATA_TYPE in [PARDISO_DATA_TYPE](#).

pardiso iparm Parameter

The following table describes all individual components of the Intel MKL PARDISO *iparm* parameter. Components which are not used must be initialized with 0. Default values are denoted with an asterisk (*).

| Component | Description |
|------------------|---|
| <i>iparm</i> [0] | Use default values. |
| input | 0 <i>iparm</i> [1] - <i>iparm</i> [63] are filled with default values. #0 You must supply all values in components <i>iparm</i> [1] - <i>iparm</i> [63]. |
| <i>iparm</i> [1] | Fill-in reducing ordering for the input matrix. |
| input | <p>CAUTION</p> <p>You can control the parallel execution of the solver by explicitly setting the MKL_NUM_THREADS environment variable. If fewer OpenMP threads are available than specified, the execution may slow down instead of speeding up. If MKL_NUM_THREADS is not defined, then the solver uses all available processors.</p> |

| Component | Description |
|-----------|---|
| 0 | The minimum degree algorithm [Li99]. |
| 2* | The nested dissection algorithm from the METIS package [Karypis98]. |
| 3 | The parallel (OpenMP) version of the nested dissection algorithm. It can decrease the time of computations on multi-core computers, especially when Intel MKL PARDISO Phase 1 takes significant time. |

NOTE

Setting $iparm[1] = 3$ prevents the use of CNR mode ($iparm[33] > 0$) because Intel MKL PARDISO uses dynamic parallelism.

| | |
|---------------------|---|
| $iparm[2]$ | Reserved. Set to zero. |
| $iparm[3]$ input | Preconditioned CGS/CG. This parameter controls preconditioned CGS [Sonn89] for nonsymmetric or structurally symmetric matrices and Conjugate-Gradients for symmetric matrices. $iparm[3]$ has the form $iparm[3] = 10 * L + K$. |
| K=0 | The factorization is always computed as required by <i>phase</i> . |
| K=1 | CGS iteration replaces the computation of <i>LU</i> . The preconditioner is <i>LU</i> that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns. |
| K=2 | CGS iteration for symmetric positive definite matrices replaces the computation of LL^T . The preconditioner is LL^T that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns. |

The value *L* controls the stopping criterion of the Krylow-Subspace iteration:

$eps_{CGS} = 10^{-L}$ is used in the stopping criterion

$$||dx_i|| / ||dx_0|| < eps_{CGS}$$

where $||dx_i|| = ||inv(L*U)*r_i||$ for $K = 1$ or $||dx_i|| = ||inv(L*L^T)*r_i||$ for $K = 2$ and r_i is the residue at iteration *i* of the preconditioned Krylow-Subspace iteration.

A maximum number of 150 iterations is fixed with the assumption that the iteration will converge before consuming half the factorization time. Intermediate convergence rates and residue excursions are checked and can terminate the iteration process. If *phase* =23, then the factorization for a given *A* is automatically recomputed in cases where the Krylow-Subspace iteration failed, and the corresponding direct solution is returned. Otherwise the solution from the preconditioned Krylow-Subspace iteration is returned. Using *phase* =33 results in an error message (*error*=-4) if the stopping criteria for the Krylow-Subspace iteration can not be reached. More information on the failure can be obtained from $iparm[19]$.

The default is $iparm[3]=0$, and other values are only recommended for an advanced user. $iparm[3]$ must be greater than or equal to zero.

Examples:

| $iparm[3]$ | Description |
|------------|---|
| 31 | <i>LU</i> -preconditioned CGS iteration with a stopping criterion of 1.0E-3 for nonsymmetric matrices |
| 61 | <i>LU</i> -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for nonsymmetric matrices |
| 62 | LL^T -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for symmetric positive definite matrices |

| | |
|------------|-------------------|
| $iparm[4]$ | User permutation. |
|------------|-------------------|

| Component | Description |
|----------------------------|--|
| input | <p>This parameter controls whether user supplied fill-in reducing permutation is used instead of the integrated multiple-minimum degree or nested dissection algorithms. Another use of this parameter is to control obtaining the fill-in reducing permutation vector calculated during the reordering stage of Intel MKL PARDISO.</p> <p>This option is useful for testing reordering algorithms, adapting the code to special applications problems (for instance, to move zero diagonal elements to the end of $P^*A^*P^T$), or for using the permutation vector more than once for matrices with identical sparsity structures. For definition of the permutation, see the description of the <i>perm</i> parameter.</p> <hr/> <p>CAUTION You can only set one of <i>iparm</i>[4], <i>iparm</i>[30], and <i>iparm</i>[35], so be sure that the <i>iparm</i>[30] (partial solution) and the <i>iparm</i>[35] (Schur complement) parameters are 0 if you set <i>iparm</i>[4].</p> <hr/> <p>0* User permutation in the <i>perm</i> array is ignored.</p> <hr/> <p>1 Intel MKL PARDISO uses the user supplied fill-in reducing permutation from the <i>perm</i> array. <i>iparm</i>[1] is ignored.</p> <hr/> <p>NOTE Setting <i>iparm</i>[4] = 1 prevents use of a parallel algorithm for the solve step.</p> <hr/> <p>2 Intel MKL PARDISO returns the permutation vector computed at phase 1 in the <i>perm</i> array.</p> |
| <i>iparm</i> [5] input | <p>Write solution on <i>x</i>.</p> <hr/> <p>NOTE The array <i>x</i> is always used.</p> <hr/> <p>0* The array <i>x</i> contains the solution; right-hand side vector <i>b</i> is kept unchanged.</p> <hr/> <p>1 The solver stores the solution on the right-hand side <i>b</i>.</p> |
| <i>iparm</i> [6] output | <p>Number of iterative refinement steps performed.</p> <p>Reports the number of iterative refinement steps that were actually performed during the solve step.</p> |
| <i>iparm</i> [7] input | <p>Iterative refinement step.</p> <p>On entry to the solve and iterative refinement step, <i>iparm</i>[7] must be set to the maximum number of iterative refinement steps that the solver performs.</p> <hr/> <p>0* The solver automatically performs two steps of iterative refinement when perturbed pivots are obtained during the numerical factorization.</p> <hr/> <p>>0 Maximum number of iterative refinement steps that the solver performs. The solver performs not more than the absolute value of <i>iparm</i>[7] steps of iterative refinement. The solver might stop the process before the maximum number of steps if</p> <ul style="list-style-type: none"> • a satisfactory level of accuracy of the solution in terms of backward error is achieved, |

| Component | Description |
|---------------------------|--|
| | <ul style="list-style-type: none"> or if it determines that the required accuracy cannot be reached. In this case Intel MKL PARDISO returns -4 in the <i>error</i> parameter. <p>The number of executed iterations is reported in <i>iparm[6]</i>.</p> |
| <0 | <p>Same as above, but the accumulation of the residuum uses extended precision real and complex data types.</p> <p>Perturbed pivots result in iterative refinement (independent of <i>iparm[7]=0</i>) and the number of executed iterations is reported in <i>iparm[6]</i>.</p> |
| <i>iparm[8]</i> | Reserved. Set to zero. |
| <i>iparm[9]</i> input | <p>Pivoting perturbation.</p> <p>This parameter instructs Intel MKL PARDISO how to handle small pivots or zero pivots for nonsymmetric matrices (<i>mtype</i> =11 or <i>mtype</i> =13) and symmetric matrices (<i>mtype</i> =-2, <i>mtype</i> =-4, or <i>mtype</i> =6). For these matrices the solver uses a complete supernode pivoting approach. When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99], [Schenk04].</p> <p>Small pivots are perturbed with $\text{eps} = 10^{-\text{iparm}[9]}$.</p> <p>The magnitude of the potential pivot is tested against a constant threshold of $\alpha = \text{eps} * \ A2\ _{\text{inf}}$, where $\text{eps} = 10^{(-\text{iparm}[9])}$, $A2 = P * P_{\text{MPS}} * D_r * A * D_c * P$, and $\ A2\ _{\text{inf}}$ is the infinity norm of the scaled and permuted matrix <i>A</i>. Any tiny pivots encountered during elimination are set to the sign (<i>1</i> or <i>-1</i>) * $\text{eps} * \ A2\ _{\text{inf}}$, which trades off some numerical stability for the ability to keep pivots from getting too small. Small pivots are therefore perturbed with $\text{eps} = 10^{(-\text{iparm}[9])}$.</p> |
| 13* | The default value for nonsymmetric matrices(<i>mtype</i> =11, <i>mtype</i> =13), $\text{eps} = 10^{-13}$. |
| 8* | The default value for symmetric indefinite matrices (<i>mtype</i> =-2, <i>mtype</i> =-4, <i>mtype</i> =6), $\text{eps} = 10^{-8}$. |
| <i>iparm[10]</i> input | <p>Scaling vectors.</p> <p>Intel MKL PARDISO uses a maximum weight matching algorithm to permute large elements on the diagonal and to scale so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less than or equal to 1. This scaling method is applied only to nonsymmetric matrices (<i>mtype</i> = 11 or <i>mtype</i> = 13). The scaling can also be used for symmetric indefinite matrices (<i>mtype</i> = -2, <i>mtype</i> =-4, or <i>mtype</i> = 6) when the symmetric weighted matchings are applied (<i>iparm[12]</i> = 1).</p> <p>Use <i>iparm[10]</i> = 1 (scaling) and <i>iparm[12]</i> = 1 (matching) for highly indefinite symmetric matrices, for example, from interior point optimizations or saddle point problems. Note that in the analysis phase (<i>phase</i>=11) you must provide the numerical values of the matrix <i>A</i> in array <i>a</i> in case of scaling and symmetric weighted matching.</p> |
| 0* | Disable scaling. Default for symmetric indefinite matrices. |
| 1* | <p>Enable scaling. Default for nonsymmetric matrices.</p> <p>Scale the matrix so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less than or equal to 1. This scaling method is applied to nonsymmetric matrices (<i>mtype</i> = 11, <i>mtype</i> = 13). The scaling can also be used for symmetric indefinite matrices (<i>mtype</i> = -2, <i>mtype</i> = -4, <i>mtype</i> = 6) when the symmetric weighted matchings are applied (<i>iparm[12]</i> = 1).</p> |

| Component | Description |
|-----------------------------|---|
| | Note that in the analysis phase (<i>phase</i> =11) you must provide the numerical values of the matrix <i>A</i> in case of scaling. |
| <i>iparm</i> [11] input | Solve with transposed or conjugate transposed matrix <i>A</i> . |
| | NOTE For real matrices the terms <i>transposed</i> and <i>conjugate transposed</i> are equivalent. |
| | 0* Solve a linear system $AX = B$. |
| | 1 Solve a conjugate transposed system $A^HX = B$ based on the factorization of the matrix <i>A</i> . |
| | 2 Solve a transposed system $A^TX = B$ based on the factorization of the matrix <i>A</i> . |
| <i>iparm</i> [12] input | Improved accuracy using (non-) symmetric weighted matching. Intel MKL PARDISO can use a maximum weighted matching algorithm to permute large elements close the diagonal. This strategy adds an additional level of reliability to the factorization methods and complements the alternative of using more complete pivoting techniques during the numerical factorization. |
| | 0* Disable matching. Default for symmetric indefinite matrices. |
| | 1* Enable matching. Default for nonsymmetric matrices. Maximum weighted matching algorithm to permute large elements close to the diagonal. It is recommended to use <i>iparm</i> [10] = 1 (scaling) and <i>iparm</i> [12] = 1 (matching) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems. Note that in the analysis phase (<i>phase</i> =11) you must provide the numerical values of the matrix <i>A</i> in case of symmetric weighted matching. |
| <i>iparm</i> [13] output | Number of perturbed pivots. After factorization, contains the number of perturbed pivots for the matrix types: 11, 13, -2, -4 and -6. |
| <i>iparm</i> [14] output | Peak memory on symbolic factorization. The total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase. This value is only computed in phase 1. |
| <i>iparm</i> [15] output | Permanent memory on symbolic factorization. Permanent memory from the analysis and symbolic factorization phase in kilobytes that the solver needs in the factorization and solve phases. This value is only computed in phase 1. |
| <i>iparm</i> [16] output | Size of factors/Peak memory on numerical factorization and solution. This parameter provides the size in kilobytes of the total memory consumed by in-core Intel MKL PARDISO for internal floating point arrays. This parameter is computed in phase 1. See <i>iparm</i> [62] for the OOC mode. The total peak memory consumed by Intel MKL PARDISO is $\max(iparm[14], iparm[15]+iparm[16])$ |

| Component | Description |
|-----------------------------------|--|
| <i>iparm</i> [17] input/output | Report the number of non-zero elements in the factors. <hr/> <0 Enable reporting if <i>iparm</i> [17] < 0 on entry. The default value is -1. <hr/> >=0 Disable reporting. |
| <i>iparm</i> [18] input/output | Report number of floating point operations (in 10 ⁶ floating point operations) that are necessary to factor the matrix <i>A</i> . <hr/> <0 Enable report if <i>iparm</i> [18] < 0 on entry. This increases the reordering time. <hr/> >=0 Disable report. * |
| <i>iparm</i> [19] output | Report CG/CGS diagnostics. <hr/> >0 CGS succeeded, reports the number of completed iterations. <hr/> <0 CG/CGS failed (<i>error</i> =-4 after the solution phase). If <i>phase</i> = 23, then the factors <i>L</i> and <i>U</i> are recomputed for the matrix <i>A</i> and the error flag <i>error</i> =0 in case of a successful factorization. If <i>phase</i> = 33, then <i>error</i> = -4 signals failure. $iparm[19] = - it_cgs * 10 - cgs_error.$ Possible values of <i>cgs_error</i> : 1 - fluctuations of the residuum are too large 2 - $ dx_{max_it_cgs}/2 $ is too large (slow convergence) 3 - stopping criterion is not reached at <i>max_it_cgs</i> 4 - perturbed pivots caused iterative refinement 5 - factorization is too fast for this matrix. It is better to use the factorization method with <i>iparm</i> [3] = 0 |
| <i>iparm</i> [20] input | Pivoting for symmetric indefinite matrices. <hr/> NOTE Use <i>iparm</i> [10] = 1 (scaling) and <i>iparm</i> [12] = 1 (matchings) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems. <hr/> 0 Apply 1x1 diagonal pivoting during the factorization process. <hr/> 1* Apply 1x1 and 2x2 Bunch-Kaufman pivoting during the factorization process. Bunch-Kaufman pivoting is available for matrices of <i>mtype</i> =-2, <i>mtype</i> =-4, or <i>mtype</i> =6. <hr/> 2 Apply 1x1 diagonal pivoting during the factorization process. Using this value is the same as using <i>iparm</i> [20] = 0 except that the solve step does not automatically make iterative refinements when perturbed pivots are obtained during numerical factorization. The number of iterations is limited to the number of iterative refinements specified by <i>iparm</i> [7] (0 by default). <hr/> 3 Apply 1x1 and 2x2 Bunch-Kaufman pivoting during the factorization process. Bunch-Kaufman pivoting is available for matrices of <i>mtype</i> =-2, <i>mtype</i> =-4, or <i>mtype</i> =6. Using this value is the same as using <i>iparm</i> [20] = 1 except that the |

| Component | Description |
|-----------------------------|--|
| | solve step does not automatically make iterative refinements when perturbed pivots are obtained during numerical factorization. The number of iterations is limited to the number of iterative refinements specified by <i>iparm</i> [7] (0 by default). |
| <i>iparm</i> [21] output | Inertia: number of positive eigenvalues. Intel MKL PARDISO reports the number of positive eigenvalues for symmetric indefinite matrices. |
| <i>iparm</i> [22] output | Inertia: number of negative eigenvalues. Intel MKL PARDISO reports the number of negative eigenvalues for symmetric indefinite matrices. |
| <i>iparm</i> [23] input | Parallel factorization control. |
| | NOTE The two-level factorization algorithm does not improve performance in OOC mode. |
| | 0* Intel MKL PARDISO uses the classic algorithm for factorization. |
| | 1 Intel MKL PARDISO uses a two-level factorization algorithm. This algorithm generally improves scalability in case of parallel factorization on many OpenMP threads (more than eight). |
| <i>iparm</i> [24] input | Parallel forward/backward solve control. |
| | 0* Intel MKL PARDISO uses a parallel algorithm for the solve step. |
| | 1 Intel MKL PARDISO uses the sequential forward and backward solve. This feature is available only for in-core Intel MKL PARDISO (see <i>iparm</i> [59]). |
| <i>iparm</i> [25] | Reserved. Set to zero. |
| <i>iparm</i> [26] input | Matrix checker. |
| | 0* Intel MKL PARDISO does not check the sparse matrix representation for errors. |
| | 1 Intel MKL PARDISO checks integer arrays <i>ia</i> and <i>ja</i> . In particular, Intel MKL PARDISO checks whether column indices are sorted in increasing order within each row. |
| <i>iparm</i> [27] input | Single or double precision Intel MKL PARDISO. See <i>iparm</i> [7] for information on controlling the precision of the refinement steps. |
| | Important The <i>iparm</i> [27] value is stored in the Intel MKL PARDISO handle between Intel MKL PARDISO calls, so the precision mode can be changed only during phase 1. |
| | 0* Input arrays (<i>a</i> , <i>x</i> and <i>b</i>) and all internal arrays must be presented in double precision. |
| | 1 Input arrays (<i>a</i> , <i>x</i> and <i>b</i>) must be presented in single precision. In this case all internal computations are performed in single precision. |
| <i>iparm</i> [28] | Reserved. Set to zero. |
| <i>iparm</i> [29] | Number of zero or negative pivots. |

| Component | Description |
|---|--|
| output | If Intel MKL PARDISO detects zero or negative pivot for $mtype=2$ or $mtype=4$ matrix types, the factorization is stopped, Intel MKL PARDISO returns immediately with an $error = -4$, and $iparm[29]$ reports the number of the equation where the first zero or negative pivot is detected. |
| $iparm[30]$ | Partial solve and computing selected components of the solution vectors. |
| input | <p>This parameter controls the solve step of Intel MKL PARDISO. It can be used if only a few components of the solution vectors are needed or if you want to reduce the computation cost at the solve step by utilizing the sparsity of the right-hand sides. To use this option the input permutation vector define $perm$ so that when $perm(i) = 1$ it means that either the i-th component in the right-hand sides is nonzero, or the i-th component in the solution vectors is computed, or both, depending on the value of $iparm[30]$.</p> <p>The permutation vector $perm$ must be present in all phases of Intel MKL PARDISO software. At the reordering step, the software overwrites the input vector $perm$ by a permutation vector used by the software at the factorization and solver step. If m is the number of components such that $perm(i) = 1$, then the last m components of the output vector $perm$ are a set of the indices i satisfying the condition $perm(i) = 1$ on input.</p> |
| <p>NOTE</p> <p>Turning on this option often increases the time used by Intel MKL PARDISO for factorization and reordering steps, but it can reduce the time required for the solver step.</p> | |
| <p>Important</p> <p>This feature is only available for in-core Intel MKL PARDISO, so to use it you must set $iparm[59] = 0$. Set the parameters $iparm[7]$ (iterative refinement steps), $iparm[3]$ (preconditioned CGS), $iparm[4]$ (user permutation), and $iparm[35]$ (Schur complement) to 0 as well.</p> | |
| 0* | Disables this option. |
| 1 | it is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector $perm$ is defined so that $perm(i) = 1$ means that the (i)-th component in the right-hand sides is nonzero. In this case Intel MKL PARDISO only uses the non-zero components of the right-hand side vectors and computes only corresponding components in the solution vectors. That means the i -th component in the solution vectors is only computed if $perm(i) = 1$. |
| 2 | <p>It is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector $perm$ is defined so that $perm(i) = 1$ means that the i-th component in the right-hand sides is nonzero.</p> <p>Unlike for $iparm[30]=1$, all components of the solution vector are computed for this setting and all components of the right-hand sides are used. Because all components are used, for $iparm[30]=2$ you must set the i-th component of the right-hand sides to zero explicitly if $perm(i)$ is not equal to 1.</p> |
| 3 | Selected components of the solution vectors are computed. The $perm$ array is not related to the right-hand sides and it only indicates which components of the solution vectors should be computed. In this case $perm(i) = 1$ means that the i -th component in the solution vectors is computed. |
| $iparm[31]$ | Reserved. Set to zero. |
| $iparm[32]$ | |

| Component | Description |
|----------------------------|---|
| <i>iparm</i> [33] input | <p>Optimal number of OpenMP threads for conditional numerical reproducibility (CNR) mode. Intel MKL PARDISO reads the value of <i>iparm</i>[33] during the analysis phase (phase 1), so you cannot change it later.</p> <p>Because Intel MKL PARDISO uses C random number generator facilities during the analysis phase (phase 1) you must take these precautions to get numerically reproducible results:</p> <ul style="list-style-type: none"> • Do not alter the states of the random number generators. • Do not run multiple instances of Intel MKL PARDISO in parallel in the analysis phase (phase 1). <hr/> <p>NOTE</p> <p>CNR is only available for the in-core version of Intel MKL PARDISO and the non-parallel version of the nested dissection algorithm. You must also:</p> <ul style="list-style-type: none"> • set <i>iparm</i>[59] to 0 in order to use the in-core version, • not set <i>iparm</i>[1] to 3 in order to not use the parallel version of the nested dissection algorithm. <p>Otherwise Intel MKL PARDISO does not produce numerically repeatable results even if CNR is enabled for Intel MKL using the functionality described in Support Functions for CNR.</p> <hr/> <p>0*</p> <p>CNR mode for Intel MKL PARDISO is enabled only if it is enabled for Intel MKL using the functionality described in Support Functions for CNR and the in-core version is used. Intel MKL PARDISO determines the optimal number of OpenMP threads automatically, and produces numerically reproducible results regardless of the number of threads.</p> <hr/> <p>>0</p> <p>CNR mode is enabled for Intel MKL PARDISO if in-core version is used and the optimal number of OpenMP threads for Intel MKL PARDISO to rely on is defined by the value of <i>iparm</i>[33]. You can use <i>iparm</i>[33] to enable CNR mode independent from other Intel MKL domains. To get the best performance, set <i>iparm</i>[33] to the actual number of hardware threads dedicated for Intel MKL PARDISO. Setting <i>iparm</i>[33] to fewer OpenMP threads than the maximum number of them in use reduces the scalability of the problem being solved. Setting <i>iparm</i>[33] to more threads than are available can reduce the performance of Intel MKL PARDISO.</p> |
| <i>iparm</i> [34] input | <p>One- or zero-based indexing of columns and rows.</p> <hr/> <p>0*</p> <p>One-based indexing: columns and rows indexing in arrays <i>ia</i>, <i>ja</i>, and <i>perm</i> starts from 1 (Fortran-style indexing).</p> <hr/> <p>1</p> <p>Zero-based indexing: columns and rows indexing in arrays <i>ia</i>, <i>ja</i>, and <i>perm</i> starts from 0 (C-style indexing).</p> |
| <i>iparm</i> [35] input | <p>Schur complement matrix computation control. To calculate this matrix, you must set the input permutation vector <i>perm</i> to a set of indexes such that when $perm(i) = 1$, the <i>i</i>-th element of the initial matrix is an element of the Schur matrix.</p> <hr/> <p>CAUTION</p> <p>You can only set one of <i>iparm</i>[4], <i>iparm</i>[30], and <i>iparm</i>[35], so be sure that the <i>iparm</i>[4] (user permutation) and the <i>iparm</i>[30] (partial solution) parameters are 0 if you set <i>iparm</i>[35].</p> <hr/> <p>0*</p> <p>Do not compute Schur complement.</p> |

| Component | Description |
|-------------------|---|
| | <p>1 Compute Schur complement matrix as part of Intel MKL PARDISO factorization step and return it in the solution vector.</p> <hr/> <p>NOTE This option only computes the Schur complement matrix, and does not calculate factorization arrays.</p> |
| | <p>2 Compute Schur complement matrix as part of Intel MKL PARDISO factorization step and return it in the solution vector. Since this option calculates factorization arrays you can use it to launch partial or full solution of the entire problem after the factorization step.</p> |
| <i>iparm</i> [36] | Format for matrix storage. |
| input | <p>0* Use CSR format (see Three Array Variation of CSR Format) for matrix storage.</p> <hr/> <p>> 0 Use BSR format (see Three Array Variation of BSR Format) for matrix storage with blocks of size <i>iparm</i>[36].</p> <hr/> <p>NOTE Intel MKL does not support BSR format in these cases:</p> <ul style="list-style-type: none"> • <i>iparm</i>[10] > 0: Scaling vectors • <i>iparm</i>[12] > 0: Weighted matching • <i>iparm</i>[30] > 0: Partial solution • <i>iparm</i>[35] > 0: Schur complement • <i>iparm</i>[55] > 0: Pivoting control • <i>iparm</i>[59] > 0: OOC Intel MKL PARDISO |
| | <p>< 0 Convert supplied matrix to variable BSR (VBSR) format (see Sparse Data Storage) for matrix storage. Intel MKL PARDISO analyzes the matrix provided in CSR3 format and converts it to an internal VBSR format. Set <i>iparm</i>[36] = -<i>t</i>, 0 < <i>t</i> ≤ 100.</p> <hr/> <p>NOTE Intel MKL only supports VBSR format for real and symmetric positive definite or indefinite matrices (<i>mtype</i> = 2 or <i>mtype</i> = -2). Intel MKL does not support VBSR format in these cases:</p> <ul style="list-style-type: none"> • <i>iparm</i>[10] > 0: Scaling vectors • <i>iparm</i>[12] > 0: Weighted matching • <i>iparm</i>[30] > 0: Partial solution • <i>iparm</i>[35] > 0: Schur complement • <i>iparm</i>[55] > 0: Pivoting control • <i>iparm</i>[59] > 0: OOC Intel MKL PARDISO |
| <i>iparm</i> [37] | Reserved. Set to zero. |
| <i>iparm</i> [54] | |
| <i>iparm</i> [55] | Diagonal and pivoting control. |
| | <p>0* Internal function used to work with pivot and calculation of diagonal arrays turned off.</p> |

