<i>i_l, i_u</i>	<p>If <math>range='I'</math>, the indices (in ascending order) of the smallest eigenvalue, to be returned in <math>w[i_l-1]</math>, and largest eigenvalue, to be returned in <math>w[i_u-1]</math>. <math>1 \leq i_l \leq i_u \leq n</math>, if <math>n &gt; 0</math>.</p> <p>Not referenced if <math>range = 'A'</math> or <math>'V'</math>.</p>
<i>ldz</i>	The leading dimension of the array $z$ . $ldz \geq 1$ , and if $jobz = 'V'$ , then $ldz \geq \max(1, n)$ .
<i>nzc</i>	<p>The number of eigenvectors to be held in the array <math>z</math>.</p> <p>If <math>range = 'A'</math>, then <math>nzc \geq \max(1, n)</math>.</p> <p>If <math>range = 'V'</math>, then <math>nzc \geq</math> the number of eigenvalues in <math>(v_l, v_u]</math>.</p> <p>If <math>range = 'I'</math>, then <math>nzc \geq i_u - i_l + 1</math>.</p> <p>If <math>nzc = -1</math>, then a workspace query is assumed; the function calculates the number of columns of the matrix stored in array <math>z</math> that are needed to hold the eigenvectors. This value is returned as the first entry of the <math>z</math> array, and no error message related to <math>nzc</math> is issued.</p>
<i>lwork</i>	<p>The size of the array <math>work</math>. <math>lwork \geq \max(1, 18*n)</math> if <math>jobz = 'V'</math>, and <math>lwork \geq \max(1, 12*n)</math> if <math>jobz = 'N'</math>.</p> <p>If <math>lwork = -1</math>, then a workspace query is assumed; the function only calculates the optimal size of the <math>work</math> array, returns this value as the first entry of the <math>work</math> array, and no error message related to <math>lwork</math> is issued.</p>
<i>liwork</i>	The size of the array $iwork$ . $liwork \geq \max(1, 10*n)$ if the eigenvectors are desired, and $liwork \geq \max(1, 8*n)$ if only the eigenvalues are to be computed.

If  $liwork = -1$ , then a workspace query is assumed; the function only calculates the optimal size of the  $iwork$  array, returns this value as the first entry of the  $iwork$  array, and no error message related to  $liwork$  is issued.

$dol, dou$

From all the eigenvalues  $w[0]$  through  $w[m-1]$ , only eigenvalues  $w[dol-1]$  through  $w[dou-1]$  are computed.

## OUTPUT Parameters

$m$

Globally summed over all processors,  $m$  equals the total number of eigenvalues found.  $0 \leq m \leq n$ .

If  $range = 'A'$ ,  $m = n$ , and if  $range = 'I'$ ,  $m = iu-il+1$ .

The local output equals  $m = dou - dol + 1$ .

$w$

Array of size  $n$

The first  $m$  elements contain approximations to the selected eigenvalues in ascending order. Note that immediately after exiting this function, only the eigenvalues indexed  $dol-1$  through  $dou-1$  are reliable on this processor because the eigenvalue computation is done in parallel. The other entries are very crude preliminary approximations. Other processors hold reliable information on these other parts of the  $w$  array.

This information is communicated in the ScaLAPACK driver.

$z$

Array of size  $ldz * \max(1, m)$ .

`?stegr2a` does not compute eigenvectors, this is done in `?stegr2b`. The argument  $z$  as well as all related other arguments only appear to keep the interface consistent and to signal to the user that this function is meant to be used when eigenvectors are computed.

$work$

On exit, if  $info = 0$ ,  $work[0]$  returns the optimal (and minimal)  $lwork$ .

$iwork$

On exit, if  $info = 0$ ,  $iwork[0]$  returns the optimal  $liwork$ .

$needil, neediu$

The indices of the leftmost and rightmost eigenvalues needed to accurately compute the relevant part of the representation tree. This information can be used to find out which processors have the relevant eigenvalue information needed so that it can be communicated.

$inderr$

$inderr$  points to the place in the work space where the eigenvalue uncertainties (errors) are stored.

$nsplit$

The number of blocks into which  $T$  splits.  $1 \leq nsplit \leq n$ .

$pivmin$

The minimum pivot in the sturm sequence for  $T$ .

$scale$

The scaling factor for the tridiagonal  $T$ .

$wl, wu$

The interval  $(wl, wu]$  contains all the wanted eigenvalues.

It is either given by the user or computed in `?larre2a`.

$info$

On exit,  $info = 0$ : successful exit

other: if  $info = -i$ , the  $i$ -th argument had an illegal value

if  $info = 10x$ , internal error in `?larre2a`,

Here, the digit  $x = \text{abs}(iinfo) < 10$ , where  $iinfo$  is the nonzero error code returned by `?larre2a`.

## Description

`?stegr2b` should only be called after a call to `?stegr2a`. From eigenvalues and initial representations computed by `?stegr2a`, `?stegr2b` computes the selected eigenvalues and eigenvectors of the real symmetric tridiagonal matrix in parallel on multiple processors. It is potentially invoked multiple times on a given processor because the locally relevant representation tree might depend on spectral information that is "owned" by other processors and might need to be communicated.

Please note:

- The calling sequence has two additional integer parameters, `dol` and `dou`, that should satisfy  $m \geq dou \geq dol \geq 1$ . These parameters are only relevant for the case `jobz = 'V'`. `?stegr2b` only computes the eigenvectors corresponding to eigenvalues `dol` through `dou` in `w`, indexed `dol-1` through `dou-1`. (That is, instead of computing the eigenvectors belonging to `w[0]` through `w[m-1]`, only the eigenvectors belonging to eigenvalues `w[dol-1]` through `w[dou-1]` are computed. In this case, only the eigenvalues `dol` through `dou` are guaranteed to be accurately refined to all figures by Rayleigh-Quotient iteration.
- The additional arguments `vstart`, `finish`, `ndepth`, `parity`, `zoffset` are included as a thread-safe implementation equivalent to save variables. These variables store details about the local representation tree which is computed layerwise. For scalability reasons, eigenvalues belonging to the locally relevant representation tree might be computed on other processors. These need to be communicated before the inspection of the RRRs can proceed on any given layer. Note that only when the variable `finish` is non-zero, the computation has ended. All eigenpairs between `dol` and `dou` have been computed. `m` is set to `dou - dol + 1`.
- `?stegr2b` needs more workspace in `z` than the sequential `?stegr`. It is used to store the conformal embedding of the local representation tree.

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

**Input Parameters**

<i>jobz</i>	= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.
<i>n</i>	The order of the matrix. $n \geq 0$ .
<i>d</i>	Array of size <i>n</i> The <i>n</i> diagonal elements of the tridiagonal matrix T. Overwritten on exit.
<i>e</i>	Array of size <i>n</i> The ( <i>n</i> -1) subdiagonal elements of the tridiagonal matrix <i>T</i> in elements 0 to <i>n</i> -2 of <i>e</i> . <i>e</i> [ <i>n</i> -1] need not be set on input, but is used internally as workspace. Overwritten on exit.
<i>m</i>	The total number of eigenvalues found in <code>?stegr2a</code> . $0 \leq m \leq n$ .
<i>w</i>	Array of size <i>n</i> The first <i>m</i> elements contain approximations to the selected eigenvalues in ascending order. Note that only the eigenvalues from the locally relevant part of the representation tree, that is all the clusters that include eigenvalues from <i>dol</i> through <i>dou</i> , are reliable on this processor. (It does not need to know about any others anyway.)
<i>ldz</i>	The leading dimension of the array <i>z</i> . $ldz \geq 1$ , and if <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$ .
<i>nzc</i>	The number of eigenvectors to be held in the array <i>z</i> , storing the matrix Z.
<i>lwork</i>	The size of the array <i>work</i> . $lwork \geq \max(1, 18 * n)$ if <i>jobz</i> = 'V', and $lwork \geq \max(1, 12 * n)$ if <i>jobz</i> = 'N'. If <i>lwork</i> = -1, then a workspace query is assumed; the function only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued.
<i>liwork</i>	The size of the array <i>iwork</i> . $liwork \geq \max(1, 10 * n)$ if the eigenvectors are desired, and $liwork \geq \max(1, 8 * n)$ if only the eigenvalues are to be computed. If <i>liwork</i> = -1, then a workspace query is assumed; the function only calculates the optimal size of the <i>iwork</i> array, returns this value as the first entry of the <i>iwork</i> array, and no error message related to <i>liwork</i> is issued.
<i>dol, dou</i>	From the eigenvalues <i>w</i> [0] through <i>w</i> [ <i>m</i> -1], only eigenvectors Z(:, <i>dol</i> ) to Z(:, <i>dou</i> ) are computed. If <i>dol</i> > 1, then Z(:, <i>dol</i> -1- <i>zoffset</i> ) is used and overwritten.

	If $dou < m$ , then $Z(:,dou+1-zoffset)$ is used and overwritten.
<i>needil, neediu</i>	Describes which are the left and right outermost eigenvalues still to be computed. Initially computed by <code>?larre2a</code> , modified in the course of the algorithm.
<i>pivmin</i>	The minimum pivot in the sturm sequence for $T$ .
<i>scale</i>	The scaling factor for $T$ . Used for unscaling the eigenvalues at the very end of the algorithm.
<i>wl, wu</i>	The interval $(wl, wu]$ contains all the wanted eigenvalues.
<i>vstart</i>	Non-zero on initialization, set to zero afterwards.
<i>finish</i>	Indicates whether all eigenpairs have been computed.
<i>maxcls</i>	The largest cluster worked on by this processor in the representation tree.
<i>ndepth</i>	The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.
<i>parity</i>	An internal parameter needed for the storage of the clusters on the current level of the representation tree.
<i>zoffset</i>	Offset for storing the eigenpairs when $z$ is distributed in 1D-cyclic fashion.

## OUTPUT Parameters

<i>z</i>	<p>Array of size <math>ldz * \max(1,m)</math></p> <p>If <math>jobz = 'V'</math>, and if <math>info = 0</math>, then a subset of the first <math>m</math> columns of the matrix <math>Z</math>, stored in <math>z</math>, contain the orthonormal eigenvectors of the matrix <math>T</math> corresponding to the selected eigenvalues, with the <math>i</math>-th column of <math>Z</math> holding the eigenvector associated with <math>w[i-1]</math>.</p> <p>See <i>dol, dou</i> for more information.</p>
<i>isuppz</i>	<p>array of size <math>2 * \max(1,m)</math>.</p> <p>The support of the eigenvectors in <math>z</math>, i.e., the indices indicating the nonzero elements in <math>z</math>. The <math>i</math>-th computed eigenvector is nonzero only in elements <math>isuppz[2*i-2]</math> through <math>isuppz[2*i-1]</math>. This is relevant in the case when the matrix is split. <i>isuppz</i> is only set if <math>n &gt; 2</math>.</p>
<i>work</i>	On exit, if $info = 0$ , $work[0]$ returns the optimal (and minimal) $lwork$ .
<i>iwork</i>	On exit, if $info = 0$ , $iwork[0]$ returns the optimal $liwork$ .
<i>needil, neediu</i>	Modified in the course of the algorithm.
<i>indwlc</i>	Pointer into the workspace location where the local eigenvalue representations are stored. ("Local eigenvalues" are those relative to the individual shifts of the RRRs.)
<i>vstart</i>	Non-zero on initialization, set to zero afterwards.
<i>finish</i>	Indicates whether all eigenpairs have been computed
<i>maxcls</i>	The largest cluster worked on by this processor in the representation tree.

<i>ndepth</i>	The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.
<i>parity</i>	An internal parameter needed for the storage of the clusters on the current level of the representation tree.
<i>info</i>	On exit, <i>info</i> = 0: successful exit other: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value if <i>info</i> = 20 <i>x</i> , internal error in <a href="#">?larrv2</a> . Here, the digit <i>x</i> = abs( <i>iinfo</i> ) < 10, where <i>iinfo</i> is the nonzero error code returned by <a href="#">?larrv2</a>

## ?stein2

*Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix, using inverse iteration.*

## Syntax

```
void sstein2 (MKL_INT *n , float *d , float *e , MKL_INT *m , float *w , MKL_INT
*iblock , MKL_INT *isplit , float *orfac , float *z , MKL_INT *ldz , float *work ,
MKL_INT *iwork , MKL_INT *ifail , MKL_INT *info );
```

```
void dstein2 (MKL_INT *n , double *d , double *e , MKL_INT *m , double *w , MKL_INT
*iblock , MKL_INT *isplit , double *orfac , double *z , MKL_INT *ldz , double *work ,
MKL_INT *iwork , MKL_INT *ifail , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

The [?stein2](#) function is a modified LAPACK function [?stein](#). It computes the eigenvectors of a real symmetric tridiagonal matrix  $T$  corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter *maxits* (currently set to 5).

## Input Parameters

<i>n</i>	The order of the matrix $T$ ( $n \geq 0$ ).
<i>m</i>	The number of eigenvectors to be found ( $0 \leq m \leq n$ ).
<i>d, e, w</i>	Arrays: <i>d</i> , of size $n$ . The $n$ diagonal elements of the tridiagonal matrix $T$ . <i>e</i> , of size $n$ . The $(n-1)$ subdiagonal elements of the tridiagonal matrix $T$ , in elements 1 to $n-1$ . <i>e</i> [ $n-1$ ] need not be set.

$w$ , of size  $n$ .

The first  $m$  elements of  $w$  contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array  $w$  from `?stebz` with `ORDER = 'B'` is expected here).

The size of  $w$  must be at least  $\max(1, n)$ .

*iblock*

Array of size  $n$ .

The submatrix indices associated with the corresponding eigenvalues in  $w$ ;

$iblock[i] = 1$ , if eigenvalue  $w[i]$  belongs to the first submatrix from the top,

$iblock[i] = 2$ , if eigenvalue  $w[i]$  belongs to the second submatrix, etc. (The output array *iblock* from `?stebz` is expected here).

*isplit*

Array of size  $n$ .

The splitting points, at which  $T$  breaks up into submatrices. The first submatrix consists of rows/columns 1 to  $isplit[0]$ , the second submatrix consists of rows/columns  $isplit[0]+1$  through  $isplit[1]$ , etc. (The output array *isplit* from `?stebz` is expected here).

*orfac*

*orfac* specifies which eigenvectors should be orthogonalized. Eigenvectors that correspond to eigenvalues which are within  $orfac * ||T||$  of each other are to be orthogonalized.

*ldz*

The leading dimension of the output array  $z$ ;  $ldz \geq \max(1, n)$ .

*work*

Workspace array of size  $5n$ .

*iwork*

Workspace array of size  $n$ .

## Output Parameters

*z*

Array of size  $ldz * m$ .

The computed eigenvectors. The eigenvector associated with the eigenvalue  $w[i]$  is stored in the  $(i+1)$ -th column of the matrix  $Z$  represented by  $z$ ,  $i=0, \dots, m-1$ . Any vector that fails to converge is set to its current iterate after *maxits* iterations.

*ifail*

Array of size  $m$ .

On normal exit, all elements of *ifail* are zero. If one or more eigenvectors fail to converge after *maxits* iterations, then their indices are stored in the array *ifail*.

*info*

$info = 0$ , the exit is successful.

$info < 0$ : if  $info = -i$ , the  $i$ -th had an illegal value.

$info > 0$ : if  $info = i$ , then  $i$  eigenvectors failed to converge in *maxits* iterations. Their indices are stored in the array *ifail*.

## ?dgbtf2

Computes an LU factorization of a general band matrix with no pivoting (local unblocked algorithm).

## Syntax

```
void sdbtf2 (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , float *ab , MKL_INT *ldab , MKL_INT *info );
```

```
void ddbtf2 (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , double *ab , MKL_INT *ldab , MKL_INT *info );
```

```
void cdbtf2 (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , MKL_Complex8 *ab , MKL_INT *ldab , MKL_INT *info );
```

```
void zdbtf2 (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , MKL_Complex16 *ab , MKL_INT *ldab , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `?dgbtf2` function computes an  $LU$  factorization of a general real/complex  $m$ -by- $n$  band matrix  $A$  without using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling [BLAS Routines and Functions](#).

## Input Parameters

$m$	The number of rows of the matrix $A$ ( $m \geq 0$ ).
$n$	The number of columns in $A$ ( $n \geq 0$ ).
$kl$	The number of sub-diagonals within the band of $A$ ( $kl \geq 0$ ).
$ku$	The number of super-diagonals within the band of $A$ ( $ku \geq 0$ ).
$ab$	Array of size $ldab * n$ . The matrix $A$ in band storage, in rows $kl+1$ to $2kl+ku+1$ ; rows 1 to $kl$ of the matrix need not be set. The $j$ -th column of $A$ is stored in the array $ab$ as follows: $ab[kl+ku+i-j+(j-1)*ldab] = A(i,j)$ for $\max(1, j-ku) \leq i \leq \min(m, j+kl)$ .
$ldab$	The leading dimension of the array $ab$ . ( $ldab \geq 2kl + ku + 1$ )

## Output Parameters

$ab$	On exit, details of the factorization: $U$ is stored as an upper triangular band matrix with $kl+ku$ superdiagonals in rows 1 to $kl+ku+1$ , and the multipliers used during the factorization are stored in rows $kl+ku+2$ to $2*kl+ku+1$ . See the <i>Application Notes</i> below for further details.
$info$	= 0: successful exit

< 0: if  $info = -i$ , the  $i$ -th argument had an illegal value,  
 > 0: if  $info = +i$ , the matrix element  $U(i,i)$  is 0. The factorization has been completed, but the factor  $U$  is exactly singular. Division by 0 will occur if you use the factor  $U$  for solving a system of linear equations.

## Application Notes

The band storage scheme is illustrated by the following example, when  $m = n = 6, kl = 2, ku = 1$ :

on entry	on exit
$\begin{bmatrix} * & a_{12} & a_{23} & a_{34} & a_{45} & a_{56} \\ a_{11} & a_{22} & a_{33} & a_{44} & a_{55} & a_{66} \\ a_{21} & a_{32} & a_{43} & a_{54} & a_{65} & * \\ a_{31} & a_{42} & a_{53} & a_{64} & * & * \end{bmatrix}$	$\begin{bmatrix} * & u_{12} & u_{23} & u_{34} & u_{45} \\ u_{11} & u_{22} & u_{33} & u_{44} & u_{55} \\ m_{21} & m_{32} & m_{43} & m_{54} & m_{65} \\ m_{31} & m_{42} & m_{53} & m_{64} & * \end{bmatrix}$

The function does not use array elements marked \*; elements marked + need not be set on entry, but the function requires them to store elements of  $U$ , because of fill-in resulting from the row interchanges.

## Description

The `?dttrf` function computes an  $LU$  factorization of a real or complex tridiagonal matrix  $A$  using elimination without partial pivoting.

The factorization has the form  $A = L*U$ , where  $L$  is a product of unit lower bidiagonal matrices and  $U$  is upper triangular with nonzeros only in the main diagonal and first superdiagonal.

## Input Parameters

$n$	The order of the matrix $A$ ( $n \geq 0$ ).
$dl, d, du$	Arrays containing elements of $A$ . The array $dl$ of size $(n-1)$ contains the sub-diagonal elements of $A$ . The array $d$ of size $n$ contains the diagonal elements of $A$ . The array $du$ of size $(n-1)$ contains the super-diagonal elements of $A$ .

## Output Parameters

$dl$	Overwritten by the $(n-1)$ multipliers that define the matrix $L$ from the $LU$ factorization of $A$ .
$d$	Overwritten by the $n$ diagonal elements of the upper triangular matrix $U$ from the $LU$ factorization of $A$ .
$du$	Overwritten by the $(n-1)$ elements of the first super-diagonal of $U$ .
$info$	= 0: successful exit < 0: if $info = -i$ , the $i$ -th argument had an illegal value, > 0: if $info = i$ , the matrix element $U(i,i)$ is exactly 0. The factorization has been completed, but the factor $U$ is exactly singular. Division by 0 will occur if you use the factor $U$ for solving a system of linear equations.

## ?dttrsv

*Solves a general tridiagonal system of linear equations using the  $LU$  factorization computed by `?dttrf`.*

## Syntax

```
void sdttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , float *dl , float
*d , float *du , float *b , MKL_INT *ldb , MKL_INT *info );
```

```

void ddttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , double *dl ,
double *d , double *du , double *b , MKL_INT *ldb , MKL_INT *info );

void cdttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex8
*d1 , MKL_Complex8 *d , MKL_Complex8 *du , MKL_Complex8 *b , MKL_INT *ldb , MKL_INT
*info );

void zdttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex16
*d1 , MKL_Complex16 *d , MKL_Complex16 *du , MKL_Complex16 *b , MKL_INT *ldb , MKL_INT
*info );

```

## Include Files

- mkl\_scalapack.h

## Description

The `ddttrsv` function solves one of the following systems of linear equations:

$$L * X = B, L^T * X = B, \text{ or } L^H * X = B,$$

$$U * X = B, U^T * X = B, \text{ or } U^H * X = B$$

with factors of the tridiagonal matrix  $A$  from the  $LU$  factorization computed by `dttrf`.

## Input Parameters

<code>uplo</code>	Specifies whether to solve with $L$ or $U$ .
<code>trans</code>	Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <code>trans</code> = 'N', then $A * X = B$ is solved for $X$ (no transpose). If <code>trans</code> = 'T', then $A^T * X = B$ is solved for $X$ (transpose). If <code>trans</code> = 'C', then $A^H * X = B$ is solved for $X$ (conjugate transpose).
<code>n</code>	The order of the matrix $A$ ( $n \geq 0$ ).
<code>nrhs</code>	The number of right-hand sides, that is, the number of columns in the matrix $B$ ( $nrhs \geq 0$ ).
<code>dl,d,du,b</code>	The array <code>dl</code> of size $(n - 1)$ contains the $(n - 1)$ multipliers that define the matrix $L$ from the $LU$ factorization of $A$ . The array <code>d</code> of size $n$ contains $n$ diagonal elements of the upper triangular matrix $U$ from the $LU$ factorization of $A$ . The array <code>du</code> of size $(n - 1)$ contains the $(n - 1)$ elements of the first super-diagonal of $U$ . On entry, the array <code>b</code> of size $ldb * nrhs$ contains the right-hand side of matrix $B$ .
<code>ldb</code>	The leading dimension of the array <code>b</code> ; $ldb \geq \max(1, n)$ .

## Output Parameters

<code>b</code>	Overwritten by the solution matrix $X$ .
<code>info</code>	If <code>info=0</code> , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

## ?pttrsv

*Solves a symmetric (Hermitian) positive-definite tridiagonal system of linear equations, using the  $L^*D^*L^H$  factorization computed by ?pttrf.*

## Syntax

```
void spttrsv (char *trans , MKL_INT *n , MKL_INT *nrhs , float *d , float *e , float
*b , MKL_INT *ldb , MKL_INT *info );
```

```
void dpttrsv (char *trans , MKL_INT *n , MKL_INT *nrhs , double *d , double *e , double
*b , MKL_INT *ldb , MKL_INT *info );
```

```
void cpttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , float *d ,
MKL_Complex8 *e , MKL_Complex8 *b , MKL_INT *ldb , MKL_INT *info );
```

```
void zpttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , double *d ,
MKL_Complex16 *e , MKL_Complex16 *b , MKL_INT *ldb , MKL_INT *info );
```

## Include Files

- mkl\_scalapack.h

## Description

The ?pttrsv function solves one of the triangular systems:

$L^T * X = B$ , or  $L * X = B$  for real flavors,

or

$L * X = B$ , or  $L^H * X = B$ ,

$U * X = B$ , or  $U^H * X = B$  for complex flavors,

where  $L$  (or  $U$  for complex flavors) is the Cholesky factor of a Hermitian positive-definite tridiagonal matrix  $A$  such that

$A = L^*D^*L^H$  (computed by [spttrf/dpttrf](#))

or

$A = U^H * D * U$  or  $A = L^*D^*L^H$  (computed by [cpttrf/zpttrf](#)).

## Input Parameters

*uplo*

Must be 'U' or 'L'.

Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix  $A$  is stored and the form of the factorization:

If *uplo* = 'U',  $e$  is the superdiagonal of  $U$ , and  $A = U^H * D * U$  or  $A = L^*D^*L^H$ ;

if *uplo* = 'L',  $e$  is the subdiagonal of  $L$ , and  $A = L^*D^*L^H$ .

The two forms are equivalent, if  $A$  is real.

<i>trans</i>	Specifies the form of the system of equations: for real flavors: if <i>trans</i> = 'N': $L^*X = B$ (no transpose) if <i>trans</i> = 'T': $L^T X = B$ (transpose) for complex flavors: if <i>trans</i> = 'N': $U^*X = B$ or $L^*X = B$ (no transpose) if <i>trans</i> = 'C': $U^H X = B$ or $L^H X = B$ (conjugate transpose).
<i>n</i>	The order of the tridiagonal matrix <i>A</i> . $n \geq 0$ .
<i>nrhs</i>	The number of right hand sides, that is, the number of columns of the matrix <i>B</i> . $nrhs \geq 0$ .
<i>d</i>	array of size <i>n</i> . The <i>n</i> diagonal elements of the diagonal matrix <i>D</i> from the factorization computed by <a href="#">?pttrf</a> .
<i>e</i>	array of size ( <i>n</i> -1). The ( <i>n</i> -1) off-diagonal elements of the unit bidiagonal factor <i>U</i> or <i>L</i> from the factorization computed by <a href="#">?pttrf</a> . See <i>uplo</i> .
<i>b</i>	array of size <i>ldb</i> * <i>nrhs</i> . On entry, the right hand side matrix <i>B</i> .
<i>ldb</i>	The leading dimension of the array <i>b</i> . $ldb \geq \max(1, n)$ .

## Output Parameters

<i>b</i>	On exit, the solution matrix <i>X</i> .
<i>info</i>	= 0: successful exit < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value.

## See Also

## ?steqr2

*Computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method.*

## Syntax

```
void ssteqr2 (char *compz , MKL_INT *n , float *d , float *e , float *z , MKL_INT *ldz ,
MKL_INT *nr , float *work , MKL_INT *info );
```

```
void dsteqr2 (char *compz , MKL_INT *n , double *d , double *e , double *z , MKL_INT
*ldz , MKL_INT *nr , double *work , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `?steqr2` function is a modified version of LAPACK function `?steqr`. The `?steqr2` function computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. `?steqr2` is modified from `?steqr` to allow each ScaLAPACK process running `?steqr2` to perform updates on a distributed matrix  $Q$ . Proper usage of `?steqr2` can be gleaned from examination of ScaLAPACK function `p?syev`.

## Input Parameters

<code>compz</code>	<p>Must be 'N' or 'I'.</p> <p>If <code>compz = 'N'</code>, the function computes eigenvalues only. If <code>compz = 'I'</code>, the function computes the eigenvalues and eigenvectors of the tridiagonal matrix <math>T</math>.</p> <p><math>z</math> must be initialized to the identity matrix by <code>p?laset</code> or <code>?laset</code> prior to entering this function.</p>
<code>n</code>	The order of the matrix $T$ ( $n \geq 0$ ).
<code>d, e, work</code>	<p>Arrays:</p> <p><math>d</math> contains the diagonal elements of <math>T</math>. The size of <math>d</math> must be at least <math>\max(1, n)</math>.</p> <p><math>e</math> contains the <math>(n-1)</math> subdiagonal elements of <math>T</math>. The size of <math>e</math> must be at least <math>\max(1, n-1)</math>.</p> <p><math>work</math> is a workspace array. The size of <math>work</math> is <math>\max(1, 2*n-2)</math>. If <code>compz = 'N'</code>, then <math>work</math> is not referenced.</p>
<code>z</code>	<p>(local)</p> <p>Array of global size <math>n * n</math> and of local size <math>ldz * nr</math>.</p> <p>If <code>compz = 'V'</code>, then <math>z</math> contains the orthogonal matrix used in the reduction to tridiagonal form.</p>
<code>ldz</code>	<p>The leading dimension of the array <math>z</math>. Constraints:</p> <p><math>ldz \geq 1</math>,</p> <p><math>ldz \geq \max(1, n)</math>, if eigenvectors are desired.</p>
<code>nr</code>	<p><math>nr = \max(1, \text{numroc}(n, nb, myprow, 0, nprocs))</math>.</p> <p>If <code>compz = 'N'</code>, then <math>nr</math> is not referenced.</p>

## Output Parameters

<code>d</code>	<p>On exit, the eigenvalues in ascending order, if <code>info = 0</code>.</p> <p>See also <code>info</code>.</p>
<code>e</code>	On exit, $e$ has been destroyed.
<code>z</code>	On exit, if <code>info = 0</code> , then,

if `compz = 'V'`, `z` contains the orthonormal eigenvectors of the original symmetric matrix, and if `compz = 'I'`, `z` contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If `compz = 'N'`, then `z` is not referenced.

`info`

`info = 0`, the exit is successful.

`info < 0`: if `info = -i`, the `i`-th had an illegal value.

`info > 0`: the algorithm has failed to find all the eigenvalues in a total of  $30n$  iterations;

if `info = i`, then `i` elements of `e` have not converged to zero; on exit, `d` and `e` contain the elements of a symmetric tridiagonal matrix, which is orthogonally similar to the original matrix.

## ?trmvt

*Performs matrix-vector operations.*

### Syntax

```
void strmvt (const char* uplo, const MKL_INT* n, const float* t, const MKL_INT* ldt,
float* x, const MKL_INT* incx, const float* y, const MKL_INT* incy, float* w, const
MKL_INT* incw, const float* z, const MKL_INT* incz);
```

```
void dtrmvt (const char* uplo, const MKL_INT* n, const double* t, const MKL_INT* ldt,
double* x, const MKL_INT* incx, const double* y, const MKL_INT* incy, double* w, const
MKL_INT* incw, const double* z, const MKL_INT* incz);
```

```
void ctrmvt (const char* uplo, const MKL_INT* n, const MKL_Complex8* t, const MKL_INT*
ldt, MKL_Complex8* x, const MKL_INT* incx, const MKL_Complex8* y, const MKL_INT* incy,
MKL_Complex8* w, const MKL_INT* incw, const MKL_Complex8* z, const MKL_INT* incz);
```

```
void ztrmvt (const char* uplo, const MKL_INT* n, const MKL_Complex16* t, const MKL_INT*
ldt, MKL_Complex16* x, const MKL_INT* incx, const MKL_Complex16* y, const MKL_INT*
incy, MKL_Complex16* w, const MKL_INT* incw, const MKL_Complex16* z, const MKL_INT*
incz);
```

### Include Files

- `mkl_scalapack.h`

### Description

?trmvt performs the matrix-vector operations as follows:

strmvt and dtrmvt:  $x := T^*y$ , and  $w := T^*z$

ctrmvt and ztrmvt:  $x := \text{conjg}(T^*)y$ , and  $w := T^*z$ ,

where `x` is an `n` element vector and `T` is an `n`-by-`n` upper or lower triangular matrix.

### Input Parameters

`uplo`

On entry, `uplo` specifies whether the matrix is an upper or lower triangular matrix as follows:

	<p><i>uplo</i> = 'U' or 'u'  <i>A</i> is an upper triangular matrix.</p> <p><i>uplo</i> = 'L' or 'l'  <i>A</i> is a lower triangular matrix.</p> <p>Unchanged on exit.</p>
<i>n</i>	<p>On entry, <i>n</i> specifies the order of the matrix <i>A</i>. <i>n</i> must be at least zero.</p> <p>Unchanged on exit.</p>
<i>t</i>	<p>Array of size ( <i>ldt</i>, <i>n</i> ).</p> <p>Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i>-by-<i>n</i> upper triangular part of the array <i>t</i> must contain the upper triangular matrix and the strictly lower triangular part of <i>t</i> is not referenced.</p> <p>Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i>-by-<i>n</i> lower triangular part of the array <i>t</i> must contain the lower triangular matrix and the strictly upper triangular part of <i>t</i> is not referenced.</p>
<i>lda</i>	<p>On entry, <i>lda</i> specifies the first dimension of <i>A</i> as declared in the calling (sub) program. <i>lda</i> must be at least max( 1, <i>n</i> ).</p> <p>Unchanged on exit.</p>
<i>incx</i>	<p>On entry, <i>incx</i> specifies the increment for the elements of <i>x</i>. <i>incx</i> must not be zero.</p> <p>Unchanged on exit.</p>
<i>y</i>	<p>Array of size at least ( 1 + ( <i>n</i> - 1 ) * abs( <i>incy</i> ) ).</p> <p>Before entry, the incremented array <i>y</i> must contain the <i>n</i> element vector <i>y</i>.</p> <p>Unchanged on exit.</p>
<i>incy</i>	<p>On entry, <i>incy</i> specifies the increment for the elements of <i>y</i>. <i>incy</i> must not be zero.</p> <p>Unchanged on exit.</p>
<i>incw</i>	<p>On entry, <i>incw</i> specifies the increment for the elements of <i>w</i>. <i>incw</i> must not be zero.</p> <p>Unchanged on exit.</p>
<i>z</i>	<p>Array of size at least ( 1 + ( <i>n</i> - 1 ) * abs( <i>incz</i> ) ).</p> <p>Before entry, the incremented array <i>z</i> must contain the <i>n</i> element vector <i>z</i>.</p> <p>Unchanged on exit.</p>
<i>incz</i>	<p>On entry, <i>incz</i> specifies the increment for the elements of <i>z</i>. <i>incz</i> must not be zero.</p> <p>Unchanged on exit.</p>

## Output Parameters

<i>t</i>	<p>Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i>-by-<i>n</i> upper triangular part of the array <i>t</i> must contain the upper triangular matrix and the strictly lower triangular part of <i>t</i> is not referenced.</p> <p>Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i>-by-<i>n</i> lower triangular part of the array <i>t</i> must contain the lower triangular matrix and the strictly upper triangular part of <i>t</i> is not referenced.</p>
<i>x</i>	<p>Array of size at least <math>(1 + (n - 1) * \text{abs}(incx))</math>.</p> <p>On exit, <math>x = T * y</math>.</p>
<i>w</i>	<p>Array of size at least <math>(1 + (n - 1) * \text{abs}(incw))</math>.</p> <p>On exit, <math>w = T * z</math>.</p>

## pilaenv

Returns the positive integer value of the logical blocking size.

---

### Syntax

```
MKL_INT pilaenv (const MKL_INT *ictxt , const char *prec);
```

### Include Files

- mkl\_pblas.h

### Description

*pilaenv* returns the positive integer value of the logical blocking size. This value is machine and precision specific. This version provides a logical blocking size which should give good though not optimal performance on many of the currently available distributed-memory concurrent computers. You are encouraged to modify this subroutine to set this tuning parameter for your particular machine.

### Input Parameters

<i>ictxt</i>	On entry, <i>ictxt</i> specifies the BLACS context handle, indicating the global context of the operation. The context itself is global, but the value of <i>ictxt</i> is local.
<i>prec</i>	<p>On input, <i>prec</i> specifies the precision for which the logical block size should be returned as follows:</p> <p><i>prec</i> = 'S' or 's' single precision real,</p> <p><i>prec</i> = 'D' or 'd' double precision real,</p> <p><i>prec</i> = 'C' or 'c' single precision complex,</p> <p><i>prec</i> = 'Z' or 'z' double precision complex,</p> <p><i>prec</i> = 'I' or 'i' integer.</p>

### Application Notes

Before modifying this routine to tune the library performance on your system, be aware of the following:

1. The value this function returns must be strictly larger than zero,

2. If you are planning to link your program with different instances of the library (for example, on a heterogeneous machine), you *must* compile each instance of the library with exactly the same version of this routine for obvious interoperability reasons.

## pilaenvx

Called from the ScaLAPACK routines to choose problem-dependent parameters for the local environment.

### Syntax

```
MKL_INT pilaenvx (const MKL_INT* ictxt, const MKL_INT* ispec, const char* name, const
char* opts, const MKL_INT* n1, const MKL_INT* n2, const MKL_INT* n3, const MKL_INT*
```

### Include Files

- mkl.h

### Description

`pilaenvx` is called from the ScaLAPACK routines to choose problem-dependent parameters for the local environment. See `ispec` for a description of the parameters. This version provides a set of parameters which should give good, though not optimal, performance on many of the currently available computers. You are encouraged to modify this subroutine to set the tuning parameters for your particular machine using the option and problem size information in the arguments.

### Input Parameters

<code>ictxt</code>	(local input) On entry, <code>ictxt</code> specifies the BLACS context handle, indicating the global context of the operation. The context itself is global, but the value of <code>ictxt</code> is local.
<code>ispec</code>	(global input) Specifies the parameter to be returned as the value of <code>pilaenvx</code> . = 1: the optimal blocksize; if this value is 1, an unblocked algorithm will give the best performance (unlikely). = 2: the minimum block size for which the block routine should be used; if the usable block size is less than this value, an unblocked routine should be used. = 3: the crossover point (in a block routine, for $N$ less than this value, an unblocked routine should be used). = 4: the number of shifts, used in the nonsymmetric eigenvalue routines (DEPRECATED). = 5: the minimum column dimension for blocking to be used; rectangular blocks must have dimension at least $k$ by $m$ , where $k$ is given by <code>pilaenvx(2, ...)</code> and $m$ by <code>pilaenvx(5, ...)</code> . = 6: the crossover point for the SVD (when reducing an $m$ by $n$ matrix to bidiagonal form, if $\max(m,n)/\min(m,n)$ exceeds this value, a QR factorization is used first to reduce the matrix to a triangular form). = 7: the number of processors. = 8: the crossover point for the multishift QR method for nonsymmetric eigenvalue problems (DEPRECATED).

= 9: maximum size of the subproblems at the bottom of the computation tree in the divide-and-conquer algorithm (used by `?ge1sd` and `?gesdd`).

=10: IEEE NaN arithmetic can be trusted not to trap.

=11: infinity arithmetic can be trusted not to trap.

12 <= *ispec* <= 16:

`p?hseqr` or one of its subroutines, see `piparmq` for detailed explanation.

17 <= *ispec* <= 22:

Parameters for `pb?trord/p?hseqr` (not all), as follows:

=17: maximum number of concurrent computational windows;

=18: number of eigenvalues/bulges in each window;

=19: computational window size;

=20: minimal percentage of FLOPS required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations;

=21: width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form;

=22: the maximum number of eigenvalues moved together over a process border;

=23: the number of processors involved in Aggressive Early Deflation (AED);

=99: Maximum iteration chunksize in OpenMP parallelization.

<i>name</i>	(global input) The name of the calling subroutine, in either upper case or lower case.
<i>opts</i>	(global input) The character options to the subroutine name, concatenated into a single character string. For example, <i>uplo</i> = 'U', <i>trans</i> = 'T', and <i>diag</i> = 'N' for a triangular routine would be specified as <i>opts</i> = 'UTN'.
<i>n1, n2, n3, and n4</i>	(global input) Problem dimensions for the subroutine name; these may not all be required.

## Output Parameters

<i>result</i>	(global output) >= 0: the value of the parameter specified by <i>ispec</i> . < 0: if <code>pilaenvx</code> = - <i>k</i> , the <i>k</i> -th argument had an illegal value.
---------------	---

## Application Notes

The following conventions have been used when calling `ilaenv` from the LAPACK routines:

- opts* is a concatenation of all of the character options to subroutine name, in the same order that they appear in the argument list for name, even if they are not used in determining the value of the parameter specified by *ispec*.

2. The problem dimensions  $n_1$ ,  $n_2$ ,  $n_3$ , and  $n_4$  are specified in the order that they appear in the argument list for *name*.  $n_1$  is used first,  $n_2$  second, and so on, and unused problem dimensions are passed a value of -1.
3. The parameter value returned by `ilaenv` is checked for validity in the calling subroutine. For example, `ilaenv` is used to retrieve the optimal block size for `strtri` as follows:

```
NB = ilaenv( 1, 'STRTRI', UPLO // DIAG, N, -1, -1, -1 );
if( NB<=1 ) {
    NB = MAX( 1, N );
}
```

The same conventions hold for this ScaLAPACK-style variant.

## pjlaenv

*Called from the ScaLAPACK symmetric and Hermitian tailored eigen-routines to choose problem-dependent parameters for the local environment.*

### Syntax

```
MKL_INT pjlaenv (const MKL_INT* ictxt, const MKL_INT* ispec, const char* name, const
char* opts, const MKL_INT* n1, const MKL_INT* n2, const MKL_INT* n3, const MKL_INT*
n4);
```

### Include Files

- `mkl.h`

### Description

`pjlaenv` is called from the ScaLAPACK symmetric and Hermitian tailored eigen-routines to choose problem-dependent parameters for the local environment. See *ispec* for a description of the parameters. This version provides a set of parameters which should give good, though not optimal, performance on many of the currently available computers. You are encouraged to modify this subroutine to set the tuning parameters for your particular machine using the option and problem size information in the arguments.

### Input Parameters

<i>ispec</i>	(global input) Specifies the parameter to be returned as the value of <code>pjlaenv</code> . = 1: the data layout blocksize; = 2: the panel blocking factor; = 3: the algorithmic blocking factor; = 4: execution path control; = 5: maximum size for direct call to the LAPACK routine.
<i>name</i>	(global input) The name of the calling subroutine, in either upper case or lower case.
<i>opts</i>	(global input) The character options to the subroutine name, concatenated into a single character string. For example, <i>uplo</i> = 'U', <i>trans</i> = 'T', and <i>diag</i> = 'N' for a triangular routine would be specified as <i>opts</i> = 'UTN'.

*n1, n2, n3, and n4*

(global input) Problem dimensions for the subroutine name; these may not all be required. At present, only *n1* is used, and it (*n1*) is used only for 'TTRD'.

## Output Parameters

*result*

(global or local output)

$\geq 0$ : the value of the parameter specified by *ispec*.

$< 0$ : if *pjlaenv* =  $-k$ , the  $k$ -th argument had an illegal value. Most parameters set via a call to *pjlaenv* must be identical on all processors and hence *pjlaenv* will return the same value to all procesors (i.e. global output). However some, in particular, the panel blocking factor can be different on each processor and hence *pjlaenv* can return different values on different processors (i.e. local output).

## Application Notes

The following conventions have been used when calling *pjlaenv* from the ScaLAPACK routines:

1. *opts* is a concatenation of all of the character options to subroutine name, in the same order that they appear in the argument list for name, even if they are not used in determining the value of the parameter specified by *ispec*.
2. The problem dimensions *n1, n2, n3, and n4* are specified in the order that they appear in the argument list for name. *n1* is used first, *n2* second, and so on, and unused problem dimensions are passed a value of -1.
  - a. The parameter value returned by *pjlaenv* is checked for validity in the calling subroutine. For example, *pjlaenv* is used to retrieve the optimal blocksize for STRTRI as follows:

```
NB = pjlaenv( 1, 'STRTRI', UPLO // DIAG, N, -1, -1, -1 );
IF( NB>=1 ) {
  NB = MAX( 1, N );
}
```

*pjlaenv* is patterned after *ilaenv* and keeps the same interface in anticipation of future needs, even though *pjlaenv* is only sparsely used at present in ScaLAPACK. Most ScaLAPACK codes use the input data layout blocking factor as the algorithmic blocking factor - hence there is no need or opportunity to set the algorithmic or data decomposition blocking factor. *pXYTevx.f* and *pXYTgvx.f* and *pXYTtrd.f* are the only codes which call *pjlaenv*. *pXYTevx.f* and *pXYTgvx.f* redistribute the data to the best data layout for each transformation. *pXYTtrd.f* uses a data layout blocking factor of 1.

## Additional ScaLAPACK Routines

## ScaLAPACK Utility Functions and Routines

This section describes ScaLAPACK utility functions and routines. Summary information about these routines is given in the following table:

### ScaLAPACK Utility Functions and Routines

Routine Name	Data Types	Description
<a href="#">p?labad</a>	s,d	Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.
<a href="#">p?lachIEEE</a>	s,d	Performs a simple check for the features of the IEEE standard.
<a href="#">p?lamch</a>	s,d	Determines machine parameters for floating-point arithmetic.
<a href="#">p?lasnbt</a>	s,d	Computes the position of the sign bit of a floating-point number.
<a href="#">descinit</a>	N/A	Initializes the array descriptor for distributed matrix.

Routine Name	Data Types	Description
<code>numroc</code>	N/A	Computes the number of rows or columns of a distributed matrix owned by the process.

## See Also

`pxerbla` Error handling routine called by ScaLAPACK routines.

## p?labad

Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.

## Syntax

```
void pslabad (MKL_INT *ictxt , float *small , float *large );
void pdlabad (MKL_INT *ictxt , double *small , double *large );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?labad` function takes as input the values computed by `p?lamch` for underflow and overflow, and returns the square root of each of these values if the log of *large* is sufficiently large. This function is intended to identify machines with a large exponent range, such as the Crays, and redefine the underflow and overflow limits to be the square roots of the values computed by `p?lamch`. This function is needed because `p?lamch` does not compensate for poor arithmetic in the upper half of the exponent range, as is found on a Cray.

In addition, this function performs a global minimization and maximization on these values, to support heterogeneous computing networks.

## Input Parameters

<i>ictxt</i>	(global) The BLACS context handle in which the computation takes place.
<i>small</i>	(local). On entry, the underflow threshold as computed by <code>p?lamch</code> .
<i>large</i>	(local). On entry, the overflow threshold as computed by <code>p?lamch</code> .

## Output Parameters

<i>small</i>	(local). On exit, if $\log_{10}(\textit{large})$ is sufficiently large, the square root of <i>small</i> , otherwise unchanged.
<i>large</i>	(local). On exit, if $\log_{10}(\textit{large})$ is sufficiently large, the square root of <i>large</i> , otherwise unchanged.

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## p?lachskeeee

*Performs a simple check for the features of the IEEE standard.*

---

## Syntax

```
void pslachskeeee (MKL_INT *isieeee , float *rmax , float *rmin );
```

```
void pdlachskeeee (MKL_INT *isieeee , float *rmax , float *rmin );
```

## Include Files

- mkl\_scalapack.h

## Description

The p?lachskeeee function performs a simple check to make sure that the features of the IEEE standard are implemented. In some implementations, p?lachskeeee may not return.

This is a ScaLAPACK internal function and arguments are not checked for unreasonable values.

## Input Parameters

<i>rmax</i>	(local). The overflow threshold (= ?lamch ('O')).
<i>rmin</i>	(local). The underflow threshold (= ?lamch ('U')).

## Output Parameters

<i>isieeee</i>	(local). On exit, <i>isieeee</i> = 1 implies that all the features of the IEEE standard that we rely on are implemented. On exit, <i>isieeee</i> = 0 implies that some the features of the IEEE standard that we rely on are missing.
----------------	--

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## p?lamch

*Determines machine parameters for floating-point arithmetic.*

---

## Syntax

```
float pslamch (MKL_INT *ictxt , char *cmach );
```

```
double pdlamch (MKL_INT *ictxt , char *cmach );
```

## Include Files

- mkl\_scalapack.h

## Description

The p?lamch function determines single precision machine parameters.

## Input Parameters

*ictxt* (global). The BLACS context handle in which the computation takes place.

*cmach* (global)  
Specifies the value to be returned by `p?lamch`:

- = 'E' or 'e', `p?lamch := eps`
- = 'S' or 's', `p?lamch := sfmin`
- = 'B' or 'b', `p?lamch := base`
- = 'P' or 'p', `p?lamch := eps*base`
- = 'N' or 'n', `p?lamch := t`
- = 'R' or 'r', `p?lamch := rnd`
- = 'M' or 'm', `p?lamch := emin`
- = 'U' or 'u', `p?lamch := rmin`
- = 'L' or 'l', `p?lamch := emax`
- = 'O' or 'o', `p?lamch := rmax`,

where

- `eps` = relative machine precision
- `sfmin` = safe minimum, such that  $1/\text{sfmin}$  does not overflow
- `base` = base of the machine
- `prec` =  $\text{eps} * \text{base}$
- `t` = number of (base) digits in the mantissa
- `rnd` = 1.0 when rounding occurs in addition, 0.0 otherwise
- `emin` = minimum exponent before (gradual) underflow
- `rmin` = underflow threshold -  $\text{base}^{(\text{emin}-1)}$
- `emax` = largest exponent before overflow
- `rmax` = overflow threshold -  $(\text{base}^{\text{emax}}) * (1 - \text{eps})$

## Output Parameters

*val* Value returned by the function.

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## `p?lasnbt`

*Computes the position of the sign bit of a floating-point number.*

---

## Syntax

```
void pslasnb (MKL_INT *ieflag );
void pdlasnb (MKL_INT *ieflag );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?lasnbt` function finds the position of the signbit of a single/double precision floating point number. This function assumes IEEE arithmetic, and hence, tests only the 32-nd bit (for single precision) or 32-nd and 64-th bits (for double precision) as a possibility for the signbit. `sizeof(int)` is assumed equal to 4 bytes.

If a compile time flag (`NO_IEEE`) indicates that the machine does not have IEEE arithmetic, `ieflag = 0` is returned.

## Output Parameters

`ieflag` This flag indicates the position of the signbit of any single/double precision floating point number.

`ieflag = 0`, if the compile time flag `NO_IEEE` indicates that the machine does not have IEEE arithmetic, or if `sizeof(int)` is different from 4 bytes.

`ieflag = 1` indicates that the signbit is the 32-nd bit for a single precision function.

In the case of a double precision function:

`ieflag = 1` indicates that the signbit is the 32-nd bit (Big Endian).

`ieflag = 2` indicates that the signbit is the 64-th bit (Little Endian).

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## `descinit`

Initializes the array descriptor for distributed matrix.

## Syntax

```
void descinit (MKL_INT *desc, const MKL_INT *m, const MKL_INT *n, const MKL_INT *mb,
const MKL_INT *nb, const MKL_INT *irsrc, const MKL_INT *icsrc, const MKL_INT *ictxt,
const MKL_INT *lld, MKL_INT *info);
```

## Description

The `descinit` function initializes the array descriptor for distributed matrix.

## Input Parameters

<code>desc</code>	(global) array of dimension <code>DLEN_</code> . The array descriptor of a distributed matrix to be set.
<code>m</code>	(global input) The number of rows in the distributed matrix. $M \geq 0$ .
<code>n</code>	(global input) The number of columns in the distributed matrix. $N \geq 0$ .
<code>mb</code>	(global input) The blocking factor used to distribute the rows of the matrix. $MB \geq 1$ .
<code>nb</code>	(global input) The blocking factor used to distribute the columns of the matrix. $NB \geq 1$ .

<i>lrsrc</i>	(global input) The process row over which the first row of the matrix is distributed. $0 \leq \text{IRSRC} < \text{NPROW}$ .
<i>lcsrc</i>	(global input) The process column over which the first column of the matrix is distributed. $0 \leq \text{ICSRC} < \text{NPCOL}$ .
<i>ictxt</i>	(global input) The BLACS context handle, indicating the global context of the operation on the matrix. The context itself is global.
<i>lld</i>	(local input) The leading dimension of the local array storing the local blocks of the distributed matrix. $\text{LLD} \geq \text{MAX}(1, \text{LOCr}(M))$ . $\text{LOCr}()$ denotes the number of rows of a global dense matrix that the process in a grid receives after data distributing.

## Output Parameters

<i>info</i>	(output) = 0: successful exit < 0: if $\text{INFO} = -i$ , the $i$ -th argument had an illegal value
-------------	--

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## numroc

*Computes the number of rows or columns of a distributed matrix owned by the process.*

## Syntax

```
MKL_INT numroc (const MKL_INT *n, const MKL_INT *nb, const MKL_INT *iproc, const
MKL_INT *srcproc, const MKL_INT *nprocs);
```

## Description

The `numroc` function computes the number of rows or columns of a distributed matrix owned by the process.

## Input Parameters

<i>n</i>	(global input) The number of rows/columns in distributed matrix.
<i>nb</i>	(global input) Block size, size of the blocks the distributed matrix is split into.
<i>iproc</i>	(local input) The coordinate of the process whose local array row or column is to be determined.
<i>srcproc</i>	(global input) The coordinate of the process that possesses the first row or column of the distributed matrix.
<i>nprocs</i>	(global input) The total number processes over which the matrix is distributed.

## Output Parameters

<i>info</i>	(output) Value returned by the function.
-------------	--

*ictxt );

void pzgemr2d (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb ,
MKL_INT *ictxt );

void pigemr2d (MKL_INT *m , MKL_INT *n , MKL_INT *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , MKL_INT
*ictxt );
```

### Include Files

- `mkl_scalapack.h`

### Description

The `p?gemr2d` function copies the indicated matrix or submatrix of  $A$  to the indicated matrix or submatrix of  $B$ . It provides a truly general copy from any block cyclicly-distributed matrix or submatrix to any other block cyclicly-distributed matrix or submatrix. With `p?trmr2d`, these functions are the only ones in the ScaLAPACK library which provide inter-context operations: they can take a matrix or submatrix  $A$  in context  $A$  (distributed over process grid  $A$ ) and copy it to a matrix or submatrix  $B$  in context  $B$  (distributed over process grid  $B$ ).

There does not need to be a relationship between the two operand matrices or submatrices other than their global size and the fact that they are both legal block cyclicly-distributed matrices or submatrices. This means that they can, for example, be distributed across different process grids, have varying block sizes and differing matrix starting points, or be contained in different sized distributed matrices.

Take care when context  $A$  is disjoint from context  $B$ . The general rules for which parameters need to be set are:

- All calling processes must have the correct  $m$  and  $n$ .
- Processes in context  $A$  must correctly define all parameters describing  $A$ .
- Processes in context  $B$  must correctly define all parameters describing  $B$ .
- Processes which are not members of context  $A$  must pass  $ctxt\_a = -1$  and need not set other parameters describing  $A$ .
- Processes which are not members of context  $B$  must pass  $ctxt\_b = -1$  and need not set other parameters describing  $B$ .

Because of its generality, `p?gemr2d` can be used for many operations not usually associated with copy functions. For instance, it can be used to take a matrix on one process and distribute it across a process grid, or the reverse. If a supercomputer is grouped into a virtual parallel machine with a workstation, for instance, this function can be used to move the matrix from the workstation to the supercomputer and back. In ScaLAPACK, it is called to copy matrices from a two-dimensional process grid to a one-dimensional process grid. It can be used to redistribute matrices so that distributions providing maximal performance can be used by various component libraries, as well.

Note that this function requires an array descriptor with  $dtype_ = 1$ .

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

$m$	(global) The number of rows of matrix $A$ to be copied ( $m \geq 0$ ).
$n$	(global) The number of columns of matrix $A$ to be copied ( $n \geq 0$ ).
$a$	(local) Pointer into the local memory to array of size $lld\_a * LOCC(ja+n-1)$ containing the source matrix $A$ .
$ia, ja$	(global) The row and column indices in the array $A$ indicating the first row and the first column, respectively, of the submatrix of $A$ to copy. $1 \leq ia \leq total\_rows\_in\_a - m + 1, 1 \leq ja \leq total\_columns\_in\_a - n + 1$ .
$desca$	(global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $A$ . Only $dtype\_a = 1$ is supported, so $dlen_ = 9$ . If the calling process is not part of the context of $A$ , $ctxt\_a$ must be equal to -1.
$ib, jb$	(global) The row and column indices in the array $B$ indicating the first row and the first column, respectively, of the submatrix $B$ to which to copy the matrix. $1 \leq ib \leq total\_rows\_in\_b - m + 1, 1 \leq jb \leq total\_columns\_in\_b - n + 1$ .
$descb$	(global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $B$ . Only $dtype\_b = 1$ is supported, so $dlen_ = 9$ .

If the calling process is not part of the context of  $B$ ,  $ctxt_b$  must be equal to -1.

$ictxt$

(global).

The context encompassing at least the union of all processes in context  $A$  and context  $B$ . All processes in the context  $ictxt$  must call this function, even if they do not own a piece of either matrix.

## Output Parameters

$b$

Pointer into the local memory to array of size  $lld_b * LOCC(jb+n-1)$ .

Overwritten by the submatrix from  $A$ .

## Include Files

- `mkl_scalapack.h`

## Description

The `p?trmr2d` function copies the indicated matrix or submatrix of  $A$  to the indicated matrix or submatrix of  $B$ . It provides a truly general copy from any block cyclicly-distributed matrix or submatrix to any other block cyclicly-distributed matrix or submatrix. With `p?gemr2d`, these functions are the only ones in the ScaLAPACK library which provide inter-context operations: they can take a matrix or submatrix  $A$  in context  $A$  (distributed over process grid  $A$ ) and copy it to a matrix or submatrix  $B$  in context  $B$  (distributed over process grid  $B$ ).

The `p?trmr2d` function assumes the matrix or submatrix to be trapezoidal. Only the upper or lower part is copied, and the other part is unchanged.

There does not need to be a relationship between the two operand matrices or submatrices other than their global size and the fact that they are both legal block cyclicly-distributed matrices or submatrices. This means that they can, for example, be distributed across different process grids, have varying block sizes and differing matrix starting points, or be contained in different sized distributed matrices.

Take care when context *A* is disjoint from context *B*. The general rules for which parameters need to be set are:

- All calling processes must have the correct *m* and *n*.
- Processes in context *A* must correctly define all parameters describing *A*.
- Processes in context *B* must correctly define all parameters describing *B*.
- Processes which are not members of context *A* must pass *ctxt\_a* = -1 and need not set other parameters describing *A*.
- Processes which are not members of context *B* must pass *ctxt\_b* = -1 and need not set other parameters describing *B*.

Because of its generality, `p?trmr2d` can be used for many operations not usually associated with copy functions. For instance, it can be used to take a matrix on one process and distribute it across a process grid, or the reverse. If a supercomputer is grouped into a virtual parallel machine with a workstation, for instance, this function can be used to move the matrix from the workstation to the supercomputer and back. In ScaLAPACK, it is called to copy matrices from a two-dimensional process grid to a one-dimensional process grid. It can be used to redistribute matrices so that distributions providing maximal performance can be used by various component libraries, as well.

Note that this function requires an array descriptor with *dtype\_* = 1.

Notice revision #20201201

#### Input Parameters

<i>uplo</i>	(global) Specifies whether to copy the upper or lower part of the matrix or submatrix.
	<i>uplo</i> = 'U' Copy the upper triangular part.
	<i>uplo</i> = 'L' Copy the lower triangular part.
<i>diag</i>	(global) Specifies whether to copy the diagonal of the matrix or submatrix.
	<i>diag</i> = 'U' Do not copy the diagonal.
	<i>diag</i> = 'N' Copy the diagonal.
<i>m</i>	(global) The number of rows of matrix <i>A</i> to be copied ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns of matrix <i>A</i> to be copied ( $n \geq 0$ ).
<i>a</i>	(local) Pointer into the local memory to array of size $lld\_a * LOcc(ja+n-1)$ containing the source matrix <i>A</i> .
<i>ia, ja</i>	(global) The row and column indices in the array <i>A</i> indicating the first row and the first column, respectively, of the submatrix of <i>A</i> to copy. $1 \leq ia \leq total\_rows\_in\_a - m + 1, 1 \leq ja \leq total\_columns\_in\_a - n + 1$ .

<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . Only <i>dtype_a</i> = 1 is supported, so <i>dlen_</i> = 9. If the calling process is not part of the context of <i>A</i> , <i>ctxt_a</i> must be equal to -1.
<i>ib, jb</i>	(global) The row and column indices in the array <i>B</i> indicating the first row and the first column, respectively, of the submatrix <i>B</i> to which to copy the matrix. $1 \leq ib \leq total\_rows\_in\_b - m + 1$ , $1 \leq jb \leq total\_columns\_in\_b - n + 1$ .
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> . Only <i>dtype_b</i> = 1 is supported, so <i>dlen_</i> = 9. If the calling process is not part of the context of <i>B</i> , <i>ctxt_b</i> must be equal to -1.
<i>ictxt</i>	(global). The context encompassing at least the union of all processes in context <i>A</i> and context <i>B</i> . All processes in the context <i>ictxt</i> must call this function, even if they do not own a piece of either matrix.

## Output Parameters

<i>b</i>	Pointer into the local memory to array of size $lld\_b * LOcc(jb+n-1)$ . Overwritten by the submatrix from <i>A</i> .

## Sparse Solver Routines

Intel® oneAPI Math Kernel Library (oneMKL) sparse solver algorithms for solving real or complex, symmetric, structurally symmetric or nonsymmetric, positive definite, indefinite or Hermitian square sparse linear system of algebraic equations.

The terms and concepts required to understand the use of the Intel® oneAPI Math Kernel Library (oneMKL) sparse solver routines are discussed in the [Appendix "Linear Solvers Basics"](#). If you are familiar with linear sparse solvers and sparse matrix storage schemes, you can skip these sections and go directly to the interface descriptions.

See the description of

- the direct sparse solver based on PARDISO\*, which is referred to here as [Intel MKL PARDISO](#);
- the alternative interface for the direct sparse solver, which is referred to here as the [DSS interface](#);
- [iterative sparse solvers \(ISS\)](#) based on the reverse communication interface (RCI);
- [preconditioners](#) based on the incomplete LU factorization technique.
- a direct sparse [solver](#) based on QR decomposition.

## oneMKL PARDISO - Parallel Direct Sparse Solver Interface

This section describes the interface to the shared-memory multiprocessing parallel direct sparse solver known as the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver.

The Intel® oneAPI Math Kernel Library (oneMKL) PARDISO package is a high-performance, robust, memory efficient, and easy to use software package for solving large sparse linear systems of equations on shared memory multiprocessors. The solver uses a combination of left- and right-looking Level-3 BLAS supernode

techniques [Schenk00-2]. To improve sequential and parallel sparse numerical factorization performance, the algorithms are based on a Level-3 BLAS update and pipelining parallelism is used with a combination of left- and right-looking supernode techniques [Schenk00, Schenk01, Schenk02, Schenk03]. The parallel pivoting methods allow complete supernode pivoting to compromise numerical stability and scalability during the factorization process. For sufficiently large problem sizes, numerical experiments demonstrate that the scalability of the parallel algorithm is nearly independent of the shared-memory multiprocessing architecture.

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

The following table lists the names of the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO routines and describes their general use.

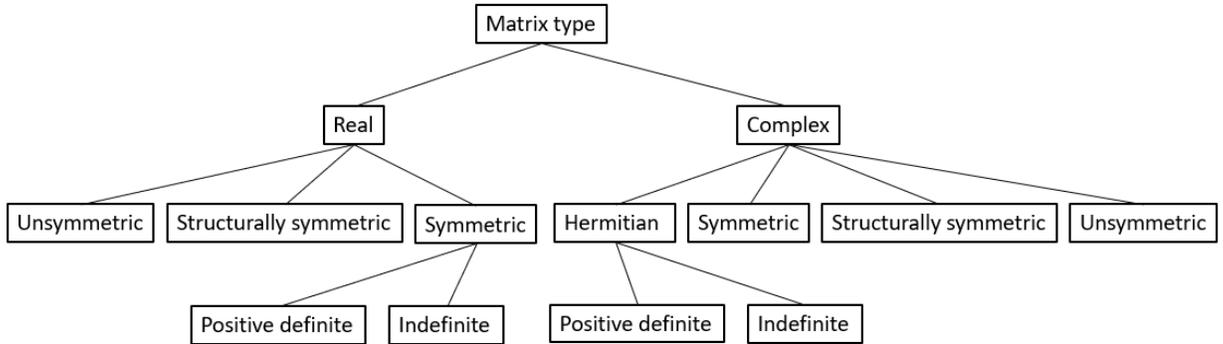

### oneMKL PARDISO Routines

Routine	Description
<code>pardisoinit</code>	Initializes Intel® oneAPI Math Kernel Library (oneMKL) PARDISO with default parameters depending on the matrix type.
<code>pardiso</code>	Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.
<code>pardiso_64</code>	Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides, 64-bit integer version.
<code>mkl_pardiso_pivot</code>	Replaces routine which handles Intel® oneAPI Math Kernel Library (oneMKL) PARDISO pivots with user-defined routine.
<code>pardiso_getdiag</code>	Returns diagonal elements of initial and factorized matrix.
<code>pardiso_export</code>	Places pointers dedicated for sparse representation of requested matrix into MKL PARDISO.
<code>pardiso_handle_store</code>	Store internal structures from <code>pardiso</code> to a file.
<code>pardiso_handle_restore</code>	Restore <code>pardiso</code> internal structures from a file.
<code>pardiso_handle_delete</code>	Delete files with <code>pardiso</code> internal structure data.
<code>pardiso_handle_store_64</code>	Store internal structures from <code>pardiso_64</code> to a file.
<code>pardiso_handle_restore_64</code>	Restore <code>pardiso_64</code> internal structures from a file.
<code>pardiso_handle_delete_64</code>	Delete files with <code>pardiso_64</code> internal structure data.

The Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver supports a wide range of real and complex sparse matrix types (see [the figure](#) below).

[\\_\\_border\\_\\_top](#)

## Sparse Matrices That Can Be Solved with the oneMKL PARDISO Solver

The Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver performs four tasks:

- analysis and symbolic factorization
- numerical factorization
- forward and backward substitution including iterative refinement
- termination to release all internal solver memory.

To find code examples that use Intel® oneAPI Math Kernel Library (oneMKL) PARDISO routines to solve systems of linear equations, unzip theC archive file in the `examples` folder of the Intel® oneAPI Math Kernel Library (oneMKL) installation directory. Code examples will be in the `examples/solverc/source` folder.

### Supported Matrix Types

The analysis steps performed by Intel® oneAPI Math Kernel Library (oneMKL) PARDISO depend on the structure of the input matrix  $A$ .

#### Symmetric Matrices

The solver first computes a symmetric fill-in reducing permutation  $P$  based on either the minimum degree algorithm [Liu85] or the nested dissection algorithm from the METIS package [Karypis98] (both included with Intel® oneAPI Math Kernel Library (oneMKL)), followed by the parallel left-right looking numerical Cholesky factorization [Schenk00-2] of  $PAP^T = LL^T$  for symmetric positive-definite matrices, or  $PAP^T = LDL^T$  for symmetric indefinite matrices. The solver uses diagonal pivoting, or 1x1 and 2x2 Bunch-Kaufman pivoting for symmetric indefinite matrices. An approximation of  $X$  is found by forward and backward substitution and optional iterative refinement.

Whenever numerically acceptable 1x1 and 2x2 pivots cannot be found within the diagonal supernode block, the coefficient matrix is perturbed. One or two passes of iterative refinement may be required to correct the effect of the perturbations. This restricting notion of pivoting with iterative refinement is effective for highly indefinite symmetric systems. Furthermore, for a large set of matrices from different applications areas, this method is as accurate as a direct factorization method that uses complete sparse pivoting techniques [Schenk04].

Another method of improving the pivoting accuracy is to use symmetric weighted matching algorithms. These algorithms identify large entries in the coefficient matrix  $A$  that, if permuted close to the diagonal, permit the factorization process

to identify more acceptable pivots and proceed with fewer pivot perturbations. These algorithms are based on maximum weighted matchings and improve the quality of the factor in a complementary way to the alternative of using more complete pivoting techniques.

The inertia is also computed for real symmetric indefinite matrices.

#### Structurally Symmetric Matrices

The solver first computes a symmetric fill-in reducing permutation  $P$  followed by the parallel numerical factorization of  $PAP^T = QLU^T$ . The solver uses partial pivoting in the supernodes and an approximation of  $X$  is found by forward and backward substitution and optional iterative refinement.

#### Nonsymmetric Matrices

The solver first computes a nonsymmetric permutation  $P_{MPS}$  and scaling matrices  $D_r$  and  $D_c$  with the aim of placing large entries on the diagonal to enhance reliability of the numerical factorization process [Duff99]. In the next step the solver computes a fill-in reducing permutation  $P$  based on the matrix  $P_{MPS}A + (P_{MPS}A)^T$  followed by the parallel numerical factorization

$$QLUR = PP_{MPS}D_rAD_cP$$

with supernode pivoting matrices  $Q$  and  $R$ . When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99]. The magnitude of the potential pivot is tested against a constant threshold of

$$\alpha = \text{eps} * ||A2||_{\text{inf}},$$

where  $\text{eps}$  is the machine precision,  $A2 = P * P_{MPS} * D_r * A * D_c * P$ , and  $||A2||_{\text{inf}}$  is the infinity norm of  $A$ . Any tiny pivots encountered during elimination are set to the sign  $(l_{II}) * \text{eps} * ||A2||_{\text{inf}}$ , which trades off some numerical stability for the ability to keep pivots from getting too small. Although many failures could render the factorization well-defined but essentially useless, in practice the diagonal elements are rarely modified for a large class of matrices. The result of this pivoting approach is that the factorization is, in general, not exact and iterative refinement may be needed.

## Sparse Data Storage

Intel® oneAPI Math Kernel Library (oneMKL) PARDISO stores sparse data in several formats:

- CSR3: The 3-array variation of the compressed sparse row format described in [Three Array Variation of CSR Format](#).
- BSR3: The three-array variation of the block compressed sparse row format described in [Three Array Variation of BSR Format](#). Use `iparm[36]` to specify the block size.
- VBSR: Variable BSR format. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO analyzes the matrix provided in CSR3 format and converts it into an internal structure which can improve performance for matrices with a block structure. Use `iparm[36] = -t` ( $0 < t \leq 100$ ) to specify use of internal VBSR format and to set the degree of similarity required to combine elements of the matrix. For example, if you set `iparm[36] = -80`, two rows of the input matrix are combined when their non-zero patterns are 80% or more similar.

**NOTE**

Intel® oneAPI Math Kernel Library (oneMKL) supports only the VBSR format for real and symmetric positive definite or indefinite matrices ( $mtype = 2$  or  $mtype = -2$ ).

Intel® oneAPI Math Kernel Library (oneMKL) supports these features for all matrix types as long as  $iparm[23] = 1$ :

- $iparm[30] > 0$ : Partial solution
- $iparm[35] > 0$ : Schur complement
- $iparm[59] > 0$ : OOC Intel® oneAPI Math Kernel Library (oneMKL) PARDISO

For all storage formats, the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO parameter  $ja$  is used for the  $columns$  array,  $ia$  is used for  $rowIndex$ , and  $a$  is used for  $values$ . The algorithms in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO require column indices  $ja$  to be in increasing order per row and that the diagonal element in each row be present for any structurally symmetric matrix. For symmetric or nonsymmetric matrices the diagonal elements which are equal to zero are not necessary.

**Caution**

Intel® oneAPI Math Kernel Library (oneMKL) PARDISO column indices  $ja$  must be in increasing order per row. You can validate the sparse matrix structure with the matrix checker ( $iparm[26]$ )

**NOTE**

While the presence of zero diagonal elements for symmetric matrices is not required, you should explicitly set zero diagonal elements for symmetric matrices. Otherwise, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO creates internal copies of arrays  $ia$ ,  $ja$ , and  $a$  full of diagonal elements, which require additional memory and computational time. However, the memory and time required the diagonal elements in internal arrays is usually not significant compared to the memory and the time required to factor and solve the matrix.

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

**Storage of Matrices**

By default, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO stores data in RAM. This is referred to as In-Core (IC) mode. However, you can specify that Intel® oneAPI Math Kernel Library (oneMKL) PARDISO store matrices on disk by setting  $iparm[59]$ . This mode is called the Out-of-Core (OOC) mode.

You can set the following parameters for the OOC mode.

Parameter/Environment Variable Name	Description
MKL_PARDISO_OOC_PATH	Directory for storing data created in the OOC mode.
MKL_PARDISO_OOC_FILE_NAME	Full file name (incl. path) which will be used for the OOC files

Parameter/Environment Variable Name	Description
MKL_PARDISO_OOC_MAX_CORE_SIZE	Maximum size of RAM (in megabytes) available for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO
MKL_PARDISO_OOC_MAX_SWAP_SIZE	Maximum swap size (in megabytes) available for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO
MKL_PARDISO_OOC_KEEP_FILE	A flag which determines whether temporary data files will be deleted or stored

By default, the current working directory is used in the OOC mode as a directory path for storing data. All work arrays will be stored in files named `ooc_temp` with different extensions. When `MKL_PARDISO_OOC_FILE_NAME` is not set and `MKL_PARDISO_OOC_PATH` is set, the names for the created files will contain `<path>/mkl_pardiso` or `<path>\mkl_pardiso` depending on the OS. Setting `MKL_PARDISO_OOC_FILE_NAME=<filename>` will override the path which could have been set in `MKL_PARDISO_OOC_PATH`. In this case `<filename>` will be used for naming the OOC files.

By default, `MKL_PARDISO_OOC_MAX_CORE_SIZE` is 2000 (MB) and `MKL_PARDISO_OOC_MAX_SWAP_SIZE` is 0.

---

#### NOTE

Do not set the sum of `MKL_PARDISO_OOC_MAX_CORE_SIZE` and `MKL_PARDISO_OOC_MAX_SWAP_SIZE` greater than the size of the RAM plus the size of the swap memory. Be sure to allow enough free memory for the operating system and any other processes which need to be running.

---

By default, all temporary data files will be deleted. For keeping them it is required to set `MKL_PARDISO_OOC_KEEP_FILE` to 0.

OOC parameters can be set in a configuration file. You can set the path to this file and its name using environmental variables `MKL_PARDISO_OOC_CFG_PATH` and `MKL_PARDISO_OOC_CFG_FILE_NAME`.

For setting parameters of OOC mode either environment variables or a configuration file can be used. When the last option is chosen, by default the name of the file is `pardiso_ooc.cfg` and it should be placed in the working directory. If needed, the user can set the path to the configuration file using environmental variables `MKL_PARDISO_OOC_CFG_PATH` and `MKL_PARDISO_OOC_CFG_FILE_NAME`. These variables specify the path and filename as follows:

- Linux\* OS and OS X\*: `<MKL_PARDISO_OOC_CFG_PATH>/ <MKL_PARDISO_OOC_CFG_FILE_NAME>`
- Windows\* OS: `<MKL_PARDISO_OOC_CFG_PATH>\<MKL_PARDISO_OOC_CFG_FILE_NAME>`

An example of the configuration file:

```
MKL_PARDISO_OOC_PATH = <path>
MKL_PARDISO_OOC_MAX_CORE_SIZE = N
MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

---

#### Caution

The maximum length of the path lines in the configuration files is 1000 characters.

---

Alternatively, the OOC parameters can be set as environment variables via command line.

For Linux\* OS and OS X\*:

```
export MKL_PARDISO_OOC_PATH = <path>
export MKL_PARDISO_OOC_MAX_CORE_SIZE = N
export MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
export MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

For Windows\* OS:

```
set MKL_PARDISO_OOC_PATH = <path>
set MKL_PARDISO_OOC_MAX_CORE_SIZE = N
set MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
set MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

where <path> should follow the OS naming convention.

## Direct-Iterative Preconditioning for Nonsymmetric Linear Systems

The solver uses a combination of direct and iterative methods [Sonn89] to accelerate the linear solution process for transient simulation. Most applications of sparse solvers require solutions of systems with gradually changing values of the nonzero coefficient matrix, but with an identical sparsity pattern. In these applications, the analysis phase of the solvers has to be performed only once and the numerical factorizations are the important time-consuming steps during the simulation. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses a numerical factorization and applies the factors in a preconditioned Krylov Subspace iteration. If the iteration does not converge, the solver automatically switches back to the numerical factorization. This method can be applied to nonsymmetric matrices in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. You can select the method using the `iparm[3]` input parameter. The `iparm[19]` parameter returns the error status after running Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.

## Single and Double Precision Computations

Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solves tasks using single or double precision. Each precision has its benefits and drawbacks. Double precision variables have more digits to store value, so the solver uses more memory for keeping data. But this mode solves matrices with better accuracy, which is especially important for input matrices with large condition numbers.

Single precision variables have fewer digits to store values, so the solver uses less memory than in the double precision mode. Additionally this mode usually takes less time. But as computations are made less precisely, only some systems of equations can be solved accurately enough using single precision.

## Separate Forward and Backward Substitution

The solver execution step (see `parameterphase = 33` below) can be divided into two or three separate substitutions: forward, backward, and possible diagonal. This separation can be explained by the examples of solving systems with different matrix types.

A real symmetric positive definite matrix  $A$  (`mtype = 2`) is factored by Intel® oneAPI Math Kernel Library (oneMKL) PARDISO as  $A = L^*L^T$ . In this case the solution of the system  $A^*x=b$  can be found as sequence of substitutions:  $L^*y=b$  (forward substitution, `phase = 331`) and  $L^T*x=y$  (backward substitution, `phase = 333`).

A real nonsymmetric matrix  $A$  (`mtype = 11`) is factored by Intel® oneAPI Math Kernel Library (oneMKL) PARDISO as  $A = L^*U$ . In this case the solution of the system  $A^*x=b$  can be found by the following sequence:  $L^*y=b$  (forward substitution, `phase = 331`) and  $U^*x=y$  (backward substitution, `phase = 333`).

Solving a system with a real symmetric indefinite matrix  $A$  (`mtype = -2`) is slightly different from the cases above. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO factors this matrix as  $A=LDL^T$ , and the solution of the system  $A^*x=b$  can be calculated as the following sequence of substitutions:  $L^*y=b$  (forward

substitution,  $phase = 331$ ),  $D^*v=y$  (diagonal substitution,  $phase = 332$ ), and finally  $L^T*x=v$  (backward substitution,  $phase = 333$ ). Diagonal substitution makes sense only for symmetric indefinite matrices ( $mtype = -2, -4, 6$ ). For matrices of other types a solution can be found as described in the first two examples.

---

**Caution**

The number of refinement steps ( $iparm[7]$ ) must be set to zero if a solution is calculated with separate substitutions ( $phase = 331, 332, 333$ ), otherwise Intel® oneAPI Math Kernel Library (oneMKL) PARDISO produces the wrong result.

---

---

**NOTE**

Different pivoting ( $iparm[20]$ ) produces different  $LDL^T$  factorization. Therefore results of forward, diagonal and backward substitutions with diagonal pivoting can differ from results of the same steps with Bunch-Kaufman pivoting. Of course, the final results of sequential execution of forward, diagonal and backward substitution are equal to the results of the full solving step ( $phase=33$ ) regardless of the pivoting used.

---

## Callback Function for Pivoting Control

In-core Intel® oneAPI Math Kernel Library (oneMKL) PARDISO allows you to control pivoting with a callback routine, `mkl_pardiso_pivot`. You can then use the `pardiso_getdiag` routine to access the diagonal elements. Set  $iparm[55]$  to 1 in order to use the callback functionality.

## Low Rank Update

Use low rank update to accelerate the factorization step in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO when you use multiple matrices with identical structure and similar values. After calling `pardiso` in the usual manner for factorization ( $phase = 12, 13, 22, \text{ or } 23$ ) for some matrix  $A1$ , low rank update can be applied to the factorization step ( $phase = 22 \text{ or } 23$ ) of some matrix  $A2$  with identical structure.

To use the low rank update feature, set  $iparm[38] = 1$  while also setting  $iparm[23] = 10$ . Additionally, supply an array that lists the values in  $A2$  that are different from  $A1$  using the `perm` parameter as outlined in the `pardiso perm` parameter description.

---

**Important**

Low rank update can only be called for matrices with the exact same pattern of nonzero values. As such, the value of the `mtype`, `ia`, `ja`, and  $iparm[23]$  parameters should also be identical. In general, the low rank factorization should be called with the same parameters as the preceding factorization step for the same internal data structure handle (except for array `a`,  $iparm[38]$ , and `perm`).

Low rank update does not currently support Intel TBB threading. In this case, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO defaults to full factorization instead.

Low rank update cannot be used in combination with a user-supplied permutation vector - in other words, you must use the default values of  $iparm[4] = 0$ ,  $iparm[30] = 0$ , and  $iparm[35] = 0$ . Additionally,  $iparm[3]$ ,  $iparm[5]$ ,  $iparm[27]$ ,  $iparm[36]$ ,  $iparm[55]$ , and  $iparm[59]$  must all be set to the default value of 0.

---

## `pardiso`

*Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.*

---

## Syntax

```
void pardiso (_MKL_DSS_HANDLE_t pt, const MKL_INT *maxfct, const MKL_INT *mnum, const
MKL_INT *mtype, const MKL_INT *phase, const MKL_INT *n, const void *a, const MKL_INT
*ia, const MKL_INT *ja, MKL_INT *perm, const MKL_INT *nrhs, MKL_INT *iparm, const
MKL_INT *msglvl, void *b, void *x, MKL_INT *error);
```

## Include Files

- mkl.h

## Description

The `pardiso` routine calculates the solution of a set of sparse linear equations

$$A \cdot X = B$$

with single or multiple right-hand sides, using a parallel *LU*, *LDL*, or *LL<sup>T</sup>* factorization, where *A* is an *n*-by-*n* matrix, and *X* and *B* are *n*-by-*nrhs* vectors or matrices.

### Notes

- This routine supports usage of the `mkl_progress` with OpenMP, TBB, and sequential threading. See [mkl\\_progress](#) for details. The case of `iparm[23]=10` does not support this feature.
- If `iparm[26]` is set to 1 (Matrix checker), Intel® oneAPI Math Kernel Library PARDISO uses the auxiliary routine `sparse_matrix_checker` to check integer arrays `ia` and `ja`. `sparse_matrix_checker` has its own set of error values (from 21 to 24) that are returned in the event of an unsuccessful matrix check. For more details, refer to the `sparse_matrix_checker` documentation.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

*pt* Array with size of 64.  
Handle to internal data structure. The entries must be set to zero prior to the first call to `pardiso`. Unique for factorization.

### Caution

After the first call to `pardiso` do not directly modify *pt*, as that could cause a serious memory leak.

Use the [pardiso\\_handle\\_store](#) or [pardiso\\_handle\\_store\\_64](#) routine to store the content of *pt* to a file. Restore the contents of *pt* from the file using [pardiso\\_handle\\_restore](#) or [pardiso\\_handle\\_restore\\_64](#). Use `pardiso_handle_store` and `pardiso_handle_restore` with `pardiso`, and `pardiso_handle_store_64` and `pardiso_handle_restore_64` with `pardiso_64`.

*maxfct* Maximum number of factors with identical sparsity structure that must be kept in memory at the same time. In most applications this value is equal to 1. It is possible to store several different factorizations with the same nonzero structure at the same time in the internal data structure management of the solver.

`pardiso` can process several matrices with an identical matrix sparsity pattern and it can store the factors of these matrices at the same time. Matrices with a different sparsity structure can be kept in memory with different memory address pointers *pt*.

*mnum* Indicates the actual matrix for the solution phase. With this scalar you can define which matrix to factorize. The value must be:  $1 \leq mnum \leq maxfct$ .

In most applications this value is 1.

*mtype* Defines the matrix type, which influences the pivoting method. The Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver supports the following matrices:

1	real and structurally symmetric
2	real and symmetric positive definite
-2	real and symmetric indefinite
3	complex and structurally symmetric
4	complex and Hermitian positive definite
-4	complex and Hermitian indefinite
6	complex and symmetric
11	real and nonsymmetric
13	complex and nonsymmetric

*phase* Controls the execution of the solver. Usually it is a two- or three-digit integer. The first digit indicates the starting phase of execution and the second digit indicates the ending phase. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO has the following phases of execution:

- Phase 1: Fill-reduction analysis and symbolic factorization
- Phase 2: Numerical factorization
- Phase 3: Forward and Backward solve including optional iterative refinement

This phase can be divided into two or three separate substitutions: forward, backward, and diagonal (see [Separate Forward and Backward Substitution](#)).

- Memory release phase (*phase*= 0 or *phase*= -1)

If a previous call to the routine has computed information from previous phases, execution may start at any phase. The *phase* parameter can have the following values:

<i>phase</i>	<b>Solver Execution Steps</b>
11	Analysis

<i>phase</i>	<b>Solver Execution Steps</b>
12	Analysis, numerical factorization
13	Analysis, numerical factorization, solve, iterative refinement
22	Numerical factorization
23	Numerical factorization, solve, iterative refinement
33	Solve, iterative refinement
331	like <i>phase</i> =33, but only forward substitution
332	like <i>phase</i> =33, but only diagonal substitution (if available)
333	like <i>phase</i> =33, but only backward substitution
0	Release internal memory for <i>L</i> and <i>U</i> matrix number <i>mnum</i>
-1	Release all internal memory for all matrices

If *iparm*[35] = 0, phases 331, 332, and 333 perform this decomposition:

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{12} & L_{22} \end{bmatrix} \begin{bmatrix} D_{11} & 0 \\ 0 & D_{22} \end{bmatrix} \begin{bmatrix} U_{11} & U_{21} \\ 0 & U_{22} \end{bmatrix}$$

If *iparm*[35] = 2, phases 331, 332, and 333 perform a different decomposition:

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{12} & I \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & S \end{bmatrix} \begin{bmatrix} U_{11} & U_{21} \\ 0 & I \end{bmatrix}$$

You can supply a custom implementation for phase 332 instead of calling `pardiso`. For example, it can be implemented with dense LAPACK functionality. Custom implementation also allows you to substitute the matrix *S* with your own.

---

#### **NOTE**

For very large Schur complement matrices use LAPACK functionality to compute the Schur complement vector instead of the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO phase 332 implementation.

---

*n*

Number of equations in the sparse linear systems of equations  $A^*X = B$ .  
Constraint:  $n > 0$ .

*a*

Array. Contains the non-zero elements of the coefficient matrix *A* corresponding to the indices in *ja*. The coefficient matrix can be either real or complex. The matrix must be stored in the three-array variant of the compressed sparse row (CSR3) or in the three-array variant of the block compressed sparse row (BSR3) format, and the matrix must be stored with increasing values of *ja* for each row.

For CSR3 format, the size of  $a$  is the same as that of  $ja$ . Refer to the *values* array description in [Three Array Variation of CSR Format](#) for more details.

For BSR3 format the size of  $a$  is the size of  $ja$  multiplied by the square of the block size. Refer to the *values* array description in [Three Array Variation of BSR Format](#) for more details.

---

**NOTE**

If you set  $iparm[36]$  to a negative value, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO converts the data from CSR3 format to an internal variable BSR (VBSR) format. See [Sparse Data Storage](#).

---

$ia$

Array, size  $(n+1)$ .

For CSR3 format,  $ia[i]$  ( $i < n$ ) points to the first column index of row  $i$  in the array  $ja$ . That is,  $ia[i]$  gives the index of the element in array  $a$  that contains the first non-zero element from row  $i$  of  $A$ . The last element  $ia[n]$  is taken to be equal to the number of non-zero elements in  $A$ , plus one. Refer to *rowIndex* array description in [Three Array Variation of CSR Format](#) for more details.

For BSR3 format,  $ia[i]$  ( $i < n$ ) points to the first column index of row  $i$  in the array  $ja$ . That is,  $ia[i]$  gives the index of the element in array  $a$  that contains the first non-zero block from row  $i$  of  $A$ . The last element  $ia[n]$  is taken to be equal to the number of non-zero blocks in  $A$ , plus one. Refer to *rowIndex* array description in [Three Array Variation of BSR Format](#) for more details.

The array  $ia$  is accessed in all phases of the solution process.

Indexing of  $ia$  is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter  $iparm[34]$ .

$ja$

For CSR3 format, array  $ja$  contains column indices of the sparse matrix  $A$ . It is important that the indices are in increasing order per row. For structurally symmetric matrices it is assumed that all diagonal elements are stored (even if they are zeros) in the list of non-zero elements in  $a$  and  $ja$ . For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in [Three Array Variation of CSR Format](#).

For BSR3 format, array  $ja$  contains column indices of the sparse matrix  $A$ . It is important that the indices are in increasing order per row. For structurally symmetric matrices it is assumed that all diagonal blocks are stored (even if they are zeros) in the list of non-zero blocks in  $a$  and  $ja$ . For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in [Three Array Variation of BSR Format](#).

The array  $ja$  is accessed in all phases of the solution process.

Indexing of  $ja$  is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter  $iparm[34]$ .

<i>perm</i>	<p>Array, size (<math>n</math>). Depending on the value of <i>iparm</i>[4] and <i>iparm</i>[30], holds the permutation vector of size <math>n</math>, specifies elements used for computing a partial solution, or specifies differing values of the input matrices for low rank update.</p> <ul style="list-style-type: none"> <li>• If <i>iparm</i>[4] = 1, <i>iparm</i>[30] = 0, and <i>iparm</i>[35] = 0, <i>perm</i> specifies the fill-in reducing ordering to the solver. Let <math>A</math> be the original matrix and <math>C = P^*A^*P^T</math> be the permuted matrix. Row (column) <math>i</math> of <math>C</math> is the <i>perm</i>[<math>i</math>] row (column) of <math>A</math>. The array <i>perm</i> is also used to return the permutation vector calculated during fill-in reducing ordering stage.</li> </ul> <hr/> <p><b>NOTE</b> Be aware that setting <i>iparm</i>[4] = 1 prevents use of a parallel algorithm for the solve step.</p> <hr/> <ul style="list-style-type: none"> <li>• If <i>iparm</i>[4] = 2, <i>iparm</i>[30] = 0, and <i>iparm</i>[35] = 0, the permutation vector computed in phase 11 is returned in the <i>perm</i> array.</li> <li>• If <i>iparm</i>[4] = 0, <i>iparm</i>[30] &gt; 0, and <i>iparm</i>[35] = 0, <i>perm</i> specifies elements of the right-hand side to use or of the solution to compute for a partial solution.</li> <li>• If <i>iparm</i>[4] = 0, <i>iparm</i>[30] = 0, and <i>iparm</i>[35] &gt; 0, <i>perm</i> specifies elements for a Schur complement.</li> <li>• If <i>iparm</i>[38] = 1, <i>perm</i> specifies values that differ in <math>A</math> for low rank update (see <a href="#">Low Rank Update</a>). The size of the array must be at least <math>2*ndiff + 1</math>, where <i>ndiff</i> is the number of values of <math>A</math> that are different. The values of <i>perm</i> should be:  <pre>perm = {ndiff, row_index1, column_index1, row_index2, column_index2, ..., row_index_ndiff, column_index_ndiff}</pre>           where <i>row_index_m</i> and <i>column_index_m</i> are the row and column indices of the <math>m</math>-th differing non-zero value in matrix <math>A</math>. The row and column index pairs can be in any order, but must use zero-based indexing regardless of the value of <i>iparm</i>[34].</li> </ul> <p>See <a href="#">iparm</a>[4], <a href="#">iparm</a>[30], and <a href="#">iparm</a>[38] for more details.</p> <p>Indexing of <i>perm</i> is one-based by default, but unless <i>iparm</i>[38] = 1 it can be changed to zero-based by setting the appropriate value to the parameter <a href="#">iparm</a>[34].</p>
<i>nrhs</i>	Number of right-hand sides that need to be solved for.
<i>iparm</i>	<p>Array, size (64). This array is used to pass various parameters to Intel® oneAPI Math Kernel Library (oneMKL) PARDISO and to return some useful information after execution of the solver.</p> <p>See <a href="#">pardiso iparm Parameter</a> for more details about the <i>iparm</i> parameters.</p>
<i>msglvl</i>	Message level information. If <i>msglvl</i> = 0 then <i>pardiso</i> generates no output, if <i>msglvl</i> = 1 the solver prints statistical information to the screen.
<i>b</i>	Array, size ( $n*nrhs$ ). On entry, contains the right-hand side vector/matrix $B$ , which is placed in memory contiguously. The <i>b</i> [ $+k*nrhs$ ] element must hold the $i$ -th component of $k$ -th right-hand side vector. Note that <i>b</i> is only accessed in the solution phase.

## Output Parameters

(See also [Intel MKL PARDISO Parameters in Tabular Form.](#))

<i>pt</i>	Handle to internal data structure.
<i>perm</i>	See the Input Parameter description of the <i>perm</i> array.
<i>iparm</i>	On output, some <i>iparm</i> values report information such as the numbers of non-zero elements in the factors. See <a href="#">pardiso iparm Parameter</a> for more details about the <i>iparm</i> parameters.
<i>b</i>	On output, the array is replaced with the solution if <i>iparm</i> [5] = 1.
<i>x</i>	Array, size ( $n * nrhs$ ). If <i>iparm</i> [5] = 0 it contains solution vector/matrix <i>X</i> , which is placed contiguously in memory. The $x[i + k * n]$ element must hold the <i>i</i> -th component of the <i>k</i> -th solution vector. Note that <i>x</i> is only accessed in the solution phase.
<i>error</i>	The error indicator according to the below table:

<b>error</b>	<b>Information</b>
0	no error
-1	input inconsistent
-2	not enough memory
-3	reordering problem
-4	Zero pivot, numerical factorization or iterative refinement problem. If the error appears during the solution phase, try to change the pivoting perturbation ( <i>iparm</i> [9]) and also increase the number of iterative refinement steps. If it does not help, consider changing the scaling, matching and pivoting options ( <i>iparm</i> [10], <i>iparm</i> [12], <i>iparm</i> [20])
-5	unclassified (internal) error
-6	reordering failed (matrix types 11 and 13 only)
-7	diagonal matrix is singular
-8	32-bit integer overflow problem
-9	not enough memory for OOC
-10	error opening OOC files
-11	read/write error with OOC files
-12	( <i>pardiso_64</i> only) <i>pardiso_64</i> called from 32-bit library
-13	interrupted by the (user-defined) <a href="#">mkl_progress</a> function

**error**

-15

**Information**

internal error which can appear for `iparm[23]=10` and `iparm[12]=1`. Try switch matching off (set `iparm[12]=0` and rerun.)

**pardisoinit**

Initialize Intel® oneAPI Math Kernel Library (oneMKL) PARDISO with default parameters in accordance with the matrix type.

**Syntax**

```
void pardisoinit (_MKL_DSS_HANDLE_t pt, const MKL_INT *mtype, MKL_INT *iparm );
```

**Include Files**

- `mkl.h`

**Description**

This function initializes the solver handle `pt` for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO with zero values (as needed for the very first call of `pardiso`) and sets default `iparm` values in accordance with the matrix type `mtype`.

The recommended way is to avoid using `pardisoinit` and to initialize `pt` and set the values of the `iparm` array manually as the default parameters might not be the best for a particular use case.

An alternative method to set default `iparm` values is to call `pardiso` in the analysis phase with `iparm(1)=0`. In this case, the solver handle `pt` must be initialized with zero values.

The `pardisoinit` routine initializes only the in-core version of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. Switching to the out-of-core version of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO as well as changing default `iparm` values can be done after the call to `pardisoinit` but before the first call to `pardiso`.

The `pardisoinit` routine cannot be used together with the `pardiso_64` routine.

**Input Parameters**

`mtype` Matrix type. Based on this value `pardisoinit` chooses default values for the `iparm` array. Refer to the section [oneMKL PARDISO Parameters in Tabular Form](#) for more details about the default values of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.

**Output Parameters**

`pt` Array of size 64. Handle to internal data structure. The `pardisoinit` routine nullifies the array `pt`.

**NOTE**

It is very important that `pt` is initialized with zero before the first call of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. After that first call you must never modify the array, because it could cause a serious memory leak or a crash.

`iparm`

Array of size 64. This array is used to set various options for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO and to return some useful information after execution of the solver. The `pardisoinit` routine fills in the `iparm` array with the default values. Refer to the section [oneMKL PARDISO Parameters in Tabular Form](#) for more details about the default values of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.

**pardiso\_64**

*Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides, 64-bit integer version.*

**Syntax**

```
void pardiso_64 (_MKL_DSS_HANDLE_t pt, const long long int *maxfct, const long long int *mnum, const long long int *mtype, const long long int *phase, const long long int *n, const void *a, const long long int *ia, const long long int *ja, long long int *perm, const long long int *nrhs, long long int *iparm, const long long int *msglvl, void *b, void *x, long long int *error);
```

**Include Files**

- `mkl.h`

**Description**

`pardiso_64` is an alternative ILP64 (64-bit integer) version of the [pardiso](#) routine (see [Description](#) section for more details). The interface of `pardiso_64` is the same as the interface of `pardiso`, but it accepts and returns all integer data as `long long int`.

Use `pardiso_64` when `pardiso` for solving large matrices (with the number of non-zero elements on the order of 500 million or more). You can use it together with the usual LP64 interfaces for the rest of Intel® oneAPI Math Kernel Library (oneMKL) functionality. In other words, if you use 64-bit integer version (`pardiso_64`), you do not need to re-link your applications with ILP64 libraries. Take into account that `pardiso_64` may perform slower than regular `pardiso` on the reordering and symbolic factorization phase.

**NOTE**

`pardiso_64` is supported only in the 64-bit libraries. If `pardiso_64` is called from the 32-bit libraries, it returns `error == -12`.

**NOTE**

This routine supports the Progress Routine feature. See [Progress Function](#) for details.

## Input Parameters

The input parameters of `pardiso_64` are the same as the input parameters of `pardiso`, but `pardiso_64` accepts all integer data as `long long int`.

## Output Parameters

The output parameters of `pardiso_64` are the same as the [output parameters of `pardiso`](#), but `pardiso_64` returns all integer data as `long long int`.

## `mkl_pardiso_pivot`

*Replaces routine which handles Intel® oneAPI Math Kernel Library (oneMKL) PARDISO pivots with user-defined routine.*

---

### Syntax

```
void mkl_pardiso_pivot (const void *ai, void *bi, const void *eps);
```

### Include Files

- `mkl.h`

### Description

The `mkl_pardiso_pivot` routine allows you to handle diagonal elements which arise during numerical factorization that are zero or near zero. By default, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO determines that a diagonal element  $bi$  is a pivot if  $bi < eps$ , and if so, replaces it with  $eps$ . But you can provide your own routine to modify the resulting factorized matrix in case there are small elements on the diagonal during the factorization step.

---

#### NOTE

To use this routine, you must set `iparm[55]` to 1 before the main `pardiso` loop.

---

## Input Parameters

<code>ai</code>	Diagonal element of initial matrix corresponding to pivot element.
<code>bi</code>	Diagonal element of factorized matrix that could be chosen as a pivot element.
<code>eps</code>	Scalar to compare with diagonal of factorized matrix. On input equal to parameter described by <code>iparm[9]</code> .

## Output Parameters

<code>bi</code>	In case element is chosen as a pivot, value with which to replace the pivot.
-----------------	--

## `pardiso_getdiag`

*Returns diagonal elements of initial and factorized matrix.*

---

### Syntax

```
void pardiso_getdiag (const _MKL_DSS_HANDLE_t pt, void *df, void *da, const MKL_INT *mnum, MKL_INT *error);
```

## Include Files

- `mkl.h`

## Description

This routine returns the diagonal elements of the initial and factorized matrix for a real or Hermitian matrix.

---

### NOTE

In order to use this routine, you must set `iparm[55]` to 1 before the main `pardiso` loop.

If `iparm[23]` is set to 10 (an improved two-level factorization algorithm for nonsymmetric matrices), Intel® oneAPI Math Kernel Library PARDISO will automatically use the classic algorithm for factorization.

---

## Input Parameters

<i>pt</i>	Array with a size of 64. Handle to internal data structure for the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver. The entries must be set to zero prior to the first call <code>topardiso</code> . Unique for factorization.
<i>mnum</i>	Indicates the actual matrix for the solution phase of the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver. With this scalar you can define the diagonal elements of the factorized matrix that you want to obtain. The value must be: $1 \leq mnum \leq maxfct$ . In most applications this value is 1.

## Output Parameters

<i>df</i>	Array with a dimension of <i>n</i> . Contains diagonal elements of the factorized matrix after factorization.
-----------	---

---

### NOTE

Elements of *df* correspond to diagonal elements of matrix *L* computed during phase 22. Because during phase 22 Intel® oneAPI Math Kernel Library (oneMKL) PARDISO makes additional permutations to improve stability, it is possible that array *df* is not in line with the *perm* array computed during phase 11.

---

<i>da</i>	Array with a dimension of <i>n</i> . Contains diagonal elements of the initial matrix.
-----------	--

---

### NOTE

Elements of *da* correspond to diagonal elements of matrix *L* computed during phase 22. Because during phase 22 Intel® oneAPI Math Kernel Library (oneMKL) PARDISO makes additional permutations to improve stability, it is possible that array *da* is not in line with the *perm* array computed during phase 11.

---

<i>error</i>	The error indicator.
--------------	----------------------

<b>error</b>	<b>Information</b>
0	no error
-1	Diagonal information not turned on before <code>pardiso</code> main loop ( <code>iparm[55]=0</code> ).

## **pardiso\_export**

Places pointers dedicated for sparse representation of a requested matrix (values, rows, and columns) into MKL PARDISO

### **Syntax**

```
void pardiso_export (const _MKL_DSS_HANDLE_t pt, void* values, MKL_INT* rows, MKL_INT* columns, MKL_INT* step, MKL_INT* iparm, MKL_INT* error);
```

### **Include Files**

- `mkl.h`

### **Description**

This auxiliary routine places pointers dedicated for sparse representation of a requested matrix (values, rows, and columns) into MKL PARDISO. The matrix will be stored in the three-array variant of the compressed sparse row (CSR3 format) with 0-based indexing.

#### **NOTE**

Currently, this routine can be used only for a sparse Schur complement matrix. All parameters related to the Schur complement matrix (`perm`, `iparm`) must be set before the reordering stage of MKL PARDISO (phase = 11) is called.

### **Input Parameters**

<i>pt</i>	Array with a size of 64. Handle to internal data structure for the Intel® MKL PARDISO solver. The entries must be set to zero prior to the first call to <code>pardiso</code> . Unique for factorization.
<i>iparm</i>	This array is used to pass various parameters to Intel® MKL PARDISO and to return some useful information after execution of the solver.
<i>step</i>	Stage indicator. These are the currently supported values:

<b>Step value</b>	<b>Notes</b>
1	Used to place pointers related to a Schur complement matrix in MKL PARDISO. The routine with <i>step</i> equal to 1 must be called between the reordering and factorization phases of MKL PARDISO.
-1	Used to clean the internal handle.

## Input/Output Parameters

<i>values</i>	<p>Parameter type: input/output parameter.</p> <p>This array contains the non-zero elements of the requested matrix.</p>
<i>rows</i>	<p>Parameter type: input/output parameter.</p> <p>Array of size (<i>size</i> + 1)</p> <p>For CSR3 format, <i>rows</i>[<i>i</i>] ( <i>i</i> &lt; <i>size</i> ) points to the first column index of row <i>i</i> in the array columns; that is, <i>rows</i>[<i>i</i>] gives the index of the element in the array values that contains the first non-zero element from row <i>i</i> of the sparse matrix. The last element, <i>rows</i>[<i>size</i>], is equal to the number of non-zero elements in the sparse matrix.</p>
<i>columns</i>	<p>Parameter type: input/output parameter.</p> <p>This array contains the column indices for the non-zero elements of the requested matrix.</p>
<i>error</i>	<p>Parameter type: output parameter.</p> <p>The error status:</p> <ul style="list-style-type: none"> <li>• 0 indicates no error.</li> <li>• 1 indicates inconsistent input data.</li> </ul>

## Usage Example

The following C-style example demonstrates how to use the `pardiso_export` routine to get the sparse representation (that is, three-array CSR format) of a Schur complement matrix.

```
#include "mkl.h"

/*
 * Call the reordering phase of MKL PARDISO with iparm[35] set to -1 in
 * order to compute the Schur complement matrix only, or -2 to compute all
 * factorization arrays. perm array indices related to the Schur complement
 * matrix must be set to 1.
 */
phase = 11;
for ( i = 0; i < schur_size; i++ ) { perm[i] = 1.; }
iparm[35] = -1;
pardiso(pt, &maxfct, &mnum, &mtype, &phase, &n, a, ia, ja, perm, &nrhs,
        iparm, &msglvl, b, x, &error);

/*
 * After the reordering phase, iparm[35] will contain the number of non-zero
 * elements for the Schur complement matrix. Arrays dedicated to the sparse
 * representation of the Schur complement matrix must be allocated before
 * the factorization stage of MKL PARDISO is called.
 */
schur_nnz      = iparm[35];
schur_rows    = (MKL_INT *) mkl_malloc(schur_size+1, ALIGNMENT);
schur_columns = (MKL_INT *) mkl_malloc(schur_nnz , ALIGNMENT);
schur_values  = (DATA_TYPE *) mkl_malloc(schur_nnz , ALIGNMENT);

/*
 * Call to the pardiso_export routine with step equal to 1 in order to put
```

```

* pointers related to the three-array CSR format into MKL PARDISO:
*/
pardiso_export(pt, schur_values, schur_ia, schur_ja, &step, iparm, &error);

/*
* Call the factorization phase of PARDISO with iparm[35] equal to -1 or -2
* to compute the Schur complement matrix:
*/
phase = 22;
iparm[35] = -1;
pardiso(pt, &maxfct, &mnum, &mtype, &phase, &n, a, ia, ja, perm, &nrhs,
        iparm, &msglvl, b, x, &error);

/*
* After the factorization stage, schur_values, schur_rows, and
* schur_columns will contain the Schur complement matrix in CSR3 format.
*/

```

## **pardiso\_handle\_store**

Store internal structures from `pardiso` to a file.

### **Syntax**

```
void pardiso_handle_store (_MKL_DSS_HANDLE_t pt, const char *dirname, MKL_INT *error);
```

### **Include Files**

- `mkl.h`

### **Description**

This function stores Intel® oneAPI Math Kernel Library (oneMKL) PARDISO structures to a file, allowing you to store Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures between the stages of the `pardiso` routine. The `pardiso_handle_restore` routine can restore the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures from the file.

### **Input Parameters**

<code>pt</code>	Array with a size of 64. Handle to internal data structure.
<code>dirname</code>	String containing the name of the directory to which to write the files with the content of the internal structures. Use an empty string ("") to specify the current directory. The routine creates a file named <code>handle.pds</code> in the directory.

### **Output Parameters**

<code>pt</code>	Handle to internal data structure.
<code>error</code>	The error indicator.

<b>error</b>	<b>Information</b>
0	No error.
-2	Not enough memory.
-10	Cannot open file for writing.

<b>error</b>	<b>Information</b>
-11	Error while writing to file.
-13	Wrong file format.

## **pardiso\_handle\_restore**

*Restore pardiso internal structures from a file.*

### **Syntax**

```
void pardiso_handle_restore (_MKL_DSS_HANDLE_t pt, const char *dirname, MKL_INT *error);
```

### **Include Files**

- mkl.h

### **Description**

This function restores Intel® oneAPI Math Kernel Library (oneMKL) PARDISO structures from a file. This allows you to restore Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures stored by `pardiso_handle_store` after a phase of the `pardiso` routine and continue execution of the next phase.

### **Input Parameters**

*dirname* String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

### **Output Parameters**

*pt* Array with a dimension of 64. Handle to internal data structure.

*error* The error indicator.

<b>error</b>	<b>Information</b>
0	No error.
-2	Not enough memory.
-10	Cannot open file for reading.
-11	Error while reading from file.
-13	Wrong file format.

## **pardiso\_handle\_delete**

*Delete files with pardiso internal structure data.*

### **Syntax**

```
void pardiso_handle_delete (const char *dirname, MKL_INT *error);
```

### **Include Files**

- mkl.h

## Description

This function deletes files generated with `pardiso_handle_store` that contain Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures.

## Input Parameters

*dirname* String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

## Output Parameters

*error* The error indicator.

<b>error</b>	<b>Information</b>
0	No error.
-10	Cannot delete files.

## `pardiso_handle_store_64`

*Store internal structures from `pardiso_64` to a file.*

## Syntax

```
void pardiso_handle_store_64 (_MKL_DSS_HANDLE_t pt, const char *dirname, MKL_INT *error);
```

## Include Files

- `mkl.h`

## Description

This function stores Intel® oneAPI Math Kernel Library (oneMKL) PARDISO structures to a file, allowing you to store Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures between the stages of the `pardiso_64` routine. The `pardiso_handle_restore_64` routine can restore the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures from the file.

## Input Parameters

*pt* Array with a dimension of 64. Handle to internal data structure.

*dirname* String containing the name of the directory to which to write the files with the content of the internal structures. Use an empty string ("") to specify the current directory. The routine creates a file named `handle.pds` in the directory.

## Output Parameters

*pt* Handle to internal data structure.

*error* The error indicator.

<b>error</b>	<b>Information</b>
0	No error.

<b>error</b>	<b>Information</b>
-2	Not enough memory.
-10	Cannot open file for writing.
-11	Error while writing to file.
-12	Not supported in 32-bit library - routine is only supported in 64-bit libraries.
-13	Wrong file format.

## pardiso\_handle\_restore\_64

*Restore pardiso\_64 internal structures from a file.*

### Syntax

```
void pardiso_handle_restore_64 (_MKL_DSS_HANDLE_t pt, const char *dirname, MKL_INT *error);
```

### Include Files

- mkl.h

### Description

This function restores Intel® oneAPI Math Kernel Library (oneMKL) PARDISO structures from a file. This allows you to restore Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures stored by `pardiso_handle_store_64` after a phase of the `pardiso_64` routine and continue execution of the next phase.

### Input Parameters

*dirname* String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

### Input Parameters

*pt* Array with a dimension of 64. Handle to internal data structure.

*error* The error indicator.

<b>error</b>	<b>Information</b>
0	No error.
-2	Not enough memory.
-10	Cannot open file for reading.
-11	Error while reading from file.
-13	Wrong file format.

## pardiso\_handle\_delete\_64

### Syntax

Delete files with `pardiso_64` internal structure data.