| Component | Description |
|---------------------------------|--|
| | <p>1 You can use the mkl_pardiso_pivot callback routine to control pivot elements which appear during numerical factorization. Additionally, you can obtain the elements of initial matrix and factorized matrices after the <code>pardiso</code> factorization step diagonal using the pardiso_getdiag routine. This parameter can be turned on only in the in-core version of Intel MKL PARDISO.</p> |
| <code>iparm[56]</code> - | Reserved. Set to zero. |
| <code>iparm[58]</code> | |
| <code>iparm[59]</code> input | <p>Intel MKL PARDISO mode.</p> <p><code>iparm[59]</code> switches between in-core (IC) and out-of-core (OOC) Intel MKL PARDISO. OOC can solve very large problems by holding the matrix factors in files on the disk, which requires a reduced amount of main memory compared to IC.</p> <p>Unless you are operating in sequential mode, you can switch between IC and OOC modes after the reordering phase. However, you can get better Intel MKL PARDISO performance by setting <code>iparm[59]</code> before the reordering phase.</p> <hr/> <p>NOTE The amount of memory used in OOC mode depends on the number of OpenMP threads.</p> <hr/> <p>WARNING Do not increase the number of OpenMP threads used for Intel MKL PARDISO between the first call to <code>pardiso</code> and the factorization or solution phase. Because the minimum amount of memory required for out-of-core execution depends on the number of OpenMP threads, increasing it after the initial call can cause incorrect results.</p> <hr/> |
| 0* | IC mode. |
| 1 | <p>IC mode is used if the total amount of RAM (in megabytes) needed for storing the matrix factors is less than sum of two values of the environment variables: <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code> (default value 2000 MB) and <code>MKL_PARDISO_OOC_MAX_SWAP_SIZE</code> (default value 0 MB); otherwise OOC mode is used. In this case amount of RAM used by OOC mode cannot exceed the value of <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code>.</p> <p>If the total peak memory needed for storing the local arrays is more than <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code>, increase <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code> if possible.</p> <hr/> <p>NOTE Conditional numerical reproducibility (CNR) is not supported for this mode.</p> <hr/> |
| 2 | <p>OOC mode.</p> <p>The OOC mode can solve very large problems by holding the matrix factors in files on the disk. Hence the amount of RAM required by OOC mode is significantly reduced compared to IC mode.</p> <p>If the total peak memory needed for storing the local arrays is more than <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code>, increase <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code> if possible.</p> |

| Component | Description |
|-------------------|---|
| | To obtain better Intel MKL PARDISO performance, during the numerical factorization phase you can provide the maximum number of right-hand sides, which can be used further during the solving phase. |
| <i>iparm</i> [60] | Reserved. Set to zero. |
| <i>iparm</i> [61] | |
| <i>iparm</i> [62] | Size of the minimum OOC memory for numerical factorization and solution. |
| output | This parameter provides the size in kilobytes of the minimum memory required by OOC Intel MKL PARDISO for internal floating point arrays. This parameter is computed in phase 1. Total peak memory consumption of OOC Intel MKL PARDISO can be estimated as $\max(iparm[14], iparm[15] + iparm[62])$. |
| <i>iparm</i> [63] | Reserved. Set to zero. |

NOTE

Generally in sparse matrices, components which are equal to zero can be considered non-zero if necessary. For example, in order to make a matrix structurally symmetric, elements which are zero can be considered non-zero. See [Sparse Matrix Storage Formats](#) for an example.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Notice revision #20110804

PARDISO_DATA_TYPE

The following table lists the values of `PARDISO_DATA_TYPE` depending on the matrix types and values of the parameter `iparm[27]`.

| Data type value | Matrix type <i>mtype</i> | <i>iparm</i> [27] | comments |
|-----------------|--------------------------|-------------------|------------------------------------|
| double | 1, 2, -2, 11 | 0 | Real matrices, double precision |
| float | | 1 | Real matrices, single precision |
| MKL_Complex16 | 3, 6, 13, 4, -4 | 0 | Complex matrices, double precision |
| MKL_Complex8 | | 1 | Complex matrices, single precision |

Parallel Direct Sparse Solver for Clusters Interface

The Parallel Direct Sparse Solver for Clusters Interface solves large linear systems of equations with sparse matrices on clusters. It is

- high performing
- robust
- memory efficient
- easy to use

A hybrid implementation combines Message Passing Interface (MPI) technology for data exchange between parallel tasks (processes) running on different nodes, and OpenMP* technology for parallelism inside each node of the cluster. This approach effectively uses modern hardware resources such as clusters consisting of nodes with multi-core processors. The solver code is optimized for the latest Intel processors, but also performs well on clusters consisting of non-Intel processors.

Code examples are available in the Intel MKL installation `examples` directory.

Optimization Notice

Notice revision #20110804

Parallel Direct Sparse Solver for Clusters Interface Algorithm

Parallel Direct Sparse Solver for Clusters Interface solves a set of sparse linear equations

$$A * X = B$$

with multiple right-hand sides using a distributed LU , LL^T , LDL^T or LDL^* factorization, where A is an n -by- n matrix, and X and B are n -by- $nrhs$ matrices.

The solution comprises four tasks:

- analysis and symbolic factorization;
- numerical factorization;
- forward and backward substitution including iterative refinement;
- termination to release all internal solver memory.

The solver first computes a symmetric fill-in reducing permutation P based on the nested dissection algorithm from the METIS package [Karypis98] (included with Intel MKL), followed by the Cholesky or other type of factorization (depending on matrix type) [Schenk00-2] of PAP^T . The solver uses either diagonal pivoting, or 1x1 and 2x2 Bunch and Kaufman pivoting for symmetric indefinite or Hermitian matrices before finding an approximation of X by forward and backward substitution and iterative refinement.

The initial matrix A is perturbed whenever numerically acceptable 1x1 and 2x2 pivots cannot be found within the diagonal blocks. One or two passes of iterative refinement may be required to correct the effect of the perturbations. This restricted notion of pivoting with iterative refinement is effective for highly indefinite symmetric systems. For a large set of matrices from different application areas, the accuracy of this method is comparable to a direct factorization method that uses complete sparse pivoting techniques [Schenk04].

Parallel Direct Sparse Solver for Clusters additionally improves the pivoting accuracy by applying symmetric weighted matching algorithms. These methods identify large entries in the coefficient matrix A that, if permuted close to the diagonal, enable the factorization process to identify more acceptable pivots and

proceed with fewer pivot perturbations. The methods are based on maximum weighted matching and improve the quality of the factor in a complementary way to the alternative idea of using more complete pivoting techniques.

Parallel Direct Sparse Solver for Clusters Interface Matrix Storage

The sparse data storage in the Parallel Direct Sparse Solver for Clusters Interface follows the scheme described in the [Sparse Matrix Storage Formats](#) section using the variable *ja* for *columns*, *ia* for *rowIndex*, and *a* for *values*. Column indices *ja* must be in increasing order per row.

When an input data structure is not accessed in a call, a NULL pointer or any valid address can be passed as a placeholder for that argument.

Algorithm Parallelization and Data Distribution

Intel® MKL Parallel Direct Sparse Solver for Clusters enables parallel execution of the solution algorithm with efficient data distribution.

The master MPI process performs the symbolic factorization phase to represent matrix *A* as computational tree. Then matrix *A* is divided among all MPI processes in a one-dimensional manner. The same distribution is used for *L-factor* (the lower triangular matrix in Cholesky decomposition). Matrix *A* and all required internal data are broadcast to slave MPI processes. Each MPI process fills in its own parts of *L-factor* with initial values of the matrix *A*.

Parallel Direct Sparse Solver for Clusters Interface computes all independent parts of *L-factor* completely in parallel. When a block of the factor must be updated by other blocks, these updates are independently passed to a temporary array on each updating MPI process. It further gathers the result into an updated block using the `MPI_Reduce()` routine. The computations within an MPI process are dynamically divided among OpenMP threads using pipelining parallelism with a combination of left- and right-looking techniques similar to those of the PARDISO* software. Level 3 BLAS operations from Intel MKL ensure highly efficient performance of block-to-block update operations.

During forward/backward substitutions, respective Right Hand Side (RHS) parts are distributed among all MPI processes. All these processes participate in the computation of the solution. Finally, the solution is gathered on the master MPI process.

This approach demonstrates good scalability on clusters with Infiniband* technology. Another advantage of the approach is the effective distribution of *L-factor* among cluster nodes. This enables the solution of tasks with a much higher number of non-zero elements than it is possible with any Symmetric Multiprocessing (SMP) in-core direct solver.

The algorithm ensures that the memory required to keep internal data on each MPI process is decreased when the number of MPI processes in a run increases. However, the solver requires that matrix *A* and some other internal arrays completely fit into the memory of each MPI process.

To get the best performance, run one MPI process per physical node and set the number of OpenMP* threads per node equal to the number of physical cores on the node.

NOTE

Instead of calling `MPI_Init()`, initialize MPI with `MPI_Init_thread()` and set the MPI threading level to `MPI_THREAD_FUNNELED` or higher. For details, see the code examples in `<install_dir>/examples`.

cluster_sparse_solver

Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.

Syntax

```
void cluster_sparse_solver (_MKL_DSS_HANDLE_t pt, const MKL_INT *maxfct, const MKL_INT *mnum, const MKL_INT *mtype, const MKL_INT *phase, const MKL_INT *n, const void *a, const MKL_INT *ia, const MKL_INT *ja, MKL_INT *perm, const MKL_INT *nrhs, MKL_INT *iparm, const MKL_INT *msglvl, void *b, void *x, const int *comm, MKL_INT *error);
```

Include Files

- `mkl_cluster_sparse_solver.h`

Description

The routine `cluster_sparse_solver` calculates the solution of a set of sparse linear equations

$$A * X = B$$

with single or multiple right-hand sides, using a parallel *LU*, *LDL*, or *LL^T* factorization, where *A* is an *n*-by-*n* matrix, and *X* and *B* are *n*-by-*nrhs* vectors or matrices.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

NOTE

Most of the input parameters (except for the *pt*, *phase*, and *comm* parameters and, for the distributed format, the *a*, *ia*, and *ja* arrays) must be set on the master MPI process only, and ignored on other processes. Other MPI processes get all required data from the master MPI process using the MPI communicator, *comm*.

| | |
|-----------|---|
| <i>pt</i> | Array of size 64. Handle to internal data structure. The entries must be set to zero before the first call to <code>cluster_sparse_solver</code> . |
|-----------|---|

CAUTION

After the first call to `cluster_sparse_solver` do not modify *pt*, as that could cause a serious memory leak.

| | | | | | | | | | |
|---------------|---|---|---------------------------------|---|--------------------------------------|----|-------------------------------|---|------------------------------------|
| <i>maxfct</i> | Ignored; assumed equal to 1. | | | | | | | | |
| <i>mnum</i> | Ignored; assumed equal to 1. | | | | | | | | |
| <i>mtype</i> | Defines the matrix type, which influences the pivoting method. The Parallel Direct Sparse Solver for Clusters solver supports the following matrices: <table style="margin-left: 2em;"> <tr> <td>1</td> <td>real and structurally symmetric</td> </tr> <tr> <td>2</td> <td>real and symmetric positive definite</td> </tr> <tr> <td>-2</td> <td>real and symmetric indefinite</td> </tr> <tr> <td>3</td> <td>complex and structurally symmetric</td> </tr> </table> | 1 | real and structurally symmetric | 2 | real and symmetric positive definite | -2 | real and symmetric indefinite | 3 | complex and structurally symmetric |
| 1 | real and structurally symmetric | | | | | | | | |
| 2 | real and symmetric positive definite | | | | | | | | |
| -2 | real and symmetric indefinite | | | | | | | | |
| 3 | complex and structurally symmetric | | | | | | | | |

| | |
|----|---|
| 4 | complex and Hermitian positive definite |
| -4 | complex and Hermitian indefinite |
| 6 | complex and symmetric |
| 11 | real and nonsymmetric |
| 13 | complex and nonsymmetric |

phase

Controls the execution of the solver. Usually it is a two- or three-digit integer. The first digit indicates the starting phase of execution and the second digit indicates the ending phase. Parallel Direct Sparse Solver for Clusters has the following phases of execution:

- Phase 1: Fill-reduction analysis and symbolic factorization
- Phase 2: Numerical factorization
- Phase 3: Forward and Backward solve including optional iterative refinement
- Memory release (*phase*= -1)

If a previous call to the routine has computed information from previous phases, execution may start at any phase. The *phase* parameter can have the following values:

| <i>phase</i> | Solver Execution Steps |
|--------------|--|
| 11 | Analysis |
| 12 | Analysis, numerical factorization |
| 13 | Analysis, numerical factorization, solve, iterative refinement |
| 22 | Numerical factorization |
| 23 | Numerical factorization, solve, iterative refinement |
| 33 | Solve, iterative refinement |
| -1 | Release all internal memory for all matrices |

n

Number of equations in the sparse linear systems of equations $A^*X = B$.
Constraint: $n > 0$.

a

Array. Contains the non-zero elements of the coefficient matrix *A* corresponding to the indices in *ja*. The coefficient matrix can be either real or complex. The matrix must be stored in the three-array variant of the compressed sparse row (CSR3) or in the three-array variant of the block compressed sparse row (BSR3) format, and the matrix must be stored with increasing values of *ja* for each row.

For CSR3 format, the size of *a* is the same as that of *ja*. Refer to the *values* array description in [Three Array Variation of CSR Format](#) for more details.

For BSR3 format the size of a is the size of ja multiplied by the square of the block size. Refer to the *values* array description in [Three Array Variation of BSR Format](#) for more details.

NOTE

For centralized input ($iparm[39]=0$), provide the a array for the master MPI process only. For distributed assembled input ($iparm[39]=1$ or $iparm[39]=2$), provide it for all MPI processes.

Important

The column indices of non-zero elements of each row of the matrix A must be stored in increasing order.

ia

For CSR3 format, $ia[i]$ ($i < n$) points to the first column index of row i in the array ja . That is, $ia[i]$ gives the index of the element in array a that contains the first non-zero element from row i of A . The last element $ia[n]$ is taken to be equal to the number of non-zero elements in A , plus one. Refer to *rowIndex* array description in [Three Array Variation of CSR Format](#) for more details.

For BSR3 format, $ia[i]$ ($i < n$) points to the first column index of row i in the array ja . That is, $ia[i]$ gives the index of the element in array a that contains the first non-zero block from row i of A . The last element $ia[n]$ is taken to be equal to the number of non-zero blocks in A , plus one. Refer to *rowIndex* array description in [Three Array Variation of BSR Format](#) for more details.

The array ia is accessed in all phases of the solution process.

Indexing of ia is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter $iparm[34]$. For zero-based indexing, the last element $ia[n]$ is assumed to be equal to the number of non-zero elements in matrix A .

NOTE

For centralized input ($iparm[39]=0$), provide the ia array at the master MPI process only. For distributed assembled input ($iparm[39]=1$ or $iparm[39]=2$), provide it at all MPI processes.

ja

For CSR3 format, array ja contains column indices of the sparse matrix A . It is important that the indices are in increasing order per row. For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in [Three Array Variation of CSR Format](#).

For BSR3 format, array ja contains column indices of the sparse matrix A . It is important that the indices are in increasing order per row. For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in [Three Array Variation of BSR Format](#).

The array ja is accessed in all phases of the solution process.

Indexing of *ja* is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter *iparm(35)*.

NOTE

For centralized input (*iparm(40)=0*), provide the *ja* array at the master MPI process only. For distributed assembled input (*iparm(40)=1* or *iparm(40)=2*), provide it at all MPI processes.

| | |
|---------------|--|
| <i>perm</i> | Ignored. |
| <i>nrhs</i> | Number of right-hand sides that need to be solved for. |
| <i>iparm</i> | <p>Array, size 64. This array is used to pass various parameters to Parallel Direct Sparse Solver for Clusters Interface and to return some useful information after execution of the solver.</p> <p>See cluster_sparse_solver iparm Parameter for more details about the <i>iparm</i> parameters.</p> |
| <i>msglvl</i> | <p>Message level information. If <i>msglvl = 0</i> then <i>cluster_sparse_solver</i> generates no output, if <i>msglvl = 1</i> the solver prints statistical information to the screen.</p> <p>Statistics include information such as the number of non-zero elements in <i>L-factor</i> and the timing for each phase.</p> <p>Set <i>msglvl = 1</i> if you report a problem with the solver, since the additional information provided can facilitate a solution.</p> |
| <i>b</i> | <p>Array, size $n * nrhs$. On entry, contains the right-hand side vector/matrix <i>B</i>, which is placed in memory contiguously. The $b[i+k*n]$ must hold the <i>i</i>-th component of <i>k</i>-th right-hand side vector. Note that <i>b</i> is only accessed in the solution phase.</p> |
| <i>comm</i> | <p>MPI communicator. The solver uses the Fortran MPI communicator internally. Convert the MPI communicator to Fortran using the <code>MPI_Comm_c2f()</code> function. See the examples in the <code><install_dir>/examples</code> directory.</p> |

Output Parameters

| | |
|--------------|---|
| <i>pt</i> | Handle to internal data structure. |
| <i>perm</i> | Ignored. |
| <i>iparm</i> | <p>On output, some <i>iparm</i> values report information such as the numbers of non-zero elements in the factors.</p> <p>See cluster_sparse_solver iparm Parameter for more details about the <i>iparm</i> parameters.</p> |
| <i>b</i> | On output, the array is replaced with the solution if <i>iparm[5] = 1</i> . |

x Array, size ($n * nrhs$). If *iparm*[5]=0 it contains solution vector/matrix *X*, which is placed contiguously in memory. The $x[i+k*n]$ element must hold the *i*-th component of the *k*-th solution vector. Note that *x* is only accessed in the solution phase.

error The error indicator according to the below table:

| error | Information |
|--------------|-------------------------------|
| 0 | no error |
| -1 | input inconsistent |
| -2 | not enough memory |
| -3 | reordering problem |
| -5 | unclassified (internal) error |

cluster_sparse_solver_64

Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.

Syntax

```
void cluster_sparse_solver_64 (void *pt, const long long int *maxfct, const long long int *mnum, const long long int *mtype, const long long int *phase, const long long int *n, const void *a, const long long int *ia, const long long int *ja, long long int *perm, const long long int *nrhs, long long int *iparm, const long long int *msglvl, void *b, void *x, const int *comm, long long int *error);
```

Include Files

- mkl_cluster_sparse_solver.h

Description

The routine `cluster_sparse_solver_64` is an alternative ILP64 (64-bit integer) version of the `cluster_sparse_solver` routine (see the Description section for more details). The interface of `cluster_sparse_solver_64` is the same as the interface of `cluster_sparse_solver`, but it accepts and returns all integer data as `long long int`.

Use `cluster_sparse_solver_64` when `cluster_sparse_solver` for solving large matrices (with the number of non-zero elements on the order of 500 million or more). You can use it together with the usual LP64 interfaces for the rest of Intel MKL functionality. In other words, if you use 64-bit integer version (`cluster_sparse_solver_64`), you do not need to re-link your applications with ILP64 libraries. Take into account that `cluster_sparse_solver_64` may perform slower than regular `cluster_sparse_solver` on the reordering and symbolic factorization phase.

NOTE

`cluster_sparse_solver_64` is supported only in the 64-bit libraries. If `cluster_sparse_solver_64` is called from the 32-bit libraries, it returns `error == -12`.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

The input parameters of `cluster_sparse_solver_64` are the same as the input parameters of `cluster_sparse_solver`, but `cluster_sparse_solver_64` accepts all integer data as long long int.

Output Parameters

The output parameters of `cluster_sparse_solver_64` are the same as the output parameters of `cluster_sparse_solver`, but `cluster_sparse_solver_64` returns all integer data as long long int.

cluster_sparse_solver iparm Parameter

The following table describes all individual components of the Parallel Direct Sparse Solver for Clusters Interface `iparm` parameter. Components which are not used must be initialized with 0. Default values are denoted with an asterisk (*).

| Component | Description |
|---|---|
| <code>iparm[0]</code> | Use default values. |
| input | 0 <code>iparm[1] - iparm(64)</code> are filled with default values. !=0 You must supply all values in components <code>iparm[1] - iparm(64)</code> . |
| <code>iparm[1]</code> | Fill-in reducing ordering for the input matrix. |
| input | 2* The nested dissection algorithm from the METIS package [Karypis98] . 3 The parallel version of the nested dissection algorithm. It can decrease the time of computations on multi-core computers, especially when Phase 1 takes significant time. 10 The MPI version of the nested dissection and symbolic factorization algorithms. The input matrix for the reordering must be distributed among different MPI processes without any intersection. Use <code>iparm[40]</code> and <code>iparm[41]</code> to set the bounds of the domain. During all of Phase 1, the entire matrix is not gathered on any one process, which can decrease computation time (especially when Phase 1 takes significant time) and decrease memory usage for each MPI process on the cluster. |
| <p>NOTE If you set <code>iparm[1] = 10</code>, <code>comm = -1</code> (MPI communicator), and if there is one MPI process, optimization and full parallelization with the OpenMP version of the nested dissection and symbolic factorization algorithms proceeds. This can decrease computation time on multi-core computers. In this case, set <code>iparm[40] = 1</code> and <code>iparm[41] = n</code> for one-based indexing, or to 0 and <code>n - 1</code>, respectively, for zero-based indexing.</p> | |
| <code>iparm[2]</code> | Reserved. Set to zero. |
| <code>iparm[5]</code> | Write solution on <code>x</code> . |
| input | <p>NOTE The array <code>x</code> is always used.</p> <p>0* The array <code>x</code> contains the solution; right-hand side vector <code>b</code> is kept unchanged. 1 The solver stores the solution on the right-hand side <code>b</code>.</p> |

| Component | Description |
|----------------------------|---|
| <i>iparm</i> [6] output | Number of iterative refinement steps performed. Reports the number of iterative refinement steps that were actually performed during the solve step. |
| <i>iparm</i> [7] input | Iterative refinement step. On entry to the solve and iterative refinement step, <i>iparm</i> [7] must be set to the maximum number of iterative refinement steps that the solver performs. |
| | 0* The solver automatically performs two steps of iterative refinement when perturbed pivots are obtained during the numerical factorization. |
| | >0 Maximum number of iterative refinement steps that the solver performs. The solver performs not more than the absolute value of <i>iparm</i> [7] steps of iterative refinement. The solver might stop the process before the maximum number of steps if <ul style="list-style-type: none"> a satisfactory level of accuracy of the solution in terms of backward error is achieved, or if it determines that the required accuracy cannot be reached. In this case Parallel Direct Sparse Solver for Clusters Interface returns -4 in the <i>error</i> parameter. The number of executed iterations is reported in <i>iparm</i> [6]. |
| | <0 Same as above, but the accumulation of the residuum uses extended precision real and complex data types. Perturbed pivots result in iterative refinement (independent of <i>iparm</i> [7]=0) and the number of executed iterations is reported in <i>iparm</i> [6]. |
| <i>iparm</i> [8] | Reserved. Set to zero. |
| <i>iparm</i> [9] input | Pivoting perturbation. This parameter instructs Parallel Direct Sparse Solver for Clusters Interface how to handle small pivots or zero pivots for nonsymmetric matrices (<i>mtype</i> =11 or <i>mtype</i> =13) and symmetric matrices (<i>mtype</i> =-2, <i>mtype</i> =-4, or <i>mtype</i> =6). For these matrices the solver uses a complete supernode pivoting approach. When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99], [Schenk04]. Small pivots are perturbed with $\text{eps} = 10^{-iparm[9]}$. The magnitude of the potential pivot is tested against a constant threshold of $\alpha = \text{eps} * A2 _{inf}$, where $\text{eps} = 10^{(-iparm[9])}$, $A2 = P * P_{MPS} * D_r * A * D_c * P$, and $ A2 _{inf}$ is the infinity norm of the scaled and permuted matrix <i>A</i> . Any tiny pivots encountered during elimination are set to the sign (<i>111</i>)* $\text{eps} * A2 _{inf}$, which trades off some numerical stability for the ability to keep pivots from getting too small. Small pivots are therefore perturbed with $\text{eps} = 10^{(-iparm[9])}$. |
| | 13* The default value for nonsymmetric matrices(<i>mtype</i> =11, <i>mtype</i> =13), $\text{eps} = 10^{-13}$. |
| | 8* The default value for symmetric indefinite matrices (<i>mtype</i> =-2, <i>mtype</i> =-4, <i>mtype</i> =6), $\text{eps} = 10^{-8}$. |
| <i>iparm</i> [10] input | Scaling vectors. Parallel Direct Sparse Solver for Clusters Interface uses a maximum weight matching algorithm to permute large elements on the diagonal and to scale. |

| Component | Description |
|---|---|
| | Use <code>iparm[10] = 1</code> (scaling) and <code>iparm[12] = 1</code> (matching) for highly indefinite symmetric matrices, for example, from interior point optimizations or saddle point problems. Note that in the analysis phase (<code>phase=11</code>) you must provide the numerical values of the matrix <i>A</i> in array <i>a</i> in case of scaling and symmetric weighted matching. |
| | 0* Disable scaling. Default for symmetric indefinite matrices. |
| | 1* Enable scaling. Default for nonsymmetric matrices. Scale the matrix so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less or equal to 1. This scaling method is applied to nonsymmetric matrices (<code>mtype = 11</code> , <code>mtype = 13</code>). The scaling can also be used for symmetric indefinite matrices (<code>mtype = -2</code> , <code>mtype = -4</code> , <code>mtype = 6</code>) when the symmetric weighted matchings are applied (<code>iparm[12] = 1</code>). Note that in the analysis phase (<code>phase=11</code>) you must provide the numerical values of the matrix <i>A</i> in case of scaling. |
| <code>iparm[11]</code> | Reserved. Set to zero. |
| <code>iparm[12]</code> input | Improved accuracy using (non-) symmetric weighted matching. Parallel Direct Sparse Solver for Clusters Interface can use a maximum weighted matching algorithm to permute large elements close the diagonal. This strategy adds an additional level of reliability to the factorization methods and complements the alternative of using more complete pivoting techniques during the numerical factorization. |
| | 0* Disable matching. Default for symmetric indefinite matrices. |
| | 1* Enable matching. Default for nonsymmetric matrices. Maximum weighted matching algorithm to permute large elements close to the diagonal. It is recommended to use <code>iparm[10] = 1</code> (scaling) and <code>iparm[12] = 1</code> (matching) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems. Note that in the analysis phase (<code>phase=11</code>) you must provide the numerical values of the matrix <i>A</i> in case of symmetric weighted matching. |
| <code>iparm[13]</code> - | Reserved. Set to zero. |
| <code>iparm[19]</code> <code>iparm[20]</code> input | Pivoting for symmetric indefinite matrices. |
| | 0 Apply 1x1 diagonal pivoting during the factorization process. |
| | 1* Apply 1x1 and 2x2 Bunch-Kaufman pivoting during the factorization process. Bunch-Kaufman pivoting is available for matrices of <code>mtype=-2</code> , <code>mtype=-4</code> , or <code>mtype=6</code> . |
| <code>iparm[21]</code> - | Reserved. Set to zero. |
| <code>iparm[25]</code> <code>iparm[26]</code> input | Matrix checker. |
| | 0* Do not check the sparse matrix representation for errors. |
| | 1 Check integer arrays <i>ia</i> and <i>ja</i> . In particular, check whether the column indices are sorted in increasing order within each row. |

| Component | Description |
|----------------------------|--|
| <i>iparm</i> [27] input | Single or double precision Parallel Direct Sparse Solver for Clusters Interface. See <i>iparm</i> [7] for information on controlling the precision of the refinement steps. |
| | 0* Input arrays (<i>a</i> , <i>x</i> and <i>b</i>) and all internal arrays must be presented in double precision. |
| | 1 Input arrays (<i>a</i> , <i>x</i> and <i>b</i>) must be presented in single precision. In this case all internal computations are performed in single precision. |
| <i>iparm</i> [28] - | Reserved. Set to zero. |
| <i>iparm</i> [33] | |
| <i>iparm</i> [34] input | One- or zero-based indexing of columns and rows. |
| | 0* One-based indexing: columns and rows indexing in arrays <i>ia</i> , <i>ja</i> , and <i>perm</i> starts from 1 (Fortran-style indexing). |
| | 1 Zero-based indexing: columns and rows indexing in arrays <i>ia</i> , <i>ja</i> , and <i>perm</i> starts from 0 (C-style indexing). |
| <i>iparm</i> [36] input | Format for matrix storage. |
| | 0* Use CSR format (see Three Array Variation of BSR Format) for matrix storage. |
| | > 0 Use BSR format (see Three Array Variation of BSR Format) for matrix storage with blocks of size <i>iparm</i> [36]. |
| | NOTE Intel MKL does not support BSR format in these cases: |
| | <i>iparm</i> [10] > 0 Scaling vectors |
| | <i>iparm</i> [12] > 0 Weighted matching |
| | <i>iparm</i> [30] > 0 Partial solution |
| | <i>iparm</i> [35] > 0 Schur complement |
| | <i>iparm</i> [55] > 0 Pivoting control |
| | <i>iparm</i> [59] > 0 OOC Intel MKL PARDISO |
| <i>iparm</i> [37] - | Reserved. Set to zero. |
| <i>iparm</i> [38] | |
| <i>iparm</i> [39] input | Matrix input format. |
| | NOTE Performance of the reordering step of the Parallel Direct Sparse Solver for Clusters Interface is slightly better for assembled format (CSR, <i>iparm</i> [39] = 0) than for distributed format (DCSR, <i>iparm</i> [39] > 0) for the same matrices, so if the matrix is assembled on one node do not distribute it before calling <code>cluster_sparse_solver</code> . |
| | 0* Provide the matrix in usual centralized input format: the master MPI process stores all data from matrix <i>A</i> , with rank=0. |

| Component | Description |
|--|---|
| 1 | Provide the matrix in distributed assembled matrix input format. In this case, each MPI process stores only a part (or domain) of the matrix <i>A</i> data. Set the bounds of the domain using <i>iparm</i> [40] and <i>iparm</i> [41]. The solution vector is placed on the master process. |
| 2 | Provide the matrix in distributed assembled matrix input format. In this case, each MPI process stores only a part (or domain) of the matrix <i>A</i> data. Set the bounds of the domain using <i>iparm</i> [40] and <i>iparm</i> [41]. The solution vector, <i>A</i> , and RHS elements are distributed between processes in same manner. |
| 3 | Provide the matrix in distributed assembled matrix input format. In this case, each MPI process stores only a part (or domain) of the matrix <i>A</i> data. Set the bounds of the domain using <i>iparm</i> [40] and <i>iparm</i> [41]. The <i>A</i> and RHS elements are distributed between processes in same manner and the solution vector is the same on each process |
| <i>iparm</i> [40] input | <p>Beginning of input domain.</p> <p>The number of the matrix <i>A</i> row, RHS element, and, for <i>iparm</i>[39]=2, solution vector that begins the input domain belonging to this MPI process.</p> <p>Only applicable to the distributed assembled matrix input format (<i>iparm</i>[39] > 0).</p> <p>See Sparse Matrix Storage Formats for more details.</p> |
| <i>iparm</i> [41] input | <p>End of input domain.</p> <p>The number of the matrix <i>A</i> row, RHS element, and, for <i>iparm</i>[39]=2, solution vector that ends the input domain belonging to this MPI process.</p> <p>Only applicable to the distributed assembled matrix input format (<i>iparm</i>[39] > 0).</p> <p>See Sparse Matrix Storage Formats for more details.</p> |
| <i>iparm</i> [42] - <i>iparm</i> [63] input | <p>Reserved. Set to zero.</p> |

NOTE

Generally in sparse matrices, components which are equal to zero can be considered non-zero if necessary. For example, in order to make a matrix structurally symmetric, elements which are zero can be considered non-zero. See [Sparse Matrix Storage Formats](#) for an example.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Direct Sparse Solver (DSS) Interface Routines

Intel MKL supports the DSS interface, an alternative to the Intel MKL PARDISO interface for the direct sparse solver. The DSS interface implements a group of user-callable routines that are used in the step-by-step solving process and utilizes the general scheme described in [Appendix A Linear Solvers Basics](#) for solving sparse systems of linear equations. This interface also includes one routine for gathering statistics related to the solving process.

The DSS interface also supports the out-of-core (OOC) mode.

Table "DSS Interface Routines" lists the names of the routines and describes their general use.

DSS Interface Routines

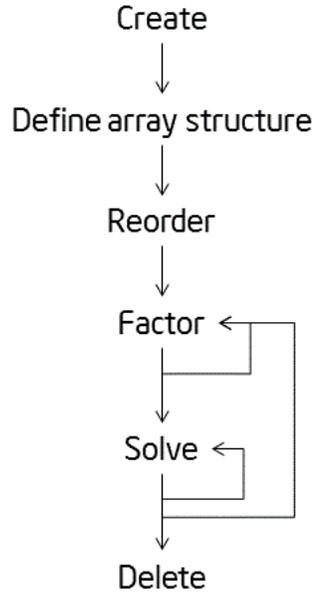

| Routine | Description |
|--|--|
| <code>dss_create</code> | Initializes the solver and creates the basic data structures necessary for the solver. This routine must be called before any other DSS routine. |
| <code>dss_define_structure</code> | Informs the solver of the locations of the non-zero elements of the matrix. |
| <code>dss_reorder</code> | Based on the non-zero structure of the matrix, computes a permutation vector to reduce fill-in during the factoring process. |
| <code>dss_factor_real</code> , <code>dss_factor_complex</code> | Computes the LU , LDL^T or LL^T factorization of a real or complex matrix. |
| <code>dss_solve_real</code> , <code>dss_solve_complex</code> | Computes the solution vector for a system of equations based on the factorization computed in the previous phase. |
| <code>dss_delete</code> | Deletes all data structures created during the solving process. |
| <code>dss_statistics</code> | Returns statistics about various phases of the solving process. |

To find a single solution vector for a single system of equations with a single right-hand side, invoke the Intel MKL DSS interface routines in this order:

1. `dss_create`
2. `dss_define_structure`
3. `dss_reorder`
4. `dss_factor_real`, `dss_factor_complex`
5. `dss_solve_real`, `dss_solve_complex`
6. `dss_delete`

However, in certain applications it is necessary to produce solution vectors for multiple right-hand sides for a given factorization and/or factor several matrices with the same non-zero structure. Consequently, it is sometimes necessary to invoke the Intel MKL sparse routines in an order other than that listed, which is possible using the DSS interface. The solving process is conceptually divided into six phases. [Figure "Typical order for invoking DSS interface routines"](#) indicates the typical order in which the DSS interface routines can be invoked.

Typical order for invoking DSS interface routines

See the code examples that use the DSS interface routines to solve systems of linear equations in the Intel MKL installation directory (`dss_*.c`).

- `examples/solverc/source`

DSS Interface Description

Each DSS routine reads from or writes to a data object called a *handle*. Refer to [Memory Allocation and Handles](#) to determine the correct method for declaring a handle argument for each language. For simplicity, the descriptions in DSS routines refer to the data type as `MKL_DSS_HANDLE`.

Routine Options

The DSS routines have an integer argument (referred below to as *opt*) for passing various options to the routines. The permissible values for *opt* should be specified using only the symbol constants defined in the language-specific header files (see [Implementation Details](#)). The routines accept options for setting the message and termination levels as described in [Table "Symbolic Names for the Message and Termination Levels Options"](#). Additionally, each routine accepts the option `MKL_DSS_DEFAULTS` that sets the default values (as documented) for *opt* to the routine.

Symbolic Names for the Message and Termination Levels Options

| Message Level | Termination Level |
|--------------------------------------|---------------------------------------|
| <code>MKL_DSS_MSG_LVL_SUCCESS</code> | <code>MKL_DSS_TERM_LVL_SUCCESS</code> |
| <code>MKL_DSS_MSG_LVL_INFO</code> | <code>MKL_DSS_TERM_LVL_INFO</code> |
| <code>MKL_DSS_MSG_LVL_WARNING</code> | <code>MKL_DSS_TERM_LVL_WARNING</code> |
| <code>MKL_DSS_MSG_LVL_ERROR</code> | <code>MKL_DSS_TERM_LVL_ERROR</code> |
| <code>MKL_DSS_MSG_LVL_FATAL</code> | <code>MKL_DSS_TERM_LVL_FATAL</code> |

The settings for message and termination levels can be set on any call to a DSS routine. However, once set to a particular level, they remain at that level until they are changed in another call to a DSS routine.

You can specify both message and termination level for a DSS routine by adding the options together. For example, to set the message level to `debug` and the termination level to `error` for all the DSS routines, use the following call:

```
dss_create( handle, MKL_DSS_MSG_LVL_INFO + MKL_DSS_TERM_LVL_ERROR)
```

User Data Arrays

Many of the DSS routines take arrays of user data as input. For example, pointers to user arrays are passed to the routine `dss_define_structure` to describe the location of the non-zero entries in the matrix.

CAUTION

Do not modify the contents of these arrays after they are passed to one of the solver routines.

DSS Implementation Details

To promote portability across platforms and ease of use across different languages, use the appropriate Intel MKL DSS header file:

- `mkl_dss.h`

The header file defines symbolic constants for returned error values, function options, certain defined data types, and function prototypes.

NOTE

Constants for options, returned error values, and message severities must be referred only by the symbolic names that are defined in these header files. Use of the Intel MKL DSS software without including one of the above header files is not supported.

Memory Allocation and Handles

You do not need to allocate any temporary working storage in order to use the Intel MKL DSS routines, because the solver itself allocates any required storage. To enable multiple users to access the solver simultaneously, the solver keeps track of the storage allocated for a particular application by using a *handle* data object.

Each of the Intel MKL DSS routines creates, uses, or deletes a handle. Consequently, any program calling an Intel MKL DSS routine must be able to allocate storage for a handle. The exact syntax for allocating storage for a handle varies from language to language. To standardize the handle declarations, the language-specific header files declare constants and defined data types that must be used when declaring a handle object in your code.

- ```
#include "mkl_dss.h"
_MKL_DSS_HANDLE_t handle;
```

In addition to the definition for the correct declaration of a handle, the include file also defines the following:

- function prototypes for languages that support prototypes
- symbolic constants that are used for the returned error values
- user options for the solver routines
- constants indicating message severity.

## DSS Routines

## dss\_create

Initializes the solver.

---

### Syntax

```
MKL_INT dss_create(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt)
```

### Include Files

- mkl.h

### Description

The `dss_create` routine initializes the solver. After the call to `dss_create`, all subsequent invocations of the Intel MKL DSS routines must use the value of the handle returned by `dss_create`.

---

**WARNING**

Do not write the value of handle directly.

---

The default value of the parameter `opt` is

```
MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR.
```

By default, the DSS routines use double precision for solving systems of linear equations. The precision used by the DSS routines can be set to single mode by adding the following value to the `opt` parameter:

```
MKL_DSS_SINGLE_PRECISION.
```

Input data and internal arrays are required to have single precision.

By default, the DSS routines use Fortran style (one-based) indexing for input arrays of integer types (the first value is referenced as array element 1). To set indexing to C style (the first value is referenced as array element 0), add the following value to the `opt` parameter:

```
MKL_DSS_ZERO_BASED_INDEXING.
```

The `opt` parameter can also control number of refinement steps used on the solution stage by specifying the two following values:

```
MKL_DSS_REFINEMENT_OFF - maximum number of refinement steps is set to zero;
```

```
MKL_DSS_REFINEMENT_ON (default value) - maximum number of refinement steps is set to 2.
```

By default, DSS uses in-core computations. To launch the out-of-core version of DSS (OOC DSS) you can add to this parameter one of two possible values: `MKL_DSS_OOC_STRONG` and `MKL_DSS_OOC_VARIABLE`.

```
MKL_DSS_OOC_STRONG - OOC DSS is used.
```

```
MKL_DSS_OOC_VARIABLE - if the memory needed for the matrix factors is less than the value of the environment variable MKL_PARDISO_OOC_MAX_CORE_SIZE, then the OOC DSS uses the in-core kernels of Intel MKL PARDISO, otherwise it uses the OOC computations.
```

The variable `MKL_PARDISO_OOC_MAX_CORE_SIZE` defines the maximum size of RAM allowed for storing work arrays associated with the matrix factors. It is ignored if `MKL_DSS_OOC_STRONG` is set. The default value of `MKL_PARDISO_OOC_MAX_CORE_SIZE` is 2000 MB. This value and default path and file name for storing temporary data can be changed using the configuration file `pardiso_ooc.cfg` or command line (See more details in the description of the [pardiso](#) routine).

---

**WARNING**

Other than message and termination level options, do not change the OOC DSS settings after they are specified in the routine `dss_create`.

---

## Input Parameters

*opt* Parameter to pass the DSS options. The default value is MKL\_DSS\_MSG\_LVL\_WARNING + MKL\_DSS\_TERM\_LVL\_ERROR.

## Output Parameters

*handle* Pointer to the data structure storing internal DSS results (MKL\_DSS\_HANDLE).

## Return Values

MKL\_DSS\_SUCCESS

MKL\_DSS\_INVALID\_OPTION

MKL\_DSS\_OUT\_OF\_MEMORY

MKL\_DSS\_MSG\_LVL\_ERR

MKL\_DSS\_TERM\_LVL\_ERR

## dss\_define\_structure

*Communicates locations of non-zero elements in the matrix to the solver.*

---

### Syntax

```
MKL_INT dss_define_structure(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, MKL_INT const *rowIndex, MKL_INT const *nRows, MKL_INT const *nCols, MKL_INT const *columns, MKL_INT const *nNonZeros);
```

### Include Files

- mkl.h

### Description

The routine `dss_define_structure` communicates the locations of the `nNonZeros` number of non-zero elements in a matrix of `nRows * nCols` size to the solver.

---

#### NOTE

The Intel MKL DSS software operates only on square matrices, so `nRows` must be equal to `nCols`.

---

To communicate the locations of non-zero elements in the matrix, do the following:

1. Define the general non-zero structure of the matrix by specifying the value for the options argument `opt`. You can set the following values for real matrices:

- MKL\_DSS\_SYMMETRIC\_STRUCTURE
- MKL\_DSS\_SYMMETRIC
- MKL\_DSS\_NON\_SYMMETRIC

and for complex matrices:

- MKL\_DSS\_SYMMETRIC\_STRUCTURE\_COMPLEX
- MKL\_DSS\_SYMMETRIC\_COMPLEX

- MKL\_DSS\_NON\_SYMMETRIC\_COMPLEX

The information about the matrix type must be defined in `dss_define_structure`.

2. Provide the actual locations of the non-zeros by means of the arrays `rowIndex` and `columns` (see [Sparse Matrix Storage Format](#)).

## Input Parameters

|                        |                                                                                                                   |
|------------------------|-------------------------------------------------------------------------------------------------------------------|
| <code>opt</code>       | Parameter to pass the DSS options. The default value for the matrix structure is <code>MKL_DSS_SYMMETRIC</code> . |
| <code>rowIndex</code>  | Array of size <code>nRows+1</code> . Defines the location of non-zero entries in the matrix.                      |
| <code>nRows</code>     | Number of rows in the matrix.                                                                                     |
| <code>nCols</code>     | Number of columns in the matrix; must be equal to <code>nRows</code> .                                            |
| <code>columns</code>   | Array of size <code>nNonZeros</code> . Defines the column location of non-zero entries in the matrix.             |
| <code>nNonZeros</code> | Number of non-zero elements in the matrix.                                                                        |

## Output Parameters

|                     |                                                                                             |
|---------------------|---------------------------------------------------------------------------------------------|
| <code>handle</code> | Pointer to the data structure storing internal DSS results ( <code>MKL_DSS_HANDLE</code> ). |
|---------------------|---------------------------------------------------------------------------------------------|

## Return Values

`MKL_DSS_SUCCESS`  
`MKL_DSS_STATE_ERR`  
`MKL_DSS_INVALID_OPTION`  
`MKL_DSS_STRUCTURE_ERR`  
`MKL_DSS_ROW_ERR`  
`MKL_DSS_COL_ERR`  
`MKL_DSS_NOT_SQUARE`  
`MKL_DSS_TOO_FEW_VALUES`  
`MKL_DSS_TOO_MANY_VALUES`  
`MKL_DSS_OUT_OF_MEMORY`  
`MKL_DSS_MSG_LVL_ERR`  
`MKL_DSS_TERM_LVL_ERR`

## **dss\_reorder**

*Computes or sets a permutation vector that minimizes the fill-in during the factorization phase.*

---

## Syntax

```
MKL_INT dss_reorder(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, MKL_INT const *perm)
```

## Include Files

- `mk1.h`

## Description

If `opt` contains the option `MKL_DSS_AUTO_ORDER`, then the routine `dss_reorder` computes a permutation vector that minimizes the fill-in during the factorization phase. For this option, the routine ignores the contents of the `perm` array.

If `opt` contains the option `MKL_DSS_METIS_OPENMP_ORDER`, then the routine `dss_reorder` computes permutation vector using the parallel nested dissections algorithm to minimize the fill-in during the factorization phase. This option can be used to decrease the time of `dss_reorder` call on multi-core computers. For this option, the routine ignores the contents of the `perm` array.

If `opt` contains the option `MKL_DSS_MY_ORDER`, then you must supply a permutation vector in the array `perm`. In this case, the array `perm` is of length `nRows`, where `nRows` is the number of rows in the matrix as defined by the previous call to `dss_define_structure`.

If `opt` contains the option `MKL_DSS_GET_ORDER`, then the permutation vector computed during the `dss_reorder` call is copied to the array `perm`. In this case you must allocate the array `perm` beforehand. The permutation vector is computed in the same way as if the option `MKL_DSS_AUTO_ORDER` is set.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

## Input Parameters

|                   |                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>opt</code>  | Parameter to pass the DSS options. The default value for the permutation type is <code>MKL_DSS_AUTO_ORDER</code> .                                                                             |
| <code>perm</code> | Array of length <code>nRows</code> . Contains a user-defined permutation vector (accessed only if <code>opt</code> contains <code>MKL_DSS_MY_ORDER</code> or <code>MKL_DSS_GET_ORDER</code> ). |

## Output Parameters

|                     |                                                                                             |
|---------------------|---------------------------------------------------------------------------------------------|
| <code>handle</code> | Pointer to the data structure storing internal DSS results ( <code>MKL_DSS_HANDLE</code> ). |
|---------------------|---------------------------------------------------------------------------------------------|

## Return Values

`MKL_DSS_SUCCESS`  
`MKL_DSS_STATE_ERR`  
`MKL_DSS_INVALID_OPTION`  
`MKL_DSS_REORDER_ERR`  
`MKL_DSS_REORDER1_ERR`

MKL\_DSS\_I32BIT\_ERR  
MKL\_DSS\_FAILURE  
MKL\_DSS\_OUT\_OF\_MEMORY  
MKL\_DSS\_MSG\_LVL\_ERR  
MKL\_DSS\_TERM\_LVL\_ERR

## dss\_factor\_real, dss\_factor\_complex

Compute factorization of the matrix with previously specified location of non-zero elements.

---

### Syntax

```
MKL_INT dss_factor_real(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, void const *rValues)
```

```
MKL_INT dss_factor_complex(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, void const *cValues)
```

### Include Files

- mkl.h

### Description

These routines compute factorization of the matrix whose non-zero locations were previously specified by a call to [dss\\_define\\_structure](#) and whose non-zero values are given in the array *rValues*, *cValues* or *Values*. Data type These arrays must be of length *nNonZeros* as defined in a previous call to [dss\\_define\\_structure](#).

---

#### NOTE

The data type (single or double precision) of *rValues*, *cValues*, *Values* must be in correspondence with precision specified by the parameter *opt* in the routine [dss\\_create](#).

---

The *opt* argument can contain one of the following options:

- MKL\_DSS\_POSITIVE\_DEFINITE
- MKL\_DSS\_INDEFINITE
- MKL\_DSS\_HERMITIAN\_POSITIVE\_DEFINITE
- MKL\_DSS\_HERMITIAN\_INDEFINITE

depending on your matrix's type.