```
void pardiso_handle_delete_64 (const char *dirname, MKL_INT *error);
```

### Include Files

- `mkl.h`

### Description

This function deletes files generated with `pardiso_handle_store_64` that contain Intel® oneAPI Math Kernel Library (oneMKL) PARDISO internal structures.

### Input Parameters

*dirname* String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

### Output Parameters

*error* The error indicator.

<b>error</b>	<b>Information</b>
0	No error.
-10	Cannot delete files.
-12	Not supported in 32-bit library - routine is only supported in 64-bit libraries.

## oneMKL PARDISO Parameters in Tabular Form

The following table lists all parameters of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO and gives their brief descriptions.

Parameter	Type	Description	Values	Comments	In/Out
<i>pt</i>	void*	Solver internal data address pointer	0	Must be initialized with zeros and never be modified later	in/out
<i>maxfct</i>	MKL_INT*	Maximal number of factors in memory	>0	Generally used value is 1	in
<i>mnum</i>	MKL_INT*	The number of matrix (from 1 to <i>maxfct</i> ) to solve	[1: <i>maxfct</i> ]	Generally used value is 1	in
<i>mtype</i>	MKL_INT*	Matrix type	1	Real and structurally symmetric	in
			2	Real and symmetric positive definite	

Parameter	Type	Description	Values	Comments	In/Out
			-2	Real and symmetric indefinite	
			3	Complex and structurally symmetric	
			4	Complex and Hermitian positive definite	
			-4	Complex and Hermitian indefinite	
			6	Complex and symmetric matrix	
			11	Real and nonsymmetric matrix	
			13	Complex and nonsymmetric matrix	
<i>phase</i>	MKL_INT*	Controls the execution of the solver  For <i>iparm</i> [35] > 0, phases 331, 332, and 333 perform a different decomposition. See the <i>phase</i> parameter of <a href="#">pardiso</a> for details.	11	Analysis	in
			12	Analysis, numerical factorization	
			13	Analysis, numerical factorization, solve	
			22	Numerical factorization	
			23	Numerical factorization, solve	
			33	Solve, iterative refinement	
			331	<i>phase</i> =33, but only forward substitution	
			332	<i>phase</i> =33, but only diagonal substitution	
			333	<i>phase</i> =33, but only backward substitution	
			0	Release internal memory for L and U of the matrix number <i>mnum</i>	
			-1	Release all internal memory for all matrices	
<i>n</i>	MKL_INT*	Number of equations in the sparse linear system $A \cdot X = B$	>0		in
<i>a</i>	void*	Contains the non-zero elements of the coefficient matrix <i>A</i>	*	The size of <i>a</i> is the same as that of <i>ja</i> , and the coefficient matrix can be either real or complex. The	in

Parameter	Type	Description	Values	Comments	In/Out
$ia[n]$	MKL_INT*	<i>rowIndex</i> array in CSR3 format	$\geq 0$	<p>matrix must be stored in the 3-array variation of compressed sparse row (CSR3) format with increasing values of <math>ja</math> for each row</p> <p><math>ia[i]</math> gives the index of the element in array <math>a</math> that contains the first non-zero element from row <math>i</math> of <math>A</math>. The last element <math>ia(n)</math> is taken to be equal to the number of non-zero elements in <math>A</math>.</p> <p>Note: <math>iparm[34]</math> indicates whether row/column indexing starts from 1 or 0.</p>	in
$ja$	MKL_INT*	<i>columns</i> array in CSR3 format	$\geq 0$	<p>The column indices for each row of <math>A</math> must be sorted in increasing order. For structurally symmetric matrices zero diagonal elements must be stored in <math>a</math> and <math>ja</math>. Zero diagonal elements should be stored for symmetric matrices, although they are not required. For symmetric matrices, the solver needs only the upper triangular part of the system.</p> <p>Note: <math>iparm[34]</math> indicates whether row/column indexing starts from 1 or 0.</p>	in
$perm[n]$	MKL_INT*	Holds the permutation vector of size $n$ , specifies elements used for computing a partial solution, or specifies differing values of the input matrices for low rank update	$\geq 0$	<p>You can apply your own fill-in reducing ordering (<math>iparm[4] = 1</math>) or return the permutation from the solver (<math>iparm[4] = 2</math>).</p> <p>Let <math>C = P^*A^*P^T</math> be the permuted matrix. Row (column) <math>i</math> of <math>C</math> is the <math>perm(i)</math> row (column) of <math>A</math>. The numbering of the array must describe a permutation.</p>	in/out

Parameter	Type	Description	Values	Comments	In/Out
				<p>To specify elements for a partial solution, set <math>iparm[4] = 0</math>, <math>iparm[30] &gt; 0</math>, and <math>iparm[35] = 0</math>.</p> <p>To specify elements for a Schur complement, set <math>iparm[4] = 0</math>, <math>iparm[30] = 0</math>, and <math>iparm[35] &gt; 0</math>.</p> <p>To specify values that differ in <math>A</math> for low rank update (see <a href="#">Low Rank Update</a>), set <math>iparm[38] = 1</math>. The size of the array must be at least <math>2*ndiff + 1</math>, where <math>ndiff</math> is the number of values of <math>A</math> that are different. The values of <math>perm</math> should be:</p> <pre>perm = {ndiff, row_index1, column_index1, row_index2, column_index2, ..., row_index_ndiff, column_index_ndiff}</pre> <p>where <math>row\_index\_m</math> and <math>column\_index\_m</math> are the row and column indices of the <math>m</math>-th differing non-zero value in matrix <math>A</math>. The row and column index pairs can be in any order, but must use zero-based indexing regardless of the value of <math>iparm[34]</math>.</p> <hr/> <p><b>NOTE</b> Unless you have specified low rank update, <math>iparm[34]</math> indicates whether row/column indexing starts from 1 or 0.</p>	
$nrhs$	MKL_INT*	Number of right-hand sides that need to be solved for	$\geq 0$	<p>Generally used value is 1</p> <p>To obtain better Intel® oneAPI Math Kernel Library (oneMKL) PARDISO performance, during the numerical factorization phase you can provide the maximum number of</p>	in

Parameter	Type	Description	Values	Comments	In/Out
<i>iparm</i> [64]	MKL_INT*	This array is used to pass various parameters to Intel® oneAPI Math Kernel Library (oneMKL) PARDISO and to return some useful information after execution of the solver (see <a href="#">pardiso iparm Parameter</a> for more details)	*	right-hand sides, which can be used further during the solving phase.  If <i>iparm</i> [0]=0, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO fills <i>iparm</i> [1] through <i>iparm</i> [63] with default values and uses them.	in/out
<i>msglvl</i>	MKL_INT*	Message level information	0  1	Intel® oneAPI Math Kernel Library (oneMKL) PARDISO generates no output  Intel® oneAPI Math Kernel Library (oneMKL) PARDISO prints statistical information	in
<i>b</i> [ <i>n*nrhs</i> ]	void*	Right-hand side vectors	*	On entry, contains the right-hand side vector/matrix <i>B</i> , which is placed contiguously in memory. The <i>b</i> [ <i>i+k*n</i> ] element must hold the <i>i</i> -th component of <i>k</i> -th right-hand side vector. Note that <i>b</i> is only accessed in the solution phase.  On output, the array is replaced with the solution if <i>iparm</i> [5]=1.	in/out
<i>x</i> [ <i>n*nrhs</i> ]	void*	Solution vectors	*	On output, if <i>iparm</i> [5]=0, contains solution vector/matrix <i>X</i> which is placed contiguously in memory. The <i>x</i> [ <i>i+k*n</i> ] element must hold the <i>i</i> -th component of <i>k</i> -th solution vector. Note that <i>x</i> is only accessed in the solution phase.	out
<i>error</i>	MKL_INT*	Error indicator	0  -1  -2	No error  Input inconsistent  Not enough memory	out

Parameter	Type	Description	Values	Comments	In/Out
			-3	Reordering problem	
			-4	Zero pivot, numerical factorization or iterative refinement problem	
			-5	Unclassified (internal) error	
			-6	Reordering failed (matrix types 11 and 13 only)	
			-7	Diagonal matrix is singular	
			-8	32-bit integer overflow problem	
			-9	Not enough memory for OOC	
			-10	Problems with opening OOC temporary files	
			-11	Read/write problems with the OOC data file	

1) See description of PARDISO\_DATA\_TYPE in PARDISO\_DATA\_TYPE.

## pardiso iparm Parameter

This table describes all individual components of the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO *iparm* parameter. Components which are not used must be initialized with 0. Default values are denoted with an asterisk (\*).

Component	Description						
<i>iparm</i> [0]	Use default values.						
input	<table border="1"> <tr> <td>0</td> <td><i>iparm</i>[1] - <i>iparm</i>[63] are filled with default values.</td> </tr> <tr> <td>≠0</td> <td>You must supply all values in components <i>iparm</i>[1] - <i>iparm</i>[63].</td> </tr> </table>	0	<i>iparm</i> [1] - <i>iparm</i> [63] are filled with default values.	≠0	You must supply all values in components <i>iparm</i> [1] - <i>iparm</i> [63].		
0	<i>iparm</i> [1] - <i>iparm</i> [63] are filled with default values.						
≠0	You must supply all values in components <i>iparm</i> [1] - <i>iparm</i> [63].						
<i>iparm</i> [1]	Fill-in reducing ordering for the input matrix.						
input	<p><b>Caution</b> You can control the parallel execution of the solver by explicitly setting the MKL_NUM_THREADS environment variable. If fewer OpenMP threads are available than specified, the execution may slow down instead of speeding up. If MKL_NUM_THREADS is not defined, then the solver uses all available processors.</p> <table border="1"> <tr> <td>0</td> <td>The minimum degree algorithm [Li99].</td> </tr> <tr> <td>2*</td> <td>The nested dissection algorithm from the METIS package [Karypis98].</td> </tr> <tr> <td>3</td> <td>The parallel (OpenMP) version of the nested dissection algorithm. It can decrease the time of computations on multi-core computers, especially when Intel® oneAPI Math Kernel Library (oneMKL) PARDISO Phase 1 takes significant time.</td> </tr> </table>	0	The minimum degree algorithm [Li99].	2*	The nested dissection algorithm from the METIS package [Karypis98].	3	The parallel (OpenMP) version of the nested dissection algorithm. It can decrease the time of computations on multi-core computers, especially when Intel® oneAPI Math Kernel Library (oneMKL) PARDISO Phase 1 takes significant time.
0	The minimum degree algorithm [Li99].						
2*	The nested dissection algorithm from the METIS package [Karypis98].						
3	The parallel (OpenMP) version of the nested dissection algorithm. It can decrease the time of computations on multi-core computers, especially when Intel® oneAPI Math Kernel Library (oneMKL) PARDISO Phase 1 takes significant time.						

Component	Description														
	<p><b>NOTE</b> Setting <math>iparm[1] = 3</math> prevents the use of CNR mode (<math>iparm[33] &gt; 0</math>) because Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses dynamic parallelism.</p>														
$iparm[2]$	Reserved. Set to zero.														
$iparm[3]$ input	<p>Preconditioned CGS/CG.</p> <p>This parameter controls preconditioned CGS [Sonn89] for nonsymmetric or structurally symmetric matrices and Conjugate-Gradients for symmetric matrices. <math>iparm[3]</math> has the form <math>iparm[3] = 10 * L + K</math>.</p> <table border="1"> <tbody> <tr> <td><math>K=0</math></td> <td>The factorization is always computed as required by <i>phase</i>.</td> </tr> <tr> <td><math>K=1</math></td> <td>CGS iteration replaces the computation of <math>LU</math>. The preconditioner is <math>LU</math> that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.</td> </tr> <tr> <td><math>K=2</math></td> <td>CGS iteration for symmetric positive definite matrices replaces the computation of <math>LL^T</math>. The preconditioner is <math>LL^T</math> that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.</td> </tr> </tbody> </table> <p>The value <math>L</math> controls the stopping criterion of the Krylov Subspace iteration:  <math>eps_{CGS} = 10^{-L}</math> is used in the stopping criterion  <math>  dx_i   /   dx_0   &lt; eps_{CGS}</math>  where <math>  dx_i   =   inv(L*U)*r_i  </math> for <math>K = 1</math> or <math>  dx_i   =   inv(L*L^T)*r_i  </math> for <math>K = 2</math> and <math>r_i</math> is the residue at iteration <math>i</math> of the preconditioned Krylov Subspace iteration.</p> <p>A maximum number of 150 iterations is fixed with the assumption that the iteration will converge before consuming half the factorization time. Intermediate convergence rates and residue excursions are checked and can terminate the iteration process. If <math>phase = 23</math>, then the factorization for a given <math>A</math> is automatically recomputed in cases where the Krylov Subspace iteration failed, and the corresponding direct solution is returned. Otherwise the solution from the preconditioned Krylov Subspace iteration is returned. Using <math>phase = 33</math> results in an error message (<math>error=-4</math>) if the stopping criteria for the Krylov Subspace iteration can not be reached. More information on the failure can be obtained from <math>iparm[19]</math>.</p> <p>The default is <math>iparm[3]=0</math>, and other values are only recommended for an advanced user. <math>iparm[3]</math> must be greater than or equal to zero.</p> <p>Examples:</p> <table border="1"> <thead> <tr> <th><math>iparm[3]</math></th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>31</td> <td><math>LU</math>-preconditioned CGS iteration with a stopping criterion of 1.0E-3 for nonsymmetric matrices</td> </tr> <tr> <td>61</td> <td><math>LU</math>-preconditioned CGS iteration with a stopping criterion of 1.0E-6 for nonsymmetric matrices</td> </tr> <tr> <td>62</td> <td><math>LL^T</math>-preconditioned CGS iteration with a stopping criterion of 1.0E-6 for symmetric positive definite matrices</td> </tr> </tbody> </table>	$K=0$	The factorization is always computed as required by <i>phase</i> .	$K=1$	CGS iteration replaces the computation of $LU$ . The preconditioner is $LU$ that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.	$K=2$	CGS iteration for symmetric positive definite matrices replaces the computation of $LL^T$ . The preconditioner is $LL^T$ that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.	$iparm[3]$	Description	31	$LU$ -preconditioned CGS iteration with a stopping criterion of 1.0E-3 for nonsymmetric matrices	61	$LU$ -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for nonsymmetric matrices	62	$LL^T$ -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for symmetric positive definite matrices
$K=0$	The factorization is always computed as required by <i>phase</i> .														
$K=1$	CGS iteration replaces the computation of $LU$ . The preconditioner is $LU$ that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.														
$K=2$	CGS iteration for symmetric positive definite matrices replaces the computation of $LL^T$ . The preconditioner is $LL^T$ that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.														
$iparm[3]$	Description														
31	$LU$ -preconditioned CGS iteration with a stopping criterion of 1.0E-3 for nonsymmetric matrices														
61	$LU$ -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for nonsymmetric matrices														
62	$LL^T$ -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for symmetric positive definite matrices														
$iparm[4]$ input	User permutation.														

Component	Description
	<p>This parameter controls whether user supplied fill-in reducing permutation is used instead of the integrated multiple-minimum degree or nested dissection algorithms. Another use of this parameter is to control obtaining the fill-in reducing permutation vector calculated during the reordering stage of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.</p> <p>This option is useful for testing reordering algorithms, adapting the code to special applications problems (for instance, to move zero diagonal elements to the end of <math>P^*A^*P^T</math>), or for using the permutation vector more than once for matrices with identical sparsity structures. For definition of the permutation, see the description of the <i>perm</i> parameter.</p>
	<p><b>Caution</b> You can only set one of <i>iparm</i>[4], <i>iparm</i>[30], and <i>iparm</i>[35], so be sure that the <i>iparm</i>[30] (partial solution) and the <i>iparm</i>[35] (Schur complement) parameters are 0 if you set <i>iparm</i>[4].</p>
	<p>0* User permutation in the <i>perm</i> array is ignored.</p>
	<p>1 Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses the user supplied fill-in reducing permutation from the <i>perm</i> array. <i>iparm</i>[1] is ignored.</p>
	<p><b>NOTE</b> Setting <i>iparm</i>[4] = 1 prevents use of a parallel algorithm for the solve step.</p>
	<p>2 Intel® oneAPI Math Kernel Library (oneMKL) PARDISO returns the permutation vector computed at phase 1 in the <i>perm</i> array.</p>
<i>iparm</i> [5] input	<p>Write solution on <i>x</i>.</p>
	<p><b>NOTE</b> The array <i>x</i> is always used.</p>
	<p>0* The array <i>x</i> contains the solution; right-hand side vector <i>b</i> is kept unchanged.</p>
	<p>1 The solver stores the solution on the right-hand side <i>b</i>.</p>
<i>iparm</i> [6] output	<p>Number of iterative refinement steps performed. Reports the number of iterative refinement steps that were actually performed during the solve step.</p>
<i>iparm</i> [7] input	<p>Iterative refinement step. On entry to the solve and iterative refinement step, <i>iparm</i>[7] must be set to the maximum number of iterative refinement steps that the solver performs.</p>
	<p><b>NOTE</b> Perturbed pivots result in iterative refinement (independent of the value of <i>iparm</i>[7]) and the number of executed iterations is reported in <i>iparm</i>[6].</p>
	<p>0* The solver automatically performs two steps of iterative refinement when perturbed pivots are obtained during the numerical factorization.</p>

Component	Description
	<p>&gt;0</p> <p>Maximum number of iterative refinement steps that the solver performs. The solver performs not more than the absolute value of <i>iparm</i>[7] steps of iterative refinement. The solver might stop the process before the maximum number of steps if</p> <ul style="list-style-type: none"> <li>• a satisfactory level of accuracy of the solution in terms of backward error is achieved,</li> <li>• or if it determines that the required accuracy cannot be reached. In this case the solver returns -4 in the <i>error</i> parameter.</li> </ul> <p>The number of executed iterations is reported in <i>iparm</i>[6].</p> <hr/> <p>&lt;0</p> <p>Maximum number of iterative refinement steps with a negative sign. Unlike the case above the accumulation of the residuum uses extended precision real and complex data types.</p> <hr/> <p><b>NOTE</b> Currently, this feature is only supported for sequential and OpenMP threading.</p> <hr/>
<i>iparm</i> [8] input	<p>Tolerance level for the relative residual in the iterative refinement process. If set to a non-zero value, an additional criterion is used for stopping the iterative refinement:</p> $\frac{\ r\ }{\ b\ } < 10^{-iparm[8]}$ <p>If set to zero, default checks are used to determine when to stop the iterations (see <i>iparm</i>[7] description).</p> <hr/> <p><b>NOTE</b> Currently it is only used for <i>iparm</i>[23]=1 or 10 and OpenMP threading.</p> <hr/>
<i>iparm</i> [9] input	<p>Pivoting perturbation.</p> <p>This parameter instructs Intel® oneAPI Math Kernel Library (oneMKL) PARDISO how to handle small pivots or zero pivots for nonsymmetric matrices (<i>mtype</i> =11 or <i>mtype</i> =13) and symmetric matrices (<i>mtype</i> =-2, <i>mtype</i> =-4, or <i>mtype</i> =6). For these matrices the solver uses a complete supernode pivoting approach. When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99], [Schenk04].</p> <p>Small pivots are perturbed with <math>eps = 10^{-iparm[9]}</math>.</p> <p>The magnitude of the potential pivot is tested against a constant threshold of</p> $\alpha = eps * \ A2\ _{inf},$ <p>where <math>eps = 10^{-iparm[9]}</math>, <math>A2 = P * P_{MPS} * D_r * A * D_c * P</math>, and <math>\ A2\ _{inf}</math> is the infinity norm of the scaled and permuted matrix <i>A</i>. Any tiny pivots encountered during elimination are set to the sign (<i>l<sub>II</sub></i>) * <math>eps * \ A2\ _{inf}</math>, which trades off some numerical stability for the ability to keep pivots from getting too small. Small pivots are therefore perturbed with <math>eps = 10^{-iparm[9]}</math>.</p> <hr/> <p>13*</p> <p>The default value for nonsymmetric matrices (<i>mtype</i> =11, <i>mtype</i>=13), <math>eps = 10^{-13}</math>.</p> <hr/> <p>8*</p> <p>The default value for symmetric indefinite matrices (<i>mtype</i> =-2, <i>mtype</i>=-4, <i>mtype</i>=6), <math>eps = 10^{-8}</math>.</p> <hr/>
<i>iparm</i> [10] input	<p>Scaling vectors.</p> <hr/>

Component	Description
	<p>Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses a maximum weight matching algorithm to permute large elements on the diagonal and to scale so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less than or equal to 1. This scaling method is applied only to nonsymmetric matrices (<i>mtype</i> = 11 or <i>mtype</i> = 13). The scaling can also be used for symmetric indefinite matrices (<i>mtype</i> = -2, <i>mtype</i> = -4, or <i>mtype</i> = 6) when the symmetric weighted matchings are applied (<i>iparm</i>[12] = 1).</p> <p>Use <i>iparm</i>[10] = 1 (scaling) and <i>iparm</i>[12] = 1 (matching) for highly indefinite symmetric matrices, for example, from interior point optimizations or saddle point problems. Note that in the analysis phase (<i>phase</i>=11) you must provide the numerical values of the matrix <i>A</i> in array <i>a</i> in case of scaling and symmetric weighted matching.</p>
	<p>0*      Disable scaling. Default for symmetric indefinite matrices.</p>
	<p>1*      Enable scaling. Default for nonsymmetric matrices.</p> <p>Scale the matrix so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less or equal to 1. This scaling method is applied to nonsymmetric matrices (<i>mtype</i> = 11, <i>mtype</i> = 13). The scaling can also be used for symmetric indefinite matrices (<i>mtype</i> = -2, <i>mtype</i> = -4, <i>mtype</i> = 6) when the symmetric weighted matchings are applied (<i>iparm</i>[12] = 1).</p> <p>Note that in the analysis phase (<i>phase</i>=11) you must provide the numerical values of the matrix <i>A</i> in case of scaling.</p>
<i>iparm</i> [11] input	<p>Solve with transposed or conjugate transposed matrix <i>A</i>.</p> <p><b>NOTE</b> For real matrices, the terms <i>transposed</i> and <i>conjugate transposed</i> are equivalent.</p>
	<p>0*      Solve a linear system <math>AX = B</math>.</p>
	<p>1        Solve a conjugate transposed system <math>A^HX = B</math> based on the factorization of the matrix <i>A</i>.</p>
	<p>2        Solve a transposed system <math>A^TX = B</math> based on the factorization of the matrix <i>A</i>.</p>
<i>iparm</i> [12] input	<p>Improved accuracy using (non-) symmetric weighted matching.</p> <p>Intel® oneAPI Math Kernel Library (oneMKL) PARDISO can use a maximum weighted matching algorithm to permute large elements close the diagonal. This strategy adds an additional level of reliability to the factorization methods and complements the alternative of using more complete pivoting techniques during the numerical factorization.</p>
	<p>0*      Disable matching. Default for symmetric indefinite matrices.</p>
	<p>1*      Enable matching. Default for nonsymmetric matrices.</p> <p>Maximum weighted matching algorithm to permute large elements close to the diagonal.</p> <p>It is recommended to use <i>iparm</i>[10] = 1 (scaling) and <i>iparm</i>[12] = 1 (matching) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems.</p>

Component	Description				
	Note that in the analysis phase ( <i>phase=11</i> ) you must provide the numerical values of the matrix <i>A</i> in case of symmetric weighted matching.				
<i>iparm</i> [13] output	Number of perturbed pivots. After factorization, contains the number of perturbed pivots for the matrix types: 1, 3, 11, 13, -2, -4 and 6.				
<i>iparm</i> [14] output	Peak memory on symbolic factorization. The total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase. This value is only computed in phase 1.				
<i>iparm</i> [15] output	Permanent memory on symbolic factorization. Permanent memory from the analysis and symbolic factorization phase in kilobytes that the solver needs in the factorization and solve phases. This value is only computed in phase 1.				
<i>iparm</i> [16] output	Size of factors/Peak memory on numerical factorization and solution. This parameter provides the size in kilobytes of the total memory consumed by in-core Intel® oneAPI Math Kernel Library (oneMKL) PARDISO for internal floating point arrays. This parameter is computed in phase 1. See <i>iparm</i> [62] for the OOC mode. The total peak memory consumed by Intel® oneAPI Math Kernel Library (oneMKL) PARDISO is $\max(iparm[14], iparm[15]+iparm[16])$				
<i>iparm</i> [17] input/output	Report the number of non-zero elements in the factors. <table border="1"> <tr> <td>&lt;0</td> <td>Enable reporting if <i>iparm</i>[17] &lt; 0 on entry. The default value is -1.</td> </tr> <tr> <td>&gt;=0</td> <td>Disable reporting.</td> </tr> </table>	<0	Enable reporting if <i>iparm</i> [17] < 0 on entry. The default value is -1.	>=0	Disable reporting.
<0	Enable reporting if <i>iparm</i> [17] < 0 on entry. The default value is -1.				
>=0	Disable reporting.				
<i>iparm</i> [18] input/output	Report number of floating point operations (in 10 <sup>6</sup> floating point operations) that are necessary to factor the matrix <i>A</i> . <table border="1"> <tr> <td>&lt;0</td> <td>Enable report if <i>iparm</i>[18] &lt; 0 on entry. This increases the reordering time.</td> </tr> <tr> <td>&gt;=0</td> <td>Disable report.</td> </tr> </table>	<0	Enable report if <i>iparm</i> [18] < 0 on entry. This increases the reordering time.	>=0	Disable report.
<0	Enable report if <i>iparm</i> [18] < 0 on entry. This increases the reordering time.				
>=0	Disable report.				
<i>iparm</i> [19] output	Report CG/CGS diagnostics. <table border="1"> <tr> <td>&gt;0</td> <td>CGS succeeded, reports the number of completed iterations.</td> </tr> <tr> <td>&lt;0</td> <td>CG/CGS failed (<i>error=-4</i> after the solution phase). If <i>phase= 23</i>, then the factors <i>L</i> and <i>U</i> are recomputed for the matrix <i>A</i> and the error flag <i>error=0</i> in case of a successful factorization. If <i>phase = 33</i>, then <i>error = -4</i> signals failure. <i>iparm</i>[19]= - <i>it_cgs</i>*10 - <i>cgs_error</i>. Possible values of <i>cgs_error</i>: 1 - fluctuations of the residuum are too large 2 - <math>\ dx_{\max\_it\_cgs}/2\ </math> is too large (slow convergence) 3 - stopping criterion is not reached at <i>max_it_cgs</i> 4 - perturbed pivots caused iterative refinement</td> </tr> </table>	>0	CGS succeeded, reports the number of completed iterations.	<0	CG/CGS failed ( <i>error=-4</i> after the solution phase). If <i>phase= 23</i> , then the factors <i>L</i> and <i>U</i> are recomputed for the matrix <i>A</i> and the error flag <i>error=0</i> in case of a successful factorization. If <i>phase = 33</i> , then <i>error = -4</i> signals failure. <i>iparm</i> [19]= - <i>it_cgs</i> *10 - <i>cgs_error</i> . Possible values of <i>cgs_error</i> : 1 - fluctuations of the residuum are too large 2 - $\ dx_{\max\_it\_cgs}/2\ $ is too large (slow convergence) 3 - stopping criterion is not reached at <i>max_it_cgs</i> 4 - perturbed pivots caused iterative refinement
>0	CGS succeeded, reports the number of completed iterations.				
<0	CG/CGS failed ( <i>error=-4</i> after the solution phase). If <i>phase= 23</i> , then the factors <i>L</i> and <i>U</i> are recomputed for the matrix <i>A</i> and the error flag <i>error=0</i> in case of a successful factorization. If <i>phase = 33</i> , then <i>error = -4</i> signals failure. <i>iparm</i> [19]= - <i>it_cgs</i> *10 - <i>cgs_error</i> . Possible values of <i>cgs_error</i> : 1 - fluctuations of the residuum are too large 2 - $\ dx_{\max\_it\_cgs}/2\ $ is too large (slow convergence) 3 - stopping criterion is not reached at <i>max_it_cgs</i> 4 - perturbed pivots caused iterative refinement				

Component	Description
	5 - factorization is too fast for this matrix. It is better to use the factorization method with <code>iparm[3] = 0</code>
<code>iparm[20]</code> input	<p>Pivoting for symmetric indefinite matrices.</p> <p><b>NOTE</b> Use <code>iparm[10] = 1</code> (scaling) and <code>iparm[12] = 1</code> (matchings) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems.</p> <hr/> <p>0 Apply 1x1 diagonal pivoting during the factorization process.</p> <hr/> <p>1* Apply 1x1 and 2x2 Bunch-Kaufman pivoting during the factorization process. Using this value is the same as using <code>iparm[20] = 0</code> except that the solve step does not automatically make iterative refinements when perturbed pivots are obtained during numerical factorization. The number of iterations is limited to the number of iterative refinements specified by <code>iparm[7]</code> (0 by default).</p> <hr/> <p>3 Apply 1x1 and 2x2 Bunch-Kaufman pivoting during the factorization process. Bunch-Kaufman pivoting is available for matrices of <code>mtype=-2</code>, <code>mtype=-4</code>, or <code>mtype=6</code>. Using this value is the same as using <code>iparm[20] = 1</code> except that the solve step does not automatically make iterative refinements when perturbed pivots are obtained during numerical factorization. The number of iterations is limited to the number of iterative refinements specified by <code>iparm[7]</code> (0 by default).</p>
<code>iparm[21]</code> output	<p>Inertia: number of positive eigenvalues.</p> <p>Intel® oneAPI Math Kernel Library (oneMKL) PARDISO reports the number of positive eigenvalues for symmetric indefinite matrices.</p>
<code>iparm[22]</code> output	<p>Inertia: number of negative eigenvalues.</p> <p>Intel® oneAPI Math Kernel Library (oneMKL) PARDISO reports the number of negative eigenvalues for symmetric indefinite matrices.</p>
<code>iparm[23]</code> input	<p>Parallel factorization control.</p> <hr/> <p>0* Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses the classic algorithm for factorization.</p> <hr/> <p>1 Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses a two-level factorization algorithm. This algorithm generally improves scalability in case of parallel factorization on many OpenMP threads (more than eight).</p> <hr/> <p><b>NOTE</b> Disable <code>iparm[10]</code> (scaling) and <code>iparm[12] = 1</code> (matching) when using the two-level factorization algorithm. Otherwise Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses the classic factorization algorithm.</p> <hr/> <p>10 Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses an improved two-level factorization algorithm for nonsymmetric matrices.</p>
<code>iparm[24]</code> input	Parallel forward/backward solve control.

Component	Description
	<p>0* Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses the following strategy for parallelizing the solving step:</p> <p>In the case of the one right-hand side, the parallelization will be performed by partitioning the matrix.</p> <p>Otherwise, the parallelization will be over the right-hand sides.</p> <p>This feature is available only for in-core Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (see <a href="#">iparm[59]</a>).</p>
	<p>1 Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses the sequential forward and backward solve.</p>
	<p>2 Independent from the number of the right-hand sides, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses the parallel algorithm based on the matrix partitioning.</p> <p>This feature is available only for in-core Intel® oneAPI Math Kernel Library (oneMKL) PARDISO (see <a href="#">iparm[59]</a>).</p>
<a href="#">iparm[25]</a>	Reserved. Set to zero.
<a href="#">iparm[26]</a>	Matrix checker.
input	<p>0* Intel® oneAPI Math Kernel Library (oneMKL) PARDISO does not check the sparse matrix representation for errors.</p>
	<p>1 Intel® oneAPI Math Kernel Library (oneMKL) PARDISO checks integer arrays <i>ia</i> and <i>ja</i>. In particular, Intel® oneAPI Math Kernel Library (oneMKL) PARDISO checks whether column indices are sorted in increasing order within each row.</p>
<a href="#">iparm[27]</a>	Single or double precision Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.
input	See <a href="#">iparm[7]</a> for information on controlling the precision of the refinement steps.
	<p><b>Important</b></p> <p>The <a href="#">iparm[27]</a> value is stored in the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO handle between Intel® oneAPI Math Kernel Library (oneMKL) PARDISO calls, so the precision mode can be changed only during phase 1.</p>
	<p>0* Input arrays (<i>a</i>, <i>x</i> and <i>b</i>) and all internal arrays must be presented in double precision.</p>
	<p>1 Input arrays (<i>a</i>, <i>x</i> and <i>b</i>) must be presented in single precision.</p> <p>In this case all internal computations are performed in single precision.</p>
<a href="#">iparm[28]</a>	Reserved. Set to zero.
<a href="#">iparm[29]</a>	Number of zero or negative pivots.
output	<p>If Intel® oneAPI Math Kernel Library (oneMKL) PARDISO detects zero or negative pivot for <i>mtype=2</i> or <i>mtype=4</i> matrix types, the factorization is stopped. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO returns immediately with an <i>error = -4</i>, and <a href="#">iparm[29]</a> reports the number of the equation where the zero or negative pivot is detected.</p> <p>Note: The returned value can be different for the parallel and sequential version in case of several zero/negative pivots.</p>
<a href="#">iparm[30]</a>	Partial solve and computing selected components of the solution vectors.

Component	Description
input	<p>This parameter controls the solve step of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. It can be used if only a few components of the solution vectors are needed or if you want to reduce the computation cost at the solve step by utilizing the sparsity of the right-hand sides. To use this option the input permutation vector define <math>perm</math> so that when <math>perm(i) = 1</math> it means that either the <math>i</math>-th component in the right-hand sides is nonzero, or the <math>i</math>-th component in the solution vectors is computed, or both, depending on the value of <math>iparm[30]</math>.</p> <p>The permutation vector <math>perm</math> must be present in all phases of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO software. At the reordering step, the software overwrites the input vector <math>perm</math> by a permutation vector used by the software at the factorization and solver step. If <math>m</math> is the number of components such that <math>perm(i) = 1</math>, then the last <math>m</math> components of the output vector <math>perm</math> are a set of the indices <math>i</math> satisfying the condition <math>perm(i) = 1</math> on input.</p>
	<p><b>NOTE</b> Turning on this option often increases the time used by Intel® oneAPI Math Kernel Library (oneMKL) PARDISO for factorization and reordering steps, but it can reduce the time required for the solver step.</p>
	<p><b>Important</b> You can use this feature for both in-core and out-of-core Intel® oneAPI Math Kernel Library (oneMKL) PARDISO as long as <math>iparm[23]=1</math>. Otherwise, you cannot use partial solve for out-of-core mode and you will need to set <math>iparm[59]=0</math> for in-core mode. Set the parameters <math>iparm[7]</math> (iterative refinement steps), <math>iparm[3]</math> (preconditioned CGS), <math>iparm[4]</math> (user permutation), and <math>iparm[35]</math> (Schur complement) to 0 as well.</p>
0*	Disables this option.
1	<p>it is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector <math>perm</math> is defined so that <math>perm(i) = 1</math> means that the (<math>i</math>)-th component in the right-hand sides is nonzero. In this case Intel® oneAPI Math Kernel Library (oneMKL) PARDISO only uses the non-zero components of the right-hand side vectors and computes only corresponding components in the solution vectors. That means the <math>i</math>-th component in the solution vectors is only computed if <math>perm(i) = 1</math>.</p>
2	<p>It is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector <math>perm</math> is defined so that <math>perm(i) = 1</math> means that the <math>i</math>-th component in the right-hand sides is nonzero.</p> <p>Unlike for <math>iparm[30]=1</math>, all components of the solution vector are computed for this setting and all components of the right-hand sides are used. Because all components are used, for <math>iparm[30]=2</math> you must set the <math>i</math>-th component of the right-hand sides to zero explicitly if <math>perm(i)</math> is not equal to 1.</p>
3	<p>Selected components of the solution vectors are computed. The <math>perm</math> array is not related to the right-hand sides and it only indicates which components of the solution vectors should be computed. In this case <math>perm(i) = 1</math> means that the <math>i</math>-th component in the solution vectors is computed.</p>
$iparm[31]$ - $iparm[32]$	Reserved. Set to zero.
$iparm[33]$	Optimal number of OpenMP threads for conditional numerical reproducibility (CNR) mode.

Component	Description
	<p>Intel® oneAPI Math Kernel Library (oneMKL) PARDISO reads the value of <code>iparm[33]</code> during the analysis phase (phase 1), so you cannot change it later.</p> <p>Because Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses C random number generator facilities during the analysis phase (phase 1) you must take these precautions to get numerically reproducible results:</p> <ul style="list-style-type: none"> <li>• Do not alter the states of the random number generators.</li> <li>• Do not run multiple instances of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO in parallel in the analysis phase (phase 1).</li> </ul>
	<p><b>NOTE</b> CNR is only available for the in-core version of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO and the non-parallel version of the nested dissection algorithm. You must also:</p> <ul style="list-style-type: none"> <li>• set <code>iparm[59]</code> to 0 in order to use the in-core version,</li> <li>• not set <code>iparm[1]</code> to 3 in order to not use the parallel version of the nested dissection algorithm.</li> </ul> <p>Otherwise Intel® oneAPI Math Kernel Library (oneMKL) PARDISO does not produce numerically repeatable results even if CNR is enabled for Intel® oneAPI Math Kernel Library (oneMKL) using the functionality described in <a href="#">Support Functions for CNR</a>.</p>
0*	<p>CNR mode for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO is enabled only if it is enabled for Intel® oneAPI Math Kernel Library (oneMKL) using the functionality described in <a href="#">Support Functions for CNR</a> and the in-core version is used. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO determines the optimal number of OpenMP threads automatically, and produces numerically reproducible results regardless of the number of threads.</p>
>0	<p>CNR mode is enabled for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO if in-core version is used and the optimal number of OpenMP threads for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO to rely on is defined by the value of <code>iparm[33]</code>. You can use <code>iparm[33]</code> to enable CNR mode independent from other Intel® oneAPI Math Kernel Library (oneMKL) domains. To get the best performance, set <code>iparm[33]</code> to the actual number of hardware threads dedicated for Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. Setting <code>iparm[33]</code> to fewer OpenMP threads than the maximum number of them in use reduces the scalability of the problem being solved. Setting <code>iparm[33]</code> to more threads than are available can reduce the performance of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.</p>
<code>iparm[34]</code> input	<p>One- or zero-based indexing of columns and rows.</p>
	<p><b>NOTE</b> Schur complement may be inaccurate or incorrect if pivots are detected. Please, check the output of <code>iparm[28]</code>.</p>
0*	<p>One-based indexing: columns and rows indexing in arrays <code>ia</code>, <code>ja</code>, and <code>perm</code> starts from 1 (Fortran-style indexing).</p>
1	<p>Zero-based indexing: columns and rows indexing in arrays <code>ia</code>, <code>ja</code>, and <code>perm</code> starts from 0 (C-style indexing).</p>

Component	Description
<i>iparm</i> [35] input/output	<p>Schur complement matrix computation control. To calculate this matrix, you must set the input permutation vector <i>perm</i> to a set of indexes such that when <math>perm(i) = 1</math>, the <i>i</i>-th element of the initial matrix is an element of the Schur matrix.</p> <hr/> <p><b>Caution</b> You can only set one of <i>iparm</i>[4], <i>iparm</i>[30], and <i>iparm</i>[35], so be sure that the <i>iparm</i>[4] (user permutation) and the <i>iparm</i>[30] (partial solution) parameters are 0 if you set <i>iparm</i>[35].</p> <hr/> <p>0* Do not compute Schur complement.</p> <hr/> <p>1 Compute Schur complement matrix as part of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO factorization step and return it in the solution vector.</p> <hr/> <p><b>NOTE</b> This option only computes the Schur complement matrix, and does not calculate factorization arrays.</p> <hr/> <p>2 Compute Schur complement matrix as part of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO factorization step and return it in the solution vector. Since this option calculates factorization arrays you can use it to launch partial or full solution of the entire problem after the factorization step.</p> <hr/> <p>-1 Same as <i>iparm</i>[35] equals 1, but the Schur complement matrix is provided in 3-array CSR sparse format. Use in combination with <i>pardiso_export</i>. After reordering stage of MKL PARDISO, <i>iparm</i>[35] contains number of nonzero elements for Schur complement matrix. Set it once again before calling the factorization phase.</p> <hr/> <p><b>NOTE</b> This option is available only when <i>iparm</i>[23] is not equal to 0.</p> <hr/> <p>-2 Same as <i>iparm</i>[35] equals 2, but the Schur complement matrix is provided in 3-array CSR sparse format. Use in combination with <i>pardiso_export</i>. After reordering stage of MKL PARDISO, <i>iparm</i>[35] contains number of nonzero elements for Schur complement matrix. Set it once again before calling the factorization phase.</p> <hr/> <p><b>NOTE</b> This option is available only when <i>iparm</i>[23] is not equal to 0.</p> <hr/>
<i>iparm</i> [36] input	<p>Format for matrix storage.</p> <hr/> <p>0* Use CSR format (see <a href="#">Three Array Variation of CSR Format</a>) for matrix storage.</p> <hr/> <p>&gt; 0 Use BSR format (see <a href="#">Three Array Variation of BSR Format</a>) for matrix storage with blocks of size <i>iparm</i>[36].</p> <hr/>

Component	Description
	<p><b>NOTE</b> Intel® oneAPI Math Kernel Library (oneMKL) does not support BSR format in these cases:</p> <ul style="list-style-type: none"> <li>• <math>iparm[10] &gt; 0</math>: Scaling vectors</li> <li>• <math>iparm[12] &gt; 0</math>: Weighted matching</li> <li>• <math>iparm[30] &gt; 0</math>: Partial solution</li> <li>• <math>iparm[35] &gt; 0</math>: Schur complement</li> <li>• <math>iparm[55] &gt; 0</math>: Pivoting control</li> <li>• <math>iparm[59] &gt; 0</math>: OOC Intel® oneAPI Math Kernel Library (oneMKL) PARDISO</li> </ul>
< 0	<p>Convert supplied matrix to variable BSR (VBSR) format (see <a href="#">Sparse Data Storage</a>) for matrix storage. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO analyzes the matrix provided in CSR3 format and converts it to an internal VBSR format. Set <math>iparm[36] = -t, 0 &lt; t \leq 100</math>.</p> <p><b>NOTE</b> Intel® oneAPI Math Kernel Library (oneMKL) supports only the VBSR format for real and symmetric positive definite or indefinite matrices (<math>mtype = 2</math> or <math>mtype = -2</math>). Intel® oneAPI Math Kernel Library (oneMKL) does not support VBSR format in these cases:</p> <ul style="list-style-type: none"> <li>• <math>iparm[10] &gt; 0</math>: Scaling vectors</li> <li>• <math>iparm[12] &gt; 0</math>: Weighted matching</li> <li>• <math>iparm[55] &gt; 0</math>: Pivoting control</li> </ul> <p><b>NOTE</b> Intel® oneAPI Math Kernel Library (oneMKL) supports these features for all matrix types as long as <math>iparm[23] = 1</math>:</p> <ul style="list-style-type: none"> <li>• <math>iparm[30] &gt; 0</math>: Partial solution</li> <li>• <math>iparm[35] &gt; 0</math>: Schur complement</li> <li>• <math>iparm[59] &gt; 0</math>: OOC Intel® oneAPI Math Kernel Library (oneMKL) PARDISO</li> </ul>
$iparm[37]$	Reserved. Set to zero.
$iparm[38]$	<p>Enable low rank update (see <a href="#">Low Rank Update</a>) to accelerate factorization for multiple matrices with identical structure and similar values.</p> <p>0* Do not use low rank update functionality.</p> <p>1 Use low rank update functionality. You must also set <math>iparm[23] = 10</math> and provide a list of changed values in the <i>perm</i> array.</p> <p>This option requires the default settings of <math>iparm[3]</math>, <math>iparm[4]</math>, <math>iparm[5]</math>, <math>iparm[27]</math>, <math>iparm[30]</math>, <math>iparm[35]</math>, <math>iparm[36]</math>, <math>iparm[55]</math>, and <math>iparm[59]</math> as well.</p>
$iparm[39]$ - $iparm[41]$	Reserved. Set to zero.
$iparm[42]$	<p>Control parameter for the computation of the diagonal of inverse matrix.</p> <p>0* Do not compute the diagonal of inverse matrix.</p>

Component	Description
	<p>1 Intel® oneAPI Math Kernel Library (oneMKL) PARDISO computes the diagonal of the inverse matrix during the factorization phase. This feature is only available with two-level factorization algorithm (<i>iparm</i>[23] = 1) and real symmetric matrices (<i>mtype</i> = 2 or <i>mtype</i> = -2). The diagonal is returned in the solution vector.</p>
<i>iparm</i> [43] - <i>iparm</i> [54]	Reserved. Set to zero.
<i>iparm</i> [55]	Diagonal and pivoting control.
	<p>0* Internal function used to work with pivot and calculation of diagonal arrays turned off.</p>
	<p>1 You can use the <a href="#">mkl_pardiso_pivot</a> callback routine to control pivot elements which appear during numerical factorization. Additionally, you can obtain the elements of initial matrix and factorized matrices after the <code>pardiso</code> factorization step diagonal using the <a href="#">pardiso_getdiag</a> routine. This parameter can be turned on only in the in-core version of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.</p>
<i>iparm</i> [56] - <i>iparm</i> [58]	Reserved. Set to zero.
<i>iparm</i> [59]	Intel® oneAPI Math Kernel Library (oneMKL) PARDISO mode.
input	<p><i>iparm</i>[59] switches between in-core (IC) and out-of-core (OOC) Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. OOC can solve very large problems by holding the matrix factors in files on the disk, which requires a reduced amount of main memory compared to IC.</p> <p>Unless you are operating in sequential mode, you can switch between IC and OOC modes after the reordering phase. However, you can get better Intel® oneAPI Math Kernel Library (oneMKL) PARDISO performance by setting <i>iparm</i>[59] before the reordering phase.</p> <p>The amount of memory used in OOC mode depends on the number of OpenMP threads.</p>
	<p><b>NOTE</b> When <i>iparm</i>[59] &gt; 0, use the <code>MKL_PARDISO_OOC_FILE_NAME</code> environment variable to store factors.</p>
	<p><b>Warning</b> Do not increase the number of OpenMP threads used for <code>cluster_sparse_solver</code> between the first call and the factorization or solution phase. Because the minimum amount of memory required for out-of-core execution depends on the number of OpenMP threads, increasing it after the initial call can cause incorrect results.</p>
	<p>0* IC mode.</p>
	<p>1 IC mode is used if the total amount of RAM (in megabytes) needed for storing the matrix factors is less than sum of two values of the environment variables: <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code> (default value 2000 MB) and <code>MKL_PARDISO_OOC_MAX_SWAP_SIZE</code> (default value 0 MB); otherwise OOC mode is used. In this case amount of RAM used by OOC mode cannot exceed the value of <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code>.</p>

Component	Description
	<p>If the total peak memory needed for storing the local arrays is more than MKL_PARDISO_OOC_MAX_CORE_SIZE, increase MKL_PARDISO_OOC_MAX_CORE_SIZE if possible.</p> <hr/> <p><b>NOTE</b> Conditional numerical reproducibility (CNR) is not supported for this mode.</p> <hr/>
2	<p>OOO mode.</p> <p>The OOO mode can solve very large problems by holding the matrix factors in files on the disk. Hence the amount of RAM required by OOO mode is significantly reduced compared to IC mode.</p> <p>If the total peak memory needed for storing the local arrays is more than MKL_PARDISO_OOC_MAX_CORE_SIZE, increase MKL_PARDISO_OOC_MAX_CORE_SIZE if possible.</p> <p>To obtain better Intel® oneAPI Math Kernel Library (oneMKL) PARDISO performance, during the numerical factorization phase you can provide the maximum number of right-hand sides, which can be used further during the solving phase.</p> <p>Refer to <a href="#">How to use Intel® MKL OOO PARDISO</a> and <a href="#">Storage of Matrices</a> for more details about OOO.</p> <hr/>
<i>iparm</i> [60] - <i>iparm</i> [61]	Reserved. Set to zero.
<i>iparm</i> [62] output	<p>Size of the minimum OOO memory for numerical factorization and solution.</p> <p>This parameter provides the size in kilobytes of the minimum memory required by OOO Intel® oneAPI Math Kernel Library (oneMKL) PARDISO for internal floating point arrays. This parameter is computed in phase 1.</p> <p>Total peak memory consumption of OOO Intel® oneAPI Math Kernel Library (oneMKL) PARDISO can be estimated as <math>\max(iparm[14], iparm[15] + iparm[62])</math>.</p> <hr/>
<i>iparm</i> [63]	Reserved. Set to zero.

**NOTE**

Generally in sparse matrices, components which are equal to zero can be considered non-zero if necessary. For example, in order to make a matrix structurally symmetric, elements which are zero can be considered non-zero. See [Sparse Matrix Storage Formats](#) for an example.

Notice revision #20201201

**PARDISO\_DATA\_TYPE**

The following table lists the values of PARDISO\_DATA\_TYPE depending on the matrix types and values of the parameter *iparm*[27].

Data type value	Matrix type <i>mtype</i>	<i>iparm</i> [27]	comments
double	1, 2, -2, 11	0	Real matrices, do
float		1	Real matrices, sin
MKL_Complex16	3, 6, 13, 4, -4	0	Complex matrices precision
MKL_Complex8		1	Complex matrices precision

## Parallel Direct Sparse Solver for Clusters Interface

The Parallel Direct Sparse Solver for Clusters Interface solves large linear systems of equations with sparse matrices on clusters. It is

- high performing
- robust
- memory efficient
- easy to use

A hybrid implementation combines Message Passing Interface (MPI) technology for data exchange between parallel tasks (processes) running on different nodes, and OpenMP\* technology for parallelism inside each node of the cluster. This approach effectively uses modern hardware resources such as clusters consisting of nodes with multi-core processors. The solver code is optimized for the latest Intel processors, but also performs well on clusters consisting of non-Intel processors.

Code examples are available in the Intel® oneAPI Math Kernel Library (oneMKL) installation `examples` directory.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Parallel Direct Sparse Solver for Clusters Interface Algorithm

Parallel Direct Sparse Solver for Clusters Interface solves a set of sparse linear equations

$$A * X = B$$

with multiple right-hand sides using a distributed  $LU$ ,  $LL^T$ ,  $LDL^T$  or  $LDL^*$  factorization, where  $A$  is an  $n$ -by- $n$  matrix, and  $X$  and  $B$  are  $n$ -by- $nrhs$  matrices.

The solution comprises four tasks:

- analysis and symbolic factorization;
- numerical factorization;
- forward and backward substitution including iterative refinement;
- termination to release all internal solver memory.

The solver first computes a symmetric fill-in reducing permutation  $P$  based on the nested dissection algorithm from the METIS package [Karypis98] (included with Intel® oneAPI Math Kernel Library (oneMKL)), followed by the Cholesky or other type of factorization (depending on matrix type) [Schenk00-2] of  $PAP^T$ . The solver uses either diagonal pivoting, or 1x1 and 2x2 Bunch and Kaufman pivoting for symmetric indefinite or Hermitian matrices before finding an approximation of  $X$  by forward and backward substitution and iterative refinement.

The initial matrix  $A$  is perturbed whenever numerically acceptable 1x1 and 2x2 pivots cannot be found within the diagonal blocks. One or two passes of iterative refinement may be required to correct the effect of the perturbations. This restricted notion of pivoting with iterative refinement is effective for highly indefinite symmetric systems. For a large set of matrices from different application areas, the accuracy of this method is comparable to a direct factorization method that uses complete sparse pivoting techniques [Schenk04].

Parallel Direct Sparse Solver for Clusters additionally improves the pivoting accuracy by applying symmetric weighted matching algorithms. These methods identify large entries in the coefficient matrix  $A$  that, if permuted close to the diagonal, enable the factorization process to identify more acceptable pivots and proceed with fewer pivot perturbations. The methods are based on maximum weighted matching and improve the quality of the factor in a complementary way to the alternative idea of using more complete pivoting techniques.

### Parallel Direct Sparse Solver for Clusters Interface Matrix Storage

The sparse data storage in the Parallel Direct Sparse Solver for Clusters Interface follows the scheme described in the [Sparse Matrix Storage Formats](#) section using the variable  $ja$  for *columns*,  $ia$  for *rowIndex*, and  $a$  for *values*. Column indices  $ja$  must be in increasing order per row.

When an input data structure is not accessed in a call, a NULL pointer or any valid address can be passed as a placeholder for that argument.

### Algorithm Parallelization and Data Distribution

Intel® oneAPI Math Kernel Library (oneMKL) Parallel Direct Sparse Solver for Clusters enables parallel execution of the solution algorithm with efficient data distribution.

The master MPI process performs the symbolic factorization phase to represent matrix  $A$  as computational tree. Then matrix  $A$  is divided among all MPI processes in a one-dimensional manner. The same distribution is used for  $L$ -factor (the lower triangular matrix in Cholesky decomposition). Matrix  $A$  and all required internal data are broadcast to subordinate MPI processes. Each MPI process fills in its own parts of  $L$ -factor with initial values of the matrix  $A$ .

Parallel Direct Sparse Solver for Clusters Interface computes all independent parts of  $L$ -factor completely in parallel. When a block of the factor must be updated by other blocks, these updates are independently passed to a temporary array on each updating MPI process. It further gathers the result into an updated block using the `MPI_Reduce()` routine. The computations within an MPI process are dynamically divided among OpenMP threads using pipelining parallelism with a combination of left- and right-looking techniques similar to those of the PARDISO\* software. Level 3 BLAS operations from Intel® oneAPI Math Kernel Library (oneMKL) ensure highly efficient performance of block-to-block update operations.

During forward/backward substitutions, respective Right Hand Side (RHS) parts are distributed among all MPI processes. All these processes participate in the computation of the solution. Finally, the solution is gathered on the master MPI process.

This approach demonstrates good scalability on clusters with Infiniband\* technology. Another advantage of the approach is the effective distribution of  $L$ -factor among cluster nodes. This enables the solution of tasks with a much higher number of non-zero elements than it is possible with any Symmetric Multiprocessing (SMP) in-core direct solver.

The algorithm ensures that the memory required to keep internal data on each MPI process is decreased when the number of MPI processes in a run increases. However, the solver requires that matrix  $A$  and some other internal arrays completely fit into the memory of each MPI process.

To get the best performance, run one MPI process per physical node and set the number of OpenMP\* threads per node equal to the number of physical cores on the node.

**NOTE**

Instead of calling `MPI_Init()`, initialize MPI with `MPI_Init_thread()` and set the MPI threading level to `MPI_THREAD_FUNNELED` or higher. For details, see the code examples in `<install_dir>/examples`.

**cluster\_sparse\_solver**

*Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.*

**Syntax**

```
void cluster_sparse_solver (_MKL_DSS_HANDLE_t pt, const MKL_INT *maxfct, const MKL_INT *mnum, const MKL_INT *mtype, const MKL_INT *phase, const MKL_INT *n, const void *a, const MKL_INT *ia, const MKL_INT *ja, MKL_INT *perm, const MKL_INT *nrhs, MKL_INT *iparm, const MKL_INT *msglvl, void *b, void *x, const int *comm, MKL_INT *error);
```

**Include Files**

- `mkl_cluster_sparse_solver.h`

**Description**

The routine `cluster_sparse_solver` calculates the solution of a set of sparse linear equations

$$A \cdot X = B$$

with single or multiple right-hand sides, using a parallel *LU*, *LDL*, or *LL<sup>T</sup>* factorization, where *A* is an *n*-by-*n* matrix, and *X* and *B* are *n*-by-*nrhs* vectors or matrices.

**NOTE**

This routine supports the Progress Routine feature. See [Progress Function](#) for details.

**Input Parameters****NOTE**

Most of the input parameters (except for the *pt*, *phase*, and *comm* parameters and, for the distributed format, the *a*, *ia*, and *ja* arrays) must be set on the master MPI process only, and ignored on other processes. Other MPI processes get all required data from the master MPI process using the MPI communicator, *comm*.

*pt*

Array of size 64.

Handle to internal data structure. The entries must be set to zero before the first call to `cluster_sparse_solver`.

**Caution**

After the first call to `cluster_sparse_solver` do not modify *pt*, as that could cause a serious memory leak.

*maxfct*

Ignored; assumed equal to 1.

<i>mnum</i>	Ignored; assumed equal to 1.																		
<i>mtype</i>	<p>Defines the matrix type, which influences the pivoting method. The Parallel Direct Sparse Solver for Clusters solver supports the following matrices:</p> <table> <tr> <td>1</td> <td>real and structurally symmetric</td> </tr> <tr> <td>2</td> <td>real and symmetric positive definite</td> </tr> <tr> <td>-2</td> <td>real and symmetric indefinite</td> </tr> <tr> <td>3</td> <td>complex and structurally symmetric</td> </tr> <tr> <td>4</td> <td>complex and Hermitian positive definite</td> </tr> <tr> <td>-4</td> <td>complex and Hermitian indefinite</td> </tr> <tr> <td>6</td> <td>complex and symmetric</td> </tr> <tr> <td>11</td> <td>real and nonsymmetric</td> </tr> <tr> <td>13</td> <td>complex and nonsymmetric</td> </tr> </table>	1	real and structurally symmetric	2	real and symmetric positive definite	-2	real and symmetric indefinite	3	complex and structurally symmetric	4	complex and Hermitian positive definite	-4	complex and Hermitian indefinite	6	complex and symmetric	11	real and nonsymmetric	13	complex and nonsymmetric

22	Numerical factorization																		
23	Numerical factorization, solve, iterative refinement																		
33	Solve, iterative refinement																		
-1	Release all internal memory for all matrices																		
<i>n</i>	Number of equations in the sparse linear systems of equations $A^*X = B$ . Constraint: $n > 0$ .																		
<i>a</i>	Array. Contains the non-zero elements of the coefficient matrix <i>A</i> corresponding to the indices in <i>ja</i> . The coefficient matrix can be either real or complex. The matrix must be stored in the three-array variant of the																		

compressed sparse row (CSR3) or in the three-array variant of the block compressed sparse row (BSR3) format, and the matrix must be stored with increasing values of  $ja$  for each row.

For CSR3 format, the size of  $a$  is the same as that of  $ja$ . Refer to the *values* array description in [Three Array Variation of CSR Format](#) for more details.

For BSR3 format the size of  $a$  is the size of  $ja$  multiplied by the square of the block size. Refer to the *values* array description in [Three Array Variation of BSR Format](#) for more details.

---

#### NOTE

For centralized input ( $iparm[39]=0$ ), provide the  $a$  array for the master MPI process only. For distributed assembled input ( $iparm[39]=1$  or  $iparm[39]=2$ ), provide it for all MPI processes.

---

---

#### Important

The column indices of non-zero elements of each row of the matrix  $A$  must be stored in increasing order.

---

$ia$

For CSR3 format,  $ia[i]$  ( $i < n$ ) points to the first column index of row  $i$  in the array  $ja$ . That is,  $ia[i]$  gives the index of the element in array  $a$  that contains the first non-zero element from row  $i$  of  $A$ . The last element  $ia[n]$  is taken to be equal to the number of non-zero elements in  $A$ , plus one. Refer to *rowIndex* array description in [Three Array Variation of CSR Format](#) for more details.

For BSR3 format,  $ia[i]$  ( $i < n$ ) points to the first column index of row  $i$  in the array  $ja$ . That is,  $ia[i]$  gives the index of the element in array  $a$  that contains the first non-zero block from row  $i$  of  $A$ . The last element  $ia[n]$  is taken to be equal to the number of non-zero blocks in  $A$ , plus one. Refer to *rowIndex* array description in [Three Array Variation of BSR Format](#) for more details.

The array  $ia$  is accessed in all phases of the solution process.

Indexing of  $ia$  is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter  $iparm[34]$ . For zero-based indexing, the last element  $ia[n]$  is assumed to be equal to the number of non-zero elements in matrix  $A$ .

---

#### NOTE

For centralized input ( $iparm[39]=0$ ), provide the  $ia$  array at the master MPI process only. For distributed assembled input ( $iparm[39]=1$  or  $iparm[39]=2$ ), provide it at all MPI processes.

---

$ja$

For CSR3 format, array  $ja$  contains column indices of the sparse matrix  $A$ . It is important that the indices are in increasing order per row. For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in [Three Array Variation of CSR Format](#).

For BSR3 format, array *ja* contains column indices of the sparse matrix *A*. It is important that the indices are in increasing order per row. For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in [Three Array Variation of BSR Format](#).

The array *ja* is accessed in all phases of the solution process.

Indexing of *ja* is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter *iparm(35)*.

---

#### NOTE

For centralized input (*iparm(40)=0*), provide the *ja* array at the master MPI process only. For distributed assembled input (*iparm(40)=1* or *iparm(40)=2*), provide it at all MPI processes.

---

<i>perm</i>	Ignored.
<i>nrhs</i>	Number of right-hand sides that need to be solved for.
<i>iparm</i>	Array, size 64. This array is used to pass various parameters to Parallel Direct Sparse Solver for Clusters Interface and to return some useful information after execution of the solver.  See <a href="#">cluster_sparse_solver iparm Parameter</a> for more details about the <i>iparm</i> parameters.
<i>msglvl</i>	Message level information. If <i>msglvl = 0</i> then <i>cluster_sparse_solver</i> generates no output, if <i>msglvl = 1</i> the solver prints statistical information to the screen.  Statistics include information such as the number of non-zero elements in <i>L-factor</i> and the timing for each phase.  Set <i>msglvl = 1</i> if you report a problem with the solver, since the additional information provided can facilitate a solution.
<i>b</i>	Array, size $n * nrhs$ . On entry, contains the right-hand side vector/matrix <i>B</i> , which is placed in memory contiguously. The $b[i+k*n]$ must hold the <i>i</i> -th component of <i>k</i> -th right-hand side vector. Note that <i>b</i> is only accessed in the solution phase.
<i>comm</i>	MPI communicator. The solver uses the Fortran MPI communicator internally. Convert the MPI communicator to Fortran using the <code>MPI_Comm_c2f()</code> function. See the examples in the <code>&lt;install_dir&gt;/examples</code> directory.

## Output Parameters

<i>pt</i>	Handle to internal data structure.
<i>perm</i>	Ignored.
<i>iparm</i>	On output, some <i>iparm</i> values report information such as the numbers of non-zero elements in the factors.

See [cluster\\_sparse\\_solver iparm Parameter](#) for more details about the *iparm* parameters.

*b*

On output, the array is replaced with the solution if *iparm*[5] = 1.

*x*

Array, size ( $n * nrhs$ ). If *iparm*[5]=0 it contains solution vector/matrix *X*, which is placed contiguously in memory. The  $x[i+k*n]$  element must hold the *i*-th component of the *k*-th solution vector. Note that *x* is only accessed in the solution phase.

*error*

The error indicator according to the below table:

<b>error</b>	<b>Information</b>
0	no error
-1	input inconsistent
-2	not enough memory
-3	reordering problem
-4	Zero pivot, numerical factorization or iterative refinement problem. If the error appears during the solution phase, try to change the pivoting perturbation ( <i>iparm</i> [9]) and also increase the number of iterative refinement steps. If it does not help, consider changing the scaling, matching and pivoting options ( <i>iparm</i> [10], <i>iparm</i> [12], <i>iparm</i> [20])
-5	unclassified (internal) error
-6	reordering failed (matrix types 11 and 13 only)
-7	diagonal matrix is singular
-8	32-bit integer overflow problem
-9	not enough memory for OOC
-10	error opening OOC files
-11	read/write error with OOC files

## cluster\_sparse\_solver\_64

*Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.*

### Syntax

```
void cluster_sparse_solver_64 (_MKL_DSS_HANDLE_t pt, const long long int *maxfct, const long long int *mnum, const long long int *mtype, const long long int *phase, const long long int *n, const void *a, const long long int *ia, const long long int *ja, long long int *perm, const long long int *nrhs, long long int *iparm, const long long int *msglvl, void *b, void *x, const int *comm, long long int *error);
```

### Include Files

- `mkl_cluster_sparse_solver.h`

## Description

The routine `cluster_sparse_solver_64` is an alternative ILP64 (64-bit integer) version of the `cluster_sparse_solver` routine (see the Description section for more details). The interface of `cluster_sparse_solver_64` is the same as the interface of `cluster_sparse_solver`, but it accepts and returns all integer data as `long long int`.

Use `cluster_sparse_solver_64` when `cluster_sparse_solver` for solving large matrices (with the number of non-zero elements on the order of 500 million or more). You can use it together with the usual LP64 interfaces for the rest of Intel® oneAPI Math Kernel Library (oneMKL) functionality. In other words, if you use 64-bit integer version (`cluster_sparse_solver_64`), you do not need to re-link your applications with ILP64 libraries. Take into account that `cluster_sparse_solver_64` may perform slower than regular `cluster_sparse_solver` on the reordering and symbolic factorization phase.

---

### NOTE

`cluster_sparse_solver_64` is supported only in the 64-bit libraries. If `cluster_sparse_solver_64` is called from the 32-bit libraries, it returns `error == -12`.

---

---

### NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) for details.

---

## Input Parameters

The input parameters of `cluster_sparse_solver_64` are the same as the input parameters of `cluster_sparse_solver`, but `cluster_sparse_solver_64` accepts all integer data as `long long int`.

## Output Parameters

The output parameters of `cluster_sparse_solver_64` are the same as the output parameters of `cluster_sparse_solver`, but `cluster_sparse_solver_64` returns all integer data as `long long int`.

## `cluster_sparse_solver_get_csr_size`

*Computes the (local) number of rows and (local) number of nonzero entries for (distributed) CSR data corresponding to the provided name.*

---

## Syntax

```
void cluster_sparse_solver_get_csr_size (_MKL_DSS_HANDLE_t pt, _MKL_DSS_EXPORT_DATA
name , MKL_INT *local_nrows, MKL_INT *local_nnz, const int*comm, MKL_INT *error);
```

## Include Files

- `mkl_cluster_sparse_solver.h`

## Description

This routine uses the internal data created during the factorization phase of `cluster_sparse_solver` for matrix *A*. The routine then:

- Computes the local number of rows and the local number of nonzeros for CSR data that correspond to the provided *name*
- Returns the computed values in `local_nrows` and `local_nnz`

It is assumed that the CSR data defined by the *name* will be distributed in the same way as the matrix *A* (as defined by *iparm*[39]) used in `cluster_sparse_solver`.

The returned values can be used for allocating CSR arrays for factors *L* and *U*, and also for allocating arrays for permutations *P* and *Q*, or scaling matrix *D* which can then be used with

`cluster_sparse_solver_set_csr_ptrs` or `cluster_sparse_solver_set_ptr` for exporting corresponding data via `cluster_sparse_solver_export`.

---

#### NOTE

Only call this routine after the factorization phase (*phase*=22) of the `cluster_sparse_solver` has been called. Neither *pt*, nor *iparm* should be changed after the preceding call to `cluster_sparse_solver`.

---

### Input Parameters

*pt* Array with size of 64.  
Handle to internal data structure used in the prior calls to `cluster_sparse_solver`.

---

#### Caution

Do not modify *pt* after the calls to `cluster_sparse_solver`.

---

*name* Specifies CSR data for which the output values are computed.

<code>SPARSE_PTLUQT_L</code>	Factor <i>L</i> from $P^*A^*Q=L^*U$ .
<code>SPARSE_PTLUQT_U</code>	Factor <i>U</i> from $P^*A^*Q=L^*U$ .
<code>SPARSE_DPTLUQT_L</code>	Factor <i>L</i> from $P^* (D^{-1}A) *Q=L^*U$ .
<code>SPARSE_DPTLUQT_U</code>	Factor <i>U</i> from $P^* (D^{-1}A) *Q=L^*U$ .

*local\_nrows* On entry, an array of size 1.

*local\_nnz* On entry, an array of size 1.

*comm* MPI communicator. The solver uses the Fortran MPI communicator internally. Convert the MPI communicator to Fortran using the `MPI_Comm_c2f()` function. See the examples in the `<install_dir>/examples` directory.

### Output Parameters

*local\_nrows* On output, the local number of rows for the CSR data which correspond to the *name*.

*local\_nnz* On output, the local number of nonzero entries for the CSR data which correspond to the *name*.

*error* The error indicator:

<b>error</b>	<b>Information</b>
0	no error

Handle to internal data structure used in the prior calls to `cluster_sparse_solver`.

---

### Caution

Do not modify `pt` after the calls to `cluster_sparse_solver`.

---

<i>name</i>	<p>Specifies for which CSR data the pointers are provided.</p> <p><code>SPARSE_PTLUQT_L</code>     Factor <math>L</math> from <math>P^*A^*Q=L^*U</math>.</p> <p><code>SPARSE_PTLUQT_U</code>     Factor <math>U</math> from <math>P^*A^*Q=L^*U</math>.</p> <p><code>SPARSE_DPTLUQT_L</code>     Factor <math>L</math> from <math>P^* (D^{-1}A) *Q=L^*U</math>.</p> <p><code>SPARSE_DPTLUQT_U</code>     Factor <math>U</math> from <math>P^* (D^{-1}A) *Q=L^*U</math>.</p>
<i>rowptr</i>	<p>Array of length at least <math>(local\_nrows+1)</math> where <math>local\_nrows</math> is the local number of rows, which can be obtained by calling <code>cluster_sparse_solver_get_csr_size</code>. This array contains row indices, such that <math>rowptr[i] - indexing</math> is the first index of row <math>i</math> in the array's <code>vals</code> and <code>colindx</code>. Here, the value of <code>indexing</code> is 0 for zero-based indexing and 1 for one-based indexing, and must be the same as it was for the matrix <math>A</math> used in the preceding calls to <code>cluster_sparse_solver</code> (also stored in <code>iparm[34]</code>).</p> <p>Refer to <code>pointerB</code> array description in <a href="#">CSR Format</a> for more details.</p>
<i>colindx</i>	<p>Array of length at least <math>rowptr[local\_nrows] - rowptr[0]</math>. Indexing (zero- or one-based) must be the same as for <code>rowptr</code>. For one-based indexing, the array contains the column indices plus one for each non-zero element of the matrix which corresponds to the <code>name</code>. For zero-based indexing, the array contains the column indices for each non-zero element of the matrix.</p>
<i>vals</i>	<p>Array containing non-zero elements of the matrix which corresponds to the <code>name</code>. Its length is equal to length of the <code>colindx</code> array. Refer to values array description in <a href="#">CSR Format</a> for more details.</p> <p>It will be interpreted internally as <code>float*/double*(MKL_Complex8*/MKL_Complex16*)</code> depending on <code>mtype</code> (type of the matrix <math>A</math>) and <code>iparm[27]</code> (precision) specified in the preceding call to <code>cluster_sparse_solver</code>.</p>
<i>comm</i>	<p>MPI communicator. The solver uses the Fortran MPI communicator internally. Convert the MPI communicator to Fortran using the <code>MPI_Comm_c2f()</code> function. See the examples in the <code>&lt;install_dir&gt;/examples</code> directory.</p>

## Output Parameters

<i>error</i>	<p>The error indicator:</p> <table> <thead> <tr> <th style="text-align: left;"><b>error</b></th> <th style="text-align: left;"><b>Information</b></th> </tr> </thead> <tbody> <tr> <td>0</td> <td>no error</td> </tr> </tbody> </table>	<b>error</b>	<b>Information</b>	0	no error
<b>error</b>	<b>Information</b>				
0	no error				

<i>name</i>	Specifies the data for which the pointer is provided.
	SPARSE_PTLUQT_P      Permutation $P$ from $P^*A^*Q=L^*U$ .
	SPARSE_PTLUQT_Q      Permutation $Q$ from $P^*A^*Q=L^*U$ .
	SPARSE_DPTLUQT_P      Permutation $P$ from $P^* (D^{-1}A) ^*Q=L^*U$ .
	SPARSE_DPTLUQT_Q      Permutation $Q$ from $P^* (D^{-1}A) ^*Q=L^*U$ .
	SPARSE_DPTLUQT_D      Scaling (diagonal) $D$ from $P^* (D^{-1}A) ^*Q=L^*U$ .
<i>vals</i>	<p>Array containing elements of the vector representation for the data which corresponds to the <i>name</i>. Its length should be at least <i>local_nrows</i>, where <i>local_nrows</i> is the local number of rows in a corresponding matrix (obtained from <code>cluster_sparse_solver_get_csr_size</code>, for example).</p> <p>For permutations <math>P</math> and <math>Q</math>, <i>vals</i> is interpreted as <code>MKL_INT*</code>, while for the scaling it is interpreted as <code>float*/double*(MKL_Complex8*/MKL_Complex16*)</code> depending on <i>mtype</i> (type of the matrix <math>A</math>) and <i>iparm[27]</i> (precision) specified in the preceding call to <code>cluster_sparse_solver</code>.</p>
<i>comm</i>	MPI communicator. The solver uses the Fortran MPI communicator internally. Convert the MPI communicator to Fortran using the <code>MPI_Comm_c2f()</code> function. See the examples in the <code>&lt;install_dir&gt;/examples</code> directory.

## Output Parameters

<i>error</i>	The error indicator:																
	<table> <thead> <tr> <th><b>error</b></th> <th><b>Information</b></th> </tr> </thead> <tbody> <tr> <td>0</td> <td>no error</td> </tr> <tr> <td>-1</td> <td><i>pt</i> is a null pointer</td> </tr> <tr> <td>-2</td> <td>invalid <i>pt</i></td> </tr> <tr> <td>-3</td> <td>invalid <i>name</i></td> </tr> <tr> <td>-4</td> <td>unsupported <i>name</i></td> </tr> <tr> <td>-9</td> <td>unsupported internal code path, consider switching off non-default <i>iparm</i> parameters for <code>cluster_sparse_solver</code></td> </tr> <tr> <td>-12</td> <td>internal memory error</td> </tr> </tbody> </table>	<b>error</b>	<b>Information</b>	0	no error	-1	<i>pt</i> is a null pointer	-2	invalid <i>pt</i>	-3	invalid <i>name</i>	-4	unsupported <i>name</i>	-9	unsupported internal code path, consider switching off non-default <i>iparm</i> parameters for <code>cluster_sparse_solver</code>	-12	internal memory error

0	no error																
-1	<i>pt</i> is a null pointer																
-2	invalid <i>pt</i>																
-3	invalid <i>name</i>																
-4	unsupported <i>name</i>																
-9	unsupported internal code path, consider switching off non-default <i>iparm</i> parameters for <code>cluster_sparse_solver</code>																
-12	internal memory error																

---

**NOTE** Refer to `cl_solver_export_c.c` for an example using this functionality.

---

**NOTE**

Currently, for *operation*=SPARSE\_DPTLUQT a real (complex) unit vector is provided for the scaling matrix *D*. Do not turn on *scaling(iparm[10]>0)* or *matching(iparm[12]>0)* in the *iparm* during the call to `cluster_sparse_solver` for this value of *operation*.

*comm*

MPI communicator. The solver uses the Fortran MPI communicator internally. Convert the MPI communicator to Fortran using the `MPI_Comm_c2f()` function. See the examples in the `<install_dir>/examples` directory.

**Output Parameters***error*

The error indicator:

<b>error</b>	<b>Information</b>
0	no error
-1	<i>pt</i> is a null pointer
-2	invalid <i>pt</i>
-5	invalid <i>operation</i>
-6	pointers to some of the data required for the specified <i>operation</i> were not provided prior to calling <code>cluster_sparse_solver_export</code>
-9	unsupported internal code path, consider switching off non-default <i>iparm</i> parameters for <code>cluster_sparse_solver</code>
-10	unsupported case when the matrix <i>A</i> is distributed among processes with overlap in the preceding calls to <code>cluster_sparse_solver</code>
-12	internal memory error

**NOTE** Refer to `cl_solver_export_c.c` for an example using this functionality.

**cluster\_sparse\_solver iparm Parameter**

The following table describes all individual components of the Parallel Direct Sparse Solver for Clusters Interface *iparm* parameter. Components which are not used must be initialized with 0. Default values are denoted with an asterisk (\*).

<b>Component</b>	<b>Description</b>
<i>iparm</i> [0]	Use default values.
input	0 <i>iparm</i> [1] - <i>iparm</i> (64) are filled with default values.
	!=0 You must supply all values in components <i>iparm</i> [1] - <i>iparm</i> (64).

Component	Description
<i>iparm</i> [1] input	Fill-in reducing ordering for the input matrix.
	2* The nested dissection algorithm from the METIS package [Karypis98].
	3 The parallel version of the nested dissection algorithm. It can decrease the time of computations on multi-core computers, especially when Phase 1 takes significant time.
	10 The MPI version of the nested dissection and symbolic factorization algorithms for the matrix in distributed assembled matrix input format ( <i>iparm</i> [39] > 0). The input matrix for the reordering must be distributed among different MPI processes without any intersection and all MPI ranks must have at least one row of the input matrix. Use <i>iparm</i> [40] and <i>iparm</i> [41] to set the bounds of the domain. During all of Phase 1, the entire matrix is not gathered on any one process, which can decrease computation time (especially when Phase 1 takes significant time) and decrease memory usage for each MPI process on the cluster.
	<p><b>NOTE</b> Distributed reordering does not work if any of <code>matching(iparm[12]=1) / scaling(iparm[10]=1) / BSR format(iparm[36]&gt;1) / Schur complement matrix computation control(iparm[35]&gt;0) / Partial solve(iparm[30] &gt; 0)</code> is turned on, or if the distributed input matrix has overlapping distribution of rows across MPI processes.</p>
	<p><b>NOTE</b> If you set <code>iparm[1] = 10, comm = -1</code> (MPI communicator), and if there is one MPI process, optimization and full parallelization with the OpenMP version of the nested dissection and symbolic factorization algorithms proceeds. This can decrease computation time on multi-core computers. In this case, set <code>iparm[40] = 1</code> and <code>iparm[41] = n</code> for one-based indexing, or to 0 and <code>n - 1</code>, respectively, for zero-based indexing.</p>
<i>iparm</i> [2]	Reserved. Set to zero.
<i>iparm</i> [3]	Reserved. Set to zero.
<i>iparm</i> [4] input	User permutation.
	<p>This parameter controls whether user supplied fill-in reducing permutation is used instead of the integrated multiple-minimum degree or nested dissection algorithms. Another use of this parameter is to control obtaining the fill-in reducing permutation vector calculated during the reordering stage of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.</p> <p>This option is useful for testing reordering algorithms, adapting the code to special applications problems (for instance, to move zero diagonal elements to the end of <math>P^*A^*P^T</math>), or for using the permutation vector more than once for matrices with identical sparsity structures. For definition of the permutation, see the description of the <i>perm</i> parameter.</p>
	<p><b>Caution</b> You can only set one of <code>iparm[4]</code>, <code>iparm[30]</code>, and <code>iparm[35]</code>, so be sure that the <code>iparm[30]</code> (partial solution) and the <code>iparm[35]</code> (Schur complement) parameters are 0 if you set <code>iparm[4]</code>.</p>
	<p>0 User permutation in the <i>perm</i> array is ignored.</p>
	<p>1 Intel® oneAPI Math Kernel Library (oneMKL) PARDISO uses the user supplied fill-in reducing permutation from the <i>perm</i> array. <code>iparm[1]</code> is ignored.</p>
	<p>2 Intel® oneAPI Math Kernel Library (oneMKL) PARDISO returns the permutation vector computed at phase 1 in the <i>perm</i> array.</p>

Component	Description
<i>iparm</i> [5] input	Write solution on <i>x</i> .  <b>NOTE</b> The array <i>x</i> is always used.
	0*      The array <i>x</i> contains the solution; right-hand side vector <i>b</i> is kept unchanged.
	1      The solver stores the solution on the right-hand side <i>b</i> .
<i>iparm</i> [6] output	Number of iterative refinement steps performed. Reports the number of iterative refinement steps that were actually performed during the solve step.
<i>iparm</i> [7] input	Iterative refinement step. On entry to the solve and iterative refinement step, <i>iparm</i> [7] must be set to the maximum number of iterative refinement steps that the solver performs.
	0*      The solver automatically performs two steps of iterative refinement when perturbed pivots are obtained during the numerical factorization.
	>0      Maximum number of iterative refinement steps that the solver performs. The solver performs not more than the absolute value of <i>iparm</i> [7] steps of iterative refinement. The solver might stop the process before the maximum number of steps if <ul style="list-style-type: none"> <li>• a satisfactory level of accuracy of the solution in terms of backward error is achieved,</li> <li>• or if it determines that the required accuracy cannot be reached. In this case Parallel Direct Sparse Solver for Clusters Interface returns -4 in the <i>error</i> parameter.</li> </ul> The number of executed iterations is reported in <i>iparm</i> [6].
	<0      Same as above, but the accumulation of the residuum uses extended precision real and complex data types.  Perturbed pivots result in iterative refinement (independent of <i>iparm</i> [7]=0) and the number of executed iterations is reported in <i>iparm</i> [6].
<i>iparm</i> [8]	Reserved. Set to zero.
<i>iparm</i> [9] input	Pivoting perturbation. This parameter instructs Parallel Direct Sparse Solver for Clusters Interface how to handle small pivots or zero pivots for nonsymmetric matrices ( <i>mtype</i> =11 or <i>mtype</i> =13) and symmetric matrices ( <i>mtype</i> =-2, <i>mtype</i> =-4, or <i>mtype</i> =6). For these matrices the solver uses a complete supernode pivoting approach. When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99], [Schenk04]. Small pivots are perturbed with $\text{eps} = 10^{-iparm[9]}$ . The magnitude of the potential pivot is tested against a constant threshold of $\text{alpha} = \text{eps} *   A2  _{inf}$ ,

Component	Description
	where $\text{eps} = 10^{-\text{iparm}[9]}$ , $A2 = P^*P_{\text{MPS}}*D_r*A*D_c*P$ , and $\ A2\ _{\text{inf}}$ is the infinity norm of the scaled and permuted matrix $A$ . Any tiny pivots encountered during elimination are set to the sign $(I_{II}) * \text{eps} * \ A2\ _{\text{inf}}$ , which trades off some numerical stability for the ability to keep pivots from getting too small. Small pivots are therefore perturbed with $\text{eps} = 10^{-\text{iparm}[9]}$ .
	13* The default value for nonsymmetric matrices ( $\text{mtype} = 11, \text{mtype} = 13$ ), $\text{eps} = 10^{-13}$ .
	8* The default value for symmetric indefinite matrices ( $\text{mtype} = -2, \text{mtype} = -4, \text{mtype} = 6$ ), $\text{eps} = 10^{-8}$ .
<code>iparm[10]</code> input	<p>Scaling vectors.</p> <p>Parallel Direct Sparse Solver for Clusters Interface uses a maximum weight matching algorithm to permute large elements on the diagonal and to scale.</p> <p>Use <code>iparm[10] = 1</code> (scaling) and <code>iparm[12] = 1</code> (matching) for highly indefinite symmetric matrices, for example, from interior point optimizations or saddle point problems. Note that in the analysis phase (<code>phase=11</code>) you must provide the numerical values of the matrix <math>A</math> in array <math>a</math> in case of scaling and symmetric weighted matching.</p>
	0* Disable scaling. Default for symmetric indefinite matrices.
	1* Enable scaling. Default for nonsymmetric matrices.
	Scale the matrix so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less or equal to 1. This scaling method is applied to nonsymmetric matrices ( $\text{mtype} = 11, \text{mtype} = 13$ ). The scaling can also be used for symmetric indefinite matrices ( $\text{mtype} = -2, \text{mtype} = -4, \text{mtype} = 6$ ) when the symmetric weighted matchings are applied ( <code>iparm[12] = 1</code> ).
	Note that in the analysis phase ( <code>phase=11</code> ) you must provide the numerical values of the matrix $A$ in case of scaling.
<code>iparm[11]</code>	Solve with transposed or conjugate transposed matrix $A$ .
	<b>NOTE</b> For real matrices, the terms <i>transposed</i> and <i>conjugate transposed</i> are equivalent.
	0* Solve a linear system $AX = B$ .
	1 Solve a conjugate transposed system $A^H X = B$ based on the factorization of the matrix $A$ .
	2 Solve a transposed system $A^T X = B$ based on the factorization of the matrix $A$ .
<code>iparm[12]</code> input	<p>Improved accuracy using (non-) symmetric weighted matching.</p> <p>Parallel Direct Sparse Solver for Clusters Interface can use a maximum weighted matching algorithm to permute large elements close the diagonal. This strategy adds an additional level of reliability to the factorization methods and complements the alternative of using more complete pivoting techniques during the numerical factorization.</p>
	0* Disable matching. Default for symmetric indefinite matrices.
	1* Enable matching. Default for nonsymmetric matrices.

Component	Description
	<p>Maximum weighted matching algorithm to permute large elements close to the diagonal.</p> <p>It is recommended to use <code>iparm[10] = 1</code> (scaling) and <code>iparm[12] = 1</code> (matching) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems.</p> <p>Note that in the analysis phase (<code>phase=11</code>) you must provide the numerical values of the matrix <i>A</i> in case of symmetric weighted matching.</p>
<code>iparm[13]</code> output	<p>Number of perturbed pivots.</p> <p>After factorization, contains the number of perturbed pivots for the matrix types: 1, 3, 11, 13, -2, -4 and 6.</p>
<code>iparm[14]</code> output	<p>Peak memory on symbolic factorization.</p> <p>The total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase.</p> <p>This value is only computed in phase 1.</p>
<code>iparm[15]</code> output	<p>Permanent memory on symbolic factorization.</p> <p>Permanent memory from the analysis and symbolic factorization phase in kilobytes that the solver needs in the factorization and solve phases.</p> <p>This value is only computed in phase 1.</p>
<code>iparm[16]</code> output	<p>Size of factors/Peak memory on numerical factorization and solution.</p> <p>This parameter provides the size in kilobytes of the total memory consumed by in-core Intel® oneAPI Math Kernel Library (oneMKL) PARDISO for internal floating point arrays. This parameter is computed in phase 1. See <code>iparm[62]</code> for the OOC mode.</p> <p>The total peak memory consumed by Intel® oneAPI Math Kernel Library (oneMKL) PARDISO is <math>\max(iparm[14], iparm[15] + iparm[16])</math></p>
<code>iparm[17]</code> input/output	<p>Report the number of non-zero elements in the factors.</p> <p>&lt;0      Enable reporting if <code>iparm[17] &lt; 0</code> on entry. The default value is -1.</p> <p>&gt;=0     Disable reporting.</p>
<code>iparm[18]</code> - <code>iparm[19]</code>	Reserved. Set to zero.
<code>iparm[20]</code> input	<p>Pivoting for symmetric indefinite matrices.</p> <p>0      Apply 1x1 diagonal pivoting during the factorization process.</p> <p>1*     Apply 1x1 and 2x2 Bunch-Kaufman pivoting during the factorization process. Bunch-Kaufman pivoting is available for matrices of <code>mtype=-2</code>, <code>mtype=-4</code>, or <code>mtype=6</code>.</p>
<code>iparm[21]</code> output	<p>Inertia: number of positive eigenvalues.</p> <p>Intel® oneAPI Math Kernel Library (oneMKL) PARDISO reports the number of positive eigenvalues for symmetric indefinite matrices.</p>
<code>iparm[22]</code> output	<p>Inertia: number of negative eigenvalues.</p> <p>Intel® oneAPI Math Kernel Library (oneMKL) PARDISO reports the number of negative eigenvalues for symmetric indefinite matrices.</p>

Component	Description				
<i>iparm</i> [23] - <i>iparm</i> [25]	Reserved. Set to zero.				
<i>iparm</i> [26]	Matrix checker.				
input	<table border="1"> <tr> <td>0*</td> <td>Do not check the sparse matrix representation for errors.</td> </tr> <tr> <td>1</td> <td>Check integer arrays <i>ia</i> and <i>ja</i>. In particular, check whether the column indices are sorted in increasing order within each row.</td> </tr> </table>	0*	Do not check the sparse matrix representation for errors.	1	Check integer arrays <i>ia</i> and <i>ja</i> . In particular, check whether the column indices are sorted in increasing order within each row.
0*	Do not check the sparse matrix representation for errors.				
1	Check integer arrays <i>ia</i> and <i>ja</i> . In particular, check whether the column indices are sorted in increasing order within each row.				
<i>iparm</i> [27]	Single or double precision Parallel Direct Sparse Solver for Clusters Interface.				
input	<p>See <a href="#">iparm[7]</a> for information on controlling the precision of the refinement steps.</p> <table border="1"> <tr> <td>0*</td> <td>Input arrays (<i>a</i>, <i>x</i> and <i>b</i>) and all internal arrays must be presented in double precision.</td> </tr> <tr> <td>1</td> <td>Input arrays (<i>a</i>, <i>x</i> and <i>b</i>) must be presented in single precision. In this case all internal computations are performed in single precision.</td> </tr> </table>	0*	Input arrays ( <i>a</i> , <i>x</i> and <i>b</i> ) and all internal arrays must be presented in double precision.	1	Input arrays ( <i>a</i> , <i>x</i> and <i>b</i> ) must be presented in single precision. In this case all internal computations are performed in single precision.
0*	Input arrays ( <i>a</i> , <i>x</i> and <i>b</i> ) and all internal arrays must be presented in double precision.				
1	Input arrays ( <i>a</i> , <i>x</i> and <i>b</i> ) must be presented in single precision. In this case all internal computations are performed in single precision.				
<i>iparm</i> [28]	Reserved. Set to zero.				
<i>iparm</i> [29]	Number of zero or negative pivots.				
output	<p>If Intel® oneAPI Math Kernel Library (oneMKL) PARDISO detects zero or negative pivot for <i>mtype</i>=2 or <i>mtype</i>=4 matrix types, the factorization is stopped. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO returns immediately with an <i>error</i> = -4, and <i>iparm</i>[29] reports the number of the equation where the zero or negative pivot is detected.</p> <p>Note: The returned value can be different for the parallel and sequential version in case of several zero/negative pivots.</p>				
<i>iparm</i> [30]	Partial solve and computing selected components of the solution vectors.				
input	<p>This parameter controls the solve step of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. It can be used if only a few components of the solution vectors are needed or if you want to reduce the computation cost at the solve step by utilizing the sparsity of the right-hand sides. To use this option the input permutation vector <i>defineperm</i> so that when <i>perm</i>(<i>i</i>) = 1 it means that either the <i>i</i>-th component in the right-hand sides is nonzero, or the <i>i</i>-th component in the solution vectors is computed, or both, depending on the value of <i>iparm</i>[30].</p> <p>The permutation vector <i>perm</i> must be present in all phases of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO software. At the reordering step, the software overwrites the input vector <i>perm</i> by a permutation vector used by the software at the factorization and solver step. If <i>m</i> is the number of components such that <i>perm</i>(<i>i</i>) = 1, then the last <i>m</i> components of the output vector <i>perm</i> are a set of the indices <i>i</i> satisfying the condition <i>perm</i>(<i>i</i>) = 1 on input.</p>				
<p><b>NOTE</b> Turning on this option often increases the time used by Intel® oneAPI Math Kernel Library (oneMKL) PARDISO for factorization and reordering steps, but it can reduce the time required for the solver step.</p>					
<p><b>Important</b> Set the parameters <a href="#">iparm[7]</a> (iterative refinement steps), <a href="#">iparm[3]</a> (preconditioned CGS), <a href="#">iparm[4]</a> (user permutation), and <a href="#">iparm[35]</a> (Schur complement) to 0 as well.</p>					

Component	Description
	0* Disables this option.
	1 it is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector <i>perm</i> is defined so that $perm(i) = 1$ means that the ( <i>i</i> )-th component in the right-hand sides is nonzero. In this case Intel® oneAPI Math Kernel Library (oneMKL) PARDISO only uses the non-zero components of the right-hand side vectors and computes only corresponding components in the solution vectors. That means the <i>i</i> -th component in the solution vectors is only computed if $perm(i) = 1$ .
	2 It is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector <i>perm</i> is defined so that $perm(i) = 1$ means that the <i>i</i> -th component in the right-hand sides is nonzero.  Unlike for $iparm[30]=1$ , all components of the solution vector are computed for this setting and all components of the right-hand sides are used. Because all components are used, for $iparm[30]=2$ you must set the <i>i</i> -th component of the right-hand sides to zero explicitly if $perm(i)$ is not equal to 1.
	3 Selected components of the solution vectors are computed. The <i>perm</i> array is not related to the right-hand sides and it only indicates which components of the solution vectors should be computed. In this case $perm(i) = 1$ means that the <i>i</i> -th component in the solution vectors is computed.
<i>iparm</i> [31] - <i>iparm</i> [33]	Reserved. Set to zero.
<i>iparm</i> [34]	One- or zero-based indexing of columns and rows.
input	0* One-based indexing: columns and rows indexing in arrays <i>ia</i> , <i>ja</i> , and <i>perm</i> starts from 1 (Fortran-style indexing).
	1 Zero-based indexing: columns and rows indexing in arrays <i>ia</i> , <i>ja</i> , and <i>perm</i> starts from 0 (C-style indexing).
<i>iparm</i> [35]	Schur complement matrix computation control. To calculate this matrix, you must set the input permutation vector <i>perm</i> to a set of indexes such that when $perm(i) = 1$ , the <i>i</i> -th element of the initial matrix is an element of the Schur matrix.
	<b>Caution</b> You can only set one of <i>iparm</i> [4], <i>iparm</i> [30], and <i>iparm</i> [35], so be sure that the <i>iparm</i> [4] (user permutation) and the <i>iparm</i> [30] (partial solution) parameters are 0 if you set <i>iparm</i> [35].
	0* Do not compute Schur complement.
	1 Compute Schur complement matrix as part of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO factorization step and return it in the solution vector.
	<b>NOTE</b> This option only computes the Schur complement matrix, and does not calculate factorization arrays.
	2 Compute Schur complement matrix as part of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO factorization step and return it in the solution vector. Since this option calculates factorization arrays you can use it to launch partial or full solution of the entire problem after the factorization step.

Component	Description
<i>iparm</i> [36]	Format for matrix storage.
input	<p>0* Use CSR format (see <a href="#">Three Array Variation of BSR Format</a>) for matrix storage.</p> <p>1 Use CSR format (see <a href="#">Three Array Variation of BSR Format</a>) for matrix storage.</p> <p>&lt; 0 Convert supplied matrix to variable BSR (VBSR) format (see <a href="#">Sparse Data Storage</a>) for matrix storage. Intel® oneAPI Math Kernel Library (oneMKL) PARDISO analyzes the matrix provided in CSR3 format and converts it to an internal VBSR format. Set <math>iparm[36] = -t, 0 &lt; t \leq 100</math>.</p>
<i>iparm</i> [37] - <i>iparm</i> [38]	Reserved. Set to zero.
<i>iparm</i> [39]	Matrix input format.
input	<p><b>NOTE</b> Performance of the reordering step of the Parallel Direct Sparse Solver for Clusters Interface is slightly better for assembled format (CSR, <math>iparm[39] = 0</math>) than for distributed format (DCSR, <math>iparm[39] &gt; 0</math>) for the same matrices, so if the matrix is assembled on one node do not distribute it before calling <code>cluster_sparse_solver</code>.</p> <p>0* Provide the matrix in usual centralized input format: the master MPI process stores all data from matrix <i>A</i>, with rank=0.</p> <p>1 Provide the matrix in distributed assembled matrix input format. In this case, each MPI process stores only a part (or domain) of the matrix <i>A</i> data. Set the bounds of the domain using <i>iparm</i>[40] and <i>iparm</i>[41]. The solution vector is placed on the master process.</p> <p>2 Provide the matrix in distributed assembled matrix input format. In this case, each MPI process stores only a part (or domain) of the matrix <i>A</i> data. Set the bounds of the domain using <i>iparm</i>[40] and <i>iparm</i>[41]. The solution vector, <i>A</i>, and RHS elements are distributed between processes in same manner.</p> <p>3 Provide the matrix in distributed assembled matrix input format. In this case, each MPI process stores only a part (or domain) of the matrix <i>A</i> data. Set the bounds of the domain using <i>iparm</i>[40] and <i>iparm</i>[41]. The <i>A</i> and RHS elements are distributed between processes in same manner and the solution vector is the same on each process</p>
<i>iparm</i> [40]	Beginning of input domain.
input	<p>The number of the matrix <i>A</i> row, RHS element, and, for <math>iparm[39]=2</math>, solution vector that begins the input domain belonging to this MPI process.</p> <p>Only applicable to the distributed assembled matrix input format (<math>iparm[39] &gt; 0</math>).</p> <p>See <a href="#">Sparse Matrix Storage Formats</a> for more details.</p>
<i>iparm</i> [41]	End of input domain.
input	<p>The number of the matrix <i>A</i> row, RHS element, and, for <math>iparm[39]=2</math>, solution vector that ends the input domain belonging to this MPI process.</p> <p>Only applicable to the distributed assembled matrix input format (<math>iparm[39] &gt; 0</math>).</p> <p>See <a href="#">Sparse Matrix Storage Formats</a> for more details.</p>
<i>iparm</i> [42] - <i>iparm</i> [58]	Reserved. Set to zero.

Component	Description
input	
<i>iparm</i> [59]	cluster_sparse_solver mode.
input	<p><i>iparm</i>[59] switches between in-core (IC) and out-of-core (OOC) of cluster_sparse_solver. OOC can solve very large problems by holding the matrix factors in files on the disk, which requires a reduced amount of main memory compared to IC.</p> <p>Unless you are operating in sequential mode, you can switch between IC and OOC modes after the reordering phase. However, you can get better cluster_sparse_solver performance by setting <i>iparm</i>[59] before the reordering phase.</p> <p>The amount of memory used in OOC mode depends on the number of OpenMP threads.</p> <hr/> <p><b>NOTE</b> When <i>iparm</i>[59] &gt; 0, use the MKL_PARDISO_OOC_FILE_NAME environment variable to store factors.</p> <hr/> <p><b>Warning</b> Do not increase the number of OpenMP threads used for cluster_sparse_solver between the first call and the factorization or solution phase. Because the minimum amount of memory required for out-of-core execution depends on the number of OpenMP threads, increasing it after the initial call can cause incorrect results.</p> <hr/> <p>0* IC mode.</p> <hr/> <p>1 IC mode is used if the total amount of RAM (in megabytes) needed for storing the matrix factors is less than sum of two values of the environment variables: MKL_PARDISO_OOC_MAX_CORE_SIZE (default value 2000 MB) and MKL_PARDISO_OOC_MAX_SWAP_SIZE (default value 0 MB); otherwise OOC mode is used. In this case amount of RAM used by OOC mode cannot exceed the value of MKL_PARDISO_OOC_MAX_CORE_SIZE.</p> <p>If the total peak memory needed for storing the local arrays is more than MKL_PARDISO_OOC_MAX_CORE_SIZE, increase MKL_PARDISO_OOC_MAX_CORE_SIZE if possible.</p> <hr/> <p><b>NOTE</b> Conditional numerical reproducibility (CNR) is not supported for this mode.</p> <hr/> <p>2 OOC mode.</p> <p>The OOC mode can solve very large problems by holding the matrix factors in files on the disk. Hence the amount of RAM required by OOC mode is significantly reduced compared to IC mode.</p> <p>If the total peak memory needed for storing the local arrays is more than MKL_PARDISO_OOC_MAX_CORE_SIZE, increase MKL_PARDISO_OOC_MAX_CORE_SIZE if possible.</p> <p>To obtain better cluster_sparse_solver performance, during the numerical factorization phase you can provide the maximum number of right-hand sides, which can be used further during the solving phase.</p>

Component	Description
	<b>NOTE</b> To use OOC mode, you must disable <code>iparm[10]</code> (scaling) and <code>iparm[12] = 1</code> (matching).
<code>iparm[60]</code> - <code>iparm[61]</code> input	Reserved. Set to zero.
<code>iparm[62]</code> output	Size of the minimum OOC memory for numerical factorization and solution. This parameter provides the size in kilobytes of the minimum memory required by OOC Intel® oneAPI Math Kernel Library (oneMKL) PARDISO for internal floating point arrays. This parameter is computed in phase 1. Total peak memory consumption of OOC Intel® oneAPI Math Kernel Library (oneMKL) PARDISO can be estimated as $\text{as}_{\max}(\text{iparm}[14], \text{iparm}[15] + \text{iparm}[62])$ .
<code>iparm[63]</code> input	Reserved. Set to zero.

**NOTE**

Generally in sparse matrices, components which are equal to zero can be considered non-zero if necessary. For example, in order to make a matrix structurally symmetric, elements which are zero can be considered non-zero. See [Sparse Matrix Storage Formats](#) for an example.

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

**Direct Sparse Solver (DSS) Interface Routines**

Intel® oneAPI Math Kernel Library (oneMKL) supports the DSS interface, an alternative to the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO interface for the direct sparse solver. The DSS interface implements a group of user-callable routines that are used in the step-by-step solving process and utilizes the general scheme described in [Appendix A Linear Solvers Basics](#) for solving sparse systems of linear equations. This interface also includes one routine for gathering statistics related to the solving process.

The DSS interface also supports the out-of-core (OOC) mode.

Table "DSS Interface Routines" lists the names of the routines and describes their general use.

**DSS Interface Routines**

Routine	Description
<code>dss_create</code>	Initializes the solver and creates the basic data structures necessary for the solver. This routine must be called before any other DSS routine.
<code>dss_define_structure</code>	Informs the solver of the locations of the non-zero elements of the matrix.

Routine	Description
<code>dss_reorder</code>	Based on the non-zero structure of the matrix, computes a permutation vector to reduce fill-in during the factoring process.
<code>dss_factor_real</code> , <code>dss_factor_complex</code>	Computes the $LU$ , $LDL^T$ or $LL^T$ factorization of a real or complex matrix.
<code>dss_solve_real</code> , <code>dss_solve_complex</code>	Computes the solution vector for a system of equations based on the factorization computed in the previous phase.
<code>dss_delete</code>	Deletes all data structures created during the solving process.
<code>dss_statistics</code>	Returns statistics about various phases of the solving process.

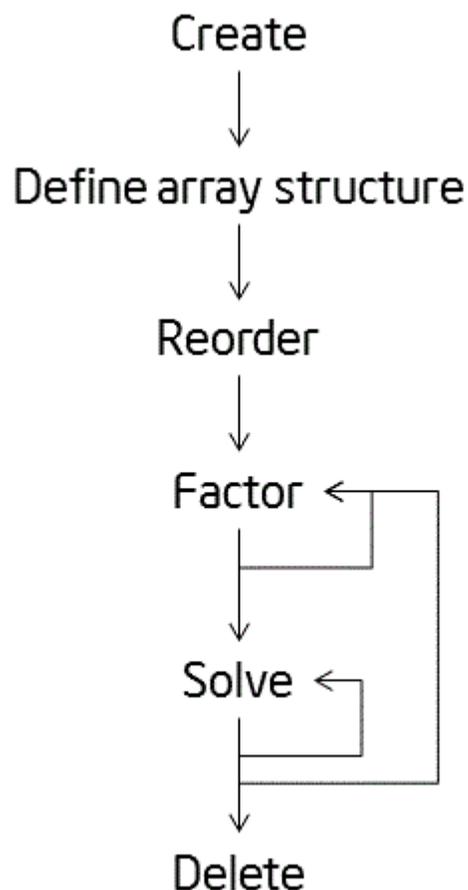

To find a single solution vector for a single system of equations with a single right-hand side, invoke the Intel® oneAPI Math Kernel Library (oneMKL) DSS interface routines in this order:

1. `dss_create`
2. `dss_define_structure`
3. `dss_reorder`
4. `dss_factor_real`, `dss_factor_complex`
5. `dss_solve_real`, `dss_solve_complex`
6. `dss_delete`

However, in certain applications it is necessary to produce solution vectors for multiple right-hand sides for a given factorization and/or factor several matrices with the same non-zero structure. Consequently, it is sometimes necessary to invoke the Intel® oneAPI Math Kernel Library (oneMKL) sparse routines in an order other than that listed, which is possible using the DSS interface. The solving process is conceptually divided into six phases. [Figure "Typical order for invoking DSS interface routines"](#) indicates the typical order in which the DSS interface routines can be invoked.

\_\_border\_\_top

### Typical order for invoking DSS interface routines

See the code examples that use the DSS interface routines to solve systems of linear equations in the Intel® oneAPI Math Kernel Library (oneMKL) installation directory (`dss_*.c`).

- `examples/solverc/source`

## DSS Interface Description

Each DSS routine reads from or writes to a data object called a *handle*. Refer to [Memory Allocation and Handles](#) to determine the correct method for declaring a handle argument for each language. For simplicity, the descriptions in DSS routines refer to the data type as `MKL_DSS_HANDLE`.

## Routine Options

The DSS routines have an integer argument (referred below to as *opt*) for passing various options to the routines. The permissible values for *opt* should be specified using only the symbol constants defined in the language-specific header files (see [Implementation Details](#)). The routines accept options for setting the message and termination levels as described in [Table "Symbolic Names for the Message and Termination Levels Options"](#). Additionally, each routine accepts the option `MKL_DSS_DEFAULTS` that sets the default values (as documented) for *opt* to the routine.

## Symbolic Names for the Message and Termination Levels Options

Message Level	Termination Level
MKL_DSS_MSG_LVL_SUCCESS	MKL_DSS_TERM_LVL_SUCCESS
MKL_DSS_MSG_LVL_INFO	MKL_DSS_TERM_LVL_INFO
MKL_DSS_MSG_LVL_WARNING	MKL_DSS_TERM_LVL_WARNING
MKL_DSS_MSG_LVL_ERROR	MKL_DSS_TERM_LVL_ERROR
MKL_DSS_MSG_LVL_FATAL	MKL_DSS_TERM_LVL_FATAL

The settings for message and termination levels can be set on any call to a DSS routine. However, once set to a particular level, they remain at that level until they are changed in another call to a DSS routine.

You can specify both message and termination level for a DSS routine by adding the options together. For example, to set the message level to `debug` and the termination level to `error` for all the DSS routines, use the following call:

```
dss_create( handle, MKL_DSS_MSG_LVL_INFO + MKL_DSS_TERM_LVL_ERROR)
```

## User Data Arrays

Many of the DSS routines take arrays of user data as input. For example, pointers to user arrays are passed to the routine `dss_define_structure` to describe the location of the non-zero entries in the matrix.

---

### Caution

Do not modify the contents of these arrays after they are passed to one of the solver routines.

---

## DSS Implementation Details

To promote portability across platforms and ease of use across different languages, use the `mkl_dss.h` header file.

The header file defines symbolic constants for returned error values, function options, certain defined data types, and function prototypes.

---

### NOTE

Constants for options, returned error values, and message severities must be referred only by the symbolic names that are defined in these header files. Use of the Intel® oneAPI Math Kernel Library (oneMKL) DSS software without including one of the above header files is not supported.

---

## Memory Allocation and Handles

You do not need to allocate any temporary working storage in order to use the Intel® oneAPI Math Kernel Library (oneMKL) DSS routines, because the solver itself allocates any required storage. To enable multiple users to access the solver simultaneously, the solver keeps track of the storage allocated for a particular application by using *ahandle* data object.

Each of the Intel® oneAPI Math Kernel Library (oneMKL) DSS routines creates, uses, or deletes a handle. Consequently, any program calling an Intel® oneAPI Math Kernel Library (oneMKL) DSS routine must be able to allocate storage for a handle. The exact syntax for allocating storage for a handle varies from language to language. To standardize the handle declarations, the language-specific header files declare constants and defined data types that must be used when declaring a handle object in your code.

```
#include "mkl_dss.h"
MKL_DSS_HANDLE_t handle;
```

In addition to the definition for the correct declaration of a handle, the include file also defines the following:

- function prototypes for languages that support prototypes
- symbolic constants that are used for the returned error values
- user options for the solver routines
- constants indicating message severity.

## DSS Routines

### dss\_create

*Initializes the solver.*

---

#### Syntax

```
MKL_INT dss_create(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt)
```

#### Include Files

- mkl.h

#### Description

The `dss_create` routine initializes the solver. After the call to `dss_create`, all subsequent invocations of the Intel® oneAPI Math Kernel Library (oneMKL) DSS routines must use the value of the handle returned by `dss_create`.

---

#### **WARNING**

Do not write the value of handle directly.

---

The default value of the parameter `opt` is

```
MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR.
```

By default, the DSS routines use double precision for solving systems of linear equations. The precision used by the DSS routines can be set to single mode by adding the following value to the `opt` parameter:

```
MKL_DSS_SINGLE_PRECISION.
```

Input data and internal arrays are required to have single precision.

By default, the DSS routines use Fortran style (one-based) indexing for input arrays of integer types (the first value is referenced as array element 1). To set indexing to C style (the first value is referenced as array element 0), add the following value to the `opt` parameter:

```
MKL_DSS_ZERO_BASED_INDEXING.
```

The `opt` parameter can also control number of refinement steps used on the solution stage by specifying the two following values:

```
MKL_DSS_REFINEMENT_OFF - maximum number of refinement steps is set to zero;
```

```
MKL_DSS_REFINEMENT_ON (default value) - maximum number of refinement steps is set to 2.
```

By default, DSS uses in-core computations. To launch the out-of-core version of DSS (OOC DSS) you can add to this parameter one of two possible values: `MKL_DSS_OOC_STRONG` and `MKL_DSS_OOC_VARIABLE`.

```
MKL_DSS_OOC_STRONG - OOC DSS is used.
```

```
MKL_DSS_OOC_VARIABLE - if the memory needed for the matrix factors is less than the value of the environment variable MKL_PARDISO_OOC_MAX_CORE_SIZE, then the OOC DSS uses the in-core kernels of Intel® oneAPI Math Kernel Library (oneMKL) PARDISO, otherwise it uses the OOC computations.
```

The variable `MKL_PARDISO_OOC_MAX_CORE_SIZE` defines the maximum size of RAM allowed for storing work arrays associated with the matrix factors. It is ignored if `MKL_DSS_OOC_STRONG` is set. The default value of `MKL_PARDISO_OOC_MAX_CORE_SIZE` is 2000 MB. This value and default path and file name for storing temporary data can be changed using the configuration file `pardiso_ooc.cfg` or command line (See more details in the description of the [pardiso](#) routine).

---

**WARNING**

Other than message and termination level options, do not change the OOC DSS settings after they are specified in the routine `dss_create`.

---

## Input Parameters

*opt* Parameter to pass the DSS options. The default value is `MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR`.

## Output Parameters

*handle* Pointer to the data structure storing internal DSS results (`MKL_DSS_HANDLE`).

## Return Values

`MKL_DSS_SUCCESS`

`MKL_DSS_INVALID_OPTION`

`MKL_DSS_OUT_OF_MEMORY`

`MKL_DSS_MSG_LVL_ERR`

`MKL_DSS_TERM_LVL_ERR`

## **dss\_define\_structure**

*Communicates locations of non-zero elements in the matrix to the solver.*

---

## Syntax

```
MKL_INT dss_define_structure(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, MKL_INT const *rowIndex, MKL_INT const *nRows, MKL_INT const *nCols, MKL_INT const *columns, MKL_INT const *nNonZeros);
```

## Include Files

- `mk1.h`

## Description

The routine `dss_define_structure` communicates the locations of the *nNonZeros* number of non-zero elements in a matrix of *nRows* \* *nCols* size to the solver.

---

**NOTE**

The Intel® oneAPI Math Kernel Library (oneMKL) DSS software operates only on square matrices, so *nRows* must be equal to *nCols*.

---

To communicate the locations of non-zero elements in the matrix, do the following:

1. Define the general non-zero structure of the matrix by specifying the value for the options argument *opt*. You can set the following values for real matrices:

- MKL\_DSS\_SYMMETRIC\_STRUCTURE
- MKL\_DSS\_SYMMETRIC
- MKL\_DSS\_NON\_SYMMETRIC

and for complex matrices:

- MKL\_DSS\_SYMMETRIC\_STRUCTURE\_COMPLEX
- MKL\_DSS\_SYMMETRIC\_COMPLEX
- MKL\_DSS\_NON\_SYMMETRIC\_COMPLEX

The information about the matrix type must be defined in `dss_define_structure`.

2. Provide the actual locations of the non-zeros by means of the arrays *rowIndex* and *columns* (see [Sparse Matrix Storage Format](#)).

---

**NOTE** No diagonal element can be omitted from the values array. If there is a zero value on the diagonal, for example, that element nonetheless must be explicitly represented.

---

## Input Parameters

<i>opt</i>	Parameter to pass the DSS options. The default value for the matrix structure is <code>MKL_DSS_SYMMETRIC</code> .
<i>rowIndex</i>	Array of size <i>nRows</i> +1. Defines the location of non-zero entries in the matrix.
<i>nRows</i>	Number of rows in the matrix.
<i>nCols</i>	Number of columns in the matrix; must be equal to <i>nRows</i> .
<i>columns</i>	Array of size <i>nNonZeros</i> . Defines the column location of non-zero entries in the matrix.
<i>nNonZeros</i>	Number of non-zero elements in the matrix.

## Output Parameters

<i>handle</i>	Pointer to the data structure storing internal DSS results ( <code>MKL_DSS_HANDLE</code> ).
---------------	---

## Return Values

`MKL_DSS_SUCCESS`  
`MKL_DSS_STATE_ERR`  
`MKL_DSS_INVALID_OPTION`  
`MKL_DSS_STRUCTURE_ERR`  
`MKL_DSS_ROW_ERR`  
`MKL_DSS_COL_ERR`  
`MKL_DSS_NOT_SQUARE`

MKL\_DSS\_TOO\_FEW\_VALUES  
 MKL\_DSS\_TOO\_MANY\_VALUES  
 MKL\_DSS\_OUT\_OF\_MEMORY  
 MKL\_DSS\_MSG\_LVL\_ERR  
 MKL\_DSS\_TERM\_LVL\_ERR

### dss\_reorder

*Computes or sets a permutation vector that minimizes the fill-in during the factorization phase.*

### Syntax

```
MKL_INT dss_reorder( MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, MKL_INT const *perm)
```

### Include Files

- mkl.h

### Description

If *opt* contains the option MKL\_DSS\_AUTO\_ORDER, then the routine `dss_reorder` computes a permutation vector that minimizes the fill-in during the factorization phase. For this option, the routine ignores the contents of the *perm* array.

If *opt* contains the option MKL\_DSS\_METIS\_OPENMP\_ORDER, then the routine `dss_reorder` computes permutation vector using the parallel nested dissections algorithm to minimize the fill-in during the factorization phase. This option can be used to decrease the time of `dss_reorder` call on multi-core computers. For this option, the routine ignores the contents of the *perm* array.

If *opt* contains the option MKL\_DSS\_MY\_ORDER, then you must supply a permutation vector in the array *perm*. In this case, the array *perm* is of length *nRows*, where *nRows* is the number of rows in the matrix as defined by the previous call to `dss_define_structure`.

If *opt* contains the option MKL\_DSS\_GET\_ORDER, then the permutation vector computed during the `dss_reorder` call is copied to the array *perm*. In this case you must allocate the array *perm* beforehand. The permutation vector is computed in the same way as if the option MKL\_DSS\_AUTO\_ORDER is set.

#### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

### Input Parameters

<i>opt</i>	Parameter to pass the DSS options. The default value for the permutation type is MKL_DSS_AUTO_ORDER.
<i>perm</i>	Array of length <i>nRows</i> . Contains a user-defined permutation vector (accessed only if <i>opt</i> contains MKL_DSS_MY_ORDER or MKL_DSS_GET_ORDER).

## Output Parameters

*handle* Pointer to the data structure storing internal DSS results (MKL\_DSS\_HANDLE).

## Return Values

MKL\_DSS\_SUCCESS

MKL\_DSS\_STATE\_ERR

MKL\_DSS\_INVALID\_OPTION

MKL\_DSS\_REORDER\_ERR

MKL\_DSS\_REORDER1\_ERR

MKL\_DSS\_I32BIT\_ERR

MKL\_DSS\_FAILURE

MKL\_DSS\_OUT\_OF\_MEMORY

MKL\_DSS\_MSG\_LVL\_ERR

MKL\_DSS\_TERM\_LVL\_ERR

## **dss\_factor\_real, dss\_factor\_complex**

*Compute factorization of the matrix with previously specified location of non-zero elements.*

### Syntax

```
MKL_INT dss_factor_real(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, void const *rValues)
```

```
MKL_INT dss_factor_complex(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, void const *cValues)
```

### Include Files

- mkl.h

### Description

These routines compute factorization of the matrix whose non-zero locations were previously specified by a call to [dss\\_define\\_structure](#) and whose non-zero values are given in the array *rValues*, *cValues* or *Values*. Data type These arrays must be of length *nNonZeros* as defined in a previous call to [dss\\_define\\_structure](#).

---

#### NOTE

The data type (single or double precision) of *rValues*, *cValues*, *Values* must be in correspondence with precision specified by the parameter *opt* in the routine [dss\\_create](#).

---

The *opt* argument can contain one of the following options:

- MKL\_DSS\_POSITIVE\_DEFINITE
- MKL\_DSS\_INDEFINITE
- MKL\_DSS\_HERMITIAN\_POSITIVE\_DEFINITE

- MKL\_DSS\_HERMITIAN\_INDEFINITE

depending on your matrix's type.

---

**NOTE**

This routine supports the Progress Routine feature. See [Progress Function](#) for details.

---

## Input Parameters

<i>handle</i>	Pointer to the data structure storing internal DSS results (MKL_DSS_HANDLE).
<i>opt</i>	Parameter to pass the DSS options. The default value is MKL_DSS_POSITIVE_DEFINITE.
<i>rValues</i>	Array of elements of the matrix <i>A</i> . Real data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <i>dss_create</i> .
<i>cValues</i>	Array of elements of the matrix <i>A</i> . Complex data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <i>dss_create</i> .

## Return Values

MKL\_DSS\_SUCCESS  
MKL\_DSS\_STATE\_ERR  
MKL\_DSS\_INVALID\_OPTION  
MKL\_DSS\_OPTION\_CONFLICT  
MKL\_DSS\_VALUES\_ERR  
MKL\_DSS\_OUT\_OF\_MEMORY  
MKL\_DSS\_ZERO\_PIVOT  
MKL\_DSS\_FAILURE  
MKL\_DSS\_MSG\_LVL\_ERR  
MKL\_DSS\_TERM\_LVL\_ERR  
MKL\_DSS\_OOC\_MEM\_ERR  
MKL\_DSS\_OOC\_OC\_ERR  
MKL\_DSS\_OOC\_RW\_ERR

## **dss\_solve\_real, dss\_solve\_complex**

*Compute the corresponding solution vector and place it in the output array.*

---

## Syntax

```
MKL_INT dss_solve_real(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, void const *rRhsValues, MKL_INT const *nRhs, void *rSolValues)
```

```
MKL_INT dss_solve_complex(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, void const *cRhsValues, MKL_INT const *nRhs, void *cSolValues)
```

## Include Files

- `mk1.h`

## Description

For each right-hand side column vector defined in the arrays `rRhsValues`, `cRhsValues`, or `RhsValues`, these routines compute the corresponding solution vector and place it in the arrays `rSolValues`, `cSolValues`, or `SolValues` respectively.

---

### NOTE

The data type (single or double precision) of all arrays must be in correspondence with precision specified by the parameter `opt` in the routine `dss_create`.

---

The lengths of the right-hand side and solution vectors, `nRows` and `nCols` respectively, must be defined in a previous call to `dss_define_structure`.

By default, both routines perform the full solution step (it corresponds to `phase = 33` in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO). The parameter `opt` enables you to calculate the final solution step-by-step, calling forward and backward substitutions.

If it is set to `MKL_DSS_FORWARD_SOLVE`, the forward substitution (corresponding to `phase = 331` in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO) is performed;

if it is set to `MKL_DSS_DIAGONAL_SOLVE`, the diagonal substitution (corresponding to `phase = 332` in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO) is performed, if possible;

if it is set to `MKL_DSS_BACKWARD_SOLVE`, the backward substitution (corresponding to `phase = 333` in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO) is performed.

For more details about using these substitutions for different types of matrices, see [Separate Forward and Backward Substitution](#) in the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver description.

This parameter also can control the number of refinement steps that is used on the solution stage: if it is set to `MKL_DSS_REFINEMENT_OFF`, the maximum number of refinement steps equal to zero, and if it is set to `MKL_DSS_REFINEMENT_ON` (default value), the maximum number of refinement steps is equal to 2.

`MKL_DSS_CONJUGATE_SOLVE` option added to the parameter `opt` enables solving a conjugate transposed system  $A^H X = B$  based on the factorization of the matrix  $A$ . This option is equivalent to the parameter `iparm[11] = 1` in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.

`MKL_DSS_TRANSPOSE_SOLVE` option added to the parameter `opt` enables solving a transposed system  $A^T X = B$  based on the factorization of the matrix  $A$ . This option is equivalent to the parameter `iparm[11] = 2` in Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.

## Input Parameters

<code>handle</code>	Pointer to the data structure storing internal DSS results ( <code>MKL_DSS_HANDLE</code> ).
<code>opt</code>	Parameter to pass the DSS options.
<code>nRhs</code>	Number of the right-hand sides in the system of linear equations.
<code>rRhsValues</code>	Array of size <code>nRows * nRhs</code> . Contains real right-hand side vectors. Real data, single or double precision as it is specified by the parameter <code>opt</code> in the routine <code>dss_create</code> .

<i>cRhsValues</i>	Array of size $nRows * nRhs$ . Contains complex right-hand side vectors. Complex data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .
<i>RhsValues</i>	Array of size $nRows * nRhs$ . Contains right-hand side vectors. Real or complex data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .

## Output Parameters

<i>rSolValues</i>	Array of size $nCols * nRhs$ . Contains real solution vectors. Real data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .
<i>cSolValues</i>	Array of size $nCols * nRhs$ . Contains complex solution vectors. Complex data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .

## Return Values

MKL\_DSS\_SUCCESS  
 MKL\_DSS\_STATE\_ERR  
 MKL\_DSS\_INVALID\_OPTION  
 MKL\_DSS\_OUT\_OF\_MEMORY  
 MKL\_DSS\_DIAG\_ERR  
 MKL\_DSS\_FAILURE  
 MKL\_DSS\_MSG\_LVL\_ERR  
 MKL\_DSS\_TERM\_LVL\_ERR  
 MKL\_DSS\_OOC\_MEM\_ERR  
 MKL\_DSS\_OOC\_OC\_ERR  
 MKL\_DSS\_OOC\_RW\_ERR

## **dss\_delete**

*Deletes all of the data structures created during the solutions process.*

---

## Syntax

```
MKL_INT dss_delete(_MKL_DSS_HANDLE_t const *handle, MKL_INT const *opt)
```

## Include Files

- `mkl.h`

## Description

The routine `dss_delete` deletes all data structures created during the solving process.

## Input Parameters

*opt*

Parameter to pass the DSS options. The default value is `MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR`.

## Output Parameters

*handle* Pointer to the data structure storing internal DSS results (`MKL_DSS_HANDLE`).

## Return Values

`MKL_DSS_SUCCESS`

`MKL_DSS_STATE_ERR`

`MKL_DSS_INVALID_OPTION`

`MKL_DSS_OUT_OF_MEMORY`

`MKL_DSS_MSG_LVL_ERR`

`MKL_DSS_TERM_LVL_ERR`

## `dss_statistics`

Returns statistics about various phases of the solving process.

## Syntax

```
MKL_INT dss_statistics(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, _CHARACTER_STR_t const *statArr, _DOUBLE_PRECISION_t *retValues)
```

## Include Files

- `mkl.h`

## Description

The `dss_statistics` routine returns statistics about various phases of the solving process. This routine gathers the following statistics:

- time taken to do reordering,
- time taken to do factorization,
- duration of problem solving,
- determinant of the symmetric indefinite input matrix,
- inertia of the symmetric indefinite input matrix,
- number of floating point operations taken during factorization,
- total peak memory needed during the analysis and symbolic factorization,
- permanent memory needed from the analysis and symbolic factorization,
- memory consumption for the factorization and solve phases.

Statistics are returned in accordance with the input string specified by the parameter `statArr`. The value of the statistics is returned in double precision in a return array, which you must allocate beforehand.

For multiple statistics, multiple string constants separated by commas can be used as input. Return values are put into the return array in the same order as specified in the input string.

Statistics can only be requested at the appropriate stages of the solving process. For example, requesting `FactorTime` before a matrix is factored leads to an error.

The following table shows the point at which each individual statistics item can be requested:

## Statistics Calling Sequences

Type of Statistics	When to Call
ReorderTime	After <code>dss_reorder</code> is completed successfully.
FactorTime	After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.
SolveTime	After <code>dss_solve_real</code> or <code>dss_solve_complex</code> is completed successfully.
Determinant	After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.
Inertia	After <code>dss_factor_real</code> is completed successfully and the matrix is real, symmetric, and indefinite.
Flops	After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.
Peakmem	After <code>dss_reorder</code> is completed successfully.
Factormem	After <code>dss_reorder</code> is completed successfully.
Solvemem	After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.

## Input Parameters

<i>handle</i>	Pointer to the data structure storing internal DSS results (MKL_DSS_HANDLE).										
<i>opt</i>	Parameter to pass the DSS options.										
<i>statArr</i>	Input string that defines the type of the returned statistics. The parameter can include one or more of the following string constants (case of the input string has no effect): <table border="0" style="margin-left: 20px;"> <tbody> <tr> <td>ReorderTime</td> <td>Amount of time taken to do the reordering.</td> </tr> <tr> <td>FactorTime</td> <td>Amount of time taken to do the factorization.</td> </tr> <tr> <td>SolveTime</td> <td>Amount of time taken to solve the problem after factorization.</td> </tr> <tr> <td>Determinant</td> <td>Determinant of the matrix <i>A</i>.                For real matrices: the determinant is returned as <i>det_pow</i>, <i>det_base</i> in two consecutive return array locations, where <math>1.0 \leq \text{abs}(\text{det\_base}) &lt; 10.0</math> and <math>\text{determinant} = \text{det\_base} * 10^{(\text{det\_pow})}</math>.                For complex matrices: the determinant is returned as <i>det_pow</i>, <i>det_re</i>, <i>det_im</i> in three consecutive return array locations, where <math>1.0 \leq \text{abs}(\text{det\_re}) + \text{abs}(\text{det\_im}) &lt; 10.0</math> and <math>\text{determinant} = (\text{det\_re} + \text{det\_im} * 10^{(\text{det\_pow})})</math>.             </td> </tr> <tr> <td>Inertia</td> <td>Inertia of a real symmetric matrix is defined as a triplet of nonnegative integers (<i>p</i>, <i>n</i>, <i>z</i>), where <i>p</i> is the number of positive eigenvalues, <i>n</i> is the number of negative eigenvalues, and <i>z</i> is the number of zero eigenvalues.                 Inertia is returned as three consecutive return array locations <i>p</i>, <i>n</i>, <i>z</i>.             </td> </tr> </tbody> </table>	ReorderTime	Amount of time taken to do the reordering.	FactorTime	Amount of time taken to do the factorization.	SolveTime	Amount of time taken to solve the problem after factorization.	Determinant	Determinant of the matrix <i>A</i> . For real matrices: the determinant is returned as <i>det_pow</i> , <i>det_base</i> in two consecutive return array locations, where $1.0 \leq \text{abs}(\text{det\_base}) < 10.0$ and $\text{determinant} = \text{det\_base} * 10^{(\text{det\_pow})}$ . For complex matrices: the determinant is returned as <i>det_pow</i> , <i>det_re</i> , <i>det_im</i> in three consecutive return array locations, where $1.0 \leq \text{abs}(\text{det\_re}) + \text{abs}(\text{det\_im}) < 10.0$ and $\text{determinant} = (\text{det\_re} + \text{det\_im} * 10^{(\text{det\_pow})})$ .	Inertia	Inertia of a real symmetric matrix is defined as a triplet of nonnegative integers ( <i>p</i> , <i>n</i> , <i>z</i> ), where <i>p</i> is the number of positive eigenvalues, <i>n</i> is the number of negative eigenvalues, and <i>z</i> is the number of zero eigenvalues.  Inertia is returned as three consecutive return array locations <i>p</i> , <i>n</i> , <i>z</i> .
ReorderTime	Amount of time taken to do the reordering.										
FactorTime	Amount of time taken to do the factorization.										
SolveTime	Amount of time taken to solve the problem after factorization.										
Determinant	Determinant of the matrix <i>A</i> . For real matrices: the determinant is returned as <i>det_pow</i> , <i>det_base</i> in two consecutive return array locations, where $1.0 \leq \text{abs}(\text{det\_base}) < 10.0$ and $\text{determinant} = \text{det\_base} * 10^{(\text{det\_pow})}$ . For complex matrices: the determinant is returned as <i>det_pow</i> , <i>det_re</i> , <i>det_im</i> in three consecutive return array locations, where $1.0 \leq \text{abs}(\text{det\_re}) + \text{abs}(\text{det\_im}) < 10.0$ and $\text{determinant} = (\text{det\_re} + \text{det\_im} * 10^{(\text{det\_pow})})$ .										
Inertia	Inertia of a real symmetric matrix is defined as a triplet of nonnegative integers ( <i>p</i> , <i>n</i> , <i>z</i> ), where <i>p</i> is the number of positive eigenvalues, <i>n</i> is the number of negative eigenvalues, and <i>z</i> is the number of zero eigenvalues.  Inertia is returned as three consecutive return array locations <i>p</i> , <i>n</i> , <i>z</i> .										

Computing inertia can lead to incorrect results for matrixes with a cluster of eigenvalues which are near 0.

Inertia of a  $k$ -by- $k$  real symmetric positive definite matrix is always  $(k, 0, 0)$ . Therefore `Inertia` is returned only in cases of real symmetric indefinite matrices. For all other matrix types, an error message is returned.

<code>Flops</code>	Number of floating point operations performed during the factorization.
<code>Peakmem</code>	Total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase.
<code>Factormem</code>	Permanent memory in kilobytes that the solver needs from the analysis and symbolic factorization phase in the factorization and solve phases.
<code>Solvemem</code>	Total double precision memory consumption (kilobytes) of the solver for the factorization and solve phases.

## Output Parameters

`retValues` Value of the statistics returned.

## Finding 'time used to reorder' and 'inertia' of a matrix

The example below illustrates the use of the `dss_statistics` routine.

To find the above values, call `dss_statistics(handle, opt, statArr, retValue)`, where `statArr` is "ReorderTime,Inertia"

In this example, `retValue` has the following values:

<code>retValue[0]</code>	Time to reorder.
<code>retValue[1]</code>	Positive Eigenvalues.
<code>retValue[2]</code>	Negative Eigenvalues.
<code>retValue[3]</code>	Zero Eigenvalues.

## Return Values

`MKL_DSS_SUCCESS`  
`MKL_DSS_INVALID_OPTION`  
`MKL_DSS_STATISTICS_INVALID_MATRIX`  
`MKL_DSS_STATISTICS_INVALID_STATE`  
`MKL_DSS_STATISTICS_INVALID_STRING`  
`MKL_DSS_MSG_LVL_ERR`

MKL\_DSS\_TERM\_LVL\_ERR

## Iterative Sparse Solvers based on Reverse Communication Interface (RCI ISS)

Intel® oneAPI Math Kernel Library (oneMKL) supports iterative sparse solvers (ISS) based on the reverse communication interface (RCI), referred to here as the RCI ISS interface. The RCI ISS interface implements a group of user-callable routines that are used in the step-by-step solving process of a symmetric positive definite system (RCI conjugate gradient solver, or RCI CG), and of a non-symmetric indefinite (non-degenerate) system (RCI flexible generalized minimal residual solver, or RCI FGMRES) of linear algebraic equations. This interface uses the general RCI scheme described in [Dong95].

See the [Appendix A Linear Solvers Basics](#) for discussion of terms and concepts related to the ISS routines.

The term *RCI* indicates that when the solver needs the results of certain operations (for example, matrix-vector multiplications), the user performs them and passes the result to the solver. This makes the solver more universal as it is independent of the specific implementation of the operations like the matrix-vector multiplication. To perform such operations, the user can use the built-in sparse matrix-vector multiplications and triangular solvers routines described in [Sparse BLAS Level 2 and Level 3 Routines](#).

---

### NOTE

The RCI CG solver is implemented in two versions: for system of equations with a single right-hand side, and for systems of equations with multiple right-hand sides.

The CG method may fail to compute the solution or compute the wrong solution if the matrix of the system is not symmetric and not positive definite.

The FGMRES method may fail if the matrix is degenerate.

---

Table "RCI CG Interface Routines" lists the names of the routines, and describes their general use.

### RCI ISS Interface Routines

Routine	Description
<a href="#">dcg_init</a> , <a href="#">dcgmrhs_init</a> , <a href="#">dfgmres_init</a>	Initializes the solver.
<a href="#">dcg_check</a> , <a href="#">dcgmrhs_check</a> , <a href="#">dfgmres_check</a>	Checks the consistency and correctness of the user defined data.
<a href="#">dcg</a> , <a href="#">dcgmrhs</a> , <a href="#">dfgmres</a>	Computes the approximate solution vector.
<a href="#">dcg_get</a> , <a href="#">dcgmrhs_get</a> , <a href="#">dfgmres_get</a>	Retrieves the number of the current iteration.

The Intel® oneAPI Math Kernel Library (oneMKL) RCI ISS interface routines are normally invoked in this order:

1. `<system_type>_init`
2. `<system_type>_check`
3. `<system_type>`
4. `<system_type>_get`

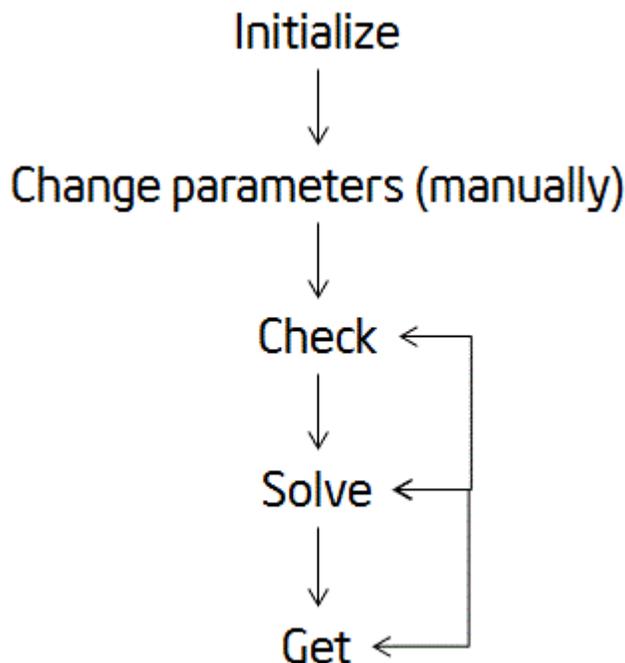

Advanced users can change that order if they need it. Others should follow the above order of calls.

The following diagram indicates the typical order in which the RCI ISS interface routines are invoked.

\_\_border\_\_ top

### Typical Order for Invoking RCI ISS interface Routines

---

See the code examples that use the RCI ISS interface routines to solve systems of linear equations in the Intel® oneAPI Math Kernel Library (oneMKL) installation directory.

- `examples/solverc/source`

## CG Interface Description

Each routine for the RCI CG solver is implemented in two versions: for a system of equations with a single right-hand side (SRHS), and for a system of equations with multiple right-hand sides (MRHS). The names of routines for a system with MRHS contain the suffix `mrhs`.

## Routine Options

All of the RCI CG routines have common parameters for passing various options to the routines (see [CG Common Parameters](#)). The values for these parameters can be changed during computations.

## User Data Arrays

Many of the RCI CG routines take arrays of user data as input. For example, user arrays are passed to the routine `dcgto` to compute the solution of a system of linear algebraic equations. The Intel® oneAPI Math Kernel Library (oneMKL) RCI CG routines do not make copies of the user input arrays to minimize storage requirements and improve overall run-time efficiency.

## CG Common Parameters

---

### NOTE

The default and initial values listed below are assigned to the parameters by calling the `dcg_init/dcgmrhs_init` routine.

---

<i>n</i>	MKL_INT, this parameter sets the size of the problem in the <code>dcg_init/dcgmrhs_init</code> routine. All the other routines use the <code>ipar[0]</code> parameter instead. Note that the coefficient matrix <i>A</i> is a square matrix of size $n*n$ .						
<i>x</i>	double array of size <i>n</i> for SRHS, or matrix of size ( $n*nrhs$ ) for MRHS. This parameter contains the current approximation to the solution. Before the first call to the <code>dcg/dcgmrhs</code> routine, it contains the initial approximation to the solution.						
<i>nrhs</i>	MKL_INT, this parameter sets the number of right-hand sides for MRHS routines.						
<i>b</i>	double array containing a single right-hand side vector, or matrix of size $n*nrhs$ containing right-hand side vectors.						
<i>RCI_request</i>	MKL_INT, this parameter gives information about the result of work of the RCI CG routines. Negative values of the parameter indicate that the routine completed with errors or warnings. The 0 value indicates successful completion of the task. Positive values mean that you must perform specific actions: <table border="0" style="margin-left: 2em;"> <tr> <td style="vertical-align: top;"><i>RCI_request</i>= 1</td> <td>multiply the matrix by <code>tmp [0:n - 1)</code>, put the result in <code>tmp[n:2*n - 1)</code>, and return the control to the <code>dcg/dcgmrhs</code> routine;</td> </tr> <tr> <td style="vertical-align: top;"><i>RCI_request</i>= 2</td> <td>to perform the stopping tests. If they fail, return the control to the <code>dcg/dcgmrhs</code> routine. If the stopping tests succeed, it indicates that the solution is found and stored in the <i>x</i> array;</td> </tr> <tr> <td style="vertical-align: top;"><i>RCI_request</i>= 3</td> <td>for SRHS: apply the preconditioner to <code>tmp[2*n:3*n - 1)</code>, put the result in <code>tmp[3*n:4*n - 1)</code>, and return the control to the <code>dcg</code> routine;  for MRHS: apply the preconditioner to <code>tmp[2+ipar[2]*n:(3 + ipar[2])*n - 1)</code>, put the result in <code>tmp[3*n:4*n - 1)</code>, and return the control to the <code>dcgmrhs</code> routine.</td> </tr> </table>	<i>RCI_request</i> = 1	multiply the matrix by <code>tmp [0:n - 1)</code> , put the result in <code>tmp[n:2*n - 1)</code> , and return the control to the <code>dcg/dcgmrhs</code> routine;	<i>RCI_request</i> = 2	to perform the stopping tests. If they fail, return the control to the <code>dcg/dcgmrhs</code> routine. If the stopping tests succeed, it indicates that the solution is found and stored in the <i>x</i> array;	<i>RCI_request</i> = 3	for SRHS: apply the preconditioner to <code>tmp[2*n:3*n - 1)</code> , put the result in <code>tmp[3*n:4*n - 1)</code> , and return the control to the <code>dcg</code> routine;  for MRHS: apply the preconditioner to <code>tmp[2+ipar[2]*n:(3 + ipar[2])*n - 1)</code> , put the result in <code>tmp[3*n:4*n - 1)</code> , and return the control to the <code>dcgmrhs</code> routine.
<i>RCI_request</i> = 1	multiply the matrix by <code>tmp [0:n - 1)</code> , put the result in <code>tmp[n:2*n - 1)</code> , and return the control to the <code>dcg/dcgmrhs</code> routine;						
<i>RCI_request</i> = 2	to perform the stopping tests. If they fail, return the control to the <code>dcg/dcgmrhs</code> routine. If the stopping tests succeed, it indicates that the solution is found and stored in the <i>x</i> array;						
<i>RCI_request</i> = 3	for SRHS: apply the preconditioner to <code>tmp[2*n:3*n - 1)</code> , put the result in <code>tmp[3*n:4*n - 1)</code> , and return the control to the <code>dcg</code> routine;  for MRHS: apply the preconditioner to <code>tmp[2+ipar[2]*n:(3 + ipar[2])*n - 1)</code> , put the result in <code>tmp[3*n:4*n - 1)</code> , and return the control to the <code>dcgmrhs</code> routine.						
	Note that the <code>dcg_get/dcgmrhs_get</code> routine does not change the parameter <i>RCI_request</i> . This enables use of this routine inside the <i>reverse communication</i> computations.						
<i>ipar</i>	MKL_INT array, of size 128 for SRHS, and of size ( $128+2*nrhs$ ) for MRHS. This parameter specifies the integer set of data for the RCI CG computations: <table border="0" style="margin-left: 2em;"> <tr> <td style="vertical-align: top;"><i>ipar</i>[0]</td> <td>specifies the size of the problem. The <code>dcg_init/dcgmrhs_init</code> routine assigns <code>ipar[0]=n</code>. All the other routines use this parameter instead of <i>n</i>. There is no default value for this parameter.</td> </tr> <tr> <td style="vertical-align: top;"><i>ipar</i>[1]</td> <td>specifies the type of output for error and warning messages generated by the RCI CG routines. The default value 6 means that all</td> </tr> </table>	<i>ipar</i> [0]	specifies the size of the problem. The <code>dcg_init/dcgmrhs_init</code> routine assigns <code>ipar[0]=n</code> . All the other routines use this parameter instead of <i>n</i> . There is no default value for this parameter.	<i>ipar</i> [1]	specifies the type of output for error and warning messages generated by the RCI CG routines. The default value 6 means that all		
<i>ipar</i> [0]	specifies the size of the problem. The <code>dcg_init/dcgmrhs_init</code> routine assigns <code>ipar[0]=n</code> . All the other routines use this parameter instead of <i>n</i> . There is no default value for this parameter.						
<i>ipar</i> [1]	specifies the type of output for error and warning messages generated by the RCI CG routines. The default value 6 means that all						

messages are displayed on the screen. Otherwise, the error and warning messages are written to the newly created files `dcg_errors.txt` and `dcg_check_warnings.txt`, respectively. Note that if `ipar[5]` and `ipar[6]` parameters are set to 0, error and warning messages are not generated at all.

`ipar[2]` for SRHS: contains the current stage of the RCI CG computations. The initial value is 1;  
for MRHS: contains the number of the right-hand side for which the calculations are currently performed.

---

#### **WARNING**

Avoid altering this variable during computations.

---

`ipar[3]` contains the current iteration number. The initial value is 0.

`ipar[4]` specifies the maximum number of iterations. The default value is  $\min(150, n)$ .

`ipar[5]` if the value is not equal to 0, the routines output error messages in accordance with the parameter `ipar[1]`. Otherwise, the routines do not output error messages at all, but return a negative value of the parameter `RCI_request`. The default value is 1.

`ipar[6]` if the value is not equal to 0, the routines output warning messages in accordance with the parameter `ipar[1]`. Otherwise, the routines do not output warning messages at all, but they return a negative value of the parameter `RCI_request`. The default value is 1.

`ipar[7]` if the value is not equal to 0, the `dcg/dcgmrhs` routine performs the stopping test for the maximum number of iterations:  $ipar[3] \leq ipar[4]$ . Otherwise, the method is stopped and the corresponding value is assigned to the `RCI_request`. If the value is 0, the routine does not perform this stopping test. The default value is 1.

`ipar[8]` if the value is not equal to 0, the `dcg/dcgmrhs` routine performs the residual stopping test:  $dpar(5) \leq dpar(4) = dpar(1) * dpar(3) + dpar(2)$ . Otherwise, the method is stopped and corresponding value is assigned to the

*RCI\_request*. If the value is 0, the routine does not perform this stopping test. The default value is 0.

*ipar*[9]

if the value is not equal to 0, the *dcg/dcgmrhs* routine requests a user-defined stopping test by setting the output parameter *RCI\_request*=2. If the value is 0, the routine does not perform the user defined stopping test. The default value is 1.

---

**NOTE**

At least one of the parameters *ipar*[7]-*ipar*[9] must be set to 1.

---

*ipar*[10]

if the value is equal to 0, the *dcg/dcgmrhs* routine runs the non-preconditioned version of the corresponding CG method. Otherwise, the routine runs the preconditioned version of the CG method, and by setting the output parameter *RCI\_request*=3, indicates that you must perform the preconditioning step. The default value is 0.

*ipar*[11:127]

are reserved and not used in the current RCI CG SRHS and MRHS routines.

---

**NOTE**

For future compatibility, you must declare the array *ipar* with length 128 for a single right-hand side.

---

*ipar*[11:127 +  
2\**nrhs*]

are reserved for internal use in the current RCI CG SRHS and MRHS routines.

---

**NOTE**

For future compatibility, you must declare the array *ipar* with length 128+2\**nrhs* for multiple right-hand sides.

---

*dpar*

double array, for SRHS of size 128, for MRHS of size (128+2\**nrhs*); this parameter is used to specify the double precision set of data for the RCI CG computations, specifically:

*dpar*[0]

specifies the relative tolerance. The default value is  $1.0 \times 10^{-6}$ .

*dpar*[1]

specifies the absolute tolerance. The default value is 0.0.

<code>dpar[2]</code>	specifies the square norm of the initial residual (if it is computed in the <code>dcg/dcgmrhs</code> routine). The initial value is 0.0.
<code>dpar[3]</code>	service variable equal to $dpar[0]*dpar[2]+dpar[1]$ (if it is computed in the <code>dcg/dcgmrhs</code> routine). The initial value is 0.0.
<code>dpar[4]</code>	specifies the square norm of the current residual. The initial value is 0.0.
<code>dpar[5]</code>	specifies the square norm of residual from the previous iteration step (if available). The initial value is 0.0.
<code>dpar[6]</code>	contains the <i>alpha</i> parameter of the CG method. The initial value is 0.0.
<code>dpar[7]</code>	contains the <i>beta</i> parameter of the CG method, it is equal to $dpar[4]/dpar[5]$ The initial value is 0.0.
<code>dpar[8:127]</code>	are reserved and not used in the current RCI CG SRHS and MRHS routines.

**NOTE**

For future compatibility, you must declare the array `dpar` with length 128 for a single right-hand side.

<code>dpar(9:128+2*nrhs)</code> <code>[8:127 + 2*nrhs]</code>	are reserved for internal use in the current RCI CG SRHS and MRHS routines.
--	---

**NOTE**

For future compatibility, you must declare the array `dpar` with length  $128+2*nrhs$  for multiple right-hand sides.

`tmp`

double array of size  $(n*4)$  for SRHS, and  $(n*(3+nrhs))$  for MRHS. This parameter is used to supply the double precision temporary space for the RCI CG computations, specifically:

<code>tmp[0:n - 1]</code>	specifies the current search direction. The initial value is 0.0.
<code>tmp[n:2*n - 1]</code>	contains the matrix multiplied by the current search direction. The initial value is 0.0.
<code>tmp[2*n:3*n - 1]</code>	contains the current residual. The initial value is 0.0.

<code>tmp[3*n:4*n - 1]</code>	contains the inverse of the preconditioner applied to the current residual for the SRHS version of CG. There is no initial value for this parameter.
<code>tmp[4*n:(4 + nrhs)*n - 1]</code>	contains the inverse of the preconditioner applied to the current residual for the MRHS version of CG. There is no initial value for this parameter.

**NOTE**

You can define this array in the code using RCI CG SRHS as `double tmp[3*n]` if you run only non-preconditioned CG iterations.

## FGMRES Interface Description

### Routine Options

All of the RCI FGMRES routines have common parameters for passing various options to the routines (see [FGMRES Common Parameters](#)). The values for these parameters can be changed during computations.

### User Data Arrays

Many of the RCI FGMRES routines take arrays of user data as input. For example, user arrays are passed to the routine `dfgmresto` to compute the solution of a system of linear algebraic equations. To minimize storage requirements and improve overall run-time efficiency, the Intel® oneAPI Math Kernel Library (oneMKL) RCI FGMRES routines do not make copies of the user input arrays.

## FGMRES Common Parameters

**NOTE**

The default and initial values listed below are assigned to the parameters by calling the `dfgmres_init` routine.

<code>n</code>	MKL_INT, this parameter sets the size of the problem in the <code>dfgmres_init</code> routine. All the other routines use the <code>ipar[0]</code> parameter instead. Note that the coefficient matrix <i>A</i> is a square matrix of size $n*n$ .
<code>x</code>	double array, this parameter contains the current approximation to the solution vector. Before the first call to the <code>dfgmres</code> routine, it contains the initial approximation to the solution vector.
<code>b</code>	double array, this parameter contains the right-hand side vector. Depending on user requests (see the parameter <code>ipar[12]</code> ), it might contain the approximate solution after execution.
<code>RCI_request</code>	MKL_INT, this parameter gives information about the result of work of the RCI FGMRES routines. Negative values of the parameter indicate that the routine completed with errors or warnings. The 0 value indicates successful completion of the task. Positive values mean that you must perform specific actions:

<code>RCI_request= 1</code>	multiply the matrix by <code>tmp[ipar[21] - 1:ipar[21] + n - 2]</code> , put the result in <code>tmp[ipar[22] - 1:ipar[22] + n - 2]</code> , and return the control to the <code>dfgmres</code> routine;
<code>RCI_request= 2</code>	perform the stopping tests. If they fail, return the control to the <code>dfgres</code> routine. Otherwise, the solution can be updated by a subsequent call to <code>dfgmres_get</code> routine;
<code>RCI_request= 3</code>	apply the preconditioner to <code>tmp[ipar[21] - 1:ipar[21] + n - 2]</code> , put the result in <code>tmp[ipar[22] - 1:ipar[22] + n - 2]</code> , and return the control to the <code>dfgmres</code> routine.
<code>RCI_request= 4</code>	check if the norm of the current orthogonal vector is zero, within the rounding or computational errors. Return the control to the <code>dfgmres</code> routine if it is not zero, otherwise complete the solution process by calling <code>dfgmres_get</code> routine.

`ipar[128]`

MKL\_INT array, this parameter specifies the integer set of data for the RCI FGMRES computations:

<code>ipar[0]</code>	specifies the size of the problem. The <code>dfgmres_init</code> routine assigns <code>ipar[0]=n</code> . All the other routines uses this parameter instead of <code>n</code> . There is no default value for this parameter.
<code>ipar[1]</code>	specifies the type of output for error and warning messages that are generated by the RCI FGMRES routines. The default value 6 means that all messages are displayed on the screen. Otherwise the error and warning messages are written to the newly created file <code>MKL_RCI_FGMRES_Log.txt</code> . Note that if <code>ipar[5]</code> and <code>ipar[6]</code> parameters are set to 0, error and warning messages are not generated at all.
<code>ipar[2]</code>	contains the current stage of the RCI FGMRES computations. The initial value is 1.

---

**WARNING**

Avoid altering this variable during computations.

---

<code>ipar[3]</code>	contains the current iteration number. The initial value is 0.
<code>ipar[4]</code>	specifies the maximum number of iterations. The default value is <code>min(150,n)</code> .

<code>ipar[5]</code>	if the value is not 0, the routines output error messages in accordance with the parameter <code>ipar[1]</code> . If it is 0, the routines do not output error messages at all, but return a negative value of the parameter <code>RCI_request</code> . The default value is 1.
<code>ipar[6]</code>	if the value is not 0, the routines output warning messages in accordance with the parameter <code>ipar[1]</code> . Otherwise, the routines do not output warning messages at all, but they return a negative value of the parameter <code>RCI_request</code> . The default value is 1.
<code>ipar[7]</code>	if the value is not equal to 0, the <code>dfgmres</code> routine performs the stopping test for the maximum number of iterations: <code>ipar[3] ≤ ipar[4]</code> . If the value is 0, the <code>dfgmres</code> routine does not perform this stopping test. The default value is 1.
<code>ipar[8]</code>	if the value is not 0, the <code>dfgmres</code> routine performs the residual stopping test: <code>dpar[4] ≤ dpar[3]</code> . If the value is 0, the <code>dfgmres</code> routine does not perform this stopping test. The default value is 0.
<code>ipar[9]</code>	if the value is not 0, the <code>dfgmres</code> routine indicates that the user-defined stopping test should be performed by setting <code>RCI_request=2</code> . If the value is 0, the <code>dfgmres</code> routine does not perform the user-defined stopping test. The default value is 1.
<hr/> <b>NOTE</b> At least one of the parameters <code>ipar[7]</code> - <code>ipar[9]</code> must be set to 1. <hr/>	
<code>ipar[10]</code>	if the value is 0, the <code>dfgmres</code> routine runs the non-preconditioned version of the FGMRES method. Otherwise, the routine runs the preconditioned version of the FGMRES method, and requests that you perform the preconditioning step by setting the output parameter <code>RCI_request=3</code> . The default value is 0.
<code>ipar[11]</code>	if the value is not equal to 0, the <code>dfgmres</code> routine performs the automatic test for zero norm of the currently generated vector: <code>dpar[6] ≤ dpar[7]</code> , where <code>dpar[7]</code> contains the tolerance value. Otherwise, the routine indicates

that you must perform this check by setting the output parameter `RCI_request=4`. The default value is 0.

`ipar[12]`

if the value is equal to 0, the `dfgmres_get` routine updates the solution to the vector  $x$  according to the computations done by the `dfgmres` routine. If the value is positive, the routine writes the solution to the right-hand side vector  $b$ . If the value is negative, the routine returns only the number of the current iteration, and does not update the solution. The default value is 0.

---

**NOTE**

It is possible to call the `dfgmres_get` routine at any place in the code, but you must pay special attention to the parameter `ipar[12]`. The RCI FGMRES iterations can be continued after the call to `dfgmres_get` routine only if the parameter `ipar[12]` is not equal to zero. If `ipar[12]` is positive, then the updated solution overwrites the right-hand side in the vector  $b$ . If you want to run the restarted version of FGMRES with the same right-hand side, then it must be saved in a different memory location before the first call to the `dfgmres_get` routine with positive `ipar[12]`.

---

`ipar[13]`

contains the internal iteration counter that counts the number of iterations before the restart takes place. The initial value is 0.

---

**WARNING**

Do not alter this variable during computations.

---

`ipar[14]`

specifies the number of the non-restarted FGMRES iterations. To run the restarted version of the FGMRES method, assign the number of iterations to `ipar[14]` before the restart. The default value is  $\min(150, n)$ , which means that by default the non-restarted version of FGMRES method is used.

`ipar[15]`

service variable specifying the location of the rotated Hessenberg matrix from which the matrix stored in the packed format (see [Matrix Arguments](#) in the Appendix B for details) is started in the `tmp` array.

<code>ipar[16]</code>	service variable specifying the location of the rotation cosines from which the vector of cosines is started in the <code>tmp</code> array.
<code>ipar[17]</code>	service variable specifying the location of the rotation sines from which the vector of sines is started in the <code>tmp</code> array.
<code>ipar[18]</code>	service variable specifying the location of the rotated residual vector from which the vector is started in the <code>tmp</code> array.
<code>ipar[19]</code>	service variable, specifies the location of the least squares solution vector from which the vector is started in the <code>tmp</code> array.
<code>ipar[20]</code>	service variable specifying the location of the set of preconditioned vectors from which the set is started in the <code>tmp</code> array. The memory locations in the <code>tmp</code> array starting from <code>ipar[20]</code> are used only for the preconditioned FGMRES method.
<code>ipar[21]</code>	specifies the memory location from which the first vector (source) used in operations requested via <code>RCI_request</code> is started in the <code>tmp</code> array.
<code>ipar[22]</code>	specifies the memory location from which the second vector (output) used in operations requested via <code>RCI_request</code> is started in the <code>tmp</code> array.
<code>ipar[23:127]</code>	are reserved and not used in the current RCI FGMRES routines.

**NOTE**

You must declare the array `ipar` with length 128. While defining the array in the code as `ipar[23]` works, there is no guarantee of future compatibility with Intel® oneAPI Math Kernel Library (oneMKL).

<code>dpar(128)</code>	double array, this parameter specifies the double precision set of data for the RCI CG computations, specifically:
<code>dpar[0]</code>	specifies the relative tolerance. The default value is 1.0e-6.
<code>dpar[1]</code>	specifies the absolute tolerance. The default value is 0.0e-0.
<code>dpar[2]</code>	specifies the Euclidean norm of the initial residual (if it is computed in the <code>dfgmres</code> routine). The initial value is 0.0.

<code>dpar[3]</code>	service variable equal to $dpar[0] * dpar[2] + dpar[1]$ (if it is computed in the <code>dfgmres</code> routine). The initial value is 0.0.
<code>dpar[4]</code>	specifies the Euclidean norm of the current residual. The initial value is 0.0.
<code>dpar[5]</code>	specifies the Euclidean norm of residual from the previous iteration step (if available). The initial value is 0.0.
<code>dpar[6]</code>	contains the norm of the generated vector. The initial value is 0.0.

**NOTE**

In terms of [Saad03] this parameter is the coefficient  $h_{k+1,k}$  of the Hessenberg matrix.

<code>dpar[7]</code>	contains the tolerance for the zero norm of the currently generated vector. The default value is 1.0e-12.
<code>dpar[8:127]</code>	are reserved and not used in the current RCI FGMRES routines.

**NOTE**

You must declare the array `dpar` with length 128. While defining the array in the code as `double dpar[8]` works, there is no guarantee of future compatibility with Intel® oneAPI Math Kernel Library (oneMKL).

*tmp*

double array of size  $((2 * ipar[14] + 1) * n + ipar[14] * (ipar[14] + 9) / 2 + 1)$  used to supply the double precision temporary space for the RCI FGMRES computations, specifically:

<code>tmp[0:ipar[15] - 2]</code>	contains the sequence of vectors generated by the FGMRES method. The initial value is 0.0.
<code>tmp[ipar[15] - 1:ipar[16] - 2]</code>	contains the rotated Hessenberg matrix generated by the FGMRES method; the matrix is stored in the packed format. There is no initial value for this part of <code>tmp</code> array.
<code>tmp[ipar[16] - 1:ipar[17] - 2]</code>	contains the rotation cosines vector generated by the FGMRES method. There is no initial value for this part of <code>tmp</code> array.
<code>tmp[ipar[17] - 1:ipar[18] - 2]</code>	contains the rotation sines vector generated by the FGMRES method. There is no initial value for this part of <code>tmp</code> array.

```
tmp[ipar[18] -
1:ipar[19] - 2]
```

contains the rotated residual vector generated by the FGMRES method. There is no initial value for this part of *tmp* array.

```
tmp[ipar[19] -
1:ipar[20] - 2]
```

contains the solution vector to the least squares problem generated by the FGMRES method. There is no initial value for this part of *tmp* array.

```
tmp[ipar[20] - 1:*
```

contains the set of preconditioned vectors generated for the FGMRES method by the user. This part of *tmp* array is not used if the non-preconditioned version of FGMRES method is called. There is no initial value for this part of *tmp* array.

---

#### NOTE

You can define this array in the code as `double tmp[(2*ipar[14] + 1)*n + ipar[14]*(ipar[14] + 9)/2 + 1]` if you run only non-preconditioned FGMRES iterations.

---

## RCI ISS Routines

### dcg\_init

Initializes the solver.

---

#### Syntax

```
void dcg_init (const MKL_INT *n , const double *x , const double *b , MKL_INT
*RCI_request , MKL_INT *ipar , double *dpar , double *tmp );
```

#### Include Files

- mkl.h

#### Description

The routine `dcg_init` initializes the solver. After initialization, all subsequent invocations of the Intel® oneAPI Math Kernel Library (oneMKL) RCI CG routines use the values of all parameters returned by the routine `dcg_init`. Advanced users can skip this step and set the values in the *ipar* and *dpar* arrays directly.

---

#### Caution

You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dcg_check` routine, but it does not guarantee that the method will work correctly.

---

## Input Parameters

$n$	Sets the size of the problem.
$x$	Array of size $n$ . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to $b$ .
$b$	Array of size $n$ . Contains the right-hand side vector.

## Output Parameters

$RCI\_request$	Gives information about the result of the routine.
$ipar$	Array of size 128. Refer to the <a href="#">CG Common Parameters</a> .
$dpar$	Array of size 128. Refer to the <a href="#">CG Common Parameters</a> .
$tmp$	Array of size $(n*4)$ . Refer to the <a href="#">CG Common Parameters</a> .

## Return Values

$RCI\_request = 0$	Indicates that the task completed normally.
$RCI\_request = -10000$	Indicates failure to complete the task.

## dcg\_check

*Checks consistency and correctness of the user defined data.*

---

## Syntax

```
void dcg_check (const MKL_INT *n , const double *x , const double *b , MKL_INT
*RCI_request , MKL_INT *ipar , double *dpar , double *tmp );
```

## Include Files

- `mkl.h`

## Description

The routine `dcg_check` checks consistency and correctness of the parameters to be passed to the solver routine `dcg`. However this operation does not guarantee that the solver returns the correct result. It only reduces the chance of making a mistake in the parameters of the method. Skip this operation only if you are sure that the correct data is specified in the solver parameters.

The lengths of all vectors must be defined in a previous call to the `dcg_init` routine.

If none of the stopping criteria ( $ipar[7]-ipar[9]$ ) has been enabled, both  $ipar[7]$  and  $ipar[8]$  will be set to 1.

## Input Parameters

$ipar$	Array of size 128. Refer to the <a href="#">FGMRES Common Parameters</a> .
$n$	Sets the size of the problem.
$x$	Array of size $n$ . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to $b$ .

*b* Array of size  $n$ . Contains the right-hand side vector.

## Output Parameters

*RCI\_request* Gives information about result of the routine.

*ipar* Array of size 128. Refer to the [CG Common Parameters](#). Only *ipar*[7]-*ipar*[8] might be changed

*dpar* Array of size 128. Refer to the [CG Common Parameters](#).

*tmp* Array of size  $(n*4)$ . Refer to the [CG Common Parameters](#).

## Return Values

*RCI\_request*= 0 Indicates that the task completed normally.

*RCI\_request*= -1100 Indicates that the task is interrupted and the errors occur.

*RCI\_request*= -1001 Indicates that there are some warning messages.

*RCI\_request*= -1010 Indicates that the routine changed some parameters to make them consistent or correct.

*RCI\_request*= -1011 Indicates that there are some warning messages and that the routine changed some parameters.

## dcg

*Computes the approximate solution vector.*

## Syntax

```
void dcg (const MKL_INT *n , double *x , const double *b , MKL_INT *RCI_request ,
MKL_INT *ipar , double *dpar , double *tmp );
```

## Include Files

- mkl.h

## Description

The `dcg` routine computes the approximate solution vector using the CG method [Young71]. The routine `dcg` uses the vector in the array  $x$  before the first call as an initial approximation to the solution. The parameter *RCI\_request* gives you information about the task completion and requests results of certain operations that are required by the solver.

Note that lengths of all vectors must be defined in a previous call to the `dcg_init` routine.

## Input Parameters

*n* Sets the size of the problem.

*x* Array of size  $n$ . Contains the initial approximation to the solution vector.

*b* Array of size  $n$ . Contains the right-hand side vector.

*tmp* Array of size  $(n*4)$ . Refer to the [CG Common Parameters](#).

## Output Parameters

<code>RCI_request</code>	Gives information about result of work of the routine.
<code>x</code>	Array of size $n$ . Contains the updated approximation to the solution vector.
<code>ipar</code>	Array of size 128. Refer to the <a href="#">CG Common Parameters</a> .
<code>dpar</code>	Array of size 128. Refer to the <a href="#">CG Common Parameters</a> .
<code>tmp</code>	Array of size $(n*4)$ . Refer to the <a href="#">CG Common Parameters</a> .

## Return Values

<code>RCI_request=0</code>	Indicates that the task completed normally and the solution is found and stored in the vector <code>x</code> . This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the <code>RCI_request= 2</code> .
<code>RCI_request=-1</code>	Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if you request both tests.
<code>RCI_request=-2</code>	Indicates that the routine was interrupted because of an attempt to divide by zero. This situation happens if the matrix is non-positive definite or almost non-positive definite.
<code>RCI_request=- 10</code>	Indicates that the routine was interrupted because the residual norm is invalid. This usually happens because the value <code>dpar[5]</code> was altered outside of the routine, or the <code>dcg_check</code> routine was not called.
<code>RCI_request=-11</code>	Indicates that the routine was interrupted because it enters the infinite cycle. This usually happens because the values <code>ipar[7]</code> , <code>ipar[8]</code> , <code>ipar[9]</code> were altered outside of the routine, or the <code>dcg_check</code> routine was not called.
<code>RCI_request= 1</code>	Indicates that you must multiply the matrix by <code>tmp[0:n - 1]</code> , put the result in the <code>tmp[n:2*n - 1]</code> , and return control back to the routine <code>dcg</code> .
<code>RCI_request= 2</code>	Indicates that you must perform the stopping tests. If they fail, return control back to the <code>dcg</code> routine. Otherwise, the solution is found and stored in the vector <code>x</code> .
<code>RCI_request= 3</code>	Indicates that you must apply the preconditioner to <code>[2*n:3*n - 1]</code> , put the result in the <code>[3*n:4*n - 1]</code> , and return control back to the routine <code>dcg</code> .

### `dcg_get`

Retrieves the number of the current iteration.

## Syntax

```
void dcg_get (const MKL_INT *n , const double *x , const double *b , const MKL_INT
*RCI_request , const MKL_INT *ipar , const double *dpar , const double *tmp , MKL_INT
*itercount );
```

## Include Files

- mkl.h

## Description

The routine `dcg_get` retrieves the current iteration number of the solutions process.

## Input Parameters

<code>n</code>	Sets the size of the problem.
<code>x</code>	Array of size <code>n</code> . Contains the approximation vector to the solution.
<code>b</code>	Array of size <code>n</code> . Contains the right-hand side vector.
<code>RCI_request</code>	This parameter is not used.
<code>ipar</code>	Array of size 128. Refer to the <a href="#">CG Common Parameters</a> .
<code>dpar</code>	Array of size 128. Refer to the <a href="#">CG Common Parameters</a> .
<code>tmp</code>	Array of size $(n*4)$ . Refer to the <a href="#">CG Common Parameters</a> .

## Output Parameters

<code>itercount</code>	Returns the current iteration number.
------------------------	---------------------------------------

## Return Values

The routine `dcg_get` has no return values.

## `dcgmrhs_init`

*Initializes the RCI CG solver with MHRS.*

---

## Syntax

```
void dcgmrhs_init (const MKL_INT *n , const double *x , const MKL_INT *nrhs , const
double *b , const MKL_INT *method , MKL_INT *RCI_request , MKL_INT *ipar , double
*dpar , double *tmp );
```

## Include Files

- mkl.h

## Description

The routine `dcgmrhs_init` initializes the solver. After initialization all subsequent invocations of the Intel® oneAPI Math Kernel Library (oneMKL) RCI CG with multiple right-hand sides (MRHS) routines use the values of all parameters that are returned by `dcgmrhs_init`. Advanced users may skip this step and set the values to these parameters directly in the appropriate routines.

**WARNING**

You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dcgmrhs_check` routine, but it does not guarantee that the method will work correctly.

**Input Parameters**

<code>n</code>	Sets the size of the problem.
<code>x</code>	Array of size $n * nrhs$ . Contains the initial approximation to the solution vectors. Normally it is equal to 0 or to <code>b</code> .
<code>nrhs</code>	Sets the number of right-hand sides.
<code>b</code>	Array of size $n * nrhs$ . Contains the right-hand side vectors.
<code>method</code>	Specifies the method of solution: A value of 1 indicates CG with multiple right-hand sides (default value)

**Output Parameters**

<code>RCI_request</code>	Gives information about the result of the routine.
<code>ipar</code>	Array of size $(128 + 2 * nrhs)$ . Refer to the <a href="#">CG Common Parameters</a> .
<code>dpar</code>	Array of size $(128 + 2 * nrhs)$ . Refer to the <a href="#">CG Common Parameters</a> .
<code>tmp</code>	Array of size $(n * (3 + nrhs))$ . Refer to the <a href="#">CG Common Parameters</a> .

**Return Values**

<code>RCI_request = 0</code>	Indicates that the task completed normally.
<code>RCI_request = -10000</code>	Indicates failure to complete the task.

**dcgmrhs\_check**

*Checks consistency and correctness of the user defined data.*

**Syntax**

```
void dcgmrhs_check (const MKL_INT *n , const double *x , const MKL_INT *nrhs , const double *b , MKL_INT *RCI_request , MKL_INT *ipar , double *dpar , double *tmp );
```

**Include Files**

- `mkl.h`

**Description**

The routine `dcgmrhs_check` checks the consistency and correctness of the parameters to be passed to the solver routine `dcgmrhs`. While this operation reduces the chance of making a mistake in the parameters, it does not guarantee that the solver returns the correct result.

If you are sure that the correct data is *specified* in the solver parameters, you can skip this operation.

The lengths of all vectors must be defined in a previous call to the `dcgmrhs_init` routine.

If none of the stopping criteria ( $ipar[7]$ - $ipar[9]$ ) has been enabled, both  $ipar[7]$  and  $ipar[8]$  will be set to 1.

## Input Parameters

$n$	Sets the size of the problem.
$x$	Array of size $n*nrhs$ . Contains the initial approximation to the solution vectors. Normally it is equal to 0 or to $b$ .
$nrhs$	This parameter sets the number of right-hand sides.
$b$	Array of size $n*nrhs$ . Contains the right-hand side vectors.

## Output Parameters

$RCI\_request$	Returns information about the results of the routine.
$ipar$	Array of size $(128+2*nrhs)$ . Refer to the <a href="#">CG Common Parameters</a> . Only $ipar[7]$ - $ipar[8]$ might be changed.
$dpar$	Array of size $(128+2*nrhs)$ . Refer to the <a href="#">CG Common Parameters</a> .
$tmp$	Array of size $(n*(3+nrhs))$ . Refer to the <a href="#">CG Common Parameters</a> .

## Return Values

$RCI\_request = 0$	Indicates that the task completed normally.
$RCI\_request = -1100$	Indicates that the task is interrupted and the errors occur.
$RCI\_request = -1001$	Indicates that there are some warning messages.
$RCI\_request = -1010$	Indicates that the routine changed some parameters to make them consistent or correct.
$RCI\_request = -1011$	Indicates that there are some warning messages and that the routine changed some parameters.

## dcgmrhs

Computes the approximate solution vectors.

## Syntax

```
void dcgmrhs (const MKL_INT *n , double *x , const MKL_INT *nrhs , const double *b ,
MKL_INT *RCI_request , MKL_INT *ipar , double *dpar , double *tmp );
```

## Include Files

- mkl.h

## Description

The routine `dcgmrhs` computes approximate solution vectors using the CG with multiple right-hand sides (MRHS) method [Young71]. The routine `dcgmrhs` uses the value that was in the  $x$  before the first call as an initial approximation to the solution. The parameter  $RCI\_request$  gives information about task completion status and requests results of certain operations that are required by the solver.

Note that lengths of all vectors are assumed to have been defined in a previous call to the `dcgmrhs_init` routine.

## Input Parameters

<i>n</i>	Sets the size of the problem, and the sizes of arrays <i>x</i> and <i>b</i> .
<i>x</i>	Array of size $n * nrhs$ . Contains the initial approximation to the solution vectors.
<i>nrhs</i>	Sets the number of right-hand sides.
<i>b</i>	Array of size $n * nrhs$ . Contains the right-hand side vectors.
<i>tmp</i>	Array of size $(n, 3 + nrhs)$ . Refer to the <a href="#">CG Common Parameters</a> .

## Output Parameters

<i>RCI_request</i>	Gives information about result of work of the routine.
<i>x</i>	Array of size $(n * nrhs)$ . Contains the updated approximation to the solution vectors.
<i>ipar</i>	Array of size $(128 + 2 * nrhs)$ . Refer to the <a href="#">CG Common Parameters</a> .
<i>dpar</i>	Array of size $(128 + 2 * nrhs)$ . Refer to the <a href="#">CG Common Parameters</a> .
<i>tmp</i>	Array of size $(n * (3 + nrhs))$ . Refer to the <a href="#">CG Common Parameters</a> .

## Return Values

<i>RCI_request</i> =0	Indicates that the task completed normally and the solution is found and stored in the vector <i>x</i> . This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the <i>RCI_request</i> = 2.
<i>RCI_request</i> =-1	Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if both tests are requested by the user.
<i>RCI_request</i> =-2	The routine was interrupted because of an attempt to divide by zero. This situation happens if the matrix is non-positive definite or almost non-positive definite.
<i>RCI_request</i> =- 10	Indicates that the routine was interrupted because the residual norm is invalid. This usually happens because the value <i>dpar</i> [5] was altered outside of the routine, or the <i>dcg_check</i> routine was not called.
<i>RCI_request</i> =-11	Indicates that the routine was interrupted because it enters the infinite cycle. This usually happens because the values <i>ipar</i> [7], <i>ipar</i> [8], <i>ipar</i> [9] were altered outside of the routine, or the <i>dcg_check</i> routine was not called.
<i>RCI_request</i> = 1	Indicates that you must multiply the matrix by <i>tmp</i> [0: <i>n</i> - 1], put the result in the <i>tmp</i> [ <i>n</i> :2* <i>n</i> - 1], and return control back to the routine <i>dcg</i> .

`RCI_request= 2`

Indicates that you must perform the stopping tests. If they fail, return control back to the `dcg` routine. Otherwise, the solution is found and stored in the vector `x`.

`RCI_request= 3`

Indicates that you must apply the preconditioner to `tmp[2*n:3*n - 1]`, put the result in the `tmp[3*n:4*n - 1]`, and return control back to the routine `dcg`.

## dcgmrhs\_get

*Retrieves the number of the current iteration.*

### Syntax

```
void dcgmrhs_get (const MKL_INT *n , const double *x , const MKL_INT *nrhs , const
double *b , const MKL_INT *RCI_request , const MKL_INT *ipar , const double *dpar ,
const double *tmp , MKL_INT *itercount );
```

### Include Files

- `mkl.h`

### Description

The routine `dcgmrhs_get` retrieves the current iteration number of the solving process.

### Input Parameters

<code>n</code>	Sets the size of the problem.
<code>x</code>	Array of size $n * nrhs$ . Contains the initial approximation to the solution vectors.
<code>nrhs</code>	Sets the number of right-hand sides.
<code>b</code>	Array of size $n * nrhs$ . Contains the right-hand side .
<code>RCI_request</code>	This parameter is not used.
<code>ipar</code>	Array of size $(128 + 2 * nrhs)$ . Refer to the <a href="#">CG Common Parameters</a> .
<code>dpar</code>	Array of size $(128 + 2 * nrhs)$ . Refer to the <a href="#">CG Common Parameters</a> .
<code>tmp</code>	Array of size $(n * (3 + nrhs))$ . Refer to the <a href="#">CG Common Parameters</a> .

### Output Parameters

<code>itercount</code>	Array of size <code>nrhs</code> . Returns the current iteration number for each right-hand side.
------------------------	--

### Return Values

The routine `dcgmrhs_get` has no return values.

## dfgmres\_init

*Initializes the solver.*

## Syntax

```
void dfgmres_init (const MKL_INT *n , const double *x , const double *b , MKL_INT
*RCI_request , MKL_INT *ipar , double *dpar , double *tmp );
```

## Include Files

- mkl.h

## Description

The routine `dfgmres_init` initializes the solver. After initialization all subsequent invocations of Intel® oneAPI Math Kernel Library (oneMKL) RCI FGMRES routines use the values of all parameters that are returned by `dfgmres_init`. Advanced users can skip this step and set the values in the `ipar` and `dpar` arrays directly.

### WARNING

You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dfgmres_check` routine, but it does not guarantee that the method will work correctly.

## Input Parameters

<code>n</code>	Sets the size of the problem.
<code>x</code>	Array of size <code>n</code> . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to <code>b</code> .
<code>b</code>	Array of size <code>n</code> . Contains the right-hand side vector.

## Output Parameters

<code>RCI_request</code>	Gives information about the result of the routine.
<code>ipar</code>	Array of size 128. Refer to the <a href="#">FGMRES Common Parameters</a> .
<code>dpar</code>	Array of size 128. Refer to the <a href="#">FGMRES Common Parameters</a> .
<code>tmp</code>	Array of size $((2 * ipar[14] + 1) * n + ipar[14] * (ipar[14] + 9) / 2 + 1)$ . Refer to the <a href="#">FGMRES Common Parameters</a> .

## Return Values

<code>RCI_request = 0</code>	Indicates that the task completed normally.
<code>RCI_request = -10000</code>	Indicates failure to complete the task.

## dfgmres\_check

*Checks consistency and correctness of the user defined data.*

## Syntax

```
void dfgmres_check (const MKL_INT *n, const double *x, const double *b, MKL_INT
*RCI_request, MKL_INT *ipar, double *dpar, double *tmp );
```

## Include Files

- `mkl.h`

## Description

The routine `dfgmres_check` checks consistency and correctness of the parameters to be passed to the solver routine `dfgmres`. However, this operation does not guarantee that the method gives the correct result. It only reduces the chance of making a mistake in the parameters of the routine. Skip this operation only if you are sure that the correct data is specified in the solver parameters.

The lengths of all vectors are assumed to have been defined in a previous call to the `dfgmres_init` routine.

In particular, the routine checks the consistency of `ipar[15]-ipar[20]` and `ipar[0], ipar[14]`. If the values do not agree, the routine emits a warning and modifies `ipar[15]-ipar[20]` to comply with the values of `ipar[0], ipar[14]`. A possible use case for this modification is a non-default value (not the one set by a possible call to `dfgmres_init`) of `ipar[14]`.

Also, if none of the stopping criteria (`ipar[7]-ipar[9]`) has been enabled, both `ipar[7]` and `ipar[9]` will be set to 1.

NOTE: It is not strictly necessary to call the `dfgmres_check` routine unless the values of `ipar[14]` or `ipar[0]` are changed after the last call to `dfgmres_init`.

## Input Parameters

<code>ipar</code>	Array of size 128. Refer to the <a href="#">FGMRES Common Parameters</a> .
<code>n</code>	Sets the size of the problem.
<code>x</code>	Array of size <code>n</code> . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to <code>b</code> .
<code>b</code>	Array of size <code>n</code> . Contains the right-hand side vector.

## Output Parameters

<code>RCI_request</code>	Gives information about result of the routine.
<code>ipar</code>	Array of size 128. Refer to the <a href="#">FGMRES Common Parameters</a> . Only <code>ipar[7]-ipar[8]</code> and <code>ipar[15]-ipar[20]</code> might be changed.
<code>dpar</code>	Array of size 128. Refer to the <a href="#">FGMRES Common Parameters</a> .
<code>tmp</code>	Array of size $((2 * ipar[14] + 1) * n + ipar[14] * (ipar[14] + 9) / 2 + 1)$ . Refer to the <a href="#">FGMRES Common Parameters</a> .

## Return Values

<code>RCI_request = 0</code>	Indicates that the task completed normally.
<code>RCI_request = -1100</code>	Indicates that the task is interrupted and the errors occur.
<code>RCI_request = -1001</code>	Indicates that there are some warning messages.
<code>RCI_request = -1010</code>	Indicates that the routine changed some parameters to make them consistent or correct.
<code>RCI_request = -1011</code>	Indicates that there are some warning messages and that the routine changed some parameters.

## dfgmres

Makes the FGMRES iterations.

### Syntax

```
void dfgmres (const MKL_INT *n, double *x, double *b, MKL_INT *RCI_request, MKL_INT
*ipar, double *dpar, double *tmp );
```

### Include Files

- mkl.h

### Description

The routine `dfgmres` performs the FGMRES iterations [Saad03], using the value that was in the array  $x$  before the first call as an initial approximation of the solution vector. To update the current approximation to the solution, the `dfgmres_get` routine must be called. The RCI FGMRES iterations can be continued after the call to the `dfgmres_get` routine only if the value of the parameter `ipar[12]` is not equal to 0 (default value). Note that the updated solution overwrites the right-hand side in the vector  $b$  if the parameter `ipar[12]` is positive, and the restarted version of the FGMRES method can not be run. If you want to keep the right-hand side, you must save it in a different memory location before the first call to the `dfgmres_get` routine with a positive `ipar[12]`.

The parameter `RCI_request` gives information about the task completion and requests results of certain operations that the solver requires.

The lengths of all the vectors must be defined in a previous call to the `dfgmres_init` routine.

### Input Parameters

$n$	Sets the size of the problem.
$x$	Array of size $n$ . Contains the initial approximation to the solution vector.
$b$	Array of size $n$ . Contains the right-hand side vector.
$tmp$	Array of size [12]. Refer to the <a href="#">FGMRES Common Parameters</a> .

### Output Parameters

<code>RCI_request</code>	Informs about result of work of the routine.
<code>ipar</code>	Array of size 128. Refer to the <a href="#">FGMRES Common Parameters</a> .
<code>dpar</code>	Array of size 128. Refer to the <a href="#">FGMRES Common Parameters</a> .
<code>tmp</code>	Array of size $((2*ipar[14]+1)*n+ipar[14]*ipar[14]+9)/2 + 1$ . Refer to the <a href="#">FGMRES Common Parameters</a> .

### Return Values

<code>RCI_request=0</code>	Indicates that the task completed normally and the solution is found and stored in the vector $x$ . This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the <code>RCI_request= 2</code> or 4.
----------------------------	---

<code>RCI_request=-1</code>	Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if you request both tests.
<code>RCI_request= -10</code>	Indicates that the routine was interrupted because of an attempt to divide by zero. Usually this happens if the matrix is degenerate or almost degenerate. However, it may happen if the parameter <code>dpar</code> is altered, or if the method is not stopped when the solution is found.
<code>RCI_request= -11</code>	Indicates that the routine was interrupted because it entered an infinite cycle. Usually this happens because the values <code>ipar[7]</code> , <code>ipar[8]</code> , <code>ipar[9]</code> were altered outside of the routine, or the <code>dfgmres_check</code> routine was not called.
<code>RCI_request= -12</code>	Indicates that the routine was interrupted because errors were found in the method parameters. Usually this happens if the parameters <code>ipar</code> and <code>dpar</code> were altered by mistake outside the routine.
<code>RCI_request= 1</code>	Indicates that you must multiply the matrix by <code>tmp[ipar[21] - 1:ipar[21] + n - 2]</code> , put the result in the <code>tmp[ipar[22] - 1:ipar[22] + n - 2]</code> , and return control back to the routine <code>dfgmres</code> .
<code>RCI_request= 2</code>	Indicates that you must perform the stopping tests. If they fail, return control to the <code>dfgmres</code> routine. Otherwise, the FGMRES solution is found, and you can run the <code>fgmres_get</code> routine to update the computed solution in the vector <code>x</code> .
<code>RCI_request= 3</code>	Indicates that you must apply the inverse preconditioner to <code>tmp[ipar[21] - 1:ipar[21] + n - 2]</code> , put the result in the <code>tmp[ipar[22] - 1:ipar[22] + n - 2]</code> , and return control back to the routine <code>dfgmres</code> .
<code>RCI_request= 4</code>	Indicates that you must check the norm of the currently generated vector. If it is not zero within the computational/rounding errors, return control to the <code>dfgmres</code> routine. Otherwise, the FGMRES solution is found, and you can run the <code>dfgmres_get</code> routine to update the computed solution in the vector <code>x</code> .

### **dfgmres\_get**

Retrieves the number of the current iteration and updates the solution.

### **Syntax**

```
void dfgmres_get (const MKL_INT *n, double *x, double *b, MKL_INT *RCI_request, const MKL_INT *ipar, const double *dpar, double *tmp, MKL_INT *itercount );
```

### **Include Files**

- `mkl.h`

## Description

The routine `dfgmres_get` retrieves the current iteration number of the solution process and updates the solution according to the computations performed by the `dfgmres` routine. To retrieve the current iteration number only, set the parameter `ipar[12] = -1` beforehand. Normally, you should do this before proceeding further with the computations. If the intermediate solution is needed, the method parameters must be set properly. For details see [FGMRES Common Parameters](#) and the Iterative Sparse Solver code examples in the Intel® oneAPI Math Kernel Library (oneMKL) installation directory:

- `examples/solverc/source`

## Input Parameters

<code>n</code>	Sets the size of the problem.
<code>ipar</code>	Array of size 128. Refer to the <a href="#">FGMRES Common Parameters</a> .
<code>dpar</code>	Array of size 128. Refer to the <a href="#">FGMRES Common Parameters</a> .
<code>tmp</code>	Array of size $((2 * ipar[14] + 1) * n + ipar[14] * ipar[14] + 9) / 2 + 1$ . Refer to the <a href="#">FGMRES Common Parameters</a> .

## Output Parameters

<code>x</code>	Array of size <code>n</code> . If <code>ipar[12] = 0</code> , it contains the updated approximation to the solution according to the computations done in <code>dfgmres</code> routine. Otherwise, it is not changed.
<code>b</code>	Array of size <code>n</code> . If <code>ipar(13) &gt; 0</code> , it contains the updated approximation to the solution according to the computations done in <code>dfgmres</code> routine. Otherwise, it is not changed.
<code>RCI_request</code>	Gives information about result of the routine.
<code>itercount</code>	Contains the value of the current iteration number.

## Return Values

<code>RCI_request = 0</code>	Indicates that the task completed normally.
<code>RCI_request = -12</code>	Indicates that the routine was interrupted because errors were found in the routine parameters. Usually this happens if the parameters <code>ipar</code> and <code>dpar</code> were altered by mistake outside of the routine.
<code>RCI_request = -10000</code>	Indicates that the routine failed to complete the task.

## RCI ISS Implementation Details

Several aspects of the Intel® oneAPI Math Kernel Library (oneMKL) RCI ISS interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, include one of the Intel® oneAPI Math Kernel Library (oneMKL) RCI ISS language-specific header files.

---

### NOTE

Intel® oneAPI Math Kernel Library (oneMKL) does not support the RCI ISS interface unless you include the language-specific header file.

---

## Preconditioners based on Incomplete LU Factorization Technique

Preconditioners, or accelerators are used to accelerate an iterative solution process. In some cases, their use can reduce the number of iterations dramatically and thus lead to better solver performance. Although the terms *preconditioner* and *accelerator* are synonyms, hereafter only *preconditioner* is used.

Intel® oneAPI Math Kernel Library (oneMKL) provides two preconditioners, ILU0 and ILUT, for sparse matrices presented in the format accepted in the Intel® oneAPI Math Kernel Library (oneMKL) direct sparse solvers (three-array variation of the CSR storage format described in [Sparse Matrix Storage Format](#)). The algorithms used are described in [Saad03].

The ILU0 preconditioner is based on a well-known factorization of the original matrix into a product of two triangular matrices: lower and upper triangular matrices. Usually, such decomposition leads to some fill-in in the resulting matrix structure in comparison with the original matrix. The distinctive feature of the ILU0 preconditioner is that it preserves the structure of the original matrix in the result.

Unlike the ILU0 preconditioner, the ILUT preconditioner preserves some resulting fill-in in the preconditioner matrix structure. The distinctive feature of the ILUT algorithm is that it calculates each element of the preconditioner and saves each one if it satisfies two conditions simultaneously: its value is greater than the product of the given tolerance and matrix row norm, and its value is in the given bandwidth of the resulting preconditioner matrix.

Both ILU0 and ILUT preconditioners can apply to any non-degenerate matrix. They can be used alone or together with the Intel® oneAPI Math Kernel Library (oneMKL) RCI FGMRES solver (see [Sparse Solver Routines](#)). Avoid using these preconditioners with MKL RCI CG solver because in general, they produce a non-symmetric resulting matrix even if the original matrix is symmetric. Usually, an inverse of the preconditioner is required in this case. To do this the Intel® oneAPI Math Kernel Library (oneMKL) triangular solver routine `mkl_dcsrtrsv` must be applied twice: for the lower triangular part of the preconditioner, and then for its upper triangular part.

---

### NOTE

Although ILU0 and ILUT preconditioners apply to any non-degenerate matrix, in some cases the algorithm may fail to ensure successful termination and the required result. Whether or not the preconditioner produces an acceptable result can only be determined in practice.

A preconditioner may increase the number of iterations for an arbitrary case of the system and the initial solution, and even ruin the convergence. It is your responsibility as a user to choose a suitable preconditioner.

---

## General Scheme of Using ILUT and RCI FGMRES Routines

The general scheme for use is the same for both preconditioners. Some differences exist in the calling parameters of the preconditioners and in the subsequent call of two triangular solvers. You can see all these differences in the preconditioner code examples (`dcsrilu*.*`) in the `examples` folder of the Intel® oneAPI Math Kernel Library (oneMKL) installation directory:

- `examples/solverc/source`

## ILU0 and ILUT Preconditioners Interface Description

The concepts required to understand the use of the Intel® oneAPI Math Kernel Library (oneMKL) preconditioner routines are discussed in the [Appendix A Linear Solvers Basics](#).

## User Data Arrays

The preconditioner routines take arrays of user data as input. To minimize storage requirements and improve overall run-time efficiency, the Intel® oneAPI Math Kernel Library (oneMKL) preconditioner routines do not make copies of the user input arrays.

## Common Parameters

Some parameters of the preconditioners are common with the [FGMRES Common Parameters](#). The routine `dfgmres_init` specifies their default and initial values. However, some parameters can be redefined with other values. These parameters are listed below.

### For the ILU0 preconditioner:

`ipar[1]` - specifies the destination of error messages generated by the ILU0 routine. The default value 6 means that all error messages are displayed on the screen. Otherwise routine creates a log file called `MKL_PREC_log.txt` and writes error messages to it. Note if the parameter `ipar[5]` is set to 0, then error messages are not generated at all.

`ipar[5]` - specifies whether error messages are generated. If its value is not equal to 0, the ILU0 routine returns error messages as specified by the parameter `ipar[1]`. Otherwise, the routine does not generate error messages at all, but returns a negative value for the parameter `ierr`. The default value is 1.

### For the ILUT preconditioner:

`ipar[1]` - specifies the destination of error messages generated by the ILUT routine. The default value 6 means that all messages are displayed on the screen. Otherwise routine creates a log file called `MKL_PREC_log.txt` and writes error messages to it. Note if the parameter `ipar[5]` is set to 0, then error messages are not generated at all.

`ipar[5]` - specifies whether error messages are generated. If its value is not equal to 0, the ILUT routine returns error messages as specified by the parameter `ipar[1]`. Otherwise, the routine does not generate error messages at all, but returns a negative value for the parameter `ierr`. The default value is 1.

`ipar[6]` - if its value is greater than 0, the ILUT routine generates warning messages as specified by the parameter `ipar[1]` and continues calculations. If its value is equal to 0, the routine returns a positive value of the parameter `ierr`. If its value is less than 0, the routine generates a warning message as specified by the parameter `ipar[1]` and returns a positive value of the parameter `ierr`. The default value is 1.

## dcsrilu0

*ILU0 preconditioner based on incomplete LU factorization of a sparse matrix.*

### Syntax

```
void dcsrilu0 (const MKL_INT *n , const double *a , const MKL_INT *ia , const MKL_INT *ja , double *bilu0 , const MKL_INT *ipar , const double *dpar , MKL_INT *ierr );
```

### Include Files

- `mkl.h`

### Description

The routine `dcsrilu0` computes a preconditioner  $B$  [Saad03] of a given sparse matrix  $A$  stored in the format accepted in the direct sparse solvers:

$A \sim B = L * U$ , where  $L$  is a lower triangular matrix with a unit diagonal,  $U$  is an upper triangular matrix with a non-unit diagonal, and the portrait of the original matrix  $A$  is used to store the incomplete factors  $L$  and  $U$ .

---

### Caution

This routine supports only one-based indexing of the array parameters.

---

## Input Parameters

<i>n</i>	Size (number of rows or columns) of the original square <i>n</i> -by- <i>n</i> matrix <i>A</i> .
<i>a</i>	Array containing the set of elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to the <i>values</i> array description in the <a href="#">Sparse Matrix Storage Format</a> for more details.
<i>ia</i>	Array of size $(n+1)$ containing begin indices of rows of the matrix <i>A</i> such that <i>ia</i> [ <i>i</i> ] is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i> . The value of the last element <i>ia</i> [ <i>n</i> ] is equal to the number of non-zero elements in the matrix <i>A</i> , plus one. Refer to the <i>rowIndex</i> array description in the <a href="#">Sparse Matrix Storage Format</a> for more details.
<i>ja</i>	Array containing the column indices for each non-zero element of the matrix <i>A</i> . It is important that the indices are in increasing order per row. The matrix size is equal to the size of the array <i>a</i> . Refer to the <i>columns</i> array description in the <a href="#">Sparse Matrix Storage Format</a> for more details.

---

### Caution

If column indices are not stored in ascending order for each row of matrix, the result of the routine might not be correct.

---

*ipar* Array of size 128. This parameter specifies the integer set of data for both the ILU0 and RCI FGMRES computations. Refer to the *ipar* array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries that are specific to ILU0 are listed below.

<i>ipar</i> [30]	specifies how the routine operates when a zero diagonal element occurs during calculation. If this parameter is set to 0 (the default value set by the routine <code>dfgmres_init</code> ), then the calculations are stopped and the routine returns a non-zero error value. Otherwise, the diagonal element is set to the value of <i>dpar</i> [31] and the calculations continue.
------------------	--

---

### NOTE

You can declare the *ipar* array with a size of 32. However, for future compatibility you must declare the array *ipar* with length 128.

---

*dpar* Array of size 128. This parameter specifies the double precision set of data for both the ILU0 and RCI FGMRES computations. Refer to the *dpar* array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries specific to ILU0 are listed below.

<i>dpar</i> [30]	specifies a small value, which is compared with the computed diagonal elements. When <i>ipar</i> [30] is not 0, then diagonal elements less than <i>dpar</i> [30] are set to <i>dpar</i> [31]. The default value is 1.0e-16.
------------------	--

**NOTE**

This parameter can be set to the negative value, because the calculation uses its absolute value.

If this parameter is set to 0, the comparison with the diagonal element is not performed.

*dpar*[31] specifies the value that is assigned to the diagonal element if its value is less than *dpar*[30] (see above). The default value is 1.0e-10.

**NOTE**

You can declare the *dpar* array with a size of 32. However, for future compatibility you must declare the array *dpar* with length 128.

**Output Parameters**

*bilu0* Array *B* containing non-zero elements of the resulting preconditioning matrix *B*, stored in the format accepted in direct sparse solvers. Its size is equal to the number of non-zero elements in the matrix *A*. Refer to the *values* array description in the [Sparse Matrix Storage Format](#) section for more details.

*ierr* Error flag, gives information about the routine completion.

**NOTE**

To present the resulting preconditioning matrix in the CSR3 format the arrays *ia* (row indices) and *ja* (column indices) of the input matrix must be used.

**Return Values**

*ierr*=0 Indicates that the task completed normally.

*ierr*=-101 Indicates that the routine was interrupted and that error occurred: at least one diagonal element is omitted from the matrix in CSR3 format (see [Sparse Matrix Storage Format](#)).

*ierr*=-102 Indicates that the routine was interrupted because the matrix contains a diagonal element with the value of zero.

*ierr*=-103 Indicates that the routine was interrupted because the matrix contains a diagonal element which is so small that it could cause an overflow, or that it would cause a bad approximation to ILU0.

*ierr*=-104 Indicates that the routine was interrupted because the memory is insufficient for the internal work array.

`ierr=-105`

Indicates that the routine was interrupted because the input matrix size  $n$  is less than or equal to 0.

`ierr=-106`

Indicates that the routine was interrupted because the column indices  $ja$  are not in the ascending order.

## dcsrilut

*ILUT preconditioner based on the incomplete LU factorization with a threshold of a sparse matrix.*

### Syntax

```
void dcsrilit (const MKL_INT *n, const double *a, const MKL_INT *ia, const MKL_INT *ja,
double *bilut, MKL_INT *ibilut, MKL_INT *jbilut, const double *tol, const MKL_INT
*maxfil, const MKL_INT *ipar, const double *dpar, MKL_INT *ierr);
```

### Include Files

- mkl.h

### Description

The routine `dcscrilit` computes a preconditioner  $B$  [Saad03] of a given sparse matrix  $A$  stored in the format accepted in the direct sparse solvers:

$A \sim B = L * U$ , where  $L$  is a lower triangular matrix with unit diagonal and  $U$  is an upper triangular matrix with non-unit diagonal.

The following threshold criteria are used to generate the incomplete factors  $L$  and  $U$ :

- 1) the resulting entry must be greater than the matrix current row norm multiplied by the parameter `tol`, and
- 2) the number of the non-zero elements in each row of the resulting  $L$  and  $U$  factors must not be greater than the value of the parameter `maxfil`.

---

### Caution

This routine supports only one-based indexing of the array parameters.

---

### Input Parameters

<code>n</code>	Size (number of rows or columns) of the original square $n$ -by- $n$ matrix $A$ .
<code>a</code>	Array containing all non-zero elements of the matrix $A$ . The length of the array is equal to their number. Refer to <code>values</code> array description in the <a href="#">Sparse Matrix Storage Format</a> section for more details.
<code>ia</code>	Array of size $(n+1)$ containing indices of non-zero elements in the array $a$ . <code>ia[i]</code> is the index of the first non-zero element from the row $i$ . The value of the last element <code>ia[n]</code> is equal to the number of non-zeros in the matrix $A$ , plus one. Refer to the <code>rowIndex</code> array description in the <a href="#">Sparse Matrix Storage Format</a> for more details.

*ja* Array of size equal to the size of the array *a*. This array contains the column numbers for each non-zero element of the matrix *A*. It is important that the indices are in increasing order per row. Refer to the *columns* array description in the [Sparse Matrix Storage Format](#) for more details.

---

**Caution**

If column indices are not stored in ascending order for each row of matrix, the result of the routine might not be correct.

---

*tol* Tolerance for threshold criterion for the resulting entries of the preconditioner.

*maxfil* Maximum fill-in, which is half of the preconditioner bandwidth. The number of non-zero elements in the rows of the preconditioner cannot exceed  $(2 * \text{maxfil} + 1)$ .

*ipar* Array of size 128. This parameter is used to specify the integer set of data for both the ILUT and RCI FGMRES computations. Refer to the *ipar* array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries specific to ILUT are listed below.

*ipar*[30] specifies how the routine operates if the value of the computed diagonal element is less than the current matrix row norm multiplied by the value of the parameter *tol*. If *ipar*[30] = 0, then the calculation is stopped and the routine returns non-zero error value. Otherwise, the value of the diagonal element is set to a value determined by *dpar*[30] (see its description below), and the calculations continue.

---

**NOTE**

There is no default value for *ipar*[30] even if the preconditioner is used within the RCI ISS context. Always set the value of this entry.

---

---

**NOTE**

You must declare the array *ipar* with length 128. While defining the array in the code as *ipar*[30] works, there is no guarantee of future compatibility with Intel® oneAPI Math Kernel Library (oneMKL).

---

*dpar* Array of size 128. This parameter specifies the double precision set of data for both ILUT and RCI FGMRES computations. Refer to the *dpar* array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries that are specific to ILUT are listed below.

`dpar[30]`

used to adjust the value of small diagonal elements. Diagonal elements with a value less than the current matrix row norm multiplied by `tol` are replaced with the value of `dpar[30]` multiplied by the matrix row norm.

**NOTE**

There is no default value for `dpar[30]` entry even if the preconditioner is used within RCI ISS context. Always set the value of this entry.

**NOTE**

You must declare the array `dpar` with length 128. While defining the array in the code as `ipar[30]` works, there is no guarantee of future compatibility with Intel® oneAPI Math Kernel Library (oneMKL).

**Output Parameters**`bilut`

Array containing non-zero elements of the resulting preconditioning matrix  $B$ , stored in the format accepted in the direct sparse solvers. Refer to the `values` array description in the [Sparse Matrix Storage Format](#) for more details. The size of the array is equal to  $(2 * \text{maxfil} + 1) * n - \text{maxfil} * (\text{maxfil} + 1) + 1$ .

**NOTE**

Provide enough memory for this array before calling the routine. Otherwise, the routine may fail to complete successfully with a correct result.

`ibilut`

Array of size  $(n+1)$  containing indices of non-zero elements in the array `bilut`. `ibilut[i]` is the index of the first non-zero element from the row  $i$ . The value of the last element `ibilut[n]` is equal to the number of non-zeros in the matrix  $B$ , plus one. Refer to the `rowIndex` array description in the [Sparse Matrix Storage Format](#) for more details.

`jbilut`

Array, its size is equal to the size of the array `bilut`. This array contains the column numbers for each non-zero element of the matrix  $B$ . Refer to the `columns` array description in the [Sparse Matrix Storage Format](#) for more details.

`ierr`

Error flag, gives information about the routine completion.

**Return Values**`ierr=0`

Indicates that the task completed normally.

<code>ierr=-101</code>	Indicates that the routine was interrupted because of an error: the number of elements in some matrix row specified in the sparse format is equal to or less than 0.
<code>ierr=-102</code>	Indicates that the routine was interrupted because the value of the computed diagonal element is less than the product of the given tolerance and the current matrix row norm, and it cannot be replaced as <code>ipar[30]=0</code> .
<code>ierr=-103</code>	Indicates that the routine was interrupted because the element <code>ia[i]</code> is less than or equal to the element <code>ia[i - 1]</code> (see <a href="#">Sparse Matrix Storage Format</a> ).
<code>ierr=-104</code>	Indicates that the routine was interrupted because the memory is insufficient for the internal work arrays.
<code>ierr=-105</code>	Indicates that the routine was interrupted because the input value of <code>maxfil</code> is less than 0.
<code>ierr=-106</code>	Indicates that the routine was interrupted because the size <code>n</code> of the input matrix is less than 0.
<code>ierr=-107</code>	Indicates that the routine was interrupted because an element of the array <code>ja</code> is less than 1, or greater than <code>n</code> (see <a href="#">Sparse Matrix Storage Format</a> ).
<code>ierr=101</code>	The value of <code>maxfil</code> is greater than or equal to <code>n</code> . The calculation is performed with the value of <code>maxfil</code> set to <code>(n-1)</code> .
<code>ierr=102</code>	The value of <code>tol</code> is less than 0. The calculation is performed with the value of the parameter set to <code>(-tol)</code> .
<code>ierr=103</code>	The absolute value of <code>tol</code> is greater than value of <code>dpar[30]</code> ; it can result in instability of the calculation.
<code>ierr=104</code>	The value of <code>dpar[30]</code> is equal to 0. It can cause calculations to fail.

## Sparse Matrix Checker Routines

Intel® oneAPI Math Kernel Library (oneMKL) provides a sparse matrix checker so that you can find errors in the storage of sparse matrices before calling Intel® oneAPI Math Kernel Library (oneMKL) PARDISO, DSS, or Sparse BLAS routines.

### `sparse_matrix_checker`

*Checks the correctness of a sparse matrix.*

#### Syntax

```
MKL_INT sparse_matrix_checker (sparse_struct* handle);
```

#### Include Files

- `mkl.h`

## Description

The `sparse_matrix_checker` routine checks a user-defined array used to store a sparse matrix in order to detect issues which could cause problems in routines that require sparse input matrices, such as Intel® oneAPI Math Kernel Library (oneMKL) PARDISO, DSS, or Sparse BLAS.

## Input Parameters

`handle` Pointer to the data structure describing the sparse array to check.

## Return Values

The routine returns a value `error`. Additionally, the `check_result` parameter returns information about where the error occurred, which can be used when `message_level` is `MKL_NO_PRINT`.

## Sparse Matrix Checker Error Values

<i>error</i> value	Meaning	Location
<code>MKL_SPARSE_CHECKER_SUCCESS</code>	The input array successfully passed all checks.	
<code>MKL_SPARSE_CHECKER_NON_MONOTONIC</code>	The input array is not 0 or 1 based ( <code>ia[0]</code> is not 0 or 1) or elements of <code>ia</code> are not in non-decreasing order as required.	<b>C:</b> <code>ia[i]</code> and <code>ia[i + 1]</code> are incompatible. <code>check_result[0] = i</code> <code>check_result[1] = ia[i]</code> <code>check_result[2] = ia[i + 1]</code>
<code>MKL_SPARSE_CHECKER_OUT_OF_RANGE</code>	The value of the <code>ja</code> array is lower than the number of the first column or greater than the number of the last column.	<b>C:</b> <code>ia[i]</code> and <code>ia[i + 1]</code> are incompatible. <code>check_result[0] = i</code> <code>check_result[1] = ia[i]</code> <code>check_result[2] = ia[i + 1]</code>
<code>MKL_SPARSE_CHECKER_NON_TRIANGULAR</code>	The <code>matrix_structure</code> parameter is <code>MKL_UPPER_TRIANGULAR</code> and both <code>ia</code> and <code>ja</code> are not upper triangular, or the <code>matrix_structure</code> parameter is <code>MKL_LOWER_TRIANGULAR</code> and both <code>ia</code> and <code>ja</code> are not lower triangular	<b>C:</b> <code>ia[i]</code> and <code>ja[j]</code> are incompatible. <code>check_result[0] = i</code> <code>check_result[1] = ia[i] = j</code> <code>check_result[2] = ja[j]</code>
<code>MKL_SPARSE_CHECKER_NON_ORDERED</code>	The elements of the <code>ja</code> array are not in non-decreasing order in each row as required.	<b>C:</b> <code>ia[i]</code> and <code>ia[i + 1]</code> are incompatible. <code>check_result[0] = j</code> <code>check_result[1] = ja[j]</code> <code>check_result[2] = ja[j + 1]</code>

## sparse\_matrix\_checker\_init

*Initializes handle for sparse matrix checker.*

## Syntax

```
void sparse_matrix_checker_init (sparse_struct* handle);
```

## Include Files

- mkl.h

## Description

The `sparse_matrix_checker_init` routine initializes the handle for the `sparse_matrix_checker` routine. The `handle` variable contains this data:

### Description of `sparse_matrix_checker` *handle* Data

Field	Type	Possible Values	Meaning
<code>n</code>	<code>MKL_INT</code>		Order of the matrix stored in sparse array.
<code>csr_ia</code>	<code>MKL_INT*</code>	Pointer to <code>ia</code> array for <code>matrix_format = MKL_CSR</code>	
<code>csr_ja</code>	<code>MKL_INT*</code>	Pointer to <code>ja</code> array for <code>matrix_format = MKL_CSR</code>	
<code>check_result[3]</code>	<code>MKL_INT</code>	See <a href="#">Sparse Matrix Checker Error Values</a> for a description of the values returned in <code>check_result</code> .	Indicates location of problem in array when <code>message_level = MKL_NO_PRINT</code> .
<code>indexing</code>	<code>sparse_matrix_indexing</code>	<code>MKL_ZERO_BASED</code> <code>MKL_ONE_BASED</code>	Indexing style used in array.
<code>matrix_structure</code>	<code>sparse_matrix_structures</code>	<code>MKL_GENERAL_STRUCTURE</code> <code>MKL_UPPER_TRIANGULAR</code> <code>MKL_LOWER_TRIANGULAR</code> <code>MKL_STRUCTURAL_SYMMETRIC</code>	Type of sparse matrix stored in array.

Field	Type	Possible Values	Meaning
matrix_format	sparse_matrix_formats	MKL_CSR	Format of array used for sparse matrix storage.
message_level	sparse_matrix_message_levels	MKL_NO_PRINT MKL_PRINT	Determines whether or not feedback is provided on the screen.
print_style	sparse_matrix_print_styles	MKL_C_STYLE MKL_FORTRAN_STYLE	Determines style of messages when message_level = MKL_PRINT.

## Input Parameters

*handle* Pointer to the data structure describing the sparse array to check.

## Output Parameters

*handle* Pointer to the initialized data structure.

## Extended Eigensolver Routines

### NOTE

Intel® oneAPI Math Kernel Library (oneMKL) only supports the shared memory programming (SMP) version of the eigenvalue solver.

- [The FEAST Algorithm](#) gives a brief description of the algorithm underlying the Extended Eigensolver.
- [Extended Eigensolver Functionality](#) describes the problems that can and cannot be solved with the Extended Eigensolver and how to get the best results from the routines.
- [Extended Eigensolver Interfaces](#) gives a reference for calling Extended Eigensolver routines.
- 

## The FEAST Algorithm

The Extended Eigensolver functionality is a set of high-performance numerical routines for solving symmetric standard eigenvalue problems,  $Ax=\lambda x$ , or generalized symmetric-definite eigenvalue problems,  $Ax=\lambda Bx$ . It yields all the eigenvalues ( $\lambda$ ) and eigenvectors ( $x$ ) within a given search interval  $[\lambda_{\min}, \lambda_{\max}]$ . It is based on the FEAST algorithm, an innovative fast and stable numerical algorithm presented in [Polizzi09], which fundamentally differs from the traditional Krylov subspace iteration based techniques (Arnoldi and Lanczos algorithms [Bai00]) or other Davidson-Jacobi techniques [Sleijpen96]. The FEAST algorithm is inspired by the density-matrix representation and contour integration techniques in quantum mechanics.

The FEAST numerical algorithm obtains eigenpair solutions using a numerically efficient contour integration technique. The main computational tasks in the FEAST algorithm consist of solving a few independent linear systems along the contour and solving a reduced eigenvalue problem. Consider a circle centered in the

middle of the search interval  $[\lambda_{\min}, \lambda_{\max}]$ . The numerical integration over the circle in the current version of FEAST is performed using  $N_e$ -point Gauss-Legendre quadrature with  $x_e$  the  $e$ -th Gauss node associated with the weight  $\omega_e$ . For example, for the case  $N_e = 8$ :

$(x_1, \omega_1) = (0.183434642495649, 0.362683783378361),$   
 $(x_2, \omega_2) = (-0.183434642495649, 0.362683783378361),$   
 $(x_3, \omega_3) = (0.525532409916328, 0.313706645877887),$   
 $(x_4, \omega_4) = (-0.525532409916328, 0.313706645877887),$   
 $(x_5, \omega_5) = (0.796666477413626, 0.222381034453374),$   
 $(x_6, \omega_6) = (-0.796666477413626, 0.222381034453374),$   
 $(x_7, \omega_7) = (0.960289856497536, 0.101228536290376),$  and  
 $(x_8, \omega_8) = (-0.960289856497536, 0.101228536290376).$

The figure [FEAST Pseudocode](#) shows the basic pseudocode for the FEAST algorithm for the case of real symmetric (left pane) and complex Hermitian (right pane) generalized eigenvalue problems, using  $N$  for the size of the system and  $M$  for the number of eigenvalues in the search interval (see [\[Polizzi09\]](#)).

---

#### NOTE

The pseudocode presents a simplified version of the actual algorithm. Refer to <http://arxiv.org/abs/1302.0432> for an in-depth presentation and mathematical proof of convergence of FEAST.

---

#### FEAST Pseudocode

$A$ : real symmetric

$B$ : symmetric positive definite (SPD)

$\Re\{x\}$ : real part of  $x$

$A$ : complex Hermitian

$B$ : Hermitian positive definite (HPD)

### Extended Eigensolver Functionality

The eigenvalue problems covered are as follows:

- standard,  $Ax = \lambda x$ 
  - $A$  complex Hermitian
  - $A$  real symmetric
- generalized,  $Ax = \lambda Bx$ 
  - $A$  complex Hermitian,  $B$  Hermitian positive definite (hpd)
  - $A$  real symmetric and  $B$  real symmetric positive definite (spd)

The Extended Eigensolver functionality offers:

- Real/Complex and Single/Double precisions: double precision is recommended to provide better accuracy of eigenpairs.
- Reverse communication interfaces (RCI) provide maximum flexibility for specific applications. RCI are independent of matrix format and inner system solvers, so you must provide your own linear system solvers (direct or iterative) and matrix-matrix multiply routines.
- Predefined driver interfaces for dense, LAPACK banded, and sparse (CSR) formats are less flexible but are optimized and easy to use:
  - The Extended Eigensolver interfaces for dense matrices are likely to be slower than the comparable LAPACK routines because the FEAST algorithm has a higher computational cost.
  - The Extended Eigensolver interfaces for banded matrices support banded LAPACK-type storage.
  - The Extended Eigensolver sparse interfaces support compressed sparse row format and use the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver.

Notice revision #20201201

### Parallelism in Extended Eigensolver Routines

How you achieve parallelism in Extended Eigensolver routines depends on which interface you use. Parallelism (via shared memory programming) is not *explicitly* implemented in Extended Eigensolver routines within one node: the inner linear systems are currently solved one after another.

- Using the Extended Eigensolver RCI interfaces, you can achieve parallelism by providing a threaded inner system solver and a matrix-matrix multiplication routine. When using the RCI interfaces, you are responsible for activating the threaded capabilities of your BLAS and LAPACK libraries most likely using the shell variable `OMP_NUM_THREADS`.
- Using the predefined Extended Eigensolver interfaces, parallelism can be implicitly obtained within the shared memory version of BLAS, LAPACK or Intel® oneAPI Math Kernel Library (oneMKL) PARDISO. The shell variable `MKL_NUM_THREADS` can be used for automatically setting the number of OpenMP threads (cores) for BLAS, LAPACK, and Intel® oneAPI Math Kernel Library (oneMKL) PARDISO.

Notice revision #20201201

### Achieving Performance With Extended Eigensolver Routines

In order to use the Extended Eigensolver Routines, you need to provide

- the search interval and the size of the subspace  $M_0$  (overestimation of the number of eigenvalues  $M$  within a given search interval);
- the system matrix in dense, banded, or sparse CSR format if the Extended Eigensolver predefined interfaces are used, or a high-performance complex direct or iterative system solver and matrix-vector multiplication routine if RCI interfaces are used.

In return, you can expect

- fast convergence with very high accuracy when seeking up to 1000 eigenpairs (in two to four iterations using  $M_0 = 1.5M$ , and  $N_e = 8$  or at most using  $N_e = 16$  contour points);
- an extremely robust approach.

The performance of the basic FEAST algorithm depends on a trade-off between the choices of the number of Gauss quadrature points  $N_e$ , the size of the subspace  $M_0$ , and the number of outer refinement loops to reach the desired accuracy. In practice you should use  $M_0 > 1.5 M$ ,  $N_e = 8$ , and at most two refinement loops.

For better performance:

- $M_0$  should be much smaller than the size of the eigenvalue problem, so that the arithmetic complexity depends mainly on the inner system solver ( $O(NM)$  for narrow-banded or sparse systems).
- Parallel scalability performance depends on the shared memory capabilities of the of the inner system solver.
- For very large sparse and challenging systems, application users should make use of the Extended Eigensolver RCI interfaces with customized highly-efficient iterative systems solvers and preconditioners.
- For the Extended Eigensolver interfaces for banded matrices, the parallel performance scalability is limited.

Notice revision #20201201

## Extended Eigensolver Interfaces for Eigenvalues within Interval

### Extended Eigensolver Naming Conventions

There are two different types of interfaces available in the Extended Eigensolver routines:

1. The reverse communication interfaces (RCI):

`?feast_<matrix type>_rci`

These interfaces are matrix free format (the interfaces are independent of the matrix data formats). You must provide matrix-vector multiply and direct/iterative linear system solvers for your own explicit or implicit data format.

2. The predefined interfaces:

`?feast_<matrix type><type of eigenvalue problem>`

are predefined drivers for `?feast` reverse communication interface that act on commonly used matrix data storage (dense, banded and compressed sparse row representation), using internal matrix-vector routines and selected inner linear system solvers.

For these interfaces:

- ? indicates the data type of matrix *A* (and matrix *B* if any) defined as follows:

s	float
d	double
c	MKL_Complex8
z	MKL_Complex16

- `<matrix type>` defined as follows:

Value of <code>&lt;matrix type&gt;</code>	Matrix format	Inner linear system solver used by Extended Eigensolver
sy (symmetric real)		
he (Hermitian complex)	Dense	LAPACK dense solvers
sb (symmetric banded real)	Banded-LAPACK	Internal banded solver

Value of <i>&lt;matrix type&gt;</i>	Matrix format	Inner linear system solver used by Extended Eigensolver
hb	(Hermitian banded complex)	
scsr	(symmetric real)	
hcsr	(Hermitian complex)	Compressed sparse row PARDISO solver
s	(symmetric real)	
h	(Hermitian complex)	Reverse communications interfaces User defined

- <type of eigenvalue problem>* is:

gv	generalized eigenvalue problem
ev	standard eigenvalue problem

For example, `sfeast_scsrev` is a single-precision routine with a symmetric real matrix stored in sparse compressed-row format for a standard eigenvalue problem, and `zfeast_hrci` is a complex double-precision routine with a Hermitian matrix using the reverse communication interface.

Note that:

- ? can be `s` or `d` if a matrix is real symmetric: *<matrix type>* is `sy`, `sb`, or `scsr`.
- ? can be `c` or `z` if a matrix is complex Hermitian: *<matrix type>* is `he`, `hb`, or `hcsr`.
- ? can be `c` or `z` if the Extended Eigensolver RCI interface is used for solving a complex Hermitian problem.
- ? can be `s` or `d` if the Extended Eigensolver RCI interface is used for solving a real symmetric problem.

## feastinit

Initialize Extended Eigensolver input parameters with default values.

### Syntax

```
feastinit (MKL_INT* fpm);
```

### Include Files

- `mk1.h`

### Description

This routine sets all Extended Eigensolver parameters to their default values.

### Output Parameters

*fpm* Array, size 128. This array is used to pass various parameters to Extended Eigensolver routines. See [Extended Eigensolver Input Parameters](#) for a complete description of the parameters and their default values.

## Extended Eigensolver Input Parameters

The input parameters for Extended Eigensolver routines are contained in an `MKL_INT` array named *fpm*. To call the Extended Eigensolver interfaces, this array should be initialized using the routine `feastinit`.

Parameter	Default	Description
$fpm[0]$	0	Specifies whether Extended Eigensolver routines print runtime status.  $fpm[0]=0$ Extended Eigensolver routines do not generate runtime messages at all.  $fpm[0]=1$ Extended Eigensolver routines print runtime status to the screen.
$fpm[1]$	8	The number of contour points $N_e = 8$ (see the description of FEAST algorithm). Must be one of $\{3,4,5,6,8,10,12,16,20,24,32,40,48\}$ .
$fpm[2]$	12	Error trace double precision stopping criteria $\varepsilon$ ( $\varepsilon = 10^{-fpm[2]}$ ).
$fpm[3]$	20	Maximum number of Extended Eigensolver refinement loops allowed. If no convergence is reached within $fpm[3]$ refinement loops, Extended Eigensolver routines return $info=2$ .
$fpm[4]$	0	User initial subspace. If $fpm[4]=0$ then Extended Eigensolver routines generate initial subspace, if $fpm[4]=1$ the user supplied initial subspace is used.
$fpm[5]$	0	Extended Eigensolver stopping test.  $fpm[5]=0$ Extended Eigensolvers are stopped if this residual stopping test is satisfied: <ul style="list-style-type: none"> <li>generalized eigenvalue problem: <math display="block">\max_{i=1:mode} \frac{\ Ax_i - \lambda_i Bx_i\ _1}{\max( E_{\min} ,  E_{\max} ) \ Bx_i\ _1} &lt; \varepsilon</math> </li> <li>standard eigenvalue problem: <math display="block">\max_{i=1:mode} \frac{\ Ax_i - \lambda_i x_i\ _1}{\max( E_{\min} ,  E_{\max} ) \ x_i\ _1} &lt; \varepsilon</math> </li> </ul> where $mode$ is the total number of eigenvalues found in the search interval and $\varepsilon = 10^{-fpm[6]}$ for real and complex or $\varepsilon = 10^{-fpm[2]}$ for double precision and double complex.
	$fpm[5]=1$	Extended Eigensolvers are stopped if this trace stopping test is satisfied: $\frac{ trace_j - trace_{j-1} }{\max( E_{\min} ,  E_{\max} )} < \varepsilon$ where $trace_j$ denotes the sum of all eigenvalues found in the search interval $[emin, emax]$ at the $j$ -th Extended Eigensolver iteration: $trace_j = \sum_{i=1}^M \lambda_i^{(j)}$
$fpm[6]$	5	Error trace single precision stopping criteria ( $10^{-fpm[6]}$ ).
$fpm[13]$	0	$fpm[13]=0$ Standard use for Extended Eigensolver routines.

Parameter	Default	Description
		$fpm[13] = 1$ Non-standard use for Extended Eigensolver routines: return the computed eigenvectors subspace after one single contour integration.
$fpm[26]$	0	Specifies whether Extended Eigensolver routines check input matrices (applies to CSR format only). $fpm[26] = 0$ Extended Eigensolver routines do not check input matrices. $fpm[26] = 1$ Extended Eigensolver routines check input matrices.
$fpm[27]$	0	Check if matrix $B$ is positive definite. Set $fpm[27] = 1$ to check if $B$ is positive definite.
$fpm[29]$ to $fpm[62]$	-	Reserved for future use.
$fpm[63]$	0	Use the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO solver with the user-defined PARDISO $iparm$ array settings.
<b>NOTE</b> This option can only be used by Extended Eigensolver Predefined Interfaces for Sparse Matrices.		
		$fpm[63] = 0$ Extended Eigensolver routines use the Intel® oneAPI Math Kernel Library (oneMKL) PARDISO default $iparm$ settings defined by calling the <code>pardisoinit</code> subroutine.
		$fpm[63] = 1$ The values from $fpm[64]$ to $fpm[127]$ correspond to $iparm[0]$ to $iparm[63]$ respectively according to the formula $fpm[64 + i] = iparm[i]$ for $i = 0, 1, \dots, 63$ .

## Extended Eigensolver Output Details

Errors and warnings encountered during a run of the Extended Eigensolver routines are stored in an integer variable, `info`. If the value of the output `info` parameter is not 0, either an error or warning was encountered. The possible return values for the `info` parameter along with the error code descriptions are given in the following table.

### Return Codes for info Parameter

<code>info</code>	Classification	Description
202	Error	Problem with size of the system $n$ ( $n \leq 0$ )
201	Error	Problem with size of initial subspace $m0$ ( $m0 \leq 0$ or $m0 > n$ )
200	Error	Problem with $emin, emax$ ( $emin \geq emax$ )
(100+i)	Error	Problem with $i$ -th value of the input Extended Eigensolver parameter ( $fpm[i - 1]$ ). Only the parameters in use are checked.
4	Warning	Successful return of only the computed subspace after call with $fpm[13] = 1$

<i>info</i>	Classification	Description
3	Warning	Size of the subspace $m0$ is too small ( $m0 < m$ )
2	Warning	No Convergence (number of iteration loops $> fpm[3]$ )
1	Warning	No eigenvalue found in the search interval. See remark below for further details.
0	Successful exit	
-1	Error	Internal error for allocation memory.
-2	Error	Internal error of the inner system solver. Possible reasons: not enough memory for inner linear system solver or inconsistent input.
-3	Error	Internal error of the reduced eigenvalue solver Possible cause: matrix $B$ may not be positive definite. It can be checked by setting $fpm[27] = 1$ before calling an Extended Eigensolver routine, or by using LAPACK routines.
-4	Error	Matrix $B$ is not positive definite.
-(100+i)	Error	Problem with the $i$ -th argument of the Extended Eigensolver interface.

In some extreme cases the return value  $info=1$  may indicate that the Extended Eigensolver routine has failed to find the eigenvalues in the search interval. This situation could arise if a very large search interval is used to locate a small and isolated cluster of eigenvalues (i.e. the dimension of the search interval is many orders of magnitude larger than the number of contour points. It is then either recommended to increase the number of contour points  $fpm[1]$  or simply rescale more appropriately the search interval. Rescaling means the initial problem of finding all eigenvalues the search interval  $[\lambda_{min}, \lambda_{max}]$  for the standard eigenvalue problem  $Ax = \lambda x$  is replaced with the problem of finding all eigenvalues in the search interval  $[\lambda_{min}/t, \lambda_{max}/t]$  for the standard eigenvalue problem  $(A/t)x = (\lambda/t)x$  where  $t$  is a scaling factor.

## Extended Eigensolver RCI Routines

If you do not require specific linear system solvers or matrix storage schemes, you can skip this section and go directly to [Extended Eigensolver Predefined Interfaces](#).

### Extended Eigensolver RCI Interface Description

The Extended Eigensolver RCI interfaces can be used to solve standard or generalized eigenvalue problems, and are independent of the format of the matrices. As mentioned earlier, the Extended Eigensolver algorithm is based on the contour integration techniques of the matrix resolvent  $G(\sigma) = (\sigma B - A)^{-1}$  over a circle. For solving a generalized eigenvalue problem, Extended Eigensolver has to perform one or more of the following operations at each contour point denoted below by  $Z_e$ :

- Factorize the matrix  $(Z_e * B - A)$
- Solve the linear system  $(Z_e * B - A)X = Y$  or  $(Z_e * B - A)^H X = Y$  with multiple right hand sides, where  $H$  means transpose conjugate
- Matrix-matrix multiply  $BX = Y$  or  $AX = Y$

For solving a standard eigenvalue problem, replace the matrix  $B$  with the identity matrix  $I$ .

The primary aim of RCI interfaces is to isolate these operations: the linear system solver, factorization of the matrix resolvent at each contour point, and matrix-matrix multiplication. This gives universality to RCI interfaces as they are independent of data structures and the specific implementation of the operations like matrix-vector multiplication or inner system solvers. However, this approach requires some additional effort when calling the interface. In particular, operations listed above are performed by routines that you supply on data structures that you find most appropriate for the problem at hand.

To initialize an Extended Eigensolver RCI routine, set the job indicator (*ijob*) parameter to the value -1. When the routine requires the results of an operation, it generates a special value of *ijob* to indicate the operation that needs to be performed. The routine also returns *ze*, the coordinate along the complex contour, the values of array *work* or *workc*, and the number of columns to be used. Your subroutine then must perform the operation at the given contour point *ze*, store the results in prescribed array, and return control to the Extended Eigensolver RCI routine.

The following pseudocode shows the general scheme for using the Extended Eigensolver RCI functionality for a real symmetric problem:

```

ijob=-1; // initialization
do while (ijob!=0) {
    ?feast_src1(&ijob, &N, &Ze, work, workc, Aq, Bq,
               fpm, &epsout, &loop, &Emin, &Emax, &M0, E, lambda, &q, res, &info);

    switch(ijob) {
    case 10: // Factorize the complex matrix (ZeB-A)
        break;

    case 11: // Solve the complex linear system (ZeB-A)x=workc
        // Put result in workc
        break;

    case 30: // Perform multiplication A by Qi..Qj columns of QNxM0
        // where i = fpm[23] and j = fpm[23]+fpm[24]-1
        // Qi..Qj located in q starting from q+N*(i-1)
        break;

    case 40: // Perform multiplication B by Qi..Qj columns of QNxM0
        // where i = fpm[23] and j = fpm[23]+fpm[24]-1
        // Qi..Qj located in q starting from q+N*(i-1)
        // Result is stored in work+N*(i-1)

        break;

    }
}

```

---

#### NOTE

The ? option in ?feast in the pseudocode given above should be replaced by either s or d, depending on the matrix data type of the eigenvalue system.

---

The next pseudocode shows the general scheme for using the Extended Eigensolver RCI functionality for a complex Hermitian problem:

```

ijob=-1; // initialization
while (ijob!=0) {
    ?feast_hrc1(&ijob, &N, &Ze, work, workc, Aq, Bq,
               fpm, &epsout, &loop, &Emin, &Emax, &M0, E, lambda, &q, res, &info);

    switch (ijob) {
    case 10: // Factorize the complex matrix (ZeB-A)
        break;

    case 11: // Solve the linear system (ZeB-A)y=workc
        // Put result in workc
        break;

    case 20: // Factorize (if needed by case 21) the complex matrix (ZeB-A)H

```

```

        // ATTENTION: This option requires additional memory storage
        // (i.e . the resulting matrix from case 10 cannot be overwritten)
break;

case 21: // Solve the linear system (ZeB-A)^Hy=workc
        // Put result in workc
        // REMARK: case 20 becomes obsolete if this solve can be performed
        // using the factorization in case 10
break;

case 30: // Multiply A by Q_i..Q_j columns of Q_{Nxm0},
        // where i = fpm[23] and j = fpm[23]+fpm[24]-1
        // Q_i..Q_j located in q starting from q+N*(i-1)
        // Result is stored in work+N*(i-1)
break;

case 40: // Perform multiplication B by Q_i..Q_j columns of Q_{Nxm0}
        // where i = fpm[23] and j = fpm[23]+fpm[24]-1
        // Q_i..Q_j located in q starting from q+N*(i-1)
        // Result is stored in work+N*(i-1)
break;

    }
}
end do

```

**NOTE**

The `?feast` option in the pseudocode given above should be replaced by either `c` or `z`, depending on the matrix data type of the eigenvalue system.

If case 20 can be avoided, performance could be up to twice as fast, and Extended Eigensolver functionality would use half of the memory.

If an iterative solver is used along with a preconditioner, the factorization of the preconditioner could be performed with `ijob = 10` (and `ijob = 20` if applicable) for a given value of  $Z_e$ , and the associated iterative solve would then be performed with `ijob = 11` (and `ijob = 21` if applicable).

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

## Include Files

- mkl.h

## Description

Compute eigenvalues as described in [Extended Eigensolver RCI Interface Description](#).

## Input Parameters

<i>ijob</i>	Job indicator variable. On entry, a call to <code>?feast_src1/?feast_hrc1</code> with <i>ijob</i> =-1 initializes the eigensolver.
<i>n</i>	Sets the size of the problem. $n > 0$ .
<i>work</i>	Workspace array of size $n$ by $m0$ .
<i>workc</i>	Workspace array of size $n$ by $m0$ .
<i>aq, sq</i>	Workspace arrays of size $m0$ by $m0$ .
<i>fpm</i>	Array, size of 128. This array is used to pass various parameters to Extended Eigensolver routines. See <a href="#">Extended Eigensolver Input Parameters</a> for a complete description of the parameters and their default values.
<i>emin, emax</i>	The lower and upper bounds of the interval to be searched for eigenvalues; $emin \leq emax$ .

---

**NOTE** Users are advised to avoid situations in which eigenvalues nearly coincide with the interval endpoints. This may lead to unpredictable selection or omission of such eigenvalues. Users should instead specify a slightly larger interval than needed and, if required, pick valid eigenvalues and their corresponding eigenvectors for subsequent use.

---

<i>m0</i>	On entry, specifies the initial guess for subspace size to be used, $0 < m0 \leq n$ . Set $m0 \geq m$ where $m$ is the total number of eigenvalues located in the interval $[emin, emax]$ . If the initial guess is wrong, Extended Eigensolver routines return <i>info</i> =3.
<i>q</i>	On entry, if <i>fpm</i> [4]=1, the array <i>q</i> of size $n$ by $m$ contains a basis of guess subspace where $n$ is the order of the input matrix.

## Output Parameters

*ijob*

On exit, the parameter carries the status flag that indicates the condition of the return. The status information is divided into three categories:

1. A zero value indicates successful completion of the task.
2. A positive value indicates that the solver requires a matrix-vector multiplication or solving a specific system with a complex coefficient.
3. A negative value indicates successful initiation.

A non-zero value of *ijob* specifically means the following:

- *ijob* = 10 - factorize the complex matrix  $Z_e * B - A$  at a given contour point  $Z_e$  and return the control to the `?feast_src`/`?feast_hrci` routine where  $Z_e$  is a complex number meaning contour point and its value is defined internally in `?feast_src`/`?feast_hrci`.
- *ijob* = 11 - solve the complex linear system  $(Z_e * B - A) * y = workc$ , put the solution in `workc` and return the control to the `?feast_src`/`?feast_hrci` routine.
- *ijob* = 20 - factorize the complex matrix  $(Z_e * B - A)^H$  at a given contour point  $Z_e$  and return the control to the `?feast_src`/`?feast_hrci` routine where  $Z_e$  is a complex number meaning contour point and its value is defined internally in `?feast_src`/`?feast_hrci`.

The symbol  $X^H$  means transpose conjugate of matrix  $X$ .

- *ijob* = 21 - solve the complex linear system  $(Z_e * B - A)^H * y = workc$ , put the solution in `workc` and return the control to the `?feast_src`/`?feast_hrci` routine. The case *ijob*=20 becomes obsolete if the solve can be performed using the factorization computed for *ijob*=10.

The symbol  $X^H$  mean transpose conjugate of matrix  $X$ .

- *ijob* = 30 - multiply matrix  $A$  by  $Q_j \cdot Q_i$ , put the result in `work + N*(i - 1)`, and return the control to the `?feast_src`/`?feast_hrci` routine.  
*i* is `fpm[24]`, and *j* is `fpm[23] + fpm[24] - 1`.
- *ijob* = 40 - multiply matrix  $B$  by  $Q_j \cdot Q_i$ , put the result in `work + N*(i - 1)` and return the control to the `?feast_src`/`?feast_hrci` routine. If a standard eigenvalue problem is solved, just return `work = q`.  
*i* is `fpm[24]`, and *j* is `fpm[23] + fpm[24] - 1`.
- *ijob* = -2 - rerun the `?feast_src`/`?feast_hrci` task with the same parameters.

*ze*

Defines the coordinate along the complex contour. All values of *ze* are generated by `?feast_src`/`?feast_hrci` internally.

*fpm*

On output, contains coordinates of columns of work array needed for iterative refinement. (See [Extended Eigensolver RCI Interface Description](#).)

*epsout*

On output, contains the relative error on the trace:  $|trace_i - trace_{i-1}| / \max(|emin|, |emax|)$

*loop*

On output, contains the number of refinement loop executed. Ignored on input.

*lambda*

Array of length *m0*. On output, the first *m* entries of *lambda* are eigenvalues found in the interval.

<i>q</i>	On output, <i>q</i> contains all eigenvectors corresponding to <i>lambda</i> .
<i>m</i>	The total number of eigenvalues found in the interval [ <i>emin</i> , <i>emax</i> ]: $0 \leq m \leq m0$ .
<i>res</i>	<p>Array of length <i>m0</i>. On exit, the first <i>m</i> components contain the relative residual vector:</p> <ul style="list-style-type: none"> <li>generalized eigenvalue problem:           <math display="block">\frac{\ Ax_i - \lambda_i Bx_i\ _1}{\max( E_{\min} ,  E_{\max} ) \ Bx_i\ _1}</math> </li> <li>standard eigenvalue problem:           <math display="block">\frac{\ Ax_i - \lambda_i x_i\ _1}{\max( E_{\min} ,  E_{\max} ) \ x_i\ _1}</math> </li> </ul> <p>for <math>i=0, 1, \dots, m-1</math>, and where <i>m</i> is the total number of eigenvalues found in the search interval.</p>
<i>info</i>	If <i>info</i> =0, the execution is successful. If <i>info</i> ≠ 0, see <a href="#">Output Eigensolver info Details</a> .

## Extended Eigensolver Predefined Interfaces

The predefined interfaces include routines for standard and generalized eigenvalue problems, and for dense, banded, and sparse matrices.

Matrix Type	Standard Eigenvalue Problem	Generalized Eigenvalue Problem
Dense	?feast_syev ?feast_heev	?feast_sygv ?feast_hegv
Banded	?feast_sbev ?feast_hbev	?feast_sbgv ?feast_hbgv
Sparse	?feast_scsrev ?feast_hcsrev	?feast_scsrgv ?feast_hcsrgv

## Matrix Storage

The symmetric and Hermitian matrices used in Extended Eigensolvers predefined interfaces can be stored in full, band, and sparse formats.

- In the full storage format (described in [Full Storage](#) in additional detail) you store all elements, all of the elements in the upper triangle of the matrix, or all of the elements in the lower triangle of the matrix.
- In the band storage format (described in [Band storage](#) in additional detail), you store only the elements along a diagonal band of the matrix.
- In the sparse format (described in [Storage Arrays for a Matrix in CSR Format \(3-Array Variation\)](#)), you store only the non-zero elements of the matrix.

In generalized eigenvalue systems you must use the same family of storage format for both matrices *A* and *B*. The bandwidth can be different for the banded format (*k1b* can be different from *k1a*), and the position of the non-zero elements can also be different for the sparse format (CSR coordinates *ib* and *jb* can be different from *ia* and *ja*).

## ?feast\_syev/?feast\_heev

Extended Eigensolver interface for standard eigenvalue problem with dense matrices.

### Syntax

```
void sfeast_syev (const char * uplo, const MKL_INT * n, const float * a, const MKL_INT * lda, MKL_INT * fpm, float * epsout, MKL_INT * loop, const float * emin, const float * emax, MKL_INT * m0, float * e, float * x, MKL_INT * m, float * res, MKL_INT * info);
```

```
void dfeast_syev (const char * uplo, const MKL_INT * n, const double * a, const MKL_INT * lda, MKL_INT * fpm, double * epsout, MKL_INT * loop, const double * emin, const double * emax, MKL_INT * m0, double * e, double * x, MKL_INT * m, double * res, MKL_INT * info);
```

```
void cfeast_heev (const char * uplo, const MKL_INT * n, const MKL_Complex8 * a, const MKL_INT * lda, MKL_INT * fpm, float * epsout, MKL_INT * loop, const float * emin, const float * emax, MKL_INT * m0, float * e, MKL_Complex8 * x, MKL_INT * m, float * res, MKL_INT * info);
```

```
void zfeast_heev (const char * uplo, const MKL_INT * n, const MKL_Complex16 * a, const MKL_INT * lda, MKL_INT * fpm, double * epsout, MKL_INT * loop, const double * emin, const double * emax, MKL_INT * m0, double * e, MKL_Complex16 * x, MKL_INT * m, double * res, MKL_INT * info);
```

### Include Files

- mkl.h

### Description

The routines compute all the eigenvalues and eigenvectors for standard eigenvalue problems,  $Ax = \lambda x$ , within a given search interval.

### Input Parameters

<i>uplo</i>	Must be 'U' or 'L' or 'F' . If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular parts of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular parts of <i>A</i> . If <i>uplo</i> = 'F', <i>a</i> stores the full matrix <i>A</i> .
<i>n</i>	Sets the size of the problem. $n > 0$ .
<i>a</i>	Array of dimension <i>lda</i> by <i>n</i> , contains either full matrix <i>A</i> or upper or lower triangular part of the matrix <i>A</i> , as specified by <i>uplo</i>
<i>lda</i>	The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$ .
<i>fpm</i>	Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See <a href="#">Extended Eigensolver Input Parameters</a> for a complete description of the parameters and their default values.
<i>emin</i> , <i>emax</i>	The lower and upper bounds of the interval to be searched for eigenvalues; $emin \leq emax$ .

---

**NOTE** Users are advised to avoid situations in which eigenvalues nearly coincide with the interval endpoints. This may lead to unpredictable selection or omission of such eigenvalues. Users should instead specify a slightly larger interval than needed and, if required, pick valid eigenvalues and their corresponding eigenvectors for subsequent use.

---

*m0* On entry, specifies the initial guess for subspace dimension to be used,  $0 < m0 \leq n$ . Set  $m0 \geq m$  where  $m$  is the total number of eigenvalues located in the interval  $[emin, emax]$ . If the initial guess is wrong, Extended Eigensolver routines return *info*=3.

*x* On entry, if *fpm*[4]=1, the array *x* of size  $n$  by  $m$  contains a basis of guess subspace where  $n$  is the order of the input matrix.

## Output Parameters

*epsout* On output, contains the relative error on the trace:  $|trace_i - trace_{i-1}| / \max(|emin|, |emax|)$

*loop* On output, contains the number of refinement loop executed. Ignored on input.

*e* Array of length  $m0$ . On output, the first  $m$  entries of *e* are eigenvalues found in the interval.

*x* On output, the first  $m$  columns of *x* contain the orthonormal eigenvectors corresponding to the computed eigenvalues *e*, with the *i*-th column of *x* holding the eigenvector associated with *e*[*i*].

*m* The total number of eigenvalues found in the interval  $[emin, emax]$ :  $0 \leq m \leq m0$ .

*res* Array of length  $m0$ . On exit, the first  $m$  components contain the relative residual vector:

$$\frac{\|Ax_i - \lambda_i x_i\|_1}{\max(|E_{\min}|, |E_{\max}|) \|x_i\|_1}$$

for  $i=1, 2, \dots, m$ , and where  $m$  is the total number of eigenvalues found in the search interval.

*info* If *info*=0, the execution is successful. If *info*  $\neq$  0, see [Output Eigensolver info Details](#).

## [?feast\\_sygv/?feast\\_hgv](#)

Extended Eigensolver interface for generalized eigenvalue problem with dense matrices.

---

## Syntax

```
void sfeast_sygv (const char * uplo, const MKL_INT * n, const float * a, const MKL_INT * lda, const float * b, const MKL_INT * ldb, MKL_INT * fpm, float * epsout, MKL_INT * loop, const float * emin, const float * emax, MKL_INT * m0, float * e, float * x, MKL_INT * m, float * res, MKL_INT * info);
```

```
void dfeast_sygv (const char * uplo, const MKL_INT * n, const double * a, const MKL_INT * lda, const double * b, const MKL_INT * ldb, MKL_INT * fpm, double * epsout, MKL_INT * loop, const double * emin, const double * emax, MKL_INT * m0, double * e, double * x, MKL_INT * m, double * res, MKL_INT * info);
```

## Include Files

- mkl.h

## Description

The routines compute all the eigenvalues and eigenvectors for generalized eigenvalue problems,  $Ax = \lambda Bx$ , within a given search interval.

---

### NOTE

Both matrices  $A$  and  $B$  must use the same family of storage format. The bandwidth, however, can be different ( $klb$  can be different from  $kla$ ).

---

## Input Parameters

<i>uplo</i>	Must be 'U' or 'L' or 'F' .  If <i>UPLO</i> = 'U', <i>a</i> and <i>b</i> store the upper triangular parts of <i>A</i> and <i>B</i> respectively.  If <i>UPLO</i> = 'L', <i>a</i> and <i>b</i> store the lower triangular parts of <i>A</i> and <i>B</i> respectively.  If <i>UPLO</i> = 'F', <i>a</i> and <i>b</i> store the full matrices <i>A</i> and <i>B</i> respectively.
<i>n</i>	Sets the size of the problem. $n > 0$ .
<i>kla</i>	The number of super- or sub-diagonals within the band in <i>A</i> ( $kla \geq 0$ ).
<i>a</i>	Array of dimension <i>lda</i> by <i>n</i> , contains either full matrix <i>A</i> or upper or lower triangular part of the matrix <i>A</i> , as specified by <i>uplo</i>
<i>lda</i>	The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$ .

<i>klb</i>	The number of super- or sub-diagonals within the band in $B$ ( $klb \geq 0$ ).
<i>b</i>	Array of dimension $ldb$ by $n$ , contains either full matrix $B$ or upper or lower triangular part of the matrix $B$ , as specified by <i>uplo</i>
<i>ldb</i>	The leading dimension of the array $B$ . Must be at least $\max(1, n)$ .
<i>fpm</i>	Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See <a href="#">Extended Eigensolver Input Parameters</a> for a complete description of the parameters and their default values.
<i>emin, emax</i>	The lower and upper bounds of the interval to be searched for eigenvalues; $emin \leq emax$ .

---

**NOTE** Users are advised to avoid situations in which eigenvalues nearly coincide with the interval endpoints. This may lead to unpredictable selection or omission of such eigenvalues. Users should instead specify a slightly larger interval than needed and, if required, pick valid eigenvalues and their corresponding eigenvectors for subsequent use.

---

<i>m0</i>	On entry, specifies the initial guess for subspace dimension to be used, $0 < m0 \leq n$ . Set $m0 \geq m$ where $m$ is the total number of eigenvalues located in the interval $[emin, emax]$ . If the initial guess is wrong, Extended Eigensolver routines return <i>info</i> =3.
<i>x</i>	On entry, if <i>fpm</i> [4]=1, the array <i>x</i> of size $n$ by $m$ contains a basis of guess subspace where $n$ is the order of the input matrix.

## Output Parameters

<i>epsout</i>	On output, contains the relative error on the trace: $ trace_i - trace_{i-1}  / \max( emin ,  emax )$
<i>loop</i>	On output, contains the number of refinement loop executed. Ignored on input.
<i>e</i>	Array of length $m0$ . On output, the first $m$ entries of <i>e</i> are eigenvalues found in the interval.
<i>x</i>	On output, the first $m$ columns of <i>x</i> contain the orthonormal eigenvectors corresponding to the computed eigenvalues <i>e</i> , with the $i$ -th column of <i>x</i> holding the eigenvector associated with $e[i]$ .
<i>m</i>	The total number of eigenvalues found in the interval $[emin, emax]$ : $0 \leq m \leq m0$ .
<i>res</i>	Array of length $m0$ . On exit, the first $m$ components contain the relative residual vector:

$$\frac{\|Ax_i - \lambda_i Bx_i\|_1}{\max(|E_{\min}|, |E_{\max}|) \|Bx_i\|_1}$$

for  $i=1, 2, \dots, m$ , and where  $m$  is the total number of eigenvalues found in the search interval.

*info*

If *info*=0, the execution is successful. If *info*  $\neq$  0, see [Output Eigensolver info Details](#).

```

#### Include Files

- mkl.h

#### Description

The routines compute all the eigenvalues and eigenvectors for standard eigenvalue problems,  $Ax = \lambda x$ , within a given search interval.

#### Input Parameters

<i>uplo</i>	Must be 'U' or 'L' or 'F' . If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular parts of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular parts of <i>A</i> . If <i>uplo</i> = 'F' , <i>a</i> stores the full matrix <i>A</i> .
<i>n</i>	Sets the size of the problem. $n > 0$ .
<i>a</i>	Array containing the nonzero elements of either the full matrix <i>A</i> or the upper or lower triangular part of the matrix <i>A</i> , as specified by <i>uplo</i> .

<i>ia</i>	Array of length $n + 1$ , containing indices of elements in the array $a$ , such that $ia[i]$ is the index in the array $a$ of the first non-zero element from the row $i$ . The value of the last element $ia[n]$ is equal to the number of non-zeros plus one.
<i>ja</i>	Array containing the column indices for each non-zero element of the matrix $A$ being represented in the array $a$ . Its length is equal to the length of the array $a$ .
<i>fpm</i>	Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See <a href="#">Extended Eigensolver Input Parameters</a> for a complete description of the parameters and their default values.
<i>emin, emax</i>	The lower and upper bounds of the interval to be searched for eigenvalues; $emin \leq emax$ .

---

**NOTE** Users are advised to avoid situations in which eigenvalues nearly coincide with the interval endpoints. This may lead to unpredictable selection or omission of such eigenvalues. Users should instead specify a slightly larger interval than needed and, if required, pick valid eigenvalues and their corresponding eigenvectors for subsequent use.

---

<i>m0</i>	On entry, specifies the initial guess for subspace dimension to be used, $0 < m0 \leq n$ . Set $m0 \geq m$ where $m$ is the total number of eigenvalues located in the interval $[emin, emax]$ . If the initial guess is wrong, Extended Eigensolver routines return $info=3$ .
<i>x</i>	On entry, if $fpm[4]=1$ , the array $x$ of size $n$ by $m$ contains a basis of guess subspace where $n$ is the order of the input matrix.

## Output Parameters

<i>fpm</i>	On output, the last 64 values correspond to Intel® oneAPI Math Kernel Library (oneMKL) PARDISO $iparm[0]$ to $iparm[63]$ (regardless of the value of $fpm[63]$ on input).
<i>epsout</i>	On output, contains the relative error on the trace: $ trace_i - trace_{i-1}  / \max( emin ,  emax )$
<i>loop</i>	On output, contains the number of refinement loop executed. Ignored on input.
<i>e</i>	Array of length $m0$ . On output, the first $m$ entries of $e$ are eigenvalues found in the interval.
<i>x</i>	On output, the first $m$ columns of $x$ contain the orthonormal eigenvectors corresponding to the computed eigenvalues $e$ , with the $i$ -th column of $x$ holding the eigenvector associated with $e[i]$ .
<i>m</i>	The total number of eigenvalues found in the interval $[emin, emax]$ : $0 \leq m \leq m0$ .
<i>res</i>	Array of length $m0$ . On exit, the first $m$ components contain the relative residual vector:

$$\frac{\|Ax_i - \lambda_i x_i\|_1}{\max(|E_{\min}|, |E_{\max}|) \|x_i\|_1}$$

for  $i=1, 2, \dots, m$ , and where  $m$  is the total number of eigenvalues found in the search interval.

*info*

If *info*=0, the execution is successful. If *info* ≠ 0, see [Output Eigensolver info Details](#).

## [?feast\\_scsrgv/?feast\\_hcsrgv](#)

*Extended Eigensolver interface for generalized eigenvalue problem with sparse matrices.*

---

### Syntax

```
void sfeast_scsrgv (const char * uplo, const MKL_INT * n, const float * a, const
MKL_INT * ia, const MKL_INT * ja, const float * b, const MKL_INT * ib, const MKL_INT *
jb, MKL_INT * fpm, float * epsout, MKL_INT * loop, const float * emin, const float *
emax, MKL_INT * m0, float * e, float * x, MKL_INT * m, float * res, MKL_INT * info);

void dfeast_scsrgv (const char * uplo, const MKL_INT * n, const double * a, const
MKL_INT * ia, const MKL_INT * ja, const double * b, const MKL_INT * ib, const MKL_INT *
jb, MKL_INT * fpm, double * epsout, MKL_INT * loop, const double * emin, const double *
emax, MKL_INT * m0, double * e, double * x, MKL_INT * m, double * res, MKL_INT * info);

void cfeast_hcsrgv (const char * uplo, const MKL_INT * n, const MKL_Complex8 * a, const
MKL_INT * ia, const MKL_INT * ja, const MKL_Complex8 * b, const MKL_INT * ib, const
MKL_INT * jb, MKL_INT * fpm, float * epsout, MKL_INT * loop, const float * emin, const
float * emax, MKL_INT * m0, float * e, MKL_Complex8 * x, MKL_INT * m, float * res,
MKL_INT * info);

void zfeast_hcsrgv (const char * uplo, const MKL_INT * n, const MKL_Complex16 * a,

const MKL_INT * jb, MKL_INT * fpm, double * epsout, MKL_INT * loop, const double *
emin, const double * emax, MKL_INT * m0, double * e, MKL_Complex16 * x, MKL_INT * m,
double * res, MKL_INT * info);
```

### Include Files

- mkl.h

### Description

The routines compute all the eigenvalues and eigenvectors for generalized eigenvalue problems,  $Ax = \lambda Bx$ , within a given search interval.

---

#### NOTE

Both matrices  $A$  and  $B$  must use the same family of storage format. The position of the non-zero elements can be different (CSR coordinates  $ib$  and  $jb$  can be different from  $ia$  and  $ja$ ).

---

### Input Parameters

*uplo*

Must be 'U' or 'L' or 'F' .

If  $UPLO = 'U'$ ,  $a$  and  $b$  store the upper triangular parts of  $A$  and  $B$  respectively.

If  $UPLO = 'L'$ ,  $a$  and  $b$  store the lower triangular parts of  $A$  and  $B$  respectively.

If  $UPLO = 'F'$ ,  $a$  and  $b$  store the full matrices  $A$  and  $B$  respectively.

$n$	Sets the size of the problem. $n > 0$ .
$a$	Array containing the nonzero elements of either the full matrix $A$ or the upper or lower triangular part of the matrix $A$ , as specified by $uplo$ .
$ia$	Array of length $n + 1$ , containing indices of elements in the array $a$ , such that $ia[i - 1]$ is the index in the array $a$ of the first non-zero element from the row $i$ . The value of the last element $ia[n]$ is equal to the number of non-zeros plus one.
$ja$	Array containing the column indices for each non-zero element of the matrix $A$ being represented in the array $a$ . Its length is equal to the length of the array $a$ .
$b$	Array of dimension $ldb$ by $*$ , contains the nonzero elements of either the full matrix $B$ or the upper or lower triangular part of the matrix $B$ , as specified by $uplo$ .
$ib$	Array of length $n + 1$ , containing indices of elements in the array $b$ , such that $ib[i - 1]$ is the index in the array $b$ of the first non-zero element from the row $i$ . The value of the last element $ib[n]$ is equal to the number of non-zeros plus one.
$jb$	Array containing the column indices for each non-zero element of the matrix $B$ being represented in the array $b$ . Its length is equal to the length of the array $b$ .
$fpm$	Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See <a href="#">Extended Eigensolver Input Parameters</a> for a complete description of the parameters and their default values.
$emin, emax$	The lower and upper bounds of the interval to be searched for eigenvalues; $emin \leq emax$ .

---

**NOTE** Users are advised to avoid situations in which eigenvalues nearly coincide with the interval endpoints. This may lead to unpredictable selection or omission of such eigenvalues. Users should instead specify a slightly larger interval than needed and, if required, pick valid eigenvalues and their corresponding eigenvectors for subsequent use.

---

$m0$	On entry, specifies the initial guess for subspace dimension to be used, $0 < m0 \leq n$ . Set $m0 \geq m$ where $m$ is the total number of eigenvalues located in the interval $[emin, emax]$ . If the initial guess is wrong, Extended Eigensolver routines return $info=3$ .
$x$	On entry, if $fpm[4]=1$ , the array $x$ of size $n$ by $m$ contains a basis of guess subspace where $n$ is the order of the input matrix.

## Output Parameters

<i>fpm</i>	On output, the last 64 values correspond to Intel® oneAPI Math Kernel Library (oneMKL) PARDISO <i>iparm</i> [0] to <i>iparm</i> [63] (regardless of the value of <i>fpm</i> [63] on input).
<i>epsout</i>	On output, contains the relative error on the trace: $ trace_i - trace_{i-1}  / \max( e_{min} ,  e_{max} )$
<i>loop</i>	On output, contains the number of refinement loop executed. Ignored on input.
<i>e</i>	Array of length <i>m0</i> . On output, the first <i>m</i> entries of <i>e</i> are eigenvalues found in the interval.
<i>x</i>	On output, the first <i>m</i> columns of <i>x</i> contain the orthonormal eigenvectors corresponding to the computed eigenvalues <i>e</i> , with the <i>i</i> -th column of <i>x</i> holding the eigenvector associated with <i>e</i> [ <i>i</i> ].
<i>m</i>	The total number of eigenvalues found in the interval [ <i>e<sub>min</sub></i> , <i>e<sub>max</sub></i> ]: $0 \leq m \leq m0$ .
<i>res</i>	Array of length <i>m0</i> . On exit, the first <i>m</i> components contain the relative residual vector: $\frac{\ Ax_i - \lambda_i Bx_i\ _1}{\max( E_{min} ,  E_{max} ) \ Bx_i\ _1}$ for <i>i</i> =1, 2, ..., <i>m</i> , and where <i>m</i> is the total number of eigenvalues found in the search interval.
<i>info</i>	If <i>info</i> =0, the execution is successful. If <i>info</i> ≠ 0, see <a href="#">Output Eigensolver info Details</a> .

## Extended Eigensolver Interfaces for Extremal Eigenvalues/Singular Values

The topics in this section discuss Extended Eigensolver interfaces to find extremal eigenvalues as well as singular values.

### Extended Eigensolver Interfaces to find largest/smallest eigenvalues

The predefined interfaces include routines for standard and generalized eigenvalue problems and sparse matrices.

Matrix Type	Standard Eigenvalue Problem	Generalized Eigenvalue Problem
Sparse	<a href="#">mkl_sparse_?_ev</a>	<a href="#">mkl_sparse_?_gv</a>

#### [mkl\\_sparse\\_?\\_ev](#)

*Computes the largest/smallest eigenvalues and corresponding eigenvectors of a standard eigenvalue problem*

## Syntax

```
sparse_status_t mkl_sparse_s_ev (char *which, MKL_INT *pm, sparse_matrix_t A, struct
matrix_descr descrA, MKL_INT k0, MKL_INT *k, float *E, float *X, float *res);
```

```
sparse_status_t mkl_sparse_d_ev (char *which, MKL_INT *pm, sparse_matrix_t A, struct
matrix_descr descrA, MKL_INT k0, MKL_INT *k, double *E, double *X, double *res);
```

## Include Files

- mkl\_solvers\_ee.h

## Description

The `mkl_sparse_?_ev` routine computes the largest/smallest eigenvalues and corresponding eigenvectors of a standard eigenvalue problem.

$$Ax = \lambda x$$

where  $A$  is the real symmetric matrix.

## Input Parameters

which	Indicates eigenvalues for which to search: <ul style="list-style-type: none"> <li>• which = 'L' indicates the largest eigenvalues.</li> <li>• which = 'S' indicates the smallest eigenvalues.</li> </ul>
pm	Array of size 128. This array is used to pass various parameters to Extended Eigensolver routines. See • <a href="#">Extended Eigensolver Input Parameters for Extremal Eigenvalue Problem</a> for a complete description of the parameters and their default values.
A	Handle containing sparse matrix in internal data structure.
descrA	Structure specifying sparse matrix properties.
sparse_matrix_type_t <i>type</i>	Specifies the type of a sparse matrix: <ul style="list-style-type: none"> <li>• SPARSE_MATRIX_TYPE_GENERAL The matrix is processed as-is.</li> <li>• SPARSE_MATRIX_TYPE_SYMMETRIC The matrix is symmetric (only the requested triangle is processed).</li> </ul>
sparse_fill_mode_t <i>mode</i>	Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices: <ul style="list-style-type: none"> <li>• SPARSE_FILL_MODE_LOWER The lower triangular matrix part is processed.</li> <li>• SPARSE_FILL_MODE_UPPER The upper triangular matrix part is processed.</li> </ul>
sparse_diag_type_t <i>diag</i>	Specifies the diagonal type for non-general matrices:

- `SPARSE_DIAG_NON_UNIT`

Diagonal elements might not be equal to one.

- `SPARSE_DIAG_UNIT`

Diagonal elements are equal to one

`k0` The desired number of the largest/smallest eigenvalues to find.

## Output Parameters

`k` Number of eigenvalues found.

`E` Array of size `k0`. Contains `k` largest/smallest eigenvalues.

`X` Array of size `k0`\*Number of columns of the matrix `A`. Contains `k` eigenvectors.

`Res` Array of size `k0`. Contains `k` residuals.

## Return Values

The function returns a value indicating whether the operation was successful or not, and why.

`SPARSE_STATUS_SUCCESS` The operation was successful.

`SPARSE_STATUS_NOT_INITIALIZED` The routine encountered an empty handle or matrix array.

`SPARSE_STATUS_ALLOC_FAILED` Internal memory allocation failed.

`SPARSE_STATUS_INVALID_VALUE` The input parameters contain an invalid value.

`SPARSE_STATUS_EXECUTION_FAILED` Execution failed.

`SPARSE_STATUS_INTERNAL_ERROR` An error in algorithm implementation occurred.

`SPARSE_STATUS_NOT_SUPPORTED` The requested operation is not supported.

## `mkl_sparse_?_gv`

*Computes the largest/smallest eigenvalues and corresponding eigenvectors of a generalized eigenvalue problem*

### Syntax

```
sparse_status_t mkl_sparse_s_gv (char *which, MKL_INT *pm, sparse_matrix_t A, struct
matrix_descr descrA, sparse_matrix_t B, struct matrix_descr descrB, MKL_INT k0, MKL_INT
*k, float *E, float *X, float *res);
```

```
sparse_status_t mkl_sparse_d_gv (char *which, MKL_INT *pm, sparse_matrix_t A, struct
matrix_descr descrA, sparse_matrix_t B, struct matrix_descr descrB, MKL_INT k0, MKL_INT
*k, double *E, double *X, double *res);
```

### Include Files

- `mkl_solvers_ee.h`

## Description

The `mk1_sparse_?_gv` routine computes the largest/smallest eigenvalues and corresponding eigenvectors of a generalized eigenvalue problem.

$$Ax = \lambda Bx$$

where **A** is the real symmetric matrix and **B** is the real symmetric positive definite matrix.

## Input Parameters

which	Indicates eigenvalues for which to search: <ul style="list-style-type: none"> <li>• <code>which = 'L'</code> indicates the largest eigenvalues.</li> <li>• <code>which = 'S'</code> indicates the smallest eigenvalues.</li> </ul>
pm	Array of size 128. This array is used to pass various parameters to Extended Eigensolver routines. See • <a href="#">Extended Eigensolver Input Parameters for Extremal Eigenvalue Problem</a> for a complete description of the parameters and their default values.
A	Handle containing sparse matrix in internal data structure.
descrA	Structure specifying sparse matrix properties. <p><code>sparse_matrix_type_t</code> <i>type</i></p> <p>Specifies the type of a sparse matrix:</p> <ul style="list-style-type: none"> <li>• <code>SPARSE_MATRIX_TYPE_GENERAL</code> The matrix is processed as-is.</li> <li>• <code>SPARSE_MATRIX_TYPE_SYMMETRIC</code> The matrix is symmetric (only the requested triangle is processed).</li> </ul> <p><code>sparse_fill_mode_t</code> <i>mode</i></p> <p>Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:</p> <ul style="list-style-type: none"> <li>• <code>SPARSE_FILL_MODE_LOWER</code> The lower triangular matrix part is processed.</li> <li>• <code>SPARSE_FILL_MODE_UPPER</code> The upper triangular matrix part is processed.</li> </ul> <p><code>sparse_diag_type_t</code> <i>diag</i></p> <p>Specifies the diagonal type for non-general matrices:</p> <ul style="list-style-type: none"> <li>• <code>SPARSE_DIAG_NON_UNIT</code> Diagonal elements might not be equal to one.</li> <li>• <code>SPARSE_DIAG_UNIT</code> Diagonal elements are equal to one</li> </ul>
B	Handle containing sparse matrix in internal data structure.
descrB	Structure specifying sparse matrix properties.

<code>sparse_matrix_type_t</code> <i>type</i>	Specifies the type of a sparse matrix: <ul style="list-style-type: none"> <li>• <code>SPARSE_MATRIX_TYPE_GENERAL</code> The matrix is processed as-is.</li> <li>• <code>SPARSE_MATRIX_TYPE_SYMMETRIC</code> The matrix is symmetric (only the requested triangle is processed).</li> </ul>

<code>sparse_diag_type_t</code> <i>diag</i>	Specifies the diagonal type for non-general matrices: <ul style="list-style-type: none"> <li>• <code>SPARSE_DIAG_NON_UNIT</code> Diagonal elements might not be equal to one.</li> <li>• <code>SPARSE_DIAG_UNIT</code> Diagonal elements are equal to one</li> </ul>

`k0` The desired number of the largest/smallest eigenvalues to find.

## Output Parameters

<code>k</code>	Number of eigenvalues found.
<code>E</code>	Array of size <code>k0</code> . Contains <code>k</code> largest/smallest eigenvalues.
<code>X</code>	Array of size <code>k0*Number of columns of matrix A</code> . Contains <code>k</code> eigenvectors.
<code>Res</code>	Array of size <code>k0</code> . Contains <code>k</code> residuals.

## Return Values

The function returns a value indicating whether the operation was successful or not, and why.

<code>SPARSE_STATUS_SUCCESS</code>	The operation was successful.
<code>SPARSE_STATUS_NOT_INITIALIZED</code>	The routine encountered an empty handle or matrix array.
<code>SPARSE_STATUS_ALLOC_FAILED</code>	Internal memory allocation failed.
<code>SPARSE_STATUS_INVALID_VALUE</code>	The input parameters contain an invalid value.
<code>SPARSE_STATUS_EXECUTION_FAILED</code>	Execution failed.
<code>SPARSE_STATUS_INTERNAL_ERROR</code>	An error in algorithm implementation occurred.

SPARSE\_STATUS\_NOT\_SUPPORTED

The requested operation is not supported.

## Extended Eigensolver Interfaces to find largest/smallest singular values

The predefined interfaces include routines to find the largest and smallest singular values and the corresponding singular vectors of sparse matrices.

Matrix Type	Standard singular value problem
Sparse	<code>mkl_sparse_?_svd</code>

### `mkl_sparse_?_svd`

*Computes the largest/smallest singular values of a singular-value problem*

#### Syntax

```
sparse_status_t mkl_sparse_s_svd (char *whichS, char *whichV, MKL_INT *pm,
sparse_matrix_t A, struct matrix_descr descrA, MKL_INT k0, MKL_INT *k, float *E, float
*XL, float *XR, float *res);
```

```
sparse_status_t mkl_sparse_d_svd (char *whichS, char *whichV, MKL_INT *pm,
sparse_matrix_t A, struct matrix_descr descrA, MKL_INT k0, MKL_INT *k, double *E,
double *XL, double *XR, double *res);
```

#### Include Files

- `mkl_solvers_ee.h`

#### Description

The `mkl_sparse_?_svd` routine computes the largest/smallest singular values of a singular-value problem.

$AATx = \sigma x$  or  $ATAx = \sigma x$ , where  $A$  is the real rectangular matrix.

#### Input Parameters

<code>whichS</code>	Indicates eigenvalues for which to search: <ul style="list-style-type: none"> <li>• <code>whichS = 'L'</code> indicates the largest eigenvalues.</li> <li>• <code>whichS = 'S'</code> indicates the smallest eigenvalues.</li> </ul>
<code>whichV</code>	Indicates singular vectors for which to search: <ul style="list-style-type: none"> <li>• <code>whichV = 'R'</code> indicates right singular vectors.</li> <li>• <code>whichV = 'L'</code> indicates left singular vectors.</li> </ul>
<code>pm</code>	Array of size 128. This array is used to pass various parameters to Extended Eigensolver routines. See • <a href="#">Extended Eigensolver Input Parameters for Extremal Eigenvalue Problem</a> for a complete description of the parameters and their default values.
<code>A</code>	Handle containing sparse matrix in internal data structure.
<code>descrA</code>	Structure specifying sparse matrix properties. <p><code>sparse_matrix_type_t</code> Specifies the type of a sparse matrix: <i>type</i></p>

	<ul style="list-style-type: none"> <li>● <code>SPARSE_MATRIX_TYPE_GENERAL</code> The matrix is processed as-is.</li> <li>● <code>SPARSE_MATRIX_TYPE_SYMMETRIC</code> The matrix is symmetric (only the requested triangle is processed).</li> </ul>
<code>sparse_fill_mode_t mode</code>	<p>Specifies the triangular matrix part for symmetric, Hermitian, triangular, and block-triangular matrices:</p> <ul style="list-style-type: none"> <li>● <code>SPARSE_FILL_MODE_LOWER</code> The lower triangular matrix part is processed.</li> <li>● <code>SPARSE_FILL_MODE_UPPER</code> The upper triangular matrix part is processed.</li> </ul>
<code>sparse_diag_type_t diag</code>	<p>Specifies the diagonal type for non-general matrices:</p> <ul style="list-style-type: none"> <li>● <code>SPARSE_DIAG_NON_UNIT</code> Diagonal elements might not be equal to one.</li> <li>● <code>SPARSE_DIAG_UNIT</code> Diagonal elements are equal to one</li> </ul>
<code>k0</code>	The desired number of the largest/smallest eigenvalues to find.

## Output Parameters

<code>k</code>	Number of eigenvalues found.
<code>E</code>	Array of size $k0$ . Contains $k$ largest/smallest eigenvalues.
<code>XL</code>	Array of size $k0$ *Number of rows of matrix A. Contains $k$ left singular vectors.
<code>XR</code>	Array of size $k0$ *Number of columns of matrix A. Contains $k$ right singular vectors.
<code>Res</code>	Array that contains $k$ residuals.

## Return Values

The function returns a value indicating whether the operation was successful or not, and why.

<code>SPARSE_STATUS_SUCCESS</code>	The operation was successful.
<code>SPARSE_STATUS_NOT_INITIALIZED</code>	The routine encountered an empty handle or matrix array.
<code>SPARSE_STATUS_ALLOC_FAILED</code>	Internal memory allocation failed.
<code>SPARSE_STATUS_INVALID_VALUE</code>	The input parameters contain an invalid value.
<code>SPARSE_STATUS_EXECUTION_FAILED</code>	Execution failed.

<code>SPARSE_STATUS_INTERNAL_ERROR</code>	An error in algorithm implementation occurred.
<code>SPARSE_STATUS_NOT_SUPPORTED</code>	The requested operation is not supported.

## **mkl\_sparse\_ee\_init**

*Initializes Extended Eigensolver input parameters with default values*

### **Syntax**

```
sparse_status_t mkl_sparse_ee_init (MKL_INT* pm);
```

### **Include Files**

- `mkl_solvers_ee.h`

### **Description**

This routine sets all Extended Eigensolver parameters to their default values.

### **Output Parameters**

<code>pm</code>	Array of size 128. This array is used to pass various parameters to Extended Eigensolver routines. See • <a href="#">Extended Eigensolver Input Parameters for Extremal Eigenvalue Problem</a> for a complete description of the parameters and their default values.
-----------------	---

## **Extended Eigensolver Input Parameters for Extremal Eigenvalue Problem**

The input parameters for Extended Eigensolver routines are contained in an `MKL_INT` array named `pm`. To call the Extended Eigensolver interfaces, initialize this array using the `mkl_sparse_ee_init` routine.

<b>Parameter</b>	<b>Default</b>	<b>Description</b>
<code>pm[0]</code>	0	Reserved for future use.
<code>pm[1]</code>	6	Defines the tolerance for the stopping criteria: $\epsilon = 10^{-pm[1]+1}$
<code>pm[2]</code>	0	Specifies the algorithm to use: <ul style="list-style-type: none"> <li>• 0 - Decided at runtime</li> <li>• 1 - The Krylov-Schur method</li> <li>• 2 - Subspace Iteration technique based on FEAST algorithm</li> </ul>
<code>pm[3]</code>	*	This parameter is referenced only for Krylov-Schur Method. It indicates the number of Lanczos/Arnoldi vectors (NCV) generated at each iteration. This parameter must be less than or equal to size of matrix and greater than number of eigenvalues (k0) to be computed. If unspecified, NCV is set to be at least 1.5 times larger than k0.
<code>pm[4]</code>	*	Maximum number of iterations. If unspecified, this parameter is set to 10000 for the Krylov-Schur method and 60 for the subspace iteration method.

Parameter	Default	Description
<code>pm[5]</code>	0	Power of Chebychev expansion for approximate spectral projector. Only referenced when <code>pm[2]=1</code>
<code>pm[6]</code>	1	Used only for Krylov-Schur Method. If 0, then the method only computes eigenvalues. If 1, then the method computes eigenvalues and eigenvectors. The subspace iteration method always computes eigenvectors/singular vectors. You must allocate the required memory space.
<code>pm[7]</code>	0	Convergence stopping criteria. Defines whether the stopping criteria for the iterations with respect to the true residuals (used if <code>pm[8]</code> is not zero) and residual norm estimates are relative to the eigenvalues/singular values or not. If 0, the stopping criteria with respect to the true residuals is: $\frac{\ Ax - \lambda x\ }{ \lambda } < 10^{-pm[1] + 1}$ or $\frac{\ Ax - \lambda Bx\ }{ \lambda } < 10^{-pm[1] + 1}$ If 1, the stopping criteria with respect to the true residuals is: $\ Ax - \lambda x\  < 10^{-pm[1] + 1}$ or $\ Ax - \lambda Bx\  < 10^{-pm[1] + 1}$ for a generalized eigenproblem. The residual norm estimates are based on the magnitude of the last eigenvector of the Schur decomposition matrix and the exact formula can be found in the literature. When <code>pm[7]=0</code> , the residual norm estimate is additionally divided by the magnitude of the computed eigenvalue and compared to $10^{-(pm[1]+1)}$ .
<code>pm[8]</code>	0	Specifies if for detecting convergence the solver must compute the true residuals for eigenpairs for the Krylov-Schur method or it can only use the residual norm estimates. If 0, only residual norm estimates are used. If 1, the solver computes not just residual norm estimates but also the true residuals as defined in the description of <code>pm[7]</code> .
<code>pm[9]</code>	0	Used only for the Krylov-Schur method and only as an output parameter. Reports the reason for exiting the iteration loop of the method: <ul style="list-style-type: none"> <li>• If 0, the iterations stopped since convergence has been detected.</li> <li>• If -1, maximum number of iterations has been reached and even the residual norm estimates have not converged.</li> </ul>

Parameter	Default	Description
		<ul style="list-style-type: none"> <li>• If -2, maximum number of iterations has been reached despite the residual norm estimates have converged (but the true residuals for eigenpairs have not).</li> <li>• If -3, the iterations stagnated and even the residual norm estimates have not converged.</li> <li>• If -4, the iterations stagnated while the eigenvalues have converged (but the true residuals for eigenpairs do not).</li> </ul>
<code>pm[10]</code> to <code>pm[128]</code>	-	Reserved for future use.

## Vector Mathematical Functions

Intel® oneAPI Math Kernel Library (oneMKL) Vector Mathematics functions (VM) compute a mathematical function of each of the vector elements. VM includes a set of highly optimized functions (arithmetic, power, trigonometric, exponential, hyperbolic, special, and rounding) that operate on vectors of real and complex numbers.

Application programs that improve performance with VM include nonlinear programming software, computation of integrals, financial calculations, computer graphics, and many others.

VM functions fall into the following groups according to the operations they perform:

- [VM Mathematical Functions](#) compute values of mathematical functions, such as sine, cosine, exponential, or logarithm, on vectors stored contiguously in memory.
- [VM Pack/Unpack Functions](#) convert to and from vectors with positive increment indexing, vector indexing, and mask indexing (see [Appendix "Vector Arguments in VM"](#) for details on vector indexing methods).
- [VM Service Functions](#) set/get the accuracy modes and the error codes, and free memory.

The VM mathematical functions take an input vector as an argument, compute values of the respective function element-wise, and return the results in an output vector. All the VM mathematical functions can perform in-place operations, where the input and output arrays are at the same memory locations. For VM mathematical functions with positive increment indexing, in-place operations are supported only when the input and output increments have the same value.

The Intel® oneAPI Math Kernel Library (oneMKL) interfaces are given in `mkl_vml_functions.h`.

**NOTE** On 64-bit platforms, oneMKL provides VML C interfaces with the `_64` suffix to support large data arrays in the LP64 interface library. For more interface library details, see "Using the ILP64 Interface vs. LP64 Interface" in the developer guide.

Examples that demonstrate how to use the VM functions are located in:

```
$(MKL)/examples/vmlc/source
```

See VM performance and accuracy data in the online VM Performance and Accuracy Data document available at <https://www.intel.com/content/www/us/en/developer/tools/oneapi/onemkl-documentation.html>.

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## VM Data Types, Accuracy Modes, and Performance Tips

VM includes mathematical and pack/unpack vector functions for single and double precision vector arguments of real and complex types. Intel® oneAPI Math Kernel Library (oneMKL) provides Fortran and C interfaces for all VM functions, including the associated service functions. The Function Naming Conventions topic shows how to call these functions.

Performance depends on a number of factors, including vectorization and threading overhead. The recommended usage is as follows:

- Use VM for vector lengths larger than 40 elements.
- Use the Intel® Compiler for vector lengths less than 40 elements.

All VM vector functions support the following accuracy modes:

- High Accuracy (HA), the default mode
- Low Accuracy (LA), which improves performance by reducing accuracy of the two least significant bits
- Enhanced Performance (EP), which provides better performance at the cost of significantly reduced accuracy. Approximately half of the bits in the mantissa are correct.

Note that using the EP mode does not guarantee accurate processing of corner cases and special values. Although the default accuracy is HA, LA is sufficient in most cases. For applications that require less accuracy (for example, media applications, some Monte Carlo simulations, etc.), the EP mode may be sufficient.

VM handles special values in accordance with the C99 standard [C99].

Intel® oneAPI Math Kernel Library (oneMKL) offers both functions and environment variables to switch between modes for VM. See the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for details about the environment variables. Use the `vm1SetMode(mode)` function (see Table "Values of the *mode* Parameter") to switch between the HA, LA, and EP modes. The `vm1GetMode()` function returns the current mode.

[Function Naming Conventions](#)

## VM Naming Conventions

The VM function names are of mixed (lower and upper) case.

The VM mathematical and pack/unpack function names have the following structure:

`v[m]<?><name><mod>`

where

- `v` is a prefix indicating vector operations.
- `[m]` is an optional prefix for mathematical functions that indicates additional argument to specify a VM mode for a given function call (see `vm1SetMode` for possible values and their description).
- `<?>` is a precision prefix that indicates one of the following data types:

<code>s</code>	<code>float.</code>
<code>d</code>	<code>double.</code>
<code>c</code>	<code>MKL_Complex8.</code>
<code>z</code>	<code>MKL_Complex16.</code>

- `<name>` indicates the function short name, with some of its letters in uppercase. See examples in [Table "VM Mathematical Functions"](#).
- `<mod>` field (written in uppercase) is present only in the pack/unpack functions and indicates the indexing method used:

<code>j</code>	indexing with a positive increment
<code>v</code>	indexing with an index vector
<code>m</code>	indexing with a mask vector.

The VM service function names have the following structure:

`vm<name>`

where

`<name>` indicates the function short name, with some of its letters in uppercase. See examples in [Table "VM Service Functions"](#).

To call VM functions from an application program, use conventional function calls. For example, call the vector single precision real exponential function as

```
vsExp ( n, a, y );
```

## VM Function Interfaces

VM interfaces include the function names and argument lists. The following sections describe the interfaces for the VM functions. Note that some of the functions have multiple input and output arguments

Some VM functions may also take scalar arguments as input. See the function description for the naming conventions of such arguments.

### VM Mathematical Function Interfaces

```
v<?><name>( n, a, [scalar input arguments], y );
v<?><name>I( n, a, inca, [scalar input arguments], y, incy );
v<?><name>( n, a, b, [scalar input arguments], y );
v<?><name>I( n, a, inca, b, incb, [scalar input arguments], y, incy );
v<?><name>( n, a, y, z );
v<?><name>I( n, a, inca, y, incy, z, incz );
vm<?><name>( n, a, [scalar input arguments], y, mode );
vm<?><name>I( n, a, inca, [scalar input arguments], y, incy, mode );
vm<?><name>( n, a, b, [scalar input arguments], y, mode );
vm<?><name>I( n, a, inca, b, incb, [scalar input arguments], y, incy, mode );
vm<?><name>( n, a, y, z, mode );
vm<?><name>I( n, a, inca, y, incy, z, incz, mode );
```

## VM Mathematical Functions

### VM Pack Function Interfaces

```
v<?>PackI( n, a, inca, y );
v<?>PackV( n, a, ia, y );
v<?>PackM( n, a, ma, y );
```

### VM Unpack Function Interfaces

```
v<?>UnpackI( n, a, y, incy );
v<?>UnpackV( n, a, y, iy );
```

```
v<?>UnpackM( n, a, y, my );
```

## VM Service Function Interfaces

```
oldmode = vmlSetMode( mode );
mode = vmlGetMode( void );
olderr = vmlSetErrStatus ( err );
err = vmlGetErrStatus( void );
olderr = vmlClearErrStatus( void );
oldcallback = vmlSetErrorCallBack( callback );
callback = vmlGetErrorCallBack( void );
oldcallback = vmlClearErrorCallBack( void );
```

Note that *oldmode*, *olderr*, and *oldcallback* refer to settings prior to the call.

## VM Input Parameters

<i>n</i>	number of elements to be calculated
<i>a</i>	first input vector
<i>b</i>	second input vector
<i>inca</i>	vector increment for the input vector <i>a</i>
<i>incb</i>	vector increment for the input vector <i>b</i>
<i>ia</i>	index vector for the input vector <i>a</i>
<i>ma</i>	mask vector for the input vector <i>a</i>
<i>incy</i>	vector increment for the output vector <i>y</i>
<i>incz</i>	vector increment for the output vector <i>z</i>
<i>iy</i>	index vector for the output vector <i>y</i>
<i>my</i>	mask vector for the output vector <i>y</i>
<i>err</i>	error code
<i>mode</i>	VM mode
<i>callback</i>	address of the callback function

## VM Output Parameters

<i>y</i>	first output vector
<i>z</i>	second output vector
<i>err</i>	error code
<i>mode</i>	VM mode
<i>olderr</i>	former error code
<i>oldmode</i>	former VM mode
<i>callback</i>	address of the callback function
<i>oldcallback</i>	address of the former callback function

See the data types of the parameters used in each function in the respective function description section. All Intel® oneAPI Math Kernel Library (oneMKL) VM mathematical functions can perform in-place operations. For VM mathematical functions with positive increment indexing, (for example, `v?PowI`), in-place operations are supported only when the input and output increments have the same value.

## Vector Indexing Methods

Classic VM mathematical functions work with unit stride. Strided VM mathematical functions (names with "I" suffix) work with arbitrary integer increments. Increments may be positive, negative or equal to zero. For example:

```
vsExpI (n, a, inca, r, incr)
```

is equivalent to:

```
for (i=0; i<n; i++)
{
    r[i * incr] = exp (a[i * inca]);
}
```

where

*i* – current index,

*inca* – input index increment,

*incr* – output index increment.

*n* – the number of elements to be computed (important: *n* is not the maximum array size).

So, when calling `vsExpI(n, a, inca, r, incr)` be sure that the input vector *a* is allocated at least for  $1 + (n-1)*inca$  elements and the result vector *r* has a space for  $1 + (n-1)*incr$  elements.

---

**NOTE** The order of computations is not guaranteed and no array bounds-checking is performed; therefore, the results for overlapped and in-place arrays are not generally deterministic for increments other than 1.

---

For output index increment, equal to 0, the result is not deterministic and generally nonsensical.

Use negative increments to step from base pointers in reverse order.

For example:

```
vsExpI (n, a, -2, r, -3)
```

is equivalent to:

```
for (i=0; i<n; i++)
{
    r[- i*3] = exp (a[-i*2]);
}
```

---

**NOTE** Pass pointers to the desired ending array element in memory as an argument for negative strides.

---

For example:

```
vsExpI (n, a, 2, r + 1000, -3).
```

Use a zero increment for one fixed argument rather than an array.

For example:

```
vsMulI (n, a, 1, b, 0, r, 1)
```

is equivalent to:

```
for (i=0; i<n; i++)
{
    r[i] = a[i] * b[0];
}
```

VM Pack/Unpack functions use the following indexing methods to do this task:

- positive increment
- index vector
- mask vector

The indexing method used in a particular function is indicated by the indexing modifier (see the description of the `<mod>` field in [Function Naming Conventions](#)). For more information on the indexing methods, see [Vector Arguments in VM](#).

## VM Pack/Unpack Functions

### VM Error Diagnostics

The VM mathematical functions incorporate the error handling mechanism, which is controlled by the following service functions:

<code>vmlGetErrStatus,</code> <code>vmlSetErrStatus,</code> <code>vmlClearErrStatus</code>	These functions operate with a global variable called VM Error Status. The VM Error Status flags an error, a warning, or a successful execution of a VM function.
<code>vmlGetErrCallBack,</code> <code>vmlSetErrCallBack,</code> <code>vmlClearErrCallBack</code>	These functions enable you to customize the error handling. For example, you can identify a particular argument in a vector where an error occurred or that caused a warning.
<code>vmlSetMode, vmlGetMode</code>	These functions get and set a VM mode. If you set a new VM mode using the <code>vmlSetMode</code> function, you can store the previous VM mode returned by the routine and restore it at any point of your application.

If both an error and a warning situation occur during the function call, the VM Error Status variable keeps only the value of the error code. See [Table "Values of the VM Error Status"](#) for possible values. If a VM function does not encounter errors or warnings, it sets the VM Error Status to `VML_STATUS_OK`.

If you use incorrect input arguments to a VM function (`VML_STATUS_BADSIZE` and `VML_STATUS_BADMEM`), the function calls `xerbla` to report errors. See [Table "Values of the VM Error Status"](#) for details.

You can use the `vmlSetMode` and `vmlGetMode` functions to modify error handling behavior. Depending on the VM mode, the error handling behavior includes the following operations:

- setting the VM Error Status to a value corresponding to the observed error or warning
- setting the `errno` variable to one of the values described in [Table "Set Values of the `errno` Variable"](#)
- writing error text information to the `stderr` stream
- raising the appropriate exception on an error, if necessary
- calling the additional error handler callback function that is set by `vmlSetErrorCallBack`.

#### Set Values of the `errno` Variable

Value of <code>errno</code>	Description
<code>0</code>	No errors are detected.
<code>EINVAL</code>	The array dimension is not positive.
<code>EACCES</code>	NULL pointer is passed.
<code>EDOM</code>	At least one of array values is out of a range of definition.
<code>ERANGE</code>	At least one of array values caused a singularity, overflow or underflow.

## See Also

`vmlGetErrStatus` Gets the VM Error Status.

`vmlSetErrStatus` Sets the new VM Error Status according to *err* and stores the previous VM Error Status to *olderr*. Sets the global VM Status according to new values and returns the previous VM Status.

`vmlClearErrStatus` Sets the VM Error Status to `VML_STATUS_OK` and stores the previous VM Error Status to *olderr*.

`vmlSetErrorCallBack` Sets the additional error handler callback function and gets the old callback function.

`vmlGetErrorCallBack` Gets the additional error handler callback function.

`vmlClearErrorCallBack` Deletes the additional error handler callback function and retrieves the former callback function.

`vmlGetMode` Gets the VM mode.

`vmlSetMode` Sets a new mode for VM functions according to the *mode* parameter and stores the previous VM mode to *oldmode*.

## VM Mathematical Functions

This section describes VM functions that compute values of mathematical functions on real and complex vector arguments.

Each function is introduced by its short name, a brief description of its purpose, and the calling sequence for each type of data, as well as a description of the input/output arguments.

The input range of parameters is equal to the mathematical range of the input data type, unless the function description specifies input threshold values, which mark off the precision overflow, as follows:

- `FLT_MAX` denotes the maximum number representable in single precision real data type
- `DBL_MAX` denotes the maximum number representable in double precision real data type

Table "VM Mathematical Functions" lists available mathematical functions and associated data types.

### VM Mathematical Functions

Function	Data Types	Description
<b>Arithmetic Functions</b>		
<code>v?Add</code>	<i>s, d, c, z</i>	Adds vector elements
<code>v?Sub</code>	<i>s, d, c, z</i>	Subtracts vector elements
<code>v?Sqr</code>	<i>s, d</i>	Squares vector elements
<code>v?Mul</code>	<i>s, d, c, z</i>	Multiplies vector elements
<code>v?MulByConj</code>	<i>c, z</i>	Multiplies elements of one vector by conjugated elements of the second vector
<code>v?Conj</code>	<i>c, z</i>	Conjugates vector elements
<code>v?Abs</code>	<i>s, d, c, z</i>	Computes the absolute value of vector elements
<code>v?Arg</code>	<i>c, z</i>	Computes the argument of vector elements
<code>v?LinearFrac</code>	<i>s, d</i>	Performs linear fraction transformation of vectors
<code>v?Fmod</code>	<i>s, d</i>	Performs element by element computation of the modulus function of vector <i>a</i> with respect to vector <i>b</i>
<code>v?Remainder</code>	<i>s, d</i>	Performs element by element computation of the remainder function on the elements of vector <i>a</i> and the corresponding elements of vector <i>b</i>
<b>Power and Root Functions</b>		
<code>v?Inv</code>	<i>s, d</i>	Inverts vector elements
<code>v?Div</code>	<i>s, d, c, z</i>	Divides elements of one vector by elements of the second vector
<code>v?Sqrt</code>	<i>s, d, c, z</i>	Computes the square root of vector elements
<code>v?InvSqrt</code>	<i>s, d</i>	Computes the inverse square root of vector elements
<code>v?Cbirt</code>	<i>s, d</i>	Computes the cube root of vector elements

Function	Data Types	Description
<code>v?InvCbrt</code>	<i>s, d</i>	Computes the inverse cube root of vector elements
<code>v?Pow2o3</code>	<i>s, d</i>	Computes the cube root of the square of each vector element
<code>v?Pow3o2</code>	<i>s, d</i>	Computes the square root of the cube of each vector element
<code>v?Pow</code>	<i>s, d, c, z</i>	Raises each vector element to the specified power
<code>v?Powx</code>	<i>s, d, c, z</i>	Raises each vector element to the constant power
<code>v?Powr</code>	<i>s, d</i>	Computes $a$ to the power $b$ for elements of two vectors, where the elements of vector argument $a$ are all non-negative
<code>v?Hypot</code>	<i>s, d</i>	Computes the square root of sum of squares
<b>Exponential and Logarithmic Functions</b>		
<code>v?Exp</code>	<i>s, d, c, z</i>	Computes the base $e$ exponential of vector elements
<code>v?Exp2</code>	<i>s, d</i>	Computes the base 2 exponential of vector elements
<code>v?Exp10</code>	<i>s, d</i>	Computes the base 10 exponential of vector elements
<code>v?Expml</code>	<i>s, d</i>	Computes the base $e$ exponential of vector elements decreased by 1
<code>v?Ln</code>	<i>s, d, c, z</i>	Computes the natural logarithm of vector elements
<code>v?Log2</code>	<i>s, d</i>	Computes the base 2 logarithm of vector elements
<code>v?Log10</code>	<i>s, d, c, z</i>	Computes the base 10 logarithm of vector elements
<code>v?Log1p</code>	<i>s, d</i>	Computes the natural logarithm of vector elements that are increased by 1
<code>v?Logb</code>	<i>s, d</i>	Computes the exponents of the elements of input vector $a$
<b>Trigonometric Functions</b>		
<code>v?Cos</code>	<i>s, d, c, z</i>	Computes the cosine of vector elements
<code>v?Sin</code>	<i>s, d, c, z</i>	Computes the sine of vector elements
<code>v?SinCos</code>	<i>s, d</i>	Computes the sine and cosine of vector elements
<code>v?CIS</code>	<i>c, z</i>	Computes the complex exponent of vector elements (cosine and sine combined to complex value)
<code>v?Tan</code>	<i>s, d, c, z</i>	Computes the tangent of vector elements
<code>v?Acos</code>	<i>s, d, c, z</i>	Computes the inverse cosine of vector elements
<code>v?Asin</code>	<i>s, d, c, z</i>	Computes the inverse sine of vector elements
<code>v?Atan</code>	<i>s, d, c, z</i>	Computes the inverse tangent of vector elements
<code>v?Atan2</code>	<i>s, d</i>	Computes the four-quadrant inverse tangent of ratios of the elements of two vectors
<code>v?Cospi</code>	<i>s, d</i>	Computes the cosine of vector elements multiplied by $\pi$
<code>v?Sinpi</code>	<i>s, d</i>	Computes the sine of vector elements multiplied by $\pi$
<code>v?Tanpi</code>	<i>s, d</i>	Computes the tangent of vector elements multiplied by $\pi$
<code>v?Acospi</code>	<i>s, d</i>	Computes the inverse cosine of vector elements divided by $\pi$
<code>v?Asinpi</code>	<i>s, d</i>	Computes the inverse sine of vector elements divided by $\pi$
<code>v?Atanpi</code>	<i>s, d</i>	Computes the inverse tangent of vector elements divided by $\pi$
<code>v?Atan2pi</code>	<i>s, d</i>	Computes the four-quadrant inverse tangent of the ratios of the corresponding elements of two vectors divided by $\pi$
<code>v?Cosd</code>	<i>s, d</i>	Computes the cosine of vector elements multiplied by $\pi/180$
<code>v?Sind</code>	<i>s, d</i>	Computes the sine of vector elements multiplied by $\pi/180$
<code>v?Tand</code>	<i>s, d</i>	Computes the tangent of vector elements multiplied by $\pi/180$
<b>Hyperbolic Functions</b>		
<code>v?Cosh</code>	<i>s, d, c, z</i>	Computes the hyperbolic cosine of vector elements
<code>v?Sinh</code>	<i>s, d, c, z</i>	Computes the hyperbolic sine of vector elements
<code>v?Tanh</code>	<i>s, d, c, z</i>	Computes the hyperbolic tangent of vector elements
<code>v?Acosh</code>	<i>s, d, c, z</i>	Computes the inverse hyperbolic cosine of vector elements
<code>v?Asinh</code>	<i>s, d, c, z</i>	Computes the inverse hyperbolic sine of vector elements
<code>v?Atanh</code>	<i>s, d, c, z</i>	Computes the inverse hyperbolic tangent of vector elements.
<b>Special Functions</b>		
<code>v?Erf</code>	<i>s, d</i>	Computes the error function value of vector elements

Function	Data Types	Description
<code>v?Erfc</code>	<i>s, d</i>	Computes the complementary error function value of vector elements
<code>v?CdfNorm</code>	<i>s, d</i>	Computes the cumulative normal distribution function value of vector elements
<code>v?ErfInv</code>	<i>s, d</i>	Computes the inverse error function value of vector elements
<code>v?ErfcInv</code>	<i>s, d</i>	Computes the inverse complementary error function value of vector elements
<code>v?CdfNormInv</code>	<i>s, d</i>	Computes the inverse cumulative normal distribution function value of vector elements
<code>v?LGamma</code>	<i>s, d</i>	Computes the natural logarithm for the absolute value of the gamma function of vector elements
<code>v?TGamma</code>	<i>s, d</i>	Computes the gamma function of vector elements
<code>v?ExpInt1</code>	<i>s, d</i>	Computes the exponential integral of vector elements
<b>Rounding Functions</b>		
<code>v?Floor</code>	<i>s, d</i>	Rounds towards minus infinity
<code>v?Ceil</code>	<i>s, d</i>	Rounds towards plus infinity
<code>v?Trunc</code>	<i>s, d</i>	Rounds towards zero infinity
<code>v?Round</code>	<i>s, d</i>	Rounds to nearest integer
<code>v?NearbyInt</code>	<i>s, d</i>	Rounds according to current mode
<code>v?Rint</code>	<i>s, d</i>	Rounds according to current mode and raising inexact result exception
<code>v?Modf</code>	<i>s, d</i>	Computes the integer and fractional parts
<code>v?Frac</code>	<i>s, d</i>	Computes the fractional part
<b>Miscellaneous Functions</b>		
<code>v?CopySign</code>	<i>s, d</i>	Returns vector of elements of one argument with signs changed to match other argument elements
<code>v?NextAfter</code>	<i>s, d</i>	Returns vector of elements containing the next representable floating-point values following the values from the elements of one vector in the direction of the corresponding elements of another vector
<code>v?Fdim</code>	<i>s, d</i>	Returns vector containing the differences of the corresponding elements of the vector arguments if the first is larger and +0 otherwise
<code>v?Fmax</code>	<i>s, d</i>	Returns the larger of each pair of elements of the two vector arguments
<code>v?Fmin</code>	<i>s, d</i>	Returns the smaller of each pair of elements of the two vector arguments
<code>v?MaxMag</code>	<i>s, d</i>	Returns the element with the larger magnitude between each pair of elements of the two vector arguments
<code>v?MinMag</code>	<i>s, d</i>	Returns the element with the smaller magnitude between each pair of elements of the two vector arguments

## Special Value Notations

This topic defines notations of special values for complex functions. The definitions are provided in text, tables, or formulas.

- $z, z1, z2$ , etc. denote complex numbers.
- $i, i^2=-1$  is the imaginary unit.
- $x, X, x1, x2$ , etc. denote real imaginary parts.
- $y, Y, y1, y2$ , etc. denote imaginary parts.
- $X$  and  $Y$  represent any finite positive IEEE-754 floating point values, if not stated otherwise.
- Quiet NaN and signaling NaN are denoted with `QNaN` and `SNAN`, respectively.
- The IEEE-754 positive infinities or floating-point numbers are denoted with a + sign before  $X, Y$ , etc.
- The IEEE-754 negative infinities or floating-point numbers are denoted with a - sign before  $X, Y$ , etc.

`CONJ(z)` and `CIS(z)` are defined as follows:

$$\text{CONJ}(x+i\cdot y)=x-i\cdot y$$

$\text{CIS}(y) = \cos(y) + i \cdot \sin(y)$ .

The special value tables show the result of the function for the  $z$  argument at the intersection of the  $\text{RE}(z)$  column and the  $i \cdot \text{IM}(z)$  row. If the function raises an exception on the argument  $z$ , the lower part of this cell shows the raised exception and the VM Error Status. An empty cell indicates that this argument is normal and the result is defined mathematically.

## Arithmetic Functions

Arithmetic functions perform the basic mathematical operations like addition, subtraction, multiplication or computation of the absolute value of the vector elements.

### v?Add

*Performs element by element addition of vector  $a$  and vector  $b$ .*

#### Syntax

```
vsAdd( n, a, b, y );
vsAddI(n, a, inca, b, incb, y, incy);
vmsAdd( n, a, b, y, mode );
vmsAddI(n, a, inca, b, incb, y, incy, mode);
vdAdd( n, a, b, y );
vdAddI(n, a, inca, b, incb, y, incy);
vmdAdd( n, a, b, y, mode );
vmdAddI(n, a, inca, b, incb, y, incy, mode);
vcAdd( n, a, b, y );
vcAddI(n, a, inca, b, incb, y, incy);
vmcAdd( n, a, b, y, mode );
vmcAddI(n, a, inca, b, incb, y, incy, mode);
vzAdd( n, a, b, y );
vzAddI(n, a, inca, b, incb, y, incy);
vmzAdd( n, a, b, y, mode );
vmzAddI(n, a, inca, b, incb, y, incy, mode);
```

#### Include Files

- mkl.h

#### Input Parameters

Name	Type	Description
$n$	const MKL_INT	Specifies the number of elements to be calculated.
$a, b$	const float* for vsAdd, vmsAdd const double* for vdAdd, vmdAdd	Pointers to arrays that contain the input vectors $a$ and $b$ .

Name	Type	Description
	const MKL_Complex8* for vcAdd, vmcAdd	
	const MKL_Complex16* for vzAdd, vmzAdd	
<i>inca, incb, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> , <i>b</i> , and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsAdd, vmsAdd double* for vdAdd, vmdAdd MKL_Complex8* for vcAdd, vmcAdd MKL_Complex16* for vzAdd, vmzAdd	Pointer to an array that contains the output vector <i>y</i> .

## Description

The *v?Add* function performs element by element addition of vector *a* and vector *b*.

### Special values for Real Function *v?Add*

Argument 1	Argument 2	Result	Exception
+0	+0	+0	
+0	-0	+0	
-0	+0	+0	
-0	-0	-0	
+∞	+∞	+∞	
+∞	-∞	QNAN	INVALID
-∞	+∞	QNAN	INVALID
-∞	-∞	-∞	
SNAN	any value	QNAN	INVALID
any value	SNAN	QNAN	INVALID
QNAN	non-SNAN	QNAN	
non-SNAN	QNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Add}(x1+i*y1, x2+i*y2) = (x1+x2) + i*(y1+y2)$$

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when all  $\text{RE}(x)$ ,  $\text{RE}(y)$ ,  $\text{IM}(x)$ ,  $\text{IM}(y)$  arguments are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns  $\infty$  in that part of the result, raises the `OVERFLOW` exception, and sets the VM Error Status to `VML_STATUS_OVERFLOW` (overriding any possible `VML_STATUS_ACCURACYWARNING` status).

**v?Sub**

Performs element by element subtraction of vector *b* from vector *a*.

**Syntax**

```
vsSub( n, a, b, y );
vsSubI(n, a, inca, b, incb, y, incy);
vmsSub( n, a, b, y, mode );
vmsSubI(n, a, inca, b, incb, y, incy, mode);
vdSub( n, a, b, y );
vdSubI(n, a, inca, b, incb, y, incy);
vmdSub( n, a, b, y, mode );
vmdSubI(n, a, inca, b, incb, y, incy, mode);
vcSub( n, a, b, y );
vcSubI(n, a, inca, b, incb, y, incy);
vmcSub( n, a, b, y, mode );
vmcSubI(n, a, inca, b, incb, y, incy, mode);
vzSub( n, a, b, y );
vzSubI(n, a, inca, b, incb, y, incy);
vmzSub( n, a, b, y, mode );
vmzSubI(n, a, inca, b, incb, y, incy, mode);
```

**Include Files**

- mkl.h

**Input Parameters**

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a, b</i>	const float* for vsSub, vmsSub const double* for vdSub, vmdSub const MKL_Complex8* for vcSub, vmcSub const MKL_Complex16* for vzSub, vmzSub	Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .
<i>inca, incb, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> , <i>b</i> , and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vm1SetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
$y$	float* for vsSub, vmsSub double* for vdSub, vmdSub MKL_Complex8* for vcSub, vmcSub MKL_Complex16* for vzSub, vmzSub	Pointer to an array that contains the output vector $y$ .

## Description

The  $v?Sub$  function performs element by element subtraction of vector  $b$  from vector  $a$ .

### Special values for Real Function $v?Sub(x)$

Argument 1	Argument 2	Result	Exception
+0	+0	+0	
+0	-0	+0	
-0	+0	-0	
-0	-0	+0

non-SNAN	QNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Sub}(x1+i*y1, x2+i*y2) = (x1-x2) + i*(y1-y2).$$

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when all  $\text{RE}(x)$ ,  $\text{RE}(y)$ ,  $\text{IM}(x)$ ,  $\text{IM}(y)$  arguments are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns  $\infty$  in that part of the result, raises the `OVERFLOW` exception, and sets the VM Error Status to `VML_STATUS_OVERFLOW` (overriding any possible `VML_STATUS_ACCURACYWARNING` status).

## $v?Sqr$

Performs element by element squaring of the vector.

### Syntax

```
vsSqr( n, a, y );
vsSqrI(n, a, inca, y, incy);
vmsSqr( n, a, y, mode );
vmsSqrI(n, a, inca, y, incy, mode);
vdSqr( n, a, y );
vdSqrI(n, a, inca, y, incy);
vmdSqr( n, a, y, mode );
```

```
vmdSqrI(n, a, inca, y, incy, mode);
```

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a, b</i>	const MKL_Complex8* for vcMulByConj, vmcMulByConj const MKL_Complex16* for vzMulByConj, vmzMulByConj	Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .
<i>inca, incb, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> , <i>b</i> , and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	MKL_Complex8* for vcMulByConj, vmcMulByConj MKL_Complex16* for vzMulByConj, vmzMulByConj	Pointer to an array that contains the output vector <i>y</i> .

## Description

The `v?MulByConj` function performs element by element multiplication of vector *a* element and conjugated vector *b* element.

Specifications for special values of the functions are found according to the formula

$$\text{MulByConj}(x1+i*y1, x2+i*y2) = \text{Mul}(x1+i*y1, x2-i*y2).$$

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when all  $\text{RE}(x)$ ,  $\text{RE}(y)$ ,  $\text{IM}(x)$ ,  $\text{IM}(y)$  arguments are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns  $\infty$  in that part of the result, raises the `OVERFLOW` exception, and sets the VM Error Status to `VML_STATUS_OVERFLOW` (overriding any possible `VML_STATUS_ACCURACYWARNING` status).

### v?Conj

*Performs element by element conjugation of the vector.*

### Syntax

```
vcConj( n, a, y );
vcConjI(n, a, inca, y, incy);
vmcConj( n, a, y, mode );
```

```

vmcConjI(n, a, inca, y, incy, mode);
vzConj( n, a, y );

vmzConj( n, a, y, mode );
vmzConjI(n, a, inca, y, incy, mode);

```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const MKL_Complex8* for vcConj, vmcConj const MKL_Complex16* for vzConj, vmzConj	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	MKL_Complex8* for vcConj, vmcConj MKL_Complex16* for vzConj, vmzConj	Pointer to an array that contains the output vector <i>y</i> .

## Description

The `v?Conj` function performs element by element conjugation of the vector.

No special values are specified. The function does not raise floating-point exceptions.

### **v?Abs**

*Computes absolute value of vector elements.*

---

### Syntax

```

vsAbs( n, a, y );
vsAbsI(n, a, inca, y, incy);
vmsAbs( n, a, y, mode );
vmsAbsI(n, a, inca, y, incy, mode);
vdAbs( n, a, y );
vdAbsI(n, a, inca, y, incy);

```

```

vmdAbs( n, a, y, mode );
vmdAbsI(n, a, inca, y, incy, mode);
vcAbs( n, a, y );
vcAbsI(n, a, inca, y, incy);
vmcAbs( n, a, y, mode );
vmcAbsI(n, a, inca, y, incy, mode);
vzAbs( n, a, y );
vzAbsI(n, a, inca, y, incy);
vmzAbs( n, a, y, mode );
vmzAbsI(n, a, inca, y, incy, mode);

```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsAbs, vmsAbs const double* for vdAbs, vmdAbs const MKL_Complex8* for vcAbs, vmcAbs const MKL_Complex16* for vzAbs, vmzAbs	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsAbs, vmsAbs, vcAbs, vmcAbs double* for vdAbs, vmdAbs, vzAbs, vmzAbs	Pointer to an array that contains the output vector <i>y</i> .

## Description

The `v?Abs` function computes an absolute value of vector elements.

## Special Values for Real Function $v?Abs(x)$

Argument	Result	Exception
+0	+0	
-0	+0	
$+\infty$	$+\infty$	
$-\infty$	$+\infty$	
QNAN	QNAN	
SNAN	QNAN	INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$Abs(z) = Hypot(Re(z), Im(z)).$$

## $v?Arg$

*Computes argument of vector elements.*

### Syntax

```
vcArg( n, a, y );
vcArgI(n, a, inca, y, incy);
vmcArg( n, a, y, mode );
vmcArgI(n, a, inca, y, incy, mode);
vzArg( n, a, y );
vzArgI(n, a, inca, y, incy);
vmzArg( n, a, y, mode );
vmzArgI(n, a, inca, y, incy, mode);
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const MKL_Complex8* for vcArg, vmcArg const MKL_Complex16* for vzArg, vmzArg	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vm1SetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
$y$	float* for vcArg, vmcArg double* for vzArg, vmcArg	Pointer to an array that contains the output vector $y$ .

## Description

The  $v?Arg$  function computes argument of vector elements.

See [Special Value Notations](#) for the conventions used in the table below.

### Special Values for Complex Function $v?Arg(z)$

<b>RE(z)</b> <b>i·IM(z)</b> <b>)</b>	<b>-∞</b>	<b>-X</b>	<b>-0</b>	<b>+0</b>	<b>+X</b>	<b>+∞</b>	<b>NAN</b>
$+i·∞$	$+3·\pi/4$	$+\pi/2$	$+\pi/2$	$+\pi/2$	$+\pi/2$	$+\pi/4$	NAN
$+i·Y$	$+\pi$		$+\pi/2$	$+\pi/2$		$+0$	NAN
$+i·0$	$+\pi$	$+\pi$	$+\pi$	$+0$	$+0$	$+0$	NAN
$-i·0$	$-\pi$	$-\pi$	$-\pi$	$-0$	$-0$	$-0$	NAN
$-i·Y$	$-\pi$		$-\pi/2$	$-\pi/2$		$-0$	NAN
$-i·∞$	$-3·\pi/4$	$-\pi/2$	$-\pi/2$	$-\pi/2$	$-\pi/2$	$-\pi/4$	NAN
$+i·NAN$	NAN	NAN	NAN	NAN	NAN	NAN	NAN

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- $Arg(z) = \text{Atan2}(IM(z), RE(z))$ .

## $v?LinearFrac$

Performs linear fraction transformation of vectors  $a$  and  $b$  with scalar parameters.

### Syntax

```
vsLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y );
vsLinearFracI( n, a, inca, b, incb, scalea, shifta, scaleb, shiftb, y, incy );
vmsLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y, mode );
vmsLinearFracI( n, a, inca, b, incb, scalea, shifta, scaleb, shiftb, y, incy, mode );
vdLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y )
vdLinearFracI( n, a, inca, b, incb, scalea, shifta, scaleb, shiftb, y, incy );
vmdLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y, mode );
vmdLinearFracI( n, a, inca, b, incb, scalea, shifta, scaleb, shiftb, y, incy, mode );
```

### Include Files

- `mk1.h`

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a, b</i>	const float* for vsLinearFrac, vmsLinearFrac  const double* for vdLinearFrac, vmdLinearFrac	Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .
<i>inca, incb, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> , <i>b</i> , and <i>y</i> .
<i>scalea, scaleb</i>	const float for vsLinearFrac, vmsLinearFrac  const double for vdLinearFrac, vmdLinearFrac	Constant values for scaling multipliers of vectors <i>a</i> and <i>b</i> .
<i>shiftda, shiftb</i>	const float for vsLinearFrac, vmsLinearFrac  const double for vdLinearFrac, vmdLinearFrac	Constant values for shifting addends of vectors <i>a</i> and <i>b</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsLinearFrac, vmsLinearFrac  double* for vdLinearFrac, vmdLinearFrac	Pointer to an array that contains the output vector <i>y</i> .

## Description

The `v?LinearFrac` function performs a linear fraction transformation of vector *a* by vector *b* with scalar parameters: scaling multipliers *scalea*, *scaleb* and shifting addends *shiftda*, *shiftb*:

$$y[i] = (scalea \cdot a[i] + shiftda) / (scaleb \cdot b[i] + shiftb), i = 1, 2 \dots n$$

The `v?LinearFrac` function is implemented in the EP accuracy mode only, therefore no special values are defined for this function. If used in HA or LA mode, `v?LinearFrac` sets the VM Error Status to `VML_STATUS_ACCURACYWARNING` (see the [Values of the VM Status](#) table). Correctness is guaranteed within the threshold limitations defined for each input parameter (see the table below); otherwise, the behavior is unspecified.

---

### Threshold Limitations on Input Parameters

---

$$2^{E_{MIN}/2} \leq |scalea| \leq 2^{(E_{MAX}-2)/2}$$

---

**Threshold Limitations on Input Parameters**

---

$$2^{E_{\text{MIN}}/2} \leq |scaleb| \leq 2^{(E_{\text{MAX}}-2)/2}$$

$$|shiffta| \leq 2^{E_{\text{MAX}}-2}$$

$$|shifftb| \leq 2^{E_{\text{MAX}}-2}$$

$$2^{E_{\text{MIN}}/2} \leq a[i] \leq 2^{(E_{\text{MAX}}-2)/2}$$

$$2^{E_{\text{MIN}}/2} \leq b[i] \leq 2^{(E_{\text{MAX}}-2)/2}$$

$$a[i] \neq - (shiffta/scalea) * (1-\delta_1), \quad |\delta_1| \leq 2^{1-(p-1)/2}$$

$$b[i] \neq - (shifftb/scaleb) * (1-\delta_2), \quad |\delta_2| \leq 2^{1-(p-1)/2}$$

---

$E_{\text{MIN}}$  and  $E_{\text{MAX}}$  are the minimum and maximum exponents and  $p$  is the number of significant bits (precision) for the corresponding data type according to the ANSI/IEEE Standard 754-2008 ([IEEE754]):

- for single precision  $E_{\text{MIN}} = -126$ ,  $E_{\text{MAX}} = 127$ ,  $p = 24$
- for double precision  $E_{\text{MIN}} = -1022$ ,  $E_{\text{MAX}} = 1023$ ,  $p = 53$

The thresholds become less strict for common cases with  $scalea=0$  and/or  $scaleb=0$ :

- if  $scalea=0$ , there are no limitations for the values of  $a[i]$  and  $shiffta$ .
- if  $scaleb=0$ , there are no limitations for the values of  $b[i]$  and  $shifftb$ .

### Example

To use the `v?LinearFrac` to shift vector  $a$  by a scalar value, set  $scaleb$  to 0. Note that even if  $scaleb$  is 0,  $b$  must be declared.

```
#include <stdio.h>
#include "mkl_vml.h"

int main()
{
    double a[10], *b;
    double r[10];
    double scalea = 1.0, scaleb = 0.0;
    double shiffta = -1.0, shifftb = 1.0;

    MKL_INT i=0,n=10;

    a[0]=-10000.0000;
    a[1]=-7777.7777;
    a[2]=-5555.5555;
    a[3]=-3333.3333;
    a[4]=-1111.1111;
    a[5]=1111.1111;
    a[6]=3333.3333;
    a[7]=5555.5555;
    a[8]=7777.7777;
    a[9]=10000.0000;

    vdLinearFrac( n, a, b, scalea, shiffta, scaleb, shifftb, r );

    for(i=0;i<10;i++) {
        printf("%25.14f %25.14f\n",a[i],r[i]);
    }
}
```

```
return 0;
}
```

To use the `v?LinearFrac` to compute  $shifta/(scaleb \cdot b[i] + shiftb)$ , set `scalea` to 0. Note that even if `scalea` is 0, `a` must be declared.

### v?Fmod

The `v?Fmod` function performs element by element computation of the modulus function of vector `a` with respect to vector `b`.

### Syntax

```
vsFmod (n, a, b, y);
vsFmodI(n, a, inca, b, incb, y, incy);
vmsFmod (n, a, b, y, mode);
vmsFmodI(n, a, inca, b, incb, y, incy, mode);
vdFmod (n, a, b, y);
vdFmodI(n, a, inca, b, incb, y, incy);
vmdFmod (n, a, b, y, mode);
vmdFmodI(n, a, inca, b, incb, y, incy, mode);
```

### Include Files

- `mkl.h`

### Input Parameters

Name	Type	Description
<code>n</code>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<code>a, b</code>	<code>const float*</code> for <code>vsFmod</code> <code>const float*</code> for <code>vmsFmod</code> <code>const double*</code> for <code>vdFmod</code> <code>const double*</code> for <code>vmdFmod</code>	Pointers to arrays containing the input vectors <code>a</code> and <code>b</code> .
<code>inca, incb, incy</code>	<code>const MKL_INT</code>	Specifies increments for the elements of <code>a</code> , <code>b</code> , and <code>y</code> .
<code>mode</code>	<code>const MKL_INT64</code>	Overrides the global VM <code>mode</code> setting for this function call. See <code>vm1SetMode</code> for possible values and their description.

## Output Parameters

Name	Type	Description
$y$	float* for vsFmod float* for vmsFmod double* for vdFmod double* for vmdFmod	Pointer to an array containing the output vector $y$ .

## Description

The  $v?Fmod$  function computes the modulus function of each element of vector  $a$ , with respect to the corresponding elements of vector  $b$ :

$$a_i - b_i * \text{trunc}(a_i/b_i)$$

In general, the modulus function  $fmod(a_i, b_i)$  returns the value  $a_i - n*b_i$  for some integer  $n$  such that if  $b_i$  is nonzero, the result has the same sign as  $a_i$  and a magnitude less than the magnitude of  $b_i$ .

### Special values for Real Function $v?Fmod(x, y)$

Argument 1	Argument 2	Result	VM Error Status	Exception
$x$ not NAN	$\pm 0$	NAN	VML_STATUS_SING	INVALID
$\pm\infty$	$y$ not NAN	NAN	VML_STATUS_SING	INVALID
$\pm 0$	$y \neq 0$ , not NAN	$\pm 0$		
$x$ finite	$\pm\infty$	$x$		UNDERFLOW if $x$ is subnormal
NAN	$y$	NAN		
$x$	NAN	NAN		

### NOTE

If element  $i$  in the result of  $v?Fmod$  is 0, its sign is that of  $a_i$ .

## See Also

[Div](#) Performs element by element division of vector  $a$  by vector  $b$

[Remainder](#) Performs element by element computation of the remainder function on the elements of vector  $a$  and the corresponding elements of vector  $b$ .

### $v?Remainder$

*Performs element by element computation of the remainder function on the elements of vector  $a$  and the corresponding elements of vector  $b$ .*

## Syntax

```
vsRemainder (n, a, b, y);
vsRemainderI(n, a, inca, b, incb, y, incy);
vmsRemainder (n, a, b, y, mode);
vmsRemainderI(n, a, inca, b, incb, y, incy, mode);
vdRemainder (n, a, b, y);
vdRemainderI(n, a, inca, b, incb, y, incy);
```

```
vmdRemainder (n, a, b, y, mode);
```

```
vmdRemainderI(n, a, inca, b, incb, y, incy, mode);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a, b</i>	const float* for vsRemainder const float* for vmsRemainder const double* for vdRemainder const double* for vmdRemainder	Pointers to arrays containing the input vectors <i>a</i> and <i>b</i> .
<i>inca, incb, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> , <i>b</i> , and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides the global VM <i>mode</i> setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsRemainder float* for vmsRemainder double* for vdRemainder double* for vmdRemainder	Pointer to an array containing the output vector <i>y</i> .

## Description

Computes the remainder of each element of vector *a*, with respect to the corresponding elements of vector *b*: compute the values of *n* such that

$$n = a_i - n * b_i$$

where *n* is the integer nearest to the exact value of  $a_i/b_i$ . If two integers are equally close to  $a_i/b_i$ , *n* is the even one. If *n* is zero, it has the same sign as  $a_i$ .

## Special values for Real Function v?Remainder(x, y)

Argument 1	Argument 2	Result	VM Error Status	Exception
x not NAN	±0	NAN	VML_STATUS_DOM	INVALID
±∞	y not NAN	NAN		INVALID
±0	y ≠ 0, not NAN	±0		
x finite	±∞	x		UNDERFLOW if x is subnormal
NAN	y	NAN		

Argument 1	Argument 2	Result	VM Error Status	Exception
$x$	NAN	NAN		

**NOTE**

If element  $i$  in the result of `v?Remainder` is 0, its sign is that of  $a_i$ .

**See Also**

**Div** Performs element by element division of vector  $a$  by vector  $b$

**Fmod** The `v?Fmod` function performs element by element computation of the modulus function of vector  $a$  with respect to vector  $b$ .

**Power and Root Functions****v?Inv**

*Performs element by element inversion of the vector.*

**Syntax**

```
vsInv( n, a, y );
vsInvI(n, a, inca, y, incy);
vmsInv( n, a, y, mode );
vmsInvI(n, a, inca, y, incy, mode);
vdInv( n, a, y );
vdInvI(n, a, inca, y, incy);
vmdInv( n, a, y, mode );
vmdInvI(n, a, inca, y, incy, mode);
```

**Include Files**

- `mkl.h`

**Input Parameters**

Name	Type	Description
$n$	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
$a$	<code>const float*</code> for <code>vsInv</code> , <code>vmsInv</code>  <code>const double*</code> for <code>vdInv</code> , <code>vmdInv</code>	Pointer to an array that contains the input vector $a$ .
$inca, incy$	<code>const MKL_INT</code>	Specifies increments for the elements of $a$ and $y$ .
$mode$	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
$y$	float* for vsInv, vmsInv double* for vdInv, vmdInv	Pointer to an array that contains the output vector $y$ .

## Description

The  $v?Inv$  function performs element by element inversion of the vector.

### Special Values for Real Function $v?Inv(x)$

Argument	Result	VM Error Status	Exception
+0	$+\infty$	VML_STATUS_SING	ZERODIVIDE
-0	$-\infty$	VML_STATUS_SING	ZERODIVIDE
$+\infty$	+0		
$-\infty$	-0		
QNAN	QNAN		
SNAN	QNAN		INVALID

## $v?Div$

*Performs element by element division of vector  $a$  by vector  $b$*

### Syntax

```
vsDiv( n, a, b, y );
vsDivI(n, a, inca, b, incb, y, incy);
vmsDiv( n, a, b, y, mode );
vmsDivI(n, a, inca, b, incb, y, incy, mode);
vdDiv( n, a, b, y );
vdDivI(n, a, inca, b, incb, y, incy);
vmdDiv( n, a, b, y, mode );
vmdDivI(n, a, inca, b, incb, y, incy, mode);
vcDiv( n, a, b, y );
vcDivI(n, a, inca, b, incb, y, incy);
vmcDiv( n, a, b, y, mode );
vmcDivI(n, a, inca, b, incb, y, incy, mode);
vzDiv( n, a, b, y );
vzDivI(n, a, inca, b, incb, y, incy);
vmzDiv( n, a, b, y, mode );
vmzDivI(n, a, inca, b, incb, y, incy, mode);
```

### Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a, b</i>	const float* for vsDiv, vmsDiv const double* for vdDiv, vmdDiv const MKL_Complex8* for vcDiv, vmcDiv const MKL_Complex16* for vzDiv, vmzDiv	Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .
<i>inca, incb, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> , <i>b</i> , and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Precision Overflow Thresholds for Real v?Div Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < \text{abs}(b[i]) * \text{FLT\_MAX}$
double precision	$\text{abs}(a[i]) < \text{abs}(b[i]) * \text{DBL\_MAX}$

Precision overflow thresholds for the complex v?Div function are beyond the scope of this document.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsDiv, vmsDiv double* for vdDiv, vmdDiv MKL_Complex8* for vcDiv, vmcDiv MKL_Complex16* for vzDiv, vmzDiv	Pointer to an array that contains the output vector <i>y</i> .

## Description

The v?Div function performs element by element division of vector *a* by vector *b*.

## Special values for Real Function v?Div(x)

Argument 1	Argument 2	Result	VM Error Status	Exception
X > +0	+0	+∞	VML_STATUS_SING	ZERODIVIDE
X > +0	-0	-∞	VML_STATUS_SING	ZERODIVIDE
X < +0	+0	-∞	VML_STATUS_SING	ZERODIVIDE
X < +0	-0	+∞	VML_STATUS_SING	ZERODIVIDE
+0	+0	QNAN	VML_STATUS_SING	
-0	-0	QNAN	VML_STATUS_SING	
X > +0	+∞	+0		
X > +0	-∞	-0		

Argument 1	Argument 2	Result	VM Error Status	Exception
$+\infty$	$+\infty$	QNAN		
$-\infty$	$-\infty$	QNAN		
QNAN	QNAN	QNAN		
SNAN	SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Div}(x1+i*y1, x2+i*y2) = (x1+i*y1) * (x2-i*y2) / (x2*x2+y2*y2).$$

Overflow in a complex function occurs when  $x2+i*y2$  is not zero,  $x1, x2, y1, y2$  are finite numbers, but the real or imaginary part of the exact result is so large that it does not fit the target precision. In that case, the function returns  $\infty$  in that part of the result, raises the `OVERFLOW` exception, and sets the VM Error Status to `VML_STATUS_OVERFLOW`.

## v?Sqrt

*Computes a square root of vector elements.*

### Syntax

```
vsSqrt( n, a, y );
vsSqrtI(n, a, inca, y, incy);
vmsSqrt( n, a, y, mode );
vmsSqrtI(n, a, inca, y, incy, mode);
vdSqrt( n, a, y );
vdSqrtI(n, a, inca, y, incy);
vmdSqrt( n, a, y, mode );
vmdSqrtI(n, a, inca, y, incy, mode);
vcSqrt( n, a, y );
vcSqrtI(n, a, inca, y, incy);
vmcSqrt( n, a, y, mode );
vmcSqrtI(n, a, inca, y, incy, mode);
vzSqrt( n, a, y );
vzSqrtI(n, a, inca, y, incy);
vmzSqrt( n, a, y, mode );
vmzSqrtI(n, a, inca, y, incy, mode);
```

### Include Files

- `mkl.h`

### Input Parameters

Name	Type	Description
<code>n</code>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.

Name	Type	Description
<i>a</i>	const float* for vsSqrt, vmsSqrt const double* for vdSqrt, vmdSqrt const MKL_Complex8* for vcSqrt, vmcSqrt const MKL_Complex16* for vzSqrt, vmzSqrt	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsSqrt, vmsSqrt double* for vdSqrt, vmdSqrt MKL_Complex8* for vcSqrt, vmcSqrt MKL_Complex16* for vzSqrt, vmzSqrt	Pointer to an array that contains the output vector <i>y</i> .

## Description

The `v?Sqrt` function computes a square root of vector elements.

### Special Values for Real Function `v?Sqrt(x)`

Argument	Result	VM Error Status	Exception
$X < +0$	QNAN	VML_STATUS_ERRDOM	INVALID
$+0$	$+0$		
$-0$	$-0$		
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$+\infty$	$+\infty$		
QNAN	QNAN		
SNAN	QNAN		INVALID

See [Special Value Notations](#) for the conventions used in the table below.

### Special Values for Complex Function `v?Sqrt(z)`

RE(z) i·IM(z)	$-\infty$	$-X$	$-0$	$+0$	$+X$	$+\infty$	NAN
$+i\cdot\infty$	$+\infty+i\cdot\infty$						
$+i\cdot Y$	$+0+i\cdot\infty$					$+\infty+i\cdot 0$	QNAN+i·QNAN

SNAN	QNAN		INVALID

## v?Pow

Computes *a* to the power *b* for elements of two vectors.

## Syntax

```

vsPow( n, a, b, y );
vsPowI(n, a, inca, b, incb, y, incy);
vmsPow( n, a, b, y, mode );
vmsPowI(n, a, inca, b, incb, y, incy, mode);
vdPow( n, a, b, y );
vdPowI(n, a, inca, b, incb, y, incy);
vmdPow( n, a, b, y, mode );
vmdPowI(n, a, inca, b, incb, y, incy, mode);
vcPow( n, a, b, y );
vcPowI(n, a, inca, b, incb, y, incy);
vmcPow( n, a, b, y, mode );
vmcPowI(n, a, inca, b, incb, y, incy, mode);
vzPow( n, a, b, y );
vzPowI(n, a, inca, b, incb, y, incy);
vmzPow( n, a, b, y, mode );
vmzPowI(n, a, inca, b, incb, y, incy, mode);

```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a, b</i>	const float* for vsPow, vmsPow const double* for vdPow, vmdPow const MKL_Complex8* for vcPow, vmcPow const MKL_Complex16* for vzPow, vmzPow	Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .
<i>inca, incb, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> , <i>b</i> , and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vm1SetMode</a> for possible values and their description.

## Precision Overflow Thresholds for Real v?Pow Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < (\text{FLT\_MAX})^{1/b[i]}$

Data Type	Threshold Limitations on Input Parameters
double precision	$\text{abs}(a[i]) < (\text{DBL\_MAX})^{1/b[i]}$

Precision overflow thresholds for the complex  $v?Pow$  function are beyond the scope of this document.

## Output Parameters

Name	Type	Description
$y$	float* for vsPow, vmsPow double* for vdPow, vmdPow MKL_Complex8* for vcPow, vmcPow MKL_Complex16* for vzPow, vmzPow	Pointer to an array that contains the output vector $y$ .

## Description

The  $v?Pow$  function computes  $a$  to the power  $b$  for elements of two vectors.

The real function  $v(s/d)Pow$  has certain limitations on the input range of  $a$  and  $b$  parameters. Specifically, if  $a[i]$  is positive, then  $b[i]$  may be arbitrary. For negative  $a[i]$ , the value of  $b[i]$  must be an integer (either positive or negative).

The complex function  $v(c/z)Pow$  has no input range limitations.

## Special values for Real Function $v?Pow(x,y)$

SNAN	SNAN	QNAN		INVALID

The complex double precision versions of this function, `vzPow` and `vmzPow`, are implemented in the EP accuracy mode only. If used in HA or LA mode, `vzPow` and `vmzPow` set the VM Error Status to `VML_STATUS_ACCURACYWARNING` (see the [Values of the VM Status table](#)).

\* Overflow in a real function is supported only in the HA/LA accuracy modes. The overflow occurs when  $x$  and  $y$  are finite numbers, but the result is too large to fit the target precision. In this case, the function:

1. Returns  $\infty$  in the result.
2. Raises the `OVERFLOW` exception.
3. Sets the VM Error Status to `VML_STATUS_OVERFLOW`.

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when all  $\text{RE}(x)$ ,  $\text{RE}(y)$ ,  $\text{IM}(x)$ ,  $\text{IM}(y)$  arguments are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns  $\infty$  in that part of the result, raises the `OVERFLOW` exception, and sets the VM Error Status to `VML_STATUS_OVERFLOW` (overriding any possible `VML_STATUS_ACCURACYWARNING` status).

## v?Powx

*Computes vector  $a$  to the scalar power  $b$ .*

### Syntax

```
vsPowx( n, a, b, y );
vsPowxI(n, a, inca, b, y, incy);
vmsPowx( n, a, b, y, mode );
vmsPowxI(n, a, inca, b, y, incy, mode);
vdPowx( n, a, b, y );
vdPowxI(n, a, inca, b, y, incy);
vmdPowx( n, a, b, y, mode );
vmdPowxI(n, a, inca, b, y, incy, mode);
vcPowx( n, a, b, y );
vcPowxI(n, a, inca, b, y, incy);
vmcPowx( n, a, b, y, mode );
vmcPowxI(n, a, inca, b, y, incy, mode);
vzPowx( n, a, b, y );
vzPowxI(n, a, inca, b, y, incy);
vmzPowx( n, a, b, y, mode );
vmzPowxI(n, a, inca, b, y, incy, mode);
```

### Include Files

- `mkl.h`

### Input Parameters

Name	Type	Description
$n$	<code>const MKL_INT</code>	Number of elements to be calculated.
$a$	<code>const float*</code> for <code>vsPowx</code> , <code>vmsPowx</code> <code>const double*</code> for <code>vdPowx</code> , <code>vmdPowx</code> <code>const MKL_Complex8*</code> for <code>vcPowx</code> , <code>vmcPowx</code> <code>const MKL_Complex16*</code> for <code>vzPowx</code> , <code>vmzPowx</code>	Pointer to an array that contains the input vector $a$ .
$b$	<code>const float</code> for <code>vsPowx</code> , <code>vmsPowx</code>	Constant value for power $b$ .

Name	Type	Description
	const double for vdPowx, vmdPowx	
	const MKL_Complex8 for vcPowx, vmcPowx	
	const MKL_Complex16 for vzPowx, vmzPowx	
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

### Precision Overflow Thresholds for Real v?Powx Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < (\text{FLT\_MAX})^{1/b}$
double precision	$\text{abs}(a[i]) < (\text{DBL\_MAX})^{1/b}$

Precision overflow thresholds for the complex v?Powx function are beyond the scope of this document.

### Output Parameters

Name	Type	Description
<i>y</i>	float* for vsPowx, vmsPowx double* for vdPowx, vmdPowx MKL_Complex8* for vcPowx, vmcPowx MKL_Complex16* for vzPowx, vmzPowx	Pointer to an array that contains the output vector <i>y</i> .

### Description

The v?Powx function computes *a* to the power *b* for a vector *a* and a scalar *b*.

The real function v(s/d)Powx has certain limitations on the input range of *a* and *b* parameters. Specifically, if *a*[*i*] is positive, then *b* may be arbitrary. For negative *a*[*i*], the value of *b* must be an integer (either positive or negative).

The complex function v(c/z)Powx has no input range limitations.

Special values and VM Error Status treatment are the same as for the v?Pow function.

### v?Powr

*Computes a to the power b for elements of two vectors, where the elements of vector argument a are all non-negative.*

### Syntax

```
vsPowr (n, a, b, y);
vsPowrI(n, a, inca, b, incb, y, incy);
vmsPowr (n, a, b, y, mode);
vmsPowrI(n, a, inca, b, incb, y, incy, mode);
```

```

vdPowr (n, a, b, y);
vdPowrI(n, a, inca, b, incb, y, incy);
vmdPowr (n, a, b, y, mode);
vmdPowrI(n, a, inca, b, incb, y, incy, mode);

```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a, b</i>	const float* for vsPowr const float* for vmsPowr const double* for vdPowr const double* for vmdPowr	Pointers to arrays containing the input vectors <i>a</i> and <i>b</i> .
<i>inca, incb, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> , <i>b</i> , and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides the global VM <i>mode</i> setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsPowr float* for vmsPowr double* for vdPowr double* for vmdPowr	Pointer to an array containing the output vector <i>y</i> .

## Description

The `v?Powr` function raises each element of vector *a* by the corresponding element of vector *b*. The elements of *a* are all nonnegative ( $a_i \geq 0$ ).

### Precision Overflow Thresholds for Real Function v?Powr

Data Type	Threshold Limitations on Input Parameters
single precision	$a_i < (\text{FLT\_MAX})^{1/b_i}$
double precision	$a_i < (\text{DBL\_MAX})^{1/b_i}$

Special values and VM Error Status treatment for `v?Powr` function are the same as for `v?Pow`, unless otherwise indicated in this table:

### Special values for Real Function v?Powr(x)

Argument 1	Argument 2	Result	VM Error Status	Exception

[Pow](#) Computes  $a$  to the power  $b$  for elements of two vectors.

[Powx](#) Computes vector  $a$  to the scalar power  $b$ .

## v?Hypot

Computes a square root of sum of two squared elements.

### Syntax

```
vsHypot( n, a, b, y );
vsHypotI(n, a, inca, b, incb, y, incy);
vmsHypot( n, a, b, y, mode );
vmsHypotI(n, a, inca, b, incb, y, incy, mode);
vdHypot( n, a, b, y );
vdHypotI(n, a, inca, b, incb, y, incy);
vmdHypot( n, a, b, y, mode );
vmdHypotI(n, a, inca, b, incb, y, incy, mode);
```

### Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Number of elements to be calculated.
<i>a, b</i>	const float* for vsHypot, vmsHypot const double* for vdHypot, vmdHypot	Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .
<i>inca, incb, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> , <i>b</i> , and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vm1SetMode</a> for possible values and their description.

## Precision Overflow Thresholds for Hypot Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < \text{sqrt}(\text{FLT\_MAX})$ $\text{abs}(b[i]) < \text{sqrt}(\text{FLT\_MAX})$
double precision	$\text{abs}(a[i]) < \text{sqrt}(\text{DBL\_MAX})$ $\text{abs}(b[i]) < \text{sqrt}(\text{DBL\_MAX})$

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsHypot, vmsHypot double* for vdHypot, vmdHypot	Pointer to an array that contains the output vector <i>y</i> .

## Description

The function `v?Hypot` computes a square root of sum of two squared elements.

## Special values for Real Function `v?Hypot(x)`

Argument 1	Argument 2	Result	Exception

any value	$+\infty$	$+\infty$	
SNAN	any value	QNAN	INVALID
any value	SNAN	QNAN	INVALID
QNAN	any value	QNAN	
any value	QNAN	QNAN	

## Exponential and Logarithmic Functions

**v?Exp**

Computes an exponential of vector elements.

---

**Syntax**

```
vsExp( n, a, y );
vsExpI(n, a, inca, y, incy);
vmsExp( n, a, y, mode );
vmsExpI(n, a, inca, y, incy, mode);
vdExp( n, a, y );
vdExpI(n, a, inca, y, incy);
vmdExp( n, a, y, mode );
vmdExpI(n, a, inca, y, incy, mode);
vcExp( n, a, y );
vcExpI(n, a, inca, y, incy);
vmcExp( n, a, y, mode );
vmcExpI(n, a, inca, y, incy, mode);
vzExp( n, a, y );
vzExpI(n, a, inca, y, incy);
vmzExp( n, a, y, mode );
vmzExpI(n, a, inca, y, incy, mode);
```

**Include Files**

- mkl.h

**Input Parameters**

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsExp, vmsExp const double* for vdExp, vmdExp const MKL_Complex8* for vcExp, vmcExp const MKL_Complex16* for vzExp, vmzExp	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vm1SetMode</a> for possible values and their description.

## Precision Overflow Thresholds for Real $v?Exp$ Function

Data Type	Threshold Limitations on Input Parameters
single precision	$a[i] < \text{Ln}(\text{FLT\_MAX})$
double precision	$a[i] < \text{Ln}(\text{DBL\_MAX})$

Precision overflow thresholds for the complex  $v?Exp$  function are beyond the scope of this document.

## Output Parameters

Name	Type	Description
$y$	float* for vsExp, vmsExp double* for vdExp, vmdExp MKL_Complex8* for vcExp, vmcExp MKL_Complex16* for vzExp, vmzExp	Pointer to an array that contains the output vector $y$ .

## Description

The  $v?Exp$  function computes an exponential of vector elements.