---

#### NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

---

### Input Parameters

|               |                                                                                    |
|---------------|------------------------------------------------------------------------------------|
| <i>handle</i> | Pointer to the data structure storing internal DSS results (MKL_DSS_HANDLE).       |
| <i>opt</i>    | Parameter to pass the DSS options. The default value is MKL_DSS_POSITIVE_DEFINITE. |

|                |                                                                                                                                                                             |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>rValues</i> | Array of elements of the matrix <i>A</i> . Real data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .    |
| <i>cValues</i> | Array of elements of the matrix <i>A</i> . Complex data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> . |

## Return Values

MKL\_DSS\_SUCCESS  
 MKL\_DSS\_STATE\_ERR  
 MKL\_DSS\_INVALID\_OPTION  
 MKL\_DSS\_OPTION\_CONFLICT  
 MKL\_DSS\_VALUES\_ERR  
 MKL\_DSS\_OUT\_OF\_MEMORY  
 MKL\_DSS\_ZERO\_PIVOT  
 MKL\_DSS\_FAILURE  
 MKL\_DSS\_MSG\_LVL\_ERR  
 MKL\_DSS\_TERM\_LVL\_ERR  
 MKL\_DSS\_OOC\_MEM\_ERR  
 MKL\_DSS\_OOC\_OC\_ERR  
 MKL\_DSS\_OOC\_RW\_ERR

## `dss_solve_real`, `dss_solve_complex`

Compute the corresponding solution vector and place it in the output array.

### Syntax

```

MKL_INT dss_solve_real(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, void const
*rRhsValues, MKL_INT const *nRhs, void *rSolValues)

MKL_INT dss_solve_complex(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, void const
*cRhsValues, MKL_INT const *nRhs, void *cSolValues)

```

### Include Files

- `mkl.h`

### Description

For each right-hand side column vector defined in the arrays *rRhsValues*, *cRhsValues*, or *RhsValues*, these routines compute the corresponding solution vector and place it in the arrays *rSolValues*, *cSolValues*, or *SolValues* respectively.

---

#### NOTE

The data type (single or double precision) of all arrays must be in correspondence with precision specified by the parameter *opt* in the routine `dss_create`.

---

The lengths of the right-hand side and solution vectors, *nRows* and *nCols* respectively, must be defined in a previous call to `dss_define_structure`.

By default, both routines perform the full solution step (it corresponds to *phase* = 33 in Intel MKL PARDISO). The parameter *opt* enables you to calculate the final solution step-by-step, calling forward and backward substitutions.

If it is set to `MKL_DSS_FORWARD_SOLVE`, the forward substitution (corresponding to *phase* = 331 in Intel MKL PARDISO) is performed;

if it is set to `MKL_DSS_DIAGONAL_SOLVE`, the diagonal substitution (corresponding to *phase* = 332 in Intel MKL PARDISO) is performed, if possible;

if it is set to `MKL_DSS_BACKWARD_SOLVE`, the backward substitution (corresponding to *phase* = 333 in Intel MKL PARDISO) is performed.

For more details about using these substitutions for different types of matrices, see [Separate Forward and Backward Substitution](#) in the Intel MKL PARDISO solver description.

This parameter also can control the number of refinement steps that is used on the solution stage: if it is set to `MKL_DSS_REFINEMENT_OFF`, the maximum number of refinement steps equal to zero, and if it is set to `MKL_DSS_REFINEMENT_ON` (default value), the maximum number of refinement steps is equal to 2.

`MKL_DSS_CONJUGATE_SOLVE` option added to the parameter *opt* enables solving a conjugate transposed system  $A^HX = B$  based on the factorization of the matrix *A*. This option is equivalent to the parameter *iparm*[11]= 1 in Intel MKL PARDISO.

`MKL_DSS_TRANSPOSE_SOLVE` option added to the parameter *opt* enables solving a transposed system  $A^TX = B$  based on the factorization of the matrix *A*. This option is equivalent to the parameter *iparm*[11]= 2 in Intel MKL PARDISO.

## Input Parameters

|                   |                                                                                                                                                                                                                       |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>handle</i>     | Pointer to the data structure storing internal DSS results ( <code>MKL_DSS_HANDLE</code> ).                                                                                                                           |
| <i>opt</i>        | Parameter to pass the DSS options.                                                                                                                                                                                    |
| <i>nRhs</i>       | Number of the right-hand sides in the system of linear equations.                                                                                                                                                     |
| <i>rRhsValues</i> | Array of size <i>nRows</i> * <i>nRhs</i> . Contains real right-hand side vectors. Real data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .       |
| <i>cRhsValues</i> | Array of size <i>nRows</i> * <i>nRhs</i> . Contains complex right-hand side vectors. Complex data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> . |
| <i>RhsValues</i>  | Array of size <i>nRows</i> * <i>nRhs</i> . Contains right-hand side vectors. Real or complex data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> . |

## Output Parameters

|                   |                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>rSolValues</i> | Array of size <i>nCols</i> * <i>nRhs</i> . Contains real solution vectors. Real data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .       |
| <i>cSolValues</i> | Array of size <i>nCols</i> * <i>nRhs</i> . Contains complex solution vectors. Complex data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> . |

## dss\_statistics

Returns statistics about various phases of the solving process.

---

### Syntax

```
MKL_INT dss_statistics(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, _CHARACTER_STR_t const *statArr, _DOUBLE_PRECISION_t *retValues)
```

### Include Files

- mkl.h

### Description

The `dss_statistics` routine returns statistics about various phases of the solving process. This routine gathers the following statistics:

- time taken to do reordering,
- time taken to do factorization,
- duration of problem solving,
- determinant of the symmetric indefinite input matrix,
- inertia of the symmetric indefinite input matrix,
- number of floating point operations taken during factorization,
- total peak memory needed during the analysis and symbolic factorization,
- permanent memory needed from the analysis and symbolic factorization,
- memory consumption for the factorization and solve phases.

Statistics are returned in accordance with the input string specified by the parameter `statArr`. The value of the statistics is returned in double precision in a return array, which you must allocate beforehand.

For multiple statistics, multiple string constants separated by commas can be used as input. Return values are put into the return array in the same order as specified in the input string.

Statistics can only be requested at the appropriate stages of the solving process. For example, requesting `FactorTime` before a matrix is factored leads to an error.

The following table shows the point at which each individual statistics item can be requested:

### Statistics Calling Sequences

| Type of Statistics | When to Call                                                                                                    |
|--------------------|-----------------------------------------------------------------------------------------------------------------|
| ReorderTime        | After <code>dss_reorder</code> is completed successfully.                                                       |
| FactorTime         | After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.                |
| SolveTime          | After <code>dss_solve_real</code> or <code>dss_solve_complex</code> is completed successfully.                  |
| Determinant        | After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.                |
| Inertia            | After <code>dss_factor_real</code> is completed successfully and the matrix is real, symmetric, and indefinite. |
| Flops              | After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.                |
| Peakmem            | After <code>dss_reorder</code> is completed successfully.                                                       |
| Factormem          | After <code>dss_reorder</code> is completed successfully.                                                       |
| Solvemem           | After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.                |

## Input Parameters

| <i>statArr</i> | Input string that defines the type of the returned statistics. The parameter can include one or more of the following string constants (case of the input string has no effect): <table> <tr> <td>ReorderTime</td> <td>Amount of time taken to do the reordering.</td> </tr> <tr> <td>FactorTime</td> <td>Amount of time taken to do the factorization.</td> </tr> <tr> <td>SolveTime</td> <td>Amount of time taken to solve the problem after factorization.</td> </tr> <tr> <td>Determinant</td> <td>Determinant of the matrix <math>A</math>.<br/><br/>For real matrices: the determinant is returned as <math>det\_pow</math>, <math>det\_base</math> in two consecutive return array locations, where <math>1.0 \leq abs(det\_base) &lt; 10.0</math> and <math>determinant = det\_base * 10^{(det\_pow)}</math>.<br/><br/>For complex matrices: the determinant is returned as <math>det\_pow</math>, <math>det\_re</math>, <math>det\_im</math> in three consecutive return array locations, where <math>1.0 \leq abs(det\_re) + abs(det\_im) &lt; 10.0</math> and <math>determinant = (det\_re, det\_im) * 10^{(det\_pow)}</math>.</td> </tr> <tr> <td>Inertia</td> <td>Inertia of a real symmetric matrix is defined as a triplet of nonnegative integers <math>(p, n, z)</math>, where <math>p</math> is the number of positive eigenvalues, <math>n</math> is the number of negative eigenvalues, and <math>z</math> is the number of zero eigenvalues.<br/><br/>Inertia is returned as three consecutive return array locations <math>p, n, z</math>.<br/><br/>Computing inertia can lead to incorrect results for matrixes with a cluster of eigenvalues which are near 0.<br/><br/>Inertia of a <math>k</math>-by-<math>k</math> real symmetric positive definite matrix is always <math>(k, 0, 0)</math>. Therefore Inertia is returned only in cases of real symmetric indefinite matrices. For all other matrix types, an error message is returned.</td> </tr> <tr> <td>Flops</td> <td>Number of floating point operations performed during the factorization.</td> </tr> <tr> <td>Peakmem</td> <td>Total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase.</td> </tr> </table> | ReorderTime | Amount of time taken to do the reordering. | FactorTime | Amount of time taken to do the factorization. | SolveTime | Amount of time taken to solve the problem after factorization. | Determinant | Determinant of the matrix $A$ .<br><br>For real matrices: the determinant is returned as $det\_pow$ , $det\_base$ in two consecutive return array locations, where $1.0 \leq abs(det\_base) < 10.0$ and $determinant = det\_base * 10^{(det\_pow)}$ .<br><br>For complex matrices: the determinant is returned as $det\_pow$ , $det\_re$ , $det\_im$ in three consecutive return array locations, where $1.0 \leq abs(det\_re) + abs(det\_im) < 10.0$ and $determinant = (det\_re, det\_im) * 10^{(det\_pow)}$ . | Inertia | Inertia of a real symmetric matrix is defined as a triplet of nonnegative integers $(p, n, z)$ , where $p$ is the number of positive eigenvalues, $n$ is the number of negative eigenvalues, and $z$ is the number of zero eigenvalues.<br><br>Inertia is returned as three consecutive return array locations $p, n, z$ .<br><br>Computing inertia can lead to incorrect results for matrixes with a cluster of eigenvalues which are near 0.<br><br>Inertia of a $k$ -by- $k$ real symmetric positive definite matrix is always $(k, 0, 0)$ . Therefore Inertia is returned only in cases of real symmetric indefinite matrices. For all other matrix types, an error message is returned. | Flops | Number of floating point operations performed during the factorization. | Peakmem | Total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase. |
| ReorderTime    | Amount of time taken to do the reordering.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |             |                                            |            |                                               |           |                                                                |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |       |                                                                         |         |                                                                                                            |

| SolveTime      | Amount of time taken to solve the problem after factorization.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |             |                                            |            |                                               |           |                                                                |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |       |                                                                         |         |                                                                                                            |
| Determinant    | Determinant of the matrix $A$ .<br><br>For real matrices: the determinant is returned as $det\_pow$ , $det\_base$ in two consecutive return array locations, where $1.0 \leq abs(det\_base) < 10.0$ and $determinant = det\_base * 10^{(det\_pow)}$ .<br><br>For complex matrices: the determinant is returned as $det\_pow$ , $det\_re$ , $det\_im$ in three consecutive return array locations, where $1.0 \leq abs(det\_re) + abs(det\_im) < 10.0$ and $determinant = (det\_re, det\_im) * 10^{(det\_pow)}$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |             |                                            |            |                                               |           |                                                                |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |       |                                                                         |         |                                                                                                            |
| Inertia        | Inertia of a real symmetric matrix is defined as a triplet of nonnegative integers $(p, n, z)$ , where $p$ is the number of positive eigenvalues, $n$ is the number of negative eigenvalues, and $z$ is the number of zero eigenvalues.<br><br>Inertia is returned as three consecutive return array locations $p, n, z$ .<br><br>Computing inertia can lead to incorrect results for matrixes with a cluster of eigenvalues which are near 0.<br><br>Inertia of a $k$ -by- $k$ real symmetric positive definite matrix is always $(k, 0, 0)$ . Therefore Inertia is returned only in cases of real symmetric indefinite matrices. For all other matrix types, an error message is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |             |                                            |            |                                               |           |                                                                |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |       |                                                                         |         |                                                                                                            |
| Flops          | Number of floating point operations performed during the factorization.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |             |                                            |            |                                               |           |                                                                |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |       |                                                                         |         |                                                                                                            |
| Peakmem        | Total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |             |                                            |            |                                               |           |                                                                |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |       |                                                                         |         |                                                                                                            |

|           |                                                                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| Factormem | Permanent memory in kilobytes that the solver needs from the analysis and symbolic factorization phase in the factorization and solve phases. |
| Solvemem  | Total double precision memory consumption (kilobytes) of the solver for the factorization and solve phases.                                   |

## Output Parameters

*retValues* Value of the statistics returned.

## Finding 'time used to reorder' and 'inertia' of a matrix

The example below illustrates the use of the `dss_statistics` routine.

To find the above values, call `dss_statistics(handle, opt, statArr, retValue)`, where *statArr* is "ReorderTime,Inertia"

In this example, *retValue* has the following values:

|                     |                       |
|---------------------|-----------------------|
| <i>retValue</i> [0] | Time to reorder.      |
| <i>retValue</i> [1] | Positive Eigenvalues. |
| <i>retValue</i> [2] | Negative Eigenvalues. |
| <i>retValue</i> [3] | Zero Eigenvalues.     |

## Return Values

MKL\_DSS\_SUCCESS  
MKL\_DSS\_INVALID\_OPTION  
MKL\_DSS\_STATISTICS\_INVALID\_MATRIX  
MKL\_DSS\_STATISTICS\_INVALID\_STATE  
MKL\_DSS\_STATISTICS\_INVALID\_STRING  
MKL\_DSS\_MSG\_LVL\_ERR  
MKL\_DSS\_TERM\_LVL\_ERR

## Iterative Sparse Solvers based on Reverse Communication Interface (RCI ISS)

---

Intel MKL supports iterative sparse solvers (ISS) based on the reverse communication interface (RCI), referred to here as the RCI ISS interface. The RCI ISS interface implements a group of user-callable routines that are used in the step-by-step solving process of a symmetric positive definite system (RCI conjugate gradient solver, or RCI CG), and of a non-symmetric indefinite (non-degenerate) system (RCI flexible generalized minimal residual solver, or RCI FGMRES) of linear algebraic equations. This interface uses the general RCI scheme described in [Dong95].

See the [Appendix A Linear Solvers Basics](#) for discussion of terms and concepts related to the ISS routines.

The term *RCI* indicates that when the solver needs the results of certain operations (for example, matrix-vector multiplications), the user performs them and passes the result to the solver. This makes the solver more universal as it is independent of the specific implementation of the operations like the matrix-vector multiplication. To perform such operations, the user can use the built-in sparse matrix-vector multiplications and triangular solvers routines described in [Sparse BLAS Level 2 and Level 3 Routines](#).

**NOTE**

The RCI CG solver is implemented in two versions: for system of equations with a single right-hand side, and for systems of equations with multiple right-hand sides.

The CG method may fail to compute the solution or compute the wrong solution if the matrix of the system is not symmetric and not positive definite.

The FGMRES method may fail if the matrix is degenerate.

Table "RCI CG Interface Routines" lists the names of the routines, and describes their general use.

**RCI ISS Interface Routines**

| Routine                                                                                   | Description                                                      |
|-------------------------------------------------------------------------------------------|------------------------------------------------------------------|
| <a href="#">dcg_init</a> , <a href="#">dcgmrhs_init</a> , <a href="#">dfgmres_init</a>    | Initializes the solver.                                          |
| <a href="#">dcg_check</a> , <a href="#">dcgmrhs_check</a> , <a href="#">dfgmres_check</a> | Checks the consistency and correctness of the user defined data. |
| <a href="#">dcg</a> , <a href="#">dcgmrhs</a> , <a href="#">dfgmres</a>                   | Computes the approximate solution vector.                        |
| <a href="#">dcg_get</a> , <a href="#">dcgmrhs_get</a> , <a href="#">dfgmres_get</a>       | Retrieves the number of the current iteration.                   |

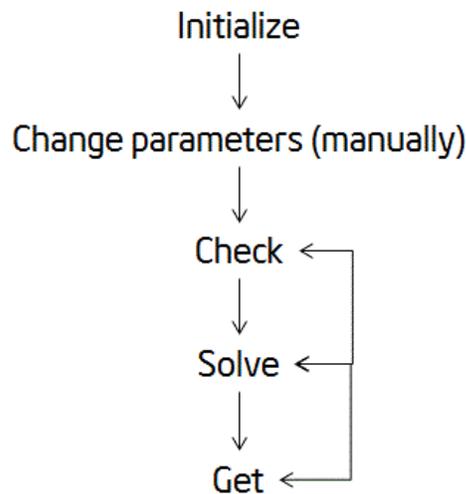

The Intel MKL RCI ISS interface routines are normally invoked in this order:

1. `<system_type>_init`
2. `<system_type>_check`
3. `<system_type>`
4. `<system_type>_get`

Advanced users can change that order if they need it. Others should follow the above order of calls.

The following diagram indicates the typical order in which the RCI ISS interface routines are invoked.

**Typical Order for Invoking RCI ISS interface Routines**

See the code examples that use the RCI ISS interface routines to solve systems of linear equations in the Intel MKL installation directory.

- `examples/solverc/source`

## CG Interface Description

Each routine for the RCI CG solver is implemented in two versions: for a system of equations with a single right-hand side (SRHS), and for a system of equations with multiple right-hand sides (MRHS). The names of routines for a system with MRHS contain the suffix `mrhs`.

### Routine Options

All of the RCI CG routines have common parameters for passing various options to the routines (see [CG Common Parameters](#)). The values for these parameters can be changed during computations.

### User Data Arrays

Many of the RCI CG routines take arrays of user data as input. For example, user arrays are passed to the routine `dcg` to compute the solution of a system of linear algebraic equations. The Intel MKL RCI CG routines do not make copies of the user input arrays to minimize storage requirements and improve overall run-time efficiency.

### CG Common Parameters

---

#### NOTE

The default and initial values listed below are assigned to the parameters by calling the `dcg_init/dcgmrhs_init` routine.

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>           | MKL_INT, this parameter sets the size of the problem in the <code>dcg_init/dcgmrhs_init</code> routine. All the other routines use the <code>ipar[0]</code> parameter instead. Note that the coefficient matrix <i>A</i> is a square matrix of size $n*n$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>x</i>           | double array of size <i>n</i> for SRHS, or matrix of size $(n*nrhs)$ for MRHS. This parameter contains the current approximation to the solution. Before the first call to the <code>dcg/dcgmrhs</code> routine, it contains the initial approximation to the solution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>nrhs</i>        | MKL_INT, this parameter sets the number of right-hand sides for MRHS routines.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>b</i>           | double array containing a single right-hand side vector, or matrix of size $n*nrhs$ containing right-hand side vectors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>RCI_request</i> | <p>MKL_INT, this parameter gives information about the result of work of the RCI CG routines. Negative values of the parameter indicate that the routine completed with errors or warnings. The 0 value indicates successful completion of the task. Positive values mean that you must perform specific actions:</p> <p><i>RCI_request</i>= 1      multiply the matrix by <code>tmp [0:n - 1)</code>, put the result in <code>tmp[n:2*n - 1)</code>, and return the control to the <code>dcg/dcgmrhs</code> routine;</p> <p><i>RCI_request</i>= 2      to perform the stopping tests. If they fail, return the control to the <code>dcg/dcgmrhs</code> routine. If the stopping tests succeed, it indicates that the solution is found and stored in the <i>x</i> array;</p> |

*RCI\_request*= 3      for SRHS: apply the preconditioner to *tmp*[2\**n*:3\**n* - 1], put the result in *tmp*[3\**n*:4\**n* - 1], and return the control to the *dcg* routine;

                          for MRHS: apply the preconditioner to *tmp*[2+*ipar*[2]\**n*:(3 + *ipar*[2])\**n* - 1], put the result in *tmp*[3\**n*:4\**n* - 1], and return the control to the *dcgmrhs* routine.

Note that the *dcg\_get/dcgmrhs\_get* routine does not change the parameter *RCI\_request*. This enables use of this routine inside the *reverse communication* computations.

*ipar*

MKL\_INT array, of size 128 for SRHS, and of size (128+2\**nrhs*) for MRHS. This parameter specifies the integer set of data for the RCI CG computations:

*ipar*[0]                specifies the size of the problem. The *dcg\_init/dcgmrhs\_init* routine assigns *ipar*[0]=*n*. All the other routines use this parameter instead of *n*. There is no default value for this parameter.

*ipar*[1]                specifies the type of output for error and warning messages generated by the RCI CG routines. The default value 6 means that all messages are displayed on the screen. Otherwise, the error and warning messages are written to the newly created files *dcg\_errors.txt* and *dcg\_check\_warnings.txt*, respectively. Note that if *ipar*[5] and *ipar*[6] parameters are set to 0, error and warning messages are not generated at all.

*ipar*[2]                for SRHS: contains the current stage of the RCI CG computations. The initial value is 1;  
                           for MRHS: contains the number of the right-hand side for which the calculations are currently performed.

---

**WARNING**

Avoid altering this variable during computations.

---

*ipar*[3]                contains the current iteration number. The initial value is 0.

*ipar*[4]                specifies the maximum number of iterations. The default value is  $\min(150, n)$ .

*ipar*[5]                if the value is not equal to 0, the routines output error messages in accordance with the parameter *ipar*[1]. Otherwise, the routines do not output error messages at all, but return a negative value of the parameter *RCI\_request*. The default value is 1.

*ipar*[6] if the value is not equal to 0, the routines output warning messages in accordance with the parameter *ipar*[1]. Otherwise, the routines do not output warning messages at all, but they return a negative value of the parameter *RCI\_request*. The default value is 1.

*ipar*[7] if the value is not equal to 0, the *dcg/dcgmrhs* routine performs the stopping test for the maximum number of iterations:  $ipar[3] \leq ipar[4]$ . Otherwise, the method is stopped and the corresponding value is assigned to the *RCI\_request*. If the value is 0, the routine does not perform this stopping test. The default value is 1.

*ipar*[8] if the value is not equal to 0, the *dcg/dcgmrhs* routine performs the residual stopping test:  $dpar(5) \leq dpar(4) = dpar(1) * dpar(3) + dpar(2)$ . Otherwise, the method is stopped and corresponding value is assigned to the *RCI\_request*. If the value is 0, the routine does not perform this stopping test. The default value is 0.

*ipar*[9] if the value is not equal to 0, the *dcg/dcgmrhs* routine requests a user-defined stopping test by setting the output parameter *RCI\_request*=2. If the value is 0, the routine does not perform the user defined stopping test. The default value is 1.

---

**NOTE**

At least one of the parameters *ipar*[7]-*ipar*[9] must be set to 1.

---

*ipar*[10] if the value is equal to 0, the *dcg/dcgmrhs* routine runs the non-preconditioned version of the corresponding CG method. Otherwise, the routine runs the preconditioned version of the CG method, and by setting the output parameter *RCI\_request*=3, indicates that you must perform the preconditioning step. The default value is 0.

*ipar*[11:127] are reserved and not used in the current RCI CG SRHS and MRHS routines.

---

**NOTE**

For future compatibility, you must declare the array *ipar* with length 128 for a single right-hand side.

---

*ipar*[11:127 + 2\**nrhs*] are reserved for internal use in the current RCI CG SRHS and MRHS routines.

**NOTE**

For future compatibility, you must declare the array *ipar* with length  $128+2*nrhs$  for multiple right-hand sides.

*dpar*

double array, for SRHS of size 128, for MRHS of size  $(128+2*nrhs)$ ; this parameter is used to specify the double precision set of data for the RCI CG computations, specifically:

|                     |                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <i>dpar</i> [0]     | specifies the relative tolerance. The default value is $1.0 \times 10^{-6}$ .                                                        |
| <i>dpar</i> [1]     | specifies the absolute tolerance. The default value is 0.0.                                                                          |
| <i>dpar</i> [2]     | specifies the square norm of the initial residual (if it is computed in the <i>dcg/dcgmrhs</i> routine). The initial value is 0.0.   |
| <i>dpar</i> [3]     | service variable equal to $dpar[0]*dpar[2]+dpar[1]$ (if it is computed in the <i>dcg/dcgmrhs</i> routine). The initial value is 0.0. |
| <i>dpar</i> [4]     | specifies the square norm of the current residual. The initial value is 0.0.                                                         |
| <i>dpar</i> [5]     | specifies the square norm of residual from the previous iteration step (if available). The initial value is 0.0.                     |
| <i>dpar</i> [6]     | contains the <i>alpha</i> parameter of the CG method. The initial value is 0.0.                                                      |
| <i>dpar</i> [7]     | contains the <i>beta</i> parameter of the CG method, it is equal to $dpar[4]/dpar[5]$ The initial value is 0.0.                      |
| <i>dpar</i> [8:127] | are reserved and not used in the current RCI CG SRHS and MRHS routines.                                                              |

**NOTE**

For future compatibility, you must declare the array *dpar* with length 128 for a single right-hand side.

*dpar*(9:128+2\*nrhs) are reserved for internal use in the current RCI CG  
 ) [8:127 + 2\*nrhs] SRHS and MRHS routines.