### Special Values for Real Function $v?Exp(x)$

Argument	Result	VM Error Status	Exception
+0	+1		
-0	+1		
$X > \text{overflow}$	$+\infty$	VML_STATUS_OVERFLOW	OVERFLOW
$X < \text{underflow}$	+0	VML_STATUS_UNDERFLOW	UNDERFLOW

<b>RE(z)</b> <b>i·IM(z)</b>	<b>-∞</b>	<b>-X</b>	<b>-0</b>	<b>+0</b>	<b>+X</b>	<b>+∞</b>	<b>NAN</b>
<b>+i·NAN</b> <b>N</b>	<b>+0+i·0</b>	<b>QNAN</b> <b>+i·QNAN</b> <b>INVALID</b>	<b>QNAN</b> <b>+i·QNAN</b> <b>INVALID</b>	<b>QNAN</b> <b>+i·QNAN</b> <b>INVALID</b>	<b>QNAN</b> <b>+i·QNAN</b> <b>INVALID</b>	<b>+∞</b> <b>+i·QNAN</b>	<b>QNAN</b> <b>+i·QNAN</b>

Notes:

- raises the `INVALID` exception when real or imaginary part of the argument is `SNAN`
- raises the `INVALID` exception on argument  $z = -\infty + i \cdot \text{QNAN}$
- raises the `OVERFLOW` exception and sets the VM Error Status to `VML_STATUS_OVERFLOW` in the case of overflow, that is, when both `RE(z)` and `IM(z)` are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.

## v?Exp2

Computes the base 2 exponential of vector elements.

### Syntax

```
vsExp2 (n, a, y);
vsExp2I(n, a, inca, y, incy);
vmsExp2 (n, a, y, mode);
vmsExp2I(n, a, inca, y, incy, mode);
vdExp2 (n, a, y);
vdExp2I(n, a, inca, y, incy);
vmdExp2 (n, a, y, mode);
vmdExp2I(n, a, inca, y, incy, mode);
```

### Include Files

- `mkl.h`

### Input Parameters

<b>Name</b>	<b>Type</b>	<b>Description</b>
<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a</i>	<code>const float*</code> for <code>vsExp2</code> <code>const float*</code> for <code>vmsExp2</code> <code>const double*</code> for <code>vdExp2</code> <code>const double*</code> for <code>vmdExp2</code>	Pointer to the array containing the input vector <i>a</i> .
<i>inca, incy</i>	<code>const MKL_INT</code>	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	<code>const MKL_INT64</code>	Overrides the global VM <i>mode</i> setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
$y$	float* for vsExp2 float* for vmsExp2 double* for vdExp2 double* for vmdExp2	Pointer to an array containing the output vector $y$ .

## Description

The  $v?Exp2$  function computes the base 2 exponential of vector elements.

### Precision Overflow Thresholds for Real Function $v?Exp2$

Data Type	Threshold Limitations on Input Parameters
single precision	$a_i < \log_2(\text{FLT\_MAX})$
double precision	$a_i < \log_2(\text{DBL\_MAX})$

See [Special Value Notations](#) for the conventions used in this table:

Notes:

- raises INVALID exception when real or imaginary part of the argument is SNAN

## v?Log2

Computes the base 2 logarithm of vector elements.

### Syntax

```
vsLog2 (n, a, y);
vsLog2I(n, a, inca, y, incy);
vmsLog2 (n, a, y, mode);
vmsLog2I(n, a, inca, y, incy, mode);
vdLog2 (n, a, y);
vdLog2I(n, a, inca, y, incy);
vmdLog2 (n, a, y, mode);
vmdLog2I(n, a, inca, y, incy, mode);
```

### Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsLog2 const float* for vmsLog2 const double* for vdLog2 const double* for vmdLog2	Pointer to the array containing the input vector <i>a</i> .
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides the global VM <i>mode</i> setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsLog2 float* for vmsLog2 double* for vdLog2 double* for vmdLog2	Pointer to an array containing the output vector <i>y</i> .

## Description

The `v?Log2` function computes the base 2 logarithm of vector elements.

See [Special Value Notations](#) for the conventions used in this table:

### Special values for Real Function `v?Log2(x)`

Argument	Result	VM Error Status	Exception
+1	+0		
$x < +0$	QNAN	VML_STATUS_ERRDOM	INVALID
+0	$-\infty$	VML_STATUS_SING	ZERODIVIDE
-0	$-\infty$	VML_STATUS_SING	ZERODIVIDE
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$+\infty$	$+\infty$		
QNAN	QNAN		
SNAN	QNAN		INVALID

## See Also

[Ln](#) Computes natural logarithm of vector elements.

[Log10](#) Computes the base 10 logarithm of vector elements.

### `v?Log10`

Computes the base 10 logarithm of vector elements.

## Syntax

```

vsLog10( n, a, y );
vsLog10I(n, a, inca, y, incy);
vmsLog10( n, a, y, mode );
vmsLog10I(n, a, inca, y, incy, mode);

### v?Log1p

Computes a natural logarithm of vector elements that are increased by 1.

### Syntax

```
vsLog1p( n, a, y );
vsLog1pI(n, a, inca, y, incy);
vmsLog1p( n, a, y, mode );
vmsLog1pI(n, a, inca, y, incy, mode);
vdLog1p( n, a, y );
vdLog1pI(n, a, inca, y, incy);
vmdLog1p( n, a, y, mode );
vmdLog1pI(n, a, inca, y, incy, mode);
```

### Include Files

- mkl.h

### Input Parameters

<b>Name</b>	<b>Type</b>	<b>Description</b>
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsLog1p, vmsLog1p  const double* for vdLog1p, vmdLog1p	Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsLog1p, vmsLog1p double* for vdLog1p, vmdLog1p	Pointer to an array that contains the output vector <i>y</i> .

## Description

The `v?Log1p` function computes a natural logarithm of vector elements that are increased by 1.

### Special Values for Real Function `v?Log1p(x)`

Argument	Result	VM Error Status	Exception
-1	$-\infty$	VML_STATUS_SING	ZERODIVIDE
$X < -1$	QNAN	VML_STATUS_ERRDOM	INVALID
+0	+0		
-0	-0

$+\infty$	$+\infty$		
QNAN	QNAN		
SNAN	QNAN		INVALID

## `v?Logb`

*Computes the exponents of the elements of input vector *a*.*

## Syntax

```
vsLogb (n, a, y);
vsLogbI(n, a, inca, y, incy);
vmsLogb (n, a, y, mode);
vmsLogbI(n, a, inca, y, incy, mode);
vdLogb (n, a, y);
vdLogbI(n, a, inca, y, incy);
vmdLogb (n, a, y, mode);
vmdLogbI(n, a, inca, y, incy, mode);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
$n$	const MKL_INT	Specifies the number of elements to be calculated.
$a$	const float* for vsLogb const float* for vmsLogb const double* for vdLogb const double* for vmdLogb	Pointer to the array containing the input vector $a$ .
$inca, incy$	const MKL_INT	Specifies increments for the elements of $a$ and $y$ .
$mode$	const MKL_INT64	Overrides the global VM $mode$ setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
$y$	float* for vsLogb float* for vmsLogb double* for vdLogb double* for vmdLogb	Pointer to an array containing the output vector $y$ .

## Description

The  $v?Logb$  function computes the exponents of the elements of the input vector  $a$ . For each element  $a_i$  of vector  $a$ , this is the integral part of  $\log_2|a_i|$ . The returned value is exact and is independent of the current rounding direction mode.

See [Special Value Notations](#) for the conventions used in this table:

### Special values for Real Function $v?Logb(x)$

## Trigonometric Functions

### $v?Cos$

*Computes cosine of vector elements.*

### Syntax

```
vsCos( n, a, y );
```

```

vsCosI(n, a, inca, y, incy);
vmsCos( n, a, y, mode );
vmsCosI(n, a, inca, y, incy, mode);
vdCos( n, a, y );
vdCosI(n, a, inca, y, incy);
vmdCos( n, a, y, mode );
vmdCosI(n, a, inca, y, incy, mode);
vcCos( n, a, y );
vcCosI(n, a, inca, y, incy);
vmcCos( n, a, y, mode );
vmcCosI(n, a, inca, y, incy, mode);
vzCos( n, a, y );
vzCosI(n, a, inca, y, incy);
vmzCos( n, a, y, mode );
vmzCosI(n, a, inca, y, incy, mode);

```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsCos, vmsCos const double* for vdCos, vmdCos const MKL_Complex8* for vcCos, vmcCos const MKL_Complex16* for vzCos, vmzCos	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vm1SetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsCos, vmsCos double* for vdCos, vmdCos MKL_Complex8* for vcCos, vmcCos	Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
------	------	-------------

MKL\_Complex16\* for vzCos, vmzCos

## Description

The `v?Cos` function computes cosine of vector elements.

Note that arguments  $\text{abs}(a[i]) \leq 2^{13}$  and  $\text{abs}(a[i]) \leq 2^{16}$  for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VM provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VM High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VM Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

### Special Values for Real Function `v?Cos(x)`

Argument	Result	VM Error Status	Exception
+0	+1		
-0	+1		
$+\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Cos}(z) = \text{Cosh}(i*z).$$

#### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

## `v?Sin`

*Computes sine of vector elements.*

### Syntax

```
vsSin( n, a, y );
vsSinI(n, a, inca, y, incy);
vmsSin( n, a, y, mode );
vmsSinI(n, a, inca, y, incy, mode);
vdSin( n, a, y );
vdSinI(n, a, inca, y, incy);
vmdSin( n, a, y, mode );
vmdSinI(n, a, inca, y, incy, mode);
vcSin( n, a, y );
vcSinI(n, a, inca, y, incy);
vmcSin( n, a, y, mode );
vmcSinI(n, a, inca, y, incy, mode);
```

```

vzSin( n, a, y );
vzSinI(n, a, inca, y, incy);
vmzSin( n, a, y, mode );
vmzSinI(n, a, inca, y, incy, mode);

```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsSin, vmsSin const double* for vdSin, vmdSin const MKL_Complex8* for vcSin, vmcSin const MKL_Complex16* for vzSin, vmzSin	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsSin, vmsSin double* for vdSin, vmdSin MKL_Complex8* for vcSin, vmcSin MKL_Complex16* for vzSin, vmzSin	Pointer to an array that contains the output vector <i>y</i> .

## Description

The function computes sine of vector elements.

Note that arguments  $\text{abs}(a[i]) \leq 2^{13}$  and  $\text{abs}(a[i]) \leq 2^{16}$  for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VM provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VM High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VM Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

### Special Values for Real Function v?Sin(x)

Notice revision #20201201

## $v?CIS$

*Computes complex exponent of real vector elements (cosine and sine of real vector elements combined to complex value).*

### Syntax

```
vcCIS( n, a, y );
vcCISI(n, a, inca, y, incy);
vmcCIS( n, a, y, mode );
vmcCISI(n, a, inca, y, incy, mode);
vzCIS( n, a, y );
vzCISI(n, a, inca, y, incy);
vmzCIS( n, a, y, mode );
vmzCISI(n, a, inca, y, incy, mode);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vcCIS, vmcCIS const double* for vzCIS, vmzCIS	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	MKL_Complex8* for vcCIS, vmcCIS MKL_Complex16* for vzCIS, vmzCIS	Pointer to an array that contains the output vector <i>y</i> .

## Description

The `v?CIS` function computes complex exponent of real vector elements (cosine and sine of real vector elements combined to complex value).

See [Special Value Notations](#) for the conventions used in the table below.

### Special Values for Complex Function `v?CIS(x)`

<b>x</b>	<b>CIS(x)</b>
+ ∞	QNAN+i·QNAN INVALID
+ 0	+1+i·0
- 0	+1-i·0
- ∞	QNAN+i·QNAN INVALID
NAN	QNAN+i·QNAN

Notes:

- raises `INVALID` exception when the argument is `SNAN`
- raises `INVALID` exception and sets the VM Error Status to `VML_STATUS_ERRDOM` for  $x=+\infty$ ,  $x=-\infty$

### `v?Tan`

*Computes tangent of vector elements.*

## Syntax

```

vsTan( n, a, y );
vsTanI(n, a, inca, y, incy);
vmsTan( n, a, y, mode );
vmsTanI(n, a, inca, y, incy, mode);
vdTan( n, a, y );
vdTanI(n, a, inca, y, incy);
vmdTan( n, a, y, mode );
vmdTanI(n, a, inca, y, incy, mode);
vcTan( n, a, y );
vcTanI(n, a, inca, y, incy);
vmcTan( n, a, y, mode );
vmcTanI(n, a, inca, y, incy, mode);
vzTan( n, a, y );
vzTanI(n, a, inca, y, incy);
vmzTan( n, a, y, mode );
vmzTanI(n, a, inca, y, incy, mode);

```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a</i>	<code>const float*</code> for <code>vsTan</code> , <code>vmsTan</code> <code>const double*</code> for <code>vdTan</code> , <code>vmdTan</code> <code>const MKL_Complex8*</code> for <code>vcTan</code> , <code>vmcTan</code> <code>const MKL_Complex16*</code> for <code>vzTan</code> , <code>vmzTan</code>	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	<code>const MKL_INT</code>	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
$y$	float* for vsTan, vmsTan double* for vdTan, vmdTan MKL_Complex8* for vcTan, vmcTan MKL_Complex16* for vzTan, vmzTan	Pointer to an array that contains the output vector $y$ .

## Description

The  $v?Tan$  function computes tangent of vector elements.

Note that arguments  $abs(a[i]) \leq 2^{13}$  and  $abs(a[i]) \leq 2^{16}$  for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VM provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VM High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VM Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

### Special Values for Real Function $v?Tan(x)$

Argument	Result	VM Error Status	Exception
+0	+0		
-0	-0		
$+\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\tan(z) = -i \cdot \tanh(i \cdot z).$$

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## $v?Acos$

*Computes inverse cosine of vector elements.*

### Syntax

```
vsAcos( n, a, y );
vsAcosI(n, a, inca, y, incy);
vmsAcos( n, a, y, mode );
vmsAcosI(n, a, inca, y, incy, mode);

$+\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Asin}(z) = -i \cdot \text{Asinh}(i \cdot z).$$

### v?Atan

*Computes inverse tangent of vector elements.*

#### Syntax

```
vsAtan( n, a, y );
vsAtanI(n, a, inca, y, incy);
vmsAtan( n, a, y, mode );
vmsAtanI(n, a, inca, y, incy, mode);
vdAtan( n, a, y );
vdAtanI(n, a, inca, y, incy);
vmdAtan( n, a, y, mode );
vmdAtanI(n, a, inca, y, incy, mode);
vcAtan( n, a, y );
vcAtanI(n, a, inca, y, incy);
vmcAtan( n, a, y, mode );
vmcAtanI(n, a, inca, y, incy, mode);
vzAtan( n, a, y );
vzAtanI(n, a, inca, y, incy);
vmzAtan( n, a, y, mode );
vmzAtanI(n, a, inca, y, incy, mode);
```

#### Include Files

- mkl.h

#### Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsAtan, vmsAtan	Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	const double* for vdAtan, vmdAtan const MKL_Complex8* for vcAtan, vmcAtan const MKL_Complex16* for vzAtan, vmzAtan	
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsAtan, vmsAtan double* for vdAtan, vmdAtan MKL_Complex8* for vcAtan, vmcAtan MKL_Complex16* for vzAtan, vmzAtan	Pointer to an array that contains the output vector <i>y</i> .

## Description

The *v?Atan* function computes inverse tangent of vector elements.

### Special Values for Real Function *v?Atan(x)*

Argument	Result	VM Error Status	Exception
+0	+0		
-0	-0		
$+\infty$	$+\pi/2$		
$-\infty$	$-\pi/2$		
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Atan}(z) = -i * \text{Atanh}(i * z).$$

### *v?Atan2*

Computes four-quadrant inverse tangent of elements of two vectors.

### Syntax

```
vsAtan2( n, a, b, y );
vsAtan2I(n, a, inca, b, incb, y, incy);
vmsAtan2( n, a, b, y, mode );
vmsAtan2I(n, a, inca, b, incb, y, incy, mode);
vdAtan2( n, a, b, y );
```

```
vdAtan2I(n, a, inca, b, incb, y, incy);
vmdAtan2( n, a, b, y, mode );
vmdAtan2I(n, a, inca, b, incb, y, incy, mode);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a, b</i>	const float* for vsAtan2, vmsAtan2  const double* for vdAtan2, vmdAtan2	Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .
<i>inca, incb, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> , <i>b</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsAtan2, vmsAtan2  double* for vdAtan2, vmdAtan2	Pointer to an array that contains the output vector <i>y</i> .

## Description

The `v?Atan2` function computes four-quadrant inverse tangent of elements of two vectors.

The elements of the output vector *y* are computed as the four-quadrant arctangent of  $a[i] / b[i]$ .

## v?Cospi

Computes the cosine of vector elements multiplied by  $\pi$ .

### Syntax

```
vsCospi (n, a, y);
```

```
vsCospiI(n, a, inca, y, incy);
```

```
vmsCospi (n, a, y, mode);
```

```
vmsCospiI(n, a, inca, y, incy, mode);
```

```
vdCospi (n, a, y);
```

```
vdCospiI(n, a, inca, y, incy);
```

```
vmdCospi (n, a, y, mode);
```

```
vmdCospiI(n, a, inca, y, incy, mode);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
$n$	const MKL_INT	Specifies the number of elements to be calculated.
$a$	const float* for vsCospi const float* for vmsCospi const double* for vdCospi const double* for vmdCospi	Pointer to the array containing the input vector $a$ .
$inca, incy$	const MKL_INT	Specifies increments for the elements of $a$ and $y$ .
$mode$	const MKL_INT64	Overrides the global VM $mode$ setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
$y$	float* for vsCospi float* for vmsCospi double* for vdCospi double* for vmdCospi	Pointer to an array containing the output vector $y$ .

## Description

The `v?Cospi` function computes the cosine of vector elements multiplied by  $n$ . For an argument  $x$ , the function computes  $\cos(n*x)$ .

### Special values for Real Function `v?Cospi(x)`

Argument	Result	VM Error Status	Exception
+0	+1		
-0	+1		
$n + 0.5$ , for any integer $n$ where $n + 0.5$ is representable	+0		
$\pm\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

## Application Notes

If arguments  $\text{abs}(a_i) \leq 2^{22}$  for single precision or  $\text{abs}(a_i) \leq 2^{43}$  for double precision, they belong to the *fast computational path*: arguments for which VM provides the best possible performance. Avoid arguments which do not belong to the fast computational path in VM High Accuracy (HA) or Low Accuracy (LA) functions. For arguments which do not belong to the fast computational path you can use VM Enhanced Performance (EP) functions, which are fast on the entire function domain. However, these functions provide lower accuracy.

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a, b</i>	const float* for vsAtan2pi const float* for vmsAtan2pi const double* for vdAtan2pi const double* for vmdAtan2pi	Pointers to the arrays containing the input vectors <i>a</i> and <i>b</i> .
<i>inca, incb, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> , <i>b</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides the global VM <i>mode</i> setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
$y$	float* for vsAtan2pi float* for vmsAtan2pi double* for vdAtan2pi double* for vmdAtan2pi	Pointer to an array containing the output vector $y$ .

## Description

The  $v?Atan2pi$  function computes the four-quadrant inverse tangent of the ratios of the corresponding elements of two vectors divided by  $n$ .

For the elements of the output vector  $y$ , the function computes the four-quadrant arctangent of  $a_i/b_i$ , with the result divided by  $n$ .

### Special values for Real Function $v?Atan2pi(x, y)$

vmdCosd (n, a, y, mode);
vmdCosdI(n, a, inca, y, incy, mode);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsCosd const float* for vmsCosd const double* for vdCosd const double* for vmdCosd	Pointer to the array containing the input vector <i>a</i> .
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .

Name	Type	Description
<code>mode</code>	<code>const MKL_INT64</code>	Overrides the global VM <code>mode</code> setting for this function call. See <code>vmlSetMode</code> for possible values and their description.

## Output Parameters

Name	Type	Description
<code>y</code>	<code>float*</code> for <code>vsCosd</code> <code>float*</code> for <code>vmsCosd</code> <code>double*</code> for <code>vdCosd</code> <code>double*</code> for <code>vmdCosd</code>	Pointer to an array containing the output vector <code>y</code> .

## Description

The `v?Cosd` function computes the cosine of vector elements multiplied by  $n/180$ . For an argument  $x$ , the function computes  $\cos(n*x/180)$ .

### Special values for Real Function `v?Cosd(x)`

Argument	Result	VM Error Status	Exception
+0	+1		
-0	+1		
$\pm\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

## Application Notes

If arguments  $\text{abs}(a_i) \leq 2^{24}$  for single precision or  $\text{abs}(a_i) \leq 2^{52}$  for double precision, they belong to the *fast computational path*: arguments for which VM provides the best possible performance. Avoid arguments which do not belong to the fast computational path in VM High Accuracy (HA) or Low Accuracy (LA) functions. For arguments which do not belong to the fast computational path you can use VM Enhanced Performance (EP) functions, which are fast on the entire function domain. However, these functions provide lower accuracy.

## Precision Overflow Thresholds for Real v?Cosh Function

Data Type	Threshold Limitations on Input Parameters
single precision	$-\ln(\text{FLT\_MAX}) - \ln 2 < a[i] < \ln(\text{FLT\_MAX}) + \ln 2$
double precision	$-\ln(\text{DBL\_MAX}) - \ln 2 < a[i] < \ln(\text{DBL\_MAX}) + \ln 2$

Precision overflow thresholds for the complex *v?Cosh* function are beyond the scope of this document.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsCosh, vmsCosh double* for vdCosh, vmdCosh MKL_Complex8* for vcCosh, vmcCosh	Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
------	------	-------------

MKL\_Complex16\* for vzCosh,  
vmzCosh

## Description

The `v?Cosh` function computes hyperbolic cosine of vector elements.

### Special Values for Real Function `v?Cosh(x)`

Argument	Result	VM Error Status	Exception
+0	+1		
-0	+1		
X > overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
X < -overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
+∞	+∞		
-∞	+∞		
QNAN	QNAN		
SNAN	QNAN		INVALID

See [Special Value Notations](#) for the conventions used in the table below.

### Special Values for Complex Function `v?Cosh(z)`

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	+∞ +i·QNAN INVALID	QNAN +i·QNAN INVALID	QNAN-i·0 INVALID	QNAN+i·0 INVALID	QNAN +i·QNAN INVALID	+∞ +i·QNAN INVALID	QNAN +i·QNAN

## Input Parameters

Name	Type	Description
<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a</i>	<code>const float*</code> for <code>vsAcosh</code> , <code>vmsAcosh</code>  <code>const double*</code> for <code>vdAcosh</code> , <code>vmdAcosh</code>  <code>const MKL_Complex8*</code> for <code>vcAcosh</code> , <code>vmcAcosh</code>  <code>const MKL_Complex16*</code> for <code>vzAcosh</code> , <code>vmzAcosh</code>	Pointer to an array that contains the input vector <i>a</i> .
<i>inca</i> , <i>incy</i>	<code>cnst MKL_INT</code>	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	<code>float*</code> for <code>vsAcosh</code> , <code>vmsAcosh</code>  <code>double*</code> for <code>vdAcosh</code> , <code>vmdAcosh</code>  <code>MKL_Complex8*</code> for <code>vcAcosh</code> , <code>vmcAcosh</code>  <code>MKL_Complex16*</code> for <code>vzAcosh</code> , <code>vmzAcosh</code>	Pointer to an array that contains the output vector <i>y</i> .

## Description

The `v?Acosh` function computes inverse hyperbolic cosine (nonnegative) of vector elements.

### Special Values for Real Function `v?Acosh(x)`

Notes:

- $Atanh(+1-i \cdot 0) = -\infty - i \cdot 0$ , and ZERODIVIDE exception is raised
- raises INVALID exception when real or imaginary part of the argument is SNAN
- $Atanh(CONJ(z)) = CONJ(Atanh(z))$
- $Atanh(-z) = -Atanh(z)$ .

## Special Functions

### $v?Erf$

*Computes the error function value of vector elements.*

#### Syntax

```
vsErf( n, a, y );
vsErfI( n, a, inca, y, incy );
vmsErf( n, a, y, mode );
vmsErfI( n, a, inca, y, incy, mode );
vdErf( n, a, y );
vdErfI( n, a, inca, y, incy );
vmdErf( n, a, y, mode );
```

```
vmdErfI(n, a, inca, y, incy, mode);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>n</code>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<code>a</code>	<code>const float*</code> for <code>vsErf</code> , <code>vmsErf</code> <code>const double*</code> for <code>vdErf</code> , <code>vmdErf</code>	Pointer to an array that contains the input vector <code>a</code> .
<code>inca</code> , <code>incy</code>	<code>const MKL_INT</code>	Specifies increments for the elements of <code>a</code> and <code>y</code> .
<code>mode</code>	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See <a href="#">vm1SetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<code>y</code>	<code>float*</code> for <code>vsErf</code> , <code>vmsErf</code> <code>double*</code> for <code>vdErf</code> , <code>vmdErf</code>	Pointer to an array that contains the output vector <code>y</code> .

## Description

The `Erf` function computes the error function values for elements of the input vector `a` and writes them to the output vector `y`.

The error function is defined as given by:

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt .$$

Useful relations:

1.  $\text{erfc}(x) = 1 - \text{erf}(x)$ ,

where `erfc` is the complementary error function.

2.  $\Phi(x) = \frac{1}{2} \text{erf}(x/\sqrt{2})$ ,

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

is the cumulative normal distribution function.

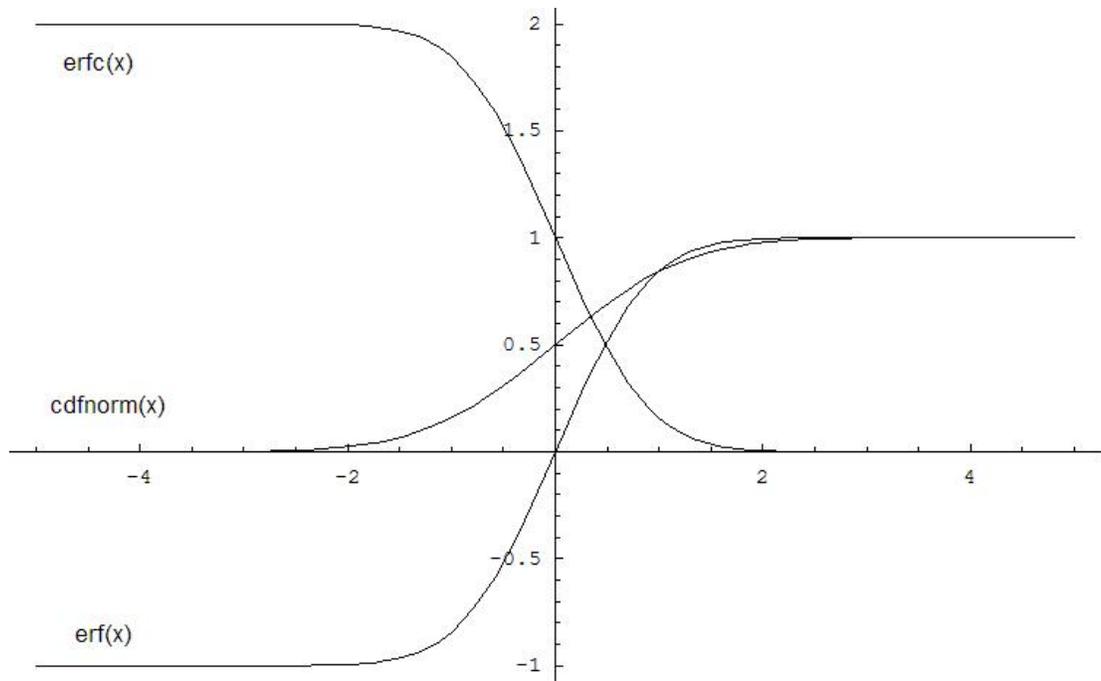

$$3. \Phi^{-1}(x) = \sqrt{2} \operatorname{erf}^{-1}(2x - 1),$$

where  $\Phi^{-1}(x)$  and  $\operatorname{erf}^{-1}(x)$  are the inverses to  $\Phi(x)$  and  $\operatorname{erf}(x)$  respectively.

The following figure illustrates the relationships among Erf family functions (Erf, Erfc, CdfNorm).

\_\_border\_\_top

### Erf Family Functions Relationship

Useful relations for these functions:

$$\operatorname{erf}(x) + \operatorname{erfc}(x) = 1$$

$$\operatorname{cdfnorm}(x) = \frac{1}{2} \left( 1 + \operatorname{erf} \left( \frac{x}{\sqrt{2}} \right) \right) = 1 - \frac{1}{2} \operatorname{erfc} \left( \frac{x}{\sqrt{2}} \right)$$

## Input Parameters

Name	Type	Description
<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a</i>	<code>const float*</code> for <code>vsErfc</code> , <code>vmsErfc</code> <code>const double*</code> for <code>vdErfc</code> , <code>vmdErfc</code>	Pointer to an array that contains the input vector <i>a</i> .
<i>inca</i> , <i>incy</i>	<code>const MKL_INT</code>	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	<code>float*</code> for <code>vsErfc</code> , <code>vmsErfc</code> <code>double*</code> for <code>vdErfc</code> , <code>vmdErfc</code>	Pointer to an array that contains the output vector <i>y</i> .

## Description

The `Erfc` function computes the complementary error function values for elements of the input vector  $a$  and writes them to the output vector  $y$ .

The complementary error function is defined as follows:

$$\operatorname{erfc}(x) = \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt .$$

Useful relations:

1.  $\operatorname{erfc}(x) = 1 - \operatorname{erf}(x)$ .
2.  $\Phi(x) = \frac{1}{2} \operatorname{erf}(x/\sqrt{2})$ ,

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

is the cumulative normal distribution function.

$$3. \Phi^{-1}(x) = \sqrt{2} \operatorname{erf}^{-1}(2x - 1),$$

where  $\Phi^{-1}(x)$  and  $\operatorname{erf}^{-1}(x)$  are the inverses to  $\Phi(x)$  and  $\operatorname{erf}(x)$  respectively.

See also [Figure "Erf Family Functions Relationship"](#) in `Erf` function description for `Erfc` function relationship with the other functions of `Erf` family.

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsCdfNorm, vmsCdfNorm  const double* for vdCdfNorm, vmdCdfNorm	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vm1SetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsCdfNorm, vmsCdfNorm double* for vdCdfNorm, vmdCdfNorm	Pointer to an array that contains the output vector <i>y</i> .

## Description

The `CdfNorm` function computes the cumulative normal distribution function values for elements of the input vector *a* and writes them to the output vector *y*.

The cumulative normal distribution function is defined as given by:

$$\text{CdfNorm}(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{t^2}{2}} dt .$$

Useful relations:

$$\text{cdfnorm}(x) = \frac{1}{2} \left( 1 + \text{erf} \left( \frac{x}{\sqrt{2}} \right) \right) = 1 - \frac{1}{2} \text{erfc} \left( \frac{x}{\sqrt{2}} \right)$$

where `Erf` and `Erfc` are the error and complementary error functions.

See also [Figure "Erf Family Functions Relationship"](#) in `Erf` function description for `CdfNorm` function relationship with the other functions of `Erf` family.

Name	Type	Description
<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a</i>	<code>const float*</code> for <code>vsErfInv</code> , <code>vmsErfInv</code>	Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	const double* for vdErfInv, vmdErfInv	
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsErfInv, vmsErfInv double* for vdErfInv, vmdErfInv	Pointer to an array that contains the output vector <i>y</i> .

## Description

The `ErfInv` function computes the inverse error function values for elements of the input vector *a* and writes them to the output vector *y*

$$y = \text{erf}^{-1}(a),$$

where `erf(x)` is the error function defined as given by:

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt .$$

Useful relations:

$$1. \text{erf}^{-1}(x) = \text{erfc}^{-1}(1 - x),$$

where `erfc` is the complementary error function.

$$2. \Phi(x) = \frac{1}{2} \text{erf}(x/\sqrt{2}),$$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

is the cumulative normal distribution function.

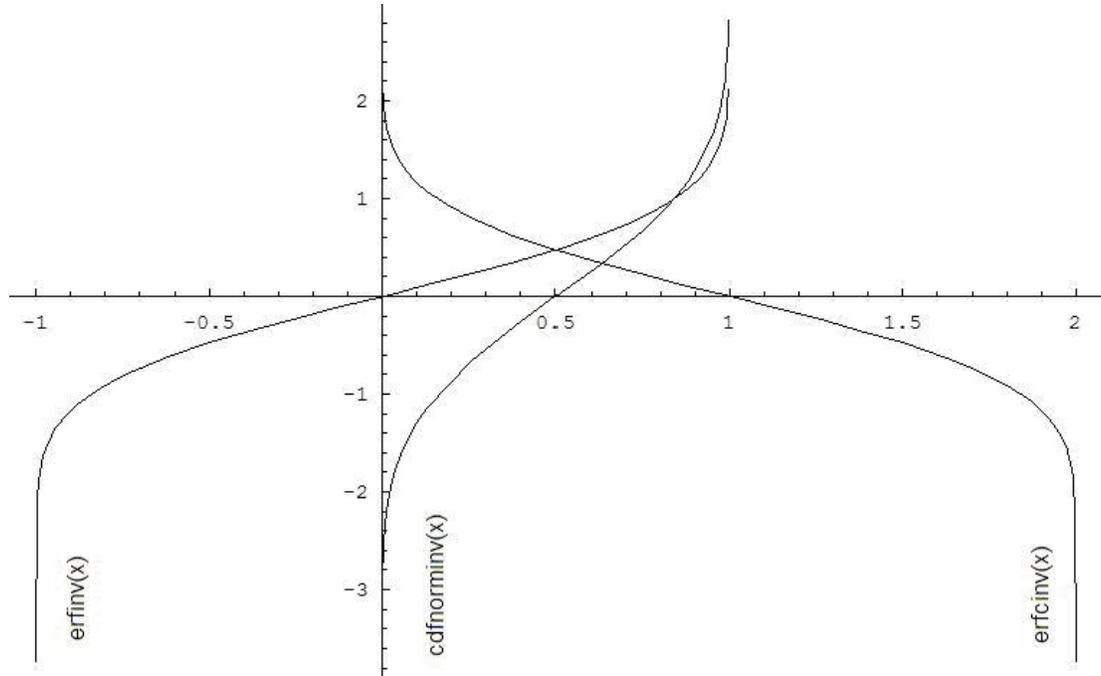

$$3. \Phi^{-1}(x) = \sqrt{2} \operatorname{erf}^{-1}(2x - 1),$$

where  $\Phi^{-1}(x)$  and  $\operatorname{erf}^{-1}(x)$  are the inverses to  $\Phi(x)$  and  $\operatorname{erf}(x)$  respectively.

Figure "ErfInv Family Functions Relationship" illustrates the relationships among ErfInv family functions (ErfInv, ErfcInv, CdfNormInv).

\_\_border\_\_top

### ErfInv Family Functions Relationship

Useful relations for these functions:

$$\operatorname{erfcinv}(x) = \operatorname{erfinv}(1 - x)$$

$$\operatorname{cdfnorminv}(x) = \sqrt{2}\operatorname{erfinv}(2x - 1) = \sqrt{2}\operatorname{erfcinv}(2 - 2x)$$

<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a</i>	<code>const float*</code> for <code>vsErfcInv</code> , <code>vmsErfcInv</code>  <code>const double*</code> for <code>vdErfcInv</code> , <code>vmdErfcInv</code>	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	<code>const MKL_INT</code>	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	<code>float*</code> for <code>vsErfcInv</code> , <code>vmsErfcInv</code> <code>double*</code> for <code>vdErfcInv</code> , <code>vmdErfcInv</code>	Pointer to an array that contains the output vector <i>y</i> .

## Description

The `ErfcInv` function computes the inverse complimentary error function values for elements of the input vector  $a$  and writes them to the output vector  $y$ .

The inverse complimentary error function is defined as given by:

$$\text{erfcinv}(x) = \text{erfinv}(1 - x)$$

$$\text{erfinv}(x) = \text{erf}^{-1}(x)$$

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

where  $\text{erf}(x)$  denotes the error function and  $\text{erfinv}(x)$  denotes the inverse error function.

See also [Figure "ErfInv Family Functions Relationship"](#) in `ErfInv` function description for `ErfcInv` function relationship with the other functions of `ErfInv` family.

#### `v?CdfNormInv`

*Computes the inverse cumulative normal distribution function values of vector elements.*

## Syntax

```

vsCdfNormInv( n, a, y );
vsCdfNormInvI(n, a, inca, y, incy);
vmsCdfNormInv( n, a, y, mode );
vmsCdfNormInvI(n, a, inca, y, incy, mode);
vdCdfNormInv( n, a, y );
vdCdfNormInvI(n, a, inca, y, incy);
vmdCdfNormInv( n, a, y, mode );
vmdCdfNormInvI(n, a, inca, y, incy, mode);

```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a</i>	<code>const float*</code> for <code>vsCdfNormInv</code> , <code>vmsCdfNormInv</code>  <code>const double*</code> for <code>vdCdfNormInv</code> , <code>vmdCdfNormInv</code>	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	<code>const MKL_INT</code>	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	<code>float*</code> for <code>vsCdfNormInv</code> , <code>vmsCdfNormInv</code>  <code>double*</code> for <code>vdCdfNormInv</code> , <code>vmdCdfNormInv</code>	Pointer to an array that contains the output vector <i>y</i> .

## Description

The `CdfNormInv` function computes the inverse cumulative normal distribution function values for elements of the input vector *a* and writes them to the output vector *y*.

The inverse cumulative normal distribution function is defined as given by:

$$\text{CdfNormInv}(x) = \text{CdfNorm}^{-1}(x) ,$$

where  $\text{CdfNorm}(x)$  denotes the cumulative normal distribution function.

Useful relations:

$$\text{cdfnorminv}(x) = \sqrt{2}\text{erfinv}(2x - 1) = \sqrt{2}\text{erfcinv}(2 - 2x)$$

where  $\text{erfinv}(x)$  denotes the inverse error function and  $\text{erfcinv}(x)$  denotes the inverse complementary error functions.

See also [Figure "ErfInv Family Functions Relationship"](#) in [ErfInv](#) function description for [CdfNormInv](#) function relationship with the other functions of [ErfInv](#) family.

### Special Values for Real Function v?CdfNormInv(x)

Argument	Result	VM Error Status	Exception
+0.5	+0		
+1	$+\infty$	VML_STATUS_SING	ZERODIVIDE

### v?LGamma

*Computes the natural logarithm of the absolute value of gamma function for vector elements.*

### Syntax

```
vsLGamma( n, a, y );
vsLGammaI(n, a, inca, y, incy);
vmsLGamma( n, a, y, mode );
vmsLGammaI(n, a, inca, y, incy, mode);
vdLGamma( n, a, y );
vdLGammaI(n, a, inca, y, incy);
vmdLGamma( n, a, y, mode );
vmdLGammaI(n, a, inca, y, incy, mode);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a</i>	<code>const float*</code> for <code>vsLGamma</code> , <code>vmsLGamma</code>  <code>const double*</code> for <code>vdLGamma</code> , <code>vmdLGamma</code>	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	<code>const MKL_INT</code>	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See <code>vmlSetMode</code> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	<code>float*</code> for <code>vsLGamma</code> , <code>vmsLGamma</code>  <code>double*</code> for <code>vdLGamma</code> , <code>vmdLGamma</code>	Pointer to an array that contains the output vector <i>y</i> .

## Description

The `v?LGamma` function computes the natural logarithm of the absolute value of gamma function for elements of the input vector *a* and writes them to the output vector *y*. Precision overflow thresholds for the `v?LGamma` function are beyond the scope of this document. If the result does not meet the target precision, the function raises the `OVERFLOW` exception and sets the VM Error Status to `VML_STATUS_OVERFLOW`.

### Special Values for Real Function `v?LGamma(x)`

Argument	Result	VM Error Status	Exception
+1	+0		
+2	+0		
+0	$+\infty$	<code>VML_STATUS_SING</code>	<code>ZERODIVIDE</code>
-0	$+\infty$	<code>VML_STATUS_SING</code>	<code>ZERODIVIDE</code>
negative integer	$+\infty$	<code>VML_STATUS_SING</code>	<code>ZERODIVIDE</code>
$-\infty$	$+\infty$		
$+\infty$	$+\infty$		
$X > \text{overflow}$	$+\infty$	<code>VML_STATUS_OVERFLOW</code>	<code>OVERFLOW</code>
QNAN	QNAN		
SNAN	QNAN		<code>INVALID</code>

## `v?TGamma`

*Computes the gamma function of vector elements.*

## Syntax

```
vsTGamma( n, a, y );
```

```

vsTGammaI(n, a, inca, y, incy);
vmsTGamma( n, a, y, mode );
vmsTGammaI(n, a, inca, y, incy, mode);
vdTGamma( n, a, y );
vdTGammaI(n, a, inca, y, incy);
vmdTGamma( n, a, y, mode );
vmdTGammaI(n, a, inca, y, incy, mode);

```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsTGamma, vmsTGamma  const double* for vdTGamma, vmdTGamma	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsTGamma, vmsTGamma double* for vdTGamma, vmdTGamma	Pointer to an array that contains the output vector <i>y</i> .

## Description

The `v?TGamma` function computes the gamma function for elements of the input vector *a* and writes them to the output vector *y*. Precision overflow thresholds for the `v?TGamma` function are beyond the scope of this document. If the result does not meet the target precision, the function raises the `OVERFLOW` exception and sets the VM Error Status to `VML_STATUS_OVERFLOW`.

## Special Values for Real Function `v?TGamma(x)`

Argument	Result	VM Error Status	Exception
+0	$+\infty$	VML_STATUS_SING	ZERODIVIDE
-0	$-\infty$	VML_STATUS_SING	ZERODIVIDE
negative integer	QNAN	VML_STATUS_ERRDOM	INVALID

$+\infty$	$+\infty$		
$X > \text{overflow}$	$+\infty$	VML_STATUS_OVERFLOW	OVERFLOW

Argument	Result	VM Error Status	Exception
QNAN	QNAN		
SNAN	QNAN		INVALID

### v?ExpInt1

*Computes the exponential integral of vector elements.*

### Syntax

```
vsExpInt1( n, a, y );
vsExpInt1I(n, a, inca, y, incy);
vmsExpInt1( n, a, y, mode );
vmsExpInt1I(n, a, inca, y, incy, mode);
vdExpInt1( n, a, y );
vdExpInt1I(n, a, inca, y, incy);
vmdExpInt1( n, a, y, mode );
vmdExpInt1I(n, a, inca, y, incy, mode);
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsExpInt1, vmsExpInt1  const double* for vdExpInt1, vmdExpInt1	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

### Output Parameters

Name	Type	Description
<i>y</i>	float* for vsExpInt1, vmsExpInt1  double* for vdExpInt1, vmdExpInt1	Pointer to an array that contains the output vector <i>y</i> .

### Description

The v?ExpInt1 function computes the exponential integral  $E_1$  of vector elements.

For positive real values  $x$ , this can be written as:

$$E_1(x) = \int_x^\infty \frac{e^{-t}}{t} dt = \int_1^\infty \frac{e^{-xt}}{t} dt.$$

For negative real values  $x$ , the result is defined as `NAN`.

### Special Values for Real Function `v?ExpInt1(x)`

Argument	Result	VM Error Status	Exception
$x < +0$	QNAN	VML_STATUS_ERRDOM	INVALID
$+0$	$+\infty$	VML_STATUS_SING	ZERODIVIDE
$-0$	$+\infty$	VML_STATUS_SING	ZERODIVIDE
$+\infty$	$+0$		
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

## Rounding Functions

### `v?Floor`

Computes an integer value rounded towards minus infinity for each vector element.

### Syntax

```
vsFloor( n, a, y );
vsFloorI(n, a, inca, y, incy);
vmsFloor( n, a, y, mode );
vmsFloorI(n, a, inca, y, incy, mode);
vdFloor( n, a, y );
vdFloorI(n, a, inca, y, incy);
vmdFloor( n, a, y, mode );
vmdFloorI(n, a, inca, y, incy, mode);
```

### Include Files

- `mk1.h`

### Input Parameters

Name	Type	Description
<code>n</code>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<code>a</code>	<code>const float*</code> for <code>vsFloor</code> , <code>vmsFloor</code>  <code>const double*</code> for <code>vdFloor</code> , <code>vmdFloor</code>	Pointer to an array that contains the input vector <code>a</code> .
<code>inca, incy</code>	<code>const MKL_INT</code>	Specifies increments for the elements of <code>a</code> and <code>y</code> .

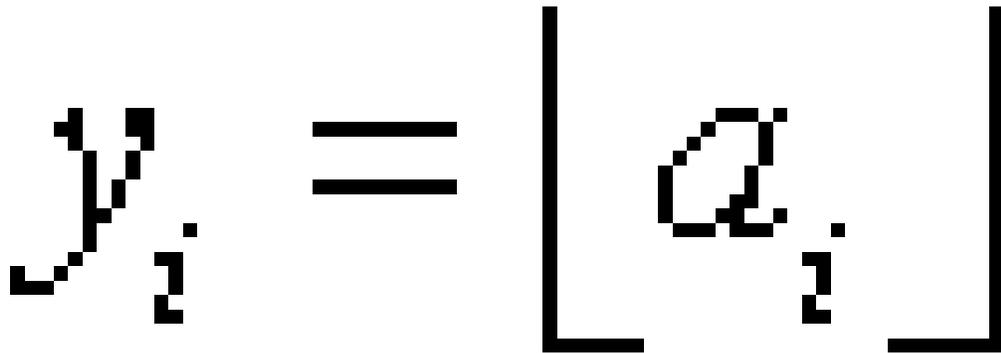

Name	Type	Description
<code>mode</code>	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See <a href="#">vm1SetMode</a> for possible values and their description.

### Output Parameters

Name	Type	Description
<code>y</code>	<code>float*</code> for <code>vsFloor</code> , <code>vmsFloor</code> <code>double*</code> for <code>vdFloor</code> , <code>vmdFloor</code>	Pointer to an array that contains the output vector <code>y</code> .

### Description

The function computes an integer value rounded towards minus infinity for each vector element.

### Special Values for Real Function `v?Floor(x)`

Argument	Result	Exception
+0	+0	
-0	-0	
$+\infty$	$+\infty$	
$-\infty$	$-\infty$	
SNAN	QNAN	INVALID
QNAN	QNAN	

### `v?Ceil`

Computes an integer value rounded towards plus infinity for each vector element.

### Syntax

```
vsCeil( n, a, y );
vsCeilI(n, a, inca, y, incy);
vmsCeil( n, a, y, mode );
vmsCeilI(n, a, inca, y, incy, mode);
vdCeil( n, a, y );
```

```
vdCeilI(n, a, inca, y, incy);
vmdCeil( n, a, y, mode );
vmdCeilI(n, a, inca, y, incy, mode);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsCeil, vmsCeil const double* for vdCeil, vmdCeil	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vm1SetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsCeil, vmsCeil double* for vdCeil, vmdCeil	Pointer to an array that contains the output vector <i>y</i> .

## Description

The function computes an integer value rounded towards plus infinity for each vector element.

$$\lceil x \rceil = \lceil a \rceil$$

## Special Values for Real Function v?Ceil(x)

Argument	Result	Exception
+0	+0	
-0	-0	

Argument	Result	Exception
$+\infty$	$+\infty$	
$-\infty$	$-\infty$	
SNAN	QNAN	INVALID
QNAN	QNAN	

### v?Trunc

Computes an integer value rounded towards zero for each vector element.

### Syntax

```
vsTrunc( n, a, y );
vsTruncI(n, a, inca, y, incy);
vmsTrunc( n, a, y, mode );
vmsTruncI(n, a, inca, y, incy, mode);
vdTrunc( n, a, y );
vdTruncI(n, a, inca, y, incy);
vmdTrunc( n, a, y, mode );
vmdTruncI(n, a, inca, y, incy, mode);
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsTrunc, vmsTrunc  const double* for vdTrunc, vmdTrunc	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

### Output Parameters

Name	Type	Description
<i>y</i>	float* for vsTrunc, vmsTrunc  double* for vdTrunc, vmdTrunc	Pointer to an array that contains the output vector <i>y</i> .

## Description

The function computes an integer value rounded towards zero for each vector element.

$$a_i \geq 0, y_i = \lfloor a_i \rfloor$$

$$a_i < 0, y_i = \lceil a_i \rceil$$

### Special Values for Real Function v?Trunc(x)

Argument	Result	Exception
+0	+0	
-0	-0	
$+\infty$	$+\infty$	
$-\infty$	$-\infty$	
SNAN	QNAN	INVALID
QNAN	QNAN	

### v?Round

Computes a value rounded to the nearest integer for each vector element.

### Syntax

```
vsRound( n, a, y );
vsRoundI( n, a, inca, y, incy );
vmsRound( n, a, y, mode );
vmsRoundI( n, a, inca, y, incy, mode );
vdRound( n, a, y );
vdRoundI( n, a, inca, y, incy );
vmdRound( n, a, y, mode );
vmdRoundI( n, a, inca, y, incy, mode );
```

### Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsRound, vmsRound  const double* for vdRound, vmdRound	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsRound, vmsRound  double* for vdRound, vmdRound	Pointer to an array that contains the output vector <i>y</i> .

## Description

The function computes a value rounded to the nearest integer for each vector element. Input elements that are halfway between two consecutive integers are always rounded away from zero regardless of the rounding mode.

### Special Values for Real Function *v?Round(x)*

Argument	Result	Exception
+0	+0	
-0	-0	
+∞	+∞	
-∞	-∞	
SNAN	QNAN	INVALID
QNAN	QNAN	

### *v?NearbyInt*

*Computes a rounded integer value in the current rounding mode for each vector element.*

### Syntax

```
vsNearbyInt( n, a, y );
vsNearbyIntI(n, a, inca, y, incy);
vmsNearbyInt( n, a, y, mode );
vmsNearbyIntI(n, a, inca, y, incy, mode);
vdNearbyInt( n, a, y );
vdNearbyIntI(n, a, inca, y, incy);
```

```
vmdNearbyInt( n, a, y, mode );
vmdNearbyIntI(n, a, inca, y, incy, mode);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsNearbyInt, vmsNearbyInt  const double* for vdNearbyInt, vmdNearbyInt	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsNearbyInt, vmsNearbyInt  double* for vdNearbyInt, vmdNearbyInt	Pointer to an array that contains the output vector <i>y</i> .

## Description

The `v?NearbyInt` function computes a rounded integer value in a current rounding mode for each vector element.

### Special Values for Real Function `v?NearbyInt(x)`

Argument	Result	Exception
+0	+0	
-0	-0	
+∞	+∞	
-∞	-∞	
SNAN	QNAN	INVALID
QNAN	QNAN	

### `v?Rint`

*Computes a rounded integer value in the current rounding mode.*

## Syntax

```
vsRint( n, a, y );
```

```
vsRintI(n, a, inca, y, incy);
vmsRint( n, a, y, mode );
vmsRintI(n, a, inca, y, incy, mode);
vdRint( n, a, y );
vdRintI(n, a, inca, y, incy);
vmdRint( n, a, y, mode );
vmdRintI(n, a, inca, y, incy, mode);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsRint, vmsRint const double* for vdRint, vmdRint	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vm1SetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsRint, vmsRint double* for vdRint, vmdRint	Pointer to an array that contains the output vector <i>y</i> .

## Description

The `v?Rint` function computes a rounded floating-point integer value using the current rounding mode for each vector element.

The rounding mode affects the results computed for inputs that fall between consecutive integers. For example:

- $f(0.5) = 0$ , for rounding modes set to round to nearest round toward zero or to minus infinity.
- $f(0.5) = 1$ , for rounding modes set to plus infinity.
- $f(-1.5) = -2$ , for rounding modes set to round to nearest or to minus infinity.
- $f(-1.5) = -1$ , for rounding modes set to round toward zero or to plus infinity.

## Special Values for Real Function `v?Rint(x)`

Argument	Result	Exception
+0	+0	
-0	-0	
$+\infty$	$+\infty$	

Argument	Result	Exception
$-\infty$	$-\infty$	
SNAN	QNAN	INVALID
QNAN	QNAN	

## v?Modf

Computes a truncated integer value and the remaining fraction part for each vector element.

### Syntax

```
vsModf( n, a, y, z );
vsModfI(n, a, inca, y, incy, z, incz);
vmsModf( n, a, y, z, mode );
vmsModfI(n, a, inca, y, incy, z, incz, mode);
vdModf( n, a, y, z );
vdModfI(n, a, inca, y, incy, z, incz);
vmdModf( n, a, y, z, mode );
vmdModfI(n, a, inca, y, incy, z, incz, mode);
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsModf, vmsModf const double* for vdModf, vmdModf	Pointer to an array that contains the input vector <i>a</i> .
<i>inca, incy, incz</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> , <i>y</i> , and <i>z</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vm1SetMode</a> for possible values and their description.

### Output Parameters

Name	Type	Description
<i>y, z</i>	float* for vsModf, vmsModf double* for vdModf, vmdModf	Pointer to an array that contains the output vector <i>y</i> and <i>z</i> .

### Description

The function computes a truncated integer value and the remaining fraction part for each vector element.

$$a_i \geq 0, \begin{cases} y_i = \lfloor a_i \rfloor \\ z_i = a_i - \lfloor a_i \rfloor \end{cases}$$

$$a_i < 0, \begin{cases} y_i = \lceil a_i \rceil \\ z_i = a_i - \lceil a_i \rceil \end{cases}$$

QNAN	QNAN	QNAN	

**v?Frac**

Computes a signed fractional part for each vector element.

**Syntax**

```
vsFrac( n, a, y );
vsFracI(n, a, inca, y, incy);
vmsFrac( n, a, y, mode );
vmsFracI(n, a, inca, y, incy, mode);
vdFrac( n, a, y );
vdFracI(n, a, inca, y, incy);
vmdFrac( n, a, y, mode );
vmdFracI(n, a, inca, y, incy, mode);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
$n$	const MKL_INT	Specifies the number of elements to be calculated.
$a$	const float* for vsFrac, vmsFrac const double* for vdFrac, vmdFrac	Pointer to an array that contains the input vector $a$ .
$inca, incy$	const MKL_INT	Specifies increments for the elements of $a$ and $y$ .
$mode$	const MKL_INT64	Overrides global VM mode setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
$y$	float* for vsFrac, vmsFrac double* for vdFrac, vmdFrac	Pointer to an array that contains the output vector $y$ .

## Description

The function computes a signed fractional part for each vector element.

$$y_i = \begin{cases} a_i - \lfloor a_i \rfloor, & a_i \geq 0 \\ a_i - \lceil a_i \rceil, & a_i < 0 \end{cases}$$

## VM Pack/Unpack Functions

This section describes VM functions that convert vectors with unit increment to and from vectors with positive increment indexing, vector indexing, and mask indexing (see Appendix "Vector Arguments in VM" for details on vector indexing methods).

The table below lists available VM Pack/Unpack functions, together with data types and indexing methods associated with them.

### VM Pack/Unpack Functions

Function Short Name	Data Types	Indexing Methods	Description
<code>v?Pack</code>	<code>s, d, c, z</code>	<code>I, V, M</code>	Gathers elements of arrays, indexed by different methods.
<code>v?Unpack</code>	<code>s, d, c, z</code>	<code>I, V, M</code>	Scatters vector elements to arrays with different indexing.

### See Also

Appendix "Vector Arguments in VM"

### `v?Pack`

*Copies elements of an array with specified indexing to a vector with unit increment.*

### Syntax

```
vsPackI( n, a, inca, y );
vsPackV( n, a, ia, y );
vsPackM( n, a, ma, y );
vdPackI( n, a, inca, y );
vdPackV( n, a, ia, y );
vdPackM( n, a, ma, y );
vcPackI( n, a, inca, y );
vcPackV( n, a, ia, y );
vcPackM( n, a, ma, y );
vzPackI( n, a, inca, y );
vzPackV( n, a, ia, y );
vzPackM( n, a, ma, y );
```

### Include Files

- `mkl.h`

### Input Parameters

Name	Type	Description
<code>n</code>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<code>a</code>	<code>const float*</code> for <code>vsPackI</code> , <code>vsPackV</code> , <code>vsPackM</code>	Specifies pointer to an array that contains the input vector <code>a</code> . The arrays must be:

Name	Type	Description
	const double* for vdPackI, vdPackV, vdPackM	for v?PackI, at least $(1 + (n-1) * inca)$
	const MKL_Complex8* for vcPackI, vcPackV, vcPackM	for v?PackV, at least $\max(n, \max(ia[j]))$ , $j=0, \dots, n-1$
	const MKL_Complex16* for vzPackI, vzPackV, vzPackM	for v?PackM, at least $n$ .
<i>inca</i>	const MKL_INT for vsPackI, vdPackI, vcPackI, vzPackI	Specifies the increment for the elements of <i>a</i> .
<i>ia</i>	const int* for vsPackV, vdPackV, vcPackV, vzPackV	Specifies the pointer to an array of size at least $n$ that contains the index vector for the elements of <i>a</i> .
<i>ma</i>	const int* for vsPackM, vdPackM, vcPackM, vzPackM	Specifies the pointer to an array of size at least $n$ that contains the mask vector for the elements of <i>a</i> .

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsPackI, vsPackV, vsPackM	Pointer to an array of size at least $n$ that contains the output vector <i>y</i> .
	double* for vdPackI, vdPackV, vdPackM	
	const MKL_Complex8* for vcPackI, vcPackV, vcPackM	
	const MKL_Complex16* for vzPackI, vzPackV, vzPackM	

## v?Unpack

*Copies elements of a vector with unit increment to an array with specified indexing.*

### Syntax

```
vsUnpackI( n, a, y, incy );
vsUnpackV( n, a, y, iy );
vsUnpackM( n, a, y, my );
vdUnpackI( n, a, y, incy );
vdUnpackV( n, a, y, iy );
vdUnpackM( n, a, y, my );
vcUnpackI( n, a, y, incy );
vcUnpackV( n, a, y, iy );
vcUnpackM( n, a, y, my );
vzUnpackI( n, a, y, incy );
```

```
vzUnpackV( n, a, y, iy );
```

```
vzUnpackM( n, a, y, my );
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsUnpackI, vsUnpackV, vsUnpackM  const double* for vdUnpackI, vdUnpackV, vdUnpackM  const MKL_Complex8* for vcUnpackI, vcUnpackV, vcUnpackM  const MKL_Complex16* for vzUnpackI, vzUnpackV, vzUnpackM	Specifies the pointer to an array of size at least <i>n</i> that contains the input vector <i>a</i> .
<i>incy</i>	const MKL_INT for vsUnpackI, vdUnpackI, vcUnpackI, vzUnpackI	Specifies the increment for the elements of <i>y</i> .
<i>iy</i>	const int* for vsUnpackV, vdUnpackV, vcUnpackV, vzUnpackV	Specifies the pointer to an array of size at least <i>n</i> that contains the index vector for the elements of <i>a</i> .
<i>my</i>	const int* for vsUnpackM, vdUnpackM, vcUnpackM, vzUnpackM	Specifies the pointer to an array of size at least <i>n</i> that contains the mask vector for the elements of <i>a</i> .

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsUnpackI, vsUnpackV, vsUnpackM  double* for vdUnpackI, vdUnpackV, vdUnpackM  const MKL_Complex8* for vcUnpackI, vcUnpackV, vcUnpackM  const MKL_Complex16* for vzUnpackI, vzUnpackV, vzUnpackM	Specifies the pointer to an array that contains the output vector <i>y</i> .  The array must be:  for v?UnpackI, at least $(1 + (n-1) * incy)$ for v?UnpackV, at least $\max(n, \max(ia[j]), j=0, \dots, n-1,$ for v?UnpackM, at least <i>n</i> .

## VM Service Functions

The VM Service functions enable you to set/get the accuracy mode and error code. These functions are available both in the Fortran and C interfaces. The table below lists available VM Service functions and their short description.

## VM Service Functions

Function Short Name	Description
<code>vmlSetMode</code>	Sets the VM mode
<code>vmlGetMode</code>	Gets the VM mode
<code>MKLFreeTls</code>	Frees allocated VM/VS thread local storage memory from within DllMain routine (Windows* OS only)
<code>vmlSetErrStatus</code>	Sets the VM Error Status
<code>vmlGetErrStatus</code>	Gets the VM Error Status
<code>vmlClearErrStatus</code>	Clears the VM Error Status
<code>vmlSetErrorCallBack</code>	Sets the additional error handler callback function
<code>vmlGetErrorCallBack</code>	Gets the additional error handler callback function
<code>vmlClearErrorCallBack</code>	Deletes the additional error handler callback function

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## vmlSetMode

Sets a new mode for VM functions according to the *mode* parameter and stores the previous VM mode to *oldmode*.

### Syntax

```
oldmode = vmlSetMode( mode );
```

### Include Files

- `mk1.h`

### Input Parameters

Name	Type	Description
<i>mode</i>	<code>const MKL_UINT</code>	Specifies the VM mode to be set.

### Output Parameters

Name	Type	Description
<i>oldmode</i>	<code>unsigned int</code>	Specifies the former VM mode.

### Description

The `vmlSetMode` function sets a new mode for VM functions according to the *mode* parameter and stores the previous VM mode to *oldmode*. The mode change has a global effect on all the VM functions within a thread.

#### NOTE

You can override the global mode setting and change the mode for a given VM function call by using a respective `vm[s,d]<Func>` variant of the function.

The *mode* parameter is designed to control accuracy, handling of denormalized numbers, and error handling. Table "Values of the *mode* Parameter" lists values of the *mode* parameter. You can obtain all other possible values of the *mode* parameter from the *mode* parameter values by a using bitwise OR ( | ) operation to combine one value for accuracy, one value for handling of denormalized numbers, and one value for error control options. The default value of the *mode* parameter is `VML_HA | VML_FTZDAZ_CURRENT | VML_ERRMODE_DEFAULT`.

The `VML_FTZDAZ_ON` mode is specifically designed to improve the performance of computations that involve denormalized numbers at the cost of reasonable accuracy loss. This mode changes the numeric behavior of the functions: denormalized input values are treated as zeros (DAZ = denormals-are-zero) and denormalized results are flushed to zero (FTZ = flush-to-zero). Accuracy loss may occur if input and/or output values are close to denormal range.

### Values of the *mode* Parameter

Value of <i>mode</i>	Description
<b>Accuracy Control</b>	
<code>VML_HA</code>	high accuracy versions of VM functions
<code>VML_LA</code>	low accuracy versions of VM functions
<code>VML_EP</code>	enhanced performance accuracy versions of VM functions
<b>Denormalized Numbers Handling Control</b>	
<code>VML_FTZDAZ_ON</code>	Faster processing of denormalized inputs is enabled.
<code>VML_FTZDAZ_OFF</code>	Faster processing of denormalized inputs is disabled.
<code>VML_FTZDAZ_CURRENT</code>	Keep the current CPU settings for denormalized inputs.
<b>Error Mode Control</b>	
<code>VML_ERRMODE_IGNORE</code>	On computation error, VM Error status is updated, but otherwise no action is set. Cannot be combined with other <code>VML_ERRMODE</code> settings.
<code>VML_ERRMODE_NOERR</code>	On computation error, VM Error status is not updated and no action is set. Cannot be combined with other <code>VML_ERRMODE</code> settings.
<code>VML_ERRMODE_ERRNO</code>	On error, the <i>errno</i> variable is set.
<code>VML_ERRMODE_STDERR</code>	On error, the error text information is written to <i>stderr</i> .
<code>VML_ERRMODE_EXCEPT</code>	On error, an exception is raised.
<code>VML_ERRMODE_CALLBACK</code>	On error, an additional error handler function is called.
<code>VML_ERRMODE_DEFAULT</code>	On error, the <i>errno</i> variable is set, an exception is raised, and an additional error handler function is called.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

### Examples

The following example shows how to set low accuracy, fast processing for denormalized numbers and `stderr` error mode:

```
vmlSetMode( VML_LA );
vmlSetMode( VML_LA | VML_FTZDAZ_ON | VML_ERRMODE_STDERR );
```

## vmlGetMode

*Gets the VM mode.*

---

### Syntax

```
mod = vmlGetMode( void );
```

### Include Files

- mkl.h

### Output Parameters

Name	Type	Description
<i>mod</i>	unsigned int	Specifies the packed <i>mode</i> parameter.

### Description

The function `vmlGetMode` returns the VM *mode* parameter that controls accuracy, handling of denormalized numbers, and error handling options. The *mod* variable value is a combination of the values listed in the table "Values of the *mode* Parameter". You can obtain these values using the respective mask from the table "Values of Mask for the *mode* Parameter".

### Values of Mask for the *mode* Parameter

Value of mask	Description
VML_ACCURACY_MASK	Specifies mask for accuracy <i>mode</i> selection.
VML_FTZDAZ_MASK	Specifies mask for FTZDAZ <i>mode</i> selection.
VML_ERRMODE_MASK	Specifies mask for error <i>mode</i> selection.

See example below:

### Examples

```
accm = vmlGetMode(void ) & VML_ACCURACY_MASK;
denm = vmlGetMode(void ) & VML_FTZDAZ_MASK;
errm = vmlGetMode(void ) & VML_ERRMODE_MASK;
```

## MKLFreeTls

*Frees allocated VM/VS thread local storage memory from within DllMain routine. Use on Windows\* OS only.*

---

### Syntax

```
void MKLFreeTls( const MKL_UINT fdwReason );
```

### Include Files

- mkl\_vml\_functions\_win.h

### Description

The `MKLFreeTls` routine frees thread local storage (TLS) memory which has been allocated when using MKL static libraries to link into a DLL on the Windows\* OS. The routine should only be used within `DllMain`.

**NOTE**

It is only necessary to use `MKLFreeTls` for TLS data in the VM and VS domains.

**Input Parameters**

Name	Type	Description
<code>fdwReason</code>	<code>const MKL_UINT</code>	Reason code from the <code>DllMain</code> call.

**Example**

```

BOOL WINAPI DllMain(HINSTANCE hInst, DWORD fdwReason, LPVOID lpvReserved)
{
    /*customer code*/
    MKLFreeTls(fdwReason);
    /*customer code*/
}

```

**vmlSetErrStatus**

Sets the new VM Error Status according to `err` and stores the previous VM Error Status to `olderr`. Sets the global VM Status according to new values and returns the previous VM Status.

**Syntax**

```
olderr = vmlSetErrStatus( status );
```

**Include Files**

- `mkl.h`

**Input Parameters**

Name	Type	Description
<code>status</code>	<code>const MKL_INT</code>	Specifies the VM error status to be set.

**Output Parameters**

Name	Type	Description
<code>olderr</code>	<code>int</code>	Specifies the former VM error status.

**Description**

Table "Values of the VM Status" lists possible values of the `err` parameter.

**Values of the VM Status**

Status	Description
--------	-------------

**Successful Execution**

<code>VML_STATUS_OK</code>	The execution was completed successfully.
----------------------------	---

**Warnings**

Status	Description
VML_STATUS_ACCURACYWARNING	The execution was completed successfully in a different accuracy mode.
<b>Errors</b>	
VML_STATUS_BADSIZE	The function does not support the preset accuracy mode. The Low Accuracy mode is used instead.
VML_STATUS_BADMEM	NULL pointer is passed.
VML_STATUS_ERRDOM	At least one of array values is out of a range of definition.
VML_STATUS_SING	At least one of the input array values causes a divide-by-zero exception or produces an invalid (QNaN) result.
VML_STATUS_OVERFLOW	An overflow has happened during the calculation process.
VML_STATUS_UNDERFLOW	An underflow has happened during the calculation process.

## Examples

```
olderr = vmlSetErrStatus( VML_STATUS_OK );
```

```
olderr = vmlSetErrStatus( VML_STATUS_ERRDOM );
```

```
olderr = vmlSetErrStatus( VML_STATUS_UNDERFLOW );
```

## vmlGetErrStatus

*Gets the VM Error Status.*

### Syntax

```
err = vmlGetErrStatus( void );
```

### Include Files

- mkl.h

### Output Parameters

Name	Type	Description
<code>err</code>	int	Specifies the VM error status.

## vmlClearErrStatus

*Sets the VM Error Status to VML\_STATUS\_OK and stores the previous VM Error Status to olderr.*

### Syntax

```
olderr = vmlClearErrStatus( void );
```

### Include Files

- mkl.h

## Output Parameters

Name	Type	Description
<i>olderr</i>	int	Specifies the former VM error status.

## vmlSetErrorCallBack

*Sets the additional error handler callback function and gets the old callback function.*

---

### Syntax

```
oldcallback = vmlSetErrorCallBack( callback );
```

### Include Files

- `mkl.h`

## Input Parameters

Name	Description
<i>callback</i>	Pointer to the callback function.

The callback function has the following format:

```
static int __cdecl  
MyHandler(DefVmlErrorContext*  
pContext)  
{  
    /* Handler body */  
};
```

**Name****Description**

The passed error structure is defined as follows:

```
typedef struct _DefVmlErrorContext
{
    int iCode; /* Error status value */
    int iIndex; /* Index for bad array
                element, or bad array
                dimension, or bad
                array pointer */
    double dbA1; /* Error argument 1 */
    double dbA2; /* Error argument 2 */
    double dbR1; /* Error result 1 */
    double dbR2; /* Error result 2 */
    char cFuncName[64]; /* Function name */
    int iFuncNameLen; /* Length of
                      functionname*/
    double dbA1Im; /* Error argument 1, imag
                   part*/
    double dbA2Im; /* Error argument 2, imag
                   part*/
    double dbR1Im; /* Error result 1, imag
                   part*/
    double dbR2Im; /* Error result 2, imag
                   part*/
} DefVmlErrorContext;
```

**Output Parameters****Name****Type**

*oldcallback*    int

**Description**

Pointer to the former callback function.

**Description**

The callback function is called on each VM mathematical function error if `VML_ERRMODE_CALLBACK` error mode is set (see "[Values of the mode Parameter](#)").

Use the `vmlSetErrorCallBack()` function if you need to define your own callback function instead of default empty callback function.

The input structure for a callback function contains the following information about the error encountered:

- the input value that caused an error
- location (array index) of this value
- the computed result value
- error code

- name of the function in which the error occurred.

You can insert your own error processing into the callback function. This may include correcting the passed result values in order to pass them back and resume computation. The standard error handler is called after the callback function only if it returns 0.

### vmlGetErrorCallback

*Gets the additional error handler callback function.*

#### Syntax

```
callback = vmlGetErrorCallback( void );
```

#### Include Files

- mkl.h

#### Output Parameters

##### Name

*callback*

##### Description

Pointer to the callback function

### vmlClearErrorCallback

*Deletes the additional error handler callback function and retrieves the former callback function.*

#### Syntax

```
oldcallback = vmlClearErrorCallback( void );
```

#### Include Files

- mkl.h

#### Output Parameters

##### Name

*oldcallback*

##### Type

int

##### Description

Pointer to the former callback function

## Miscellaneous VM Functions

### v?CopySign

*Returns vector of elements of one argument with signs changed to match other argument elements.*

#### Syntax

```
vsCopySign (n, a, y);
```

```
vsCopySignI(n, a, inca, b, incb, y, incy);
```

```
vmsCopySign (n, a, y, mode);
```

```
vmsCopySignI(n, a, inca, b, incb, y, incy, mode);
```

```
vdCopySign (n, a, y);
```

```
vdCopySignI(n, a, inca, b, incb, y, incy);
vmdCopySign (n, a, y, mode);
vmdCopySignI(n, a, inca, b, incb, y, incy, mode);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsCopySign const float* for vmsCopySign const double* for vdCopySign const double* for vmdCopySign	Pointer to the array containing the input vector <i>a</i> .
<i>inca, incb, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> , <i>b</i> , and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides the global VM <i>mode</i> setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsCopySign float* for vmsCopySign double* for vdCopySign double* for vmdCopySign	Pointer to an array containing the output vector <i>y</i> .

## Description

The `v?CopySign` function returns the first vector argument elements with the sign changed to match the sign of the second vector argument's corresponding elements.

## v?NextAfter

Returns vector of elements containing the next representable floating-point values following the values from the elements of one vector in the direction of the corresponding elements of another vector.

## Syntax

```
vsNextAfter (n, a, b, y);
vsNextAfterI(n, a, inca, b, incb, y, incy);
vmsNextAfter (n, a, b, y, mode);
```

```
vmsNextAfterI(n, a, inca, b, incb, y, incy, mode);
vdNextAfter (n, a, b, y);
vdNextAfterI(n, a, inca, b, incb, y, incy);
vmdNextAfter (n, a, b, y, mode);
vmdNextAfterI(n, a, inca, b, incb, y, incy, mode);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a, b</i>	<code>const float*</code> for <code>vsNextAfter</code> <code>const float*</code> for <code>vmsNextAfter</code> <code>const double*</code> for <code>vdNextAfter</code> <code>const double*</code> for <code>vmdNextAfter</code>	Pointers to the arrays containing the input vectors <i>a</i> and <i>b</i> .
<i>inca, incb, incy</i>	<code>const MKL_INT</code>	Specifies increments for the elements of <i>a</i> , <i>b</i> , and <i>y</i> .
<i>mode</i>	<code>const MKL_INT64</code>	Overrides the global VM <i>mode</i> setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	<code>float*</code> for <code>vsNextAfter</code> <code>float*</code> for <code>vmsNextAfter</code> <code>double*</code> for <code>vdNextAfter</code> <code>double*</code> for <code>vmdNextAfter</code>	Pointer to an array containing the output vector <i>y</i> .

## Description

The `v?NextAfter` function returns a vector containing the next representable floating-point values following the first vector argument elements in the direction of the second vector argument's corresponding elements.

Special cases:

Overflow	The function raises overflow and inexact floating-point exceptions and sets <code>VML_STATUS_OVERFLOW</code> if an input vector argument element is finite and the corresponding result vector element value is infinite.
Underflow	The function raises underflow and inexact floating-point exceptions and sets <code>VML_STATUS_UNDERFLOW</code> if a result vector element value is subnormal or zero, and different from the corresponding input vector argument element.

Even though underflow or overflow can occur, the returned value is independent of the current rounding direction mode.

## v?Fdim

Returns vector containing the differences of the corresponding elements of the vector arguments if the first is larger and +0 otherwise.

## Syntax

```
vsFdim (n, a, b, y);
vsFdimI(n, a, inca, b, incb, y, incy);
vmsFdim (n, a, b, y, mode);
vmsFdimI(n, a, inca, b, incb, y, incy, mode);
vdFdim (n, a, b, y);
vdFdimI(n, a, inca, b, incb, y, incy);
vmdFdim (n, a, b, y, mode);
vmdFdimI(n, a, inca, b, incb, y, incy, mode);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a, b</i>	const float* for vsFdim const float* for vmsFdim const double* for vdFdim const double* for vmdFdim	Pointers to the arrays containing the input vectors <i>a</i> and <i>b</i> .
<i>inca, incb, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> , <i>b</i> , and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides the global VM <i>mode</i> setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsFdim float* for vmsFdim double* for vdFdim double* for vmdFdim	Pointer to an array containing the output vector <i>y</i> .

## Description

The `v?Fdim` function returns a vector containing the differences of the corresponding elements of the first and second vector arguments if the first element is larger, and +0 otherwise.

### Special values for Real Function `v?Fdim(x, y)`

Argument 1	Argument 2	Result	VM Error Status	Exception
any	QNAN	QNAN		
any	SNAN	QNAN		INVALID
QNAN	any	QNAN		
SNAN	any	QNAN		INVALID

## `v?Fmax`

Returns the larger of each pair of elements of the two vector arguments.

### Syntax

```
vsFmax (n, a, b, y);
vsFmaxI(n, a, inca, b, incb, y, incy);
vmsFmax (n, a, b, y, mode);
vmsFmaxI(n, a, inca, b, incb, y, incy, mode);
vdFmax (n, a, b, y);
vdFmaxI(n, a, inca, b, incb, y, incy);
vmdFmax (n, a, b, y, mode);
vmdFmaxI(n, a, inca, b, incb, y, incy, mode);
```

### Include Files

- `mkl.h`

### Input Parameters

Name	Type	Description
<code>n</code>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<code>a, b</code>	<code>const float*</code> for <code>vsFmax</code> <code>const float*</code> for <code>vmsFmax</code> <code>const double*</code> for <code>vdFmax</code> <code>const double*</code> for <code>vmdFmax</code>	Pointers to the arrays containing the input vectors <code>a</code> and <code>b</code> .
<code>inca, incb, incy</code>	<code>const MKL_INT</code>	Specifies increments for the elements of <code>a</code> , <code>b</code> , and <code>y</code> .
<code>mode</code>	<code>const MKL_INT64</code>	Overrides the global VM <code>mode</code> setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
$y$	float* for vsFmax float* for vmsFmax double* for vdFmax double* for vmdFmax	Pointer to an array containing the output vector $y$ .

## Description

The  $v?Fmax$  function returns a vector with element values equal to the larger value from each pair of corresponding elements of the two vectors  $a$  and  $b$ : if  $a_i < b_i$ ,  $v?Fmax$  returns  $b_i$ , otherwise  $v?Fmax$  returns  $a_i$ .

### Special values for Real Function $v?Fmax(x, y)$

Argument 1	Argument 2	Result	VM Error Status	Exception
$a_i$ not NAN	NAN	$a_i$		
NAN	$b_i$ not NAN	$b_i$		
NAN	NAN	NAN		

## See Also

[Fmin](#) Returns the smaller of each pair of elements of the two vector arguments.

[MaxMag](#) Returns the element with the larger magnitude between each pair of elements of the two vector arguments.

## $v?Fmin$

Returns the smaller of each pair of elements of the two vector arguments.

## Syntax

```
vsFmin (n, a, b, y);
vsFminI(n, a, inca, b, incb, y, incy);
vmsFmin (n, a, b, y, mode);
vmsFminI(n, a, inca, b, incb, y, incy, mode);
vdFmin (n, a, b, y);
vdFminI(n, a, inca, b, incb, y, incy);
vmdFmin (n, a, b, y, mode);
vmdFminI(n, a, inca, b, incb, y, incy, mode);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
$n$	const MKL_INT	Specifies the number of elements to be calculated.

Name	Type	Description
$a, b$	const float* for vsFmin const float* for vmsFmin const double* for vdFmin const double* for vmdFmin	Pointers to the arrays containing the input vectors $a$ and $b$ .
$inca, incb, incy$	const MKL_INT	Specifies increments for the elements of $a, b$ , and $y$ .
$mode$	const MKL_INT64	Overrides the global VM $mode$ setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
$y$	float* for vsFmin float* for vmsFmin double* for vdFmin double* for vmdFmin	Pointer to an array containing the output vector $y$ .

## Description

The  $v?Fmin$  function returns a vector with element values equal to the smaller value from each pair of corresponding elements of the two vectors  $a$  and  $b$ : if  $b_i < a_i v?Fmin$  returns  $b_i$ , otherwise  $v?Fmin$  returns  $a_i$ .

### Special values for Real Function $v?Fmin(x, y)$

Argument 1	Argument 2	Result	VM Error Status	Exception
$a_i$ not NAN	NAN	$a_i$		
NAN	$b_i$ not NAN	$b_i$		
NAN	NAN	NAN		

## See Also

[Fmax](#) Returns the larger of each pair of elements of the two vector arguments.

[MinMag](#) Returns the element with the smaller magnitude between each pair of elements of the two vector arguments.

## $v?MaxMag$

Returns the element with the larger magnitude between each pair of elements of the two vector arguments.

## Syntax

```
vsMaxMag (n, a, b, y);
```

```
vsMaxMagI(n, a, inca, b, incb, y, incy);
```

```
vmsMaxMag (n, a, b, y, mode);
```

```
vmsMaxMagI(n, a, inca, b, incb, y, incy, mode);
```

```
vdMaxMag (n, a, b, y);
```

```
vdMaxMagI(n, a, inca, b, incb, y, incy);
vmdMaxMag (n, a, b, y, mode);
vmdMaxMagI(n, a, inca, b, incb, y, incy, mode);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a, b</i>	const float* for vsMaxMag const float* for vmsMaxMag const double* for vdMaxMag const double* for vmdMaxMag	Pointers to the arrays containing the input vectors <i>a</i> and <i>b</i> .
<i>inca, incb, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> , <i>b</i> , and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides the global VM <i>mode</i> setting for this function call. See <a href="#">vmlSetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsMaxMag float* for vmsMaxMag double* for vdMaxMag double* for vmdMaxMag	Pointer to an array containing the output vector <i>y</i> .

## Description

The `v?MaxMag` function returns a vector with element values equal to the element with the larger magnitude from each pair of corresponding elements of the two vectors *a* and *b*:

- If  $|a_i| > |b_i|$  `v?MaxMag` returns  $a_i$ , otherwise `v?MaxMag` returns  $a_i$ .
- If  $|b_i| > |a_i|$  `v?MaxMag` returns  $b_i$ , otherwise `v?MaxMag` returns  $a_i$ .
- Otherwise `v?MaxMag` behaves like `v?Fmax`.

## Special values for Real Function `v?MaxMag(x, y)`

Argument 1	Argument 2	Result	VM Error Status	Exception
$a_i$ not NAN	NAN	$a_i$		
NAN	$b_i$ not NAN	$b_i$		
NAN	NAN	NAN		

## See Also

**MinMag** Returns the element with the smaller magnitude between each pair of elements of the two vector arguments.

**Fmax** Returns the larger of each pair of elements of the two vector arguments.

## v?MinMag

*Returns the element with the smaller magnitude between each pair of elements of the two vector arguments.*

## Syntax

```
vsMinMag (n, a, b, y);
vsMinMagI(n, a, inca, b, incb, y, incy);
vmsMinMag (n, a, b, y, mode);
vmsMinMagI(n, a, inca, b, incb, y, incy, mode);
vdMinMag (n, a, b, y);
vdMinMagI(n, a, inca, b, incb, y, incy);
vmdMinMag (n, a, b, y, mode);
vmdMinMagI(n, a, inca, b, incb, y, incy, mode);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a, b</i>	const float* for vsMinMag const float* for vmsMinMag const double* for vdMinMag const double* for vmdMinMag	Pointers to the arrays containing the input vectors <i>a</i> and <i>b</i> .
<i>inca, incb, incy</i>	const MKL_INT	Specifies increments for the elements of <i>a</i> , <i>b</i> , and <i>y</i> .
<i>mode</i>	const MKL_INT64	Overrides the global VM <i>mode</i> setting for this function call. See <a href="#">vm1SetMode</a> for possible values and their description.

## Output Parameters

Name	Type	Description
<i>y</i>	float* for vsMinMag float* for vmsMinMag double* for vdMinMag	Pointer to an array containing the output vector <i>y</i> .

Name	Type	Description
------	------	-------------

	double* for vmdMinMag	
--	-----------------------	--

## Description

The `v?MinMag` function returns a vector with element values equal to the element with the smaller magnitude from each pair of corresponding elements of the two vectors  $a$  and  $b$ :

- If  $|a_i| < |b_i|$  `v?MaxMag` returns  $a_i$ , otherwise `v?MaxMag` returns  $a_i$ .
- If  $|b_i| < |a_i|$  `v?MaxMag` returns  $b_i$ , otherwise `v?MaxMag` returns  $a_i$ .
- Otherwise `v?MaxMag` behaves like `v?Fmin`.

## Special values for Real Function `v?MinMag(x, y)`

Argument 1	Argument 2	Result	VM Error Status	Exception
$a_i$ not NAN	NAN	$a_i$		
NAN	$b_i$ not NAN	$b_i$		
NAN	NAN	NAN		

## See Also

[MaxMag](#) Returns the element with the larger magnitude between each pair of elements of the two vector arguments.

[Fmin](#) Returns the smaller of each pair of elements of the two vector arguments.

## Statistical Functions

Statistical functions in Intel® oneAPI Math Kernel Library (oneMKL) are known as the Vector Statistics (VS). They are designed for the purpose of

- generating vectors of pseudorandom, quasi-random, and non-deterministic random numbers
- performing mathematical operations of convolution and correlation
- computing basic statistical estimates for single and double precision multi-dimensional datasets

The corresponding functionality is described in the respective [Random Number Generators](#), [Convolution and Correlation](#), and [Summary Statistics](#) topics.

See VS performance data in the online VS Performance Data document available at <https://www.intel.com/content/www/us/en/developer/tools/oneapi/onemkl-documentation.html>.

The basic notion in VS is a task. The task object is a data structure or descriptor that holds the parameters related to a specific statistical operation: random number generation, convolution and correlation, or summary statistics estimation. Such parameters can be an identifier of a random number generator, its internal state and parameters, data arrays, their shape and dimensions, an identifier of the operation and so forth. You can modify the VS task parameters using the VS service functions.

Notice revision #20201201

## Random Number Generators

Intel® oneAPI Math Kernel Library (oneMKL) VS provides a set of routines implementing commonly used pseudorandom, quasi-random, or non-deterministic random number generators with continuous and discrete distribution. To improve performance, all these routines were developed using the calls to the highly optimized *Basic Random Number Generators* (BRNGs) and vector mathematical functions (VM, see "[Vector Mathematical Functions](#)").

VS provides interfaces both for Fortran and C languages. For users of the C and C++ languages the `mkl_vs1.h` header file is provided. All header files are found in the following directory:

```
${MKL}/include
```

All VS routines can be classified into three major categories:

- Transformation routines for different types of statistical distributions, for example, uniform, normal (Gaussian), binomial, etc. These routines indirectly call basic random number generators, which are pseudorandom, quasi-random, or non-deterministic random number generators. Detailed description of the generators can be found in [Distribution Generators](#).
- Service routines to handle random number streams: create, initialize, delete, copy, save to a binary file, load from a binary file, get the index of a basic generator. The description of these routines can be found in [Service Routines](#).
- Registration routines for basic pseudorandom generators and routines that obtain properties of the registered generators (see [Advanced Service Routines](#)).

The last two categories are referred to as service routines.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Random Number Generators Conventions

This document makes no specific differentiation between random, pseudorandom, and quasi-random numbers, nor between random, pseudorandom, and quasi-random number generators unless the context requires otherwise. For details, refer to the '*Random Numbers*' section in [VS Notes](#) document provided at the Intel® oneAPI Math Kernel Library (oneMKL) web page.

All generators of nonuniform distributions, both discrete and continuous, are built on the basis of the uniform distribution generators, called Basic Random Number Generators (BRNGs). The pseudorandom numbers with nonuniform distribution are obtained through an appropriate transformation of the uniformly distributed pseudorandom numbers. Such transformations are referred to as *generation methods*. For a given distribution, several generation methods can be used. See [VS Notes](#) for the description of methods available for each generator.

An RNG task determines environment in which random number generation is performed, in particular parameters of the BRNG and its internal state. Output of VS generators is a stream of random numbers that are used in Monte Carlo simulations. A *random stream descriptor* and a *random stream* are used as synonyms of an *RNG task* in the document unless the context requires otherwise.

The *random stream descriptor* specifies which BRNG should be used in a given transformation method. See the *Random Streams and RNGs in Parallel Computation* section of [VS Notes](#).

The term *computational node* means a logical or physical unit that can process data in parallel.

## Random Number Generators Mathematical Notation

The following notation is used throughout the text:

$N$	The set of natural numbers $N = \{1, 2, 3 \dots\}$ .
$Z$	The set of integers $Z = \{\dots -3, -2, -1, 0, 1, 2, 3 \dots\}$ .
$R$	The set of real numbers.

$$\lfloor a \rfloor$$

The floor of  $a$  (the largest integer less than or equal to  $a$ ).

$\oplus$  or **xor**

Bitwise exclusive OR.

$$C_{\alpha}^k \text{ or } \binom{\alpha}{k}$$

Binomial coefficient or combination ( $\alpha \in R, \alpha \geq 0; k \in N \cup \{0\}$ ).

$$C_{\alpha}^0 = 1$$

For  $\alpha \geq k$  binomial coefficient is defined as

$$C_{\alpha}^k = \frac{\alpha(\alpha - 1) \dots (\alpha - k + 1)}{k!}$$

If  $\alpha < k$ , then

$$C_{\alpha}^k = 0$$

$\Phi(x)$

Cumulative Gaussian distribution function

$$\Phi(x) = \int_{-\infty}^x \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{y^2}{2}\right) dy$$

defined over  $-\infty < x < +\infty$ .

$\Phi(-\infty) = 0, \Phi(+\infty) = 1$ .

$\Gamma(\alpha)$

The complete gamma function

$$\Gamma(\alpha) = \int_0^{\infty} t^{\alpha-1} e^{-t} dt$$

where  $\alpha > 0$ .

$B(p, q)$

The complete beta function

$$B(p, q) = \int_0^1 t^{p-1} (1 - t)^{q-1} dt$$

where  $p > 0$  and  $q > 0$ .

LCG( $a, c, m$ )

Linear Congruential Generator  $x_{n+1} = (ax_n + c) \bmod m$ , where  $a$  is called the *multiplier*,  $c$  is called the *increment*, and  $m$  is called the *modulus* of the generator.

MCG( $a, m$ )

Multiplicative Congruential Generator  $x_{n+1} = (ax_n) \bmod m$  is a special case of Linear Congruential Generator, where the increment  $c$  is taken to be 0.

GFSR( $p, q$ )

Generalized Feedback Shift Register Generator

$$x_n = x_{n-p} \oplus x_{n-q}$$

### Random Number Generators Naming Conventions

The names of the routines, types, and constants in VS random number generators are case-sensitive and can contain lowercase and uppercase characters (`viRngUniform`).

The names of generator routines have the following structure:

`v<type of result>Rng<distribution>`

where

- `v` is the prefix of a VS vector function.
- `<type of result>` is either `s`, `d`, or `i` and specifies one of the following types:

<code>s</code>	float
<code>d</code>	double
<code>i</code>	int

Prefixes `s` and `d` apply to continuous distributions only, prefix `i` applies only to discrete case.

- `rng` indicates that the routine is a random generator.
- `<distribution>` specifies the type of statistical distribution.

On 64-bit platforms, routines with the `_64` suffix support large data arrays in the LP64 interface library and enable you to mix integer types in one application. For more interface library details, see "Using the ILP64 Interface vs. LP64 Interface" in the developer guide.

Names of service routines follow the template below:

`vs1<name>`

where

- `vs1` is the prefix of a VS service function.
- `<name>` contains a short function name.

For a more detailed description of service routines, refer to [Service Routines](#) and [Advanced Service Routines](#).

The prototype of each generator routine corresponding to a given probability distribution fits the following structure:

```
status = <function name>( method, stream, n, r, [<distribution parameters>] )
```

where

- *method* defines the method of generation. A detailed description of this parameter can be found in table "Values of *<method>* in *method* parameter". See below, where the structure of the *method* parameter name is explained.
- *stream* defines the descriptor of the random stream and must have a non-zero value. Random streams, descriptors, and their usage are discussed further in [Random Streams](#) and [Service Routines](#).
- *n* defines the number of random values to be generated. If *n* is less than or equal to zero, no values are generated. Furthermore, if *n* is negative, an error condition is set.
- *r* defines the destination array for the generated numbers. The dimension of the array must be large enough to store at least *n* random numbers.
- *status* defines the error status of a VS routine. See [Error Reporting](#) for a detailed description of error status values.

Additional parameters included into *<distribution parameters>* field are individual for each generator routine and are described in detail in [Distribution Generators](#).

To invoke a distribution generator, use a call to the respective VS routine. For example, to obtain a vector *r*, composed of *n* independent and identically distributed random numbers with normal (Gaussian) distribution, that have the mean value *a* and standard deviation *sigma*, write the following:

```
status = vsRngGaussian( method, stream, n, r, a, sigma )
```

The name of a *method* parameter has the following structure:

```
VSL_RNG_METHOD_<distribution>_<method>
```

```
VSL_RNG_METHOD_<distribution>_<method>_ACCURATE
```

where

- *<distribution>* is the probability distribution.
- *<method>* is the method name.

Type of the name structure for the *method* parameter corresponds to fast and accurate modes of random number generation (see "[Distribution Generators](#)" and [VS Notes](#) for details).

Method names VSL\_RNG\_METHOD\_<distribution>\_<method>

and

```
VSL_RNG_METHOD_<distribution>_<method>_ACCURATE
```

should be used with

```
v<precision>Rng<distribution>
```

function only, where

- *<precision>* is
 

<i>s</i>	for single precision continuous distribution
<i>d</i>	for double precision continuous distribution
<i>i</i>	for discrete distribution
- *<distribution>* is the probability distribution.

is the probability distribution. Table "Values of *<method>* in *method* parameter" provides specific predefined values of the *method* name. The third column contains names of the functions that use the given method.

Values of `<method>` in `method` parameter

Method	Short Description	Functions
STD	Standard method. Currently there is only one method for these functions.	Uniform (continuous), Uniform (discrete), UniformBits, UniformBits32, UniformBits64
BOXMULLER	BOXMULLER generates normally distributed random number $x$ thru the pair of uniformly distributed numbers $u_1$ and $u_2$ according to the formula: $x = \sqrt{-2 \ln u_1} \sin 2\pi u_2$	Gaussian, GaussianMV
BOXMULLER2	BOXMULLER2 generates normally distributed random numbers $x_1$ and $x_2$ thru the pair of uniformly distributed numbers $u_1$ and $u_2$ according to the formulas: $x_1 = \sqrt{-2 \ln u_1} \sin 2\pi u_2$ $x_2 = \sqrt{-2 \ln u_1} \cos 2\pi u_2$	Gaussian, GaussianMV, Lognormal
ICDF	Inverse cumulative distribution function method.	Exponential, Laplace, Weibull, Cauchy, Rayleigh, Gumbel, Bernoulli, Geometric, Gaussian, GaussianMV, Lognormal
GNORM	For $\alpha > 1$ , a gamma distributed random number is generated as a cube of properly scaled normal random number; for $0.6 \leq \alpha < 1$ , a gamma distributed random number is generated using rejection from Weibull distribution; for $\alpha < 0.6$ , a gamma distributed random number is obtained using transformation of exponential power distribution; for $\alpha = 1$ , gamma distribution is reduced to exponential distribution.	Gamma
CJA	For $\min(p, q) > 1$ , Cheng method is used; for $\min(p, q) < 1$ , Johnk method is used, if $q + K \cdot p^2 + C \leq 0$ ( $K = 0.852\dots$ , $C = -0.956\dots$ ) otherwise, Atkinson switching algorithm is used; for $\max(p, q) < 1$ , method of Johnk is used; for $\min(p, q) < 1$ , $\max(p, q) > 1$ , Atkinson switching algorithm is used (CJA stands for the first letters of Cheng, Johnk, Atkinson); for $p = 1$ or $q = 1$ , inverse cumulative distribution function method is used; for $p = 1$ and $q = 1$ , beta distribution is reduced to uniform distribution.	Beta

Method	Short Description	Functions

**NOTE**

In this document, routines are often referred to by their base name (`Gaussian`) when this does not lead to ambiguity. In the routine reference, the full name (`vsrnggaussian`, `vsRngGaussian`) is always used in prototypes and code examples.

**Basic Generators**

VS provides pseudorandom, quasi-random, and non-deterministic random number generators. This includes the following BRNGs, which differ in speed and other properties:

- the 31-bit multiplicative congruential pseudorandom number generator `MCG(1132489760, 231 - 1)` [[L'Ecuyer99](#)]
- the 32-bit generalized feedback shift register pseudorandom number generator `GFSR(250, 103)` [[Kirkpatrick81](#)]
- the combined multiple recursive pseudorandom number generator `MRG32k3a` [[L'Ecuyer99a](#)]
- the 59-bit multiplicative congruential pseudorandom number generator `MCG(1313, 259)` from NAG Numerical Libraries [[NAG](#)]
- Wichmann-Hill pseudorandom number generator (a set of 273 basic generators) from NAG Numerical Libraries [[NAG](#)]
- Mersenne Twister pseudorandom number generator `MT19937` [[Matsumoto98](#)] with period length  $2^{19937}-1$  of the produced sequence
- Set of 6024 Mersenne Twister pseudorandom number generators `MT2203` [[Matsumoto98](#)], [[Matsumoto00](#)]. Each of them generates a sequence of period length equal to  $2^{2203}-1$ . Parameters of the generators provide mutual independence of the corresponding sequences.
- SIMD-oriented Fast Mersenne Twister pseudorandom number generator `SFMT19937` [[Saito08](#)] with a period length equal to  $2^{19937}-1$  of the produced sequence.
- Sobol quasi-random number generator [[Sobol76](#)], [[Bratley88](#)], which works in arbitrary dimension. For dimensions greater than 40 the user should supply initialization parameters (initial direction numbers and primitive polynomials or direction numbers) by using `vs1NewStreamEx` function. See additional details on interface for registration of the parameters in the library in [VS Notes](#).
- Niederreiter quasi-random number generator [[Bratley92](#)], which works in arbitrary dimension. For dimensions greater than 318 the user should supply initialization parameters (irreducible polynomials or direction numbers) by using `vs1NewStreamEx` function. See additional details on interface for registration of the parameters in the library in [VS Notes](#).
- Non-deterministic random number generator (RDRAND-based generators only) [[AVX](#)], [[IntelSWMan](#)].

**NOTE**

You can use a non-deterministic random number generator only if the underlying hardware supports it. For instructions on how to detect if an Intel CPU supports a non-deterministic random number generator see, for example, [Chapter 8: Post-32nm Processor Instructions](#) in [[AVX](#)] or [Chapter 4: RdRand Instruction Usage](#) in [[BMT](#)].

**NOTE**

The time required by some non-deterministic sources to generate a random number is not constant, so you might have to make multiple requests before the next random number is available. VS limits the number of retries for requests to the non-deterministic source to 10. You can redefine the maximum number of retries during the initialization of the non-deterministic random number generator with the `vslNewStreamEx` function.

For more details on the non-deterministic source implementation for Intel CPUs please refer to Section 7.3.17, Volume 1, *Random Number Generator Instruction* in [IntelSWMAN] and Section 4.2.2, *RdRand Retry Loop* in [BMT].

- Philox4x32-10 counter-based pseudorandom number generator with a period of  $2^{128}$  *PHILOX4X32X10* [Salmon11].
- ARS-5 counter-based pseudorandom number generator with a period of  $2^{128}$ , which uses instructions from the AES-NI set *ARS5* [Salmon11].

See some testing results for the generators in [VS Notes](#) and comparative performance data at <https://www.intel.com/content/www/us/en/developer/tools/oneapi/onemkl-documentation.html>.

VS provides means of registration of such user-designed generators through the steps described in [Advanced Service Routines](#).

For some basic generators, VS provides two methods of creating independent random streams in multiprocessor computations, which are the leapfrog method and the block-splitting method. These sequence splitting methods are also useful in sequential Monte Carlo.

In addition, MT2203 pseudorandom number generator is a set of 6024 generators designed to create up to 6024 independent random sequences, which might be used in parallel Monte Carlo simulations. Another generator that has the same feature is Wichmann-Hill. It allows creating up to 273 independent random streams. The properties of the generators designed for parallel computations are discussed in detail in [Coddington94].

You may want to design and use your own basic generators. VS provides means of registration of such user-designed generators through the steps described in [Advanced Service Routines](#).

There is also an option to utilize externally generated random numbers in VS distribution generator routines. For this purpose VS provides three additional basic random number generators:

- for external random data packed in 32-bit integer array
- for external random data stored in double precision floating-point array; data is supposed to be uniformly distributed over  $(a,b)$  interval
- for external random data stored in single precision floating-point array; data is supposed to be uniformly distributed over  $(a,b)$  interval.

Such basic generators are called the abstract basic random number generators.

See [VS Notes](#) for a more detailed description of the generator properties.

**Product and Performance Information**

Notice revision #20201201

**BRNG Parameter Definition**

Predefined values for the `brng` input parameter are as follows:

**Values of `brng` parameter**

Value	Short Description
VSL_BRNG_MCG31	A 31-bit multiplicative congruential generator.

Value	Short Description
VSL_BRNG_R250	A generalized feedback shift register generator.
VSL_BRNG_MRG32K3A	A combined multiple recursive generator with two components of order 3.
VSL_BRNG_MCG59	A 59-bit multiplicative congruential generator.
VSL_BRNG_WH	A set of 273 Wichmann-Hill combined multiplicative congruential generators.
VSL_BRNG_MT19937	A Mersenne Twister pseudorandom number generator.
VSL_BRNG_MT2203	A set of 6024 Mersenne Twister pseudorandom number generators.
VSL_BRNG_SFMT19937	A SIMD-oriented Fast Mersenne Twister pseudorandom number generator.
VSL_BRNG_SOBOL	A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \leq s \leq 40$ ; user-defined dimensions are also available.
VSL_BRNG_NIEDERR	A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \leq s \leq 318$ ; user-defined dimensions are also available.
VSL_BRNG_IABSTRACT	An abstract random number generator for integer arrays.
VSL_BRNG_DABSTRACT	An abstract random number generator for double precision floating-point arrays.
VSL_BRNG_SABSTRACT	An abstract random number generator for single precision floating-point arrays.
VSL_BRNG_NONDETERM	A non-deterministic random number generator.
VSL_BRNG_PHILOX4X32X10	A Philox4x32-10 counter-based pseudorandom number generator.
VSL_BRNG_ARS5	An ARS-5 counter-based pseudorandom number generator that uses instructions from the AES-NI set.

See [VS Notes](#) for detailed description.

Notice revision #20201201

### Random Streams

*Random stream* (or *stream*) is an abstract source of pseudo- and quasi-random sequences of uniform distribution. You can operate with stream state descriptors only. A stream state descriptor, which holds state descriptive information for a particular BRNG, is a necessary parameter in each routine of a distribution generator. Only the distribution generator routines operate with random streams directly. See [VS Notes](#) for details.

**NOTE**

Random streams associated with abstract basic random number generator are called the abstract random streams. See [VS Notes](#) for detailed description of abstract streams and their use.

You can create unlimited number of random streams by VS [Service Routines](#) like [NewStream](#) and utilize them in any distribution generator to get the sequence of numbers of given probability distribution. When they are no longer needed, the streams should be deleted calling service routine [DeleteStream](#).

VS provides service functions [SaveStreamF](#) and [LoadStreamF](#) to save random stream descriptive data to a binary file and to read this data from a binary file respectively. See [VS Notes](#) for detailed description.

**BRNG Data Types**

```
typedef (void*) VSLStreamStatePtr;
```

See [Advanced Service Routines](#) for the format of the stream state structure for user-designed generators.

**Error Reporting**

VS RNG routines return status codes of the performed operation to report errors to the calling program. The application should perform error-related actions and/or recover from the error. The status codes are of integer type and have the following format:

VSL\_ERROR\_<ERROR\_NAME> - indicates VS errors common for all VS domains.

VSL\_RNG\_ERROR\_<ERROR\_NAME> - indicates VS RNG errors.

VS RNG errors are of negative values while warnings are of positive values. The status code of zero value indicates successful completion of the operation: VSL\_ERROR\_OK (or synonymic VSL\_STATUS\_OK).

**Status Codes**

Status Code	Description
<b>Common VSL</b>	
VSL_ERROR_OK, VSL_STATUS_OK	No error, execution is successful.
VSL_ERROR_BADARGS	Input argument value is not valid.
VSL_ERROR_CPU_NOT_SUPPORTED	CPU version is not supported.
VSL_ERROR_FEATURE_NOT_IMPLEMENTED	Feature invoked is not implemented.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory.
VSL_ERROR_NULL_PTR	Input pointer argument is NULL.
VSL_ERROR_UNKNOWN	Unknown error.
<b>VS RNG Specific</b>	
VSL_RNG_ERROR_BAD_FILE_FORMAT	File format is unknown.
VSL_RNG_ERROR_BAD_MEM_FORMAT	Descriptive random stream format is unknown.
VSL_RNG_ERROR_BAD_NBITS	The value in NBits field is bad.
VSL_RNG_ERROR_BAD_NSEEDS	The value in NSeeds field is bad.

Status Code	Description
VSL_RNG_ERROR_BAD_STREAM	The random stream is invalid.
VSL_RNG_ERROR_BAD_STREAM_STATE_SIZE	The value in <code>StreamStateSize</code> field is bad.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, $< 0$ or $> n_{max}$ .
VSL_RNG_ERROR_BAD_WORD_SIZE	The value in <code>WordSize</code> field is bad.
VSL_RNG_ERROR_BRNG_NOT_SUPPORTED	BRNG is not supported by the function.
VSL_RNG_ERROR_BRNG_TABLE_FULL	Registration cannot be completed due to lack of free entries in the table of registered BRNGs.
VSL_RNG_ERROR_BRNGS_INCOMPATIBLE	Two BRNGs are not compatible for the operation.
VSL_RNG_ERROR_FILE_CLOSE	Error in closing the file.
VSL_RNG_ERROR_FILE_OPEN	Error in opening the file.
VSL_RNG_ERROR_FILE_READ	Error in reading the file.
VSL_RNG_ERROR_FILE_WRITE	Error in writing the file.
VSL_RNG_ERROR_INVALID_ABSTRACT_STREAM	The abstract random stream is invalid.
VSL_RNG_ERROR_INVALID_BRNG_INDEX	BRNG index is not valid.
VSL_RNG_ERROR_LEAPFROG_UNSUPPORTED	BRNG does not support Leapfrog method.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns zero as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator is exceeded.
VSL_RNG_ERROR_SKIPAHEAD_UNSUPPORTED	BRNG does not support Skip-Ahead method.
VSL_RNG_ERROR_SKIPAHEAD_EX_UNSUPPORTED	BRNG does not support advanced Skip-Ahead method.
VSL_RNG_ERROR_UNSUPPORTED_FILE_VER	File format version is not supported.
VSL_RNG_ERROR_NONDETERM_NOT_SUPPORTED	Non-deterministic random number generator is not supported on the CPU running the application.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number using non-deterministic random number generator exceeds threshold (see Section 7.2.1.12 <i>Non-deterministic</i> in [VS Notes] for more details)
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

Notice revision #20201201

**VS RNG Usage Model** Intel® oneMKL RNG Usage Model

A typical algorithm for VSoneMKL random number generators is as follows:

1. Create and initialize stream/streams. Functions `vslNewStream`, `vslNewStreamEx`, `vslCopyStream`, `vslCopyStreamState`, `vslLeapfrogStream`, `vslSkipAheadStream`, `vslSkipAheadStreamEx`.
2. Call one or more RNGs.
3. Process the output.
4. Delete the stream or streams with the function `vslDeleteStream`.

**NOTE**

You may reiterate steps 2-3. Random number streams may be generated for different threads.

The following example demonstrates generation of a random stream that is output of basic generator MT19937. The seed is equal to 777. The stream is used to generate 10,000 normally distributed random numbers in blocks of 1,000 random numbers with parameters  $a = 5$  and  $\sigma = 2$ . Delete the streams after completing the generation. The purpose of the example is to calculate the sample mean for normal distribution with the given parameters.

**Example of VS RNG Usage**

```
#include <stdio.h>
#include "mkl_vsl.h"

int main()
{
    double r[1000]; /* buffer for random numbers */
    double s; /* average */
    VSLStreamStatePtr stream;
    int i, j;

    /* Initializing */
    s = 0.0;
    vslNewStream( &stream, VSL_BRNG_MT19937, 777 );

    /* Generating */
    for ( i=0; i<10; i++ ) {
        vdRngGaussian( VSL_RNG_METHOD_GAUSSIAN_ICDF, stream, 1000, r, 5.0, 2.0 );
        for ( j=0; j<1000; j++ ) {
            s += r[j];
        }
    }
    s /= 10000.0;

    /* Deleting the stream */
    vslDeleteStream( &stream );

    /* Printing results */
    printf( "Sample mean of normal distribution = %f\n", s );

    return 0;
}
```

Additionally, examples that demonstrate usage of VS random number generators are available in:

`$(MKL)/examples/vslc/source`

## Service Routines

Stream handling comprises routines for creating, deleting, or copying the streams and getting the index of a basic generator. A random stream can also be saved to and then read from a binary file. [Table "Service Routines"](#) lists all available service routines

### Service Routines

Routine	Short Description
<code>vslNewStream</code>	Creates and initializes a random stream.
<code>vslNewStreamEx</code>	Creates and initializes a random stream for the generators with multiple initial conditions.
<code>vslNewAbstractStream</code>	Creates and initializes an abstract random stream for integer arrays.
<code>vslNewAbstractStream</code>	Creates and initializes an abstract random stream for double precision floating-point arrays.
<code>vslNewAbstractStream</code>	Creates and initializes an abstract random stream for single precision floating-point arrays.
<code>vslDeleteStream</code>	Deletes previously created stream.
<code>vslCopyStream</code>	Copies a stream to another stream.
<code>vslCopyStreamState</code>	Creates a copy of a random stream state.
<code>vslSaveStreamF</code>	Writes a stream to a binary file.
<code>vslLoadStreamF</code>	Reads a stream from a binary file.
<code>vslSaveStreamM</code>	Writes a random stream descriptive data, including state, to a memory buffer.
<code>vslLoadStreamM</code>	Creates a new stream and reads stream descriptive data, including state, from the memory buffer.
<code>vslGetStreamSize</code>	Computes size of memory necessary to hold the random stream.
<code>vslLeapfrogStream</code>	Initializes the stream by the leapfrog method to generate a subsequence of the original sequence.
<code>vslSkipAheadStream</code>	Initializes the stream by the skip-ahead method.
<code>vslSkipAheadStreamEx</code>	Initializes the stream by the advanced skip-ahead method.
<code>vslGetStreamStateBrng</code>	Obtains the index of the basic generator responsible for the generation of a given random stream.
<code>vslGetNumRegBrngs</code>	Obtains the number of currently registered basic generators.

Most of the generator-based work comprises three basic steps:

1. Creating and initializing a stream (`vslNewStream`, `vslNewStreamEx`, `vslCopyStream`, `vslCopyStreamState`, `vslLeapfrogStream`, `vslSkipAheadStream`, `vslSkipAheadStreamEx`).
2. Generating random numbers with given distribution, see [Distribution Generators](#).
3. Deleting the stream (`vslDeleteStream`).

Note that you can concurrently create multiple streams and obtain random data from one or several generators by using the stream state. You must use the [vslDeleteStream](#) function to delete all the streams afterwards.

## vslNewStream

*Creates and initializes a random stream.*

### Syntax

```
status = vslNewStream( &stream, brng, seed );
```

### Include Files

- `mkl.h`

### Input Parameters

Name	Type	Description
<i>brng</i>	const MKL_INT	Index of the basic generator to initialize the stream. See <a href="#">Table Values of <i>brng</i> parameter</a> for specific value.
<i>seed</i>	const MKL_UINT	Initial condition of the stream. In the case of a quasi-random number generator seed parameter is used to set the dimension. If the dimension is greater than the dimension that <i>brng</i> can support or is less than 1, then the dimension is assumed to be equal to 1.

### Output Parameters

Name	Type	Description
<i>stream</i>	VSLStreamStatePtr*	Stream state descriptor

### Description

For a basic generator with number *brng*, this function creates a new stream and initializes it with a 32-bit seed. The seed is an initial value used to select a particular sequence generated by the basic generator *brng*. The function is also applicable for generators with multiple initial conditions. Use this function to create and initialize a new stream with a 32-bit seed only. If you need to provide multiple initial conditions such as several 32-bit or wider seeds, use the function [vslNewStreamEx](#). See [VS Notes](#) for a more detailed description of stream initialization for different basic generators.