---

**NOTE**

For future compatibility, you must declare the array *dpar* with length  $128+2*nrhs$  for multiple right-hand sides.

---

*tmp*

double array of size  $(n*4)$  for SRHS, and  $(n*(3+nrhs))$  for MRHS. This parameter is used to supply the double precision temporary space for the RCI CG computations, specifically:

- tmp*[0:*n* - 1] specifies the current search direction. The initial value is 0.0.
- tmp*[*n*:2\**n* - 1] contains the matrix multiplied by the current search direction. The initial value is 0.0.
- tmp*[2\**n*:3\**n* - 1] contains the current residual. The initial value is 0.0.
- tmp*[3\**n*:4\**n* - 1] contains the inverse of the preconditioner applied to the current residual for the SRHS version of CG. There is no initial value for this parameter.
- tmp*[4\**n*: (4 + *nrhs*) \* *n* - 1] contains the inverse of the preconditioner applied to the current residual for the MRHS version of CG. There is no initial value for this parameter.

---

**NOTE**

You can define this array in the code using RCI CG SRHS as `double tmp[3*n]` if you run only non-preconditioned CG iterations.

---

## FGMRES Interface Description

### Routine Options

All of the RCI FGMRES routines have common parameters for passing various options to the routines (see [FGMRES Common Parameters](#)). The values for these parameters can be changed during computations.

### User Data Arrays

Many of the RCI FGMRES routines take arrays of user data as input. For example, user arrays are passed to the routine `dfgmres` to compute the solution of a system of linear algebraic equations. To minimize storage requirements and improve overall run-time efficiency, the Intel MKL RCI FGMRES routines do not make copies of the user input arrays.

### FGMRES Common Parameters

---

**NOTE**

The default and initial values listed below are assigned to the parameters by calling the `dfgmres_init` routine.

---

| <i>n</i>               | MKL_INT, this parameter sets the size of the problem in the <code>dfgmres_init</code> routine. All the other routines use the <code>ipar[0]</code> parameter instead. Note that the coefficient matrix <i>A</i> is a square matrix of size $n*n$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                        |                                                                                                                                                                                                                          |                        |                                                                                                                                                                                                                                                                                                               |                        |                                                                                                                                                                                                               |                        |                                                                                                                                                                                                                                                                         |
| <i>x</i>               | double array, this parameter contains the current approximation to the solution vector. Before the first call to the <code>dfgmres</code> routine, it contains the initial approximation to the solution vector.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                        |                                                                                                                                                                                                                          |                        |                                                                                                                                                                                                                                                                                                               |                        |                                                                                                                                                                                                               |                        |                                                                                                                                                                                                                                                                         |
| <i>b</i>               | double array, this parameter contains the right-hand side vector. Depending on user requests (see the parameter <code>ipar[12]</code> ), it might contain the approximate solution after execution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                        |                                                                                                                                                                                                                          |                        |                                                                                                                                                                                                                                                                                                               |                        |                                                                                                                                                                                                               |                        |                                                                                                                                                                                                                                                                         |
| <i>RCI_request</i>     | MKL_INT, this parameter gives information about the result of work of the RCI FGMRES routines. Negative values of the parameter indicate that the routine completed with errors or warnings. The 0 value indicates successful completion of the task. Positive values mean that you must perform specific actions: <table border="0" style="margin-left: 2em;"> <tr> <td style="vertical-align: top;"><i>RCI_request</i>= 1</td> <td>multiply the matrix by <code>tmp[ipar[21] - 1:ipar[21] + n - 2]</code>, put the result in <code>tmp[ipar[22] - 1:ipar[22] + n - 2]</code>, and return the control to the <code>dfgmres</code> routine;</td> </tr> <tr> <td style="vertical-align: top;"><i>RCI_request</i>= 2</td> <td>perform the stopping tests. If they fail, return the control to the <code>dfgres</code> routine. Otherwise, the solution can be updated by a subsequent call to <code>dfgmres_get</code> routine;</td> </tr> <tr> <td style="vertical-align: top;"><i>RCI_request</i>= 3</td> <td>apply the preconditioner to <code>tmp[ipar[21] - 1:ipar[21] + n - 2]</code>, put the result in <code>tmp[ipar[22] - 1:ipar[22] + n - 2]</code>, and return the control to the <code>dfgmres</code> routine.</td> </tr> <tr> <td style="vertical-align: top;"><i>RCI_request</i>= 4</td> <td>check if the norm of the current orthogonal vector is zero, within the rounding or computational errors. Return the control to the <code>dfgmres</code> routine if it is not zero, otherwise complete the solution process by calling <code>dfgmres_get</code> routine.</td> </tr> </table> | <i>RCI_request</i> = 1 | multiply the matrix by <code>tmp[ipar[21] - 1:ipar[21] + n - 2]</code> , put the result in <code>tmp[ipar[22] - 1:ipar[22] + n - 2]</code> , and return the control to the <code>dfgmres</code> routine;                 | <i>RCI_request</i> = 2 | perform the stopping tests. Note |                        |                                                                                                                                                                                                               |                        |                                                                                                                                                                                                                                                                         |
| <i>ipar</i> [0]        | specifies the size of the problem. The <code>dfgmres_init</code> routine assigns <code>ipar[0]=n</code> . All the other routines uses this parameter instead of <i>n</i> . There is no default value for this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                        |                                                                                                                                                                                                                          |                        |                                                                                                                                                                                                                                                                                                               |                        |                                                                                                                                                                                                               |                        |                                                                                                                                                                                                                                                                         |
| <i>ipar</i> [1]        | specifies the type of output for error and warning messages that are generated by the RCI FGMRES routines. The default value 6 means that all messages are displayed on the screen. Otherwise the error and warning messages are written to the newly created file <code>MKL_RCI_FGMRES_Log.txt</code> . Note                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                        |                                                                                                                                                                                                                          |                        |                                                                                                                                                                                                                                                                                                               |                        |                                                                                                                                                                                                               |                        |                                                                                                                                                                                                                                                                         |

that if *ipar*[5] and *ipar*[6] parameters are set to 0, error and warning messages are not generated at all.

*ipar*[2] contains the current stage of the RCI FGMRES computations. The initial value is 1.

---

**WARNING**

Avoid altering this variable during computations.

---

*ipar*[3] contains the current iteration number. The initial value is 0.

*ipar*[4] specifies the maximum number of iterations. The default value is *min* (150,*n*).

*ipar*[5] if the value is not 0, the routines output error messages in accordance with the parameter *ipar*[1]. If it is 0, the routines do not output error messages at all, but return a negative value of the parameter *RCI\_request*. The default value is 1.

*ipar*[6] if the value is not 0, the routines output warning messages in accordance with the parameter *ipar*[1]. Otherwise, the routines do not output warning messages at all, but they return a negative value of the parameter *RCI\_request*. The default value is 1.

*ipar*[7] if the value is not equal to 0, the *dfgmres* routine performs the stopping test for the maximum number of iterations: *ipar*[3] ≤ *ipar*[4]. If the value is 0, the *dfgmres* routine does not perform this stopping test. The default value is 1.

*ipar*[8] if the value is not 0, the *dfgmres* routine performs the residual stopping test: *dpar*[4] ≤ *dpar*[3]. If the value is 0, the *dfgmres* routine does not perform this stopping test. The default value is 0.

*ipar*[9] if the value is not 0, the *dfgmres* routine indicates that the user-defined stopping test should be performed by setting *RCI\_request*=2. If the value is 0, the *dfgmres* routine does not perform the user-defined stopping test. The default value is 1.

---

**NOTE**

At least one of the parameters *ipar*[7]-*ipar*[9] must be set to 1.

---

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ipar</i> [10] | if the value is 0, the <code>dfgmres</code> routine runs the non-preconditioned version of the FGMRES method. Otherwise, the routine runs the preconditioned version of the FGMRES method, and requests that you perform the preconditioning step by setting the output parameter <code>RCI_request=3</code> . The default value is 0.                                                                                          |
| <i>ipar</i> [11] | if the value is not equal to 0, the <code>dfgmres</code> routine performs the automatic test for zero norm of the currently generated vector: $dpar[6] \leq dpar[7]$ , where <code>dpar[7]</code> contains the tolerance value. Otherwise, the routine indicates that you must perform this check by setting the output parameter <code>RCI_request=4</code> . The default value is 0.                                          |
| <i>ipar</i> [12] | if the value is equal to 0, the <code>dfgmres_get</code> routine updates the solution to the vector $x$ according to the computations done by the <code>dfgmres</code> routine. If the value is positive, the routine writes the solution to the right-hand side vector $b$ . If the value is negative, the routine returns only the number of the current iteration, and does not update the solution. The default value is 0. |

**NOTE**

---

It is possible to call the `dfgmres_get` routine at any place in the code, but you must pay special attention to the parameter `ipar[12]`. The RCI FGMRES iterations can be continued after the call to `dfgmres_get` routine only if the parameter `ipar[12]` is not equal to zero. If `ipar[12]` is positive, then the updated solution overwrites the right-hand side in the vector  $b$ . If you want to run the restarted version of FGMRES with the same right-hand side, then it must be saved in a different memory location before the first call to the `dfgmres_get` routine with positive `ipar[12]`.

|  | <i>ipar</i> [14]     | before the restart. The default value is $\min(150, n)$ , which means that by default the non-restarted version of FGMRES method is used.                                                                                                                            |
|  | <i>ipar</i> [15]     | service variable specifying the location of the rotated Hessenberg matrix from which the matrix stored in the packed format (see <a href="#">Matrix Arguments</a> in the Appendix B for details) is started in the <i>tmp</i> array.                                 |
|  | <i>ipar</i> [16]     | service variable specifying the location of the rotation cosines from which the vector of cosines is started in the <i>tmp</i> array.                                                                                                                                |
|  | <i>ipar</i> [17]     | service variable specifying the location of the rotation sines from which the vector of sines is started in the <i>tmp</i> array.                                                                                                                                    |
|  | <i>ipar</i> [18]     | service variable specifying the location of the rotated residual vector from which the vector is started in the <i>tmp</i> array.                                                                                                                                    |
|  | <i>ipar</i> [19]     | service variable, specifies the location of the least squares solution vector from which the vector is started in the <i>tmp</i> array.                                                                                                                              |
|  | <i>ipar</i> [20]     | service variable specifying the location of the set of preconditioned vectors from which the set is started in the <i>tmp</i> array. The memory locations in the <i>tmp</i> array starting from <i>ipar</i> [20] are used only for the preconditioned FGMRES method. |
|  | <i>ipar</i> [21]     | specifies the memory location from which the first vector (source) used in operations requested via <i>RCI_request</i> is started in the <i>tmp</i> array.                                                                                                           |
|  | <i>ipar</i> [22]     | specifies the memory location from which the second vector (output) used in operations requested via <i>RCI_request</i> is started in the <i>tmp</i> array.                                                                                                          |
|  | <i>ipar</i> [23:127] | are reserved and not used in the current RCI FGMRES routines.                                                                                                                                                                                                        |

**NOTE**

You must declare the array *ipar* with length 128. While defining the array in the code as *ipar*[23] works, there is no guarantee of future compatibility with Intel MKL.

*dpar*(128)

double array, this parameter specifies the double precision set of data for the RCI CG computations, specifically:

|                      |                                                                                                                                            |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dpar[0]</code> | specifies the relative tolerance. The default value is 1.0e-6.                                                                             |
| <code>dpar[1]</code> | specifies the absolute tolerance. The default value is 0.0e-0.                                                                             |
| <code>dpar[2]</code> | specifies the Euclidean norm of the initial residual (if it is computed in the <code>dfgmres</code> routine). The initial value is 0.0.    |
| <code>dpar[3]</code> | service variable equal to $dpar[0] * dpar[2] + dpar[1]$ (if it is computed in the <code>dfgmres</code> routine). The initial value is 0.0. |
| <code>dpar[4]</code> | specifies the Euclidean norm of the current residual. The initial value is 0.0.                                                            |
| <code>dpar[5]</code> | specifies the Euclidean norm of residual from the previous iteration step (if available). The initial value is 0.0.                        |
| <code>dpar[6]</code> | contains the norm of the generated vector. The initial value is 0.0.                                                                       |

**NOTE**

In terms of [Saad03] this parameter is the coefficient  $h_{k+1,k}$  of the Hessenberg matrix.

|                          |                                                                                                           |
|--------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>dpar[7]</code>     | contains the tolerance for the zero norm of the currently generated vector. The default value is 1.0e-12. |
| <code>dpar[8:127]</code> | are reserved and not used in the current RCI FGMRES routines.                                             |

**NOTE**

You must declare the array `dpar` with length 128. While defining the array in the code as `double dpar[8]` works, there is no guarantee of future compatibility with Intel MKL.

`tmp`

double array of size  $((2 * ipar[14] + 1) * n + ipar[14] * (ipar[14] + 9) / 2 + 1)$  used to supply the double precision temporary space for the RCI FGMRES computations, specifically:

|                                             |                                                                                                                                                                                      |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tmp[0:ipar[15] - 2]</code>            | contains the sequence of vectors generated by the FGMRES method. The initial value is 0.0.                                                                                           |
| <code>tmp[ipar[15] - 1:ipar[16] - 2]</code> | contains the rotated Hessenberg matrix generated by the FGMRES method; the matrix is stored in the packed format. There is no initial value for this part of <code>tmp</code> array. |

|                                             |                                                                                                                                                                                                                                                                          |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tmp[ipar[16] - 1:ipar[17] - 2]</code> | contains the rotation cosines vector generated by the FGMRES method. There is no initial value for this part of <code>tmp</code> array.                                                                                                                                  |
| <code>tmp[ipar[17] - 1:ipar[18] - 2]</code> | contains the rotation sines vector generated by the FGMRES method. There is no initial value for this part of <code>tmp</code> array.                                                                                                                                    |
| <code>tmp[ipar[18] - 1:ipar[19] - 2]</code> | contains the rotated residual vector generated by the FGMRES method. There is no initial value for this part of <code>tmp</code> array.                                                                                                                                  |
| <code>tmp[ipar[19] - 1:ipar[20] - 2]</code> | contains the solution vector to the least squares problem generated by the FGMRES method. There is no initial value for this part of <code>tmp</code> array.                                                                                                             |
| <code>tmp[ipar[20] - 1:*]</code>            | contains the set of preconditioned vectors generated for the FGMRES method by the user. This part of <code>tmp</code> array is not used if the non-preconditioned version of FGMRES method is called. There is no initial value for this part of <code>tmp</code> array. |

---

#### NOTE

You can define this array in the code as `double tmp[(2*ipar[14] + 1)*n + ipar[14]*(ipar[14] + 9)/2 + 1]` if you run only non-preconditioned FGMRES iterations.

---

## RCI ISS Routines

### dcg\_init

*Initializes the solver.*

---

#### Syntax

```
void dcg_init (const MKL_INT *n , const double *x , const double *b , MKL_INT
*RCI_request , MKL_INT *ipar , double *dpar , double *tmp);
```

#### Include Files

- `mkl.h`

#### Description

The routine `dcg_init` initializes the solver. After initialization, all subsequent invocations of the Intel MKL RCI CG routines use the values of all parameters returned by the routine `dcg_init`. Advanced users can skip this step and set the values in the `ipar` and `dpar` arrays directly.

**CAUTION**

You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dcg_check` routine, but it does not guarantee that the method will work correctly.

**Input Parameters**

|          |                                                                                                                                |
|----------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i> | Sets the size of the problem.                                                                                                  |
| <i>x</i> | Array of size <i>n</i> . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to <i>b</i> . |
| <i>b</i> | Array of size <i>n</i> . Contains the right-hand side vector.                                                                  |

**Output Parameters**

|                    |                                                                             |
|--------------------|-----------------------------------------------------------------------------|
| <i>RCI_request</i> | Gives information about the result of the routine.                          |
| <i>ipar</i>        | Array of size 128. Refer to the <a href="#">CG Common Parameters</a> .      |
| <i>dpar</i>        | Array of size 128. Refer to the <a href="#">CG Common Parameters</a> .      |
| <i>tmp</i>         | Array of size $(n*4)$ . Refer to the <a href="#">CG Common Parameters</a> . |

**Return Values**

|                             |                                             |
|-----------------------------|---------------------------------------------|
| <i>RCI_request</i> = 0      | Indicates that the task completed normally. |
| <i>RCI_request</i> = -10000 | Indicates failure to complete the task.     |

**dcg\_check**

*Checks consistency and correctness of the user defined data.*

**Syntax**

```
void dcg_check (const MKL_INT *n , const double *x , const double *b , MKL_INT
*RCI_request , MKL_INT *ipar , double *dpar , double *tmp);
```

**Include Files**

- `mkl.h`

**Description**

The routine `dcg_check` checks consistency and correctness of the parameters to be passed to the solver routine `dcg`. However this operation does not guarantee that the solver returns the correct result. It only reduces the chance of making a mistake in the parameters of the method. Skip this operation only if you are sure that the correct data is specified in the solver parameters.

The lengths of all vectors must be defined in a previous call to the `dcg_init` routine.

## Input Parameters

|     |                                                                                                                      |
|-----|----------------------------------------------------------------------------------------------------------------------|
| $n$ | Sets the size of the problem.                                                                                        |
| $x$ | Array of size $n$ . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to $b$ . |
| $b$ | Array of size $n$ . Contains the right-hand side vector.                                                             |

## Output Parameters

|                |                                                                             |
|----------------|-----------------------------------------------------------------------------|
| $RCI\_request$ | Gives information about result of the routine.                              |
| $ipar$         | Array of size 128. Refer to the <a href="#">CG Common Parameters</a> .      |
| $dpar$         | Array of size 128. Refer to the <a href="#">CG Common Parameters</a> .      |
| $tmp$          | Array of size $(n*4)$ . Refer to the <a href="#">CG Common Parameters</a> . |

## Return Values

|                        |                                                                                              |
|------------------------|----------------------------------------------------------------------------------------------|
| $RCI\_request = 0$     | Indicates that the task completed normally.                                                  |
| $RCI\_request = -1100$ | Indicates that the task is interrupted and the errors occur.                                 |
| $RCI\_request = -1001$ | Indicates that there are some warning messages.                                              |
| $RCI\_request = -1010$ | Indicates that the routine changed some parameters to make them consistent or correct.       |
| $RCI\_request = -1011$ | Indicates that there are some warning messages and that the routine changed some parameters. |

## dcg

*Computes the approximate solution vector.*

---

### Syntax

```
void dcg (const MKL_INT *n , double *x , const double *b , MKL_INT *RCI_request ,
MKL_INT *ipar , double *dpar , double *tmp);
```

### Include Files

- mkl.h

### Description

The `dcg` routine computes the approximate solution vector using the CG method [Young71]. The routine `dcg` uses the vector in the array  $x$  before the first call as an initial approximation to the solution. The parameter  $RCI\_request$  gives you information about the task completion and requests results of certain operations that are required by the solver.

Note that lengths of all vectors must be defined in a previous call to the `dcg_init` routine.

## Input Parameters

|       |                                                                                |
|-------|--------------------------------------------------------------------------------|
| $n$   | Sets the size of the problem.                                                  |
| $x$   | Array of size $n$ . Contains the initial approximation to the solution vector. |
| $b$   | Array of size $n$ . Contains the right-hand side vector.                       |
| $tmp$ | Array of size $(n*4)$ . Refer to the <a href="#">CG Common Parameters</a> .    |

## Output Parameters

|                |                                                                                |
|----------------|--------------------------------------------------------------------------------|
| $RCI\_request$ | Gives information about result of work of the routine.                         |
| $x$            | Array of size $n$ . Contains the updated approximation to the solution vector. |
| $ipar$         | Array of size 128. Refer to the <a href="#">CG Common Parameters</a> .         |
| $dpar$         | Array of size 128. Refer to the <a href="#">CG Common Parameters</a> .         |
| $tmp$          | Array of size $(n*4)$ . Refer to the <a href="#">CG Common Parameters</a> .    |

## Return Values

|                     |                                                                                                                                                                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $RCI\_request=0$    | Indicates that the task completed normally and the solution is found and stored in the vector $x$ . This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the $RCI\_request= 2$ . |
| $RCI\_request=-1$   | Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if you request both tests.                                             |
| $RCI\_request=-2$   | Indicates that the routine was interrupted because of an attempt to divide by zero. This situation happens if the matrix is non-positive definite or almost non-positive definite.                                                                  |
| $RCI\_request=- 10$ | Indicates that the routine was interrupted because the residual norm is invalid. This usually happens because the value $dpar[5]$ was altered outside of the routine, or the $dcg\_check$ routine was not called.                                   |
| $RCI\_request=-11$  | Indicates that the routine was interrupted because it enters the infinite cycle. This usually happens because the values $ipar[7]$ , $ipar[8]$ , $ipar[9]$ were altered outside of the routine, or the $dcg\_check$ routine was not called.         |
| $RCI\_request= 1$   | Indicates that you must multiply the matrix by $tmp[0:n - 1]$ , put the result in the $tmp[n:2*n - 1]$ , and return control back to the routine $dcg$ .                                                                                             |

`RCI_request= 2`

Indicates that you must perform the stopping tests. If they fail, return control back to the `dcg` routine. Otherwise, the solution is found and stored in the vector  $x$ .

`RCI_request= 3`

Indicates that you must apply the preconditioner to  $[2*n:3*n - 1]$ , put the result in the  $[3*n:4*n - 1]$ , and return control back to the routine `dcg`.

## dcg\_get

*Retrieves the number of the current iteration.*

---

### Syntax

```
void dcg_get (const MKL_INT *n , const double *x , const double *b , const MKL_INT *RCI_request , const MKL_INT *ipar , const double *dpar , const double *tmp , MKL_INT *itercount);
```

### Include Files

- `mkl.h`

### Description

The routine `dcg_get` retrieves the current iteration number of the solutions process.

### Input Parameters

|                          |                                                                             |
|--------------------------|-----------------------------------------------------------------------------|
| <code>n</code>           | Sets the size of the problem.                                               |
| <code>x</code>           | Array of size $n$ . Contains the approximation vector to the solution.      |
| <code>b</code>           | Array of size $n$ . Contains the right-hand side vector.                    |
| <code>RCI_request</code> | This parameter is not used.                                                 |
| <code>ipar</code>        | Array of size 128. Refer to the <a href="#">CG Common Parameters</a> .      |
| <code>dpar</code>        | Array of size 128. Refer to the <a href="#">CG Common Parameters</a> .      |
| <code>tmp</code>         | Array of size $(n*4)$ . Refer to the <a href="#">CG Common Parameters</a> . |

### Output Parameters

|                        |                                       |
|------------------------|---------------------------------------|
| <code>itercount</code> | Returns the current iteration number. |
|------------------------|---------------------------------------|

### Return Values

The routine `dcg_get` has no return values.

## dcgmrhs\_init

*Initializes the RCI CG solver with MHRS.*

---

### Syntax

```
void dcgmrhs_init (const MKL_INT *n , const double *x , const MKL_INT *nrhs , const double *b , const MKL_INT *method , MKL_INT *RCI_request , MKL_INT *ipar , double *dpar , double *tmp);
```

## Include Files

- `mkl.h`

## Description

The routine `dcgmrhs_init` initializes the solver. After initialization all subsequent invocations of the Intel MKL RCI CG with multiple right-hand sides (MRHS) routines use the values of all parameters that are returned by `dcgmrhs_init`. Advanced users may skip this step and set the values to these parameters directly in the appropriate routines.

---

### WARNING

You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dcgmrhs_check` routine, but it does not guarantee that the method will work correctly.

---

## Input Parameters

|                     |                                                                                                                            |
|---------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>n</code>      | Sets the size of the problem.                                                                                              |
| <code>x</code>      | Array of size $n*nrhs$ . Contains the initial approximation to the solution vectors. Normally it is equal to 0 or to $b$ . |
| <code>nrhs</code>   | Sets the number of right-hand sides.                                                                                       |
| <code>b</code>      | Array of size $n*nrhs$ . Contains the right-hand side vectors.                                                             |
| <code>method</code> | Specifies the method of solution:<br>A value of 1 indicates CG with multiple right-hand sides (default value)              |

## Output Parameters

|                          |                                                                                    |
|--------------------------|------------------------------------------------------------------------------------|
| <code>RCI_request</code> | Gives information about the result of the routine.                                 |
| <code>ipar</code>        | Array of size $(128+2*nrhs)$ . Refer to the <a href="#">CG Common Parameters</a> . |
| <code>dpar</code>        | Array of size $(128+2*nrhs)$ . Refer to the <a href="#">CG Common Parameters</a> . |
| <code>tmp</code>         | Array of size $(n*(3+nrhs))$ . Refer to the <a href="#">CG Common Parameters</a> . |

## Return Values

|                                  |                                             |
|----------------------------------|---------------------------------------------|
| <code>RCI_request= 0</code>      | Indicates that the task completed normally. |
| <code>RCI_request= -10000</code> | Indicates failure to complete the task.     |

## `dcgmrhs_check`

*Checks consistency and correctness of the user defined data.*

---

## Syntax

```
void dcgmrhs_check (const MKL_INT *n , const double *x , const MKL_INT *nrhs , const
double *b , MKL_INT *RCI_request , MKL_INT *ipar , double *dpar , double *tmp);
```

## Include Files

- `mkl.h`

## Description

The routine `dcgmrhs_check` checks the consistency and correctness of the parameters to be passed to the solver routine `dcgmrhs`. While this operation reduces the chance of making a mistake in the parameters, it does not guarantee that the solver returns the correct result.