#### NOTE

This function is not applicable for abstract basic random number generators. Please use [vslNewAbstractStream](#), [vs1sNewAbstractStream](#) or [vs1dNewAbstractStream](#) to utilize integer, single-precision or double-precision external random data respectively.

#### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_RNG_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .
VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED	Non-deterministic random number generator is not supported.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

## vslNewStreamEx

*Creates and initializes a random stream for generators with multiple initial conditions.*

### Syntax

```
status = vslNewStreamEx( &stream, brng, n, params );
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>brng</i>	const MKL_INT	Index of the basic generator to initialize the stream. See <a href="#">Table "Values of <i>brng</i> parameter"</a> for specific value.
<i>n</i>	const MKL_INT	Number of initial conditions contained in <i>params</i>
<i>params</i>	const unsigned int	Array of initial conditions necessary for the basic generator <i>brng</i> to initialize the stream. In the case of a quasi-random number generator only the first element in <i>params</i> parameter is used to set the dimension. If the dimension is greater than the dimension that <i>brng</i> can support or is less than 1, then the dimension is assumed to be equal to 1.

### Output Parameters

Name	Type	Description
<i>stream</i>	VSLStreamStatePtr*	Stream state descriptor

### Description

The `vslNewStreamEx` function provides an advanced tool to set the initial conditions for a basic generator if its input arguments imply several initialization parameters. Initial values are used to select a particular sequence generated by the basic generator *brng*. Whenever possible, use `vslNewStream`, which is analogous to `vslNewStreamEx` except that it takes only one 32-bit initial condition. In particular, `vslNewStreamEx` may be used to initialize the state table in Generalized Feedback Shift Register Generators (GFSRs). A more detailed description of this issue can be found in [VS Notes](#).

This function is also used to pass user-defined initialization parameters of quasi-random number generators into the library. See [VS Notes](#) for the format for their passing and registration in VS.

**NOTE**

This function is not applicable for abstract basic random number generators. Please use [vsliNewAbstractStream](#), [vslsNewAbstractStream](#) or [vsldNewAbstractStream](#) to utilize integer, single-precision or double-precision external random data respectively.

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

**Return Values**

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_RNG_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .
VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED	Non-deterministic random number generator is not supported.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

**vsliNewAbstractStream**

*Creates and initializes an abstract random stream for integer arrays.*

**Syntax**

```
status = vsliNewAbstractStream( &stream, n, ibuf, icallback );
```

**Include Files**

- mkl.h

**Input Parameters**

Name	Type	Description
<i>n</i>	const MKL_INT	Size of the array <i>ibuf</i>
<i>ibuf</i>	const unsigned int	Array of <i>n</i> 32-bit integers
<i>icallback</i>		Pointer to the callback function used for <i>ibuf</i> update

**NOTE**

Format of the callback function:

```
int iUpdateFunc( VSLStreamStatePtrstream, int* n, unsigned int ibuf[], int* nmin, int* nmax, int* idx );
```

The callback function returns the number of elements in the array actually updated by the function. [Table icallback Callback Function Parameters](#) gives the description of the callback function parameters.

## icallback Callback Function Parameters

Parameters	Short Description
<i>stream</i>	Abstract random stream descriptor
<i>n</i>	Size of <i>ibuf</i>
<i>ibuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>ibuf</i> to start update $0 \leq idx < n$ .

## Output Parameters

Name	Type	Description
<i>stream</i>	VSLStreamStatePtr*	Descriptor of the stream state structure

## Description

The `vslNewAbstractStream` function creates a new abstract stream and associates it with an integer array *ibuf* and your callback function *icallback* that is intended for updating of *ibuf* content.

## Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BADARGS	Parameter <i>n</i> is not positive.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .
VSL_ERROR_NULL_PTR	Either buffer or callback function parameter is a NULL pointer.

## vsldNewAbstractStream

*Creates and initializes an abstract random stream for double precision floating-point arrays.*

## Syntax

```
status = vsldNewAbstractStream( &stream, n, dbuf, a, b, dcallback );
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Size of the array <i>dbuf</i>
<i>dbuf</i>	const double	Array of <i>n</i> double precision floating-point random numbers with uniform distribution over interval ( <i>a</i> , <i>b</i> )

Name	Type	Description
<i>a</i>	const double	Left boundary <i>a</i>
<i>b</i>	const double	Right boundary <i>b</i>
<i>dcallback</i>	See <i>Note</i> below	Pointer to the callback function used for update of the array <i>dbuf</i>

## Output Parameters

Name	Type	Description
<i>stream</i>	VSLStreamStatePtr*	Descriptor of the stream state structure

### NOTE

Format of the callback function:

```
int dUpdateFunc( VSLStreamStatePtr stream, int* n, double dbuf[], int* nmin, int* nmax,
int* idx );
```

The callback function returns the number of elements in the array actually updated by the function. [Table \*dcallback\* Callback Function Parameters](#) gives the description of the callback function parameters.

## *dcallback* Callback Function Parameters

Parameters	Short Description
<i>stream</i>	Abstract random stream descriptor
<i>n</i>	Size of <i>dbuf</i>
<i>dbuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>dbuf</i> to start update $0 \leq idx < n$ .

## Description

The `vslNewAbstractStream` function creates a new abstract stream for double precision floating-point arrays with random numbers of the uniform distribution over interval  $(a,b)$ . The function associates the stream with a double precision array *dbuf* and your callback function *dcallback* that is intended for updating of *dbuf* content.

## Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BADARGS	Parameter <i>n</i> is not positive.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .
VSL_ERROR_NULL_PTR	Either buffer or callback function parameter is a NULL pointer.

## vslsNewAbstractStream

Creates and initializes an abstract random stream for single precision floating-point arrays.

### Syntax

```
status = vslsNewAbstractStream( &stream, n, sbuf, a, b, scallback );
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Size of the array <i>sbuf</i>
<i>sbuf</i>	const float	Array of <i>n</i> single precision floating-point random numbers with uniform distribution over interval (a,b)
<i>a</i>	const float	Left boundary a
<i>b</i>	const float	Right boundary b
<i>scallback</i>	See <i>Note</i> below	Pointer to the callback function used for update of the array <i>sbuf</i>

### Output Parameters

Name	Type	Description
<i>stream</i>	VSLStreamStatePtr*	Descriptor of the stream state structure

#### NOTE

Format of the callback function in C:

```
int sUpdateFunc( VSLStreamStatePtr stream, int* n, float sbuf[], int* nmin, int* nmax,
int* idx );
```

The callback function returns the number of elements in the array actually updated by the function. [Table \*scallback\* Callback Function Parameters](#) gives the description of the callback function parameters.

### *scallback* Callback Function Parameters

Parameters	Short Description
<i>stream</i>	Abstract random stream descriptor
<i>n</i>	Size of <i>sbuf</i>
<i>sbuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>sbuf</i> to start update $0 \leq idx < n$ .

## Description

The `vslsNewAbstractStream` function creates a new abstract stream for single precision floating-point arrays with random numbers of the uniform distribution over interval  $(a,b)$ . The function associates the stream with a single precision array `sbuf` and your callback function `scallback` that is intended for updating of `sbuf` content.

## Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_BADARGS</code>	Parameter <code>n</code> is not positive.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory for <code>stream</code> .
<code>VSL_ERROR_NULL_PTR</code>	Either buffer or callback function parameter is a <code>NULL</code> pointer.

## `vslDeleteStream`

*Deletes a random stream.*

---

## Syntax

```
status = vslDeleteStream( &stream );
```

## Include Files

- `mkl.h`

## Input/Output Parameters

Name	Type	Description
<code>stream</code>	<code>VSLStreamStatePtr*</code>	Stream state descriptor. Must have non-zero value. After the stream is successfully deleted, the pointer is set to <code>NULL</code> .

## Description

The function deletes the random stream created by one of the initialization functions.

## Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<code>stream</code> parameter is a <code>NULL</code> pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<code>stream</code> is not a valid random stream.

## `vslCopyStream`

*Creates a copy of a random stream.*

---

## Syntax

```
status = vslCopyStream( &newstream, srcstream );
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>srcstream</i>	const VSLStreamStatePtr	Pointer to the stream state structure to be copied

## Output Parameters

Name	Type	Description
<i>newstream</i>	VSLStreamStatePtr*	Copied random stream descriptor

## Description

The function creates an exact copy of *srcstream* and stores its descriptor to *newstream*.

## Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>srcstream</i> parameter is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>srcstream</i> is not a valid random stream.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>newstream</i> .

## vslCopyStreamState

*Creates a copy of a random stream state.*

## Syntax

```
status = vslCopyStreamState( deststream, srcstream );
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>srcstream</i>	const VSLStreamStatePtr	Pointer to the stream state structure, from which the state structure is copied

## Output Parameters

Name	Type	Description
<i>deststream</i>	VSLStreamStatePtr	Pointer to the stream state structure where the stream state is copied

## Description

The `vslCopyStreamState` function copies a stream state from *srcstream* to the existing *deststream* stream. Both the streams should be generated by the same basic generator. An error message is generated when the index of the BRNG that produced *deststream* stream differs from the index of the BRNG that generated *srcstream* stream.

Unlike `vslCopyStream` function, which creates a new stream and copies both the stream state and other data from *srcstream*, the function `vslCopyStreamState` copies only *srcstream* stream state data to the generated *deststream* stream.

## Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	Either <i>srcstream</i> or <i>deststream</i> is a NULL pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	Either <i>srcstream</i> or <i>deststream</i> is not a valid random stream.
<code>VSL_RNG_ERROR_BRNGS_INCOMPATIBLE</code>	BRNG associated with <i>srcstream</i> is not compatible with BRNG associated with <i>deststream</i> .

## vslSaveStreamF

Writes random stream descriptive data, including stream state, to binary file.

## Syntax

```
errstatus = vslSaveStreamF( stream, fname );
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<i>stream</i>	<code>const VSLStreamStatePtr</code>	Random stream to be written to the file
<i>fname</i>	<code>const char*</code>	File name specified as a null-terminated string

## Output Parameters

Name	Type	Description
<i>errstatus</i>	<code>int</code>	Error status of the operation

## Description

The `vslSaveStreamF` function writes the random stream descriptive data, including the stream state, to the binary file. Random stream descriptive data is saved to the binary file with the name *fname*. The random stream *stream* must be a valid stream created by `vslNewStream`-like or `vslCopyStream`-like service routines. If the stream cannot be saved to the file, *errstatus* has a non-zero value. The random stream can be read from the binary file using the `vslLoadStreamF` function.

## Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	Either <i>fname</i> or <i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_FILE_OPEN	Indicates an error in opening the file.
VSL_RNG_ERROR_FILE_WRITE	Indicates an error in writing the file.
VSL_RNG_ERROR_FILE_CLOSE	Indicates an error in closing the file.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for internal needs.

## vslLoadStreamF

Creates new stream and reads stream descriptive data, including stream state, from binary file.

### Syntax

```
errstatus = vslLoadStreamF( &stream, fname );
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>fname</i>	const char*	File name specified as a null-terminated string

### Output Parameters

Name	Type	Description
<i>stream</i>	VSLStreamStatePtr*	Pointer to a new random stream
<i>errstatus</i>	int	Error status of the operation

### Description

The `vslLoadStreamF` function creates a new stream and reads stream descriptive data, including the stream state, from the binary file. A new random stream is created using the stream descriptive data from the binary file with the name *fname*. If the stream cannot be read (for example, an I/O error occurs or the file format is invalid), *errstatus* has a non-zero value. To save random stream to the file, use `vslSaveStreamF` function.

---

### Caution

Calling `vslLoadStreamF` with a previously initialized *stream* pointer can have unintended consequences such as a memory leak. To initialize a stream which has been in use until calling `vslLoadStreamF`, you should call the `vslDeleteStream` function first to deallocate the resources.

---

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

**Return Values**

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>fname</i> is a NULL pointer.
VSL_RNG_ERROR_FILE_OPEN	Indicates an error in opening the file.
VSL_RNG_ERROR_FILE_WRITE	Indicates an error in writing the file.
VSL_RNG_ERROR_FILE_CLOSE	Indicates an error in closing the file.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for internal needs.
VSL_RNG_ERROR_BAD_FILE_FORMAT	Unknown file format.
VSL_RNG_ERROR_UNSUPPORTED_FILE_VER	File format version is unsupported.
VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED	Non-deterministic random number generator is not supported.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

**vslSaveStreamM**

*Writes random stream descriptive data, including stream state, to a memory buffer.*

**Syntax**

```
errstatus = vslSaveStreamM( stream, memptr );
```

**Include Files**

- mkl.h

**Input Parameters**

Name	Type	Description
<i>stream</i>	const VSLStreamStatePtr	Random stream to be written to the memory
<i>memptr</i>	char*	Memory buffer to save random stream descriptive data to

**Output Parameters**

Name	Type	Description
<i>errstatus</i>	int	Error status of the operation

## Description

The `vslSaveStreamM` function writes the random stream descriptive data, including the stream state, to the memory at `memptr`. Random stream `stream` must be a valid stream created by `vslNewStream`-like or `vslCopyStream`-like service routines. The `memptr` parameter must be a valid pointer to the memory of size sufficient to hold the random stream `stream`. Use the service routine `vslGetStreamSize` to determine this amount of memory.

If the stream cannot be saved to the memory, `errstatus` has a non-zero value. The random stream can be read from the memory pointed by `memptr` using the `vslLoadStreamM` function.

## Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	Either <code>memptr</code> or <code>stream</code> is a NULL pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<code>stream</code> is a NULL pointer.

## `vslLoadStreamM`

*Creates a new stream and reads stream descriptive data, including stream state, from the memory buffer.*

## Syntax

```
errstatus = vslLoadStreamM( &stream, memptr );
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>memptr</code>	<code>const char*</code>	Memory buffer to load random stream descriptive data from

## Output Parameters

Name	Type	Description
<code>stream</code>	<code>VSLStreamStatePtr*</code>	Pointer to a new random stream
<code>errstatus</code>	<code>int</code>	Error status of the operation

## Description

The `vslLoadStreamM` function creates a new stream and reads stream descriptive data, including the stream state, from the memory buffer. A new random stream is created using the stream descriptive data from the memory pointer by `memptr`. If the stream cannot be read (for example, `memptr` is invalid), `errstatus` has a non-zero value. To save random stream to the memory, use `vslSaveStreamM` function. Use the service routine `vslGetStreamSize` to determine the amount of memory sufficient to hold the random stream.

**Caution**

Calling `LoadStreamM` with a previously initialized `stream` pointer can have unintended consequences such as a memory leak. To initialize a stream which has been in use until calling `vslLoadStreamM`, you should call the `vslDeleteStream` function first to deallocate the resources.

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

**Return Values**

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<code>memptr</code> is a NULL pointer.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory for internal needs.
<code>VSL_RNG_ERROR_BAD_MEM_FORMAT</code>	Descriptive random stream format is unknown.
<code>VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED</code>	Non-deterministic random number generator is not supported.
<code>VSL_RNG_ERROR_ARS5_NOT_SUPPORTED</code>	ARS-5 random number generator is not supported on the CPU running the application.

**vslGetStreamSize**

Computes size of memory necessary to hold the random stream.

**Syntax**

```
memsize = vslGetStreamSize( stream );
```

**Include Files**

- `mkl.h`

**Input Parameters**

Name	Type	Description
<code>stream</code>	<code>const VSLStreamStatePtr</code>	Random stream

**Output Parameters**

Name	Type	Description
<code>memsize</code>	<code>int</code>	Amount of memory in bytes necessary to hold descriptive data of random stream <code>stream</code>

## Description

The `vslGetStreamSize` function returns the size of memory in bytes which is necessary to hold the given random stream. Use the output of the function to allocate the buffer to which you will save the random stream by means of the `vslSaveStreamM` function.

## Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<code>stream</code> is a NULL pointer.

## `vslLeapfrogStream`

Initializes a stream using the leapfrog method.

## Syntax

```
status = vslLeapfrogStream( stream, k, nstreams );
```

## Include Files

- `mkl.h`

## Input Parameters

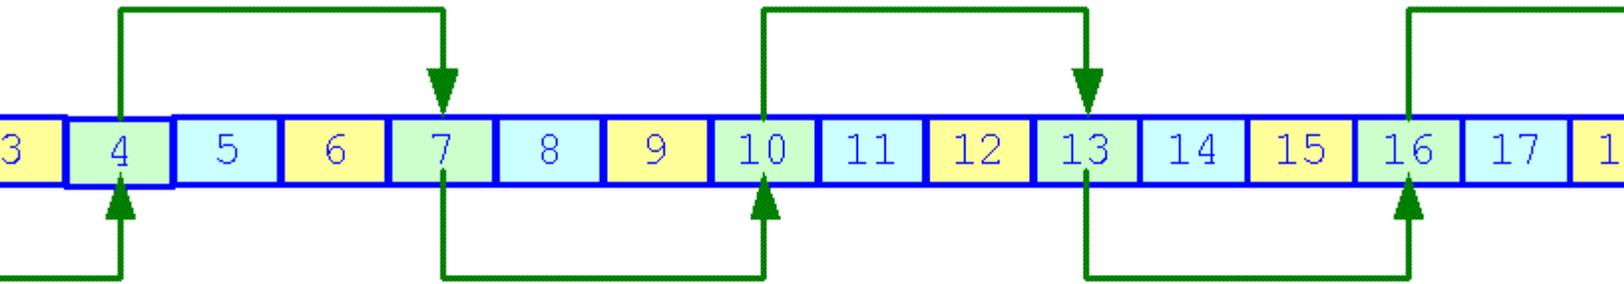

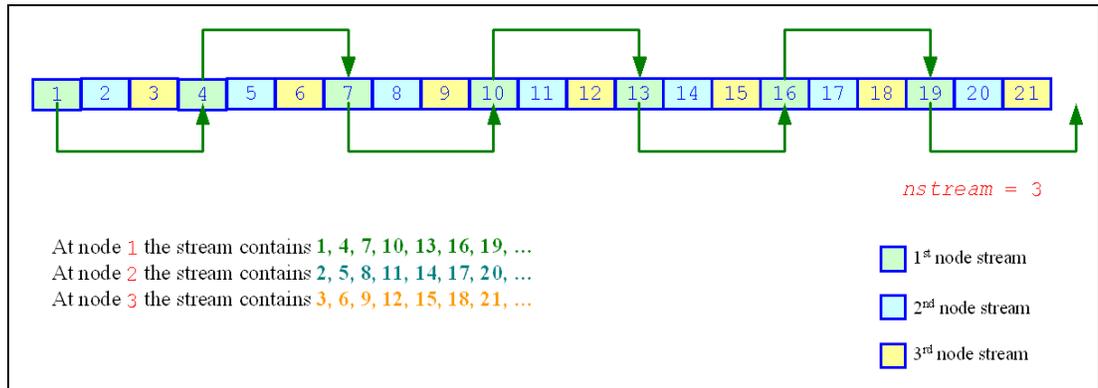

Name	Type	Description
<code>stream</code>	<code>VSLStreamStatePtr</code>	Pointer to the stream state structure to which leapfrog method is applied
<code>k</code>	<code>const MKL_INT</code>	Index of the computational node, or stream number
<code>nstreams</code>	<code>const MKL_INT</code>	Largest number of computational nodes, or stride

## Description

The `vslLeapfrogStream` function generates random numbers in a random stream with non-unit stride. This feature is particularly useful in distributing random numbers from the original stream across the `nstreams` buffers without generating the original random sequence with subsequent manual distribution.

One of the important applications of the leapfrog method is splitting the original sequence into non-overlapping subsequences across `nstreams` computational nodes. The function initializes the original random stream (see [Figure "Leapfrog Method"](#)) to generate random numbers for the computational node  $k$ ,  $0 \leq k < nstreams$ , where `nstreams` is the largest number of computational nodes used.

\_\_border\_\_top

**Leapfrog Method**

the stream contains 1, 4, 7, 10, 13, 16, 19, ...  
 the stream contains 2, 5, 8, 11, 14, 17, 20, ...  
 the stream contains 3, 6, 9, 12, 15, 18, 21, ...

The leapfrog method is supported only for those basic generators that allow splitting elements by the leapfrog method, which is more efficient than simply generating them by a generator with subsequent manual distribution across computational nodes. See [VS Notes](#) for details.

For quasi-random basic generators, the leapfrog method allows generating individual components of quasi-random vectors instead of whole quasi-random vectors. In this case *nstreams* parameter should be equal to the dimension of the quasi-random vector while *k* parameter should be the index of a component to be generated ( $0 \leq k < nstreams$ ). Other parameters values are not allowed.

The following code illustrates the initialization of three independent streams using the leapfrog method:

## Code for Leapfrog Method

```

...
VSLStreamStatePtr stream1;
VSLStreamStatePtr stream2;
VSLStreamStatePtr stream3;

/* Creating 3 identical streams */
status = vslNewStream(&stream1, VSL_BRNG_MCG31, 174);
status = vslCopyStream(&stream2, stream1);
status = vslCopyStream(&stream3, stream1);

/* Leapfrogging the streams
*/
status = vslLeapfrogStream(stream1, 0, 3);
status = vslLeapfrogStream(stream2, 1, 3);
status = vslLeapfrogStream(stream3, 2, 3);

/* Generating random numbers
*/
...
/* Deleting the streams
*/
status = vslDeleteStream(&stream1);
status = vslDeleteStream(&stream2);
status = vslDeleteStream(&stream3);
...

```

### Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_LEAPFROG_UNSUPPORTED	BRNG does not support Leapfrog method.

### vslSkipAheadStream

*Initializes a stream using the block-splitting method.*

### Syntax

```
status = vslSkipAheadStream( stream, nskip);
```

### Include Files

- mkl.h

### Input Parameters

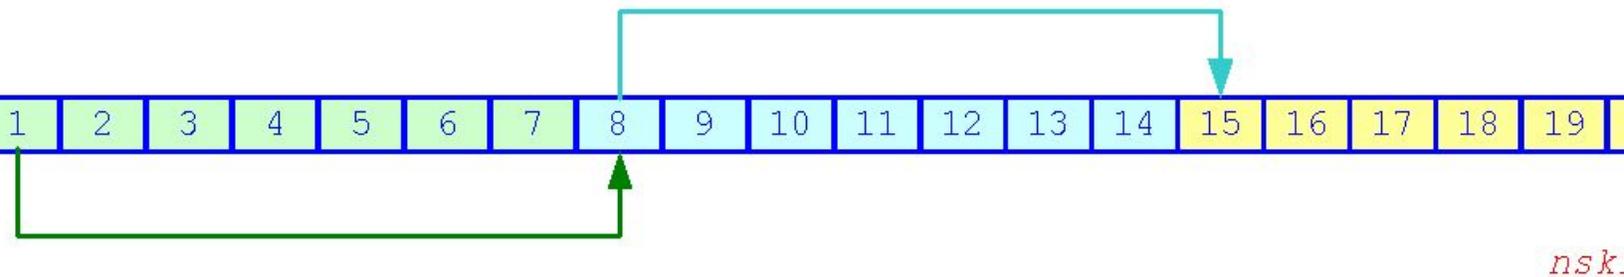

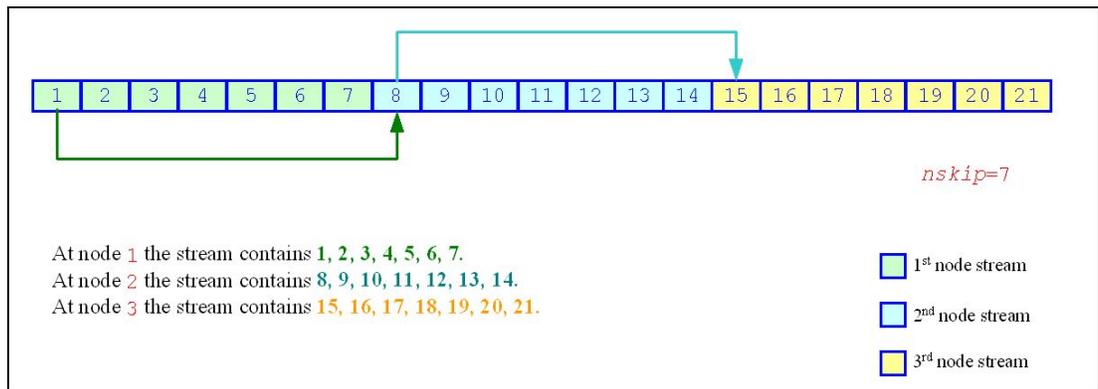

Name	Type	Description
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure to which block-splitting method is applied
<i>nskip</i>	const long long int	Number of skipped elements

## Description

The `vslSkipAheadStream` function skips a given number of elements in a random stream. This feature is particularly useful in distributing random numbers from original random stream across different computational nodes. If the largest number of random numbers used by a computational node is  $n_{skip}$ , then the original random sequence may be split by `vslSkipAheadStream` into non-overlapping blocks of  $n_{skip}$  size so that each block corresponds to the respective computational node. The number of computational nodes is unlimited. This method is known as the block-splitting method or as the skip-ahead method. (see [Figure "Block-Splitting Method"](#)).

\_\_border\_\_top

### Block-Splitting Method

At node 1 the stream contains 1, 2, 3, 4, 5, 6, 7.  
 At node 2 the stream contains 8, 9, 10, 11, 12, 13, 14.  
 At node 3 the stream contains 15, 16, 17, 18, 19, 20, 21.

- 1<sup>st</sup> nod
- 2<sup>nd</sup> nod
- 3<sup>rd</sup> nod

The skip-ahead method is supported only for those basic generators that allow skipping elements by the skip-ahead method, which is more efficient than simply generating them by generator with subsequent manual skipping. See [VS Notes](#) for details.

Please note that for quasi-random basic generators the skip-ahead method works with components of quasi-random vectors rather than with whole quasi-random vectors. Therefore, to skip `NS` quasi-random vectors, set the `nskip` parameter equal to the `NS*DIMEN`, where `DIMEN` is the dimension of the quasi-random vector. If this operation results in exceeding the period of the quasi-random number generator, which is  $2^{32}-1$ , the library returns the `VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED` error code.

The following code illustrates how to initialize three independent streams using the `vslSkipAheadStream` function:

## Code for Block-Splitting Method

---

```
VSLStreamStatePtr stream1;
VSLStreamStatePtr stream2;
VSLStreamStatePtr stream3;

/* Creating the 1st stream
*/
status = vslNewStream(&stream1, VSL_BRNG_MCG31, 174);

/* Skipping ahead by 7 elements the 2nd stream */
status = vslCopyStream(&stream2, stream1);
status = vslSkipAheadStream(stream2, 7);

/* Skipping ahead by 7 elements the 3rd stream */
status = vslCopyStream(&stream3, stream2);
status = vslSkipAheadStream(stream3, 7);

/* Generating random numbers
*/
...
/* Deleting the streams
*/
status = vslDeleteStream(&stream1);
status = vslDeleteStream(&stream2);
status = vslDeleteStream(&stream3);
...
```

## Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<code>stream</code> is a <code>NULL</code> pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<code>stream</code> is not a valid random stream.
<code>VSL_RNG_ERROR_SKIPAHEAD_UNSUPPORTED</code>	BRNG does not support the Skip-Ahead method.
<code>VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED</code>	Period of the quasi-random number generator is exceeded.

## `vslSkipAheadStreamEx`

*Initializes a stream using the block-splitting method with partitioned number of skipped elements.*

---

## Syntax

```
status = vslSkipAheadStreamEx( stream, n, nskip);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure to which block-splitting method is applied
<i>n</i>	const MKL_INT	Number of summands in <i>nskip</i>
<i>nskip</i>	const MKL_UINT64[]	Partitioned number of skipped elements

## Description

The `vslSkipAheadStreamEx` function skips a given number of elements in a random stream. This feature is particularly useful in distributing random numbers from original random stream across different computational nodes. If the largest number of random numbers used by a computational node is *nskip*, then the original random sequence may be split by `vslSkipAheadStreamEx` into non-overlapping blocks of *nskip* size so that each block corresponds to the respective computational node. The number of computational nodes is unlimited. This method is known as the block-splitting method or as the skip-ahead method.

Use this function when the number of elements to skip in a random stream is greater than  $2^{63}$ . Prior calls to the function represent the number of skipped elements with array of size *n* as shown below:

$$nskip[0] + nskip[1] * 2^{64} + nskip[2] * 2^{128} + \dots + nskip[n-1] * 2^{(64 * (n-1))};$$

When the number of skipped elements is less than  $2^{63}$  you can use either `vslSkipAheadStreamEx` or `vslSkipAheadStream`. The following code illustrates how to initialize three independent streams using the `vslSkipAheadStreamEx` function:

```
VSLStreamStatePtr stream1; VSLStreamStatePtr stream2; VSLStreamStatePtr stream3;

/* Creating the 1st stream
*/
status = vslNewStream(&stream1, VSL_BRNG_MCG31, 174);

/* To skip 2^64 elements in the random stream SkipAheadStreamEx(nskip) function should be called
with nskip represented as nskip = 2^64 = 0 + 1 * 2^64
*/
MKL_UINT64 nskip[2];
nskip[0]=0;
nskip[1]=1;

/* Skipping ahead by 2^64 elements the 2nd stream
*/
status = vslCopyStream(&stream2, stream1);
status = vslSkipAheadStreamEx (stream2, 2, nskip);

/* Skipping ahead by 2^64 elements the 3rd stream
*/
status = vslCopyStream(&stream3, stream2);
status = vslSkipAheadStreamEx (stream3, 2, nskip);

/* Generating random numbers
*/
...
/* Deleting the streams
```

```

*/
status = vslDeleteStream(&stream1);
status = vslDeleteStream(&stream2);
status = vslDeleteStream(&stream3);
...

```

## Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_SKIPAHEAD_UNSUPPORTED	BRNG does not support the advanced Skip-Ahead method.

## vslGetStreamStateBrng

Returns index of a basic generator used for generation of a given random stream.

---

## Syntax

```
brng = vslGetStreamStateBrng( stream );
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>stream</i>	const VSLStreamStatePtr	Pointer to the stream state structure

## Output Parameters

Name	Type	Description
<i>brng</i>	int	Index of the basic generator assigned for the generation of <i>stream</i> ; negative in case of an error

## Description

The `vslGetStreamStateBrng` function retrieves the index of a basic generator used for generation of a given random stream.

## Return Values

VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.

## vslGetNumRegBrngs

Obtains the number of currently registered basic generators.

---

## Syntax

```
nregbrngs = vslGetNumRegBrngs( void );
```

## Include Files

- `mkl.h`

## Output Parameters

Name	Type	Description
<code>nregbrngs</code>	<code>int</code>	Number of basic generators registered at the moment of the function call

## Description

The `vslGetNumRegBrngs` function obtains the number of currently registered basic generators. Whenever user registers a user-designed basic generator, the number of registered basic generators is incremented. The maximum number of basic generators that can be registered is determined by the `VSL_MAX_REG_BRNGS` parameter.

## Distribution Generators

oneMKLVS routines are used to generate random numbers with different types of distribution. Each function group is introduced below by the type of underlying distribution and contains a short description of its functionality, as well as specifications of the call sequence and the explanation of input and output parameters. [Table "Continuous Distribution Generators"](#) and [Table "Discrete Distribution Generators"](#) list the random number generator routines with data types and output distributions, and sets correspondence between data types of the generator routines and the basic random number generators.

### Continuous Distribution Generators

Type of Distribution	Data Types	BRNG Data Type	Description
<code>vRngUniform</code>	<code>s, d</code>	<code>s, d</code>	Uniform continuous distribution on the interval $[a,b)$
<code>vRngGaussian</code>	<code>s, d</code>	<code>s, d</code>	Normal (Gaussian) distribution
<code>vRngGaussianMV</code>	<code>s, d</code>	<code>s, d</code>	Normal (Gaussian) multivariate distribution
<code>vRngExponential</code>	<code>s, d</code>	<code>s, d</code>	Exponential distribution
<code>vRngLaplace</code>	<code>s, d</code>	<code>s, d</code>	Laplace distribution (double exponential distribution)
<code>vRngWeibull</code>	<code>s, d</code>	<code>s, d</code>	Weibull distribution
<code>vRngCauchy</code>	<code>s, d</code>	<code>s, d</code>	Cauchy distribution
<code>vRngRayleigh</code>	<code>s, d</code>	<code>s, d</code>	Rayleigh distribution
<code>vRngLognormal</code>	<code>s, d</code>	<code>s, d</code>	Lognormal distribution
<code>vRngGumbel</code>	<code>s, d</code>	<code>s, d</code>	Gumbel (extreme value) distribution
<code>vRngGamma</code>	<code>s, d</code>	<code>s, d</code>	Gamma distribution
<code>vRngBeta</code>	<code>s, d</code>	<code>s, d</code>	Beta distribution

Type of Distribution	Data Types	BRNG Data Type	Description
<code>vRngChiSquare</code>	<code>s, d</code>	<code>s, d</code>	Chi-Square distribution

### Discrete Distribution Generators

Type of Distribution	Data Types	BRNG Data Type	Description
<code>vRngUniform</code>	<code>i</code>	<code>d</code>	Uniform discrete distribution on the interval $[a,b)$
<code>vRngUniformBits</code>	<code>i</code>	<code>i</code>	Underlying BRNG integer recurrence
<code>vRngUniformBits32</code>	<code>i</code>	<code>i</code>	Uniformly distributed bits in 32-bit chunks
<code>vRngUniformBits64</code>	<code>i</code>	<code>i</code>	Uniformly distributed bits in 64-bit chunks
<code>vRngBernoulli</code>	<code>i</code>	<code>s</code>	Bernoulli distribution
<code>vRngGeometric</code>	<code>i</code>	<code>s</code>	Geometric distribution
<code>vRngBinomial</code>	<code>i</code>	<code>d</code>	Binomial distribution
<code>vRngHypergeometric</code>	<code>i</code>	<code>d</code>	Hypergeometric distribution
<code>vRngPoisson</code>	<code>i</code>	<code>s</code> (for <code>VSL_RNG_METHOD_POISSON_POISNORM</code> )  <code>s</code> (for distribution parameter $\lambda \geq 27$ ) and <code>d</code> (for $\lambda < 27$ ) (for <code>VSL_RNG_METHOD_POISSON_PTPE</code> )	Poisson distribution
<code>vRngPoisson</code>	<code>i</code>	<code>s</code>	Poisson distribution with varying mean
<code>vRngNegBinomial</code>	<code>i</code>	<code>d</code>	Negative binomial distribution, or Pascal distribution
<code>vRngMultinomial</code>	<code>i</code>	<code>d</code>	Multinomial distribution

### Modes of random number generation

The library provides two modes of random number generation, accurate and fast. Accurate generation mode is intended for the applications that are highly demanding to accuracy of calculations. When used in this mode, the generators produce random numbers lying completely within definitional domain for all values of the distribution parameters. For example, random numbers obtained from the generator of continuous distribution that is uniform on interval  $[a,b]$  belong to this interval irrespective of what  $a$  and  $b$  values may be. Fast mode provides high performance of generation and also guarantees that generated random numbers

belong to the definitional domain except for some specific values of distribution parameters. The generation mode is set by specifying relevant value of the method parameter in generator routines. List of distributions that support accurate mode of generation is given in the table below.

### Distribution Generators Supporting Accurate Mode

Type of Distribution	Data Types
<code>vRngUniform</code>	s, d
<code>vRngExponential</code>	s, d
<code>vRngWeibull</code>	s, d
<code>vRngRayleigh</code>	s, d
<code>vRngLognormal</code>	s, d
<code>vRngGamma</code>	s, d
<code>vRngBeta</code>	s, d

See additional details about accurate and fast mode of random number generation in [VS Notes](#).

### New method names

The current version of oneMKL has a modified structure of VS RNG method names. (See [RNG Naming Conventions](#) for details.) The old names are kept for backward compatibility. The tables below set correspondence between the new and legacy method names for VS random number generators.

#### Method Names for Continuous Distribution Generators

RNG	Legacy Method Name	New Method Name
<code>vRngUniform</code>	VSL_METHOD_SUNIFORM_STD, VSL_METHOD_DUNIFORM_STD, VSL_METHOD_SUNIFORM_STD_ACCURATE, VSL_METHOD_DUNIFORM_STD_ACCURATE	VSL_RNG_METHOD_UNIFORM_STD, VSL_RNG_METHOD_UNIFORM_STD_ACCURATE
<code>vRngGaussian</code>	VSL_METHOD_SGAUSSIAN_BOXMULLER, VSL_METHOD_SGAUSSIAN_BOXMULLER2, VSL_METHOD_SGAUSSIAN_ICDF, VSL_METHOD_DGAUSSIAN_BOXMULLER, VSL_METHOD_DGAUSSIAN_BOXMULLER2, VSL_METHOD_DGAUSSIAN_ICDF	VSL_RNG_METHOD_GAUSSIAN_BOXMULLER, VSL_RNG_METHOD_GAUSSIAN_BOXMULLER2, VSL_RNG_METHOD_GAUSSIAN_ICDF
<code>vRngGaussianMV</code>	VSL_METHOD_SGAUSSIANMV_BOXMULLER, VSL_METHOD_SGAUSSIANMV_BOXMULLER2, VSL_METHOD_SGAUSSIANMV_ICDF, VSL_METHOD_DGAUSSIANMV_BOXMULLER, VSL_METHOD_DGAUSSIANMV_BOXMULLER2, VSL_METHOD_DGAUSSIANMV_ICDF	VSL_RNG_METHOD_GAUSSIANMV_BOXMULLER, , VSL_RNG_METHOD_GAUSSIANMV_BOXMULLER 2, VSL_RNG_METHOD_GAUSSIANMV_ICDF
<code>vRngExponential</code>	VSL_METHOD_SEXPONENTIAL_ICDF, VSL_METHOD_DEXPONENTIAL_ICDF, VSL_METHOD_SEXPONENTIAL_ICDF_ACCURATE, VSL_METHOD_DEXPONENTIAL_ICDF_ACCURATE	VSL_RNG_METHOD_EXPONENTIAL_ICDF, VSL_RNG_METHOD_EXPONENTIAL_ICDF_ACCURATE

RNG	Legacy Method Name	New Method Name
<code>vRngLaplace</code>	<code>VSL_METHOD_SLAPLACE_ICDF,</code> <code>VSL_METHOD_DLAPLACEL_ICDF</code>	<code>VSL_RNG_METHOD_LAPLACE_ICDF</code>
<code>vRngWeibull</code>	<code>VSL_METHOD_SWEIBULL_ICDF,</code> <code>VSL_METHOD_DWEIBULL_ICDF,</code> <code>VSL_METHOD_SWEIBULL_ICDF_ACCURATE,</code> <code>VSL_METHOD_DWEIBULL_ICDF_ACCURATE</code>	<code>VSL_RNG_METHOD_WEIBULL_ICDF,</code> <code>VSL_RNG_METHOD_WEIBULL_ICDF_ACCURATE</code>

## Continuous Distributions

This section describes routines for generating random numbers with continuous distribution.

`vRngUniform` *Continuous Distribution Generators*

*Generates random numbers with uniform distribution.*

### Syntax

```
status = vsRngUniform( method, stream, n, r, a, b );
```

```
status = vdRngUniform( method, stream, n, r, a, b );
```

### Include Files

- `mkl.h`

### Description

The `vRngUniform` function generates random numbers uniformly distributed over the interval  $[a, b)$ , where  $a, b$  are the left and right bounds of the interval, respectively, and  $a, b \in \mathbb{R}$ ;  $a < b$ .

The probability density function is given by:

$$f_{a,b}(x) = \begin{cases} \frac{1}{b-a}, & x \in [a, b) \\ 0, & x \notin [a, b) \end{cases}, \quad -\infty < x < +\infty$$

The cumulative distribution function is as follows:

$$f_{a,b}(x) = \begin{cases} 0, & x < a \\ \frac{x-a}{b-a}, & a \leq x < b, \\ 1, & x \geq b \end{cases}, \quad -\infty < x < +\infty.$$

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.intel.com/PerformanceIndex](http://www.intel.com/PerformanceIndex).

## Product and Performance Information

Notice revision #20201201

### Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method; the specific values are as follows: VSL_RNG_METHOD_UNIFORM_STD VSL_RNG_METHOD_UNIFORM_STD_ACCURATE Standard method.
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated.
<i>a</i>	const float for vsRngUniform const double for vdRngUniform	Left bound a.
<i>b</i>	const float for vsRngUniform const double for vdRngUniform	Right bound b.

### Output Parameters

Name	Type	Description
<i>r</i>	float* for vsRngUniform double* for vdRngUniform	Vector of <i>n</i> random numbers uniformly distributed over the interval $[a, b)$

### Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, $< 0$ or $> nmax$ .
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

VSL\_RNG\_ERROR\_ARS5\_NOT\_SUPPORTED

ARS-5 random number generator is not supported on the CPU running the application.

**vRngGaussian***Generates normally distributed random numbers.***Syntax**`status = vsRngGaussian( method, stream, n, r, a, sigma );``status = vdRngGaussian( method, stream, n, r, a, sigma );`**Include Files**

- `mkl.h`

**Description**

The `vRngGaussian` function generates random numbers with normal (Gaussian) distribution with mean value  $a$  and standard deviation  $\sigma$ , where

$$a, \sigma \in \mathbb{R}; \sigma > 0.$$

The probability density function is given by:

$$f_{a, \sigma}(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-a)^2}{2\sigma^2}\right), \quad -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a, \sigma}(x) = \int_{-\infty}^x \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(y-a)^2}{2\sigma^2}\right) dy, \quad -\infty < x < +\infty.$$

The cumulative distribution function  $F_{a, \sigma}(x)$  can be expressed in terms of standard normal distribution  $\Phi(x)$  as

$$F_{a, \sigma}(x) = \Phi((x-a)/\sigma)$$

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: <pre>VSL_RNG_METHOD_GAUSSIAN_BOXMULLER</pre> <pre>VSL_RNG_METHOD_GAUSSIAN_BOXMULLER2</pre> <pre>VSL_RNG_METHOD_GAUSSIAN_ICDF</pre> See brief description of the methods <code>BOXMULLER</code> , <code>BOXMULLER2</code> , and <code>ICDF</code> in <a href="#">Table "Values of &lt;method&gt; in method parameter"</a>
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated.
<i>a</i>	const float for vsRngGaussian  const double for vdRngGaussian	Mean value $a$ .
<i>sigma</i>	const float for vsRngGaussian  const double for vdRngGaussian	Standard deviation $\sigma$ .

## Output Parameters

Name	Type	Description
<i>r</i>	float* for vsRngGaussian  double* for vdRngGaussian	Vector of $n$ normally distributed random numbers.

## Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.

VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, $< 0$ or $> nmax$ .
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

### *vRngGaussianMV*

*Generates random numbers from multivariate normal distribution.*

#### Syntax

```
status = vsRngGaussianMV( method, stream, n, r, dimen, mstorage, a, t );
status = vdRngGaussianMV( method, stream, n, r, dimen, mstorage, a, t );
```

#### Include Files

#### Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_GAUSSIANMV_BOXMULLER VSL_RNG_METHOD_GAUSSIANMV_BOXMULLER2 VSL_RNG_METHOD_GAUSSIANMV_ICDF See brief description of the methods BOXMULLER, BOXMULLER2, and ICDF in <a href="#">Table "Values of &lt;method&gt; in method parameter"</a>
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of $d$ -dimensional vectors to be generated
<i>dimen</i>	const MKL_INT	Dimension $d$ ( $d \geq 1$ ) of output random vectors
<i>mstorage</i>	const MKL_INT	Matrix storage scheme for lower triangular matrix $T$ . The routine supports three matrix storage schemes: <ul style="list-style-type: none"> <li>• VSL_MATRIX_STORAGE_FULL— all <math>d \times d</math> elements of the matrix <math>T</math> are passed, however, only the lower triangle part is actually used in the routine.</li> </ul>

Name	Type	Description
		<ul style="list-style-type: none"> <li>VSL_MATRIX_STORAGE_PACKED— lower triangle elements of <math>T</math> are packed by rows into a one-dimensional array.</li> <li>VSL_MATRIX_STORAGE_DIAGONAL— only diagonal elements of <math>T</math> are passed.</li> </ul>
$a$	const float* for vsRngGaussianMV const double* for vdRngGaussianMV	Mean vector $a$ of dimension $d$
$t$	const float* for vsRngGaussianMV const double* for vdRngGaussianMV	Elements of the lower triangular matrix passed according to the matrix $T$ storage scheme $mstorage$ .

## Output Parameters

Name	Type	Description
$r$	float* for vsRngGaussianMV double* for vdRngGaussianMV	Array of $n$ random vectors of dimension $dimen$

## Description

The `vsRngGaussianMV` function generates random numbers with  $d$ -variate normal (Gaussian) distribution with mean value  $a$  and variance-covariance matrix  $C$ , where  $a \in \mathbb{R}^d$ ;  $C$  is a  $d \times d$  symmetric positive-definite matrix.

The probability density function is given by:

$$f_{a,C}(x) = \frac{1}{\sqrt{\det(2\pi C)}} \exp\left(-\frac{1}{2}(x-a)^T C^{-1}(x-a)\right),$$

where  $x \in \mathbb{R}^d$ .

Matrix  $C$  can be represented as  $C = TT^T$ , where  $T$  is a lower triangular matrix - Cholesky factor of  $C$ .

Instead of variance-covariance matrix  $C$  the generation routines require Cholesky factor of  $C$  in input. To compute Cholesky factor of matrix  $C$ , the user may call Intel® oneAPI Math Kernel Library (oneMKL) LAPACK routines for matrix factorization: `?potrf` or `?pptrf` for `v?RngGaussianMV/v?rnggaussianmv` routines (? means either `s` or `d` for single and double precision respectively). See [Application Notes](#) for more details.

Notice revision #20201201

## Application Notes

Since matrices are stored in Fortran by columns, while in C they are stored by rows, the usage of Intel® oneAPI Math Kernel Library (oneMKL) factorization routines (assuming Fortran matrices storage) in combination with multivariate normal RNG (assuming C matrix storage) is slightly different in C and Fortran. The following tables help in using these routines in C and Fortran. For further information please refer to the appropriate VS example file.

### Using Cholesky Factorization Routines in C

Matrix Storage Scheme	Variance-Covariance Matrix Argument	Factorization Routine	UPLO Parameter in Factorization Routine	Result of Factorization as Input Argument for RNG
VSL_MATRIX_STORAGE_FULL	C in C two-dimensional array	spotrf for vsRngGaussianMV  dpotrf for vdRngGaussianMV	'U'	Lower triangle of $T$ . Upper triangle is not used.
VSL_MATRIX_STORAGE_PACKED	Lower triangle of C packed by columns into one-dimensional array	spptrf for vsRngGaussianMV  dpptrf for vdRngGaussianMV	'L'	Lower triangle of $T$ packed by columns into a one-dimensional array.

### Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, $< 0$ or $> nmax$ .
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

#### *vRngExponential*

Generates exponentially distributed random numbers.

## Syntax

```
status = vsRngExponential( method, stream, n, r, a, beta );
```

```
status = vdRngExponential( method, stream, n, r, a, beta );
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_EXPONENTIAL_ICDF VSL_RNG_METHOD_EXPONENTIAL_ICDF_ACCURATE Inverse cumulative distribution function method
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>a</i>	const float for vsRngExponential  const double for vdRngExponential	Displacement <i>a</i>
<i>beta</i>	const float for vsRngExponential  const double for vdRngExponential	Scalefactor $\beta$ .

## Output Parameters

Name	Type	Description
<i>r</i>	float* for vsRngExponential  double* for vdRngExponential	Vector of <i>n</i> exponentially distributed random numbers

## Description

The `vsRngExponential` function generates random numbers with exponential distribution that has displacement *a* and scalefactor  $\beta$ , where  $a, \beta \in \mathbb{R}$ ;  $\beta > 0$ .

The probability density function is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{1}{\beta} \exp(-(x-a)/\beta), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(X) = \begin{cases} 1 - \exp(- (x - a) / \beta), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Notice revision #20201201

### Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

### vRngLaplace

Generates random numbers with Laplace distribution.

### Syntax

```
status = vsRngLaplace( method, stream, n, r, a, beta );
```

```
status = vdRngLaplace( method, stream, n, r, a, beta );
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: <code>VSL_RNG_METHOD_LAPLACE_ICDF</code> Inverse cumulative distribution function method
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure

Name	Type	Description
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>a</i>	const float for vsRngLaplace const double for vdRngLaplace	Mean value <i>a</i>
<i>beta</i>	const float for vsRngLaplace const double for vdRngLaplace	Scalefactor $\beta$ .

## Output Parameters

Name	Type	Description
<i>r</i>	float* for vsRngLaplace double* for vdRngLaplace	Vector of <i>n</i> Laplace distributed random numbers

## Description

The `vsRngLaplace` function generates random numbers with Laplace distribution with mean value (or average) *a* and scalefactor  $\beta$ , where  $a, \beta \in \mathbb{R}$ ;  $\beta > 0$ . The scalefactor value determines the standard deviation as

$$\sigma = \beta\sqrt{2}$$

The probability density function is given by:

$$f_{a,\beta}(x) = \frac{1}{\sqrt{2\beta}} \exp\left(-\frac{|x-a|}{\beta}\right), \quad -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} \frac{1}{2} \exp\left(-\frac{|x-a|}{\beta}\right), & x \geq a \\ 1 - \frac{1}{2} \exp\left(-\frac{|x-a|}{\beta}\right), & x < a \end{cases}, \quad -\infty < x < +\infty.$$

Notice revision #20201201

## Return Values

VSL\_ERROR\_OK, VSL\_STATUS\_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

### *vRngWeibull*

*Generates Weibull distributed random numbers.*

### Syntax

```
status = vsRngWeibull( method, stream, n, r, alpha, a, beta );
```

```
status = vdRngWeibull( method, stream, n, r, alpha, a, beta );
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_WEIBULL_ICDF VSL_RNG_METHOD_WEIBULL_ICDF_ACCURATE Inverse cumulative distribution function method
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>alpha</i>	const float for vsRngWeibull const double for vdRngWeibull	Shape $\alpha$ .
<i>a</i>	const float for vsRngWeibull const double for vdRngWeibull	Displacement $a$
<i>beta</i>	const float for vsRngWeibull	Scalefactor $\beta$ .

Name	Type	Description
------	------	-------------

	const double for vdRngWeibull	
--	----------------------------------	--

### Output Parameters

Name	Type	Description
------	------	-------------

<i>r</i>	float* for vsRngWeibull  double* for vdRngWeibull	Vector of <i>n</i> Weibull distributed random numbers
----------	---	---

### Description

The `vdRngWeibull` function generates Weibull distributed random numbers with displacement *a*, scalefactor  $\beta$ , and shape  $\alpha$ , where  $\alpha, \beta, a \in \mathbb{R}$ ;  $\alpha > 0, \beta > 0$ .

The probability density function is given by:

$$f_{a,\alpha,\beta}(x) = \begin{cases} \frac{\alpha}{\beta^\alpha} (x - a)^{\alpha-1} \exp\left(-\left(\frac{x - a}{\beta}\right)^\alpha\right), & x \geq a \\ 0, & x < a \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\alpha,\beta}(x) = \begin{cases} 1 - \exp\left(-\left(\frac{x - a}{\beta}\right)^\alpha\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Notice revision #20201201

### Return Values

VSL\_ERROR\_OK, VSL\_STATUS\_OK

Indicates no error, execution is successful.

VSL\_ERROR\_NULL\_PTR

*stream* is a NULL pointer.

VSL\_RNG\_ERROR\_BAD\_STREAM

*stream* is not a valid random stream.

VSL\_RNG\_ERROR\_BAD\_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is,  $< 0$  or  $> nmax$ .

VSL\_RNG\_ERROR\_NO\_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

### *vRngCauchy*

*Generates Cauchy distributed random values.*

### Syntax

```
status = vsRngCauchy( method, stream, n, r, a, beta );
```

```
status = vdRngCauchy( method, stream, n, r, a, beta );
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: <code>VSL_RNG_METHOD_CAUCHY_ICDF</code> Inverse cumulative distribution function method
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>a</i>	const float for vsRngCauchy const double for vdRngCauchy	Displacement $a$ .
<i>beta</i>	const float for vsRngCauchy const double for vdRngCauchy	Scalefactor $\beta$ .

### Output Parameters

Name	Type	Description
<i>r</i>	float* for vsRngCauchy double* for vdRngCauchy	Vector of $n$ Cauchy distributed random numbers

### Description

The function generates Cauchy distributed random numbers with displacement  $a$  and scalefactor  $\beta$ , where  $a, \beta \in \mathbb{R}$  ;  $\beta > 0$ .

The probability density function is given by:

$$f_{a,\beta}(x) = \frac{1}{\pi\beta \left( 1 + \left( \frac{x-a}{\beta} \right)^2 \right)}, \quad -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \frac{1}{2} + \frac{1}{\pi} \arctan \left( \frac{x-a}{\beta} \right), \quad -\infty < x < +\infty.$$

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

### Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

### *vRngRayleigh*

*Generates Rayleigh distributed random values.*

### Syntax

```
status = vsRngRayleigh( method, stream, n, r, a, beta );
```

```
status = vdRngRayleigh( method, stream, n, r, a, beta );
```

### Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_RAYLEIGH_ICDF VSL_RNG_METHOD_RAYLEIGH_ICDF_ACCURATE Inverse cumulative distribution function method
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>a</i>	const float for vsRngRayleigh  const double for vdRngRayleigh	Displacement <i>a</i>
<i>beta</i>	const float for vsRngRayleigh  const double for vdRngRayleigh	Scalefactor $\beta$ .

## Output Parameters

Name	Type	Description
<i>r</i>	float* for vsRngRayleigh  double* for vdRngRayleigh	Vector of <i>n</i> Rayleigh distributed random numbers

## Description

The `vsRngRayleigh` function generates Rayleigh distributed random numbers with displacement *a* and scalefactor  $\beta$ , where  $a, \beta \in \mathbb{R}$ ;  $\beta > 0$ .

The Rayleigh distribution is a special case of the [Weibull](#) distribution, where the shape parameter  $\alpha = 2$ .

The probability density function is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{2(x-a)}{\beta^2} \exp\left(-\frac{(x-a)^2}{\beta^2}\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp\left(-\frac{(x-a)^2}{\beta^2}\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

## Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

### *vRngLognormal*

Generates lognormally distributed random numbers.

## Syntax

```
status = vsRngLognormal( method, stream, n, r, a, sigma, b, beta );
status = vdRngLognormal( method, stream, n, r, a, sigma, b, beta );
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_LOGNORMAL_BOXMULLER2 VSL_RNG_METHOD_LOGNORMAL_BOXMULLER2_ACCURATE Box Muller 2 based method VSL_RNG_METHOD_LOGNORMAL_ICDF VSL_RNG_METHOD_LOGNORMAL_ICDF_ACCURATE Inverse cumulative distribution function based method

Name	Type	Description
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>a</i>	const float for vsRngLognormal  const double for vdRngLognormal	Average <i>a</i> of the subject normal distribution
<i>sigma</i>	const float for vsRngLognormal  const double for vdRngLognormal	Standard deviation $\sigma$ of the subject normal distribution
<i>b</i>	const float for vsRngLognormal  const double for vdRngLognormal	Displacement <i>b</i>
<i>beta</i>	const float for vsRngLognormal  const double for vdRngLognormal	Scalefactor $\beta$ .

## Output Parameters

Name	Type	Description
<i>r</i>	float* for vsRngLognormal  double* for vdRngLognormal	Vector of <i>n</i> lognormally distributed random numbers

## Description

The `vsRngLognormal` function generates lognormally distributed random numbers with average of distribution *a* and standard deviation  $\sigma$  of subject normal distribution, displacement *b*, and scalefactor  $\beta$ , where  $a, \sigma, b, \beta \in \mathbb{R}$ ;  $\sigma > 0$ ,  $\beta > 0$ .

The probability density function is given by:

$$f_{a,\sigma,b,\beta}(x) = \begin{cases} \frac{1}{\sigma(x-b)\sqrt{2\pi}} \exp\left(-\frac{[\ln((x-b)/\beta) - a]^2}{2\sigma^2}\right), & x > b \\ 0, & x \leq b \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\sigma,b,\beta}(X) = \begin{cases} \Phi((\ln((x-b)/\beta) - a)/\sigma), & x > b \\ 0, & x \leq b \end{cases}$$

## Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

### *vRngGumbel*

*Generates Gumbel distributed random values.*

## Syntax

```
status = vsRngGumbel( method, stream, n, r, a, beta );
status = vdRngGumbel( method, stream, n, r, a, beta );
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_GUMBEL_ICDF Inverse cumulative distribution function method
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>a</i>	const float for vsRngGumbel	Displacement <i>a</i> .

Name	Type	Description
------	------	-------------

	const double for vdRngGumbel	
<i>beta</i>	const float for vsRngGumbel	Scalefactor $\beta$ .
	const double for vdRngGumbel	

## Output Parameters

Name	Type	Description
------	------	-------------

<i>r</i>	float* for vsRngGumbel	Vector of $n$ random numbers with Gumbel distribution
	double* for vdRngGumbel	

## Description

The `vdRngGumbel` function generates Gumbel distributed random numbers with displacement  $a$  and scalefactor  $\beta$ , where  $a, \beta \in R$ ;  $\beta > 0$ .

The probability density function is given by:

$$f_{a,\beta}(x) = \left\{ \frac{1}{\beta} \exp\left(\frac{x-a}{\beta}\right) \exp(-\exp((x-a)/\beta)), -\infty < x < +\infty \right.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = 1 - \exp(-\exp((x-a)/\beta)), -\infty < x < +\infty$$

VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

VSL\_RNG\_ERROR\_ARS5\_NOT\_SUPPORTED

ARS-5 random number generator is not supported on the CPU running the application.

*vRngGamma*

*Generates gamma distributed random values.*

## Syntax

```
status = vsRngGamma( method, stream, n, r, alpha, a, beta );
```

```
status = vdRngGamma( method, stream, n, r, alpha, a, beta );
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_GAMMA_GNORM VSL_RNG_METHOD_GAMMA_GNORM_ACCURATE Acceptance/rejection method using random numbers with Gaussian distribution. See brief description of the method GNORM in <a href="#">Table "Values of &lt;method&gt; in method parameter"</a>
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>alpha</i>	const float for vsRngGamma const double for vdRngGamma	Shape $\alpha$ .
<i>a</i>	const float for vsRngGamma const double for vdRngGamma	Displacement $a$ .
<i>beta</i>	const float for vsRngGamma const double for vdRngGamma	Scalefactor $\beta$ .

## Output Parameters

Name	Type	Description
<i>r</i>	float* for vsRngGamma double* for vdRngGamma	Vector of $n$ random numbers with gamma distribution

## Description

The `vRngGamma` function generates random numbers with gamma distribution that has shape parameter  $\alpha$ , displacement  $a$ , and scale parameter  $\beta$ , where  $\alpha, \beta$ , and  $a \in \mathbb{R}$ ;  $\alpha > 0$ ,  $\beta > 0$ .

The probability density function is given by:

$$f_{\alpha, a, \beta}(x) = \begin{cases} \frac{1}{\Gamma(\alpha)\beta^\alpha} (x - a)^{\alpha-1} e^{-(x-a)/\beta}, & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty$$

where  $\Gamma(\alpha)$  is the complete gamma function.

The cumulative distribution function is as follows:

$$F_{\alpha, a, \beta}(x) = \begin{cases} \int_a^x \frac{1}{\Gamma(\alpha)\beta^\alpha} (y - a)^{\alpha-1} e^{-(y-a)/\beta} dy, & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty$$

### Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, $< 0$ or $> nmax$ .
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

### vRngBeta

*Generates beta distributed random values.*

### Syntax

```
status = vsRngBeta( method, stream, n, r, p, q, a, beta );
```

```
status = vdRngBeta( method, stream, n, r, p, q, a, beta );
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: <div style="background-color: #f0f0f0; padding: 2px; margin: 2px 0;">VSL_RNG_METHOD_BETA_CJA</div> <div style="background-color: #f0f0f0; padding: 2px; margin: 2px 0;">VSL_RNG_METHOD_BETA_CJA_ACCURATE</div> See brief description of the method CJA in <a href="#">Table "Values of &lt;method&gt; in method parameter"</a>
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>p</i>	const float for vsRngBeta const double for vdRngBeta	Shape <i>p</i>
<i>q</i>	const float for vsRngBeta const double for vdRngBeta	Shape <i>q</i>
<i>a</i>	const float for vsRngBeta const double for vdRngBeta	Displacement <i>a</i> .
<i>beta</i>	const float for vsRngBeta const double for vdRngBeta	Scalefactor $\beta$ .

## Output Parameters

Name	Type	Description
<i>r</i>	float* for vsRngBeta double* for vdRngBeta	Vector of <i>n</i> random numbers with beta distribution

## Description

The `vsRngBeta` function generates random numbers with beta distribution that has shape parameters *p* and *q*, displacement *a*, and scale parameter  $\beta$ , where  $p, q, a$ , and  $\beta \in \mathbb{R}$ ;  $p > 0$ ,  $q > 0$ ,  $\beta > 0$ .

The probability density function is given by:

$$f_{p,q,a,\beta}(x) = \begin{cases} \frac{1}{B(p, q)\beta^{p+q-1}} (x - a)^{p-1}(\beta + a - x)^{q-1}, & a \leq x < a + \beta \\ 0, & x < a, x \geq a + \beta \end{cases}, -\infty < x <$$

where  $B(p, q)$  is the complete beta function.

The cumulative distribution function is as follows:

$$F_{p,q,a,\beta}(x) = \begin{cases} 0, & x < a \\ \int_a^x \frac{1}{B(p,q)\beta^{p+q-1}} (y-a)^{p-1} (\beta+a-y)^{q-1} dy, & a \leq x < a + \beta, -\infty < x \\ 1, & x \geq a + \beta \end{cases}$$

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

### Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

### *vRngChiSquare*

*Generates chi-square distributed random values.*

### Syntax

```
status = vsRngChiSquare( method, stream, n, r, v );
```

```
status = vdRngChiSquare( method, stream, n, r, v );
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific value is: VSL_RNG_METHOD_CHISQUARE_CHI2GAMMA

Name	Type	Description
		For a description of VSL_RNG_METHOD_CHISQUARE_CHI2GAMMA, see <a href="#">Random Number Generators Naming Conventions</a> .
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>v</i>	const MKL_INT	Degrees of freedom

## Output Parameters

Name	Type	Description
<i>r</i>	float* for vsRngChiSquare double* for vdRngChiSquare	Vector of <i>n</i> random numbers with chi-square distribution

## Description

The `vsRngChiSquare` function generates random numbers with chi-square distribution and *v* degrees of freedom,  $v \in \mathbb{N}$ ,  $v > 0$ .

The probability density function is:

$$f_v(x) = \begin{cases} \frac{x^{v-2} e^{-x/2}}{2^{v/2} \Gamma(\frac{v}{2})}, & x \geq 0 \\ 0, & x < 0 \end{cases}$$

The cumulative distribution function is:

$$F_v(x) = \begin{cases} \int_0^x \frac{y^{v-2} e^{-y/2}}{2^{v/2} \Gamma(\frac{v}{2})} dy, & x \geq 0 \\ 0, & x < 0 \end{cases}$$

## Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, $< 0$ or $> nmax$ .
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

## Discrete Distributions

This section describes routines for generating random numbers with discrete distribution.

`vRngUniform` *Discrete Distribution Generators*  
*Generates random numbers uniformly distributed over the interval  $[a, b)$ .*

### Syntax

```
status = viRngUniform( method, stream, n, r, a, b );
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<code>method</code>	<code>const MKL_INT</code>	Generation method; the specific value is as follows: <code>VSL_RNG_METHOD_UNIFORM_STD</code> Standard method. Currently there is only one method for this distribution generator.
<code>stream</code>	<code>VSLStreamStatePtr</code>	Pointer to the stream state structure
<code>n</code>	<code>const MKL_INT</code>	Number of random values to be generated
<code>a</code>	<code>const int</code>	Left interval bound $a$
<code>b</code>	<code>const int</code>	Right interval bound $b$

### Output Parameters

Name	Type	Description
<code>r</code>	<code>int*</code>	Vector of $n$ random numbers uniformly distributed over the interval $[a, b)$

### Description

The `vRngUniform` function generates random numbers uniformly distributed over the interval  $[a, b)$ , where  $a, b$  are the left and right bounds of the interval respectively, and  $a, b \in \mathbb{Z}; a < b$ .

The probability distribution is given by:

$$P(X = k) = \frac{1}{b - a}, k \in \{a, a + 1, \dots, b - 1\}.$$

The cumulative distribution function is as follows:

$$F_{a,b}(X) = \begin{cases} 0, & x < a \\ \frac{\lfloor x - a + 1 \rfloor}{b - a}, & a \leq x < b, x \in R. \\ 1, & x \geq b \end{cases}$$

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

**Return Values**

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

*vRngUniformBits*

Generates bits of underlying BRNG integer recurrence.

**Syntax**

```
status = viRngUniformBits( method, stream, n, r );
```

**Include Files**

- mkl.h

## Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method; the specific value is <code>VSL_RNG_METHOD_UNIFORMBITS_STD</code>
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated

## Output Parameters

Name	Type	Description
<i>r</i>	unsigned int*	Vector of <i>n</i> random integer numbers. If the <i>stream</i> was generated by a 64 or a 128-bit generator, each integer value is represented by two or four elements of <i>r</i> respectively. The number of bytes occupied by each integer is contained in the field <i>WordSize</i> of the structure <code>VSLBRngProperties</code> . The total number of bits that are actually used to store the value are contained in the field <i>NBits</i> of the same structure. See <a href="#">Advanced Service Routines</a> for a more detailed discussion of <code>VSLBRngProperties</code> .

## Description

The `vRngUniformBits` function generates integer random values with uniform bit distribution. The generators of uniformly distributed numbers can be represented as recurrence relations over integer values in modular arithmetic. Apparently, each integer can be treated as a vector of several bits. In a truly random generator, these bits are random, while in pseudorandom generators this randomness can be violated. For example, a well known drawback of linear congruential generators is that lower bits are less random than higher bits (for example, see [Knuth81]). For this reason, care should be taken when using this function. Typically, in a 32-bit LCG only 24 higher bits of an integer value can be considered random. See [VS Notes](#) for details.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<i>stream</i> is a NULL pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.
<code>VSL_RNG_ERROR_BAD_UPDATE</code>	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, $< 0$ or $> nmax$ .
<code>VSL_RNG_ERROR_NO_NUMBERS</code>	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

### *vRngUniformBits32*

Generates uniformly distributed bits in 32-bit chunks.

### Syntax

```
status = viRngUniformBits32( method, stream, n, r );
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method; the specific value is VSL_RNG_METHOD_UNIFORMBITS32_STD
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated

### Output Parameters

Name	Type	Description
<i>r</i>	unsigned int*	Vector of <i>n</i> 32-bit random integer numbers with uniform bit distribution.

### Description

The `vRngUniformBits32` function generates uniformly distributed bits in 32-bit chunks. Unlike `vRngUniformBits`, which provides the output of underlying integer recurrence and does not guarantee uniform distribution across bits, `vRngUniformBits32` is designed to ensure each bit in the 32-bit chunk is uniformly distributed. See [VS Notes](#) for details.

#### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

### Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.

VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BRNG_NOT_SUPPORTED	BRNG is not supported by the function.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

### *vRngUniformBits64*

Generates uniformly distributed bits in 64-bit chunks.

### Syntax

```
status = viRngUniformBits64( method, stream, n, r );
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method; the specific value is <code>VSL_RNG_METHOD_UNIFORMBITS64_STD</code>
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated

### Output Parameters

Name	Type	Description
<i>r</i>	unsigned MKL_INT64*	Vector of <i>n</i> 64-bit random integer numbers with uniform bit distribution.

### Description

The `vRngUniformBits64` function generates uniformly distributed bits in 64-bit chunks. Unlike `vRngUniformBits`, which provides the output of underlying integer recurrence and does not guarantee uniform distribution across bits, `vRngUniformBits64` is designed to ensure each bit in the 64-bit chunk is uniformly distributed. See [VS Notes](#) for details.

#### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

### Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
-----------------------------	--

VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BRNG_NOT_SUPPORTED	BRNG is not supported by the function.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

### *vRngBernoulli*

*Generates Bernoulli distributed random values.*

### Syntax

```
status = viRngBernoulli( method, stream, n, r, p );
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific value is as follows: <code>VSL_RNG_METHOD_BERNOULLI_ICDF</code> Inverse cumulative distribution function method.
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>p</i>	const double	Success probability <i>p</i> of a trial

### Output Parameters

Name	Type	Description
<i>r</i>	int*	Vector of <i>n</i> Bernoulli distributed random values

### Description

The `vRngBernoulli` function generates Bernoulli distributed random numbers with probability *p* of a single trial success, where

$$p \in \mathbb{R}; 0 \leq p \leq 1.$$

A variate is called Bernoulli distributed, if after a trial it is equal to 1 with probability of success *p*, and to 0 with probability 1 - *p*.

The probability distribution is given by:

$$P(X = 1) = p$$

$$P(X = 0) = 1 - p$$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - p, & 0 \leq x < 1, x \in \mathbb{R}. \\ 1, & x \geq 1 \end{cases}$$

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

### Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

### *vRngGeometric*

*Generates geometrically distributed random values.*

### Syntax

```
status = viRngGeometric( method, stream, n, r, p );
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific value is as follows: VSL_RNG_METHOD_GEOMETRIC_ICDF

Name	Type	Description
		Inverse cumulative distribution function method.
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>p</i>	const double	Success probability <i>p</i> of a trial

## Output Parameters

Name	Type	Description
<i>r</i>	int*	Vector of <i>n</i> geometrically distributed random values

## Description

The `vRngGeometric` function generates geometrically distributed random numbers with probability *p* of a single trial success, where  $p \in \mathbb{R}; 0 < p < 1$ .

A geometrically distributed variate represents the number of independent Bernoulli trials preceding the first success. The probability of a single Bernoulli trial success is *p*.

The probability distribution is given by:

$$P(X = k) = p \cdot (1 - p)^k, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - (1 - p)^{\lfloor x+1 \rfloor}, & 0 \geq x \end{cases} \quad x \in \mathbb{R}.$$

### Product and Performance Information

Notice revision #20201201

## Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, $< 0$ or $> nmax$ .
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

### *vRngBinomial*

*Generates binomially distributed random numbers.*

### Syntax

```
status = viRngBinomial( method, stream, n, r, ntrial, p );
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific value is as follows: <code>VSL_RNG_METHOD_BINOMIAL_BTPE</code> See brief description of the BTPE method in <a href="#">Table "Values of &lt;method&gt; in method parameter"</a> .
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>ntrial</i>	const int	Number of independent trials $m$
<i>p</i>	const double	Success probability $p$ of a single trial

### Output Parameters

Name	Type	Description
<i>r</i>	int*	Vector of $n$ binomially distributed random values

### Description

The `viRngBinomial` function generates binomially distributed random numbers with number of independent Bernoulli trials  $m$ , and with probability  $p$  of a single trial success, where  $p \in \mathbb{R}$ ;  $0 \leq p \leq 1$ ,  $m \in \mathbb{N}$ .

A binomially distributed variate represents the number of successes in  $m$  independent Bernoulli trials with probability of a single trial success  $p$ .

The probability distribution is given by:

$$P(X = k) = C_m^k p^k (1 - p)^{m-k}, k \in \{0, 1, \dots, m\}.$$

The cumulative distribution function is as follows:

$$F_{m,p}(X) = \begin{cases} 0, & x < 0 \\ \sum_{k=0}^{\lfloor x \rfloor} C_m^k p^k (1-p)^{m-k}, & 0 \leq x < m, x \in \mathbb{R} \\ 1, & x \geq m \end{cases}$$

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.intel.com/PerformanceIndex](http://www.intel.com/PerformanceIndex).

Notice revision #20201201

### Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

### *vRngHypergeometric*

*Generates hypergeometrically distributed random values.*

### Syntax

```
status = viRngHypergeometric( method, stream, n, r, l, s, m );
```

### Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific value is as follows:  VSL_RNG_METHOD_HYPERGEOMETRIC_H2PE  See brief description of the H2PE method in <a href="#">Table "Values of &lt;method&gt; in method parameter"</a>
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>l</i>	const int	Lot size <i>l</i>
<i>s</i>	const int	Size of sampling without replacement <i>s</i>
<i>m</i>	const int	Number of marked elements <i>m</i>

## Output Parameters

Name	Type	Description
<i>r</i>	int*	Vector of <i>n</i> hypergeometrically distributed random values

## Description

The `vRngHypergeometric` function generates hypergeometrically distributed random values with lot size *l*, size of sampling *s*, and number of marked elements in the lot *m*, where  $l, m, s \in \mathbb{N} \setminus \{0\}$ ;  $l \geq \max(s, m)$ .

Consider a lot of *l* elements comprising *m* "marked" and *l*-*m* "unmarked" elements. A trial sampling without replacement of exactly *s* elements from this lot helps to define the hypergeometric distribution, which is the probability that the group of *s* elements contains exactly *k* marked elements.

The probability distribution is given by:)

$$P(X = k) = \frac{C_m^k C_{l-m}^{s-k}}{C_l^s}$$

,  $k \in \{\max(0, s + m - l), \dots, \min(s, m)\}$

The cumulative distribution function is as follows:

$$F_{l,s,m}(x) = \begin{cases} 0, & x < \max(0, s + m - l) \\ \sum_{k=\max(0, s+m-l)}^{\lfloor x \rfloor} \frac{C_m^k C_{l-m}^{s-k}}{C_l^s}, & \max(0, s + m - l) \leq x \leq \min(s, m) \\ 1, & x > \min(s, m) \end{cases}$$

## Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

### *vRngPoisson*

*Generates Poisson distributed random values.*

## Syntax

```
status = viRngPoisson( method, stream, n, r, lambda );
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_POISSON_PTPE VSL_RNG_METHOD_POISSON_POISNORM See brief description of the PTPE and POISNORM methods in <a href="#">Table "Values of &lt;method&gt; in method parameter"</a> .
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>lambda</i>	const double	Distribution parameter $\lambda$ .

## Output Parameters

Name	Type	Description
<i>r</i>	int*	Vector of <i>n</i> Poisson distributed random values

## Description

The `vRng"Poisson` function generates Poisson distributed random numbers with distribution parameter  $\lambda$ , where  $\lambda \in \mathbb{R}$ ;  $\lambda > 0$ .

The probability distribution is given by:

$$P(X = k) = \frac{\lambda^k e^{-\lambda}}{k!},$$

$k \in \{0, 1, 2, \dots\}$ .

The cumulative distribution function is as follows:

$$F_{\lambda}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda^k e^{-\lambda}}{k!}, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in \mathbb{R}$$

### Product and Performance Information

Notice revision #20201201

## Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, $< 0$ or $> nmax$ .
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

### *vRngPoissonV*

*Generates Poisson distributed random values with varying mean.*

### Syntax

```
status = viRngPoissonV( method, stream, n, r, lambda );
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific value is as follows: <code>VSL_RNG_METHOD_POISSONV_POISNORM</code> See brief description of the POISNORM method in <a href="#">Table "Values of &lt;method&gt; in method parameter"</a>
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>lambda</i>	const double*	Array of <i>n</i> distribution parameters $\lambda_i$ .

### Output Parameters

Name	Type	Description
<i>r</i>	int*	Vector of <i>n</i> Poisson distributed random values

### Description

The `vRngPoissonV` function generates *n* Poisson distributed random numbers  $x_i (i = 1, \dots, n)$  with distribution parameter  $\lambda_i$ , where  $\lambda_i \in \mathbb{R}; \lambda_i > 0$ .

The probability distribution is given by:

$$P(X_i = k) = \frac{\lambda_i^k \exp(-\lambda_i)}{k!}, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_{\lambda_i}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda_i^k e^{-\lambda_i}}{k!}, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in \mathbb{R}$$

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

### Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

#### *vRngNegBinomial*

*Generates random numbers with negative binomial distribution.*

### Syntax

```
status = viRngNegbinomial( method, stream, n, r, a, p );
```

### Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific value is:  VSL_RNG_METHOD_NEGBINOMIAL_NBAR  See brief description of the NBAR method in <a href="#">Table "Values of &lt;method&gt; in method parameter"</a>
<i>stream</i>	VSLStreamStatePtr	pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>a</i>	const double	The first distribution parameter <i>a</i>
<i>p</i>	const double	The second distribution parameter <i>p</i>

## Output Parameters

Name	Type	Description
<i>r</i>	int*	Vector of <i>n</i> random values with negative binomial distribution.

## Description

The `vRngNegBinomial` function generates random numbers with negative binomial distribution and distribution parameters *a* and *p*, where  $p, a \in R; 0 < p < 1; a > 0$ .

If the first distribution parameter  $a \in N$ , this distribution is the same as Pascal distribution. If  $a \in N$ , the distribution can be interpreted as the expected time of *a*-th success in a sequence of Bernoulli trials, when the probability of success is *p*.

The probability distribution is given by:

$$P(X = k) = C_{a+k-1}^k p^a (1 - p)^k, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_{a,p}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} C_{a+k-1}^k p^a (1 - p)^k, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in R$$

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

### *vRngMultinomial*

Generates multinomially distributed random numbers.

## Syntax

```
status = viRngMultinomial( method, stream, n, r, ntrial, k, p );
```

## Include Files

- mkl.h

## Input Parameters

<i>method</i>	const MKL_INT Generation method. The specific value is as follows: VSL_RNG_METHOD_MULTINOMIAL_MULTPOISSON
<i>stream</i>	VSLStreamStatePtr Pointer to the stream state structure.
<i>n</i>	const MKL_INT Number of random values to be generated.
<i>ntrial</i>	const int Number of independent trials <i>m</i> .
<i>k</i>	const int Number of possible outcomes.
<i>p</i>	const double* Probability vector of <i>k</i> possible outcomes.

## Advanced Service Routine Data Types

The Advanced Service routines refer to a structure defining the properties of the basic generator.

This structure is described as follows:

```
typedef struct _VSLBRngProperties {
    int StreamStateSize;
    int NSeeds;
    int IncludesZero;
    int WordSize;
    int NBits;
    InitStreamPtr InitStream;
    sBRngPtr sBRng;
    dBRngPtr dBRng;
    iBRngPtr iBRng;
} VSLBRngProperties;
```

The following table provides brief descriptions of the fields engaged in the above structure:

### Field Descriptions

Field	Short Description
StreamStateSize	The size, in bytes, of the stream state structure for a given basic generator.
NSeeds	The number of 32-bit initial conditions (seeds) necessary to initialize the stream state structure for a given basic generator.
IncludesZero	Flag value indicating whether the generator can produce a random 0.
WordSize	Machine word size, in bytes, used in integer-value computations. Possible values: 4, 8, and 16 for 32, 64, and 128-bit generators, respectively.
NBits	The number of bits required to represent a random value in integer arithmetic. Note that, for instance, 48-bit random values are stored to 64-bit (8 byte) memory locations. In this case, $wordsize/WordSize$ is equal to 8 (number of bytes used to store the random value), while $nbits/NBits$ contains the actual number of bits occupied by the value (in this example, 48).
InitStream	Contains the pointer to the initialization routine of a given basic generator.
sBRng	Contains the pointer to the basic generator of single precision real numbers uniformly distributed over the interval $(a,b)$ (float).
dBRng	Contains the pointer to the basic generator of double precision real numbers uniformly distributed over the interval $(a,b)$ (double).
iBRng	Contains the pointer to the basic generator of integer numbers with uniform bit distribution (unsigned int).

### vslRegisterBrng

*Registers user-defined basic generator.*

### Syntax

```
brng = vslRegisterBrng( &properties );
```

<sup>1</sup> A specific generator that permits operations over single bits and bit groups of random numbers.

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<code>properties</code>	<code>const VSLBRngProperties*</code>	Pointer to the structure containing properties of the basic generator to be registered

## Output Parameters

Name	Type	Description
<code>brng</code>	<code>int</code>	Number (index) of the registered basic generator; used for identification. Negative values indicate the registration error.

## Description

An example of a registration procedure can be found in the respective directory of the VS examples.

## Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_RNG_ERROR_BRNG_TABLE_FULL</code>	Registration cannot be completed due to lack of free entries in the table of registered BRNGs.
<code>VSL_RNG_ERROR_BAD_STREAM_STATE_SIZE</code>	Bad value in <code>StreamStateSize</code> field.
<code>VSL_RNG_ERROR_BAD_WORD_SIZE</code>	Bad value in <code>WordSize</code> field.
<code>VSL_RNG_ERROR_BAD_NSEEDS</code>	Bad value in <code>NSeeds</code> field.
<code>VSL_RNG_ERROR_BAD_NBITS</code>	Bad value in <code>NBits</code> field.
<code>VSL_ERROR_NULL_PTR</code>	At least one of the fields <code>iBrng</code> , <code>dBrng</code> , <code>sBrng</code> or <code>InitStream</code> is a NULL pointer.

## **vslGetBrngProperties**

Returns structure with properties of a given basic generator.

## Syntax

```
status = vslGetBrngProperties( brng, &properties );
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>brng</i>	const int	Number (index) of the registered basic generator; used for identification. See specific values in <a href="#">Table "Values of <i>brng</i> parameter"</a> . Negative values indicate the registration error.

## Output Parameters

Name	Type	Description
<i>properties</i>	VSLBRngProperties*	Pointer to the structure containing properties of the generator with number <i>brng</i>

## Description

The `vslGetBrngProperties` function returns a structure with properties of a given basic generator.

## Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_RNG_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.

## Formats for User-Designed Generators

To register a user-designed basic generator using `vslRegisterBrng` function, you need to pass the pointer `iBrng` to the integer-value implementation of the generator; the pointers `sBrng` and `dBrng` to the generator implementations for single and double precision values, respectively; and pass the pointer `InitStream` to the stream initialization routine. See recommendations below on defining such functions with input and output arguments. An example of the registration procedure for a user-designed generator can be found in the respective directory of VS examples.

The respective pointers are defined as follows:

```
typedef int(*InitStreamPtr)( int method, VSLStreamStatePtr stream, int n, const unsigned int
params[] );
```

```
typedef int(*sBrngPtr)( VSLStreamStatePtr stream, int n, float r[], float a, float b );
```

```
typedef int(*dBrngPtr)( VSLStreamStatePtr stream, int n, double r[], double a, double b );
```

```
typedef int(*iBrngPtr)( VSLStreamStatePtr stream, int n, unsigned int r[] );
```

## InitStream

```
int MyBrngInitStream( int method, VSLStreamStatePtr stream, int n, const unsigned int params[] )
{
    /* Initialize the stream */
    ...
} /* MyBrngInitStream */
```

## Description

The initialization routine of a user-designed generator must initialize `stream` according to the specified initialization `method`, initial conditions `params` and the argument `n`. The value of `method` determines the initialization method to be used.

- If *method* is equal to 1, the initialization is by the standard generation method, which must be supported by all basic generators. In this case the function assumes that the *stream* structure was not previously initialized. The value of *n* is used as the actual number of 32-bit values passed as initial conditions through *params*. Note, that the situation when the actual number of initial conditions passed to the function is not sufficient to initialize the generator is not an error. Whenever it occurs, the basic generator must initialize the missing conditions using default settings.
- If *method* is equal to 2, the generation is by the leapfrog method, where *n* specifies the number of computational nodes (independent streams). Here the function assumes that the *stream* was previously initialized by the standard generation method. In this case *params* contains only one element, which identifies the computational node. If the generator does not support the leapfrog method, the function must return the error code `VSL_RNG_ERROR_LEAPFROG_UNSUPPORTED`.
- If *method* is equal to 3, the generation is by the block-splitting method. Same as above, the *stream* is assumed to be previously initialized by the standard generation method; *params* is not used, *n* identifies the number of skipped elements. If the generator does not support the block-splitting method, the function must return the error code `VSL_RNG_ERROR_SKIPAHEAD_UNSUPPORTED`.
- If *method* is equal to 4, the generation is by the advanced block-splitting method. The stream is assumed to be previously initialized by the standard generation method; *params* is converted to `MKL_UINT64 []` and *n* is used as actual number of 64-bit values in *params*. If the generator does not support the advanced block-splitting method, the function must return the error code `VSL_RNG_ERROR_SKIPAHEAD_EX_UNSUPPORTED`.

For a more detailed description of the leapfrog and the block-splitting methods, refer to the description of [vslLeapfrogStream](#), [vslSkipAheadStream](#), and [vslSkipAheadStreamEx](#), respectively.

Stream state structure is individual for every generator. However, each structure has a number of fields that are the same for all the generators:

```
typedef struct
{
    unsigned int Reserved1[2];
    unsigned int Reserved2[2];
    [fields specific for the given generator]
} MyStreamState;
```

The fields *Reserved1* and *Reserved2* are reserved for private needs only, and must not be modified by the user. When including specific fields into the structure, follow the rules below:

- The fields must fully describe the current state of the generator. For example, the state of a linear congruential generator can be identified by only one initial condition;
- If the generator can use both the leapfrog and the block-splitting methods, additional fields should be introduced to identify the independent streams. For example, in  $LCG(a, c, m)$ , apart from the initial conditions, two more fields should be specified: the value of the multiplier  $a^k$  and the value of the increment  $(a^k-1)c/(a-1)$ .

For a more detailed discussion, refer to [Knuth81], and [Gentle98]. An example of the registration procedure can be found in the respective directory of VS examples.

## iBRng

```
int iMyBrng( VSLStreamStatePtr stream, int n, unsigned int r[] )
{
    int i; /* Loop variable */
    /* Generating integer random numbers */
    /* Pay attention to word size needed to
    store only random number */
    for( i = 0; i < n; i++)
    {
        r[i] = ...;
```

```

}
/* Update stream state */
...
return errcode;
} /* iMyBrng */

```

**NOTE**

When using 64 and 128-bit generators, consider digit capacity to store the numbers to the random vector  $r$  correctly. For example, storing one 64-bit value requires two elements of  $r$ , the first to store the lower 32 bits and the second to store the higher 32 bits. Similarly, use 4 elements of  $r$  to store a 128-bit value.

**sBRng**

```

int sMyBrng( VSLStreamStatePtr stream, int n, float r[], float a, float b )
{
    int i; /* Loop variable */
    /* Generating float (a,b) random numbers */
    for ( i = 0; i < n; i++ )
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* sMyBrng */

```

**dBRng**

```

int dMyBrng( VSLStreamStatePtr stream, int n, double r[], double a, double b )
{
    int i; /* Loop variable */
    /* Generating double (a,b) random numbers */
    for ( i = 0; i < n; i++ )
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* dMyBrng */

```

**Convolution and Correlation**

Intel® oneAPI Math Kernel Library (oneMKL) VS provides a set of routines intended to perform linear convolution and correlation transformations for single and double precision real and complex data.

For correct definition of implemented operations, see the [Mathematical Notation and Definitions](#).

The current implementation provides:

- Fourier algorithms for one-dimensional single and double precision real and complex data
- Fourier algorithms for multi-dimensional single and double precision real and complex data
- Direct algorithms for one-dimensional single and double precision real and complex data
- Direct algorithms for multi-dimensional single and double precision real and complex data

One-dimensional algorithms cover the following functions from the IBM\* ESSL library:

```
SCONF, SCORF
```

```
SCOND, SCORD
```

```
SDCON, SDCOR
```

```
DDCON, DDCOR
```

```
SDDCON, SDDCOR.
```

Special wrappers are designed to simulate these ESSL functions. The wrappers are provided as sample sources:

```
$(MKL)/examples/vslc/essl/vsl_wrappers
```

Additionally, you can browse the examples demonstrating the calculation of the ESSL functions through the wrappers:

```
$(MKL)/examples/vslc/essl
```

The convolution and correlation API provides interfaces for Fortran 90 and C/89 languages. You can use the C89 interface with later versions of the C/C++.

Intel® oneAPI Math Kernel Library (oneMKL) provides the `mkl_vsl.h` header file. All header files are in the directory

```
$(MKL)/include
```

The convolution and correlation API is implemented through task objects, or tasks. Task object is a data structure, or descriptor, which holds parameters that determine the specific convolution or correlation operation. Such parameters may be precision, type, and number of dimensions of user data, an identifier of the computation algorithm to be used, shapes of data arrays, and so on.

All the Intel® oneAPI Math Kernel Library (oneMKL) VS convolution and correlation routines process task objects in one way or another: either create a new task descriptor, change the parameter settings, compute mathematical results of the convolution or correlation using the stored parameters, or perform other operations. Accordingly, all routines are split into the following groups:

**Task Constructors** - routines that create a new task object descriptor and set up most common parameters.

**Task Editors** - routines that can set or modify some parameter settings in the existing task descriptor.

**Task Execution Routines** - compute results of the convolution or correlation operation over the actual input data, using the operation parameters held in the task descriptor.

**Task Copy** - routines used to make several copies of the task descriptor.

**Task Destructors** - routines that delete task objects and free the memory.

When the task is executed or copied for the first time, a special process runs which is called task commitment. During this process, consistency of task parameters is checked and the required work data are prepared. If the parameters are consistent, the task is tagged as committed successfully. The task remains committed until you edit its parameters. Hence, the task can be executed multiple times after a single commitment process. Since the task commitment process may include costly intermediate calculations such as preparation of Fourier transform of input data, launching the process only once can help speed up overall performance.

## Convolution and Correlation Naming Conventions

The names of routines, types, and constants in the convolution and correlation API are case-sensitive and can contain both lowercase and uppercase characters (`vslsConvExec`).

The names of routines have the following structure:

```
vsl[datatype]{Conv|Corr}<base name>
```

where

- `vsl` is a prefix indicating that the routine belongs to Intel® MKL Vector Statistics.
- `[datatype]` is optional. If present, the symbol specifies the type of the input and output data and can be `s` (for single precision real type), `d` (for double precision real type), `c` (for single precision complex type), or `z` (for double precision complex type).
- `Conv` or `Corr` specifies whether the routine refers to convolution or correlation task, respectively.
- `<base name>` field specifies a particular functionality that the routine is designed for, for example, `NewTask`, `DeleteTask`.

## Convolution and Correlation Data Types

All convolution or correlation routines use the following types for specifying data objects:

Type	Data Object
<code>VSLConvTaskPtr</code>	Pointer to a task descriptor for convolution
<code>VSLCorrTaskPtr</code>	Pointer to a task descriptor for correlation
<code>float</code>	Input/output user real data in single precision
<code>double</code>	Input/output user real data in double precision
<code>MKL_Complex8</code>	Input/output user complex data in single precision
<code>MKL_Complex16</code>	Input/output user complex data in double precision
<code>int</code>	All other data

Generic integer type (without specifying the byte size) is used for all integer data.

### NOTE

The actual size of the generic integer type is platform-dependent. Before you compile your application, set an appropriate byte size for integers. See details in the 'Using the ILP64 Interface vs. LP64 Interface' section of the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*.

## Convolution and Correlation Parameters

Basic parameters held by the task descriptor are assigned values when the task object is created, copied, or modified by task editors. Parameters of the correlation or convolution task are initially set up by task constructors when the task object is created. Parameter changes or additional settings are made by task editors. More parameters which define location of the data being convolved need to be specified when the task execution routine is invoked.

According to how the parameters are passed or assigned values, all of them can be categorized as either explicit (directly passed as routine parameters when a task object is created or executed) or optional (assigned some default or implicit values during task construction).

The following table lists all applicable parameters used in the Intel® oneAPI Math Kernel Library (oneMKL) convolution and correlation API.

### Convolution and Correlation Task Parameters

Name	Category	Type	Default Value Label	Description
<code>job</code>	explicit	integer	Implied by the constructor name	Specifies whether the task relates to convolution or correlation

Name	Category	Type	Default Value Label	Description
<i>type</i>	explicit	integer	Implied by the constructor name	Specifies the type (real or complex) of the input/output data. Set to real in the current version.
<i>precision</i>	explicit	integer	Implied by the constructor name	Specifies precision (single or double) of the input/output data to be provided in arrays <i>x,y,z</i> .
<i>mode</i>	explicit	integer	None	Specifies whether the convolution/correlation computation should be done via Fourier transforms, or by a direct method, or by automatically choosing between the two. See <a href="#">SetMode</a> for the list of named constants for this parameter.
<i>method</i>	optional	integer	"auto"	Hints at a particular computation method if several methods are available for the given <i>mode</i> . Setting this parameter to "auto" means that software will choose the best available method.
<i>internal_precision</i>	optional	integer	Set equal to the value of <i>precision</i>	Specifies precision of internal calculations. Can enforce double precision calculations even when input/output data are single precision. See <a href="#">SetInternalPrecision</a> for the list of named constants for this parameter.
<i>dims</i>	explicit	integer	None	Specifies the rank (number of dimensions) of the user data provided in arrays <i>x,y,z</i> . Can be in the range from 1 to 7.
<i>x,y</i>	explicit	real arrays	None	Specify input data arrays. See <a href="#">Data Allocation</a> for more information.
<i>z</i>	explicit	real array	None	Specifies output data array. See <a href="#">Data Allocation</a> for more information.
<i>xshape, yshape, zshape</i>	explicit	integer arrays	None	Define shapes of the arrays <i>x, y, z</i> . See <a href="#">Data Allocation</a> for more information.
<i>xstride, ystride, zstride</i>	explicit	integer arrays	None	Define strides within arrays <i>x, y, z</i> , that is specify the physical location of the input and output data in these arrays. See <a href="#">Data Allocation</a> for more information.
<i>start</i>	optional	integer array	Undefined	Defines the first element of the mathematical result that will be stored to output array <i>z</i> . See <a href="#">SetStart</a> and <a href="#">Data Allocation</a> for more information.
<i>decimation</i>	optional	integer array	Undefined	Defines how to thin out the mathematical result that will be stored to output array <i>z</i> . See <a href="#">SetDecimation</a> and <a href="#">Data Allocation</a> for more information.

Users may pass the NULL pointer instead of either or all of the parameters *xstride*, *ystride*, or *zstride* for multi-dimensional calculations. In this case, the software assumes the dense data allocation for the arrays *x*, *y*, or *z* due to the Fortran-style "by columns" representation of multi-dimensional arrays.

## Convolution and Correlation Task Status and Error Reporting

The task status is an integer value, which is zero if no error has been detected while processing the task, or a specific non-zero error code otherwise. Negative status values indicate errors, and positive values indicate warnings.

An error can be caused by invalid parameter values, a system fault like a memory allocation failure, or can be an internal error self-detected by the software.

Each task descriptor contains the current status of the task. When creating a task object, the constructor assigns the `VSL_STATUS_OK` status to the task. When processing the task afterwards, other routines such as editors or executors can change the task status if an error occurs and write a corresponding error code into the task status field.

Note that at the stage of creating a task or editing its parameters, the set of parameters may be inconsistent. The parameter consistency check is only performed during the task commitment operation, which is implicitly invoked before task execution or task copying. If an error is detected at this stage, task execution or task copying is terminated and the task descriptor saves the corresponding error code. Once an error occurs, any further attempts to process that task descriptor is terminated and the task keeps the same error code.

Normally, every convolution or correlation function (except `DeleteTask`) returns the status assigned to the task while performing the function operation.

The header files define symbolic names for the status codes. These names are defined as macros via the `#define` statements.

If there is no error, the `VSL_STATUS_OK` status is returned, which is defined as zero:

```
#define VSL_STATUS_OK 0
```

In case of an error, a non-zero error code is returned, which indicates the origin of the failure. The following status codes for the convolution/correlation error codes are pre-defined in the header files.

### Convolution/Correlation Status Codes

Status Code	Description
<code>VSL_CC_ERROR_NOT_IMPLEMENTED</code>	Requested functionality is not implemented.
<code>VSL_CC_ERROR_ALLOCATION_FAILURE</code>	Memory allocation failure.
<code>VSL_CC_ERROR_BAD_DESCRIPTOR</code>	Task descriptor is corrupted.
<code>VSL_CC_ERROR_SERVICE_FAILURE</code>	A service function has failed.
<code>VSL_CC_ERROR_EDIT_FAILURE</code>	Failure while editing the task.
<code>VSL_CC_ERROR_EDIT_PROHIBITED</code>	You cannot edit this parameter.
<code>VSL_CC_ERROR_COMMIT_FAILURE</code>	Task commitment has failed.
<code>VSL_CC_ERROR_COPY_FAILURE</code>	Failure while copying the task.
<code>VSL_CC_ERROR_DELETE_FAILURE</code>	Failure while deleting the task.
<code>VSL_CC_ERROR_BAD_ARGUMENT</code>	Bad argument or task parameter.
<code>VSL_CC_ERROR_JOB</code>	Bad parameter: <i>job</i> .
<code>VSL_CC_ERROR_KIND</code>	Bad parameter: <i>kind</i> .

Status Code	Description
VSL_CC_ERROR_MODE	Bad parameter: <i>mode</i> .
VSL_CC_ERROR_METHOD	Bad parameter: <i>method</i> .
VSL_CC_ERROR_TYPE	Bad parameter: <i>type</i> .
VSL_CC_ERROR_EXTERNAL_PRECISION	Bad parameter: <i>external_precision</i> .
VSL_CC_ERROR_INTERNAL_PRECISION	Bad parameter: <i>internal_precision</i> .
VSL_CC_ERROR_PRECISION	Incompatible external/internal precisions.
VSL_CC_ERROR_DIMS	Bad parameter: <i>dims</i> .
VSL_CC_ERROR_XSHAPE	Bad parameter: <i>xshape</i> .
VSL_CC_ERROR_YSHAPE	Bad parameter: <i>yshape</i> .
	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_CC_ERROR_ZSHAPE	Bad parameter: <i>zshape</i> .
VSL_CC_ERROR_XSTRIDE	Bad parameter: <i>xstride</i> .
VSL_CC_ERROR_YSTRIDE	Bad parameter: <i>ystride</i> .
VSL_CC_ERROR_ZSTRIDE	Bad parameter: <i>zstride</i> .
VSL_CC_ERROR_X	Bad parameter: <i>x</i> .
VSL_CC_ERROR_Y	Bad parameter: <i>y</i> .
VSL_CC_ERROR_Z	Bad parameter: <i>z</i> .
VSL_CC_ERROR_START	Bad parameter: <i>start</i> .
VSL_CC_ERROR_DECIMATION	Bad parameter: <i>decimation</i> .
VSL_CC_ERROR_OTHER	Another error.

## Convolution and Correlation Task Constructors

Task constructors are routines intended for creating a new task descriptor and setting up basic parameters. No additional parameter adjustment is typically required and other routines can use the task object.

Intel® MKL implementation of the convolution and correlation API provides two different forms of constructors: a general form and an X-form. X-form constructors work in the same way as the general form constructors but also assign particular data to the first operand vector used in the convolution or correlation operation (stored in array *x*).

Using X-form constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector held in array *x* against different vectors held in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

Each constructor routine has an associated one-dimensional version that provides algorithmic and computational benefits.

**NOTE**

If the constructor fails to create a task descriptor, it returns the `NULL` task pointer.

The [Table "Task Constructors"](#) lists available task constructors:

**Task Constructors**

<b>Routine</b>	<b>Description</b>
<code>vslConvNewTask/vslCorrNewTask</code>	Creates a new convolution or correlation task descriptor for a multidimensional case.
<code>vslConvNewTask1D/ vslCorrNewTask1D</code>	Creates a new convolution or correlation task descriptor for a one-dimensional case.
<code>vslConvNewTaskX/vslCorrNewTaskX</code>	Creates a new convolution or correlation task descriptor as an X-form for a multidimensional case.
<code>vslConvNewTaskX1D/ vslCorrNewTaskX1D</code>	Creates a new convolution or correlation task descriptor as an X-form for a one-dimensional case.

**vslConvNewTask/vslCorrNewTask**

*Creates a new convolution or correlation task descriptor for multidimensional case.*

**Syntax**

```
status = vslsConvNewTask(task, mode, dims, xshape, yshape, zshape);
```

```
status = vsldConvNewTask(task, mode, dims, xshape, yshape, zshape);
```

```
status = vslcConvNewTask(task, mode, dims, xshape, yshape, zshape);
```

```
status = vslzConvNewTask(task, mode, dims, xshape, yshape, zshape);
```

```
status = vslsCorrNewTask(task, mode, dims, xshape, yshape, zshape);
```

```
status = vsldCorrNewTask(task, mode, dims, xshape, yshape, zshape);
```

```
status = vslcCorrNewTask(task, mode, dims, xshape, yshape, zshape);
```

```
status = vslzCorrNewTask(task, mode, dims, xshape, yshape, zshape);
```

- `mkl.h`

**Input Parameters**

<b>Name</b>	<b>Type</b>	<b>Description</b>
<code>mode</code>	<code>const MKL_INT</code>	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See <a href="#">Table "Values of mode parameter"</a> for a list of possible values.
<code>dims</code>	<code>const MKL_INT</code>	Rank of user data. Specifies number of dimensions for the input and output arrays <i>x</i> , <i>y</i> , and <i>z</i> used during the execution stage. Must be in the range from 1 to 7. The value is explicitly assigned by the constructor.

Name	Type	Description
<i>xshape</i>	const int[]	Defines the shape of the input data for the source array <i>x</i> . See <a href="#">Data Allocation</a> for more information.
<i>yshape</i>	const int[]	Defines the shape of the input data for the source array <i>y</i> . See <a href="#">Data Allocation</a> for more information.
<i>zshape</i>	const int[]	Defines the shape of the output data to be stored in array <i>z</i> . See <a href="#">Data Allocation</a> for more information.

## Output Parameters

Name	Type	Description
<i>task</i>	VSLConvTaskPtr* for vslsConvNewTask, vsldConvNewTask, vslcConvNewTask, vslzConvNewTask  VSLCorrTaskPtr* for vslsCorrNewTask, vsldCorrNewTask, vslcConvNewTask, vslzConvNewTask	Pointer to the task descriptor if created successfully or NULL pointer otherwise.
<i>status</i>	int	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

## Description

Each `vslConvNewTask/vslCorrNewTask` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)).

The parameters *xshape*, *yshape*, and *zshape* define the shapes of the input and output data provided by the arrays *x*, *y*, and *z*, respectively. Each shape parameter is an array of integers with its length equal to the value of *dims*. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter *dims* is 1, then *xshape*, *yshape*, *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. Note that values of shape parameters may differ from physical shapes of arrays *x*, *y*, and *z* if non-trivial strides are assigned.

If the constructor fails to create a task descriptor, it returns a NULL task pointer.

### **vslConvNewTask1D/vslCorrNewTask1D**

*Creates a new convolution or correlation task descriptor for one-dimensional case.*

## Syntax

```
status = vslsConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vsldConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vslcConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vslzConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vslsCorrNewTask1D(task, mode, xshape, yshape, zshape);
```

```

status = vsldCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vslcCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vslzCorrNewTask1D(task, mode, xshape, yshape, zshape);

```

## Input Parameters

Name	Type	Description
<i>mode</i>	const MKL_INT	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See <a href="#">Table "Values of mode parameter"</a> for a list of possible values.
<i>xshape</i>	const MKL_INT	Defines the length of the input data sequence for the source array <i>x</i> . See <a href="#">Data Allocation</a> for more information.
<i>yshape</i>	const MKL_INT	Defines the length of the input data sequence for the source array <i>y</i> . See <a href="#">Data Allocation</a> for more information.
<i>zshape</i>	const MKL_INT	Defines the length of the output data sequence to be stored in array <i>z</i> . See <a href="#">Data Allocation</a> for more information.

## Output Parameters

Name	Type	Description
<i>task</i>	VSLConvTaskPtr* for vs1sConvNewTask1D, vs1dConvNewTask1D, vs1cConvNewTask1D, vs1zConvNewTask1D  VSLCorrTaskPtr* for vs1sCorrNewTask1D, vs1dCorrNewTask1D, vs1cCorrNewTask1D, vs1zCorrNewTask1D	Pointer to the task descriptor if created successfully or NULL pointer otherwise.
<i>status</i>	int	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

## Description

Each vs1ConvNewTask1D/vs1CorrNewTask1D constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)). Unlike vs1ConvNewTask/vs1CorrNewTask, these routines represent a special one-dimensional version of the constructor which assumes that the value of the parameter *dims* is 1. The parameters *xshape*, *yshape*, and *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. You explicitly assign the shape parameters when calling the constructor.

**vslConvNewTaskX/vslCorrNewTaskX**

Creates a new convolution or correlation task descriptor for multidimensional case and assigns source data to the first operand vector.

**Syntax**

```
status = vslsConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vsldConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslcConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslzConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslsCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vsldCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslcCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslzCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
```

**Include Files**

<i>x</i>	const float[] for real data in single precision flavors, const double[] for real data in double precision flavors, const MKL_Complex8[] for complex data in single precision flavors, const MKL_Complex16[] for complex data in double precision flavors	Pointer to the array containing input data for the first operand vector. See <a href="#">Data Allocation</a> for more information.

Name	Type	Description
<code>xstride</code>	<code>const int[]</code>	Strides for input data in the array <code>x</code> .

## Output Parameters

Name	Type	Description
<code>task</code>	VSLConvTaskPtr* for <code>vslsConvNewTaskX</code> , <code>vsldConvNewTaskX</code> , <code>vslcConvNewTaskX</code> , <code>vslzConvNewTaskX</code>  VSLCorrTaskPtr* for <code>vslsCorrNewTaskX</code> , <code>vsldCorrNewTaskX</code> , <code>vslcCorrNewTaskX</code> , <code>vslzCorrNewTaskX</code>	Pointer to the task descriptor if created successfully or NULL pointer otherwise.
<code>status</code>	<code>int</code>	Set to <code>VSL_STATUS_OK</code> if the task is created successfully or set to non-zero error code otherwise.

## Description

Each `vslConvNewTaskX/vslCorrNewTaskX` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)).

Unlike `vslConvNewTask/vslCorrNewTask`, these routines represent the so called X-form version of the constructor, which means that in addition to creating the task descriptor they assign particular data to the first operand vector in array `x` used in convolution or correlation operation. The task descriptor created by the `vslConvNewTaskX/vslCorrNewTaskX` constructor keeps the pointer to the array `x` all the time, that is, until the task object is deleted by one of the destructor routines (see `vslConvDeleteTask/vslCorrDeleteTask`).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters `xshape`, `yshape`, and `zshape` define the shapes of the input and output data provided by the arrays `x`, `y`, and `z`, respectively. Each shape parameter is an array of integers with its length equal to the value of `dims`. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter `dims` is 1, then `xshape`, `yshape`, and `zshape` are equal to the number of elements read from the arrays `x` and `y` or stored to the array `z`. Note that values of shape parameters may differ from physical shapes of arrays `x`, `y`, and `z` if non-trivial strides are assigned.

The stride parameter `xstride` specifies the physical location of the input data in the array `x`. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter `xstride` is `s`, then only every  $s^{\text{th}}$  element of the array `x` will be used to form the input sequence. The stride value must be positive or negative but not zero.

### **`vslConvNewTaskX1D/vslCorrNewTaskX1D`**

*Creates a new convolution or correlation task descriptor for one-dimensional case and assigns source data to the first operand vector.*

## Syntax

```

status = vslsConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vsldConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslcConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslzConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslsCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vsldCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslcCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslzCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);

```

## Output Parameters

Name	Type	Description
<i>task</i>	VSLConvTaskPtr* for vslsConvNewTaskX1D, vsldConvNewTaskX1D, vs1cConvNewTaskX1D, vs1zConvNewTaskX1D  VSLCorrTaskPtr* for vslsCorrNewTaskX1D, vsldCorrNewTaskX1D, vs1cCorrNewTaskX1D, vs1zCorrNewTaskX1D	Pointer to the task descriptor if created successfully or NULL pointer otherwise.
<i>status</i>	int	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

## Description

Each `vslConvNewTaskX1D/vslCorrNewTaskX1D` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)).

These routines represent a special one-dimensional version of the so called X-form of the constructor. This assumes that the value of the parameter *dims* is 1 and that in addition to creating the task descriptor, constructor routines assign particular data to the first operand vector in array *x* used in convolution or correlation operation. The task descriptor created by the `vslConvNewTaskX1D/vslCorrNewTaskX1D` constructor keeps the pointer to the array *x* all the time, that is, until the task object is deleted by one of the destructor routines (see `vslConvDeleteTask/vslCorrDeleteTask`).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array *x* against different vectors in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters *xshape*, *yshape*, and *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. You explicitly assign the shape parameters when calling the constructor.

The [stride parameters](#) *xstride* specifies the physical location of the input data in the array *x* and is an interval between locations of consecutive elements of the array. For example, if the value of the parameter *xstride* is *s*, then only every *s*<sup>th</sup> element of the array *x* will be used to form the input sequence. The stride value must be positive or negative but not zero.

## Convolution and Correlation Task Editors

Task editors in convolution and correlation API of Intel® oneAPI Math Kernel Library (oneMKL) are routines intended for setting up or changing the following task parameters (see [Table "Convolution and Correlation Task Parameters"](#)):

- *mode*
- *internal\_precision*
- *start*
- *decimation*

For setting up or changing each of the above parameters, a separate routine exists.

**NOTE**

Fields of the task descriptor structure are accessible only through the set of task editor routines provided with the software.

The work data computed during the last commitment process may become invalid with respect to new parameter settings. That is why after applying any of the editor routines to change the task descriptor settings, the task loses its commitment status and goes through the full commitment process again during the next execution or copy operation. For more information on task commitment, see the [Introduction to Convolution and Correlation](#).

Table "Task Editors" lists available task editors.

**Task Editors**

<b>Routine</b>	<b>Description</b>
<code>vslConvSetMode/vslCorrSetMode</code>	Changes the value of the parameter <i>mode</i> for the operation of convolution or correlation.
<code>vslConvSetInternalPrecision/ vslCorrSetInternalPrecision</code>	Changes the value of the parameter <i>internal_precision</i> for the operation of convolution or correlation.
<code>vslConvSetStart/vslCorrSetStart</code>	Sets the value of the parameter <i>start</i> for the operation of convolution or correlation.
<code>vslConvSetDecimation/ vslCorrSetDecimation</code>	Sets the value of the parameter <i>decimation</i> for the operation of convolution or correlation.

**NOTE**

You can use the NULL task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

**`vslConvSetMode/vslCorrSetMode`**

*Changes the value of the parameter mode in the convolution or correlation task descriptor.*

**Syntax**

```
status = vslConvSetMode(task, newmode);
```

```
status = vslCorrSetMode(task, newmode);
```

**Include Files**

- `mkl.h`

**Input Parameters**

<b>Name</b>	<b>Type</b>	<b>Description</b>
<i>task</i>	VSLConvTaskPtr for <code>vslConvSetMode</code>  VSLCorrTaskPtr for <code>vslCorrSetMode</code>	Pointer to the task descriptor.
<i>newmode</i>	const MKL_INT	New value of the parameter <i>mode</i> .

## Output Parameters

Name	Type	Description
<code>status</code>	<code>int</code>	Current status of the task.

## Description

This function is declared in `mkl_vsl_functions.h`.

The function routine changes the value of the parameter `mode` for the operation of convolution or correlation. This parameter defines whether the computation should be done via Fourier transforms of the input/output data or using a direct algorithm. Initial value for `mode` is assigned by a task constructor.