If you are sure that the correct data is *specified* in the solver parameters, you can skip this operation.

The lengths of all vectors must be defined in a previous call to the `dcgmrhs_init` routine.

## Input Parameters

|                   |                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>n</code>    | Sets the size of the problem.                                                                                                         |
| <code>x</code>    | Array of size $n*nrhs$ . Contains the initial approximation to the solution vectors. Normally it is equal to 0 or to <code>b</code> . |
| <code>nrhs</code> | This parameter sets the number of right-hand sides.                                                                                   |
| <code>b</code>    | Array of size $n*nrhs$ . Contains the right-hand side vectors.                                                                        |

## Output Parameters

|                          |                                                                                    |
|--------------------------|------------------------------------------------------------------------------------|
| <code>RCI_request</code> | Returns information about the results of the routine.                              |
| <code>ipar</code>        | Array of size $(128+2*nrhs)$ . Refer to the <a href="#">CG Common Parameters</a> . |
| <code>dpar</code>        | Array of size $(128+2*nrhs)$ . Refer to the <a href="#">CG Common Parameters</a> . |
| <code>tmp</code>         | Array of size $(n*(3+nrhs))$ . Refer to the <a href="#">CG Common Parameters</a> . |

## Return Values

|                                 |                                                                                              |
|---------------------------------|----------------------------------------------------------------------------------------------|
| <code>RCI_request= 0</code>     | Indicates that the task completed normally.                                                  |
| <code>RCI_request= -1100</code> | Indicates that the task is interrupted and the errors occur.                                 |
| <code>RCI_request= -1001</code> | Indicates that there are some warning messages.                                              |
| <code>RCI_request= -1010</code> | Indicates that the routine changed some parameters to make them consistent or correct.       |
| <code>RCI_request= -1011</code> | Indicates that there are some warning messages and that the routine changed some parameters. |

## dcgmrhs

*Computes the approximate solution vectors.*

---

## Syntax

```
void dcgmrhs (const MKL_INT *n , double *x , const MKL_INT *nrhs , const double *b ,
MKL_INT *RCI_request , MKL_INT *ipar , double *dpar , double *tmp);
```

## Include Files

- `mkl.h`

## Description

The routine `dcgmrhs` computes approximate solution vectors using the CG with multiple right-hand sides (MRHS) method [Young71]. The routine `dcgmrhs` uses the value that was in the  $x$  before the first call as an initial approximation to the solution. The parameter `RCI_request` gives information about task completion status and requests results of certain operations that are required by the solver.

Note that lengths of all vectors are assumed to have been defined in a previous call to the `dcgmrhs_init` routine.

## Input Parameters

|        |                                                                                      |
|--------|--------------------------------------------------------------------------------------|
| $n$    | Sets the size of the problem, and the sizes of arrays $x$ and $b$ .                  |
| $x$    | Array of size $n*nrhs$ . Contains the initial approximation to the solution vectors. |
| $nrhs$ | Sets the number of right-hand sides.                                                 |
| $b$    | Array of size $n*nrhs$ . Contains the right-hand side vectors.                       |
| $tmp$  | Array of size $(n, 3+nrhs)$ . Refer to the <a href="#">CG Common Parameters</a> .    |

## Output Parameters

|                          |                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------|
| <code>RCI_request</code> | Gives information about result of work of the routine.                                 |
| $x$                      | Array of size $(n*nrhs)$ . Contains the updated approximation to the solution vectors. |
| $ipar$                   | Array of size $(128+2*nrhs)$ . Refer to the <a href="#">CG Common Parameters</a> .     |
| $dpar$                   | Array of size $(128+2*nrhs)$ . Refer to the <a href="#">CG Common Parameters</a> .     |
| $tmp$                    | Array of size $(n*(3+nrhs))$ . Refer to the <a href="#">CG Common Parameters</a> .     |

## Return Values

|                             |                                                                                                                                                                                                                                                               |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>RCI_request=0</code>  | Indicates that the task completed normally and the solution is found and stored in the vector $x$ . This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the <code>RCI_request= 2</code> . |
| <code>RCI_request=-1</code> | Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if both tests are requested by the user.                                         |
| <code>RCI_request=-2</code> | The routine was interrupted because of an attempt to divide by zero. This situation happens if the matrix is non-positive definite or almost non-positive definite.                                                                                           |

|                               |                                                                                                                                                                                                                                                                                        |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>RCI_request=- 10</code> | Indicates that the routine was interrupted because the residual norm is invalid. This usually happens because the value <code>dpar[5]</code> was altered outside of the routine, or the <code>dcg_check</code> routine was not called.                                                 |
| <code>RCI_request=-11</code>  | Indicates that the routine was interrupted because it enters the infinite cycle. This usually happens because the values <code>ipar[7]</code> , <code>ipar[8]</code> , <code>ipar[9]</code> were altered outside of the routine, or the <code>dcg_check</code> routine was not called. |
| <code>RCI_request= 1</code>   | Indicates that you must multiply the matrix by <code>tmp[0:n - 1]</code> , put the result in the <code>tmp[n:2*n - 1]</code> , and return control back to the routine <code>dcg</code> .                                                                                               |
| <code>RCI_request= 2</code>   | Indicates that you must perform the stopping tests. If they fail, return control back to the <code>dcg</code> routine. Otherwise, the solution is found and stored in the vector <code>x</code> .                                                                                      |
| <code>RCI_request= 3</code>   | Indicates that you must apply the preconditioner to <code>tmp[2*n:3*n - 1]</code> , put the result in the <code>tmp[3*n:4*n - 1]</code> , and return control back to the routine <code>dcg</code> .                                                                                    |

## dcgmrhs\_get

Retrieves the number of the current iteration.

### Syntax

```
void dcgmrhs_get (const MKL_INT *n , const double *x , const MKL_INT *nrhs , const double *b , const MKL_INT *RCI_request , const MKL_INT *ipar , const double *dpar , const double *tmp , MKL_INT *itercount);
```

### Include Files

- `mkl.h`

### Description

The routine `dcgmrhs_get` retrieves the current iteration number of the solving process.

### Input Parameters

|                          |                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------|
| <code>n</code>           | Sets the size of the problem.                                                          |
| <code>x</code>           | Array of size $n * nrhs$ . Contains the initial approximation to the solution vectors. |
| <code>nrhs</code>        | Sets the number of right-hand sides.                                                   |
| <code>b</code>           | Array of size $n * nrhs$ . Contains the right-hand side .                              |
| <code>RCI_request</code> | This parameter is not used.                                                            |
| <code>ipar</code>        | Array of size $(128 + 2 * nrhs)$ . Refer to the <a href="#">CG Common Parameters</a> . |
| <code>dpar</code>        | Array of size $(128 + 2 * nrhs)$ . Refer to the <a href="#">CG Common Parameters</a> . |

*tmp* Array of size  $(n * (3 + nrhs))$ . Refer to the [CG Common Parameters](#).

## Output Parameters

*itercount* Array of size *nrhs*. Returns the current iteration number for each right-hand side.

## Return Values

The routine `dcgmrhs_get` has no return values.

## dfgmres\_init

*Initializes the solver.*

---

### Syntax

```
void dfgmres_init (const MKL_INT *n , const double *x , const double *b , MKL_INT
*RCI_request , MKL_INT *ipar , double *dpar , double *tmp);
```

### Include Files

- `mkl.h`

### Description

The routine `dfgmres_init` initializes the solver. After initialization all subsequent invocations of Intel MKL RCI FGMRES routines use the values of all parameters that are returned by `dfgmres_init`. Advanced users can skip this step and set the values in the *ipar* and *dpar* arrays directly.

---

#### WARNING

You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dfgmres_check` routine, but it does not guarantee that the method will work correctly.

---

## Input Parameters

*n* Sets the size of the problem.

*x* Array of size *n*. Contains the initial approximation to the solution vector. Normally it is equal to 0 or to *b*.

*b* Array of size *n*. Contains the right-hand side vector.

## Output Parameters

*RCI\_request* Gives information about the result of the routine.

*ipar* Array of size 128. Refer to the [FGMRES Common Parameters](#).

*dpar* Array of size 128. Refer to the [FGMRES Common Parameters](#).

*tmp* Array of size  $((2 * ipar[14] + 1) * n + ipar[14] * (ipar[14] + 9) / 2 + 1)$ . Refer to the [FGMRES Common Parameters](#).

## Return Values

|                                  |                                             |
|----------------------------------|---------------------------------------------|
| <code>RCI_request= 0</code>      | Indicates that the task completed normally. |
| <code>RCI_request= -10000</code> | Indicates failure to complete the task.     |

## dfgmres\_check

Checks consistency and correctness of the user defined data.

---

## Syntax

```
void dfgmres_check (const MKL_INT *n, const double *x, const double *b, MKL_INT *RCI_request, MKL_INT *ipar, double *dpar, double *tmp);
```

## Include Files

- mkl.h

## Description

The routine `dfgmres_check` checks consistency and correctness of the parameters to be passed to the solver routine `dfgmres`. However, this operation does not guarantee that the method gives the correct result. It only reduces the chance of making a mistake in the parameters of the routine. Skip this operation only if you are sure that the correct data is specified in the solver parameters.

The lengths of all vectors are assumed to have been defined in a previous call to the `dfgmres_init` routine.

## Input Parameters

|                |                                                                                                                                            |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>n</code> | Sets the size of the problem.                                                                                                              |
| <code>x</code> | Array of size <code>n</code> . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to <code>b</code> . |
| <code>b</code> | Array of size <code>n</code> . Contains the right-hand side vector.                                                                        |

## Output Parameters

|                          |                                                                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>RCI_request</code> | Gives information about result of the routine.                                                                                         |
| <code>ipar</code>        | Array of size 128. Refer to the <a href="#">FGMRES Common Parameters</a> .                                                             |
| <code>dpar</code>        | Array of size 128. Refer to the <a href="#">FGMRES Common Parameters</a> .                                                             |
| <code>tmp</code>         | Array of size $((2 * ipar[14] + 1) * n + ipar[14] * (ipar[14] + 9) / 2 + 1)$ . Refer to the <a href="#">FGMRES Common Parameters</a> . |

## Return Values

|                                 |                                                              |
|---------------------------------|--------------------------------------------------------------|
| <code>RCI_request= 0</code>     | Indicates that the task completed normally.                  |
| <code>RCI_request= -1100</code> | Indicates that the task is interrupted and the errors occur. |
| <code>RCI_request= -1001</code> | Indicates that there are some warning messages.              |

|                                 |                                                                                              |
|---------------------------------|----------------------------------------------------------------------------------------------|
| <code>RCI_request= -1010</code> | Indicates that the routine changed some parameters to make them consistent or correct.       |
| <code>RCI_request= -1011</code> | Indicates that there are some warning messages and that the routine changed some parameters. |

## dfgmres

*Makes the FGMRES iterations.*

---

### Syntax

```
void dfgmres (const MKL_INT *n, double *x, double *b, MKL_INT *RCI_request, MKL_INT
*ipar, double *dpar, double *tmp);
```

### Include Files

- `mkl.h`

### Description

The routine `dfgmres` performs the FGMRES iterations [Saad03], using the value that was in the array  $x$  before the first call as an initial approximation of the solution vector. To update the current approximation to the solution, the `dfgmres_get` routine must be called. The RCI FGMRES iterations can be continued after the call to the `dfgmres_get` routine only if the value of the parameter `ipar[12]` is not equal to 0 (default value). Note that the updated solution overwrites the right-hand side in the vector  $b$  if the parameter `ipar[12]` is positive, and the restarted version of the FGMRES method can not be run. If you want to keep the right-hand side, you must save it in a different memory location before the first call to the `dfgmres_get` routine with a positive `ipar[12]`.

The parameter `RCI_request` gives information about the task completion and requests results of certain operations that the solver requires.

The lengths of all the vectors must be defined in a previous call to the `dfgmres_init` routine.

### Input Parameters

|                  |                                                                                |
|------------------|--------------------------------------------------------------------------------|
| <code>n</code>   | Sets the size of the problem.                                                  |
| <code>x</code>   | Array of size $n$ . Contains the initial approximation to the solution vector. |
| <code>b</code>   | Array of size $n$ . Contains the right-hand side vector.                       |
| <code>tmp</code> | Array of size [12]. Refer to the <a href="#">FGMRES Common Parameters</a> .    |

### Output Parameters

|                          |                                                                                                                                      |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <code>RCI_request</code> | Informs about result of work of the routine.                                                                                         |
| <code>ipar</code>        | Array of size 128. Refer to the <a href="#">FGMRES Common Parameters</a> .                                                           |
| <code>dpar</code>        | Array of size 128. Refer to the <a href="#">FGMRES Common Parameters</a> .                                                           |
| <code>tmp</code>         | Array of size $((2 * ipar(15) + 1) * n + ipar(15) * ipar(15) + 9) / 2 + 1$ . Refer to the <a href="#">FGMRES Common Parameters</a> . |

## Return Values

|                               |                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>RCI_request=0</code>    | Indicates that the task completed normally and the solution is found and stored in the vector $x$ . This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the <code>RCI_request= 2</code> or <code>4</code> .                                                             |
| <code>RCI_request=-1</code>   | Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if you request both tests.                                                                                                                                     |
| <code>RCI_request= -10</code> | Indicates that the routine was interrupted because of an attempt to divide by zero. Usually this happens if the matrix is degenerate or almost degenerate. However, it may happen if the parameter <code>dpar</code> is altered, or if the method is not stopped when the solution is found.                                                |
| <code>RCI_request= -11</code> | Indicates that the routine was interrupted because it entered an infinite cycle. Usually this happens because the values <code>ipar[7]</code> , <code>ipar[8]</code> , <code>ipar[9]</code> were altered outside of the routine, or the <code>dfgmres_check</code> routine was not called.                                                  |
| <code>RCI_request= -12</code> | Indicates that the routine was interrupted because errors were found in the method parameters. Usually this happens if the parameters <code>ipar</code> and <code>dpar</code> were altered by mistake outside the routine.                                                                                                                  |
| <code>RCI_request= 1</code>   | Indicates that you must multiply the matrix by <code>tmp[ipar[21] - 1:ipar[21] + n - 2]</code> , put the result in the <code>tmp[ipar[22] - 1:ipar[22] + n - 2]</code> , and return control back to the routine <code>dfgmres</code> .                                                                                                      |
| <code>RCI_request= 2</code>   | Indicates that you must perform the stopping tests. If they fail, return control to the <code>dfgmres</code> routine. Otherwise, the FGMRES solution is found, and you can run the <code>fgmres_get</code> routine to update the computed solution in the vector $x$ .                                                                      |
| <code>RCI_request= 3</code>   | Indicates that you must apply the inverse preconditioner to <code>tmp[ipar[21] - 1:ipar[21] + n - 2]</code> , put the result in the <code>tmp[ipar[22] - 1:ipar[22] + n - 2]</code> , and return control back to the routine <code>dfgmres</code> .                                                                                         |
| <code>RCI_request= 4</code>   | Indicates that you must check the norm of the currently generated vector. If it is not zero within the computational/rounding errors, return control to the <code>dfgmres</code> routine. Otherwise, the FGMRES solution is found, and you can run the <code>dfgmres_get</code> routine to update the computed solution in the vector $x$ . |

## dfgmres\_get

Retrieves the number of the current iteration and updates the solution.

---

### Syntax

```
void dfgmres_get (const MKL_INT *n, double *x, double *b, MKL_INT *RCI_request, const
MKL_INT *ipar, const double *dpar, double *tmp, MKL_INT *itercount);
```

### Include Files

- mkl.h

### Description

The routine `dfgmres_get` retrieves the current iteration number of the solution process and updates the solution according to the computations performed by the `dfgmres` routine. To retrieve the current iteration number only, set the parameter `ipar[12] = -1` beforehand. Normally, you should do this before proceeding further with the computations. If the intermediate solution is needed, the method parameters must be set properly. For details see [FGMRES Common Parameters](#) and the Iterative Sparse Solver code examples in the Intel MKL installation directory:

- `examples/solverc/source`

### Input Parameters

|             |                                                                                                                                      |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>    | Sets the size of the problem.                                                                                                        |
| <i>ipar</i> | Array of size 128. Refer to the <a href="#">FGMRES Common Parameters</a> .                                                           |
| <i>dpar</i> | Array of size 128. Refer to the <a href="#">FGMRES Common Parameters</a> .                                                           |
| <i>tmp</i>  | Array of size $((2 * ipar[14] + 1) * n + ipar[14] * ipar[14] + 9) / 2 + 1$ . Refer to the <a href="#">FGMRES Common Parameters</a> . |

### Output Parameters

|                    |                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>x</i>           | Array of size <i>n</i> . If <code>ipar[12] = 0</code> , it contains the updated approximation to the solution according to the computations done in <code>dfgmres</code> routine. Otherwise, it is not changed.    |
| <i>b</i>           | Array of size <i>n</i> . If <code>ipar(13) &gt; 0</code> , it contains the updated approximation to the solution according to the computations done in <code>dfgmres</code> routine. Otherwise, it is not changed. |
| <i>RCI_request</i> | Gives information about result of the routine.                                                                                                                                                                     |
| <i>itercount</i>   | Contains the value of the current iteration number.                                                                                                                                                                |

### Return Values

`RCI_request = 0` Indicates that the task completed normally.

`RCI_request= -12`

Indicates that the routine was interrupted because errors were found in the routine parameters. Usually this happens if the parameters `ipar` and `dpar` were altered by mistake outside of the routine.

`RCI_request= -10000`

Indicates that the routine failed to complete the task.

## RCI ISS Implementation Details

Several aspects of the Intel MKL RCI ISS interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, include one of the Intel MKL RCI ISS language-specific header files.

---

### NOTE

Intel MKL does not support the RCI ISS interface unless you include the language-specific header file.

---

## Preconditioners based on Incomplete LU Factorization Technique

---

Preconditioners, or accelerators are used to accelerate an iterative solution process. In some cases, their use can reduce the number of iterations dramatically and thus lead to better solver performance. Although the terms *preconditioner* and *accelerator* are synonyms, hereafter only *preconditioner* is used.

Intel MKL provides two preconditioners, ILU0 and ILUT, for sparse matrices presented in the format accepted in the Intel MKL direct sparse solvers (three-array variation of the CSR storage format described in [Sparse Matrix Storage Format](#) ). The algorithms used are described in [[Saad03](#)].

The ILU0 preconditioner is based on a well-known factorization of the original matrix into a product of two triangular matrices: lower and upper triangular matrices. Usually, such decomposition leads to some fill-in in the resulting matrix structure in comparison with the original matrix. The distinctive feature of the ILU0 preconditioner is that it preserves the structure of the original matrix in the result.

Unlike the ILU0 preconditioner, the ILUT preconditioner preserves some resulting fill-in in the preconditioner matrix structure. The distinctive feature of the ILUT algorithm is that it calculates each element of the preconditioner and saves each one if it satisfies two conditions simultaneously: its value is greater than the product of the given tolerance and matrix row norm, and its value is in the given bandwidth of the resulting preconditioner matrix.

Both ILU0 and ILUT preconditioners can apply to any non-degenerate matrix. They can be used alone or together with the Intel MKL RCI FGMRES solver (see [Sparse Solver Routines](#)). Avoid using these preconditioners with MKL RCI CG solver because in general, they produce a non-symmetric resulting matrix even if the original matrix is symmetric. Usually, an inverse of the preconditioner is required in this case. To do this the Intel MKL triangular solver routine `mkl_dcsrtrsv` must be applied twice: for the lower triangular part of the preconditioner, and then for its upper triangular part.

---

### NOTE

Although ILU0 and ILUT preconditioners apply to any non-degenerate matrix, in some cases the algorithm may fail to ensure successful termination and the required result. Whether or not the preconditioner produces an acceptable result can only be determined in practice.

A preconditioner may increase the number of iterations for an arbitrary case of the system and the initial solution, and even ruin the convergence. It is your responsibility as a user to choose a suitable preconditioner.

---

## General Scheme of Using ILUT and RCI FGMRES Routines

The general scheme for use is the same for both preconditioners. Some differences exist in the calling parameters of the preconditioners and in the subsequent call of two triangular solvers. You can see all these differences in the preconditioner code examples (`dcsrilu*.*`) in the `examples` folder of the Intel MKL installation directory:

- `examples/solverc/source`

## ILU0 and ILUT Preconditioners Interface Description

The concepts required to understand the use of the Intel MKL preconditioner routines are discussed in the [Appendix A Linear Solvers Basics](#).

### User Data Arrays

The preconditioner routines take arrays of user data as input. To minimize storage requirements and improve overall run-time efficiency, the Intel MKL preconditioner routines do not make copies of the user input arrays.

### Common Parameters

Some parameters of the preconditioners are common with the [FGMRES Common Parameters](#). The routine `dfgmres_init` specifies their default and initial values. However, some parameters can be redefined with other values. These parameters are listed below.

#### For the ILU0 preconditioner:

`ipar[1]` - specifies the destination of error messages generated by the ILU0 routine. The default value 6 means that all error messages are displayed on the screen. Otherwise routine creates a log file called `MKL_PREC_log.txt` and writes error messages to it. Note if the parameter `ipar[5]` is set to 0, then error messages are not generated at all.

`ipar[5]` - specifies whether error messages are generated. If its value is not equal to 0, the ILU0 routine returns error messages as specified by the parameter `ipar[1]`. Otherwise, the routine does not generate error messages at all, but returns a negative value for the parameter `ierr`. The default value is 1.

#### For the ILUT preconditioner:

`ipar[1]` - specifies the destination of error messages generated by the ILUT routine. The default value 6 means that all messages are displayed on the screen. Otherwise routine creates a log file called `MKL_PREC_log.txt` and writes error messages to it. Note if the parameter `ipar[5]` is set to 0, then error messages are not generated at all.

`ipar[5]` - specifies whether error messages are generated. If its value is not equal to 0, the ILUT routine returns error messages as specified by the parameter `ipar[1]`. Otherwise, the routine does not generate error messages at all, but returns a negative value for the parameter `ierr`. The default value is 1.

`ipar[6]` - if its value is greater than 0, the ILUT routine generates warning messages as specified by the parameter `ipar[1]` and continues calculations. If its value is equal to 0, the routine returns a positive value of the parameter `ierr`. If its value is less than 0, the routine generates a warning message as specified by the parameter `ipar[1]` and returns a positive value of the parameter `ierr`. The default value is 1.

## dcsrilu0

*ILU0 preconditioner based on incomplete LU factorization of a sparse matrix.*

---

### Syntax

```
void dcsrilu0 (const MKL_INT *n , const double *a , const MKL_INT *ia , const MKL_INT *ja , double *bilu0 , const MKL_INT *ipar , const double *dpar , MKL_INT *ierr);
```

## Include Files

- `mkl.h`

## Description

The routine `dcsrilu0` computes a preconditioner  $B$  [Saad03] of a given sparse matrix  $A$  stored in the format accepted in the direct sparse solvers:

$A \sim B = L * U$ , where  $L$  is a lower triangular matrix with a unit diagonal,  $U$  is an upper triangular matrix with a non-unit diagonal, and the portrait of the original matrix  $A$  is used to store the incomplete factors  $L$  and  $U$ .

---

### CAUTION

This routine supports only one-based indexing of the array parameters.

---

## Input Parameters

|           |                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>  | Size (number of rows or columns) of the original square $n$ -by- $n$ matrix $A$ .                                                                                                                                                                                                                                                                                                                                   |
| <i>a</i>  | Array containing the set of elements of the matrix $A$ . Its length is equal to the number of non-zero elements in the matrix $A$ . Refer to the <i>values</i> array description in the <a href="#">Sparse Matrix Storage Format</a> for more details.                                                                                                                                                              |
| <i>ia</i> | Array of size $(n+1)$ containing begin indices of rows of the matrix $A$ such that $ia[i]$ is the index in the array <i>a</i> of the first non-zero element from the row $i$ . The value of the last element $ia[n]$ is equal to the number of non-zero elements in the matrix $A$ , plus one. Refer to the <i>rowIndex</i> array description in the <a href="#">Sparse Matrix Storage Format</a> for more details. |
| <i>ja</i> | Array containing the column indices for each non-zero element of the matrix $A$ . It is important that the indices are in increasing order per row. The matrix size is equal to the size of the array <i>a</i> . Refer to the <i>columns</i> array description in the <a href="#">Sparse Matrix Storage Format</a> for more details.                                                                                |

---

### CAUTION

If column indices are not stored in ascending order for each row of matrix, the result of the routine might not be correct.