Predefined values for the `mode` parameter are as follows:

### Values of `mode` parameter

Value	Purpose
<code>VSL_CONV_MODE_FFT</code>	Compute convolution by using fast Fourier transform.
<code>VSL_CORR_MODE_FFT</code>	Compute correlation by using fast Fourier transform.
<code>VSL_CONV_MODE_DIRECT</code>	Compute convolution directly.
<code>VSL_CORR_MODE_DIRECT</code>	Compute correlation directly.
<code>VSL_CONV_MODE_AUTO</code>	Automatically choose direct or Fourier mode for convolution.
<code>VSL_CORR_MODE_AUTO</code>	Automatically choose direct or Fourier mode for correlation.

### [vslConvSetInternalPrecision/vslCorrSetInternalPrecision](#)

*Changes the value of the parameter `internal_precision` in the convolution or correlation task descriptor.*

## Syntax

```
status = vslConvSetInternalPrecision(task, precision);
```

```
status = vslCorrSetInternalPrecision(task, precision);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>task</code>	<code>VSLConvTaskPtr</code> for <code>vslConvSetInternalPrecision</code> <code>n</code> <code>VSLCorrTaskPtr</code> for <code>vslCorrSetInternalPrecision</code> <code>n</code>	Pointer to the task descriptor.
<code>precision</code>	<code>const MKL_INT</code>	New value of the parameter <code>internal_precision</code> .

## Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task.

## Description

The `vslConvSetInternalPrecision/vslCorrSetInternalPrecision` routine changes the value of the parameter `internal_precision` for the operation of convolution or correlation. This parameter defines whether the internal computations of the convolution or correlation result should be done in single or double precision. Initial value for `internal_precision` is assigned by a task constructor and set to either "single" or "double" according to the particular flavor of the constructor used.

Changing the `internal_precision` can be useful if the default setting of this parameter was "single" but you want to calculate the result with double precision even if input and output data are represented in single precision.

Predefined values for the `internal_precision` input parameter are as follows:

### Values of `internal_precision` Parameter

Value	Purpose
VSL_CONV_PRECISION_SINGLE	Compute convolution with single precision.
VSL_CORR_PRECISION_SINGLE	Compute correlation with single precision.
VSL_CONV_PRECISION_DOUBLE	Compute convolution with double precision.
VSL_CORR_PRECISION_DOUBLE	Compute correlation with double precision.

## `vslConvSetStart/vslCorrSetStart`

*Changes the value of the parameter `start` in the convolution or correlation task descriptor.*

## Syntax

```
status = vslConvSetStart(task, start);
```

```
status = vslCorrSetStart(task, start);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<i>task</i>	VSLConvTaskPtr for <code>vslConvSetStart</code> VSLCorrTaskPtr for <code>vslCorrSetStart</code>	Pointer to the task descriptor.
<i>start</i>	const int[]	New value of the parameter <code>start</code> .

## Output Parameters

Name	Type	Description
<code>status</code>	<code>int</code>	Current status of the task.

## Description

The `vslConvSetStart/vslCorrSetStart` routine sets the value of the parameter `start` for the operation of convolution or correlation. In a one-dimensional case, this parameter points to the first element in the mathematical result that should be stored in the output array. In a multidimensional case, `start` is an array of indices and its length is equal to the number of dimensions specified by the parameter `dims`. For more information about the definition and effect of this parameter, see [Data Allocation](#).

During the initial task descriptor construction, the default value for `start` is undefined and this parameter is not used. Therefore the only way to set and use the `start` parameter is via assigning it some value by one of the `vslConvSetStart/vslCorrSetStart` routines.

## `vslConvSetDecimation/vslCorrSetDecimation`

*Changes the value of the parameter `decimation` in the convolution or correlation task descriptor.*

## Syntax

```
status = vslConvSetDecimation(task, decimation);
status = vslCorrSetDecimation(task, decimation);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>task</code>	VSLConvTaskPtr for <code>vslConvSetDecimation</code>  VSLCorrTaskPtr for <code>vslCorrSetDecimation</code>	Pointer to the task descriptor.
<code>decimatio n</code>	<code>const int[]</code>	New value of the parameter <code>decimation</code> .

## Output Parameters

Name	Type	Description
<code>status</code>	<code>int</code>	Current status of the task.

## Description

The routine sets the value of the parameter `decimation` for the operation of convolution or correlation. This parameter determines how to thin out the mathematical result of convolution or correlation before writing it into the output data array. For example, in a one-dimensional case, if `decimation = d > 1`, only every `d`-th element of the mathematical result is written to the output array `z`. In a multidimensional case, `decimation` is an array of indices and its length is equal to the number of dimensions specified by the parameter `dims`. For more information about the definition and effect of this parameter, see [Data Allocation](#).

During the initial task descriptor construction, the default value for *decimation* is undefined and this parameter is not used. Therefore the only way to set and use the *decimation* parameter is via assigning it some value by one of the `vslSetDecimation` routines.

## Task Execution Routines

Task execution routines compute convolution or correlation results based on parameters held by the task descriptor and on the user data supplied for input vectors.

After you create and adjust a task, you can execute it multiple times by applying to different input/output data of the same type, precision, and shape.

Intel® oneAPI Math Kernel Library (oneMKL) provides the following forms of convolution/correlation execution routines:

- **General form** executors that use the task descriptor created by the general form constructor and expect to get two source data arrays *x* and *y* on input
- **X-form** executors that use the task descriptor created by the X-form constructor and expect to get only one source data array *y* on input because the first array *x* has been already specified on the construction stage

When the task is executed for the first time, the execution routine includes a task commitment operation, which involves two basic steps: parameters consistency check and preparation of auxiliary data (for example, this might be the calculation of Fourier transform for input data).

Each execution routine has an associated one-dimensional version that provides algorithmic and computational benefits.

---

### NOTE

You can use the `NULL` task pointer in calls to execution routines. In this case, the routine is terminated and no system crash occurs.

---

If the task is executed successfully, the execution routine returns the zero status code. If an error is detected, the execution routine returns an error code which signals that a specific error has occurred. In particular, an error status code is returned in the following cases:

- if the task pointer is `NULL`
- if the task descriptor is corrupted
- if calculation has failed for some other reason.

---

### NOTE

Intel® MKL does not control floating-point errors, like overflow or gradual underflow, or operations with NaNs, etc.

---

If an error occurs, the task descriptor stores the error code.

The table below lists all task execution routines.

## Task Execution Routines

<b>Routine</b>	<b>Description</b>
<code>vslConvExec/vslCorrExec</code>	Computes convolution or correlation for a multidimensional case.
<code>vslConvExec1D/vslCorrExec1D</code>	Computes convolution or correlation for a one-dimensional case.
<code>vslConvExecX/vslCorrExecX</code>	Computes convolution or correlation as X-form for a multidimensional case.
<code>vslConvExecX1D/vslCorrExecX1D</code>	Computes convolution or correlation as X-form for a one-dimensional case.

---

**vslConvExec/vslCorrExec**

Computes convolution or correlation for multidimensional case.

**Syntax**

```
status = vslsConvExec(task, x, xstride, y, ystride, z, zstride);
status = vsldConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslcConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslzConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslsCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vsldCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vslcCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vslzCorrExec(task, x, xstride, y, ystride, z, zstride);
```

**Include Files**

**Input Parameters**

Name	Type	Description
<i>task</i>	VSLConvTaskPtr for vslsConvExec, vsldConvExec, vslcConvExec, vslzConvExec  VSLCorrTaskPtr for vslsCorrExec, vsldCorrExec, vslcCorrExec, vslzCorrExec	Pointer to the task descriptor
<i>x, y</i>	const float[] for vslsConvExec and vslsCorrExec,  const double[] for vsldConvExec and vsldCorrExec,  const MKL_Complex8[] for vslcConvExec and vslcCorrExec,  const MKL_Complex16[] for vslzConvExec and vslzCorrExec	Pointers to arrays containing input data. See <a href="#">Data Allocation</a> for more information.
<i>xstride,</i> <i>ystride,</i> <i>zstride</i>	const int[]	Strides for input and output data. For more information, see <a href="#">stride parameters</a> .

## Output Parameters

Name	Type	Description
<code>z</code>	const float[] for <code>vslsConvExec</code> and <code>vslsCorrExec</code> ,  const double[] for <code>vslDConvExec</code> and <code>vslDCorrExec</code> ,  const MKL_Complex8[] for <code>vslcConvExec</code> and <code>vslcCorrExec</code> ,  const MKL_Complex16[] for <code>vslzConvExec</code> and <code>vslzCorrExec</code>	Pointer to the array that stores output data. See <a href="#">Data Allocation</a> for more information.
<code>status</code>	int	Set to <code>VSL_STATUS_OK</code> if the task is executed successfully or set to non-zero error code otherwise.

## Description

Each of the `vslConvExec/vslCorrExec` routines computes convolution or correlation of the data provided by the arrays `x` and `y` and then stores the results in the array `z`. Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTask/vslCorrNewTask` constructor and pointed to by `task`. If `task` is `NULL`, no operation is done.

The stride parameters `xstride`, `ystride`, and `zstride` specify the physical location of the input and output data in the arrays `x`, `y`, and `z`, respectively. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter `zstride` is `s`, then only every  $s^{\text{th}}$  element of the array `z` will be used to store the output data. The stride value must be positive or negative but not zero.

### **vslConvExec1D/vslCorrExec1D**

*Computes convolution or correlation for one-dimensional case.*

#### Syntax

```
status = vslsConvExec1D(task, x, xstride, y, ystride, z, zstride);
```

```
status = vslDConvExec1D(task, x, xstride, y, ystride, z, zstride);
```

```
status = vslcConvExec1D(task, x, xstride, y, ystride, z, zstride);
```

```
status = vslzConvExec1D(task, x, xstride, y, ystride, z, zstride);
```

```
status = vslsCorrExec1D(task, x, xstride, y, ystride, z, zstride);
```

```
status = vslDCorrExec1D(task, x, xstride, y, ystride, z, zstride);
```

```
status = vslcCorrExec1D(task, x, xstride, y, ystride, z, zstride);
```

```
status = vslzCorrExec1D(task, x, xstride, y, ystride, z, zstride);
```

## Input Parameters

Name	Type	Description
<i>task</i>	VSLConvTaskPtr for vs1sConvExec1D, vs1dConvExec1D, vs1cConvExec1D, vs1zConvExec1D  VSLCorrTaskPtr for vs1sCorrExec1D, vs1dCorrExec1D, vs1cCorrExec1D, vs1zCorrExec1D	Pointer to the task descriptor.
<i>x, y</i>	const float[] for vs1sConvExec1D and vs1sCorrExec1D,  const double[] for vs1dConvExec1D and vs1dCorrExec1D,  const MKL_Complex8[] for vs1cConvExec1D and vs1cCorrExec1D,  const MKL_Complex16[] for vs1zConvExec1D and vs1zCorrExec1D	Pointers to arrays containing input data. See <a href="#">Data Allocation</a> for more information.
<i>xstride,</i> <i>ystride,</i> <i>zstride</i>	const MKL_INT	Strides for input and output data. For more information, see <a href="#">stride parameters</a> .

## Output Parameters

Name	Type	Description
<i>z</i>	const float[] for vs1sConvExec1D and vs1sCorrExec1D,  const double[] for vs1dConvExec1D and vs1dCorrExec1D,  const MKL_Complex8[] for vs1cConvExec1D and vs1cCorrExec1D,  const MKL_Complex16[] for vs1zConvExec1D and vs1zCorrExec1D	Pointer to the array that stores output data. See <a href="#">Data Allocation</a> for more information.

Name	Type	Description
<code>status</code>	<code>int</code>	Set to <code>VSL_STATUS_OK</code> if the task is executed successfully or set to non-zero error code otherwise.

## Description

Each of the `vslConvExec1D/vslCorrExec1D` routines computes convolution or correlation of the data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special one-dimensional version of the operation, assuming that the value of the parameter `dims` is 1. Using this version of execution routines can help speed up performance in case of one-dimensional data.

Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTask1D/vslCorrNewTask1D` constructor and pointed to by `task`. If `task` is `NULL`, no operation is done.

## `vslConvExecX/vslCorrExecX`

*Computes convolution or correlation for multidimensional case with the fixed first operand vector.*

## Syntax

```
status = vslsConvExecX(task, y, ystride, z, zstride);
status = vsldConvExecX(task, y, ystride, z, zstride);
status = vslcConvExecX(task, y, ystride, z, zstride);
status = vslzConvExecX(task, y, ystride, z, zstride);
status = vslsCorrExecX(task, y, ystride, z, zstride);
status = vslcCorrExecX(task, y, ystride, z, zstride);
status = vslzCorrExecX(task, y, ystride, z, zstride);
status = vsldCorrExecX(task, y, ystride, z, zstride);
```

## Input Parameters

Name	Type	Description
<code>task</code>	VSLConvTaskPtr for <code>vslsConvExecX</code> , <code>vsldConvExecX</code> , <code>vslcConvExecX</code> , <code>vslzConvExecX</code>  VSLCorrTaskPtr for <code>vslsCorrExecX</code> , <code>vsldCorrExecX</code> , <code>vslcCorrExecX</code> , <code>vslzCorrExecX</code>	Pointer to the task descriptor.

Name	Type	Description
<i>x</i> , <i>y</i>	const float[] for vslsConvExecX and vslsCorrExecX,  const double[] for vsldConvExecX and vsldCorrExecX,  const MKL_Complex8[] for vslcConvExecX and vslcCorrExecX,  const MKL_Complex16[] for vslzConvExecX and vslzCorrExecX	Pointer to array containing input data (for the second operand vector). See <a href="#">Data Allocation</a> for more information.
<i>ystride</i> , <i>zstride</i>	const int[]	Strides for input and output data. For more information, see <a href="#">stride parameters</a> .

## Output Parameters

Name	Type	Description
<i>z</i>	const float[] for vslsConvExecX and vslsCorrExecX,  const double[] for vsldConvExecX and vsldCorrExecX,  const MKL_Complex8[] for vslcConvExecX and vslcCorrExecX,  const MKL_Complex16[] for vslzConvExecX and vslzCorrExecX	Pointer to the array that stores output data. See <a href="#">Data Allocation</a> for more information.
<i>status</i>	int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

## Description

Each of the `vslConvExecX/vslCorrExecX` routines computes convolution or correlation of the data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special version of the operation, which assumes that the first operand vector was set on the task construction stage and the task object keeps the pointer to the array `x`.

Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTaskX/vslCorrNewTaskX` constructor and pointed to by `task`. If `task` is NULL, no operation is done.

Using this form of execution routines is recommended when you need to compute multiple convolutions or correlations with the same data vector in array  $x$  against different vectors in array  $y$ . This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

### **vslConvExecX1D/vslCorrExecX1D**

*Computes convolution or correlation for one-dimensional case with the fixed first operand vector.*

#### **Syntax**

<i>status</i>	int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

## Description

Each of the `vslConvExecX1D/vslCorrExecX1D` routines computes convolution or correlation of one-dimensional (assuming that `dims = 1`) data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special version of the operation, which expects that the first operand vector was set on the task construction stage.

Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTaskX1D/vslCorrNewTaskX1D` constructor and pointed to by `task`. If `task` is NULL, no operation is done.

Using this form of execution routines is recommended when you need to compute multiple one-dimensional convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

## Convolution and Correlation Task Destructors

Task destructors are routines designed for deleting task objects and deallocating memory.

### `vslConvDeleteTask/vslCorrDeleteTask`

Destroys the task object and frees the memory.

## Syntax

```
errcode = vslConvDeleteTask(task);
```

```
errcode = vslCorrDeleteTask(task);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>task</i>	VSLConvTaskPtr* for vslConvDeleteTask  VSLCorrTaskPtr* for vslCorrDeleteTask	Pointer to the task descriptor.

## Output Parameters

Name	Type	Description
<i>errcode</i>	int	Contains 0 if the task object is deleted successfully. Contains an error code if an error occurred.

## Description

The `vslConvDeleteTask/vslCorrvDeleteTask` routine deletes the task descriptor object and frees any working memory and the memory allocated for the data structure. The task pointer is set to `NULL`.

Note that if the `vslConvDeleteTask/vslCorrvDeleteTask` routine does not delete the task successfully, the routine returns an error code. This error code has no relation to the task status code and does not change it.

---

### NOTE

You can use the `NULL` task pointer in calls to destructor routines. In this case, the routine terminates with no system crash.

---

## Convolution and Correlation Task Copiers

The routines are designed for copying convolution and correlation task descriptors.

### **vslConvCopyTask/vslCorrCopyTask**

*Copies a descriptor for convolution or correlation task.*

#### Syntax

```
status = vslConvCopyTask(newtask, srctask);
```

```
status = vslCorrCopyTask(newtask, srctask);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>srctask</i>	const VSLConvTaskPtr for vslConvCopyTask  const VSLCorrTaskPtr for vslCorrCopyTask	Pointer to the source task descriptor.

## Output Parameters

Name	Type	Description
<i>newtask</i>	VSLConvTaskPtr* for vslConvCopyTask  VSLCorrTaskPtr* for vslCorrCopyTask	Pointer to the new task descriptor.
<i>status</i>	int	Current status of the source task.

## Description

If a task object *srctask* already exists, you can use an appropriate `vslConvCopyTask/vslCorrCopyTask` routine to make its copy in *newtask*. After the copy operation, both source and new task objects will become committed (see [Introduction to Convolution and Correlation](#) for information about task commitment). If the source task was not previously committed, the commitment operation for this task is implicitly invoked before copying starts. If an error occurs during source task commitment, the task stores the error code in the status field. If an error occurs during copy operation, the routine returns a `NULL` pointer instead of a reference to a new task object.

## Convolution and Correlation Usage Examples

This section demonstrates how you can use the Intel® oneAPI Math Kernel Library (oneMKL) routines to perform some common convolution and correlation operations both for single-threaded and multithreaded calculations. The following two sample functions `scond1` and `sconf1` simulate the convolution and correlation functions `SCOND` and `SCONF` found in IBM ESSL\* library. The functions assume single-threaded calculations and can be used with C or C++ compilers.

## Function `scond1` for Single-Threaded Calculations

```
#include "mkl_vsl.h"

int scond1(
    float h[], int inch,
    float x[], int incx,
    float y[], int incy,
    int nh, int nx, int iy0, int ny)
{
    int status;
    VSLConvTaskPtr task;
    vslsConvNewTask1D(&task, VSL_CONV_MODE_DIRECT, nh, nx, ny);
    vslConvSetStart(task, &iy0);
    status = vslsConvExec1D(task, h, inch, x, incx, y, incy);
    vslConvDeleteTask(&task);
    return status;
}
```

## Function `sconf1` for Single-Threaded Calculations

```
#include "mkl_vsl.h"

int sconf1(
    int init,
    float h[], int inclh,
    float x[], int inclx, int inc2x,
    float y[], int incly, int inc2y,
    int nh, int nx, int m, int iy0, int ny,
    void* aux1, int naux1, void* aux2, int naux2)
{
    int status;
    /* assume that aux1!=0 and naux1 is big enough */
    VSLConvTaskPtr* task = (VSLConvTaskPtr*)aux1;
    if (init != 0)
        /* initialization: */
        status = vslsConvNewTaskX1D(task, VSL_CONV_MODE_FFT,
            nh, nx, ny, h, inclh);
    if (init == 0) {
        /* calculations: */
        int i;
        vslConvSetStart(*task, &iy0);
        for (i=0; i<m; i++) {
            float* xi = &x[inc2x * i];
            float* yi = &y[inc2y * i];
            /* task is implicitly committed at i==0 */
            status = vslsConvExecX1D(*task, xi, inclx, yi, incly);
        };
    };
    vslConvDeleteTask(task);
    return status;
}
```

## Using Multiple Threads

For functions such as `sconf1` described in the previous example, parallel calculations may be more preferable instead of cycling. If  $m > 1$ , you can use multiple threads for invoking the task execution against different data sequences. For such cases, use task copy routines to create  $m$  copies of the task object before the calculations stage and then run these copies with different threads. Ensure that you make all necessary parameter adjustments for the task (using [Task Editors](#)) before copying it.

The sample code in this case may look as follows:

```
if (init == 0) {
    int i, status, ss[M];
    VSLConvTaskPtr tasks[M];
    /* assume that M is big enough */
    . . .
    vslConvSetStart(*task, &iy0);
    . . .
    for (i=0; i<m; i++)
        /* implicit commitment at i==0 */
        vslConvCopyTask(&tasks[i],*task);
    . . .
```

Then,  $m$  threads may be started to execute different copies of the task:

```
. . .
    float* xi = &x[inc2x * i];
    float* yi = &y[inc2y * i];
    ss[i]=vslsConvExecX1D(tasks[i], xi,inc1x, yi,inc1y);
    . . .
```

And finally, after all threads have finished the calculations, overall status should be collected from all task objects. The following code signals the first error found, if any:

```
. . .
    for (i=0; i<m; i++) {
        status = ss[i];
        if (status != 0) /* 0 means "OK" */
            break;
    };
    return status;
}; /* end if init==0 */
```

Execution routines modify the task internal state (fields of the task structure). Such modifications may conflict with each other if different threads work with the same task object simultaneously. That is why different threads must use different copies of the task.

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

**Convolution and Correlation Mathematical Notation and Definitions**

The following notation is necessary to explain the underlying mathematical definitions used in the text:

$\mathbf{R} = (-\infty, +\infty)$	The set of real numbers.
$\mathbf{Z} = \{0, \pm 1, \pm 2, \dots\}$	The set of integer numbers.
$\mathbf{Z}^N = \mathbf{Z} \times \dots \times \mathbf{Z}$	The set of N-dimensional series of integer numbers.
$p = (p_1, \dots, p_N) \in \mathbf{Z}^N$	N-dimensional series of integers.
$u: \mathbf{Z}^N \rightarrow \mathbf{R}$	Function $u$ with arguments from $\mathbf{Z}^N$ and values from $\mathbf{R}$ .
$u(p) = u(p_1, \dots, p_N)$	The value of the function $u$ for the argument $(p_1, \dots, p_N)$ .
$w = u * v$	Function $w$ is the convolution of the functions $u, v$ .
$w = u \cdot v$	Function $w$ is the correlation of the functions $u, v$ .

Given series  $p, q \in \mathbf{Z}^N$ :

- series  $r = p + q$  is defined as  $r^n = p^n + q^n$  for every  $n=1, \dots, N$
- series  $r = p - q$  is defined as  $r^n = p^n - q^n$  for every  $n=1, \dots, N$
- series  $r = \sup\{p, q\}$  is defined as  $r^n = \max\{p^n, q^n\}$  for every  $n=1, \dots, N$
- series  $r = \inf\{p, q\}$  is defined as  $r^n = \min\{p^n, q^n\}$  for every  $n=1, \dots, N$
- inequality  $p \leq q$  means that  $p^n \leq q^n$  for every  $n=1, \dots, N$ .

A function  $u(p)$  is called a finite function if there exist series  $p^{\min}, p^{\max} \in \mathbf{Z}^N$  such that:

$$u(p) \neq 0$$

implies

$$p^{\min} \leq p \leq p^{\max}.$$

Operations of convolution and correlation are only defined for finite functions.

Consider functions  $u, v$  and series  $p^{\min}, p^{\max}, q^{\min}, q^{\max} \in \mathbf{Z}^N$  such that:

$$u(p) \neq 0 \text{ implies } p^{\min} \leq p \leq p^{\max}.$$

$$v(q) \neq 0 \text{ implies } q^{\min} \leq q \leq q^{\max}.$$

Definitions of linear correlation and linear convolution for functions  $u$  and  $v$  are given below.

**Linear Convolution**

If function  $w = u * v$  is the convolution of  $u$  and  $v$ , then:

$$w(r) \neq 0 \text{ implies } \mathbf{R}^{\min} \leq r \leq \mathbf{R}^{\max},$$

$$\text{where } \mathbf{R}^{\min} = p^{\min} + q^{\min} \text{ and } \mathbf{R}^{\max} = p^{\max} + q^{\max}.$$

If  $\mathbf{R}^{\min} \leq r \leq \mathbf{R}^{\max}$ , then:

$$w(r) = \sum u(t) \cdot v(r-t) \text{ is the sum for all } t \in \mathbf{Z}^N \text{ such that } \mathbf{T}^{\min} \leq t \leq \mathbf{T}^{\max},$$

$$\text{where } \mathbf{T}^{\min} = \sup\{p^{\min}, r - q^{\max}\} \text{ and } \mathbf{T}^{\max} = \inf\{p^{\max}, r - q^{\min}\}.$$

**Linear Correlation**

If function  $w = u \cdot v$  is the correlation of  $u$  and  $v$ , then:

$w(r) \neq 0$  implies  $\mathbf{R}^{\min} \leq r \leq \mathbf{R}^{\max}$ ,  
 where  $\mathbf{R}^{\min} = \mathbf{Q}^{\min} - \mathbf{P}^{\max}$  and  $\mathbf{R}^{\max} = \mathbf{Q}^{\max} - \mathbf{P}^{\min}$ .

If  $\mathbf{R}^{\min} \leq r \leq \mathbf{R}^{\max}$ , then:

$w(r) = \sum u(t) \cdot v(r+t)$  is the sum for all  $t \in \mathbf{Z}^N$  such that  $\mathbf{T}^{\min} \leq t \leq \mathbf{T}^{\max}$ ,  
 where  $\mathbf{T}^{\min} = \sup\{\mathbf{P}^{\min}, \mathbf{Q}^{\min}-r\}$  and  $\mathbf{T}^{\max} = \inf\{\mathbf{P}^{\max}, \mathbf{Q}^{\max}-r\}$ .

Representation of the functions  $u$ ,  $v$ , was the input/output data for the Intel® oneAPI Math Kernel Library (oneMKL) convolution and correlation functions is described in the [Data Allocation](#).

## Convolution and Correlation Data Allocation

This section explains the relation between:

- mathematical finite functions  $u$ ,  $v$ ,  $w$  introduced in [Mathematical Notation and Definitions](#);
- multi-dimensional input and output data vectors representing the functions  $u$ ,  $v$ ,  $w$ ;
- arrays  $u$ ,  $v$ ,  $w$  used to store the input and output data vectors in computer memory

The convolution and correlation routine parameters that determine the allocation of input and output data are the following:

- Data arrays  $x$ ,  $y$ ,  $z$
- Shape arrays  $xshape$ ,  $yshape$ ,  $zshape$
- Strides within arrays  $xstride$ ,  $ystride$ ,  $zstride$
- Parameters  $start$ ,  $decimation$

## Finite Functions and Data Vectors

The finite functions  $u(p)$ ,  $v(q)$ , and  $w(r)$  introduced above are represented as multi-dimensional vectors of input and output data:

`inputu(i1, ..., idims)` for  $u(p_1, \dots, p_N)$

`inputv(j1, ..., jdims)` for  $v(q_1, \dots, q_N)$

`output(k1, ..., kdims)` for  $w(r_1, \dots, r_N)$ .

Parameter *dims* represents the number of dimensions and is equal to  $N$ .

The parameters *xshape*, *yshape*, and *zshape* define the shapes of input/output vectors:

`inputu(i1, ..., idims)` is defined if  $1 \leq i_n \leq xshape(n)$  for every  $n=1, \dots, dims$

`inputv(j1, ..., jdims)` is defined if  $1 \leq j_n \leq yshape(n)$  for every  $n=1, \dots, dims$

`output(k1, ..., kdims)` is defined if  $1 \leq k_n \leq zshape(n)$  for every  $n=1, \dots, dims$ .

Relation between the input vectors and the functions  $u$  and  $v$  is defined by the following formulas:

`inputu(i1, ..., idims)` =  $u(p_1, \dots, p_N)$ , where  $p_n = P_n^{\min} + (i_n - 1)$  for every  $n$

`inputv(j1, ..., jdims)` =  $v(q_1, \dots, q_N)$ , where  $q_n = Q_n^{\min} + (j_n - 1)$  for every  $n$ .

The relation between the output vector and the function  $w(r)$  is similar (but only in the case when parameters *start* and *decimation* are not defined):

`output(k1, ..., kdims)` =  $w(r_1, \dots, r_N)$ , where  $r_n = R_n^{\min} + (k_n - 1)$  for every  $n$ .

If the parameter *start* is defined, it must belong to the interval  $R_n^{\min} \leq start(n) \leq R_n^{\max}$ . If defined, the *start* parameter replaces  $R^{\min}$  in the formula:

`output(k1, ..., kdims)` =  $w(r_1, \dots, r_N)$ , where  $r_n = start(n) + (k_n - 1)$

If the parameter *decimation* is defined, it changes the relation according to the following formula:

`output(k1, ..., kdims)` =  $w(r_1, \dots, r_N)$ , where  $r_n = R_n^{\min} + (k_n - 1) * decimation(n)$

If both parameters *start* and *decimation* are defined, the formula is as follows:

$\text{output}(k_1, \dots, k_{\text{dims}}) = w(r_1, \dots, r_N)$ , where  $r_n = \text{start}(n) + (k_n - 1) \cdot \text{decimation}(n)$

The convolution and correlation software checks the values of *zshape*, *start*, and *decimation* during task commitment. If  $r_n$  exceeds  $R_n^{\text{max}}$  for some  $k_n, n=1, \dots, \text{dims}$ , an error is raised.

## Allocation of Data Vectors

Both parameter arrays *x* and *y* contain input data vectors in memory, while array *z* is intended for storing output data vector. To access the memory, the convolution and correlation software uses only pointers to these arrays and ignores the array shapes.

For parameters *x*, *y*, and *z*, you can provide one-dimensional arrays with the requirement that actual length of these arrays be sufficient to store the data vectors.

The allocation of the input and output data inside the arrays *x*, *y*, and *z* is described below assuming that the arrays are one-dimensional. Given multi-dimensional indices  $i, j, k \in \mathbf{Z}^N$ , one-dimensional indices  $e, f, g \in \mathbf{Z}$  are defined such that:

$\text{inputu}(i_1, \dots, i_{\text{dims}})$  is allocated at  $x(e)$

$\text{inputv}(j_1, \dots, j_{\text{dims}})$  is allocated at  $y(f)$

$\text{output}(k_1, \dots, k_{\text{dims}})$  is allocated at  $z(g)$ .

The indices  $e, f$ , and  $g$  are defined as follows:

$e = 1 + \sum x_{\text{stride}}(n) \cdot dx(n)$  (the sum is for all  $n=1, \dots, \text{dims}$ )

$f = 1 + \sum y_{\text{stride}}(n) \cdot dy(n)$  (the sum is for all  $n=1, \dots, \text{dims}$ )

$g = 1 + \sum z_{\text{stride}}(n) \cdot dz(n)$  (the sum is for all  $n=1, \dots, \text{dims}$ )

The distances  $dx(n)$ ,  $dy(n)$ , and  $dz(n)$  depend on the signum of the stride:

$dx(n) = i_n - 1$  if  $x_{\text{stride}}(n) > 0$ , or  $dx(n) = i_n - x_{\text{shape}}(n)$  if  $x_{\text{stride}}(n) < 0$

$dy(n) = j_n - 1$  if  $y_{\text{stride}}(n) > 0$ , or  $dy(n) = j_n - y_{\text{shape}}(n)$  if  $y_{\text{stride}}(n) < 0$

$dz(n) = k_n - 1$  if  $z_{\text{stride}}(n) > 0$ , or  $dz(n) = k_n - z_{\text{shape}}(n)$  if  $z_{\text{stride}}(n) < 0$

The definitions of indices  $e, f$ , and  $g$  assume that indexes for arrays *x*, *y*, and *z* are started from unity:

$x(e)$  is defined for  $e=1, \dots, \text{length}(x)$

$y(f)$  is defined for  $f=1, \dots, \text{length}(y)$

$z(g)$  is defined for  $g=1, \dots, \text{length}(z)$

Below is a detailed explanation about how elements of the multi-dimensional output vector are stored in the array *z* for one-dimensional and two-dimensional cases.

**One-dimensional case.** If  $\text{dims}=1$ , then *zshape* is the number of the output values to be stored in the array *z*. The actual length of array *z* may be greater than *zshape* elements.

If  $z_{\text{stride}} > 1$ , output values are stored with the stride:  $\text{output}(1)$  is stored to  $z(1)$ ,  $\text{output}(2)$  is stored to  $z(1+z_{\text{stride}})$ , and so on. Hence, the actual length of *z* must be at least  $1+z_{\text{stride}} \cdot (z_{\text{shape}}-1)$  elements or more.

If  $z_{\text{stride}} < 0$ , it still defines the stride between elements of array *z*. However, the order of the used elements is the opposite. For the  $k$ -th output value,  $\text{output}(k)$  is stored in  $z(1+|z_{\text{stride}}| \cdot (z_{\text{shape}}-k))$ , where  $|z_{\text{stride}}|$  is the absolute value of  $z_{\text{stride}}$ . The actual length of the array *z* must be at least  $1+|z_{\text{stride}}| \cdot (z_{\text{shape}} - 1)$  elements.

**Two-dimensional case.** If  $dims=2$ , the output data is a two-dimensional matrix. The value  $zstride(1)$  defines the stride inside matrix columns, that is, the stride between the  $output(k_1, k_2)$  and  $output(k_1+1, k_2)$  for every pair of indices  $k_1, k_2$ . On the other hand,  $zstride(2)$  defines the stride between columns, that is, the stride between  $output(k_1, k_2)$  and  $output(k_1, k_2+1)$ .

If  $zstride(2)$  is greater than  $zshape(1)$ , this causes sparse allocation of columns. If the value of  $zstride(2)$  is smaller than  $zshape(1)$ , this may result in the transposition of the output matrix. For example, if  $zshape = (2, 3)$ , you can define  $zstride = (3, 1)$  to allocate output values like transposed matrix of the shape  $3 \times 2$ .

Whether  $zstride$  assumes this kind of transformations or not, you need to ensure that different elements output  $(k_1, \dots, k_{dims})$  will be stored in different locations  $z(g)$ .

## Summary Statistics

The Summary Statistics domain provides routines that compute basic statistical estimates for single and double precision multi-dimensional datasets.

The Summary Statistics routines calculate:

- raw and central moments up to the fourth order
- skewness and excess kurtosis (further referred to as *kurtosis* for brevity)
- variation coefficient
- quantiles and order statistics
- minimum and maximum
- variance-covariance/correlation matrix
- pooled/group variance-covariance matrix and mean
- partial variance-covariance/correlation matrix
- robust estimators for variance-covariance matrix and mean in presence of outliers
- raw/central partial sums up to the fourth order (for brevity referred to as *raw/central sums*)
- matrix of cross-products and sums of squares (for brevity referred to as *cross-product matrix*)
- median absolute deviation, mean absolute deviation

The library also contains functions to perform the following tasks:

- Detect outliers in datasets
- Support missing values in datasets
- Parameterize correlation matrices
- Compute quantiles for streaming data

[Mathematical Notation and Definitions](#) defines the supported operations in the Summary Statistics routines.

You can access the Summary Statistics routines through the Fortran 90 and C89 language interfaces. You can use the C89 interface with later versions of the C/C++.

The `mk1_vs1.h` header file is in the `$(MKL)/include` directory.

You can find examples that demonstrate calculation of the Summary Statistics estimates in the `$(MKL)/examples/vs1c` example directory.

The Summary Statistics API is implemented through task objects, or tasks. A task object is a data structure, or a descriptor, holding parameters that determine a specific Summary Statistics operation. For example, such parameters may be precision, dimensions of user data, the matrix of the observations, or shapes of data arrays.

All the Summary Statistics routines process a task object as follows:

1. Create a task.
2. Modify settings of the task parameters.
3. Compute statistical estimates.
4. Destroy the task.

The Summary Statistics functions fall into the following categories:

**Task Constructors** - routines that create a new task object descriptor and set up most common parameters (dimension, number of observations, and matrix of the observations).

**Task Editors** - routines that can set or modify some parameter settings in the existing task descriptor.

**Task Computation Routine** - a routine that computes specified statistical estimates.

**Task Destructor** - a routine that deletes the task object and frees the memory.

A Summary Statistics task object contains a series of pointers to the input and output data arrays. You can read and modify the datasets and estimates at any time but you should allocate and release memory for such data.

See detailed information on the algorithms, API, and their usage in the *Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics Application Notes* [SS Notes].

## Summary Statistics Naming Conventions

The names of Summary Statistics routines, types, and constants are case-sensitive and can contain lowercase and uppercase characters (`vslsSSEditQuantiles`).

The names of routines have the following structure:

```
vsl[datatype]SS<base name>
```

where

- `vsl` is a prefix indicating that the routine belongs to Intel® oneAPI Math Kernel Library (oneMKL) Vector Statistics.
- `[datatype]` specifies the type of the input and/or output data and can be `s` (single precision real type), `d` (double precision real type), or `i` (integer type).
- `SS/ss` indicates that the routine is intended for calculations of the Summary Statistics estimates.
- `<base name>` specifies a particular functionality that the routine is designed for, for example, `NewTask`, `Compute`, `DeleteTask`.

---

### NOTE

The Summary Statistics routine `vslDeleteTask` for deletion of the task is independent of the data type and its name omits the `[datatype]` field.

---

On 64-bit platforms, routines with the `_64` suffix support large data arrays in the LP64 interface library and enable you to mix integer types in one application. For more interface library details, see "Using the ILP64 Interface vs. LP64 Interface" in the developer guide.

## Summary Statistics Data Types

The Summary Statistics routines use the following data types for calculations:

Type	Data Object
<code>VSLSSTaskPtr</code>	Pointer to a Summary Statistics task
<code>float</code>	Input/output user data in single precision
<code>double</code>	Input/output user data in double precision
<code>MKL_INT</code> or <code>long long</code>	Other data

**NOTE**

The actual size of the generic integer type is platform-specific and can be 32 or 64 bits in length. Before you compile your application, set an appropriate size for integers. See details in the 'Using the ILP64 Interface vs. LP64 Interface' section of the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*.

## Summary Statistics Parameters

The basic parameters in the task descriptor (addresses of dimensions, number of observations, and datasets) are assigned values when the task editors create or modify the task object. Other parameters are determined by the specific task and changed by the task editors.

## Summary Statistics Task Status and Error Reporting

The task status is an integer value, which is zero if no error is detected, or a specific non-zero error code otherwise. Negative status values indicate errors, and positive values indicate warnings. An error can be caused by invalid parameter values or a memory allocation failure.

The header files define symbolic names for the status codes. These names are defined as macros via `#define` statements.

The header files define the following status codes for the Summary Statistics error codes:

### Summary Statistics Status Codes

Status Code	Description
VSL_STATUS_OK	Operation is successfully completed.
VSL_SS_ERROR_ALLOCATION_FAILURE	Memory allocation has failed.
VSL_SS_ERROR_BAD_DIMEN	Dimension value is invalid.
VSL_SS_ERROR_BAD_OBSERV_N	Invalid number (zero or negative) of observations was obtained.
VSL_SS_ERROR_STORAGE_NOT_SUPPORTED	Storage format is not supported.
VSL_SS_ERROR_BAD_INDC_ADDR	Array of indices is not defined.
VSL_SS_ERROR_BAD_WEIGHTS	Array of weights contains negative values.
VSL_SS_ERROR_BAD_MEAN_ADDR	Array of means is not defined.
VSL_SS_ERROR_BAD_2R_MOM_ADDR	Array of the second order raw moments is not defined.
VSL_SS_ERROR_BAD_3R_MOM_ADDR	Array of the third order raw moments is not defined.
VSL_SS_ERROR_BAD_4R_MOM_ADDR	Array of the fourth order raw moments is not defined.
VSL_SS_ERROR_BAD_2C_MOM_ADDR	Array of the second order central moments is not defined.
VSL_SS_ERROR_BAD_3C_MOM_ADDR	Array of the third order central moments is not defined.
VSL_SS_ERROR_BAD_4C_MOM_ADDR	Array of the fourth order central moments is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_KURTOSIS_ADDR	Array of kurtosis values is not defined.
VSL_SS_ERROR_BAD_SKEWNESS_ADDR	Array of skewness values is not defined.
VSL_SS_ERROR_BAD_MIN_ADDR	Array of minimum values is not defined.
VSL_SS_ERROR_BAD_MAX_ADDR	Array of maximum values is not defined.
VSL_SS_ERROR_BAD_VARIATION_ADDR	Array of variation coefficients is not defined.
VSL_SS_ERROR_BAD_COV_ADDR	Covariance matrix is not defined.
VSL_SS_ERROR_BAD_COR_ADDR	Correlation matrix is not defined.
VSL_SS_ERROR_BAD_QUANT_ORDER_ADDR	Array of quantile orders is not defined.
VSL_SS_ERROR_BAD_QUANT_ORDER	Quantile order value is invalid.
VSL_SS_ERROR_BAD_QUANT_ADDR	Array of quantiles is not defined.
VSL_SS_ERROR_BAD_ORDER_STATS_ADDR	Array of order statistics is not defined.
VSL_SS_ERROR_MOMORDER_NOT_SUPPORTED	Moment of requested order is not supported.
VSL_SS_NOT_FULL_RANK_MATRIX	Correlation matrix is not of full rank.
VSL_SS_ERROR_ALL_OBSERVS_OUTLIERS	All observations are outliers. (At least one observation must not be an outlier.)
VSL_SS_ERROR_BAD_ROBUST_COV_ADDR	Robust covariance matrix is not defined.
VSL_SS_ERROR_BAD_ROBUST_MEAN_ADDR	Array of robust means is not defined.
VSL_SS_ERROR_METHOD_NOT_SUPPORTED	Requested method is not supported.
VSL_SS_ERROR_NULL_TASK_DESCRIPTOR	Task descriptor is null.
VSL_SS_ERROR_BAD_OBSERV_ADDR	Dataset matrix is not defined.
VSL_SS_ERROR_BAD_ACCUM_WEIGHT_ADDR	Pointer to the variable that holds the value of accumulated weight is not defined.
VSL_SS_ERROR_SINGULAR_COV	Covariance matrix is singular.
VSL_SS_ERROR_BAD_POOLED_COV_ADDR	Pooled covariance matrix is not defined.
VSL_SS_ERROR_BAD_POOLED_MEAN_ADDR	Array of pooled means is not defined.
VSL_SS_ERROR_BAD_GROUP_COV_ADDR	Group covariance matrix is not defined.
VSL_SS_ERROR_BAD_GROUP_MEAN_ADDR	Array of group means is not defined.
VSL_SS_ERROR_BAD_GROUP_INDC_ADDR	Array of group indices is not defined.
VSL_SS_ERROR_BAD_GROUP_INDC	Group indices have improper values.
VSL_SS_ERROR_BAD_OUTLIERS_PARAMS_ADDR	Array of parameters for the outlier detection algorithm is not defined.
VSL_SS_ERROR_BAD_OUTLIERS_PARAMS_N_ADDR	Pointer to size of the parameter array for the outlier detection algorithm is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_OUTLIERS_WEIGHTS_ADDR	Output of the outlier detection algorithm is not defined.
VSL_SS_ERROR_BAD_ROBUST_COV_PARAMS_ADDR	Array of parameters of the robust covariance estimation algorithm is not defined.
VSL_SS_ERROR_BAD_ROBUST_COV_PARAMS_N_ADDR	Pointer to the number of parameters of the algorithm for robust covariance is not defined.
VSL_SS_ERROR_BAD_STORAGE_ADDR	Pointer to the variable that holds the storage format is not defined.
VSL_SS_ERROR_BAD_PARTIAL_COV_IDX_ADDR	Array that encodes sub-components of a random vector for the partial covariance algorithm is not defined.
VSL_SS_ERROR_BAD_PARTIAL_COV_IDX	Array that encodes sub-components of a random vector for partial covariance has improper values.
VSL_SS_ERROR_BAD_PARTIAL_COV_ADDR	Partial covariance matrix is not defined.
VSL_SS_ERROR_BAD_PARTIAL_COR_ADDR	Partial correlation matrix is not defined.
VSL_SS_ERROR_BAD_MI_PARAMS_ADDR	Array of parameters for the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_PARAMS_N_ADDR	Pointer to number of parameters for the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_BAD_PARAMS_N	Size of the parameter array of the Multiple Imputation method is invalid.
VSL_SS_ERROR_BAD_MI_PARAMS	Parameters of the Multiple Imputation method are invalid.
VSL_SS_ERROR_BAD_MI_INIT_ESTIMATES_N_ADDR	Pointer to the number of initial estimates in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_INIT_ESTIMATES_ADDR	Array of initial estimates for the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_SIMUL_VALS_ADDR	Array of simulated missing values in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_SIMUL_VALS_N_ADDR	Pointer to the size of the array of simulated missing values in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_ESTIMATES_N_ADDR	Pointer to the number of parameter estimates in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_ESTIMATES_ADDR	Array of parameter estimates in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_SIMUL_VALS_N	Invalid size of the array of simulated values in the Multiple Imputation method.
VSL_SS_ERROR_BAD_MI_ESTIMATES_N	Invalid size of an array to hold parameter estimates obtained using the Multiple Imputation method.

Status Code	Description
VSL_SS_ERROR_BAD_MI_OUTPUT_PARAMS	Array of output parameters in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_PRIOR_N_ADDR	Pointer to the number of prior parameters is not defined.
VSL_SS_ERROR_BAD_MI_PRIOR_ADDR	Array of prior parameters is not defined.
VSL_SS_ERROR_BAD_MI_MISSING_VALS_N	Invalid number of missing values was obtained.
VSL_SS_SEMIDEFINITE_COR	Correlation matrix passed into the parameterization function is semi-definite.
VSL_SS_ERROR_BAD_PARAMTR_COR_ADDR	Correlation matrix to be parameterized is not defined.
VSL_SS_ERROR_BAD_COR	All eigenvalues of the correlation matrix to be parameterized are non-positive.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS_N_ADDR	Pointer to the number of parameters for the quantile computation algorithm for streaming data is not defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS_ADDR	Array of parameters of the quantile computation algorithm for streaming data is not defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS_N	Invalid number of parameters of the quantile computation algorithm for streaming data has been obtained.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS	Invalid parameters of the quantile computation algorithm for streaming data have been passed.
VSL_SS_ERROR_BAD_STREAM_QUANT_ORDER_ADDR	Array of the quantile orders for streaming data is not defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_ORDER	Invalid quantile order for streaming data is defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_ADDR	Array of quantiles for streaming data is not defined.
VSL_SS_ERROR_BAD_SUM_ADDR	Array of sums is not defined.
VSL_SS_ERROR_BAD_2R_SUM_ADDR	Array of raw sums of 2nd order is not defined.
VSL_SS_ERROR_BAD_3R_SUM_ADDR	Array of raw sums of 3rd order is not defined.
VSL_SS_ERROR_BAD_4R_SUM_ADDR	Array of raw sums of 4th order is not defined.
VSL_SS_ERROR_BAD_2C_SUM_ADDR	Array of central sums of 2nd order is not defined.
VSL_SS_ERROR_BAD_3C_SUM_ADDR	Array of central sums of 3rd order is not defined.
VSL_SS_ERROR_BAD_4C_SUM_ADDR	Array of central sums of 4th order is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_CP_SUM_ADDR	Cross-product matrix is not defined.
VSL_SS_ERROR_BAD_MDAD_ADDR	Array of median absolute deviations is not defined.
VSL_SS_ERROR_BAD_MNAD_ADDR	Array of mean absolute deviations is not defined.
VSL_SS_ERROR_BAD_SORTED_OBSERV_ADDR	Array for storing observation sorting results is not defined.
VSL_SS_ERROR_ERROR_INDICES_NOT_SUPPORTED	Array of indices is not supported.

Routines for robust covariance estimation, outlier detection, partial covariance estimation, multiple imputation, and parameterization of a correlation matrix can return internal error codes that are related to a specific implementation. Such error codes indicate invalid input data or other bugs in the Intel® oneAPI Math Kernel Library (oneMKL) routines other than the Summary Statistics routines.

## Summary Statistics Task Constructors

Task constructors are routines intended for creating a new task descriptor and setting up basic parameters.

### NOTE

If the constructor fails to create a task descriptor, it returns the `NULL` task pointer.

### vsSSNewTask

*Creates and initializes a new summary statistics task descriptor.*

### Syntax

```
status = vsSSNewTask(&task, p, n, xstorage, x, w, indices);
```

```
status = vsdSSNewTask(&task, p, n, xstorage, x, w, indices);
```

### Include Files

- `mkl.h`

### Input Parameters

Name	Type	Description
<i>p</i>	<code>const MKL_INT*</code>	Dimension of the task, number of variables
<i>n</i>	<code>const MKL_INT*</code>	Number of observations
<i>xstorage</i>	<code>const MKL_INT*</code>	Storage format of matrix of observations
<i>x</i>	<code>const float*</code> for <code>vsSSNewTask</code> <code>const double*</code> for <code>vsdSSNewTask</code>	Matrix of observations

Name	Type	Description
<i>w</i>	<code>const float*</code> for <code>vslsSSNewTask</code> <code>const double*</code> for <code>vslsSSNewTask</code>	Array of weights of size $n$ . Elements of the arrays are non-negative numbers. If a <code>NULL</code> pointer is passed, each observation is assigned weight equal to 1.
<i>indices</i>	<code>const MKL_INT*</code>	Array of vector components that will be processed. Size of array is $p$ . If a <code>NULL</code> pointer is passed, all components of random vector are processed.

## Output Parameters

Name	Type	Description
<i>task</i>	<code>VSLSTaskPtr*</code>	Descriptor of the task
<i>status</i>	<code>int</code>	Set to <code>VSL_STATUS_OK</code> if the task is created successfully, otherwise a non-zero error code is returned.

## Description

Each `vslsSSNewTask` constructor routine creates a new summary statistics task descriptor with the user-specified value for a required parameter, dimension of the task. The optional parameters (matrix of observations, its storage format, number of observations, weights of observations, and indices of the random vector components) are set to their default values.

The observations of random  $p$ -dimensional vector  $\xi = (\xi_1, \dots, \xi_j, \dots, \xi_p)$ , which are  $n$  vectors of dimension  $p$ , are passed as a one-dimensional array  $x$ . The parameter `xstorage` defines the storage format of the observations and takes one of the possible values listed in [Table "Storage format of matrix of observations and order statistics"](#).

### Storage format of matrix of observations, order statistics, and matrix of sorted observations

Parameter	Description
<code>VSL_SS_MATRIX_STORAGE_ROWS</code>	The observations of random vector $\xi$ are packed by rows: $n$ data points for the vector component $\xi_1$ come first, $n$ data points for the vector component $\xi_2$ come second, and so forth.
<code>VSL_SS_MATRIX_STORAGE_COLS</code>	The observations of random vector $\xi$ are packed by columns: the first $p$ -dimensional observation of the vector $\xi$ comes first, the second $p$ -dimensional observation of the vector comes second, and so forth.

A one-dimensional array  $w$  of size  $n$  contains non-negative weights assigned to the observations. You can pass a `NULL` array into the constructor. In this case, each observation is assigned the default value of the weight.

You can choose vector components for which you wish to compute statistical estimates. If an element of the vector `indices` of size  $p$  contains 0, the observations that correspond to this component are excluded from the calculations. If you pass the `NULL` value of the parameter into the constructor, statistical estimates for all random variables are computed.

If the constructor fails to create a task descriptor, it returns the `NULL` task pointer.

## Summary Statistics Task Editors

Task editors are intended to set up or change the task parameters listed in [Table "Parameters of Summary Statistics Task to Be Initialized or Modified"](#). As an example, to compute the sample mean for a one-dimensional dataset, initialize a variable for the mean value, and pass its address into the task as shown in the example below:

```
#define DIM    1
#define N     1000

int main()
{
    VSLSSTaskPtr task;
    double x[N];
    double mean;
    MKL_INT p, n, xstorage;
    int status;
    /* initialize variables used in the computations of sample mean */
    p = DIM;
    n = N;
    xstorage = VSL_SS_MATRIX_STORAGE_ROWS;
    mean = 0.0;

    /* create task */
    status = vsldSSNewTask( &task, &p, &n, &xstorage, x, 0, 0 );

    /* initialize task parameters */
    status = vsldSSEditTask( task, VSL_SS_ED_MEAN, &mean );

    /* compute mean using SS fast method */
    status = vsldSSCompute(task, VSL_SS_MEAN, VSL_SS_METHOD_FAST );

    /* deallocate task resources */
    status = vsldSSDeleteTask( &task );

    return 0;
}
```

Use the single (`vsldSSeditTask`) or double (`vsldSSeditTask`) version of an editor, to initialize single or double precision version task parameters, respectively. Use an integer version of an editor (`vsldSSeditTask`) to initialize parameters of the integer type.

[Table "Summary Statistics Task Editors"](#) lists the task editors for Summary Statistics. Each of them initializes and/or modifies a respective group of related parameters.

### Summary Statistics Task Editors

Editor	Description
<code>vsldSSeditTask</code>	Changes a pointer in the task descriptor.
<code>vsldSSeditMoments</code>	Changes pointers to arrays associated with raw and central moments.
<code>vsldSSeditSums</code>	Modifies the pointers to arrays that hold sum estimates.
<code>vsldSSeditCovCor</code>	Changes pointers to arrays associated with covariance and/or correlation matrices.
<code>vsldSSeditCP</code>	Modifies the pointers to cross-product matrix parameters.

Editor	Description
<code>vslSSEditPartialCovCor</code>	Changes pointers to arrays associated with partial covariance and/or correlation matrices.
<code>vslSSEditQuantiles</code>	Changes pointers to arrays associated with quantile/order statistics calculations.
<code>vslSSEditStreamQuantiles</code>	Changes pointers to arrays for quantile related calculations for streaming data.
<code>vslSSEditPooledCovariance</code>	Changes pointers to arrays associated with algorithms related to a pooled covariance matrix.
<code>vslSSEditRobustCovariance</code>	Changes pointers to arrays for robust estimation of a covariance matrix and mean.
<code>vslSSEditOutliersDetection</code>	Changes pointers to arrays for detection of outliers.
<code>vslSSEditMissingValues</code>	Changes pointers to arrays associated with the method of supporting missing values in a dataset.
<code>vslSSEditCorParameterization</code>	Changes pointers to arrays associated with the algorithm for parameterization of a correlation matrix.

**NOTE**

You can use the `NULL` task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

**vslSSEditTask**

Modifies address of an input/output parameter in the task descriptor.

**Syntax**

```
status = vslsSSEditTask(task, parameter, par_addr);
```

```
status = vsldSSEditTask(task, parameter, par_addr);
```

```
status = vsliSSEditTask(task, parameter, par_addr);
```

**Include Files**

- `mkl.h`

**Input Parameters**

Name	Type	Description
<code>task</code>	<code>VSLSSTaskPtr</code>	Descriptor of the task
<code>parameter</code>	<code>const MKL_INT</code>	Parameter to change
<code>par_addr</code>	<code>const float*</code> for <code>vslsSSEditTask</code> <code>const double*</code> for <code>vsldSSEditTask</code> <code>const MKL_INT*</code> for <code>vsliSSEditTask</code>	Address of the new parameter

## Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

## Description

The `vslSSEditTask` routine replaces the pointer to the parameter stored in the Summary Statistics task descriptor with the `par_addr` pointer. If you pass the `NULL` pointer to the editor, no changes take place in the task and a corresponding error code is returned. See [Table "Parameters of Summary Statistics Task to Be Initialized or Modified"](#) for the predefined values of the parameter.

Use the single (`vslssedittask`) or double (`vslDSSedittask`) version of the editor, to initialize single or double precision version task parameters, respectively. Use an integer version of the editor (`vslisedittask`) to initialize parameters of the integer type.

## Parameters of Summary Statistics Task to Be Initialized or Modified

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_DIMEN	i	Address of a variable that holds the task dimension	Required. Positive integer value.
VSL_SS_ED_OBSERV_N	i	Address of a variable that holds the number of observations	Required. Positive integer value.
VSL_SS_ED_OBSERV	d, s	Address of the observation matrix	Required. Provide the matrix containing your observations.
VSL_SS_ED_OBSERV_STORAGE	i	Address of a variable that holds the storage format for the observation matrix	Required. Provide a storage format supported by the library whenever you pass a matrix of observations. <sup>1</sup>
VSL_SS_ED_INDC	i	Address of the array of indices	Optional. Provide this array if you need to process individual components of the random vector. Set entry <i>i</i> of the array to one to include the <i>i</i> th coordinate in the analysis. Set entry <i>i</i> of the array to zero to exclude the <i>i</i> th coordinate from the analysis.
VSL_SS_ED_WEIGHTS	d, s	Address of the array of observation weights	Optional. If the observations have weights different from the default weight (one), set entries of the array to non-negative floating point values.
VSL_SS_ED_MEAN	d, s	Address of the array of means	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_2R_MOM	d, s	Address of an array of raw moments of the second order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_3R_MOM	d, s	Address of an array of raw moments of the third order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_4R_MOM	d, s	Address of an array of raw moments of the fourth order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_2C_MOM	d, s	Address of an array of central moments of the second order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first and second order.
VSL_SS_ED_3C_MOM	d, s	Address of an array of central moments of the third order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, and third order.
VSL_SS_ED_4C_MOM	d, s	Address of an array of central moments of the fourth order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, third, and fourth order.
VSL_SS_ED_KURTOSIS	d, s	Address of the array of kurtosis estimates	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, third, and fourth order.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_SKEWNESS	d, s	Address of the array of skewness estimates	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, and third order.
VSL_SS_ED_MIN	d, s	Address of the array of minimum estimates	Optional. Set entries of array to meaningful values, such as the values of the first observation.
VSL_SS_ED_MAX	d, s	Address of the array of maximum estimates	Optional. Set entries of array to meaningful values, such as the values of the first observation.
VSL_SS_ED_VARIATION	d, s	Address of the array of variation coefficients	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first and second order.
VSL_SS_ED_COV	d, s	Address of a covariance matrix	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Make sure you also provide an array for the mean.
VSL_SS_ED_COV_STORAGE	i	Address of the variable that holds the storage format for a covariance matrix	Required. Provide a storage format supported by the library whenever you intend to compute the covariance matrix. <sup>2</sup>
VSL_SS_ED_COR	d, s	Address of a correlation matrix	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. If you initialize the matrix in non-trivial way, make sure that the main diagonal contains variance values. Also, provide an array for the mean.
VSL_SS_ED_COR_STORAGE	i	Address of the variable that holds the correlation storage format for a correlation matrix	Required. Provide a storage format supported by the library whenever you intend to compute the correlation matrix. <sup>2</sup>

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_ACCUM_WEIGHT	d, s	Address of the array of size 2 that holds the accumulated weight (sum of weights) in the first position and the sum of weights squared in the second position	Optional. Set the entries of the matrix to meaningful values (typically zero) if you intend to do progressive processing of the dataset or need the sum of weights and sum of squared weights assigned to observations.
VSL_SS_ED_QUANT_ORDER_N	i	Address of the variable that holds the number of quantile orders	Required. Positive integer value. Provide the number of quantile orders whenever you compute quantiles.
VSL_SS_ED_QUANT_ORDER	d, s	Address of the array of quantile orders	Required. Set entries of array to values from the interval (0,1). Provide this parameter whenever you compute quantiles.
VSL_SS_ED_QUANT_QUANTILE_S	d, s	Address of the array of quantiles	None.
VSL_SS_ED_ORDER_STATS	d, s	Address of the array of order statistics	None.
VSL_SS_ED_GROUP_INDC	i	Address of the array of group indices used in computation of a pooled covariance matrix	Required. Set entry $i$ to integer value $k$ if the observation belongs to group $k$ . Values of $k$ take values in the range $[0, g-1]$ , where $g$ is the number of groups.
VSL_SS_ED_POOLED_COV_STORAGE	i	Address of a variable that holds the storage format for a pooled covariance matrix	Required. Provide a storage format supported by the library whenever you intend to compute pooled covariance. <sup>2</sup>
VSL_SS_ED_POOLED_MEAN	d, s	Address of an array of pooled means	None.
VSL_SS_ED_POOLED_COV	d, s	Address of pooled covariance matrices	None.
VSL_SS_ED_GROUP_COV_INDC	i	Address of an array of indices for which covariance/means should be computed	Optional. Set the $k$ th entry of the array to 1 if you need group covariance and mean for group $k$ ; otherwise set it to zero.
VSL_SS_ED_REQ_GROUP_INDC	i	Address of an array of indices for which group estimates such as covariance or means are requested	Optional. Set the $k$ th entry of the array to 1 if you need an estimate for group $k$ ; otherwise set it to zero.
VSL_SS_ED_GROUP_MEANS	i	Address of an array of group means	None.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_GROUP_COV_STORAGE	d, s	Address of a variable that holds the storage format for a group covariance matrix	Required. Provide a storage format supported by the library whenever you intend to get group covariance. <sup>2</sup>
VSL_SS_ED_GROUP_COV	d, s	Address of group covariance matrices	None.
VSL_SS_ED_ROBUST_COV_STORAGE	d, s	Address of a variable that holds the storage format for a robust covariance matrix	Required. Provide a storage format supported by the library whenever you compute robust covariance <sup>2</sup> .
VSL_SS_ED_ROBUST_COV_PARAMS_N	i	Address of a variable that holds the number of algorithmic parameters of the method for robust covariance estimation	Required. Set to the number of TBS parameters, <i>VSL_SS_TBS_PARAMS_N</i> .
VSL_SS_ED_ROBUST_COV_PARAMS	d, s	Address of an array of parameters of the method for robust estimation of a covariance	Required. Set the entries of the array according to the description in <a href="#">vslSSEditRobustCovariance</a> .
VSL_SS_ED_ROBUST_MEAN	i	Address of an array of robust means	None.
VSL_SS_ED_ROBUST_COV	d, s	Address of a robust covariance matrix	None.
VSL_SS_ED_OUTLIERS_PARAMS_N	d, s	Address of a variable that holds the number of parameters of the outlier detection method	Required. Set to the number of outlier detection parameters, <i>VSL_SS_BACON_PARAMS_N</i> .
VSL_SS_ED_OUTLIERS_PARAMS	i	Address of an array of algorithmic parameters for the outlier detection method	Required. Set the entries of the array according to the description in <a href="#">vslSSEditOutliersDetection</a> .
VSL_SS_ED_OUTLIERS_WEIGHT	d, s	Address of an array of weights assigned to observations by the outlier detection method	None.
VSL_SS_ED_ORDER_STATS_STORAGE	d, s	Address of a variable that holds the storage format of an order statistics matrix	Required. Provide a storage format supported by the library whenever you compute a matrix of order statistics. <sup>1</sup>
VSL_SS_ED_PARTIAL_COV_IDS	i	Address of an array that encodes subcomponents of a random vector	Required. Set the entries of the array according to the description in <a href="#">vslSSEditPartialCovCor</a> .
VSL_SS_ED_PARTIAL_COV	d, s	Address of a partial covariance matrix	None.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_PARTIAL_COV_STORAGE	i	Address of a variable that holds the storage format of a partial covariance matrix	Required. Provide a storage format supported by the library whenever you compute the partial covariance. <sup>2</sup>
VSL_SS_ED_PARTIAL_COR	d, s	Address of a partial correlation matrix	None.
VSL_SS_ED_PARTIAL_COR_STORAGE	i	Address of a variable that holds the storage format for a partial correlation matrix	Required. Provide a storage format supported by the library whenever you compute the partial correlation. <sup>2</sup>
VSL_SS_ED_MI_PARAMS_N	i	Address of a variable that holds the number of algorithmic parameters for the Multiple Imputation method	Required. Set to the number of MI parameters, <i>VSL_SS_MI_PARAMS_SIZE</i> .
VSL_SS_ED_MI_PARAMS	d, s	Address of an array of algorithmic parameters for the Multiple Imputation method	Required. Set entries of the array according to the description in <a href="#">vslSSEditMissingValues</a> .
VSL_SS_ED_MI_INIT_ESTIMATES_N	i	Address of a variable that holds the number of initial estimates for the Multiple Imputation method	Optional. Set to $p+p*(p+1)/2$ , where $p$ is the task dimension.
VSL_SS_ED_MI_INIT_ESTIMATES	d, s	Address of an array of initial estimates for the Multiple Imputation method	Optional. Set the values of the array according to the description in "Basic Components of the Multiple Imputation Function in Summary Statistics" in the <i>Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics Application Notes</i> document [ <a href="#">SS Notes</a> ].
VSL_SS_ED_MI_SIMUL_VALS_N	i	Address of a variable that holds the number of simulated values in the Multiple Imputation method	Optional. Positive integer indicating the number of missing points in the observation matrix.
VSL_SS_ED_MI_SIMUL_VALS	d, s	Address of an array of simulated values in the Multiple Imputation method	None.
VSL_SS_ED_MI_ESTIMATES_N	i	Address of a variable that holds the number of estimates obtained as a result of the Multiple Imputation method	Optional. Positive integer number defined according to the description in "Basic Components of the Multiple Imputation Function in Summary Statistics" in the <i>Intel® oneAPI Math Kernel</i>

Parameter Value	Type	Purpose	Initialization
			<i>Library (oneMKL) Summary Statistics Application Notes</i> document [ <a href="#">SS Notes</a> ].
VSL_SS_ED_MI_ESTIMATES	d, s	Address of an array of estimates obtained as a result of the Multiple Imputation method	None.
VSL_SS_ED_MI_PRIOR_N	i	Address of a variable that holds the number of prior parameters for the Multiple Imputation method	Optional. If you pass a user-defined array of prior parameters, set this parameter to $(p^2+3*p+4)/2$ , where $p$ is the task dimension.
VSL_SS_ED_MI_PRIOR	d, s	Address of an array of prior parameters for the Multiple Imputation method	Optional. Set entries of the array of prior parameters according to the description in "Basic Components of the Multiple Imputation Function in Summary Statistics" in the <i>Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics Application Notes</i> document [ <a href="#">SS Notes</a> ].
VSL_SS_ED_PARAMTR_COR	d, s	Address of a parameterized correlation matrix	None.
VSL_SS_ED_PARAMTR_COR_STORAGE	i	Address of a variable that holds the storage format of a parameterized correlation matrix	Required. Provide a storage format supported by the library whenever you compute the parameterized correlation matrix. <sup>2</sup>
VSL_SS_ED_STREAM_QUANT_PARAMS_N	i	Address of a variable that holds the number of parameters of a quantile computation method for streaming data	Required. Set to the number of quantile computation parameters, <i>VSL_SS_SQUANTS_ZW_PARAMS_N</i> .
VSL_SS_ED_STREAM_QUANT_PARAMS	d, s	Address of an array of parameters of a quantile computation method for streaming data	Required. Set the entries of the array according to the description in "Computing Quantiles for Streaming Data" in the <i>Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics Application Notes</i> document [ <a href="#">SS Notes</a> ].
VSL_SS_ED_STREAM_QUANT_ORDER_N	i	Address of a variable that holds the number of quantile orders for streaming data	Required. Positive integer value.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_STREAM_QUANT_ORDER	d, s	Address of an array of quantile orders for streaming data	Required. Set entries of the array to values from the interval (0,1). Provide this parameter whenever you compute quantiles.
VSL_SS_ED_STREAM_QUANT_QUANTILES	d, s	Address of an array of quantiles for streaming data	None.
VSL_SS_ED_SUM	d, s	Address of array of sums	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_2R_SUM	d, s	Address of array of raw sums of 2nd order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_3R_SUM	d, s	Address of array of raw sums of 3rd order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_4R_SUM	d, s	Address of array of raw sums of 4th order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_2C_SUM	d, s	Address of array of central sums of 2nd order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_3C_SUM	d, s	Address of array of central sums of 3rd order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_4C_SUM	d, s	Address of array of central sums of 4th order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_CP	d, s	Address of cross-product matrix	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_MDAD	d, s	Address of array of median absolute deviations	None.
VSL_SS_ED_MNAD	d, s	Address of array of mean absolute deviations	None.
VSL_SS_ED_SORTED_OBSERV	d, s	Address of the array that stores sorted results	None.
VSL_SS_ED_SORTED_OBSERV_STORAGE	i	Address of a variable that holds the storage format of an output matrix	Required. Provide a supported storage format whenever you specify sorting of the observation matrix.

1. See [Table: "Storage format of matrix of observations and order statistics"](#) for storage formats.
2. See [Table: "Storage formats of a variance-covariance/correlation matrix"](#) for storage formats.

### vsLSSEditMoments

*Modifies the pointers to arrays that hold moment estimates.*

### Syntax

```
status = vsLSSEditMoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m);
```

```
status = vsLDSEditMoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m);
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>task</i>	VSLSSTaskPtr	Descriptor of the task
<i>mean</i>	float* for vsLSSEditMoments double* for vsLDSEditMoments	Pointer to the array of means
<i>r2m</i>	float* for vsLSSEditMoments double* for vsLDSEditMoments	Pointer to the array of raw moments of the 2 <sup>nd</sup> order
<i>r3m</i>	float* for vsLSSEditMoments double* for vsLDSEditMoments	Pointer to the array of raw moments of the 3 <sup>rd</sup> order
<i>r4m</i>	float* for vsLSSEditMoments double* for vsLDSEditMoments	Pointer to the array of raw moments of the 4 <sup>th</sup> order

Name	Type	Description
<i>c2m</i>	float* for <code>vs1sSSEditMoments</code> double* for <code>vs1dSSEditMoments</code>	Pointer to the array of central moments of the 2 <sup>nd</sup> order
<i>c3m</i>	float* for <code>vs1sSSEditMoments</code> double* for <code>vs1dSSEditMoments</code>	Pointer to the array of central moments of the 3 <sup>rd</sup> order
<i>c4m</i>	float* for <code>vs1sSSEditMoments</code> double* for <code>vs1dSSEditMoments</code>	Pointer to the array of central moments of the 4 <sup>th</sup> order

## Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

## Description

The `vs1sSSEditMoments` routine replaces pointers to the arrays that hold estimates of raw and central moments with values passed as corresponding parameters of the routine. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

## vs1sSSEditSums

*Modifies the pointers to arrays that hold sum estimates.*

## Syntax

```
status = vs1sSSEditSums(task, sum, r2s, r3s, r4s, c2s, c3s, c4s);
```

```
status = vs1dSSEditSums(task, sum, r2s, r3s, r4s, c2s, c3s, c4s);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<i>task</i>	VSLSTaskPtr	Descriptor of the task
<i>sum</i>	float* for <code>vs1sSSEditSums</code> double* for <code>vs1dSSEditSums</code>	Pointer to the array of sums
<i>r2s</i>	float* for <code>vs1sSSEditSums</code> double* for <code>vs1dSSEditSums</code>	Pointer to the array of raw sums of the second order
<i>r3s</i>	float* for <code>vs1sSSEditSums</code> double* for <code>vs1dSSEditSums</code>	Pointer to the array of raw sums of the third order
<i>r4s</i>	float* for <code>vs1sSSEditSums</code> double* for <code>vs1dSSEditSums</code>	Pointer to the array of raw sums of the fourth order

Name	Type	Description
<i>c2s</i>	float* for <code>vslsSSEditSums</code> double* for <code>vsldSSEditSums</code>	Pointer to the array of central sums of the second order
<i>c3s</i>	float* for <code>vslsSSEditSums</code> double* for <code>vsldSSEditSums</code>	Pointer to the array of central sums of the third order
<i>c4s</i>	float* for <code>vslsSSEditSums</code> double* for <code>vsldSSEditSums</code>	Pointer to the array of central sums of the fourth order

## Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

## Description

The `vs1SSEditSums` routine replaces pointers to the arrays that hold estimates of raw and central sums with values passed as corresponding parameters of the routine. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

### `vs1SSEditCovCor`

*Modifies the pointers to covariance/correlation/cross-product parameters.*

## Syntax

```
status = vs1sSSEditCovCor(task, mean, cov, cov_storage, cor, cor_storage);
```

```
status = vsldSSEditCovCor(task, mean, cov, cov_storage, cor, cor_storage);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<i>task</i>	VSLSTaskPtr	Descriptor of the task
<i>mean</i>	float* for <code>vslsSSEditCovCor</code> double* for <code>vsldSSEditCovCor</code>	Pointer to the array of means
<i>cov</i>	float* for <code>vslsSSEditCovCor</code> double* for <code>vsldSSEditCovCor</code>	Pointer to a covariance matrix
<i>cov_storage</i>	const MKL_INT*	Pointer to the storage format of the covariance matrix
<i>cor</i>	float* for <code>vslsSSEditCovCor</code> double* for <code>vsldSSEditCovCor</code>	Pointer to a correlation matrix

Name	Type	Description
<code>cor_storage</code>	<code>const MKL_INT*</code>	Pointer to the storage format of the correlation matrix

## Output Parameters

Name	Type	Description
<code>status</code>	<code>int</code>	Current status of the task

## Description

The `vslSSEditCovCor` routine replaces pointers to the array of means, covariance/correlation arrays, and their storage format with values passed as corresponding parameters of the routine. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

The storage parameters, `cov_storage` and `cor_storage`, describe the storage format used for the  $p$ -by- $p$  symmetric variance-covariance/correlation/cross-product matrix  $C$ . The matrix  $C$  can be described as

$$C = \begin{pmatrix} c_{1,1} & c_{1,2} & \cdots & \cdots & \cdots & c_{1,p} \\ c_{2,1} & c_{2,2} & \cdots & \cdots & \cdots & c_{2,p} \\ \vdots & \vdots & \ddots & & & \vdots \\ \vdots & \vdots & & c_{i,j} & & \vdots \\ \vdots & \vdots & & & \ddots & \vdots \\ c_{p,1} & c_{p,2} & \cdots & \cdots & \cdots & c_{p,p} \end{pmatrix}$$

Table "Storage formats of a variance-covariance/correlation/cross-product matrix" shows how the matrix is stored in a one-dimensional array  $cp$  for different values of the storage parameters.

## Storage formats of variance-covariance/correlation/cross-product matrices

Parameter	Description
<code>VSL_SS_MATRIX_STORAGE_FULL</code>	<p>The array <math>cp</math> contains all elements of the matrix stored sequentially, row-by-row:</p> <ul style="list-style-type: none"> <li><math>cp[0]</math> contains <math>c_{1,1}</math></li> <li><math>cp[1]</math> contains <math>c_{1,2}</math></li> <li><math>cp[p - 1]</math> contains <math>c_{1,p}</math></li> <li><math>cp[p]</math> contains <math>c_{2,1}</math></li> <li><math>cp[p*p - 1]</math> contains <math>c_{p,p}</math></li> </ul> <p>The size of array <math>cp</math> is <math>p*p</math>.</p>
<code>VSL_SS_MATRIX_STORAGE_L_PACKED</code>	<p>The array <math>cp</math> contains the lower triangular part of the symmetric matrix stored sequentially, row-by-row:</p> <ul style="list-style-type: none"> <li><math>cp[0]</math> contains <math>c_{1,1}</math></li> <li><math>cp[1]</math> contains <math>c_{2,1}</math></li> <li><math>cp[2]</math> contains <math>c_{2,2}</math></li> <li>and so on.</li> </ul> <p>The size of the array is <math>p*(p+1)/2</math>.</p>
<code>VSL_SS_MATRIX_STORAGE_U_PACKED</code>	<p>The array <math>cp</math> contains the upper triangular part of the symmetric matrix stored sequentially, row-by-row:</p>

Parameter	Description
	$cp[0]$ contains $c_{1,1}$ $cp[1]$ contains $c_{1,2}$ $cp[3]$ contains $c_{1,3}$ and so on. The size of the array is $p*(p+1)/2$ .

### vsSSEditCP

Modifies the pointers to cross-product matrix parameters.

### Syntax

```
status = vslsSSEditCP(task, mean, sum, cp, cp_storage);
```

```
status = vsldSSEditCP(task, mean, sum, cp, cp_storage);
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>task</i>	VSLSTaskPtr	Descriptor of the task
<i>mean</i>	float* for vslsSSEditCP double* for vsldSSEditCP	Pointer to array of means
<i>sum</i>	float* for vslsSSEditCP double* for vsldSSEditCP	Pointer to array of sums
<i>cp</i>	float* for vslsSSEditCP double* for vsldSSEditCP	Pointer to a cross-product matrix
<i>cp_storage</i>	const MKL_INT*	Pointer to the storage format of the cross-product matrix

### Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

### Description

The vsSSEditCP routine replaces pointers to the array of means, array of sums, cross-product matrix, and its storage format with values passed as corresponding parameters of the routine. See [Table: "Storage formats of a variance-covariance/correlation/cross-product matrix"](#) for possible values of the *cp\_storage* parameter. If you pass a value of NULL for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

## Storage formats of variance-covariance/correlation/cross-product matrices

Parameter	Description
VSL_SS_MATRIX_STORAGE_FULL	<p>The array <math>cp</math> contains all elements of the matrix stored sequentially, row-by-row:</p> <ul style="list-style-type: none"> <li><math>cp[0]</math> contains <math>c_{1,1}</math></li> <li><math>cp[1]</math> contains <math>c_{1,2}</math></li> <li><math>cp[p - 1]</math> contains <math>c_{1,p}</math></li> <li><math>cp[p]</math> contains <math>c_{2,1}</math></li> <li><math>cp[p*p - 1]</math> contains <math>c_{p,p}</math></li> </ul> <p>The size of array <math>cp</math> is <math>p*p</math>.</p>
VSL_SS_MATRIX_STORAGE_L_PACKED	<p>The array <math>cp</math> contains the lower triangular part of the symmetric matrix stored sequentially, row-by-row:</p> <ul style="list-style-type: none"> <li><math>cp[0]</math> contains <math>c_{1,1}</math></li> <li><math>cp[1]</math> contains <math>c_{2,1}</math></li> <li><math>cp[2]</math> contains <math>c_{2,2}</math></li> <li>and so on.</li> </ul> <p>The size of the array is <math>p*(p+1)/2</math>.</p>
VSL_SS_MATRIX_STORAGE_U_PACKED	<p>The array <math>cp</math> contains the upper triangular part of the symmetric matrix stored sequentially, row-by-row:</p> <ul style="list-style-type: none"> <li><math>cp[0]</math> contains <math>c_{1,1}</math></li> <li><math>cp[1]</math> contains <math>c_{1,2}</math></li> <li><math>cp[3]</math> contains <math>c_{1,3}</math></li> <li>and so on.</li> </ul> <p>The size of the array is <math>p*(p+1)/2</math>.</p>

### vsLSSEditPartialCovCor

Modifies the pointers to partial covariance/correlation parameters.

#### Syntax

```
status = vsLSSEditPartialCovCor(task, p_idx_array, cov, cov_storage, cor, cor_storage,
p_cov, p_cov_storage, p_cor, p_cor_storage);
```

```
status = vsLdSSEditPartialCovCor(task, p_idx_array, cov, cov_storage, cor, cor_storage,
p_cov, p_cov_storage, p_cor, p_cor_storage);
```

#### Include Files

- mkl.h

#### Input Parameters

Name	Type	Description
<i>task</i>	VSLSSTaskPtr	Descriptor of the task

Name	Type	Description
<i>p_idx_array</i>	const MKL_INT*	Pointer to the array that encodes indices of subcomponents <i>Z</i> and <i>Y</i> of the random vector as described in section <a href="#">Mathematical Notation and Definitions</a> .  <i>p_idx_array[i]</i> equals to  -1 if the <i>i</i> -th component of the random vector belongs to <i>Z</i>  1, if the <i>i</i> -th component of the random vector belongs to <i>Y</i> .
<i>cov</i>	const float* for vs1sSSEditPartialCovCor  const double* for vsldSSEditPartialCovCor	Pointer to a covariance matrix
<i>cov_storage</i>	const MKL_INT*	Pointer to the storage format of the covariance matrix
<i>cor</i>	const float* for vs1sSSEditPartialCovCor  const double* for vsldSSEditPartialCovCor	Pointer to a correlation matrix
<i>cor_storage</i>	const MKL_INT*	Pointer to the storage format of the correlation matrix
<i>p_cov</i>	float* for vs1sSSEditPartialCovCor double* for vsldSSEditPartialCovCor	Pointer to a partial covariance matrix
<i>p_cov_storage</i>	const MKL_INT*	Pointer to the storage format of the partial covariance matrix
<i>p_cor</i>	float* for vs1sSSEditPartialCovCor double* for vsldSSEditPartialCovCor	Pointer to a partial correlation matrix
<i>p_cor_storage</i>	const MKL_INT*	Pointer to the storage format of the partial correlation matrix

## Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

## Description

The `vs1sSSEditPartialCovCor` routine replaces pointers to covariance/correlation arrays, partial covariance/correlation arrays, and their storage format with values passed as corresponding parameters of the routine. See [Table "Storage formats of a variance-covariance/correlation matrix"](#) for possible values of the `cov_storage`, `cor_storage`, `p_cov_storage`, and `p_cor_storage` parameters. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

## vsLSSEditQuantiles

Modifies the pointers to parameters related to quantile computations.

### Syntax

```
status = vsLSSEditQuantiles(task, quant_order_n, quant_order, quants, order_stats,
order_stats_storage);
```

```
status = vsLDSEditQuantiles(task, quant_order_n, quant_order, quants, order_stats,
order_stats_storage);
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>task</i>	VSLSTaskPtr	Descriptor of the task
<i>quant_order_n</i>	const MKL_INT*	Pointer to the number of quantile orders
<i>quant_order</i>	const float* for vsLSSEditQuantiles const double* for vsLDSEditQuantiles	Pointer to the array of quantile orders
<i>quants</i>	float* for vsLSSEditQuantiles double* for vsLDSEditQuantiles	Pointer to the array of quantiles
<i>order_stats</i>	float* for vsLSSEditQuantiles double* for vsLDSEditQuantiles	Pointer to the array of order statistics
<i>order_stats_storage</i>	const MKL_INT*	Pointer to the storage format of the order statistics array

### Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

### Description

The vsLSSEditQuantiles routine replaces pointers to the number of quantile orders, the array of quantile orders, the array of quantiles, the array that holds order statistics, and the storage format for the order statistics with values passed into the routine. See [Table "Storage format of matrix of observations and order statistics"](#) for possible values of the *order\_statistics\_storage* parameter. If you pass a value of NULL for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

## vsLSSEditStreamQuantiles

Modifies the pointers to parameters related to quantile computations for streaming data.

## Syntax

```
status = vslsSSEditStreamQuantiles(task, quant_order_n, quant_order, quants, nparams,
params);
```

```
status = vsldSSEditStreamQuantiles(task, quant_order_n, quant_order, quants, nparams,
params);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>task</i>	VSLSTaskPtr	Descriptor of the task
<i>quant_order_n</i>	const MKL_INT*	Pointer to the number of quantile orders
<i>quant_order</i>	const float* for vslsSSEditStreamQuantiles  const double* for vsldSSEditStreamQuantiles	Pointer to the array of quantile orders
<i>quants</i>	float* for vslsSSEditStreamQuantiles  double* for vsldSSEditStreamQuantiles	Pointer to the array of quantiles
<i>nparams</i>	const MKL_INT*	Pointer to the number of the algorithm parameters
<i>params</i>	const float* for vslsSSEditStreamQuantiles  const double* for vsldSSEditStreamQuantiles	Pointer to the array of the algorithm parameters

## Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

## Description

The `vslsSSEditStreamQuantiles` routine replaces pointers to the number of quantile orders, the array of quantile orders, the array of quantiles, the number of the algorithm parameters, and the array of the algorithm parameters with values passed into the routine. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

## vslsSSEditPooledCovariance

*Modifies pooled/group covariance matrix array pointers.*

---

## Syntax

```
status = vslsSSEditPooledCovariance(task, grp_indices, pld_mean, pld_cov,
req_grp_indices, grp_means, grp_cov);
```

```
status = vsldSSEditPooledCovariance(task, grp_indices, pld_mean, pld_cov,
req_grp_indices, grp_means, grp_cov);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>task</i>	VSLSTaskPtr	Descriptor of the task
<i>grp_indices</i>	const MKL_INT*	Pointer to an array of size <i>n</i> . The <i>i</i> -th element of the array contains the number of the group the observation belongs to.
<i>pld_mean</i>	float* for vslsSSEditPooledCovariance double* for vsldSSEditPooledCovariance	Pointer to the array of pooled means
<i>pld_cov</i>	float* for vslsSSEditPooledCovariance double* for vsldSSEditPooledCovariance	Pointer to the array that holds a pooled covariance matrix
<i>req_grp_indices</i>	const MKL_INT*	Pointer to the array that contains indices of groups for which estimates to return (such as covariance and mean)
<i>grp_means</i>	float* for vslsSSEditPooledCovariance double* for vsldSSEditPooledCovariance	Pointer to the array of group means
<i>grp_cov</i>	float* for vslsSSEditPooledCovariance double* for vsldSSEditPooledCovariance	Pointer to the array that holds group covariance matrices

## Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

## Description

The `vs1sSEditPooledCovariance` routine replaces pointers to the array of group indices, the array of pooled means, the array for a pooled covariance matrix, and pointers to the array of indices of group matrices, the array of group means, and the array for group covariance matrices with values passed in the editors. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.. Use the `vs1sSEditTask` routine to replace the storage format for pooled and group covariance matrices.

### vs1sSEditRobustCovariance

*Modifies pointers to arrays related to a robust covariance matrix.*

## Syntax

```
status = vs1sSEditRobustCovariance(task, rcov_storage, nparams, params, rmean, rcov);
```

```
status = vsldSSEditRobustCovariance(task, rcov_storage, nparams, params, rmean, rcov);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>task</code>	<code>VSLSTaskPtr</code>	Descriptor of the task
<code>rcov_storage</code>	<code>const MKL_INT*</code>	Pointer to the storage format of a robust covariance matrix
<code>nparams</code>	<code>const MKL_INT*</code>	Pointer to the number of method parameters
<code>params</code>	<code>const float*</code> for <code>vs1sSEditRobustCovariance</code> <code>const double*</code> for <code>vsldSSEditRobustCovariance</code>	Pointer to the array of method parameters
<code>rmean</code>	<code>float*</code> for <code>vs1sSEditRobustCovariance</code> <code>double*</code> for <code>vsldSSEditRobustCovariance</code>	Pointer to the array of robust means
<code>rcov</code>	<code>float*</code> for <code>vs1sSEditRobustCovariance</code> <code>double*</code> for <code>vsldSSEditRobustCovariance</code>	Pointer to a robust covariance matrix

## Output Parameters

Name	Type	Description
<code>status</code>	<code>int</code>	Current status of the task

## Description

The `vs1SSEditRobustCovariance` routine uses values passed as parameters of the routine to replace:

- pointers to covariance matrix storage
- pointers to the number of method parameters and to the array of the method parameters of size `nparams`
- pointers to the arrays that hold robust means and covariance

See [Table "Storage formats of a variance-covariance/correlation matrix"](#) for possible values of the `rcov_storage` parameter. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

Intel® oneAPI Math Kernel Library (oneMKL) provides a Translated Biweight S-estimator (TBS) for robust estimation of a variance-covariance matrix and mean [Rocke96]. Use one iteration of the Maronna algorithm with the reweighting step [Maronna02] to compute the initial point of the algorithm. Pack the parameters of the TBS algorithm into the `params` array and pass them into the editor. [Table "Structure of the Array of TBS Parameters"](#) describes the `params` structure.

### Structure of the Array of TBS Parameters

Array Position	Algorithm Parameter	Description
0	$\epsilon$	Breakdown point, the number of outliers the algorithm can hold. By default, the value is $(n-p) / (2n)$ .
1	$\alpha$	Asymptotic rejection probability, see details in [Rocke96]. By default, the value is 0.001.
2	$\delta$	Stopping criterion: the algorithm is terminated if weights are changed less than $\delta$ . By default, the value is 0.001.
3	<code>max_iter</code>	Maximum number of iterations. The algorithm terminates after <code>max_iter</code> iterations. By default, the value is 10.  If you set this parameter to zero, the function returns a robust estimate of the variance-covariance matrix computed using the Maronna method [Maronna02] only.

The robust estimator of variance-covariance implementation in Intel® oneAPI Math Kernel Library (oneMKL) requires that the number of observations  $n$  be greater than twice the number of variables:  $n > 2p$ .

See additional details of the algorithm usage model in the *Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics Application Notes* document [[SS Notes](#)].

### vs1SSEditOutliersDetection

*Modifies array pointers related to multivariate outliers detection.*

### Syntax

```
status = vs1SSEditOutliersDetection(task, nparams, params, w);
```

```
status = vs1dSSEditOutliersDetection(task, nparams, params, w);
```

### Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<i>task</i>	VSLSSTaskPtr	Descriptor of the task
<i>nparams</i>	const MKL_INT*	Pointer to the number of method parameters
<i>params</i>	const float* for vslsSSEditOutliersDetection  const double* for vsldSSEditOutliersDetection	Pointer to the array of method parameters
<i>w</i>	float* for vslsSSEditOutliersDetection  double* for vsldSSEditOutliersDetection	Pointer to an array of size <i>n</i> . The array holds the weights of observations to be marked as outliers.

## Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

## Description

The `vslsSSEditOutliersDetection` routine uses the parameters passed to replace

- the pointers to the number of method parameters and to the array of the method parameters of size *nparams*
- the pointer to the array that holds the calculated weights of the observations

If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

Intel® oneAPI Math Kernel Library (oneMKL) provides the BACON algorithm ([Billor00]) for the detection of multivariate outliers. Pack the parameters of the BACON algorithm into the *params* array and pass them into the editor. Table "Structure of the Array of BACON Parameters" describes the *params* structure.

### Structure of the Array of BACON Parameters

Array Position	Algorithm Parameter	Description
0	Method to start the algorithm	The parameter takes one of the following possible values:  <code>VSL_SS_METHOD_BACON_MEDIAN_INIT</code> , if the algorithm is started using the median estimate. This is the default value of the parameter.  <code>VSL_SS_METHOD_BACON_MAHALANOBIS_INIT</code> , if the algorithm is started using the Mahalanobis distances.

Array Position	Algorithm Parameter	Description
1	$\alpha$	One-tailed probability that defines the $(1 - \alpha)$ quantile of $\chi^2$ distribution with $p$ degrees of freedom. The recommended value is $\alpha/n$ , where $n$ is the number of observations. By default, the value is 0.05.
2	$\delta$	Stopping criterion; the algorithm is terminated if the size of the basic subset is changed less than $\delta$ . By default, the value is 0.005.

Output of the algorithm is the vector of weights, `BaconWeights`, such that `BaconWeights(i) = 0` if  $i$ -th observation is detected as an outlier. Otherwise `BaconWeights(i) = w(i)`, where  $w$  is the vector of input weights. If you do not provide the vector of input weights, `BaconWeights(i)` is set to 1 if the  $i$ -th observation is not detected as an outlier.

See additional details about usage model of the algorithm in the *Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics Application Notes* document [[SS Notes](#)].

### **vsLSSEditMissingValues**

*Modifies pointers to arrays associated with the method of supporting missing values in a dataset.*

### **Syntax**

```
status = vsLSSEditMissingValues(task, nparams, params, init_estimates_n,
init_estimates, prior_n, prior, simul_missing_vals_n, simul_missing_vals, estimates_n,
estimates);
```

```
status = vsLDSEditMissingValues(task, nparams, params, init_estimates_n,
init_estimates, prior_n, prior, simul_missing_vals_n, simul_missing_vals, estimates_n,
estimates);
```

### **Include Files**

- `mkl.h`

### **Input Parameters**

Name	Type	Description
<code>task</code>	<code>VSLSTaskPtr</code>	Descriptor of the task
<code>nparams</code>	<code>const MKL_INT*</code>	Pointer to the number of method parameters
<code>params</code>	<code>const float*</code> for <code>vsLSSEditMissingValues</code>  <code>const double*</code> for <code>vsLDSEditMissingValues</code>	Pointer to the array of method parameters
<code>init_estimates_n</code>	<code>const MKL_INT*</code>	Pointer to the number of initial estimates for mean and a variance-covariance matrix

Name	Type	Description
<i>init_estimates</i>	const float* for vslsSSEditMissingValues  const double* for vsldSSEditMissingValues	Pointer to the array that holds initial estimates for mean and a variance-covariance matrix
<i>prior_n</i>	const MKL_INT*	Pointer to the number of prior parameters
<i>prior</i>	const float* for vslsSSEditMissingValues  const double* for vsldSSEditMissingValues	Pointer to the array of prior parameters
<i>simul_missing_vals_n</i>	const MKL_INT*	Pointer to the size of the array that holds output of the Multiple Imputation method
<i>simul_missing_vals</i>	float* for vslsSSEditMissingValues double* for vsldSSEditMissingValues	Pointer to the array of size $k*m$ , where $k$ is the total number of missing values, and $m$ is number of copies of missing values. The array holds $m$ sets of simulated missing values for the matrix of observations.
<i>estimates_n</i>	const MKL_INT*	Pointer to the number of estimates to be returned by the routine
<i>estimates</i>	float* for vslsSSEditMissingValues double* for vsldSSEditMissingValues	Pointer to the array that holds estimates of the mean and a variance-covariance matrix.

## Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

## Description

The `vslsSSEditMissingValues` routine uses values passed as parameters of the routine to replace pointers to the number and the array of the method parameters, pointers to the number and the array of initial mean/variance-covariance estimates, the pointer to the number and the array of prior parameters, pointers to the number and the array of simulated missing values, and pointers to the number and the array of the intermediate mean/covariance estimates. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

Before you call the Summary Statistics routines to process missing values, preprocess the dataset and denote missing observations with one of the following predefined constants:

- `VSL_SS_SNAN`, if the dataset is stored in single precision floating-point arithmetic
- `VSL_SS_DNAN`, if the dataset is stored in double precision floating-point arithmetic

Intel® oneAPI Math Kernel Library (oneMKL) provides the `vsl_ss_method_mi` method to support missing values in the dataset based on the Multiple Imputation (MI) approach described in [Schafer97]. The following components support Multiple Imputation:

- Expectation Maximization (EM) algorithm to compute the start point for the Data Augmentation (DA) procedure
- DA function

---

#### NOTE

The DA component of the MI procedure is simulation-based and uses the `vsl_brng_mcg59` basic random number generator with predefined `seed = 250` and the Gaussian distribution generator (`icdfmethod`) available in Intel® oneAPI Math Kernel Library (oneMKL) [[Gaussian](#)].

---

Pack the parameters of the MI algorithm into the `params` array. [Table "Structure of the Array of MI Parameters"](#) describes the `params` structure.

#### Structure of the Array of MI Parameters

Array Position	Algorithm Parameter	Description
0	<code>em_iter_num</code>	Maximal number of iterations for the EM algorithm. By default, this value is 50.
1	<code>da_iter_num</code>	Maximal number of iterations for the DA algorithm. By default, this value is 30.
2	<code>ε</code>	Stopping criterion for the EM algorithm. The algorithm terminates if the maximal module of the element-wise difference between the previous and current parameter values is less than <code>ε</code> . By default, this value is 0.001.
3	<code>m</code>	Number of sets to impute
4	<code>missing_vals_num</code>	Total number of missing values in the datasets

You can also pass initial estimates into the EM algorithm by packing both the vector of means and the variance-covariance matrix as a one-dimensional array `init_estimates`. The size of the array should be at least  $p + p(p + 1)/2$ . For  $i=0, \dots, p-1$ , the `init_estimates[i]` array contains the initial estimate of means. The remaining positions of the array are occupied by the upper triangular part of the variance-covariance matrix.

If you provide no initial estimates for the EM algorithm, the editor uses the default values, that is, the vector of zero means and the unitary matrix as a variance-covariance matrix. You can also pass `prior` parameters for  $\mu$  and  $\Sigma$  into the library:  $\mu_0$ ,  $\tau$ ,  $m$ , and  $\Lambda^{-1}$ . Pack these parameters as a one-dimensional array `prior` with a size of at least

$$(p^2 + 3p + 4)/2.$$

The storage format is as follows:

- `prior[0], \dots, prior[p-1]` contain the elements of the vector  $\mu_0$ .
- `prior[p]` contains the parameter  $\tau$ .
- `prior[p+1]` contains the parameter  $m$ .
- The remaining positions are occupied by the upper-triangular part of the inverted matrix  $\Lambda^{-1}$ .

If you provide no `prior` parameters, the editor uses their default values:

- The array of  $p$  zeros is used as  $\mu_0$ .
- $\tau$  is set to 0.
- $m$  is set to  $p$ .
- The zero matrix is used as an initial approximate of  $\Lambda^{-1}$ .

The `EditMissingValues` editor returns  $m$  sets of imputed values and/or a sequence of parameter estimates drawn during the DA procedure.

The editor returns the imputed values as the `simul_missing_vals` array. The size of the array should be sufficient to hold  $m$  sets each of the `missing_vals_num` size, that is, at least  $m \times \text{missing\_vals\_num}$  in total. The editor packs the imputed values one by one in the order of their appearance in the matrix of observations.

For example, consider a task of dimension 4. The total number of observations  $n$  is 10. The second observation vector misses variables 1 and 2, and the seventh observation vector lacks variable 1. The number of sets to impute is  $m=2$ . Then, `simul_missing_vals[0]` and `simul_missing_vals[1]` contains the first and the second points for the second observation vector, and `simul_missing_vals[2]` holds the first point for the seventh observation. Positions 3, 4, and 5 are formed similarly.

To estimate convergence of the DA algorithm and choose a proper value of the number of DA iterations, request the sequence of parameter estimates that are produced during the DA procedure. The editor returns the sequence of parameters as a single array. The size of the array is

$$m \times \text{da\_iter\_num} \times (p + (p^2 + p) / 2)$$

where

- $m$  is the number of sets of values to impute.
- `da_iter_num` is the number of DA iterations.
- The value  $p + (p^2 + p) / 2$  determines the size of the memory to hold one set of the parameter estimates.

In each set of the parameters, the vector of means occupies the first  $p$  positions and the remaining  $(p^2 + p) / 2$  positions are intended for the upper triangular part of the variance-covariance matrix.

Upon successful generation of  $m$  sets of imputed values, you can place them in cells of the data matrix with missing values and use the Summary Statistics routines to analyze and get estimates for each of the  $m$  complete datasets.

---

**NOTE**

Intel® oneAPI Math Kernel Library (oneMKL) implementation of the MI algorithm rewrites cells of the dataset that contain the `VSL_SS_SNAN/VSL_SS_DNAN` values. If you want to use the Summary Statistics routines to process the data with missing values again, mask the positions of the empty cells.

---

See additional details of the algorithm usage model in the *Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics Application Notes* document [[SS Notes](#)].

### **vsLSSEditCorParameterization**

*Modifies pointers to arrays related to the algorithm of correlation matrix parameterization.*

---

#### **Syntax**

```
status = vsLSSEditCorParameterization(task, cor, cor_storage, pcor, pcor_storage);
```

```
status = vsLDSSEditCorParameterization(task, cor, cor_storage, pcor, pcor_storage);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>task</i>	VSLSTaskPtr	Descriptor of the task
<i>cor</i>	const float* for vslsSSEditCorParameterization  const double* for vsldsSSEditCorParameterization	Pointer to the correlation matrix
<i>cor_storage</i>	const MKL_INT*	Pointer to the storage format of the correlation matrix
<i>pcor</i>	float* for vslsSSEditCorParameterization  double* for vsldsSSEditCorParameterization	Pointer to the parameterized correlation matrix
<i>por_storage</i>	const MKL_INT*	Pointer to the storage format of the parameterized correlation matrix

## Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

## Description

The `vslsSSEditCorParameterization` routine uses values passed as parameters of the routine to replace pointers to the correlation matrix, pointers to the correlation matrix storage format, a pointer to the parameterized correlation matrix, and a pointer to the parameterized correlation matrix storage format. See [Table "Storage formats of a variance-covariance/correlation matrix"](#) for possible values of the `cor_storage` and `pcor_storage` parameters. If you pass a value of `NULL` for a specific input parameter, the value of that parameter in the task descriptor is unchanged.

## Summary Statistics Task Computation Routines

Task computation routines calculate statistical estimates on the data provided and parameters held in the task descriptor. After you create the task and initialize its parameters, you can call the computation routines as many times as necessary. [Table "Summary Statistics Estimates Obtained with `vs1SSCompute` Routine"](#) lists the respective statistical estimates.

---

### NOTE

The Summary Statistics computation routines do not signal floating-point errors, such as overflow or gradual underflow, or operations with NaNs (except for the missing values in the observations).

---

## Summary Statistics Estimates Obtained with vsISSCompute Routine

Estimate	Support of Observations Available in Blocks	Description
VSL_SS_MEAN	Yes	Computes the array of means.
VSL_SS_SUM	Yes	Computes the array of sums.
VSL_SS_2R_MOM	Yes	Computes the array of the 2 <sup>nd</sup> order raw moments.
VSL_SS_2R_SUM	Yes	Computes the array of raw sums of the 2 <sup>nd</sup> order.
VSL_SS_3R_MOM	Yes	Computes the array of the 3 <sup>rd</sup> order raw moments.
VSL_SS_3R_SUM	Yes	Computes the array of raw sums of the 3 <sup>rd</sup> order.
VSL_SS_4R_MOM	Yes	Computes the array of the 4 <sup>th</sup> order raw moments.
VSL_SS_4R_SUM	Yes	Computes the array of raw sums of the 4 <sup>th</sup> order.
VSL_SS_2C_MOM	Yes	Computes the array of the 2 <sup>nd</sup> order central moments.
VSL_SS_2C_SUM	Yes	Computes the array of central sums of the 2 <sup>nd</sup> order.
VSL_SS_3C_MOM	Yes	Computes the array of the 3 <sup>rd</sup> order central moments.
VSL_SS_3C_SUM	Yes	Computes the array of central sums of the 3 <sup>rd</sup> order.
VSL_SS_4C_MOM	Yes	Computes the array of the 4 <sup>th</sup> order central moments.
VSL_SS_4C_SUM	Yes	Computes the array of central sums of the 4 <sup>th</sup> order.
VSL_SS_KURTOSIS	Yes	Computes the array of kurtosis values.
VSL_SS_SKEWNESS	Yes	Computes the array of skewness values.
VSL_SS_MIN	Yes	Computes the array of minimum values.
VSL_SS_MAX	Yes	Computes the array of maximum values.
VSL_SS_VARIATION	Yes	Computes the array of variation coefficients.
VSL_SS_COV	Yes	Computes a covariance matrix.
VSL_SS_COR	Yes	Computes a correlation matrix. The main diagonal of the correlation matrix holds variances of the random vector components.
VSL_SS_CP	Yes	Computes a cross-product matrix.
VSL_SS_POOLED_COV	No	Computes a pooled covariance matrix.

Estimate	Support of Observations Available in Blocks	Description
VSL_SS_POOLED_MEAN	No	Computes an array of pooled means.
VSL_SS_GROUP_COV	No	Computes group covariance matrices.
VSL_SS_GROUP_MEAN	No	Computes group means.
VSL_SS_QUANTS	No	Computes quantiles.
VSL_SS_ORDER_STATS	No	Computes order statistics.
VSL_SS_ROBUST_COV	No	Computes a robust covariance matrix.
VSL_SS_OUTLIERS	No	Detects outliers in the dataset.
VSL_SS_PARTIAL_COV	No	Computes a partial covariance matrix.
VSL_SS_PARTIAL_COR	No	Computes a partial correlation matrix.
VSL_SS_MISSING_VALS	No	Supports missing values in datasets.
VSL_SS_PARAMTR_COR	No	Computes a parameterized correlation matrix.
VSL_SS_STREAM_QUANTS	Yes	Computes quantiles for streaming data.
VSL_SS_MDAD	No	Computes median absolute deviation.
VSL_SS_MNAD	No	Computes mean absolute deviation.
VSL_SS_SORTED_OBSERV	No	Sorts the dataset by the components of the random vector $\xi$ .

Table "Summary Statistics Computation Method" lists estimate calculation methods supported by Intel® oneAPI Math Kernel Library (oneMKL). See the *Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics Application Notes* document [[SS Notes](#)] for a detailed description of the methods.

### Summary Statistics Computation Method

Method	Description
VSL_SS_METHOD_FAST	Fast method for calculation of the estimates: <ul style="list-style-type: none"> <li>raw/central moments/sums, skewness, kurtosis, variation, variance-covariance/correlation/cross-product matrix</li> <li>min/max/quantile/order statistics</li> <li>partial variance-covariance</li> <li>median/mean absolute deviation</li> </ul>
VSL_SS_METHOD_FAST_USER_MEAN	Fast method for calculation of the estimates given user-defined mean: <ul style="list-style-type: none"> <li>central moments/sums of 2-4 order, skewness, kurtosis, variation, variance-covariance/correlation/cross-product matrix, mean absolute deviation</li> </ul>
VSL_SS_METHOD_1PASS	One-pass method for calculation of estimates: <ul style="list-style-type: none"> <li>raw/central moments/sums, skewness, kurtosis, variation, variance-covariance/correlation/cross-product matrix</li> </ul>

Method	Description
	<ul style="list-style-type: none"> <li>pooled/group covariance matrix</li> </ul>
VSL_SS_METHOD_TBS	TBS method for robust estimation of covariance and mean
VSL_SS_METHOD_BACON	BACON method for detection of multivariate outliers
VSL_SS_METHOD_MI	Multiple imputation method for support of missing values
VSL_SS_METHOD_SD	Spectral decomposition method for parameterization of a correlation matrix
VSL_SS_METHOD_SQUANTS_ZW	Zhang-Wang (ZW) method for quantile estimation for streaming data
VSL_SS_METHOD_SQUANTS_ZW_FAST	Fast ZW method for quantile estimation for streaming data
VSL_SS_METHOD_RADIX	Radix method for dataset sorting

You can calculate all requested estimates in one call of the routine. For example, to compute a kurtosis and covariance matrix using a fast method, pass a combination of the pre-defined parameters into the `Compute` routine as shown in the example below:

```
...
method = VSL_SS_METHOD_FAST;
task_params = VSL_SS_KURTOSIS|VSL_SS_COV;
...
status = vsldSSCompute( task, task_params, method );
```

To compute statistical estimates for the next block of observations, you can do one of the following:

- copy the observations to memory, starting with the address available to the task
- use one of the appropriate [Editors](#) to modify the pointer to the new dataset in the task.

The library does not detect your changes of the dataset and computed statistical estimates. To obtain statistical estimates for a new matrix, change the observations and initialize relevant arrays. You can follow this procedure to compute statistical estimates for observations that come in portions. See [Table "Summary Statistics Estimates Obtained with vsldSSCompute Routine"](#) for information on such observations supported by the Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics estimators.

To modify parameters of the task using the Task Editors, set the address of the targeted matrix of the observations or change the respective vector component indices. After you complete editing the task parameters, you can compute statistical estimates in the modified environment.

If the task completes successfully, the computation routine returns the zero status code. If an error is detected, the computation routine returns an error code. In particular, an error status code is returned in the following cases:

- the task pointer is `NULL`
- memory allocation has failed
- the calculation has failed for some other reason

---

**NOTE**

You can use the `NULL` task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

---

**vsldSSCompute**

*Computes Summary Statistics estimates.*

---

## Syntax

```
status = vslsSSCompute(task, estimates, method);
```

```
status = vslDSSCompute(task, estimates, method);
```

## Include Files

- `mkL.h`

## Input Parameters

Name	Type	Description
<code>task</code>	<code>VSLSSTaskPtr</code>	Descriptor of the task
<code>estimates</code>	<code>const MKL_INT64</code>	List of statistical estimates to compute
<code>method</code>	<code>const MKL_INT</code>	Method to be used in calculations

## Output Parameters

Name	Type	Description
<code>status</code>	<code>int</code>	Current status of the task

## Description

The `vslSSCompute` routine calculates statistical estimates passed as the `estimates` parameter using the algorithms passed as the `method` parameter of the routine. The computations are done in the context of the task descriptor that contains pointers to all required and optional, if necessary, properly initialized arrays. In one call of the function, you can compute several estimates using proper methods for their calculation. See [Table "Summary Statistics Estimates Obtained with Compute Routine"](#) for the list of the estimates that you can calculate with the `vslSSCompute` routine. See [Table "Summary Statistics Computation Methods"](#) for the list of possible values of the `method` parameter.

To initialize single or double precision version task parameters, use the single (`vslSSscompute`) or double (`vslDSScompute`) version of the editor, respectively. To initialize parameters of the integer type, use an integer version of the editor (`vslISScompute`).

### NOTE

Requesting a combination of the `VSL_SS_MISSING_VALS` value and any other estimate parameter in the `Compute` function results in processing only the missing values.

## Application Notes

Be aware that when computing a correlation matrix, the `vslSSCompute` routine allocates an additional array for each thread which is running the task. If you are running on a large number of threads `vslSSCompute` might consume large amounts of memory.

When calculating covariance, correlation, or cross product, the number of bytes of memory required is at least  $(P*P*T + P*T)*b$ , where  $P$  is the dimension of the task or number of variables,  $T$  is the number of threads, and  $b$  is the number of bytes required for each unit of data. If observation is weighted and the method is `VSL_SS_METHOD_FAST`, then the memory required is at least  $(P*P*T + P*T + N*P)*b$ , where  $N$  is the number of observations.

## Summary Statistics Task Destructor

Task destructor is the `vslSSDeleteTask` routine intended to delete task objects and release memory.

### `vslSSDeleteTask`

*Destroys the task object and releases the memory.*

### Syntax

```
status = vslSSDeleteTask(&task);
```

### Include Files

- `mkl.h`

### Input Parameters

Name	Type	Description
<code>task</code>	<code>VSLSSTaskPtr*</code>	Descriptor of the task to destroy

### Output Parameters

Name	Type	Description
<code>status</code>	<code>int</code>	Sets to <code>VSL_STATUS_OK</code> if the task is deleted; otherwise a non-zero code is returned.

### Description

The `vslSSDeleteTask` routine deletes the task descriptor object, releases the memory allocated for the structure, and sets the task pointer to `NULL`. If `vslSSDeleteTask` fails to delete the task successfully, it returns an error code.

---

**NOTE**

Call of the destructor with the `NULL` pointer as the parameter results in termination of the function with no system crash.

---

## Summary Statistics Usage Examples

The following examples show various standard operations with Summary Statistics routines.

### Calculating Fixed Estimates for Fixed Data

The example shows recurrent calculation of the same estimates with a given set of variables for the complete life cycle of the task in the case of a variance-covariance matrix. The set of vector components to process remains unchanged, and the data comes in blocks. Before you call the `vslSSCompute` routine, initialize pointers to arrays for mean and covariance and set buffers.

```
...
double w[2];
double indices[DIM] = {1, 0, 1};

/* calculating mean for 1st and 3d random vector components */
```

```

/* Initialize parameters of the task */
p = DIM;
n = N;

xstorage   = VSL_SS_MATRIX_STORAGE_ROWS;
covstorage = VSL_SS_MATRIX_STORAGE_FULL;

w[0] = 0.0; w[1] = 0.0;

for ( i = 0; i < p; i++ ) mean[i] = 0.0;
for ( i = 0; i < p*p; i++ ) cov[i] = 0.0;

status = vsldSSNewTask( &task, &p, &n, &xstorage, x, 0, indices );

status = vsldSSEditTask ( task, VSL_SS_ED_ACCUM_WEIGHT, w );
status = vsldSSEditCovCor( task, mean, cov, &covstorage, 0, 0 );

```

You can process data arrays that come in blocks as follows:

```

for ( i = 0; i < num_of_blocks; i++ )
{
    status = vsldSSCompute( task, VSL_SS_COV, VSL_SS_METHOD_FAST );
    /* Read new data block into array x */
}
...