---

*ipar* Array of size 128. This parameter specifies the integer set of data for both the ILU0 and RCI FGMRES computations. Refer to the *ipar* array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries that are specific to ILU0 are listed below.

|                  |                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ipar</i> [30] | specifies how the routine operates when a zero diagonal element occurs during calculation. If this parameter is set to 0 (the default value set by the routine <code>dfgmres_init</code> ), then the calculations are stopped and the routine returns a non-zero error value. Otherwise, the diagonal element is set to the value of <i>dpar</i> [31] and the calculations continue. |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**NOTE**

You can declare the *ipar* array with a size of 32. However, for future compatibility you must declare the array *ipar* with length 128.

*dpar*

Array of size 128. This parameter specifies the double precision set of data for both the ILU0 and RCI FGMRES computations. Refer to the *dpar* array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries specific to ILU0 are listed below.

*dpar*[30] specifies a small value, which is compared with the computed diagonal elements. When *ipar*[30] is not 0, then diagonal elements less than *dpar*[30] are set to *dpar*[31]. The default value is 1.0e-16.

**NOTE**

This parameter can be set to the negative value, because the calculation uses its absolute value.

If this parameter is set to 0, the comparison with the diagonal element is not performed.

*dpar*[31] specifies the value that is assigned to the diagonal element if its value is less than *dpar*[30] (see above). The default value is 1.0e-10.

**NOTE**

You can declare the *dpar* array with a size of 32. However, for future compatibility you must declare the array *dpar* with length 128.

**Output Parameters***bilu0*

Array *B* containing non-zero elements of the resulting preconditioning matrix *B*, stored in the format accepted in direct sparse solvers. Its size is equal to the number of non-zero elements in the matrix *A*. Refer to the *values* array description in the [Sparse Matrix Storage Format](#) section for more details.

*ierr*

Error flag, gives information about the routine completion.

**NOTE**

To present the resulting preconditioning matrix in the CSR3 format the arrays *ia* (row indices) and *ja* (column indices) of the input matrix must be used.

**Return Values***ierr=0*

Indicates that the task completed normally.

|                        |                                                                                                                                                                                                  |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ierr=-101</code> | Indicates that the routine was interrupted and that error occurred: at least one diagonal element is omitted from the matrix in CSR3 format (see <a href="#">Sparse Matrix Storage Format</a> ). |
| <code>ierr=-102</code> | Indicates that the routine was interrupted because the matrix contains a diagonal element with the value of zero.                                                                                |
| <code>ierr=-103</code> | Indicates that the routine was interrupted because the matrix contains a diagonal element which is so small that it could cause an overflow, or that it would cause a bad approximation to ILU0. |
| <code>ierr=-104</code> | Indicates that the routine was interrupted because the memory is insufficient for the internal work array.                                                                                       |
| <code>ierr=-105</code> | Indicates that the routine was interrupted because the input matrix size $n$ is less than or equal to 0.                                                                                         |
| <code>ierr=-106</code> | Indicates that the routine was interrupted because the column indices $ja$ are not in the ascending order.                                                                                       |

## dcsrilut

*ILUT preconditioner based on the incomplete LU factorization with a threshold of a sparse matrix.*

---

### Syntax

```
void dcsrilit (const MKL_INT *n, const double *a, const MKL_INT *ia, const MKL_INT *ja,
double *bilut, MKL_INT *ibilut, MKL_INT *jbilut, const double *tol, const MKL_INT
*maxfil, const MKL_INT *ipar, const double *dpar, MKL_INT *ierr);
```

### Include Files

- `mkl.h`

### Description

The routine `dcscrilit` computes a preconditioner  $B$  [Saad03] of a given sparse matrix  $A$  stored in the format accepted in the direct sparse solvers:

$A \sim B = L * U$ , where  $L$  is a lower triangular matrix with unit diagonal and  $U$  is an upper triangular matrix with non-unit diagonal.

The following threshold criteria are used to generate the incomplete factors  $L$  and  $U$ :

- 1) the resulting entry must be greater than the matrix current row norm multiplied by the parameter `tol`, and
- 2) the number of the non-zero elements in each row of the resulting  $L$  and  $U$  factors must not be greater than the value of the parameter `maxfil`.

---

### CAUTION

This routine supports only one-based indexing of the array parameters.

---

## Input Parameters

|           |                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>n</i>  | Size (number of rows or columns) of the original square $n$ -by- $n$ matrix $A$ .                                                                                                                                                                                                                                                                                                   |
| <i>a</i>  | Array containing all non-zero elements of the matrix $A$ . The length of the array is equal to their number. Refer to <i>values</i> array description in the <a href="#">Sparse Matrix Storage Format</a> section for more details.                                                                                                                                                 |
| <i>ia</i> | Array of size $(n+1)$ containing indices of non-zero elements in the array $a$ . $ia[i]$ is the index of the first non-zero element from the row $i$ . The value of the last element $ia[n]$ is equal to the number of non-zeros in the matrix $A$ , plus one. Refer to the <i>rowIndex</i> array description in the <a href="#">Sparse Matrix Storage Format</a> for more details. |
| <i>ja</i> | Array of size equal to the size of the array $a$ . This array contains the column numbers for each non-zero element of the matrix $A$ . It is important that the indices are in increasing order per row. Refer to the <i>columns</i> array description in the <a href="#">Sparse Matrix Storage Format</a> for more details.                                                       |

---

### CAUTION

If column indices are not stored in ascending order for each row of matrix, the result of the routine might not be correct.

---

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>tol</i>       | Tolerance for threshold criterion for the resulting entries of the preconditioner.                                                                                                                                                                                                                                                                                                                                                               |
| <i>maxfil</i>    | Maximum fill-in, which is half of the preconditioner bandwidth. The number of non-zero elements in the rows of the preconditioner cannot exceed $(2*maxfil+1)$ .                                                                                                                                                                                                                                                                                 |
| <i>ipar</i>      | Array of size 128. This parameter is used to specify the integer set of data for both the ILUT and RCI FGMRES computations. Refer to the <i>ipar</i> array description in the <a href="#">FGMRES Common Parameters</a> for more details on FGMRES parameter entries. The entries specific to ILUT are listed below.                                                                                                                              |
| <i>ipar</i> [30] | specifies how the routine operates if the value of the computed diagonal element is less than the current matrix row norm multiplied by the value of the parameter <i>tol</i> . If <i>ipar</i> [30] = 0, then the calculation is stopped and the routine returns non-zero error value. Otherwise, the value of the diagonal element is set to a value determined by <i>dpar</i> [30] (see its description below), and the calculations continue. |

---

### NOTE

There is no default value for *ipar*[30] even if the preconditioner is used within the RCI ISS context. Always set the value of this entry.

---

**NOTE**

You must declare the array *ipar* with length 128. While defining the array in the code as *ipar*[30] works, there is no guarantee of future compatibility with Intel MKL.

---

*dpar*

Array of size 128. This parameter specifies the double precision set of data for both ILUT and RCI FGMRES computations. Refer to the *dpar* array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries that are specific to ILUT are listed below.

*dpar*[30]

used to adjust the value of small diagonal elements. Diagonal elements with a value less than the current matrix row norm multiplied by *tol* are replaced with the value of *dpar*[30] multiplied by the matrix row norm.

**NOTE**

There is no default value for *dpar*[30] entry even if the preconditioner is used within RCI ISS context. Always set the value of this entry.

---

**NOTE**

You must declare the array *dpar* with length 128. While defining the array in the code as *ipar*[30] works, there is no guarantee of future compatibility with Intel MKL.

---

## Output Parameters

*bilut*

Array containing non-zero elements of the resulting preconditioning matrix *B*, stored in the format accepted in the direct sparse solvers. Refer to the *values* array description in the [Sparse Matrix Storage Format](#) for more details. The size of the array is equal to  $(2 * \text{maxfil} + 1) * n - \text{maxfil} * (\text{maxfil} + 1) + 1$ .

**NOTE**

Provide enough memory for this array before calling the routine. Otherwise, the routine may fail to complete successfully with a correct result.

---

*ibilut*

Array of size  $(n+1)$  containing indices of non-zero elements in the array *bilut*. *ibilut*[*i*] is the index of the first non-zero element from the row *i*. The value of the last element *ibilut*[*n*] is equal to the number of non-zeros in the matrix *B*, plus one. Refer to the *rowIndex* array description in the [Sparse Matrix Storage Format](#) for more details.

|               |                                                                                                                                                                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>jbilut</i> | Array, its size is equal to the size of the array <i>bilut</i> . This array contains the column numbers for each non-zero element of the matrix <i>B</i> . Refer to the <i>columns</i> array description in the <a href="#">Sparse Matrix Storage Format</a> for more details. |
| <i>ierr</i>   | Error flag, gives information about the routine completion.                                                                                                                                                                                                                    |

## Return Values

|                   |                                                                                                                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ierr</i> =0    | Indicates that the task completed normally.                                                                                                                                                                                     |
| <i>ierr</i> =-101 | Indicates that the routine was interrupted because of an error: the number of elements in some matrix row specified in the sparse format is equal to or less than 0.                                                            |
| <i>ierr</i> =-102 | Indicates that the routine was interrupted because the value of the computed diagonal element is less than the product of the given tolerance and the current matrix row norm, and it cannot be replaced as <i>ipar</i> [30]=0. |
| <i>ierr</i> =-103 | Indicates that the routine was interrupted because the element <i>ia</i> [ <i>i</i> ] is less than or equal to the element <i>ia</i> [ <i>i</i> - 1] (see <a href="#">Sparse Matrix Storage Format</a> ).                       |
| <i>ierr</i> =-104 | Indicates that the routine was interrupted because the memory is insufficient for the internal work arrays.                                                                                                                     |
| <i>ierr</i> =-105 | Indicates that the routine was interrupted because the input value of <i>maxfil</i> is less than 0.                                                                                                                             |
| <i>ierr</i> =-106 | Indicates that the routine was interrupted because the size <i>n</i> of the input matrix is less than 0.                                                                                                                        |
| <i>ierr</i> =-107 | Indicates that the routine was interrupted because an element of the array <i>ja</i> is less than 1, or greater than <i>n</i> (see <a href="#">Sparse Matrix Storage Format</a> ).                                              |
| <i>ierr</i> =101  | The value of <i>maxfil</i> is greater than or equal to <i>n</i> . The calculation is performed with the value of <i>maxfil</i> set to ( <i>n</i> -1).                                                                           |
| <i>ierr</i> =102  | The value of <i>tol</i> is less than 0. The calculation is performed with the value of the parameter set to (- <i>tol</i> ).                                                                                                    |
| <i>ierr</i> =103  | The absolute value of <i>tol</i> is greater than value of <i>dpar</i> [30]; it can result in instability of the calculation.                                                                                                    |
| <i>ierr</i> =104  | The value of <i>dpar</i> [30] is equal to 0. It can cause calculations to fail.                                                                                                                                                 |

## Sparse Matrix Checker Routines

Intel MKL provides a sparse matrix checker so that you can find errors in the storage of sparse matrices before calling Intel MKL PARDISO, DSS, or Sparse BLAS routines.

## sparse\_matrix\_checker

Checks correctness of sparse matrix.

### Syntax

```
MKL_INT sparse_matrix_checker (sparse_struct* handle);
```

### Include Files

- mkl.h

### Description

The `sparse_matrix_checker` routine checks a user-defined array used to store a sparse matrix in order to detect issues which could cause problems in routines that require sparse input matrices, such as Intel MKL PARDISO, DSS, or Sparse BLAS.

### Input Parameters

*handle* Pointer to the data structure describing the sparse array to check.

### Return Values

The routine returns a value *error*. Additionally, the *check\_result* parameter returns information about where the error occurred, which can be used when *message\_level* is MKL\_NO\_PRINT.

### Sparse Matrix Checker Error Values

| <i>error value</i>                | Meaning                                                                                                                                                              | Location                                                                                                                                                                                                                                  |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MKL_SPARSE_CHECKER_SUCCESS        | The input array successfully passed all checks.                                                                                                                      |                                                                                                                                                                                                                                           |
| MKL_SPARSE_CHECKER_NON_MONOTONIC  | The input array is not 0 or 1 based ( <i>ia</i> [0] is not 0 or 1) or elements of <i>ia</i> are not in non-decreasing order as required.                             | <b>C:</b><br><i>ia</i> [ <i>i</i> ] and <i>ia</i> [ <i>i</i> + 1] are incompatible.<br><i>check_result</i> [0] = <i>i</i><br><i>check_result</i> [1] = <i>ia</i> [ <i>i</i> ]<br><i>check_result</i> [2] = <i>ia</i> [ <i>i</i> + 1]      |
| MKL_SPARSE_CHECKER_OUT_OF_RANGE   | The value of the <i>ja</i> array is lower than the number of the first column or greater than the number of the last column.                                         | <b>C:</b><br><i>ia</i> [ <i>i</i> ] and <i>ia</i> [ <i>i</i> + 1] are incompatible.<br><i>check_result</i> [0] = <i>i</i><br><i>check_result</i> [1] = <i>ia</i> [ <i>i</i> ]<br><i>check_result</i> [2] = <i>ia</i> [ <i>i</i> + 1]      |
| MKL_SPARSE_CHECKER_NON_TRIANGULAR | The <i>matrix_structure</i> parameter is MKL_UPPER_TRIANGULAR and both <i>ia</i> and <i>ja</i> are not upper triangular, or the <i>matrix_structure</i> parameter is | <b>C:</b><br><i>ia</i> [ <i>i</i> ] and <i>ja</i> [ <i>j</i> ] are incompatible.<br><i>check_result</i> [0] = <i>i</i><br><i>check_result</i> [1] = <i>ia</i> [ <i>i</i> ] = <i>j</i><br><i>check_result</i> [2] = <i>ja</i> [ <i>j</i> ] |

| <i>error value</i>                | Meaning                                                                                                | Location                                                                                                                                                                                                                             |
|-----------------------------------|--------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   | MKL_LOWER_TRIANGULAR<br>and both <i>ia</i> and <i>ja</i> are not<br>lower triangular                   |                                                                                                                                                                                                                                      |
| MKL_SPARSE_CHECKER_NON<br>ORDERED | The elements of the <i>ja</i><br>array are not in non-<br>decreasing order in each<br>row as required. | <b>C:</b><br><i>ia</i> [ <i>i</i> ] and <i>ia</i> [ <i>i</i> + 1] are incompatible.<br><i>check_result</i> [0] = <i>j</i><br><i>check_result</i> [1] = <i>ja</i> [ <i>j</i> ]<br><i>check_result</i> [2] = <i>ja</i> [ <i>j</i> + 1] |

**sparse\_matrix\_checker\_init**

*Initializes handle for sparse matrix checker.*

**Syntax**

```
void sparse_matrix_checker_init (sparse_struct* handle);
```

**Include Files**

- mkl.h

**Description**

The `sparse_matrix_checker_init` routine initializes the handle for the `sparse_matrix_checker` routine. The `handle` variable contains this data:

**Description of sparse\_matrix\_checker handle Data**

| Field                        | Type     | Possible Values                                                                                                                | Meaning                                                                                   |

# Extended Eigensolver Routines

The Extended Eigensolver functionality in Intel Math Kernel Library (Intel MKL) is based on the FEAST Eigenvalue Solver 2.0 (<http://www.ecs.umass.edu/~polizzi/feast>) in compliance with a BSD license agreement.

Extended Eigensolver uses the same naming convention as the original FEAST package.

---

## NOTE

Intel MKL only supports the shared memory programming (SMP) version of the eigenvalue solver.

---

- [The FEAST Algorithm](#) gives a brief description of the algorithm underlying the Extended Eigensolver.
- [Extended Eigensolver Functionality](#) describes the problems that can and cannot be solved with the Extended Eigensolver and how to get the best results from the routines.
- [Extended Eigensolver Interfaces](#) gives a reference for calling Extended Eigensolver routines.

## The FEAST Algorithm

---

The Extended Eigensolver functionality is a set of high-performance numerical routines for solving symmetric standard eigenvalue problems,  $Ax=\lambda x$ , or generalized symmetric-definite eigenvalue problems,  $Ax=\lambda Bx$ . It yields all the eigenvalues ( $\lambda$ ) and eigenvectors ( $x$ ) within a given search interval  $[\lambda_{\min}, \lambda_{\max}]$ . It is based on the FEAST algorithm, an innovative fast and stable numerical algorithm presented in [\[Polizzi09\]](#), which fundamentally differs from the traditional Krylov subspace iteration based techniques (Arnoldi and Lanczos algorithms [\[Bai00\]](#)) or other Davidson-Jacobi techniques [\[Sleijpen96\]](#). The FEAST algorithm is inspired by the density-matrix representation and contour integration techniques in quantum mechanics.

The FEAST numerical algorithm obtains eigenpair solutions using a numerically efficient contour integration technique. The main computational tasks in the FEAST algorithm consist of solving a few independent linear systems along the contour and solving a reduced eigenvalue problem. Consider a circle centered in the middle of the search interval  $[\lambda_{\min}, \lambda_{\max}]$ . The numerical integration over the circle in the current version of FEAST is performed using  $N_e$ -point Gauss-Legendre quadrature with  $x_e$  the  $e$ -th Gauss node associated with the weight  $\omega_e$ . For example, for the case  $N_e = 8$ :

$(x_1, \omega_1) = (0.183434642495649, 0.362683783378361),$   
 $(x_2, \omega_2) = (-0.183434642495649, 0.362683783378361),$   
 $(x_3, \omega_3) = (0.525532409916328, 0.313706645877887),$   
 $(x_4, \omega_4) = (-0.525532409916328, 0.313706645877887),$   
 $(x_5, \omega_5) = (0.796666477413626, 0.222381034453374),$   
 $(x_6, \omega_6) = (-0.796666477413626, 0.222381034453374),$   
 $(x_7, \omega_7) = (0.960289856497536, 0.101228536290376),$  and  
 $(x_8, \omega_8) = (-0.960289856497536, 0.101228536290376).$

The figure [FEAST Pseudocode](#) shows the basic pseudocode for the FEAST algorithm for the case of real symmetric (left pane) and complex Hermitian (right pane) generalized eigenvalue problems, using  $N$  for the size of the system and  $M$  for the number of eigenvalues in the search interval (see [\[Polizzi09\]](#)).

---

## NOTE

The pseudocode presents a simplified version of the actual algorithm. Refer to <http://arxiv.org/abs/1302.0432> for an in-depth presentation and mathematical proof of convergence of FEAST.

## Extended Eigensolver Functionality

Use Extended Eigensolver to compute all the eigenvalues and eigenvectors within a given search interval.

The eigenvalue problems covered are as follows:

- standard,  $Ax = \lambda x$ 
  - $A$  complex Hermitian
  - $A$  real symmetric
- generalized,  $Ax = \lambda Bx$ 
  - $A$  complex Hermitian,  $B$  Hermitian positive definite (hpd)
  - $A$  real symmetric and  $B$  real symmetric positive definite (spd)

The Extended Eigensolver functionality offers:

- Real/Complex and Single/Double precisions: double precision is recommended to provide better accuracy of eigenpairs.
- Reverse communication interfaces (RCI) provide maximum flexibility for specific applications. RCI are independent of matrix format and inner system solvers, so you must provide your own linear system solvers (direct or iterative) and matrix-matrix multiply routines.
- Predefined driver interfaces for dense, LAPACK banded, and sparse (CSR) formats are less flexible but are optimized and easy to use:
  - The Extended Eigensolver interfaces for dense matrices are likely to be slower than the comparable LAPACK routines because the FEAST algorithm has a higher computational cost.

- The Extended Eigensolver interfaces for banded matrices support banded LAPACK-type storage.
- The Extended Eigensolver sparse interfaces support compressed sparse row format and use the Intel MKL PARDISO solver.

#### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## Parallelism in Extended Eigensolver Routines

How you achieve parallelism in Extended Eigensolver routines depends on which interface you use. Parallelism (via shared memory programming) is not *explicitly* implemented in Extended Eigensolver routines within one node: the inner linear systems are currently solved one after another.

- Using the Extended Eigensolver RCI interfaces, you can achieve parallelism by providing a threaded inner system solver and a matrix-matrix multiplication routine. When using the RCI interfaces, you are responsible for activating the threaded capabilities of your BLAS and LAPACK libraries most likely using the shell variable `OMP_NUM_THREADS`.
- Using the predefined Extended Eigensolver interfaces, parallelism can be implicitly obtained within the shared memory version of BLAS, LAPACK or Intel MKL PARDISO. The shell variable `MKL_NUM_THREADS` can be used for automatically setting the number of OpenMP threads (cores) for BLAS, LAPACK, and Intel MKL PARDISO.

#### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## Achieving Performance With Extended Eigensolver Routines

In order to use the Extended Eigensolver Routines, you need to provide

- the search interval and the size of the subspace  $M_0$  (overestimation of the number of eigenvalues  $M$  within a given search interval);
- the system matrix in dense, banded, or sparse CSR format if the Extended Eigensolver predefined interfaces are used, or a high-performance complex direct or iterative system solver and matrix-vector multiplication routine if RCI interfaces are used.

In return, you can expect

- fast convergence with very high accuracy when seeking up to 1000 eigenpairs (in two to four iterations using  $M_0 = 1.5M$ , and  $N_e = 8$  or at most using  $N_e = 16$  contour points);
- an extremely robust approach.

The performance of the basic FEAST algorithm depends on a trade-off between the choices of the number of Gauss quadrature points  $N_e$ , the size of the subspace  $M_0$ , and the number of outer refinement loops to reach the desired accuracy. In practice you should use  $M_0 > 1.5 M$ ,  $N_e = 8$ , and at most two refinement loops.

For better performance:

- $M_0$  should be much smaller than the size of the eigenvalue problem, so that the arithmetic complexity depends mainly on the inner system solver ( $O(NM)$  for narrow-banded or sparse systems).
- Parallel scalability performance depends on the shared memory capabilities of the of the inner system solver.
- For very large sparse and challenging systems, application users should make use of the Extended Eigensolver RCI interfaces with customized highly-efficient iterative systems solvers and preconditioners.
- For the Extended Eigensolver interfaces for banded matrices, the parallel performance scalability is limited.

### Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

## Extended Eigensolver Interfaces

### Extended Eigensolver Naming Conventions

There are two different types of interfaces available in the Extended Eigensolver routines:

1. The reverse communication interfaces (RCI):

```
?feast_<matrix type>_rci
```

These interfaces are matrix free format (the interfaces are independent of the matrix data formats). You must provide matrix-vector multiply and direct/iterative linear system solvers for your own explicit or implicit data format.

2. The predefined interfaces:

```
?feast_<matrix type><type of eigenvalue problem>
```

are predefined drivers for `?feast` reverse communication interface that act on commonly used matrix data storage (dense, banded and compressed sparse row representation), using internal matrix-vector routines and selected inner linear system solvers.

For these interfaces:

- ? indicates the data type of matrix  $A$  (and matrix  $B$  if any) defined as follows:

|   |               |
|---|---------------|
| s | float         |
| d | double        |
| c | MKL_Complex8  |
| z | MKL_Complex16 |

- `<matrix type>` defined as follows:

|      | <b>Value of <code>&lt;matrix type&gt;</code></b> | <b>Matrix format</b>              | <b>Inner linear system solver used by Extended Eigensolver</b> |
|------|--------------------------------------------------|-----------------------------------|----------------------------------------------------------------|
| sy   | (symmetric real)                                 |                                   |                                                                |
| he   | (Hermitian complex)                              | Dense                             | LAPACK dense solvers                                           |
| sb   | (symmetric banded real)                          |                                   |                                                                |
| hb   | (Hermitian banded complex)                       | Banded-LAPACK                     | Internal banded solver                                         |

| hcsr | (Hermitian complex)                              | Compressed sparse row             | PARDISO solver                                                 |
| s    | (symmetric real)                                 | Reverse communications interfaces | User defined                                                   |
| h    | (Hermitian complex)                              |                                   |                                                                |

- `<type of eigenvalue problem>` is:

|    |                                |
|----|--------------------------------|
| gv | generalized eigenvalue problem |
| ev | standard eigenvalue problem    |

For example, `sfeast_scsrev` is a single-precision routine with a symmetric real matrix stored in sparse compressed-row format for a standard eigenvalue problem, and `zfeast_hrci` is a complex double-precision routine with a Hermitian matrix using the reverse communication interface.

Note that:

- ? can be `s` or `d` if a matrix is real symmetric: `<matrix type>` is `sy`, `sb`, or `scsr`.
- ? can be `c` or `z` if a matrix is complex Hermitian: `<matrix type>` is `he`, `hb`, or `hcsr`.
- ? can be `c` or `z` if the Extended Eigensolver RCI interface is used for solving a complex Hermitian problem.
- ? can be `s` or `d` if the Extended Eigensolver RCI interface is used for solving a real symmetric problem.

## feastinit

Initialize Extended Eigensolver input parameters with default values.

### Syntax

```
feastinit (MKL_INT* fpm);
```

### Include Files

- `mkl.h`

### Description

This routine sets all Extended Eigensolver parameters to their default values.

## Output Parameters

*fpm* Array, size 128. This array is used to pass various parameters to Extended Eigensolver routines. See [Extended Eigensolver Input Parameters](#) for a complete description of the parameters and their default values.

## Extended Eigensolver Input Parameters

The input parameters for Extended Eigensolver routines are contained in an MKL\_INT array named *fpm*. To call the Extended Eigensolver interfaces, this array should be initialized using the routine `feastinit`.

| Param          | Default          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Extended Eigensolver Output Details**

Errors and warnings encountered during a run of the Extended Eigensolver routines are stored in an integer variable, *info*. If the value of the output *info* parameter is not 0, either an error or warning was encountered. The possible return values for the *info* parameter along with the error code descriptions are given in the following table.

**Return Codes for info Parameter**

| <i>info</i> | Classification | Description                                        |
|-------------|----------------|----------------------------------------------------|
| 202         | Error          | Problem with size of the system $n$ ( $n \leq 0$ ) |

| <i>info</i> | Classification  | Description                                                                                                                                                                                                                         |

In some extreme cases the return value  $info=1$  may indicate that the Extended Eigensolver routine has failed to find the eigenvalues in the search interval. This situation could arise if a very large search interval is used to locate a small and isolated cluster of eigenvalues (i.e. the dimension of the search interval is many orders of magnitude larger than the number of contour points. It is then either recommended to increase the number of contour points  $fpm[1]$  or simply rescale more appropriately the search interval. Rescaling means the initial problem of finding all eigenvalues the search interval  $[\lambda_{min}, \lambda_{max}]$  for the standard eigenvalue problem  $Ax = \lambda x$  is replaced with the problem of finding all eigenvalues in the search interval  $[\lambda_{min}/t, \lambda_{max}/t]$  for the standard eigenvalue problem  $(A/t)x = (\lambda/t)x$  where  $t$  is a scaling factor.

## Extended Eigensolver RCI Routines

If you do not require specific linear system solvers or matrix storage schemes, you can skip this section and go directly to [Extended Eigensolver Predefined Interfaces](#).

## Extended Eigensolver RCI Interface Description

The Extended Eigensolver RCI interfaces can be used to solve standard or generalized eigenvalue problems, and are independent of the format of the matrices. As mentioned earlier, the Extended Eigensolver algorithm is based on the contour integration techniques of the matrix resolvent  $G(\sigma) = (\sigma B - A)^{-1}$  over a circle. For solving a generalized eigenvalue problem, Extended Eigensolver has to perform one or more of the following operations at each contour point denoted below by  $Z_e$  :

- Factorize the matrix  $(Z_e * B - A)$
- Solve the linear system  $(Z_e * B - A)X = Y$  or  $(Z_e * B - A)^H X = Y$  with multiple right hand sides, where H means transpose conjugate

- Matrix-matrix multiply  $BX = Y$  or  $AX = Y$

For solving a standard eigenvalue problem, replace the matrix  $B$  with the identity matrix  $I$ .

The primary aim of RCI interfaces is to isolate these operations: the linear system solver, factorization of the matrix resolvent at each contour point, and matrix-matrix multiplication. This gives universality to RCI interfaces as they are independent of data structures and the specific implementation of the operations like matrix-vector multiplication or inner system solvers. However, this approach requires some additional effort when calling the interface. In particular, operations listed above are performed by routines that you supply on data structures that you find most appropriate for the problem at hand.

To initialize an Extended Eigensolver RCI routine, set the job indicator ( $ijob$ ) parameter to the value -1. When the routine requires the results of an operation, it generates a special value of  $ijob$  to indicate the operation that needs to be performed. The routine also returns  $ze$ , the coordinate along the complex contour, the values of array  $work$  or  $workc$ , and the number of columns to be used. Your subroutine then must perform the operation at the given contour point  $ze$ , store the results in prescribed array, and return control to the Extended Eigensolver RCI routine.

The following pseudocode shows the general scheme for using the Extended Eigensolver RCI functionality for a real symmetric problem:

```

ijob=-1; // initialization
do while (ijob!=0) {
 ?feast_src1(&ijob, &N, &Ze, work, workc, Aq, Bq,
 fpm, &epsout, &loop, &Emin, &Emax, &M0, E, lambda, &q, res, &info);

 switch(ijob) {
 case 10: // Factorize the complex matrix (ZeB-A)
 break;

 case 11: // Solve the complex linear system (ZeB-A)x=workc
 // Put result in workc
 break;

 case 30: // Perform multiplication A by Qi..Qj columns of QNxM0
 // where i = fpm[23] and j = fpm[23]+fpm[24]-1
 // Qi..Qj located in q starting from q+N*(i-1)
 break;

 case 40: // Perform multiplication B by Qi..Qj columns of QNxM0
 // where i = fpm[23] and j = fpm[23]+fpm[24]-1
 // Qi..Qj located in q starting from q+N*(i-1)
 // Result is stored in work+N*(i-1)

 break;
 }
}

```

---

#### NOTE

The ? option in ?feast in the pseudocode given above should be replaced by either *s* or *d*, depending on the matrix data type of the eigenvalue system.

---

The next pseudocode shows the general scheme for using the Extended Eigensolver RCI functionality for a complex Hermitian problem:

```

ijob=-1; // initialization
while (ijob!=0) {
 ?feast_hrc1(&ijob, &N, &Ze, work, workc, Aq, Bq,
 fpm, &epsout, &loop, &Emin, &Emax, &M0, E, lambda, &q, res, &info);

 switch (ijob) {
 case 10: // Factorize the complex matrix (ZeB-A)

```

```

break;

case 11: // Solve the linear system (ZeB-A)y=workc
 // Put result in workc
break;

case 20: // Factorize (if needed by case 21) the complex matrix (ZeB-A)^H
 // ATTENTION: This option requires additional memory storage
 // (i.e . the resulting matrix from case 10 cannot be overwritten)
break;

case 21: // Solve the linear system (ZeB-A)^Hy=workc
 // Put result in workc
 // REMARK: case 20 becomes obsolete if this solve can be performed
 // using the factorization in case 10
break;

case 30: // Multiply A by Q_i..Q_j columns of Q_{NxM0},
 // where i = fpm[23] and j = fpm[23]+fpm[24]-1
 // Q_i..Q_j located in q starting from q+N*(i-1)
 // Result is stored in work+N*(i-1)
break;

case 40: // Perform multiplication B by Q_i..Q_j columns of Q_{NxM0}
 // where i = fpm[23] and j = fpm[23]+fpm[24]-1
 // Q_i..Q_j located in q starting from q+N*(i-1)
 // Result is stored in work+N*(i-1)
break;

}
}
end do

```

**NOTE**

The `?feast` option in the pseudocode given above should be replaced by either `c` or `z`, depending on the matrix data type of the eigenvalue system.

If `case 20` can be avoided, performance could be up to twice as fast, and Extended Eigensolver functionality would use half of the memory.

If an iterative solver is used along with a preconditioner, the factorization of the preconditioner could be performed with `ijob = 10` (and `ijob = 20` if applicable) for a given value of  $Z_e$ , and the associated iterative solve would then be performed with `ijob = 11` (and `ijob = 21` if applicable).

**Optimization Notice**

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

## ?feast\_srcil/?feast\_hrcil

Extended Eigensolver RCI interface.

### Syntax

```
void sfeast_srcil (MKL_INT* ijob, const MKL_INT* n, MKL_Complex8* ze, float* work,
MKL_Complex8* workc, float* aq, float* sq, MKL_INT* fpm, float* epsout, MKL_INT* loop,
const float* emin, const float* emax, MKL_INT* m0, float* lambda, float* q, MKL_INT*
m, float* res, MKL_INT* info);
```

```
void dfeast_srcil (MKL_INT* ijob, const MKL_INT* n, MKL_Complex16* ze, double* work,
MKL_Complex16* workc, double* aq, double* sq, MKL_INT* fpm, double* epsout, MKL_INT*
loop, const double* emin, const double* emax, MKL_INT* m0, double* lambda, double* q,
MKL_INT* m, double* res, MKL_INT* info);
```

```
void cfeast_hrcil (MKL_INT* ijob, const MKL_INT* n, MKL_Complex8* ze, MKL_Complex8*
work, MKL_Complex8* workc, MKL_Complex8* aq, MKL_Complex8* sq, MKL_INT* fpm, float*
epsout, MKL_INT* loop, const float* emin, const float* emax, MKL_INT* m0, float*
lambda, MKL_Complex8* q, MKL_INT* m, float* res, MKL_INT* info);
```

```
void zfeast_hrcil (MKL_INT* ijob, const MKL_INT* n, MKL_Complex16* ze, MKL_Complex16*
work, MKL_Complex16* workc, MKL_Complex16* aq, MKL_Complex16* sq, MKL_INT* fpm,
double* epsout, MKL_INT* loop, const double* emin, const double* emax, MKL_INT* m0,
double* lambda, MKL_Complex16* q, MKL_INT* m, double* res, MKL_INT* info);
```

### Include Files

- mkl.h

### Description

Compute eigenvalues as described in [Extended Eigensolver RCI Interface Description](#).

### Input Parameters

|                   |                                                                                                                                                                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ijob</i>       | Job indicator variable. On entry, a call to ?feast_srcil/?feast_hrcil with <i>ijob</i> =-1 initializes the eigensolver.                                                                                                                                                         |
| <i>n</i>          | Sets the size of the problem. $n > 0$ .                                                                                                                                                                                                                                         |
| <i>work</i>       | Workspace array of size $n$ by $m0$ .                                                                                                                                                                                                                                           |
| <i>workc</i>      | Workspace array of size $n$ by $m0$ .                                                                                                                                                                                                                                           |
| <i>aq, sq</i>     | Workspace arrays of size $m0$ by $m0$ .                                                                                                                                                                                                                                         |
| <i>fpm</i>        | Array, size of 128. This array is used to pass various parameters to Extended Eigensolver routines. See <a href="#">Extended Eigensolver Input Parameters</a> for a complete description of the parameters and their default values.                                            |
| <i>emin, emax</i> | The lower and upper bounds of the interval to be searched for eigenvalues; $emin \leq emax$ .                                                                                                                                                                                   |
| <i>m0</i>         | On entry, specifies the initial guess for subspace size to be used, $0 < m0 \leq n$ . Set $m0 \geq m$ where $m$ is the total number of eigenvalues located in the interval $[emin, emax]$ . If the initial guess is wrong, Extended Eigensolver routines return <i>info</i> =3. |

*q* On entry, if  $fpm[4]=1$ , the array *q* of size *n* by *m* contains a basis of guess subspace where *n* is the order of the input matrix.

## Output Parameters

*ijob* On exit, the parameter carries the status flag that indicates the condition of the return. The status information is divided into three categories:

1. A zero value indicates successful completion of the task.
2. A positive value indicates that the solver requires a matrix-vector multiplication or solving a specific system with a complex coefficient.
3. A negative value indicates successful initiation.

A non-zero value of *ijob* specifically means the following:

- *ijob* = 10 - factorize the complex matrix  $Z_e * B - A$  at a given contour point  $Z_e$  and return the control to the `?feast_src`/`?feast_hrc` routine where  $Z_e$  is a complex number meaning contour point and its value is defined internally in `?feast_src`/`?feast_hrc`.
- *ijob* = 11 - solve the complex linear system  $(Z_e * B - A) * y = workc$ , put the solution in *workc* and return the control to the `?feast_src`/`?feast_hrc` routine.
- *ijob* = 20 - factorize the complex matrix  $(Z_e * B - A)^H$  at a given contour point  $Z_e$  and return the control to the `?feast_src`/`?feast_hrc` routine where  $Z_e$  is a complex number meaning contour point and its value is defined internally in `?feast_src`/`?feast_hrc`.

The symbol  $X^H$  means transpose conjugate of matrix *X*.

- *ijob* = 21 - solve the complex linear system  $(Z_e * B - A)^H * y = workc$ , put the solution in *workc* and return the control to the `?feast_src`/`?feast_hrc` routine. The case *ijob*=20 becomes obsolete if the solve can be performed using the factorization computed for *ijob*=10.

The symbol  $X^H$  mean transpose conjugate of matrix *X*.

- *ijob* = 30 - multiply matrix *A* by  $Q_j \cdot Q_i$ , put the result in  $work + N * (i - 1)$ , and return the control to the `?feast_src`/`?feast_hrc` routine.  
*i* is  $fpm[24]$ , and *j* is  $fpm[23] + fpm[24] - 1$ .
- *ijob* = 40 - multiply matrix *B* by  $Q_j \cdot Q_i$ , put the result in  $work + N * (i - 1)$  and return the control to the `?feast_src`/`?feast_hrc` routine. If a standard eigenvalue problem is solved, just return  $work = q$ .  
*i* is  $fpm[24]$ , and *j* is  $fpm[23] + fpm[24] - 1$ .
- *ijob* = -2 - rerun the `?feast_src`/`?feast_hrc` task with the same parameters.

*ze* Defines the coordinate along the complex contour. All values of *ze* are generated by `?feast_src`/`?feast_hrc` internally.

*fpm* On output, contains coordinates of columns of work array needed for iterative refinement. (See [Extended Eigensolver RCI Interface Description](#).)

*epsout* On output, contains the relative error on the trace:  $|trace_i - trace_{i-1}| / \max(|emin|, |emax|)$

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>loop</i>   | On output, contains the number of refinement loop executed. Ignored on input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>lambda</i> | Array of length <i>m0</i> . On output, the first <i>m</i> entries of <i>lambda</i> are eigenvalues found in the interval.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>q</i>      | On output, <i>q</i> contains all eigenvectors corresponding to <i>lambda</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>m</i>      | The total number of eigenvalues found in the interval [ <i>emin</i> , <i>emax</i> ]: $0 \leq m \leq m0$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>res</i>    | <p>Array of length <i>m0</i>. On exit, the first <i>m</i> components contain the relative residual vector:</p> <ul style="list-style-type: none"> <li>generalized eigenvalue problem:                     <math display="block">\frac{\ Ax_i - \lambda_i Bx_i\ _1}{\max( E_{\min} ,  E_{\max} ) \ Bx_i\ _1}</math> </li> <li>standard eigenvalue problem:                     <math display="block">\frac{\ Ax_i - \lambda_i x_i\ _1}{\max( E_{\min} ,  E_{\max} ) \ x_i\ _1}</math> </li> </ul> <p>for <math>i=0, 1, \dots, m-1</math>, and where <i>m</i> is the total number of eigenvalues found in the search interval.</p> |
| <i>info</i>   | If <i>info</i> =0, the execution is successful. If <i>info</i> ≠ 0, see <a href="#">Output Eigensolver info Details</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### Extended Eigensolver Predefined Interfaces

The predefined interfaces include routines for standard and generalized eigenvalue problems, and for dense, banded, and sparse matrices.

| Matrix Type | Standard Eigenvalue Problem    | Generalized Eigenvalue Problem |
|-------------|--------------------------------|--------------------------------|
| Dense       | ?feast_syev<br>?feast_heev     | ?feast_sygv<br>?feast_hegv     |
| Banded      | ?feast_sbev<br>?feast_hbev     | ?feast_sbgv<br>?feast_hbgv     |
| Sparse      | ?feast_scsrev<br>?feast_hcsrev | ?feast_scsrgv<br>?feast_hcsrgv |

### Matrix Storage

The symmetric and Hermitian matrices used in Extended Eigensolvers predefined interfaces can be stored in full, band, and sparse formats.

- In the full storage format (described in [Full Storage](#) in additional detail) you store all elements, all of the elements in the upper triangle of the matrix, or all of the elements in the lower triangle of the matrix.

- In the band storage format (described in [Band storage](#) in additional detail), you store only the elements along a diagonal band of the matrix.
- In the sparse format (described in [Storage Arrays for a Matrix in CSR Format \(3-Array Variation\)](#)), you store only the non-zero elements of the matrix.

In generalized eigenvalue systems you must use the same family of storage format for both matrices  $A$  and  $B$ . The bandwidth can be different for the banded format ( $k_{lb}$  can be different from  $k_{la}$ ), and the position of the non-zero elements can also be different for the sparse format (CSR coordinates  $ib$  and  $jb$  can be different from  $ia$  and  $ja$ ).

## ?feast\_syev/?feast\_heev

*Extended Eigensolver interface for standard eigenvalue problem with dense matrices.*

### Syntax

```
void sfeast_syev (const char * uplo, const MKL_INT * n, const float * a, const MKL_INT * lda, MKL_INT * fpm, float * epsout, MKL_INT * loop, const float * emin, const float * emax, MKL_INT * m0, float * e, float * x, MKL_INT * m, float * res, MKL_INT * info);

void dfeast_syev (const char * uplo, const MKL_INT * n, const double * a, const MKL_INT * lda, MKL_INT * fpm, double * epsout, MKL_INT * loop, const double * emin, const double * emax, MKL_INT * m0, double * e, double * x, MKL_INT * m, double * res, MKL_INT * info);

void cfeast_heev (const char * uplo, const MKL_INT * n, const MKL_Complex8 * a, const MKL_INT * lda, MKL_INT * fpm, float * epsout, MKL_INT * loop, const float * emin, const float * emax, MKL_INT * m0, float * e, MKL_Complex8 * x, MKL_INT * m, float * res, MKL_INT * info);

void zfeast_heev (const char * uplo, const MKL_INT * n, const MKL_Complex16 * a, const MKL_INT * lda, MKL_INT * fpm, double * epsout, MKL_INT * loop, const double * emin, const double * emax, MKL_INT * m0, double * e, MKL_Complex16 * x, MKL_INT * m, double * res, MKL_INT * info);
```

### Include Files

- mkl.h

### Description

The routines compute all the eigenvalues and eigenvectors for standard eigenvalue problems,  $Ax = \lambda x$ , within a given search interval.

### Input Parameters

|             |                                                                                                                                                                                                                                                      |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>uplo</i> | Must be 'U' or 'L' or 'F' .<br>If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular parts of $A$ .<br>If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular parts of $A$ .<br>If <i>uplo</i> = 'F', <i>a</i> stores the full matrix $A$ . |
| <i>n</i>    | Sets the size of the problem. $n > 0$ .                                                                                                                                                                                                              |
| <i>a</i>    | Array of dimension <i>lda</i> by <i>n</i> , contains either full matrix $A$ or upper or lower triangular part of the matrix $A$ , as specified by <i>uplo</i>                                                                                        |
| <i>lda</i>  | The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$ .                                                                                                                                                                        |

|                   |                                                                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>fpm</i>        | Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See <a href="#">Extended Eigensolver Input Parameters</a> for a complete description of the parameters and their default values.                                            |
| <i>emin, emax</i> | The lower and upper bounds of the interval to be searched for eigenvalues; $emin \leq emax$ .                                                                                                                                                                                        |
| <i>m0</i>         | On entry, specifies the initial guess for subspace dimension to be used, $0 < m0 \leq n$ . Set $m0 \geq m$ where $m$ is the total number of eigenvalues located in the interval $[emin, emax]$ . If the initial guess is wrong, Extended Eigensolver routines return <i>info</i> =3. |
| <i>x</i>          | On entry, if <i>fpm</i> [4]=1, the array <i>x</i> of size $n$ by $m$ contains a basis of guess subspace where $n$ is the order of the input matrix.                                                                                                                                  |

## Output Parameters

|               |                                                                                                                                                                                                                                                                                    |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>epsout</i> | On output, contains the relative error on the trace: $ trace_i - trace_{i-1}  / \max( emin ,  emax )$                                                                                                                                                                              |
| <i>loop</i>   | On output, contains the number of refinement loop executed. Ignored on input.                                                                                                                                                                                                      |
| <i>e</i>      | Array of length $m0$ . On output, the first $m$ entries of <i>e</i> are eigenvalues found in the interval.                                                                                                                                                                         |
| <i>x</i>      | On output, the first $m$ columns of <i>x</i> contain the orthonormal eigenvectors corresponding to the computed eigenvalues <i>e</i> , with the $i$ -th column of <i>x</i> holding the eigenvector associated with $e[i]$ .                                                        |
| <i>m</i>      | The total number of eigenvalues found in the interval $[emin, emax]$ : $0 \leq m \leq m0$ .                                                                                                                                                                                        |
| <i>res</i>    | Array of length $m0$ . On exit, the first $m$ components contain the relative residual vector: $\frac{\ Ax_i - \lambda_i x_i\ _1}{\max( E_{\min} ,  E_{\max} ) \ x_i\ _1}$ for $i=1, 2, \dots, m$ , and where $m$ is the total number of eigenvalues found in the search interval. |
| <i>info</i>   | If <i>info</i> =0, the execution is successful. If <i>info</i> ≠0, see <a href="#">Output Eigensolver info Details</a> .                                                                                                                                                           |

## ?feast\_sylv/?feast\_hgv

Extended Eigensolver interface for generalized eigenvalue problem with dense matrices.

### Syntax

```

## Include Files

- mkl.h

## Description

The routines compute all the eigenvalues and eigenvectors for generalized eigenvalue problems,  $Ax = \lambda Bx$ , within a given search interval.

## Input Parameters

|                   |                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>uplo</i>       | Must be 'U' or 'L' or 'F' .<br><br>If <i>UPLO</i> = 'U', <i>a</i> and <i>b</i> store the upper triangular parts of <i>A</i> and <i>B</i> respectively.<br><br>If <i>UPLO</i> = 'L', <i>a</i> and <i>b</i> store the lower triangular parts of <i>A</i> and <i>B</i> respectively.<br><br>If <i>UPLO</i> = 'F', <i>a</i> and <i>b</i> store the full matrices <i>A</i> and <i>B</i> respectively. |
| <i>n</i>          | Sets the size of the problem. $n > 0$ .                                                                                                                                                                                                                                                                                                                                                          |
| <i>a</i>          | Array of dimension <i>lda</i> by <i>n</i> , contains either full matrix <i>A</i> or upper or lower triangular part of the matrix <i>A</i> , as specified by <i>uplo</i>                                                                                                                                                                                                                          |
| <i>lda</i>        | The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$ .                                                                                                                                                                                                                                                                                                                    |
| <i>b</i>          | Array of dimension <i>ldb</i> by <i>n</i> , contains either full matrix <i>B</i> or upper or lower triangular part of the matrix <i>B</i> , as specified by <i>uplo</i>                                                                                                                                                                                                                          |
| <i>ldb</i>        | The leading dimension of the array <i>B</i> . Must be at least $\max(1, n)$ .                                                                                                                                                                                                                                                                                                                    |
| <i>fpm</i>        | Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See <a href="#">Extended Eigensolver Input Parameters</a> for a complete description of the parameters and their default values.                                                                                                                                                        |
| <i>emin, emax</i> | The lower and upper bounds of the interval to be searched for eigenvalues; $emin \leq emax$ .                                                                                                                                                                                                                                                                                                    |
| <i>m0</i>         | On entry, specifies the initial guess for subspace dimension to be used, $0 < m0 \leq n$ . Set $m0 \geq m$ where <i>m</i> is the total number of eigenvalues located in the interval [ <i>emin</i> , <i>emax</i> ]. If the initial guess is wrong, Extended Eigensolver routines return <i>info</i> =3.                                                                                          |

*x* On entry, if  $f_{pm}[4]=1$ , the array *x* of size *n* by *m* contains a basis of guess subspace where *n* is the order of the input matrix.

## Output Parameters

*epsout* On output, contains the relative error on the trace:  $|trace_i - trace_{i-1}| / \max(|e_{min}|, |e_{max}|)$

*loop* On output, contains the number of refinement loop executed. Ignored on input.

*e* Array of length *m0*. On output, the first *m* entries of *e* are eigenvalues found in the interval.

*x* On output, the first *m* columns of *x* contain the orthonormal eigenvectors corresponding to the computed eigenvalues *e*, with the *i*-th column of *x* holding the eigenvector associated with *e*[*i*].

*m* The total number of eigenvalues found in the interval [*e*<sub>min</sub>, *e*<sub>max</sub>]:  $0 \leq m \leq m0$ .

*res* Array of length *m0*. On exit, the first *m* components contain the relative residual vector:

$$\frac{\|Ax_i - \lambda_i Bx_i\|_1}{\max(|E_{min}|, |E_{max}|) \|Bx_i\|_1}$$

for  $i=1, 2, \dots, m$ , and where *m* is the total number of eigenvalues found in the search interval.

*info* If *info*=0, the execution is successful. If *info*≠ 0, see [Output Eigensolver info Details](#).

## ?feast\_sbev/?feast\_hbev

*Extended Eigensolver interface for standard eigenvalue problem with banded matrices.*

### Syntax

```
void sfeast_sbev (const char * uplo, const MKL_INT * n, const MKL_INT * kla, const
float * a, const MKL_INT * lda, MKL_INT * fpm, float * epsout, MKL_INT * loop, const
float * emin, const float * emax, MKL_INT * m0, float * e, float * x, MKL_INT * m,
float * res, MKL_INT * info);