```

## Calculating Different Estimates for Variable Data

The context of your calculation may change in the process of data analysis. The example below shows the data that comes in two blocks. You need to estimate a covariance matrix for the complete data, and the third central moment for the second block of the data using the weights that were accumulated for the previous datasets. The second block of the data is stored in another array. You can proceed as follows:

```

/* Set parameters for the task */
p = DIM;
n = N;
xstorage   = VSL_SS_MATRIX_STORAGE_ROWS;
covstorage = VSL_SS_MATRIX_STORAGE_FULL;

w[0] = 0.0; w[1] = 0.0;

for ( i = 0; i < p; i++ ) mean[i] = 0.0;
for ( i = 0; i < p*p; i++ ) cov[i] = 0.0;

/* Create task */
status = vsldSSNewTask( &task, &p, &n, &xstorage, x1, 0, indices );

/* Initialize the task parameters */
status = vsldSSEditTask( task, VSL_SS_ED_ACCUM_WEIGHT, w );
status = vsldSSEditCovCor( task, mean, cov, &covstorage, 0, 0 );

/* Calculate covariance for the x1 data */
status = vsldSSCompute( task, VSL_SS_COV, VSL_SS_METHOD_FAST );

/* Initialize array of the 3d central moments and pass the pointer to the task */
for ( i = 0; i < p; i++ ) c3_m[i] = 0.0;

/* Modify task context */

```

```

status = vsldSSEditTask( task, VSL_SS_ED_3C_MOM, c3_m );
status = vsldSSEditTask( task, VSL_SS_ED_OBSERV, x2 );

/* Calculate covariance for the x1 & x2 data block */
/* Calculate the 3d central moment for the 2nd data block using earlier accumulated weight */
status = vsldSSCompute(task, VSL_SS_COV|VSL_SS_3C_MOM, VSL_SS_METHOD_FAST );
...
status = vsldSSDeleteTask( &task );

```

Similarly, you can modify indices of the variables to be processed for the next data block.

## Summary Statistics Mathematical Notation and Definitions

The following notations are used in the mathematical definitions and the description of the Intel® oneAPI Math Kernel Library (oneMKL) Summary Statistics functions.

### Matrix and Weights of Observations

For a random  $p$ -dimensional vector  $\xi = (\xi_1, \dots, \xi_i, \dots, \xi_p)$ , this manual denotes the following:

- $(X)_i = (x_{ij})_{j=1..n}$  is the result of  $n$  independent observations for the  $i$ -th component  $\xi_i$  of the vector  $\xi$ .
- The two-dimensional array  $X = (x_{ij})_{n \times p}$  is the matrix of observations.
- The column  $[X]_j = (x_{ij})_{i=1..p}$  of the matrix  $X$  is the  $j$ -th observation of the random vector  $\xi$ .

Each observation  $[X]_j$  is assigned a non-negative weight  $w_j$ , where

- The vector  $(w_j)_{j=1..n}$  is a vector of weights corresponding to  $n$  observations of the random vector  $\xi$ .

$$W = \sum_{i=1}^n w_i$$

is the accumulated weight corresponding to observations  $X$ .

### Vector of sample means

$$M(X) = (M_1(X), \dots, M_p(X)) \text{ with } M_i(X) = \frac{1}{w} \sum_{j=1}^n w_j x_{ij}$$

for all  $i = 1, \dots, p$ .

### Vector of sample partial sums

$$S(X) = (S_1(X), \dots, S_p(X)) \text{ with } S_i(X) = \sum_{j=1}^n w_j x_{ij}$$

for all  $i = 1, \dots, p$ .

### Vector of sample variances

$$V(X) = (V_1(X), \dots, V_p(X)) \text{ with } V_i(X) = \frac{1}{B} \sum_{j=1}^n w_j (x_{ij} - M_i(X))^2, B = W - \sum_{j=1}^n w_j^2 / W$$

for all  $i = 1, \dots, p$ .

### Vector of sample raw/algebraic moments of $k$ -th order, $k \geq 1$

$$R^{(k)}(X) = (R_1^{(k)}(X), \dots, R_p^{(k)}(X)) \text{ with } R_i^{(k)}(X) = \frac{1}{W} \sum_{j=1}^n w_j x_{ij}^k$$

for all  $i = 1, \dots, p$ .

### Vector of sample raw/algebraic partial sums of $k$ -th order, $k= 2, 3, 4$ (raw/algebraic partial sums of squares/cubes/fourth powers)

$$S^k(X) = (S_1^k(X), \dots, S_p^k(X)) \text{ with } S_i^k(X) = \sum_{j=1}^n w_j x_{ij}^k$$

for all  $i = 1, \dots, p$ .

### Vector of sample central moments of the third and the fourth order

$$C^{(k)}(X) = (C_1^{(k)}(X), \dots, C_p^{(k)}(X)) \text{ with } C_i^{(k)}(X) = \frac{1}{B} \sum_{j=1}^n w_j (x_{ij} - M_i(X))^k, B = \sum_{j=1}^n w_j$$

for all  $i = 1, \dots, p$  and  $k = 3, 4$ .

### Vector of sample central partial sums of $k$ -th order, $k= 2, 3, 4$ (central partial sums of squares/cubes/fourth powers)

$$S^k(X) = (S_1^k(X), \dots, S_p^k(X)) \text{ with } S_i^k(X) = \sum_{j=1}^n w_j (x_{ij} - S_i(X))^k$$

for all  $i = 1, \dots, p$ .

### Vector of sample excess kurtosis values

$$B(X) = (B_1(X), \dots, B_p(X)) \text{ with } B_i(X) = \frac{C_i^{(4)}(X)}{V_i^2(X)} - 3$$

for all  $i = 1, \dots, p$ .

### Vector of sample skewness values

$$\Gamma(X) = (\Gamma_1(X), \dots, \Gamma_p(X)) \text{ with } \Gamma_i(X) = \frac{C_i^{(3)}(X)}{V_i^{1.5}(X)}$$

for all  $i = 1, \dots, p$ .

### Vector of sample variation coefficients

$$VC(X) = (VC_1(X), \dots, VC_p(X)) \text{ with } VC_i(X) = \frac{V_i^{0.5}(X)}{M_i(X)}$$

for all  $i = 1, \dots, p$ .

### Matrix of order statistics

Matrix  $Y = (Y_{ij})_{p \times n}$ , in which the  $i$ -th row  $(Y)_i = (Y_{ij})_{j=1..n}$  is obtained as a result of sorting in the ascending order of row  $(X)_i = (X_{ij})_{j=1..n}$  in the original matrix of observations.

### Vector of sample minimum values

$$Min(X) = (Min_1(X), \dots, Min_p(X)), \text{ where } Min_i(X) = y_{i1}$$

for all  $i = 1, \dots, p$ .

## Vector of sample maximum values

$Max(X) = (Max_1(X), \dots, Max_p(X))$ , where  $Max_i(X) = y_{in}$

for all  $i = 1, \dots, p$ .

## Vector of sample median values

$Med(X) = (Med_1(X), \dots, Med_p(X))$ , where  $Med_i(X) = \begin{cases} y_{i, (n+1)/2}, & \text{if } n \text{ is odd} \\ (y_{i, n/2} + y_{i, n/2+1})/2, & \text{if } n \text{ is even} \end{cases}$

for all  $i = 1, \dots, p$ .

## Vector of sample median absolute deviations

$MDAD(X) = (MDAD_1(X), \dots, MDAD_p(X))$ , where  $MDAD_i(X) = Med_i(Z)$  with  $Z = (z_{ij})_{i=1\dots p, j=1\dots n}$

$z_{ij} = |x_{ij} - Med_i(X)|$

for all  $i = 1, \dots, p$ .

## Vector of sample mean absolute deviations

$MNAD(X) = (MNAD_1(X), \dots, MNAD_p(X))$ , where  $MNAD_i(X) = M_i(Z)$  with  $Z = (z_{ij})_{i=1\dots p, j=1\dots n}$

$z_{ij} = |x_{ij} - M_i(X)|$

for all  $i = 1, \dots, p$ .

## Vector of sample quantile values

For a positive integer number  $q$  and  $k$  belonging to the interval  $[0, q-1]$ , point  $z_i$  is the  $k$ -th  $q$  quantile of the random variable  $\xi_i$  if  $P\{\xi_i \leq z_i\} \geq \beta$  and  $P\{\xi_i \leq z_i\} \geq 1 - \beta$ , where

- $P$  is the probability measure.
- $\beta = k/n$  is the quantile order.

The calculation of quantiles is as follows:

$j = [(n-1)\beta]$  and  $f = \{(n-1)\beta\}$  as integer and fractional parts of the number  $(n-1)\beta$ , respectively, and the vector of sample quantile values is

$$Q(X, \beta) = (Q_1(X, \beta), \dots, Q_p(X, \beta))$$

where

$$(Q_i(X, \beta) = y_{i, j+1} + f(y_{i, j+2} - y_{i, j+1}))$$

for all  $i = 1, \dots, p$ .

## Variance-covariance matrix

$$C(X) = (c_{ij}(X))_{p \times p}$$

where

$$c_{ij}(X) = \frac{1}{B} \sum_{k=1}^n w_k (x_{ik} - M_i(X))(x_{jk} - M_j(X)), \quad B = W - \sum_{j=1}^n w_j^2 / W$$

## Cross-product matrix (matrix of cross-products and sums of squares)

$$CP(X) = (cp_{ij}(X))_{p \times p}$$

where

$$cp_{ij}(X) = \sum_{k=1}^n w_k (x_{ik} - M_i(X))(x_{jk} - M_j(X))$$

### Pooled and group variance-covariance matrices

The set  $N = \{1, \dots, n\}$  is partitioned into non-intersecting subsets

$$G_i, i = 1..g, N = \bigcup_{i=1}^g G_i$$

The observation  $[X]_j = (x_{ij})_{i=1..p}$  belongs to the group  $r$  if  $j \in G_r$ . One observation belongs to one group only. The group mean and variance-covariance matrices are calculated similarly to the formulas above:

$$M^{(r)}(X) = (M_1^{(r)}(X), \dots, M_p^{(r)}(X)) \text{ with } M_i^{(r)}(X) = \frac{1}{W^{(r)}} \sum_{j \in G_r} w_j x_{ij}, \quad W^{(r)} = \sum_{j \in G_r} w_j$$

for all  $i = 1, \dots, p$ ,

$$C^{(r)}(X) = (c_{ij}^{(r)}(X))_{p \times p}$$

where

$$c_{ij}^{(r)}(X) = \frac{1}{B^{(r)}} \sum_{k \in G_r} w_k (x_{ik} - M_i^{(r)}(X))(x_{jk} - M_j^{(r)}(X)), \quad B^{(r)} = W^{(r)} - \sum_{j \in G_r} w_j^2 / W^{(r)}$$

for all  $i = 1, \dots, p$  and  $j = 1, \dots, p$ .

A pooled variance-covariance matrix and a pooled mean are computed as weighted mean over group covariance matrices and group means, correspondingly:

$$M^{pooled}(X) = (M_1^{pooled}(X), \dots, M_p^{pooled}(X)) \text{ with } M_i^{pooled}(X) = \frac{1}{W^{(1)} + \dots + W^{(g)}} \sum_{r=1}^g W^{(r)} M_i^{(r)}(X)$$

for all  $i = 1, \dots, p$ ,

$$C^{pooled}(X) = (c_{ij}^{pooled}(X))_{p \times p}, \quad c_{ij}^{pooled}(X) = \frac{1}{B^{(1)} + \dots + B^{(g)}} \sum_{r=1}^g B^{(r)} c_{ij}^{(r)}(X)$$

for all  $i = 1, \dots, p$  and  $j = 1, \dots, p$ .

### Correlation matrix

$$R(X) = (r_{ij}(X))_{p \times p}, \text{ where } r_{ij}(X) = \frac{c_{ij}}{\sqrt{c_{ii}c_{jj}}}$$

for all  $i = 1, \dots, p$  and  $j = 1, \dots, p$ .

### Partial variance-covariance matrix

For a random vector  $\xi$  partitioned into two components  $Z$  and  $Y$ , a variance-covariance matrix  $C$  describes the structure of dependencies in the vector  $\xi$ :

$$C(X) = \begin{pmatrix} C_Z(X) & C_{ZY}(X) \\ C_{YZ}(X) & C_Y(X) \end{pmatrix}.$$

The partial covariance matrix  $P(X) = (p_{ij}(X))_{k \times k}$  is defined as

$$P(X) = C_Y(X) - C_{YZ}(X)C_Z^{-1}C_{ZY}(X).$$

where  $k$  is the dimension of  $Y$ .

## Partial correlation matrix

The following is a partial correlation matrix for all  $i = 1, \dots, k$  and  $j = 1, \dots, k$ :

$$RP(X) = \left( r_{p_{ij}}(X) \right)_{k \times k}, \text{ where } r_{p_{ij}}(X) = \frac{p_{ij}(X)}{\sqrt{p_{ii}(X)p_{jj}(X)}}$$

where

- $k$  is the dimension of  $Y$ .
- $p_{ij}(X)$  are elements of the partial variance-covariance matrix.

## Sorted dataset

Matrix  $Y = (y_{ij})_{p \times n}$ , in which the  $i$ -th row ( $Y$ ) $_i$  is obtained as a result of sorting in ascending order the row ( $X$ ) $_i = (x_{ij})_{j=1..n}$  in the original matrix of observations.

## Fourier Transform Functions

---

The general form of the discrete Fourier transform is

$$z_{k_1, k_2, \dots, k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \dots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1, j_2, \dots, j_d} \exp\left(\delta i 2\pi \sum_{l=1}^d j_l k_l / n_l\right)$$

for  $k_l = 0, \dots, n_l-1$  ( $l = 1, \dots, d$ ), where  $\sigma$  is a scale factor,  $\delta = -1$  for the forward transform, and  $\delta = +1$  for the inverse (backward) transform. In the forward transform, the input (periodic) sequence  $\{w_{j_1, j_2, \dots, j_d}\}$  belongs to the set of complex-valued sequences and real-valued sequences. Respective domains for the backward transform are represented by complex-valued sequences and complex-valued conjugate-even sequences.

The Intel® oneAPI Math Kernel Library (oneMKL) provides an interface for computing a discrete Fourier transform through the fast Fourier transform algorithm. Prefixes `Dfti` in function names and `DFTI` in the names of configuration parameters stand for Discrete Fourier Transform Interface.

The manual describes the following implementations of the fast Fourier transform functions available in Intel® oneAPI Math Kernel Library (oneMKL):

- Fast Fourier transform (FFT) functions for single-processor or shared-memory systems (see [FFT Functions](#))
- [Cluster FFT functions](#) for distributed-memory architectures (available only for Intel® 64 architectures)

---

### NOTE

Intel® oneAPI Math Kernel Library (oneMKL) also supports the FFTW3\* interfaces to the fast Fourier transform functionality for shared memory paradigm (SMP) systems.

---

Both FFT and Cluster FFT functions compute an FFT in five steps:

1. Allocate a fresh descriptor for the problem with a call to the `DftiCreateDescriptor` or `DftiCreateDescriptorDM` function. The descriptor captures the configuration of the transform, such as the dimensionality (or rank), sizes, number of transforms, memory layout of the input/output data (defined by strides), and scaling factors. Many of the configuration settings are assigned default values in this call which you might need to modify in your application.
2. Optionally adjust the descriptor configuration with a call to the `DftiSetValue` or `DftiSetValueDM` function as needed. Typically, you must carefully define the data storage layout for an FFT or the data distribution among processes for a Cluster FFT. The configuration settings of the descriptor, such as the default values, can be obtained with the `DftiGetValue` or `DftiGetValueDM` function.

3. Commit the descriptor with a call to the `DftiCommitDescriptor` or `DftiCommitDescriptorDM` function, that is, make the descriptor ready for the transform computation. Once the descriptor is committed, the parameters of the transform, such as the type and number of transforms, strides and distances, the type and storage layout of the data, and so on, are "frozen" in the descriptor.
4. Compute the transform with a call to the `DftiComputeForward/DftiComputeBackward` or `DftiComputeForwardDM/DftiComputeBackwardDM` functions as many times as needed. Because the descriptor is defined and committed separately, all that the compute functions do is take the input and output data and compute the transform as defined. To modify any configuration parameters for another call to a compute function, use `DftiSetValue` followed by `DftiCommitDescriptor` (`DftiSetValueDM` followed by `DftiCommitDescriptorDM`) or create and commit another descriptor.
5. Deallocate the descriptor with a call to the `DftiFreeDescriptor` or `DftiFreeDescriptorDM` function. This returns the memory internally consumed by the descriptor to the operating system.

All the above functions return an integer status value, which is zero upon successful completion of the operation. You can interpret a non-zero status with the help of the `DftiErrorClass` or `DftiErrorMessage` function.

The FFT functions support lengths with arbitrary factors. You can improve performance of the Intel® oneAPI Math Kernel Library (oneMKL) FFT if the length of your data vector permits factorization into powers of optimized radices. See the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for specific radices supported efficiently.

#### NOTE

The FFT functions assume the Cartesian representation of complex data (that is, the real and imaginary parts define a complex number). The Intel® oneAPI Math Kernel Library (oneMKL) Vector Mathematical Functions provide efficient tools for conversion to and from polar representation (see [Example "Conversion from Cartesian to polar representation of complex data"](#) and [Example "Conversion from polar to Cartesian representation of complex data"](#)).

#### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## FFT Functions

The fast Fourier transform function library of Intel® oneAPI Math Kernel Library (oneMKL) provides one-dimensional, two-dimensional, and multi-dimensional transforms (of up to seven dimensions) and offers both Fortran and C interfaces for all transform functions.

Table "FFT Functions in Intel® oneAPI Math Kernel Library (oneMKL)" lists FFT functions implemented in Intel® oneAPI Math Kernel Library (oneMKL):

#### FFT Functions in oneMKL

Function Name	Operation
Descriptor Manipulation Functions	
<code>DftiCreateDescriptor</code>	Allocates the descriptor data structure and initializes it with default configuration values.
<code>DftiCommitDescriptor</code>	Performs all initialization for the actual FFT computation.
<code>DftiFreeDescriptor</code>	Frees memory allocated for a descriptor.
<code>DftiCopyDescriptor</code>	Makes a copy of an existing descriptor.

Function Name	Operation
FFT Computation Functions	
<a href="#">DftiComputeForward</a>	Computes the forward FFT.
<a href="#">DftiComputeBackward</a>	Computes the backward FFT.
Descriptor Configuration Functions	
<a href="#">DftiSetValue</a>	Sets one particular configuration parameter with the specified configuration value.
<a href="#">DftiGetValue</a>	Gets the value of one particular configuration parameter.
Status Checking Functions	
<a href="#">DftiErrorClass</a>	Checks if the status reflects an error of a predefined class.
<a href="#">DftiErrorMessage</a>	Translates the numeric value of an error status into a message.

## FFT Interface

The Intel® oneAPI Math Kernel Library (oneMKL) FFT functions are provided with the Fortran and C interfaces. The materials presented in this section assume the availability of native complex types in C as they are specified in C9X.

To use the FFT functions, you need to include `mkl_dfti.h` in your C code.

The C interface provides the `DFTI_DESCRIPTOR_HANDLE` type, named constants of two enumeration types `DFTI_CONFIG_PARAM` and `DFTI_CONFIG_VALUE`, and functions, some of which accept different numbers of input arguments.

---

### NOTE

The current version of the library may not support some of the FFT functions or functionality. You can find the complete list of the implementation-specific exceptions in the Intel® oneAPI Math Kernel Library (oneMKL) Release Notes.

---

For the main categories of Intel® oneAPI Math Kernel Library (oneMKL) FFT functions, see [FFT Functions](#).

## Computing an FFT

You can find code examples that compute transforms in the [Fourier Transform Functions Code Examples](#).

Usually you can compute an FFT by five function calls (refer to the [usage model](#) for details). A single data structure, the descriptor, stores configuration parameters that can be changed independently.

The descriptor data structure, when created, contains information about the length and domain of the FFT to be computed, as well as the setting of several configuration parameters. Default settings for some of these parameters are as follows:

- Scale factor: none (that is,  $\sigma = 1$ )
- Number of data sets: one
- Data storage: contiguous
- Placement of results: in-place (the computed result overwrites the input data)

The default settings can be changed one at a time through the function [DftiSetValue](#) as illustrated in [Example "Changing Default Settings \(C\)"](#).

## Configuration Settings

Each of the configuration parameters is identified by a named constant in the `MKL_DFTI` module. These named constants have the enumeration type `DFTI_CONFIG_PARAM` and are declared in the `mkl_dfti.h` header file.

Though exposed in that header file, the configuration parameters `DFTI_FWD_DISTANCE` and `DFTI_BWD_DISTANCE` are specific to the DPC++ DFT routines (see the [Data Parallel C++ Developer Reference](#)): their use in another context is neither supported nor currently enabled. All other Intel® oneAPI Math Kernel Library (oneMKL) FFT configuration parameters are readable. Some of them are read-only, while others can be set using the [DftiCreateDescriptor](#) or [DftiSetValue](#) function.

Values of the configuration parameters fall into the following groups:

- Values that have native data types. For example, the number of simultaneous transforms requested has an integer value, while the scale factor for a forward transform is a floating-point number.
- Values that are discrete in nature and are provided in the `MKL_DFTI` module as named constants. For example, the domain of the forward transform requires values to be named constants. The named constants for configuration values have the enumeration type `DFTI_CONFIG_VALUE`.

The [Table "Configuration Parameters"](#) summarizes the information on configuration parameters, along with their types and values. For more details of each configuration parameter, see the subsection describing this parameter.

### Configuration Parameters

Configuration Parameter	Type/Value	Comments
<i>Most common configuration parameters, no default, must be set explicitly by <code>DftiCreateDescriptor</code></i>		
<code>DFTI_PRECISION</code>	Named constant <code>DFTI_SINGLE</code> or <code>DFTI_DOUBLE</code>	Precision of the computation.
<code>DFTI_FORWARD_DOMAIN</code>	Named constant <code>DFTI_COMPLEX</code> or <code>DFTI_REAL</code>	Type of the transform.
<code>DFTI_DIMENSION</code>	Integer scalar	Dimension of the transform.
<code>DFTI_LENGTHS</code>	Integer scalar/array	Lengths of each dimension.
<i>Common configuration parameters, settable by <code>DftiSetValue</code></i>		
<code>DFTI_PLACEMENT</code>	Named constant <code>DFTI_INPLACE</code> or <code>DFTI_NOT_INPLACE</code>	Defines whether the result overwrites the input data. Default value: <code>DFTI_INPLACE</code> .
<code>DFTI_FORWARD_SCALE</code>	Floating-point scalar	Scale factor for the forward transform. Default value: 1.0. Precision of the value should be the same as defined by <code>DFTI_PRECISION</code> .
<code>DFTI_BACKWARD_SCALE</code>	Floating-point scalar	Scale factor for the backward transform. Default value: 1.0. Precision of the value should be the same as defined by <code>DFTI_PRECISION</code> .
<code>DFTI_NUMBER_OF_USER_THREADS</code>	Integer scalar	This configuration parameter is no longer used and kept for compatibility with previous versions of Intel® oneAPI Math Kernel Library (oneMKL).

Configuration Parameter	Type/Value	Comments
<a href="#">DFTI_THREAD_LIMIT</a>	Integer scalar	Limits the number of threads for the <a href="#">DftiComputeForward</a> and <a href="#">DftiComputeBackward</a> . Default value: 0.
<a href="#">DFTI_DESCRIPTOR_NAME</a>	Character string	Assigns a name to a descriptor. Assumed length of the string is <a href="#">DFTI_MAX_NAME_LENGTH</a> . Default value: empty string.
<i>Data layout configuration parameters for single and multiple transforms. Settable by <a href="#">DftiSetValue</a></i>		
<a href="#">DFTI_INPUT_STRIDES</a>	Integer array	Defines the input data layout.  <b>NOTE</b> The default strides are set during creation of the descriptor based on the desired dimension and lengths. For more details, see <a href="#">DFTI_INPUT_STRIDES</a> , <a href="#">DFTI_OUTPUT_STRIDES</a> .
<a href="#">DFTI_OUTPUT_STRIDES</a>	Integer array	Defines the output data layout.  <b>NOTE</b> The default strides are set during creation of the descriptor based on the desired dimension and lengths. For more details, see <a href="#">DFTI_INPUT_STRIDES</a> , <a href="#">DFTI_OUTPUT_STRIDES</a> .
<a href="#">DFTI_NUMBER_OF_TRANSFORMS</a>	Integer scalar	Number of transforms. Default value: 1.
<a href="#">DFTI_INPUT_DISTANCE</a>	Integer scalar	Defines the distance between input data sets for multiple transforms. Default value: 0.
<a href="#">DFTI_OUTPUT_DISTANCE</a>	Integer scalar	Defines the distance between output data sets for multiple transforms. Default value: 0.
<a href="#">DFTI_COMPLEX_STORAGE</a>	Named constant <a href="#">DFTI_COMPLEX_COMPLEX</a> X or <a href="#">DFTI_REAL_REAL</a>	Defines whether the real and imaginary parts of data for a complex transform are interleaved in one array or split in two arrays. Default value: <a href="#">DFTI_COMPLEX_COMPLEX</a> .
<a href="#">DFTI_REAL_STORAGE</a>	Named constant <a href="#">DFTI_REAL_REAL</a>	Defines how real data for a real transform is stored. Only the <a href="#">DFTI_REAL_REAL</a> value is supported.
<a href="#">DFTI_CONJUGATE_EVEN_STORAGE</a>	Named constant <a href="#">DFTI_COMPLEX_COMPLEX</a> X or <a href="#">DFTI_COMPLEX_REAL</a>	Defines whether the complex data in the backward domain of a real transform is stored as complex elements or as real elements.

Configuration Parameter	Type/Value	Comments
		DFTI_COMPLEX_REAL is supported only for 1D transforms. The default value is DFTI_COMPLEX_COMPLEX.
DFTI_PACKED_FORMAT	Named constant DFTI_CCE_FORMAT, DFTI_CCS_FORMAT, DFTI_PACK_FORMAT, or DFTI_PERM_FORMAT	Defines the layout for the elements of the conjugate-even sequence in the backward domain of the real transform (in association with the configuration parameter DFTI_CONJUGATE_EVEN_STORAGE). The default value is DFTI_CCE_FORMAT.
<hr/>		
<b>NOTE</b> Transforms greater than 1D support only DFTI_CCE_FORMAT.		
<hr/>		
<i>Advanced configuration parameters, settable by DftiSetValue</i>		
DFTI_WORKSPACE	Named constant DFTI_ALLOW or DFTI_AVOID	Defines whether the library should prefer algorithms using additional memory. Default value: DFTI_ALLOW.
DFTI_ORDERING	Named constant DFTI_ORDERED or DFTI_BACKWARD_SCRAMBLED	Defines whether the result of a complex transform is ordered or permuted. Default value: DFTI_ORDERED.
DFTI_DESTROY_INPUT	Named constant DFTI_ALLOW or DFTI_AVOID	Defines whether the input data may be overwritten for out-of-place transforms. Default value: DFTI_AVOID.
<i>Read-Only configuration parameters</i>		
DFTI_COMMIT_STATUS	Named constant DFTI_UNCOMMITTED or DFTI_COMMITTED	Readiness of the descriptor for computation.
DFTI_VERSION	String	Version of Intel® oneAPI Math Kernel Library (oneMKL). Assumed length of the string is DFTI_VERSION_LENGTH.

## DFTI\_PRECISION

The configuration parameter DFTI\_PRECISION denotes the floating-point precision in which the transform is to be carried out. A setting of DFTI\_SINGLE stands for single precision, and a setting of DFTI\_DOUBLE stands for double precision. The data must be presented in this precision, the computation is carried out in this precision, and the result is delivered in this precision.

DFTI\_PRECISION does not have a default value. Set it explicitly by calling the DftiCreateDescriptor function.

To better understand configuration of the precision of transforms, refer to these examples in your Intel® oneAPI Math Kernel Library (oneMKL) directory:

```
./examples/dftc/source/basic_sp_complex_dft_1d.c
```

`./examples/dftc/source/basic_dp_complex_dft_1d.c`

## See Also

`DFTI_FORWARD_DOMAIN`

`DFTI_DIMENSION`, `DFTI_LENGTHS`

`DftiCreateDescriptor`

## DFTI\_FORWARD\_DOMAIN

The general form of a discrete Fourier transform is

$$z_{k_1, k_2, \dots, k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \dots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1, j_2, \dots, j_d} \exp\left(\delta i 2\pi \sum_{l=1}^d j_l k_l / n_l\right)$$

for  $k_l = 0, \dots, n_l-1$  ( $l = 1, \dots, d$ ), where  $\sigma$  is a scale factor,  $\delta = -1$  for the forward transform, and  $\delta = +1$  for the backward transform.

The Intel® oneAPI Math Kernel Library (oneMKL) implementation of the FFT algorithm, used for fast computation of discrete Fourier transforms, supports forward transforms on input sequences of two domains, as specified by the `DFTI_FORWARD_DOMAIN` configuration parameter: general complex-valued sequences (`DFTI_COMPLEX` domain) and general real-valued sequences (`DFTI_REAL` domain). The forward transform maps the forward domain to the corresponding backward domain, as shown in [Table "Correspondence of Forward and Backward Domain"](#).

The conjugate-even domain covers complex-valued sequences with the symmetry property:

$$x(k_1, k_2, \dots, k_d) = \text{conjugate}(x(n_1 - k_1, n_2 - k_2, \dots, n_d - k_d))$$

where the index arithmetic is performed modulo respective size, that is,

$$x(\dots, \text{expr}_s, \dots) \equiv x(\dots, \text{mod}(\text{expr}_s, n_s), \dots),$$

and therefore

$$x(\dots, n_s, \dots) \equiv x(\dots, 0, \dots).$$

Due to this property of conjugate-even sequences, only a part of such sequence is stored in the computer memory, as described in `DFTI_CONJUGATE_EVEN_STORAGE`.

## Correspondence of Forward and Backward Domain

Forward Domain	Implied Backward Domain
Complex ( <code>DFTI_COMPLEX</code> )	Complex ( <code>DFTI_COMPLEX</code> )
Real ( <code>DFTI_REAL</code> )	Conjugate-even

`DFTI_FORWARD_DOMAIN` does not have a default value. Set it explicitly by calling the `DftiCreateDescriptor` function.

To better understand usage of the `DFTI_FORWARD_DOMAIN` configuration parameter, you can refer to these examples in your Intel® oneAPI Math Kernel Library (oneMKL) directory:

`./examples/dftc/source/basic_sp_complex_dft_1d.c`

`./examples/dftc/source/basic_sp_real_dft_1d.c`

## See Also

`DFTI_PRECISION`

`DFTI_DIMENSION`, `DFTI_LENGTHS`

`DftiCreateDescriptor`

## DFTI\_DIMENSION, DFTI\_LENGTHS

The dimension of the transform is a positive integer value represented in an integer scalar of `MKL_LONG` data type. For a one-dimensional transform, the transform length is specified by a positive integer value represented in an integer scalar of `MKL_LONG` data type. For multi-dimensional ( $\geq 2$ ) transform, the lengths of each of the dimensions are supplied in an integer array (of `MKL_LONG` data type).

`DFTI_DIMENSION` and `DFTI_LENGTHS` do not have a default value. To set them, use the `DftiCreateDescriptor` function and not the `DftiSetValue` function.

To better understand usage of the `DFTI_DIMENSION` and `DFTI_LENGTHS` configuration parameters, you can refer to basic examples of one-, two-, and three-dimensional transforms in your Intel® oneAPI Math Kernel Library (oneMKL) directory. Naming conventions for the examples are self-explanatory. For example, refer to these examples of single-precision two-dimensional transforms:

```
./examples/dftc/source/basic_sp_real_dft_2d.c  
./examples/dftc/source/basic_sp_complex_dft_2d.c
```

## DFTI\_PLACEMENT

By default, the computational functions overwrite the input data with the output result. That is, the default setting of the configuration parameter `DFTI_PLACEMENT` is `DFTI_INPLACE`. You can change that by setting it to `DFTI_NOT_INPLACE`.

---

### NOTE

When the configuration parameter is set to `DFTI_NOT_INPLACE`, the input and output data sets must have no common elements.

---

To better understand usage of the `DFTI_PLACEMENT` configuration parameter, see this example in your Intel® oneAPI Math Kernel Library (oneMKL) directory:

```
./examples/dftc/source/config_placement.c
```

### See Also

[DftiSetValue](#)

## DFTI\_FORWARD\_SCALE, DFTI\_BACKWARD\_SCALE

The forward transform and backward transform are each associated with a scale factor  $\sigma$  of its own having the default value of 1. You can specify the scale factors using one or both of the configuration parameters `DFTI_FORWARD_SCALE` and `DFTI_BACKWARD_SCALE`. For example, for a one-dimensional transform of length  $n$ , you can use the default scale of 1 for the forward transform and set the scale factor for the backward transform to be  $1/n$ , thus making the backward transform the inverse of the forward transform.

Set the scale factor configuration parameter using a real floating-point data type of the same precision as the value for `DFTI_PRECISION`.

---

### NOTE

For inquiry of the scale factor with the `DftiGetValue` function, the `config_val` parameter must have the same floating-point precision as the descriptor.

---

## DFTI\_NUMBER\_OF\_USER\_THREADS

The `DFTI_NUMBER_OF_USER_THREADS` configuration parameter is no longer used and kept for compatibility with previous versions of Intel® oneAPI Math Kernel Library (oneMKL).

## See Also

[DftiSetValue](#)

## DFTI\_THREAD\_LIMIT

In some situations you may need to limit the number of threads that the `DftiComputeForward` and `DftiComputeBackward` functions use. For example, if more than one thread calls Intel® oneAPI Math Kernel Library (oneMKL), it might be important that the thread calling these functions does not oversubscribe computing resources (CPU cores). Similarly, a known limit of the maximum number of threads to be used in computations might help the `DftiCommitDescriptor` function to select a more optimal computation method.

Set the parameter `DFTI_THREAD_LIMIT` as follows:

- To a positive number, to specify the maximum number of threads to be used by the compute functions.
- To zero (the default value), to use the maximum number of threads permitted in Intel® oneAPI Math Kernel Library (oneMKL) FFT functions. See "Techniques to Set the Number of Threads" in the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for more information.

On an attempt to set a negative value, the `DftiSetValue` function returns an error and does not update the descriptor.

The value of the `DFTI_THREAD_LIMIT` configuration parameter returned by the `DftiGetValue` function is defined as follows:

- 1 if Intel® oneAPI Math Kernel Library (oneMKL) runs in the sequential mode
- Depends of the commit status of the descriptor if Intel® oneAPI Math Kernel Library (oneMKL) runs in a threaded mode:

Commit Status	Value
Not committed	The value of <code>DFTI_THREAD_LIMIT</code> set in a previous call to the <code>DftiSetValue</code> function or the default value
Committed	The upper limit on the number of threads used by the <code>DftiComputeForward</code> and <code>DftiComputeBackward</code> functions

To better understand usage of the `DFTI_THREAD_LIMIT` configuration parameter, see this example in your Intel® oneAPI Math Kernel Library (oneMKL) directory:

```
./examples/dftc/source/config_thread_limit.c
```

## DFTI\_INPUT\_STRIDES, DFTI\_OUTPUT\_STRIDES

The FFT interface provides configuration parameters that define the layout of multidimensional data in the computer memory. For  $d$ -dimensional data set  $X$  defined by dimensions  $N_1 \times N_2 \times \dots \times N_d$ , the layout describes where a particular element  $X(k_1, k_2, \dots, k_d)$  of the data set is located. The memory address of the element  $X(k_1, k_2, \dots, k_d)$  is expressed by the formula,

address of  $X(k_1, k_2, \dots, k_d)$  = the address stored in the pointer supplied to the compute function +  $(s_0 + k_1*s_1 + k_2*s_2 + \dots + k_d*s_d) * u$ ,

Where  $u$  is the number of bytes per element of the desired precision for the assumed data type in the corresponding domain (see Table "Assumed Element Types of the Input/Output Data" below), where  $s_0$  is the displacement, and  $s_1, \dots, s_d$  are generalized strides. The configuration parameters `DFTI_INPUT_STRIDES` and `DFTI_OUTPUT_STRIDES` enable you to get and set these values. The configuration value is an array of values  $(s_0, s_1, \dots, s_d)$  of `MKL_LONG` data type.

The `DFTI_FORWARD_DOMAIN`, `DFTI_COMPLEX_STORAGE`, and `DFTI_CONJUGATE_EVEN_STORAGE` configuration parameters define the type of the elements as shown in Table "Assumed Element Types of the Input/Output Data":

### Assumed Element Types of the Input/Output Data

Descriptor Configuration	Element Type in the Forward Domain	Element Type in the Backward Domain
<code>DFTI_FORWARD_DOMAIN=DFTI_COMPLEX</code> <code>DFTI_COMPLEX_STORAGE=DFTI_COMPLEX_COMPLEX</code>	Complex	Complex
<code>DFTI_FORWARD_DOMAIN=DFTI_COMPLEX</code> <code>DFTI_COMPLEX_STORAGE=DFTI_REAL_REAL</code>	Real	Real
<code>DFTI_FORWARD_DOMAIN=DFTI_REAL</code> <code>DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_REAL</code>	Real	Real
<code>DFTI_FORWARD_DOMAIN=DFTI_REAL</code> <code>DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX</code>	Real	Complex

The `DFTI_INPUT_STRIDES` configuration parameter defines the layout of the input data, while the element type is defined by the forward domain for the `DftiComputeForward` function and by the backward domain for the `DftiComputeBackward` function. The `DFTI_OUTPUT_STRIDES` configuration parameter defines the layout of the output data, while the element type is defined by the backward domain for the `DftiComputeForward` function and by the forward domain for `DftiComputeBackward` function.

#### NOTE

The `DFTI_INPUT_STRIDES` and `DFTI_OUTPUT_STRIDES` configuration parameters define the layout of input and output data, and not the forward-domain and backward-domain data. If the data layouts in forward domain and backward domain differ, set `DFTI_INPUT_STRIDES` and `DFTI_OUTPUT_STRIDES` explicitly and then commit the descriptor before calling computation functions.

For in-place transforms (`DFTI_PLACEMENT=DFTI_INPLACE`), the configuration set by `DFTI_OUTPUT_STRIDES` is ignored when the element types in the forward and backward domains are the same. If they are different, set `DFTI_OUTPUT_STRIDES` explicitly (even though the transform is in-place). Ensure a consistent configuration for in-place transforms, that is, the locations of the first elements on input and output must coincide in each dimension.

The FFT interface supports both positive and negative stride values. If you use negative strides, set the displacement of the data as follows:

$$s_0 = \sum_{i=1}^d (N_i - 1) \cdot \max(-s_i, 0).$$

The default setting of strides in a general multi-dimensional case assumes that the array that contains the data has no padding. The order of the strides depends on the programming language. For example:

```
MKL_LONG dims[] = { n_d, ..., n_2, n_1 };
DftiCreateDescriptor( &hand, precision, domain, d, dims );
// The above call assumes data declaration:  type X[n_d]...[n_2][n_1]
// Default strides are { 0, n_{d-1}*...*n_2*n_1, ..., n_2*n_1*1, n_1*1, 1 }
```

Note that in case of a real FFT (`DFTI_FORWARD_DOMAIN=DFTI_REAL`), where different data layouts in the backward domain are available (see [DFTI\\_PACKED\\_FORMAT](#)), the default value of the strides is not intuitive for the recommended CCE format (configuration setting `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX`). In case of an *in-place* real transform with the CCE format, set the strides explicitly, as follows:

```
MKL_LONG dims[] = { n_d, ..., n_2, n_1 };
MKL_LONG rstrides[] = { 0, 2*n_{d-1}*...*n_2*(n_1/2+1), ..., 2*n_2*(n_1/2+1), 2*(n_1/2+1), 1 };
MKL_LONG cstrides[] = { 0, n_{d-1}*...*n_2*(n_1/2+1), ..., n_2*(n_1/2+1), (n_1/2+1), 1 };
DftiCreateDescriptor( &hand, precision, DFTI_REAL, d, dims );
DftiSetValue(hand, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX);
// Set the strides appropriately for forward/backward transform
```

---

**Limitation Note** Transforms with the number of points  $N$  of a non-unit stride dimension exceeding  $2^{(27-p)} - 1$  for  $N$  a power-of-two, or  $2^{(23-p)} - 1$  for  $N$  not a power-of-two, are currently not supported, where  $p=0$  for single precision and  $p=1$  for double precision. If a descriptor is created (for example, using `DftiCreateDescriptor`) and set (for example, using `DftiSetValue`) to do such a transform, a `DFTI_1D_MEMORY_EXCEEDS_INT32` error is returned at commit time (for example, by `DftiCommitDescriptor`).

---

To better understand configuration of strides, you can also refer to these examples in your Intel® oneAPI Math Kernel Library (oneMKL) directory:

```
./examples/dftc/source/basic_sp_complex_dft_2d.c
./examples/dftc/source/basic_sp_complex_dft_3d.c

## DFTI\_NUMBER\_OF\_TRANSFORMS

If you need to perform a large number of identical FFTs, you can do this in a single call to a `DftiCompute*` function with the value of the `DFTI_NUMBER_OF_TRANSFORMS` configuration parameter equal to the actual number of the transforms. The default value of this parameter is 1. You can set this parameter to a positive integer value of the `MKL_LONG` data type. When setting the number of transforms to a value greater than one, you also need to specify the distance between the input data sets and the distance between the output data sets using one of the `DFTI_INPUT_DISTANCE` and `DFTI_OUTPUT_DISTANCE` configuration parameters or both.

---

### Important

- The data sets to be transformed must not have common elements.
  - All the sets of data must be located within the same memory block.
- 

To better understand usage of the `DFTI_NUMBER_OF_TRANSFORMS` configuration parameter, see this example in your Intel® oneAPI Math Kernel Library (oneMKL) directory:

```
./examples/dftc/source/config_number_of_transforms.c
```

## See Also

### FFT Computation Functions

`DFTI_INPUT_DISTANCE`, `DFTI_OUTPUT_DISTANCE`

`DftiSetValue`

## DFTI\_INPUT\_DISTANCE, DFTI\_OUTPUT\_DISTANCE

The FFT interface in Intel® oneAPI Math Kernel Library (oneMKL) enables computation of multiple transforms. To compute multiple transforms, you need to specify the data distribution of the multiple sets of data. The distance between the first data elements of consecutive data sets, `DFTI_INPUT_DISTANCE` for input data or `DFTI_OUTPUT_DISTANCE` for output data, specifies the distribution. The configuration setting is a value of `MKL_LONG` data type.

The default value for both configuration settings is one. You must set this parameter explicitly if the number of transforms is greater than one (see [DFTI\\_NUMBER\\_OF\\_TRANSFORMS](#)).

The distance is counted in elements of the data type defined by the descriptor configuration (rather than by the type of the variable passed to the computation functions). Specifically, the `DFTI_FORWARD_DOMAIN`, `DFTI_COMPLEX_STORAGE`, and `DFTI_CONJUGATE_EVEN_STORAGE` configuration parameters define the type of the elements as shown in [Table "Assumed Element Types of the Input/Output Data"](#).

---

### NOTE

The configuration parameters `DFTI_INPUT_DISTANCE` and `DFTI_OUTPUT_DISTANCE` define the distance within input and output data, and not within the forward-domain and backward-domain data. If the distances in the forward and backward domains differ, set `DFTI_INPUT_DISTANCE` and `DFTI_OUTPUT_DISTANCE` explicitly and then commit the descriptor before calling computation functions.

---

For in-place transforms (`DFTI_PLACEMENT=DFTI_INPLACE`), the configuration set by `DFTI_OUTPUT_DISTANCE` is ignored when the element types in the forward and backward domains are the same. If they are different, set `DFTI_OUTPUT_DISTANCE` explicitly (even though the transform is in-place). Ensure a consistent configuration for in-place transforms, that is, the locations of the data sets on input and output must coincide.

This example illustrates setting of the `DFTI_INPUT_DISTANCE` configuration parameter:

```
MKL_LONG dims[] = { nd, ..., n2, n1 };
MKL_LONG distance = nd*...*n2*n1;
DftiCreateDescriptor( &hand, precision, DFTI_COMPLEX, d, dims );
DftiSetValue( hand, DFTI_NUMBER_OF_TRANSFORMS, (MKL_LONG)howmany );
DftiSetValue( hand, DFTI_INPUT_DISTANCE, distance );
```

To better understand configuration of the distances, see these code examples in your Intel® oneAPI Math Kernel Library (oneMKL) directory:

```
./examples/dftc/source/config_number_of_transforms.c
```

## DFTI\_COMPLEX\_STORAGE, DFTI\_REAL\_STORAGE, DFTI\_CONJUGATE\_EVEN\_STORAGE

Depending on the value of the `DFTI_FORWARD_DOMAIN` configuration parameter, the implementation of FFT supports several storage schemes for input and output data (see document [3] for the rationale behind the definition of the storage schemes). The data elements are placed within contiguous memory blocks, defined with generalized strides (see [DFTI\\_INPUT\\_STRIDES](#), [DFTI\\_OUTPUT\\_STRIDES](#)). For multiple transforms, all sets of data should be located within the same memory block, and the data sets should be placed at the same distance from each other (see [DFTI\\_NUMBER\\_OF\\_TRANSFORMS](#) and [DFTI\\_INPUT\\_DISTANCE](#), [DFTI\\_OUTPUT\\_DISTANCE](#)).

---

### Tip

Avoid setting up multidimensional arrays with lists of pointers to one-dimensional arrays. Instead use a one-dimensional array with the explicit indexing to access the data elements.

---

[FFT Examples](#) demonstrate the usage of storage formats.

## DFTI\_COMPLEX\_STORAGE: storage schemes for a complex domain

For the `DFTI_COMPLEX` forward domain, both input and output sequences belong to a complex domain. In this case, the configuration parameter `DFTI_COMPLEX_STORAGE` can have one of the two values:

`DFTI_COMPLEX_COMPLEX` (default) or `DFTI_REAL_REAL`.

---

### NOTE

In the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface, storage schemes for a forward complex domain and the respective backward complex domain are the same.

---

With `DFTI_COMPLEX_COMPLEX` storage, complex-valued data sequences are referenced by a single complex parameter (array) `AZ` so that a complex-valued element  $z_{k_1, k_2, \dots, k_d}$  of the  $m$ -th  $d$ -dimensional sequence is located at `AZ[m*distance + stride0 + k1*stride1 + k2*stride2+ ... kd*strided]` as a structure consisting of the real and imaginary parts.

This code illustrates the use of the `DFTI_COMPLEX_COMPLEX` storage:

```
complex *AZ = malloc( N1*N2*N3*M * sizeof(AZ[0]) );
MKL_LONG ios[4], iodist; // input/output strides and distance
...
```

```
// on input: Z{k1,k2,k3,m}
// = AZ[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
status = DftiComputeForward( desc, AZ );
// on output: Z{k1,k2,k3,m}
// = AZ[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
```

With the `DFTI_REAL_REAL` storage, complex-valued data sequences are referenced by two real parameters `AR` and `AI` so that a complex-valued element  $z_{k_1, k_2, \dots, k_d}$  of the  $m$ -th sequence is computed as  $AR[m*distance + stride_0 + k_1*stride_1 + k_2*stride_2 + \dots + k_d*stride_d] + \sqrt{-1} * AI[m*distance + stride_0 + k_1*stride_1 + k_2*stride_2 + \dots + k_d*stride_d]$ .

This code illustrates the use of the `DFTI_REAL_REAL` storage:

```
float *AR = malloc( N1*N2*N3*M * sizeof(AR[0]) );
float *AI = malloc( N1*N2*N3*M * sizeof(AI[0]) );
MKL_LONG ios[4], iodist; // input/output strides and distance
...
// on input: Z{k1,...,kd,m}
// = AR[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
// + I*AI[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
status = DftiComputeForward( desc, AR, AI );
// on output: Z{k1,...,kd,m}
// = AR[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
// + I*AI[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
```

### DFTI\_REAL\_STORAGE: storage schemes for a real domain

The Intel® oneAPI Math Kernel Library (oneMKL) FFT interface supports only one configuration value for this storage scheme: `DFTI_REAL_REAL`. With the `DFTI_REAL_REAL` storage, real-valued data sequences in a real domain are referenced by one real parameter `AR` so that real-valued element of the  $m$ -th sequence is located as  $AR[m*distance + stride_0 + k_1*stride_1 + k_2*stride_2 + \dots + k_d*stride_d]$ .

### DFTI\_CONJUGATE\_EVEN\_STORAGE: storage scheme for a conjugate-even domain

The Intel® oneAPI Math Kernel Library (oneMKL) FFT interface supports two configuration values for this parameter: `DFTI_COMPLEX_COMPLEX` (default) and `DFTI_COMPLEX_REAL` (for 1D problems only). The conjugate-even symmetry of the data enables storing only about a half of the whole mathematical result, so that one part of it can be directly referenced in the memory while the other part can be reconstructed depending on the selected storage configuration.

With the `DFTI_COMPLEX_COMPLEX` storage, the complex-valued data sequences in the conjugate-even domain are referenced by one complex parameter `AZ` so that a complex-valued element  $z_{k_1, k_2, \dots, k_d}$  of the  $m$ -th sequence can be referenced or reconstructed as described below.

Consider a  $d$ -dimensional real-to-complex transform:

$$Z_{k_1, k_2, \dots, k_d} \equiv \sum_{n_1=0}^{N_1-1} \dots \sum_{n_d=0}^{N_d-1} R_{n_1, n_2, \dots, n_d} e^{\frac{-2\pi i}{N_1} k_1 \cdot n_1} \dots e^{\frac{-2\pi i}{N_d} k_d \cdot n_d}$$

Because the input sequence  $R$  is real-valued, the mathematical result  $Z$  has conjugate-even symmetry:

$$z_{k_1, k_2, \dots, k_d} = \text{conjugate}(z_{N_1-k_1, N_2-k_2, \dots, N_d-k_d}),$$

where index arithmetic is performed modulo the length of the respective dimension. Obviously, the first element of the result is real-valued:

$$z_{0, 0, \dots, 0} = \text{conjugate}(z_{0, 0, \dots, 0}).$$

For dimensions with even lengths, some of the other elements are real-valued too. For example, if  $N_s$  is even,  $z_0, 0, \dots, N_s/2, 0, \dots, 0 = \text{conjugate}(z_0, 0, \dots, N_s/2, 0, \dots, 0)$ .

With the conjugate-even symmetry, approximately a half of the result suffices to fully reconstruct it. For an arbitrary dimension  $h$ , it suffices to store elements  $z_{k_1, \dots, k_h, \dots, k_d}$  for the following indices:

- $k_h = 0, \dots, \lfloor N_h/2 \rfloor$
- $k_i = 0, \dots, N_i - 1$ , where  $i = 1, \dots, d$  and  $i \neq h$

The symmetry property enables reconstructing the remaining elements: for  $k_h = \lfloor N_h/2 \rfloor + 1, \dots, N_h - 1$ . In the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface, the halved dimension is the last dimension.

The following code illustrates usage of the `DFTI_COMPLEX_COMPLEX` storage for a conjugate-even domain:

```
float *AR = malloc( N1*N2*M * sizeof(AR[0]) );
complex *AZ = malloc( N1*(N2/2+1)*M * sizeof(AZ[0]) );
MKL_LONG is[3], os[3], idist, odist; // input and output strides and distance
...
// on input: R{k1,k2,m}
// = AR[is[0] + k1*is[1] + k2*is[2] + m*idist]
status = DftiComputeForward( desc, R, C );
// on output:
// for k2=0...N2/2: Z{k1,k2,m} = AZ[os[0]+k1*os[1]+k2*os[2]+m*odist]
// for k2=N2/2+1...N2-1: Z{k1,k2,m} = conj(AZ[os[0]+(N1-k1)%N1*os[1]
//                                     + (N2-k2)%N2*os[2]+m*odist])
```

For the backward transform, the input and output parameters and layouts exchange roles: set the strides describing the layout in the backward/forward domain as input/output strides, respectively. For example:

```
...
status = DftiSetValue( desc, DFTI_INPUT_STRIDES, fwd_domain_strides );
status = DftiSetValue( desc, DFTI_OUTPUT_STRIDES, bwd_domain_strides );
status = DftiCommitDescriptor( desc );
status = DftiComputeForward( desc, ... );
...
status = DftiSetValue( desc, DFTI_INPUT_STRIDES, bwd_domain_strides );
status = DftiSetValue( desc, DFTI_OUTPUT_STRIDES, fwd_domain_strides );
status = DftiCommitDescriptor( desc );
status = DftiComputeBackward( desc, ... );
```

### Important

For in-place transforms, ensure the first element of the input data has the same location as the first element of the output data for each dimension.

### DFTI\_PACKED\_FORMAT

The result of the forward transform of real data is a conjugate-even sequence. Due to the symmetry property, only a part of the complex-valued sequence is stored in memory. The combination of the `DFTI_PACKED_FORMAT` and `DFTI_CONJUGATE_EVEN_STORAGE` configuration parameters defines how the conjugate-even sequence data is packed. If `DFTI_CONJUGATE_EVEN_STORAGE` is set to `DFTI_COMPLEX_COMPLEX` (default), the only possible value of `DFTI_PACKED_FORMAT` is `DFTI_CCE_FORMAT`; this association of configuration parameters is supported for transforms of any dimension. For a description of the corresponding packed format, see [DFTI\\_CONJUGATE\\_EVEN\\_STORAGE](#). For one-dimensional transforms (only) with `DFTI_CONJUGATE_EVEN_STORAGE` set to `DFTI_COMPLEX_REAL`, the `DFTI_PACKED_FORMAT` configuration parameter must be `DFTI_CCS_FORMAT`, `DFTI_PACK_FORMAT`, or `DFTI_PERM_FORMAT`. The corresponding packed formats are explained and illustrated below.

## DFTI\_CCS\_FORMAT for One-dimensional Transforms

The following figure illustrates the storage of a one-dimensional (1D) size- $N$  conjugate-even sequence in a real array for the CCS, PACK, and PERM packed formats. The CCS format requires an array of size  $N+2$ , while the other formats require an array of size  $N$ . Zero-based indexing is used.

### Storage of a 1D Size- $N$ Conjugate-even Sequence in a Real Array

	n=	0	1	2	3	...	2L-2	2L-1	2L	2L+1	2L+2
CCS, N=2L		R <sub>0</sub>	0	R <sub>1</sub>	I <sub>1</sub>	...	R <sub>L-1</sub>	I <sub>L-1</sub>	R <sub>L</sub>	0	
PACK, N=2L		R <sub>0</sub>	R <sub>1</sub>	I <sub>1</sub>	R <sub>2</sub>	...	I <sub>L-1</sub>	R <sub>L</sub>			
PERM, N=2L		R <sub>0</sub>	R <sub>L</sub>	R <sub>1</sub>	I <sub>1</sub>	...	R <sub>L-1</sub>	I <sub>L-1</sub>			
CCS, N=2L+1		R <sub>0</sub>	0	R <sub>1</sub>	I <sub>1</sub>	...	R <sub>L-1</sub>	I <sub>L-1</sub>	R <sub>L</sub>	I <sub>L</sub>	not used
PACK, N=2L+1		R <sub>0</sub>	R <sub>1</sub>	I <sub>1</sub>	R <sub>2</sub>	...	I <sub>L-1</sub>	R <sub>L</sub>	I <sub>L</sub>		
PERM, N=2L+1		R <sub>0</sub>	R <sub>1</sub>	I <sub>1</sub>	R <sub>2</sub>	...	I <sub>L-1</sub>	R <sub>L</sub>	I <sub>L</sub>		

**NOTE** For storage of a one-dimensional conjugate-even sequence in a real array, CCS is in the same format as CCE.

The real and imaginary parts of the complex-valued conjugate-even sequence  $Z_k$  are located in a real-valued array AC as illustrated by figure "Storage of a 1D Size- $N$  Conjugate-even Sequence in a Real Array" and can be used to reconstruct the whole conjugate-even sequence as follows:

```
float *AR; // malloc( sizeof(float)*N )
float *AC; // malloc( sizeof(float)*(N+2) )
...
status = DftiSetValue( desc, DFTI_PACKED_FORMAT, DFTI_CCS_FORMAT );
...
// on input: R{k} = AR[k]
status = DftiComputeForward( desc, AR, AC ); // real-to-complex FFT
// on output:
// for k=0...N/2: Z{k} = AC[2*k+0] + I*AC[2*k+1]
// for k=N/2+1...N-1: Z{k} = AC[2*(N-k)%N + 0] - I*AC[2*(N-k)%N + 1]
```

## DFTI\_PACK\_FORMAT for One-dimensional Transforms

The real and imaginary parts of the complex-valued conjugate-even sequence  $Z_k$  are located in a real-valued array AC as illustrated by figure "Storage of a 1D Size- $N$  Conjugate-even Sequence in a Real Array" and can be used to reconstruct the whole conjugate-even sequence as follows:

```
float *AR; // malloc( sizeof(float)*N )
float *AC; // malloc( sizeof(float)*N )
...
status = DftiSetValue( desc, DFTI_PACKED_FORMAT, DFTI_PACK_FORMAT );
...
// on input: R{k} = AR[k]
status = DftiComputeForward( desc, AR, AC ); // real-to-complex FFT
// on output: Z{k} = re + I*im, where
```

```
// if (k == 0) {
//     re = AC[0];
//     im = 0;
// } else if (k == N-k) {
//     re = AC[2*k-1];
//     im = 0;
// } else if (k <= N/2) {
//     re = AC[2*k-1];
//     im = AC[2*k-0];
// } else {
//     re = AC[2*(N-k)-1];
//     im = -AC[2*(N-k)-0];
// }
```

## DFTI\_PERM\_FORMAT for One-dimensional Transforms

The real and imaginary parts of the complex-valued conjugate-even sequence  $Z_k$  are located in real-valued array AC as illustrated by figure ["Storage of a 1D Size-N Conjugate-even Sequence in a Real Array"](#) and can be used to reconstruct the whole conjugate-even sequence as follows:

```
float *AR; // malloc( sizeof(float)*N )
float *AC; // malloc( sizeof(float)*N )
...
status = DftiSetValue( desc, DFTI_PACKED_FORMAT, DFTI_PERM_FORMAT );
...
// on input: R{k} = AR[k]
status = DftiComputeForward( desc, AR, AC ); // real-to-complex FFT
// on output: Z{k} = re + I*im, where
// if (k == 0) {
//     re = AC[0];
//     im = 0;
// } else if (k == N-k) {
//     re = AC[1];
//     im = 0;
// } else if (k <= N/2) {
//     re = AC[2*k+0 - N%2];
//     im = AC[2*k+1 - N%2];
// } else {
//     re = AC[2*(N-k)+0 - N%2];
//     im = -AC[2*(N-k)+1 - N%2];
// }
```

## DFTI\_WORKSPACE

The computation step for some FFT algorithms requires a scratch space for permutation or other purposes. To manage the use of the auxiliary storage, Intel® oneAPI Math Kernel Library (oneMKL) enables you to set the configuration parameter `DFTI_WORKSPACE` with the following values:

<code>DFTI_ALLOW</code>	(default) Permits the use of the auxiliary storage.
<code>DFTI_AVOID</code>	Instructs Intel® oneAPI Math Kernel Library (oneMKL) to avoid using the auxiliary storage if possible.

## See Also

[DftiSetValue](#)

## DFTI\_COMMIT\_STATUS

The `DFTI_COMMIT_STATUS` configuration parameter indicates whether the descriptor is ready for computation. The parameter has two possible values:

<code>DFTI_UNCOMMITTED</code>	Default value, set after a successful call of <code>DftiCreateDescriptor</code> .
<code>DFTI_COMMITTED</code>	The value after a successful call to <code>DftiCommitDescriptor</code> .

A computation function called with an uncommitted descriptor returns an error.

You cannot directly set this configuration parameter in a call to `DftiSetValue`, but a change in the configuration of a committed descriptor may change the commit status of the descriptor to `DFTI_UNCOMMITTED`.

[DftiSetValue](#)

## DFTI\_ORDERING

Some FFT algorithms apply an explicit permutation stage that is time consuming [4]. The exclusion of this step is similar to applying an FFT to input data whose order is scrambled, or allowing a scrambled order of the FFT results. In applications such as convolution and power spectrum calculation, the order of result or data is unimportant and thus using scrambled data is acceptable if it leads to better performance. The following options are available in Intel® oneAPI Math Kernel Library (oneMKL):

- `DFTI_ORDERED`: Forward transform data ordered, backward transform data ordered (default option).
- `DFTI_BACKWARD_SCRAMBLED`: Forward transform data ordered, backward transform data scrambled.

Table "Scrambled Order Transform" tabulates the effect of this configuration setting.

### Scrambled Order Transform

	<code>DftiComputeForward</code>	<code>DftiComputeBackward</code>
<b>DFTI_ORDERING</b>	Input → Output	Input → Output
<code>DFTI_ORDERED</code>	ordered → ordered	ordered → ordered
<code>DFTI_BACKWARD_SCRAMBLED</code>	ordered → scrambled	scrambled → ordered

#### NOTE

The word "scrambled" in this table means "permit scrambled order if possible". In some situations permitting out-of-order data gives no performance advantage and an implementation may choose to ignore the suggestion.

## DFTI\_DESTROY\_INPUT

Allowing the library to overwrite your input data in case of out-of-place transforms may be an appropriate alternative to using `DFTI_WORKSPACE` to reduce the memory footprint of your application. Intel® oneAPI Math Kernel Library (oneMKL) enables you to communicate whether this is allowed via the configuration parameter `DFTI_DESTROY_INPUT`, with the following values:

<code>DFTI_AVOID</code>	The default. Instructs the library to leave the input data unchanged.
-------------------------	---

DFTI\_ALLOW

Permits the input data to be overwritten.

## FFT Descriptor Manipulation Functions

This category contains the following functions: create a descriptor, commit a descriptor, copy a descriptor, and free a descriptor.

### DftiCreateDescriptor

*Allocates the descriptor data structure and initializes it with default configuration values.*

### Syntax

```
status = DftiCreateDescriptor(&desc_handle, precision, forward_domain, dimension, length);
```

### Include Files

- `mkl.h`

### Input Parameters

Name	Type	Description
<i>precision</i>	enum	Precision of the transform: DFTI_SINGLE or DFTI_DOUBLE.
<i>forward_domain</i>	enum	Forward domain of the transform: DFTI_COMPLEX or DFTI_REAL.
<i>dimension</i>	MKL_LONG	Dimension of the transform.
<i>length</i>	MKL_LONG if <i>dimension</i> = 1. Array of type MKL_LONG otherwise.	Length of the transform for a one-dimensional transform. Lengths of each dimension for a multi-dimensional transform.

### Output Parameters

Name	Type	Description
<i>desc_handle</i>	DFTI_DESCRIPTOR_HANDLE	FFT descriptor.
<i>status</i>	MKL_LONG	Function completion status.

### Description

This function allocates memory for the descriptor data structure and instantiates it with all the default configuration settings for the precision, forward domain, dimension, and length of the desired transform. Because memory is allocated dynamically, the result is actually a pointer to the created descriptor. This function is slightly different from the "initialization" function that can be found in software packages or libraries that implement more traditional algorithms for computing an FFT. This function does not perform any significant computational work such as computation of twiddle factors. The function [DftiCommitDescriptor](#) does this work after the function [DftiSetValue](#) has set values of all necessary parameters.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

## Prototype

```

/* Note that the preprocessor definition provided below only illustrates
 * that the actual function called may be determined at compile time.
 * You can rely only on the declaration of the function.
 * For precise definition of the preprocessor macro, see the include/mkl_dfti.h
 * file in the Intel MKL directory.
 */
MKL_LONG DftiCreateDescriptor(DFTI_DESCRIPTOR_HANDLE * pHandle,
    enum DFTI_CONFIG_VALUE precision,
    enum DFTI_CONFIG_VALUE domain,
    MKL_LONG dimension, ... /* length/lengths */ );

#define DftiCreateDescriptor(desc, prec, domain, dim, sizes) \
    ((prec)==DFTI_SINGLE && (dim)==1) ? \
    some_actual_function_s1d((desc), (domain), (MKL_LONG)(sizes)) : \
    ...

```

Variable *length/lengths* is interpreted as a scalar (MKL\_LONG) or an array (MKL\_LONG\*), depending on the value of parameter *dimension*. If the value of parameter *precision* is known at compile time, an optimizing compiler retains only the call to the respective specific function, thereby reducing the size of the statically linked application. Avoid direct calls to the specific functions used in the preprocessor macro definition, because their interface may change in future releases of the library. If the use of the macro is undesirable, you can safely undefine it after inclusion of the Intel® oneAPI Math Kernel Library (oneMKL) FFT header file, as follows:

```

#include "mkl_dfti.h"
#undef DftiCreateDescriptor

```

## DftiCommitDescriptor

*Performs all initialization for the actual FFT computation.*

## Syntax

```
status = DftiCommitDescriptor(desc_handle);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>desc_handle</i>	DFTI_DESCRIPTOR_HANDLE	FFT descriptor.

## Output Parameters

Name	Type	Description
<code>desc_handle</code>	<code>DFTI_DESCRIPTOR_HANDLE</code>	Updated FFT descriptor.
<code>status</code>	<code>MKL_LONG</code>	Function completion status.

## Description

This function completes initialization of a previously created descriptor, which is required before the descriptor can be used for FFT computations. Typically, committing the descriptor performs all initialization that is required for the actual FFT computation. The initialization done by the function may involve exploring different factorizations of the input length to find the optimal computation method.

If you call the `DftiSetValue` function to change configuration parameters of a committed descriptor (see [Descriptor Configuration Functions](#)), you must re-commit the descriptor before invoking a computation function. Typically, a committal function call is immediately followed by a computation function call (see [FFT Computation Functions](#)).

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

## Prototype

```
MKL_LONG DftiCommitDescriptor( DFTI_DESCRIPTOR_HANDLE );
```

## DftiFreeDescriptor

*Frees the memory allocated for a descriptor.*

## Syntax

```
status = DftiFreeDescriptor(&desc_handle);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>desc_handle</code>	<code>DFTI_DESCRIPTOR_HANDLE</code>	FFT descriptor.

## Output Parameters

Name	Type	Description
<code>desc_handle</code>	<code>DFTI_DESCRIPTOR_HANDLE</code>	Memory for the FFT descriptor is released.
<code>status</code>	<code>MKL_LONG</code>	Function completion status.

## Description

This function frees all memory allocated for a descriptor.

**NOTE**

Memory allocation/deallocation inside Intel® oneAPI Math Kernel Library (oneMKL) is managed by Intel® oneAPI Math Kernel Library (oneMKL) memory management software. So, even after successful completion of `FreeDescriptor`, the memory space may continue being allocated for the application because the memory management software sometimes does not return the memory space to the OS, but considers the space free and can reuse it for future memory allocation. See [Example `mkl\_free\_buffers`: Usage with FFT Functions](#) on how to use Intel® oneAPI Math Kernel Library (oneMKL) memory management software and release memory to the OS.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

**Prototype**

```
MKL_LONG DftiFreeDescriptor( DFTI_DESCRIPTOR_HANDLE * );
```

**DftiCopyDescriptor**

*Makes a copy of an existing descriptor.*

**Syntax**

```
status = DftiCopyDescriptor(desc_handle_original, &desc_handle_copy);
```

**Include Files**

- `mkl.h`

**Input Parameters**

Name	Type	Description
<code>desc_handle_original</code>	<code>DFTI_DESCRIPTOR_HANDLE</code>	The FFT descriptor to copy.
	<code>DFTI_DESCRIPTOR_HANDLE</code>	The FFT descriptor to copy.

**Output Parameters**

Name	Type	Description
<code>dfti_handle_dst</code>	<code>DFTI_DESCRIPTOR_HANDLE</code>	The copy of the FFT descriptor.
<code>status</code>	<code>MKL_LONG</code>	Function completion status.

**Description**

This function makes a copy of an existing descriptor. The resulting descriptor `desc_handle_copy` and the existing descriptor `desc_handle_original` specify the same configuration of the transform, but do not have any memory areas in common ("deep copy").

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

## Prototype

```
MKL_LONG DftiCopyDescriptor( DFTI_DESCRIPTOR_HANDLE, DFTI_DESCRIPTOR_HANDLE * );
```

## FFT Descriptor Configuration Functions

This category contains the following functions: the value setting function [DftiSetValue](#) sets one particular configuration parameter to an appropriate value, and the value-getting function [DftiGetValue](#) reads the value of one particular configuration parameter. While all configuration parameters are readable, you cannot set a few of them. Some of these contain fixed information of a particular implementation such as version number, or dynamic information, which is derived by the implementation during execution of one of the functions. See [Configuration Settings](#) for details.

### DftiSetValue

*Sets one particular configuration parameter with the specified configuration value.*

#### Syntax

```
status = DftiSetValue(desc_handle, config_param, config_val);
```

#### Include Files

- `mkl.h`

#### Input Parameters

Name	Type	Description
<code>desc_handle</code>	<code>DFTI_DESCRIPTOR_HANDLE</code>	FFT descriptor.
<code>config_param</code>	enum	Configuration parameter.
<code>config_val</code>	Depends on the configuration parameter.	Configuration value.

#### Output Parameters

Name	Type	Description
<code>desc_handle</code>	<code>DFTI_DESCRIPTOR_HANDLE</code>	Updated FFT descriptor.
<code>status</code>	<code>MKL_LONG</code>	Function completion status.

#### Description

This function sets one particular configuration parameter with the specified configuration value. Each configuration parameter is a named constant, and the configuration value must have the corresponding type, which can be a named constant or a native type. For available configuration parameters and the corresponding configuration values, see:

- [DFTI\\_PRECISION](#)
- [DFTI\\_FORWARD\\_DOMAIN](#)
- [DFTI\\_DIMENSION](#), [DFTI\\_LENGTHS](#)
- [DFTI\\_PLACEMENT](#)
- [DFTI\\_FORWARD\\_SCALE](#), [DFTI\\_BACKWARD\\_SCALE](#)

- [DFTI\\_THREAD\\_LIMIT](#)
- [DFTI\\_INPUT\\_STRIDES, DFTI\\_OUTPUT\\_STRIDES](#)
- [DFTI\\_NUMBER\\_OF\\_TRANSFORMS](#)
- [DFTI\\_INPUT\\_DISTANCE, DFTI\\_OUTPUT\\_DISTANCE](#)
- [DFTI\\_COMPLEX\\_STORAGE, DFTI\\_REAL\\_STORAGE, DFTI\\_CONJUGATE\\_EVEN\\_STORAGE](#)
- [DFTI\\_PACKED\\_FORMAT](#)
- [DFTI\\_WORKSPACE](#)
- [DFTI\\_ORDERING](#)
- [DFTI\\_DESTROY\\_INPUT](#)

You cannot use the `DftiSetValue` function to change configuration parameters `DFTI_FORWARD_DOMAIN`, `DFTI_PRECISION`, `DFTI_DIMENSION`, and `DFTI_LENGTHS`. Use the `DftiCreateDescriptor` function to set them.

Function calls needed to configure an FFT descriptor for a particular call to an FFT computation function are summarized in [Configuring and Computing an FFT in C C++](#).

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

## Prototype

```
MKL_LONG DftiSetValue( DFTI_DESCRIPTOR_HANDLE, DFTI_CONFIG_PARAM , ... );
```

## See Also

[Configuration Settings](#) for more information on configuration parameters.

[DftiCreateDescriptor](#)

[DftiGetValue](#)

## DftiGetValue

*Gets the configuration value of one particular configuration parameter.*

## Syntax

```
status = DftiGetValue(desc_handle, config_param, &config_val);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>desc_handle</code>	<code>DFTI_DESCRIPTOR_HANDLE</code>	FFT descriptor.
<code>config_param</code>	enum	Configuration parameter. See <a href="#">Table "Configuration Parameters"</a> for allowable values of <code>config_param</code> .

## Output Parameters

Name	Type	Description
<code>config_val</code>	Depends on the configuration parameter.	Configuration value.
<code>status</code>	MKL_LONG	Function completion status.

## Description

This function gets the configuration value of one particular configuration parameter. Each configuration parameter is a named constant, and the configuration value must have the corresponding type, which can be a named constant or a native type. For available configuration parameters and the corresponding configuration values, see:

- `DFTI_PRECISION`
- `DFTI_FORWARD_DOMAIN`

- `DFTI_PACKED_FORMAT`
- `DFTI_WORKSPACE`
- `DFTI_COMMIT_STATUS`
- `DFTI_ORDERING`
- `DFTI_DESTROY_INPUT`

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

## Prototype

```
MKL_LONG DftiGetValue( DFTI_DESCRIPTOR_HANDLE,
DFTI_CONFIG_PARAM ,
... );
```

[Configuration Settings](#) for more information on configuration parameters.

`DftiSetValue`

## FFT Computation Functions

This category contains the following functions: compute the forward transform and compute the backward transform.

### **DftiComputeForward**

*Computes the forward FFT.*

### Syntax

```
status = DftiComputeForward(desc_handle, x_inout);
```

```

status = DftiComputeForward(desc_handle, x_in, y_out);
status = DftiComputeForward(desc_handle, xre_inout, xim_inout);
status = DftiComputeForward(desc_handle, xre_in, xim_in, yre_out, yim_out);

```

## Input Parameters

Name	Type	Description
<i>desc_handle</i>	DFTI_DESCRIPTOR_HANDLE	FFT descriptor.
<i>x_inout, x_in</i>	Array of type <code>float</code> or <code>double</code> depending on the precision of the transform.	Data to be transformed in case of a real forward domain or, in the case of a complex forward domain in association with <code>DFTI_COMPLEX_COMPLEX</code> , set for <code>DFTI_COMPLEX_STORAGE</code> .
<i>xre_inout, xim_inout, xre_in, xim_in</i>	Array of type <code>float</code> or <code>double</code> depending on the precision of the transform.	Real and imaginary parts of the data to be transformed in the case of a complex forward domain.

The suffix in parameter names corresponds to the value of the configuration parameter `DFTI_PLACEMENT` as follows:

- *\_inout* to `DFTI_INPLACE`
- *\_in* to `DFTI_NOT_INPLACE`

## Output Parameters

Name	Type	Description
<i>y_out</i>	Array of type <code>float</code> or <code>double</code> depending on the precision of the transform.	The transformed data in case of a real backward domain or, in the case of a complex forward domain in association with <code>DFTI_COMPLEX_COMPLEX</code> , set for <code>DFTI_COMPLEX_STORAGE</code> .
<i>xre_inout, xim_inout, yre_out, yim_out</i>	Array of type <code>float</code> or <code>double</code> depending on the precision of the transform.	Real and imaginary parts of the transformed data in the case of a complex forward domain in association with <code>DFTI_REAL_REAL</code> set for <code>DFTI_COMPLEX_STORAGE</code> .
<i>status</i>	MKL_LONG	Function completion status.

The suffix in parameter names corresponds to the value of the configuration parameter `DFTI_PLACEMENT` as follows:

- *\_inout* to `DFTI_INPLACE`
- *\_out* to `DFTI_NOT_INPLACE`

## Include Files

- `mkl.h`

## Description

The `DftiComputeForward` function accepts the descriptor handle parameter and one or more data parameters. Given a successfully configured and committed descriptor, this function computes the forward FFT, that is, the [transform](#) with the minus sign in the exponent,  $\delta = -1$ .

The `DFTI_COMPLEX_STORAGE`, `DFTI_REAL_STORAGE`, and `DFTI_CONJUGATE_EVEN_STORAGE` configuration parameters define the layout of the input and output data and must be properly set in a call to the `DftiSetValue` function. The forward domain and the precision of the transform are determined by the configuration settings `DFTI_FORWARD_DOMAIN` and `DFTI_PRECISION`, which are during construction of the descriptor.

The FFT descriptor must be properly configured prior to the function call. Function calls needed to configure an FFT descriptor for a particular call to an FFT computation function are summarized in [Configuring and Computing an FFT in C C++](#).

The number and types of the data parameters that the function requires may vary depending on the configuration of the descriptor. This variation is accommodated by variable parameters.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

## Prototype

```
MKL_LONG DftiComputeForward( DFTI_DESCRIPTOR_HANDLE, void*, ... );
```

## DftiComputeBackward

*Computes the backward FFT.*

---

## Syntax

```
status = DftiComputeBackward(desc_handle, x_inout);
```

```
status = DftiComputeBackward(desc_handle, y_in, x_out);
```

```
status = DftiComputeBackward(desc_handle, xre_inout, xim_inout);
```

```
status = DftiComputeBackward(desc_handle, yre_in, yim_in, xre_out, xim_out);
```

## Input Parameters

Name	Type	Description
<code>desc_handle</code>	<code>DFTI_DESCRIPTOR_HANDLE</code>	FFT descriptor.

Name	Type	Description
<i>x_inout, y_in</i>	Array of type <code>float</code> or <code>double</code> depending on the precision of the transform.	Data to be transformed in case of a real forward domain or, in the case of a complex forward domain in association with <code>DFTI_COMPLEX_COMPLEX</code> , set for <code>DFTI_COMPLEX_STORAGE</code> .
<i>xre_inout, xim_inout, yre_in, yim_in</i>	Array of type <code>float</code> or <code>double</code> depending on the precision of the transform.	Real and imaginary parts of the data to be transformed in the case of a complex forward domain in association with <code>DFTI_REAL_REAL</code> set for <code>DFTI_COMPLEX_STORAGE</code> .

The suffix in parameter names corresponds to the value of the configuration parameter `DFTI_PLACEMENT` as follows:

- *\_inout* to `DFTI_INPLACE`
- *\_in* to `DFTI_NOT_INPLACE`

## Output Parameters

Name	Type	Description
<i>x_out</i>	Array of type <code>float</code> or <code>double</code> depending on the precision of the transform.	The transformed data in case of a real forward domain or, in the case of a complex forward domain in association with <code>DFTI_COMPLEX_COMPLEX</code> , set for <code>DFTI_COMPLEX_STORAGE</code> .
<i>xre_inout, xim_inout, xre_out, xim_out</i>	Array of type <code>float</code> or <code>double</code> depending on the precision of the transform.	Real and imaginary parts of the transformed data in the case of a complex forward domain in association with <code>DFTI_REAL_REAL</code> set for <code>DFTI_COMPLEX_STORAGE</code> .
<i>status</i>	<code>MKL_LONG</code>	Function completion status.

The suffix in parameter names corresponds to the value of the configuration parameter `DFTI_PLACEMENT` as follows:

- *\_inout* to `DFTI_INPLACE`
- *\_out* to `DFTI_NOT_INPLACE`

## Include Files

- `mkl.h`

## Description

The function accepts the descriptor handle parameter and one or more data parameters. Given a successfully configured and committed descriptor, the `DftiComputeBackward` function computes the inverse FFT, that is, the [transform](#) with the plus sign in the exponent,  $\delta = +1$ .

The `DFTI_COMPLEX_STORAGE`, `DFTI_REAL_STORAGE`, and `DFTI_CONJUGATE_EVEN_STORAGE` configuration parameters define the layout of the input and output data and must be properly set in a call to the `DftiSetValue` function. The forward domain and the precision of the transform are determined by the configuration settings `DFTI_FORWARD_DOMAIN` and `DFTI_PRECISION`, which are during construction of the descriptor.

The FFT descriptor must be properly configured prior to the function call. Function calls needed to configure an FFT descriptor for a particular call to an FFT computation function are summarized in [Configuring and Computing an FFT in C C++](#).

The number and types of the data parameters that the function requires may vary depending on the configuration of the descriptor. This variation is accommodated by variable parameters.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

## Prototype

```
MKL_LONG DftiComputeBackward( DFTI_DESCRIPTOR_HANDLE, void *, ... );

### Configuring and Computing an FFT in C/C++

The table below summarizes information on configuring and computing an FFT in C/C++ for all kinds of transforms and possible combinations of input and output domains.

FFT to Compute	Input Data	Output Data	Required FFT Function Calls
Complex-to-complex, in-place, forward or backward	Interleaved complex numbers	Interleaved complex numbers	<pre>/* Configure a Descriptor */ status = DftiCreateDescriptor(&amp;hand, &lt;precision&gt;, DFTI_COMPLEX, &lt;dimension&gt;, &lt;sizes&gt;); status = DftiCommitDescriptor(hand);  /* Compute an FFT */ /* forward FFT */ status = DftiComputeForward(hand, X_inout); /* or backward FFT */ status = DftiComputeBackward(hand, X_inout);</pre>
Complex-to-complex, out-of-place,	Interleaved complex numbers	Interleaved complex numbers	<pre>/* Configure a Descriptor */ status = DftiCreateDescriptor(&amp;hand, &lt;precision&gt;, DFTI_COMPLEX, &lt;dimension&gt;,</pre>

FFT to Compute	Input Data	Output Data	Required FFT Function Calls
forward or backward			<pre> &lt;sizes&gt;; status = DftiSetValue(hand, DFTI_PLACEMENT, DFTI_NOT_INPLACE); status = DftiCommitDescriptor(hand);  /* Compute an FFT */ /* forward FFT */ status = DftiComputeForward(hand, X_in, Y_out); /* or backward FFT */ status = DftiComputeBackward(hand, X_in, Y_out); </pre>
Complex-to-complex, in-place, forward or backward	Split-complex numbers	Split-complex numbers	<pre> /* Configure a Descriptor */ status = DftiCreateDescriptor(&amp;hand, &lt;precision&gt;, DFTI_COMPLEX, &lt;dimension&gt;, &lt;sizes&gt;); status = DftiSetValue(hand, DFTI_COMPLEX_STORAGE, DFTI_REAL_REAL); status = DftiCommitDescriptor(hand);  /* Compute an FFT */ /* forward FFT */ status = DftiComputeForward(hand, Xre_inout, Xim_inout); /* or backward FFT */ status = DftiComputeBackward(hand, Xre_inout, Xim_inout); </pre>

Real-to-complex, in-place, forward	Real numbers	Numbers in the CCE format	<pre> /* Configure a Descriptor */ status = DftiCreateDescriptor(&amp;hand, &lt;precision&gt;, DFTI_REAL, &lt;dimension&gt;, &lt;sizes&gt;); status = DftiSetValue(hand, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX); status = DftiSetValue(hand, </pre>

FFT to Compute	Input Data	Output Data	Required FFT Function Calls
			<pre> DFTI_PACKED_FORMAT, DFTI_CCE_FORMAT); status = DftiSetValue(hand, DFTI_INPUT_STRIDES, &lt;real_strides&gt;); status = DftiSetValue(hand, DFTI_OUTPUT_STRIDES, &lt;complex_strides&gt;); status = DftiCommitDescriptor(hand);  /* Compute an FFT */ status = DftiComputeForward(hand, X_inout); </pre>
Real-to-complex, out-of-place, forward	Real numbers	Numbers in the CCE format	<pre> /* Configure a Descriptor */ status = DftiCreateDescriptor(&amp;hand, &lt;precision&gt;, DFTI_REAL, &lt;dimension&gt;, &lt;sizes&gt;); status = DftiSetValue(hand, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX); status = DftiSetValue(hand, DFTI_PACKED_FORMAT, DFTI_CCE_FORMAT); status = DftiSetValue(hand, DFTI_PLACEMENT, DFTI_NOT_INPLACE); status = DftiSetValue(hand, DFTI_INPUT_STRIDES, &lt;real_strides&gt;); status = DftiSetValue(hand, DFTI_OUTPUT_STRIDES, &lt;complex_strides&gt;); status = DftiCommitDescriptor(hand);  /* Compute an FFT */ status = DftiComputeForward(hand, X_in, Y_out); </pre>
Complex-to-real, in-place, backward	Numbers in the CCE format	Real numbers	<pre> /* Configure a Descriptor */ status = DftiCreateDescriptor(&amp;hand, &lt;precision&gt;, DFTI_REAL, &lt;dimension&gt;, &lt;sizes&gt;); status = DftiSetValue(hand, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX); status = DftiSetValue(hand, DFTI_PACKED_FORMAT, DFTI_CCE_FORMAT); status = DftiSetValue(hand, DFTI_INPUT_STRIDES, &lt;complex_strides&gt;); status = DftiSetValue(hand, DFTI_OUTPUT_STRIDES, &lt;real_strides&gt;); status = DftiCommitDescriptor(hand);  /* Compute an FFT */ status = DftiComputeBackward(hand, X_inout); </pre>
Complex-to-real, out-of-place, backward	Numbers in the CCE format	Real numbers	<pre> /* Configure a Descriptor */ status = DftiCreateDescriptor(&amp;hand, &lt;precision&gt;, DFTI_REAL, &lt;dimension&gt;, &lt;sizes&gt;); status = DftiSetValue(hand, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX); </pre>

FFT to Compute	Input Data	Output Data	Required FFT Function Calls
			<pre> status = DftiSetValue(hand, DFTI_PLACEMENT, DFTI_NOT_INPLACE); status = DftiSetValue(hand, DFTI_PACKED_FORMAT, DFTI_CCE_FORMAT); status = DftiSetValue(hand, DFTI_INPUT_STRIDES, &lt;complex_strides&gt;); status = DftiSetValue(hand, DFTI_OUTPUT_STRIDES, &lt;real_strides&gt;); status = DftiCommitDescriptor(hand);  /* Compute an FFT */ status = DftiComputeBackward(hand, X_in, Y_out); </pre>

You can find C programs that illustrate configuring and computing FFTs in the `examples/dftc/` subdirectory of your Intel® oneAPI Math Kernel Library (oneMKL) directory.

## Status Checking Functions

All of the descriptor manipulation, FFT computation, and descriptor configuration functions return an integer value denoting the status of the operation. The functions in this category check that status. The first function is a logical function that checks whether the status reflects an error of a predefined class, and the second is an error message function that returns a character string.

### DftiErrorClass

*Checks whether the status reflects an error of a predefined class.*

### Syntax

```
predicate = DftiErrorClass(status, error_class);
```

### Include Files

- `mkl.h`

### Input Parameters

Name	Type	Description
<code>status</code>	<code>MKL_LONG</code>	Completion status of a fast Fourier transform (FFT) function.
<code>error_class</code>	<code>MKL_LONG</code>	Predefined error class.

### Output Parameters

Name	Type	Description
<code>predicate</code>	<code>MKL_LONG</code>	Result of checking.

## Description

The FFT interface in Intel® oneAPI Math Kernel Library (oneMKL) provides a set of predefined error classes listed in [Table "Predefined Error Classes"](#). They are named constants and have the type `MKL_LONG`.

## Predefined Error Classes

Named Constants	Comments
DFTI_NO_ERROR	No error. The zero status belongs to this class.
DFTI_MEMORY_ERROR	Usually associated with memory allocation.
DFTI_INVALID_CONFIGURATION	Invalid settings in one or more configuration parameters.
DFTI_INCONSISTENT_CONFIGURATION	Inconsistent configuration or input parameters.
DFTI_NUMBER_OF_THREADS_ERROR	Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function).
DFTI_MULTITHREADED_ERROR	Usually associated with a value that OMP routines return in case of errors.
DFTI_BAD_DESCRIPTOR	Descriptor is unusable for computation.
DFTI_UNIMPLEMENTED	Unimplemented legitimate settings; implementation dependent.
DFTI_MKL_INTERNAL_ERROR	Internal library error.
DFTI_1D_LENGTH_EXCEEDS_INT32	Length of one of the dimensions exceeds $2^{32} - 1$ (4 bytes).
DFTI_1D_MEMORY_EXCEEDS_INT32	Data size of one of the transforms exceeds $2^{31} - 1$ bytes.

### NOTE

Use `DFTI_1D_MEMORY_EXCEEDS_INT32` instead of `DFTI_1D_LENGTH_EXCEEDS_INT32` for better accuracy.

The `DftiErrorClass` function returns a non-zero value if the status belongs to the predefined error class. To check whether a function call was successful, call `DftiErrorClass` with a specific error class. However, the zero value of the status belongs to the `DFTI_NO_ERROR` class and thus the zero status indicates successful completion of an operation. See [Example "Using Status Checking Functions"](#) for an illustration of correct use of the status checking functions.

### NOTE

It is incorrect to directly compare a status with a predefined class.

## Prototype

```
MKL_LONG DftiErrorClass( MKL_LONG , MKL_LONG );
```

## DftiErrorMessage

*Generates an error message.*

## Syntax

```
error_message = DftiErrorMessage(status);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>status</code>	<code>MKL_LONG</code>	Completion status of a function.

## Output Parameters

Name	Type	Description
<code>error_message</code>	Array of <code>char</code>	The character string with the error message.

## Description

The error message function generates an error message character string. The function returns a pointer to a constant character string, that is, a character array with terminating '\0' character, and you do not need to free this pointer.

[Example Using Status Checking Function](#) shows how this function can be used.

## Prototype

```
char *DftiErrorMessage( MKL_LONG );
```

## Cluster FFT Functions

This section describes the cluster Fast Fourier Transform (FFT) functions implemented in Intel® oneAPI Math Kernel Library (oneMKL).

---

**NOTE**

These functions are available only for Intel® 64 architectures.

---

The cluster FFT function library was designed to perform fast Fourier transforms on a cluster, that is, a group of computers interconnected via a network. Each computer (node) in the cluster has its own memory and processor(s). Data interchanges between the nodes are provided by the network.

One or more processes may be running in parallel on each cluster node. To organize communication between different processes, the cluster FFT function library uses the Message Passing Interface (MPI). To avoid dependence on a specific MPI implementation (for example, MPICH, Intel® MPI, and others), the library works with MPI via a message-passing library for linear algebra called BLACS.

Cluster FFT functions of Intel® oneAPI Math Kernel Library (oneMKL) provide one-dimensional, two-dimensional, and multi-dimensional (up to the order of 7) functions and both Fortran and C interfaces for all transform functions.

To develop applications using the cluster FFT functions, you should have basic skills in MPI programming.

The interfaces for the Intel® oneAPI Math Kernel Library (oneMKL) cluster FFT functions are similar to the corresponding interfaces for the conventional Intel® oneAPI Math Kernel Library (oneMKL) [FFT functions](#). Refer there for details not explained in this section.

Table "Cluster FFT Functions in Intel® oneAPI Math Kernel Library (oneMKL)" lists cluster FFT functions implemented in Intel® oneAPI Math Kernel Library (oneMKL):

### Cluster FFT Functions in oneMKL

Function Name	Operation
Descriptor Manipulation Functions	
<code>DftiCreateDescriptorDM</code>	Allocates memory for the descriptor data structure and preliminarily initializes it.
<code>DftiCommitDescriptorDM</code>	Performs all initialization for the actual FFT computation.
<code>DftiFreeDescriptorDM</code>	Frees memory allocated for a descriptor.
FFT Computation Functions	
<code>DftiComputeForwardDM</code>	Computes the forward FFT.
<code>DftiComputeBackwardDM</code>	Computes the backward FFT.
Descriptor Configuration Functions	
<code>DftiSetValueDM</code>	Sets one particular configuration parameter with the specified configuration value.
<code>DftiGetValueDM</code>	Gets the value of one particular configuration parameter.

### Computing Cluster FFT

The Intel® oneAPI Math Kernel Library (oneMKL) cluster FFT functions are provided with Fortran and C interfaces.

Cluster FFT computation is performed by `DftiComputeForwardDM` and `DftiComputeBackwardDM` functions, called in a program using MPI, which will be referred to as MPI program. After an MPI program starts, a number of processes are created. MPI identifies each process by its rank. The processes are independent of one another and communicate via MPI. A function called in an MPI program is invoked in all the processes. Each process manipulates data according to its rank. Input or output data for a cluster FFT transform is a sequence of real or complex values. A cluster FFT computation function operates on the local part of the input data, that is, some part of the data to be operated in a particular process, as well as generates local part of the output data. While each process performs its part of computations, running in parallel and communicating through MPI, the processes perform the entire FFT computation. FFT computations using the Intel® oneAPI Math Kernel Library (oneMKL) cluster FFT functions are typically effected by a number of steps listed below:

1. Initiate MPI by calling `MPI_Init` (the function must be called prior to calling any FFT function and any MPI function).
2. Allocate memory for the descriptor and create it by calling `DftiCreateDescriptorDM`.
3. Specify one of several values of configuration parameters by one or more calls to `DftiSetValueDM`.
4. Obtain values of configuration parameters needed to create local data arrays; the values are retrieved by calling `DftiGetValueDM`.
5. Initialize the descriptor for the FFT computation by calling `DftiCommitDescriptorDM`.
6. Create arrays for local parts of input and output data and fill the local part of input data with values. (For more information, see [Distributing Data among Processes](#).)
7. Compute the transform by calling `DftiComputeForwardDM` or `DftiComputeBackwardDM`.
8. Gather local output data into the global array using MPI functions. (This step is optional because you may need to immediately employ the data differently.)
9. Release memory allocated for the descriptor by calling `DftiFreeDescriptorDM`.
10. Finalize communication through MPI by calling `MPI_Finalize` (the function must be called after the last call to a cluster FFT function and the last call to an MPI function).

Several code examples in [Examples for Cluster FFT Functions](#) in the Code Examples appendix illustrate cluster FFT computations.

## Distributing Data Among Processes

The Intel® oneAPI Math Kernel Library (oneMKL) cluster FFT functions store all input and output multi-dimensional arrays (matrices) in one-dimensional arrays (vectors). The arrays are stored in the row-major order. For example, a two-dimensional matrix  $A$  of size  $(m,n)$  is stored in a vector  $B$  of size  $m*n$  so that

$$B[i*n+j]=A[i][j] \quad (i=0, \dots, m-1, j=0, \dots, n-1) .$$

---

### NOTE

Order of FFT dimensions is the same as the order of array dimensions in the programming language. For example, a 3-dimensional FFT with Lengths= $(m,n,l)$  can be computed over an array  $A_{r[m][n][l]}$ .

---

All MPI processes involved in cluster FFT computation operate their own portions of data. These local arrays make up the virtual global array that the fast Fourier transform is applied to. It is your responsibility to properly allocate local arrays (if needed), fill them with initial data and gather resulting data into an actual global array or process the resulting data differently. To be able do this, see sections below on how the virtual global array is composed of the local ones.

## Multi-dimensional transforms

If the dimension of transform is greater than one, the cluster FFT function library splits data in the dimension whose index changes most slowly, so that the parts contain all elements with several consecutive values of this index. It is the first dimension in  $C$ . If the global array is two-dimensional, it gives each process several consecutive rows. Local arrays are placed in memory allocated for the virtual global array consecutively, in the order determined by process ranks. For example, in case of two processes, during the computation of a three-dimensional transform whose matrix has size  $(11,15,12)$ , the processes may store local arrays of sizes  $(6,15,12)$  and  $(5,15,12)$ , respectively.

If  $p$  is the number of MPI processes and the matrix of a transform to be computed has size  $(m,n,l)$ , each MPI process works with local data array of size  $(m_q, n, l)$ , where  $\sum m_q=m$ ,  $q=0, \dots, p-1$ . Local input arrays must contain appropriate parts of the actual global input array, and then local output arrays will contain appropriate parts of the actual global output array. You can figure out which particular rows of the global array the local array must contain from the following configuration parameters of the cluster FFT interface: `CDFT_LOCAL_NX`, `CDFT_LOCAL_START_X`, and `CDFT_LOCAL_SIZE`. To retrieve values of the parameters, use the `DftiGetValueDM` function:

- `CDFT_LOCAL_NX` specifies how many rows of the global array the current process receives.
- `CDFT_LOCAL_START_X` specifies which row of the global input or output array corresponds to the first row of the local input or output array. If  $A$  is a global array and  $L$  is the appropriate local array, then

$$L[i][j][k]=A[i+cdft\_local\_start\_x][j][k], \text{ where } i=0, \dots, m_q-1, j=0, \dots, n-1, k=0, \dots, l-1.$$

Example "2D Out-of-place Cluster FFT Computation" shows how the data is distributed among processes for a two-dimensional cluster FFT computation.

## One-dimensional transforms

In this case, input and output data are distributed among processes differently and even the numbers of elements stored in a particular process before and after the transform may be different. Each local array stores a segment of consecutive elements of the appropriate global array. Such segment is determined by the number of elements and a shift with respect to the first array element. So, to specify segments of the global input and output arrays that a particular process receives, *four* configuration parameters are needed: `CDFT_LOCAL_NX`, `CDFT_LOCAL_START_X`, `CDFT_LOCAL_OUT_NX`, and `CDFT_LOCAL_OUT_START_X`. Use the `DftiGetValueDM` function to retrieve their values. The meaning of the four configuration parameters depends upon the type of the transform, as shown in Table "Data Distribution Configuration Parameters for 1D Transforms":

## Data Distribution Configuration Parameters for 1D Transforms

Meaning of the Parameter	Forward Transform	Backward Transform
Number of elements in input array	CDFT_LOCAL_NX	CDFT_LOCAL_OUT_NX
Elements shift in input array	CDFT_LOCAL_START_X	CDFT_LOCAL_OUT_START_X
Number of elements in output array	CDFT_LOCAL_OUT_NX	CDFT_LOCAL_NX
Elements shift in output array	CDFT_LOCAL_OUT_START_X	CDFT_LOCAL_START_X

### Memory size for local data

The memory size needed for local arrays cannot be just calculated from `CDFT_LOCAL_NX` (`CDFT_LOCAL_OUT_NX`), because the cluster FFT functions sometimes require allocating a little bit more memory for local data than just the size of the appropriate sub-array. The configuration parameter `CDFT_LOCAL_SIZE` specifies the size of the local input and output array in data elements. Each local input and output arrays must have size not less than `CDFT_LOCAL_SIZE*size_of_element`. Note that in the current implementation of the cluster FFT interface, data elements can be real or complex values, each complex value consisting of the real and imaginary parts. If you employ a user-defined workspace for in-place transforms (for more information, refer to [Table "Settable configuration Parameters"](#)), it must have the same size as the local arrays. [Example "1D In-place Cluster FFT Computations"](#) illustrates how the cluster FFT functions distribute data among processes in case of a one-dimensional FFT computation performed with a user-defined workspace.

### Available Auxiliary Functions

If a global input array is located on one MPI process and you want to obtain its local parts or you want to gather the global output array on one MPI process, you can use functions `MKL_CDFT_ScatterData` and `MKL_CDFT_GatherData` to distribute or gather data among processes, respectively. These functions are defined in a file that is delivered with Intel® oneAPI Math Kernel Library (oneMKL) and located in the following subdirectory of the Intel® oneAPI Math Kernel Library (oneMKL) installation directory: `examples/cdftc/source/cdft_example_support.c`.

### Restriction on Lengths of Transforms

The algorithm that the Intel® oneAPI Math Kernel Library (oneMKL) cluster FFT functions use to distribute data among processes imposes a restriction on lengths of transforms with respect to the number of MPI processes used for the FFT computation:

- For a multi-dimensional transform, the lengths of the first two dimensions must be not less than the number of MPI processes.
- The length of a one-dimensional transform must be the product of two integers each of which is not less than the number of MPI processes.

Non-compliance with the restriction causes an error `CDFT_SPREAD_ERROR` (refer to [Error Codes](#) for details). To achieve the compliance, you can change the transform lengths and/or the number of MPI processes, which is specified at start of an MPI program. MPI-2 enables changing the number of processes during execution of an MPI program.

### Cluster FFT Interface

To use the cluster FFT functions, you need to access the header file `mkl_cdft.h` through `"include"`.

The C interface provides a structure type `DFTI_DESCRIPTOR_DM_HANDLE` and a number of functions, some of which accept a different number of input arguments.

To provide communication between parallel processes through MPI, the following include statement must be present in your code:

- C/C++:

```
#include "mpi.h"
```

There are three main categories of the cluster FFT functions in Intel® oneAPI Math Kernel Library (oneMKL):

1. **Descriptor Manipulation.** There are three functions in this category. The [DftiCreateDescriptorDM](#) function creates an FFT descriptor whose storage is allocated dynamically. The [DftiCommitDescriptorDM](#) function "commits" the descriptor to all its settings. The [DftiFreeDescriptorDM](#) function frees up the memory allocated for the descriptor.
2. **FFT Computation.** There are two functions in this category. The [DftiComputeForwardDM](#) function performs the forward FFT computation, and the [DftiComputeBackwardDM](#) function performs the backward FFT computation.
3. **Descriptor Configuration.** There are two functions in this category. The [DftiSetValueDM](#) function sets one specific configuration value to one of the many configuration parameters. The [DftiGetValueDM](#) function gets the current value of any of these configuration parameters, all of which are readable. These parameters, though many, are handled one at a time.

## Cluster FFT Descriptor Manipulation Functions

There are three functions in this category: create a descriptor, commit a descriptor, and free a descriptor.

### DftiCreateDescriptorDM

*Allocates memory for the descriptor data structure and preliminarily initializes it.*

#### Syntax

```
status = DftiCreateDescriptorDM(comm, &handle, v1, v2, dim, size );
status = DftiCreateDescriptorDM(comm, &handle, v1, v2, dim, sizes );
```

#### Include Files

- mkl\_cdft.h

#### Input Parameters

<i>comm</i>	MPI communicator, e.g. <code>MPI_COMM_WORLD</code> .
<i>v1</i>	Precision of the transform.
<i>v2</i>	Type of the forward domain. Must be <code>DFTI_COMPLEX</code> for complex-to-complex transforms or <code>DFTI_REAL</code> for real-to-complex transforms.
<i>dim</i>	Dimension of the transform.
<i>size</i>	Length of the transform in a one-dimensional case.
<i>sizes</i>	Lengths of the transform in a multi-dimensional case.

#### Output Parameters

<i>handle</i>	Pointer to the descriptor handle of transform. If the function completes successfully, the pointer to the created handle is stored in the variable.
---------------	---

Any changes of configuration parameters of a committed descriptor via the set value function (see [Descriptor Configuration Functions](#)) requires a re-committal of the descriptor before a computation function can be invoked. Typically, this committal function is called right before a computation function call (see [FFT Computation Functions](#)).

## Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to [Error Codes](#)).

## Prototype

```
MKL_LONG DftiCommitDescriptorDM(DFTI_DESCRIPTOR_DM_HANDLE handle);
```

## DftiFreeDescriptorDM

*Frees memory allocated for a descriptor.*

### Syntax

```
status = DftiFreeDescriptorDM(&handle);
```

### Include Files

- `mkl_cdft.h`

### Input Parameters

*handle* The descriptor handle. Must be valid, that is, created in a call to [DftiCreateDescriptorDM](#).

### Output Parameters

*handle* The descriptor handle. Memory allocated for the handle is released on output.

### Description

This function frees up all memory allocated for a descriptor in a particular MPI process. Call the `DftiFreeDescriptorDM` function to delete the descriptor handle. Upon successful completion of `DftiFreeDescriptorDM` the descriptor handle is no longer valid.

### Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to [Error Codes](#)).

## Prototype

```
MKL_LONG DftiFreeDescriptorDM(DFTI_DESCRIPTOR_DM_HANDLE *handle);
```

## Cluster FFT Computation Functions

There are two functions in this category: compute the forward transform and compute the backward transform.

## DftiComputeForwardDM

Computes the forward FFT.

---

### Syntax

```
status = DftiComputeForwardDM(handle, in_X, out_X);
```

```
status = DftiComputeForwardDM(handle, in_out_X);
```

### Include Files

- `mkl_cdft.h`

### Input Parameters

<i>handle</i>	The descriptor handle.
<i>in_X, in_out_X</i>	Local part of input data. Array of real or complex values (depending on the forward domain type). Refer to <a href="#">Distributing Data among Processes</a> on how to allocate and initialize the array.

### Output Parameters

<i>out_X, in_out_X</i>	Local part of output data. Array of complex values. Refer to <a href="#">Distributing Data among Processes</a> on how to allocate the array.
------------------------	--

### Description

The `DftiComputeForwardDM` function computes the forward FFT. Forward FFT is the transform using the factor  $e^{-i2\pi/n}$ .

Before you call the function, the valid descriptor, created by `DftiCreateDescriptorDM`, must be configured and committed using the `DftiCommitDescriptorDM` function.

The computation is carried out by an internal call to the `DftiComputeForward` function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of `DftiComputeForward`.

The local part of input data, as well as the local part of the output data, is an appropriate sequence of real or complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See [Distributing Data Among Processes](#) for details.

Refer to [Configuration Settings](#) for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter `DFTI_PRECISION` determines the precision of input data, output data, and transform: a setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The configuration parameter `DFTI_PLACEMENT` informs the function whether the computation should be in-place. If the value of this parameter is `DFTI_INPLACE` (default), you must call the function with two parameters, otherwise you must supply three parameters. If `DFTI_PLACEMENT = DFTI_INPLACE` and three parameters are supplied, then the third parameter is ignored.

---

### Caution

Even in case of an out-of-place transform, local array of input data *in\_X* may be changed. To save data, make its copy before calling `DftiComputeForwardDM`.

---

In case of an in-place transform, `DftiComputeForwardDM` dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

---

#### NOTE

You can specify your own workspace of the same size through the configuration parameter `CDFT_WORKSPACE` to avoid redundant memory allocation.

---

### Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to [Error Codes](#)).

### Prototype

```
MKL_LONG DftiComputeForwardDM(DFTI_DESCRIPTOR_DM_HANDLE handle, void *in_X,...);
```

### DftiComputeBackwardDM

*Computes the backward FFT.*

---

#### Syntax

```
status = DftiComputeBackwardDM(handle, in_X, out_X);
```

```
status = DftiComputeBackwardDM(handle, in_out_X);
```

#### Include Files

- `mkl_cdft.h`

#### Input Parameters

<code>handle</code>	The descriptor handle.
<code>in_X, in_out_X</code>	Local part of input data. Array of complex values. Refer to <a href="#">Distributing Data among Processes</a> on how to allocate and initialize the array.

#### Output Parameters

<code>out_X, in_out_X</code>	Local part of output data. Array of real or complex values (depending on the forward domain type. Refer to <a href="#">Distributing Data among Processes</a> on how to allocate the array.
------------------------------	--

#### Description

The `DftiComputeBackwardDM` function computes the backward FFT. Backward FFT is the transform using the factor  $e^{i2\pi/n}$ .

Before you call the function, the valid descriptor, created by `DftiCreateDescriptorDM`, must be configured and committed using the `DftiCommitDescriptorDM` function.

The computation is carried out by an internal call to the `DftiComputeBackward` function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of `DftiComputeBackward`.

The local part of input data, as well as the local part of the output data, is an appropriate sequence of real or complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See [Distributing Data among Processes](#) for details.

Refer to [Configuration Settings](#) for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter `DFTI_PRECISION` determines the precision of input data, output data, and transform: a setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The configuration parameter `DFTI_PLACEMENT` informs the function whether the computation should be in-place. If the value of this parameter is `DFTI_INPLACE` (default), you must call the function with two parameters, otherwise you must supply three parameters. If `DFTI_PLACEMENT = DFTI_INPLACE` and three parameters are supplied, then the third parameter is ignored.

---

### Caution

Even in case of an out-of-place transform, local array of input data `in_X` may be changed. To save data, make its copy before calling `DftiComputeBackwardDM`.

---

In case of an in-place transform, `DftiComputeBackwardDM` dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

---

### NOTE

You can specify your own workspace of the same size through the configuration parameter `CDFT_WORKSPACE` to avoid redundant memory allocation.

---

## Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to [Error Codes](#)).

## Prototype

```
MKL_LONG DftiComputeBackwardDM(DFTI_DESCRIPTOR_DM_HANDLE handle, void *in_X, ...);
```

## Cluster FFT Descriptor Configuration Functions

There are two functions in this category: the value-setting function [DftiSetValueDM](#) sets one particular configuration parameter to an appropriate value, and the value-getting function [DftiGetValueDM](#) reads the value of one particular configuration parameter.

Some configuration parameters used by cluster FFT functions originate from the conventional FFT interface (see [Configuration Settings](#) for details).

Other configuration parameters are specific to the cluster FFT. Integer values of these parameters have type `MKL_LONG`. The exact type of the configuration parameters being floating-point scalars is `float` or `double` (matching `DFTI_PRECISION`). The configuration parameters whose values are named constants have the `enum` type. They are defined in the `mkl_cdft.h` header file.

The names of the configuration parameters specific to the cluster FFT interface have the `CDFT` prefix.

## DftiSetValueDM

Sets one particular configuration parameter with the specified configuration value.

### Syntax

```
status = DftiSetValueDM (handle, param, value);
```

### Include Files

- `mkl_cdft.h`

### Input Parameters

<i>handle</i>	The descriptor handle. Must be valid, that is, created in a call to <a href="#">DftiCreateDescriptorDM</a> .
<i>param</i>	Name of a parameter to be set up in the descriptor handle. See <a href="#">Table "Settable Configuration Parameters"</a> for the list of available parameters.
<i>value</i>	Value of the parameter.

### Description

This function sets one particular configuration parameter with the specified configuration value. The configuration parameter is one of the named constants listed in the table below, and the configuration value must have the corresponding type. See [Configuration Settings](#) for details of the meaning of each setting and for possible values of the parameters whose values are named constants.

### Settable Configuration Parameters

Parameter Name	Data Type	Description	Default Value
<code>DFTI_FORWARD_SCALE</code>	Floating-point scalar	Scale factor of forward transform.	1.0
<code>DFTI_BACKWARD_SCALE</code>	Floating-point scalar	Scale factor of backward transform.	1.0
<code>DFTI_PLACEMENT</code>	Named constant	Placement of the computation result.	<code>DFTI_INPLACE</code>
<code>DFTI_ORDERING</code>	Named constant	Scrambling of data order.	<code>DFTI_ORDERED</code>
<code>CDFT_WORKSPACE</code>	Array of an appropriate type	Auxiliary buffer, a user-defined workspace. Enables saving memory during in-place computations.	NULL (allocate workspace dynamically).
<code>DFTI_PACKED_FORMAT</code>	Named constant	Packed format for storing conjugate-even sequence (in the case of a real forward domain).	<ul style="list-style-type: none"> <li>• <code>DFTI_PERM_FORMAT</code> — default and the only available value for one-dimensional transforms</li> <li>• <code>DFTI_CCE_FORMAT</code> — default and the only available value for multi-dimensional transforms</li> </ul>

Parameter Name	Data Type	Description	Default Value
DFTI_TRANSPOSE	Named constant	This parameter determines how the output data is located for multi-dimensional transforms. If the parameter value is <code>DFTI_NONE</code> , the data is located in a usual manner described in this document. If the value is <code>DFTI_ALLOW</code> , the last (first) global transposition is not performed for a forward (backward) transform.	<code>DFTI_NONE</code>

## Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to [Error Codes](#)).

## Prototype

```
MKL_LONG DftiSetValueDM(DFTI_DESCRIPTOR_DM_HANDLE handle, int param,...);
```

## DftiGetValueDM

*Gets the value of one particular configuration parameter.*

## Syntax

```
status = DftiGetValueDM(handle, param, &value);
```

## Include Files

- `mkl_cdft.h`

## Input Parameters

<i>handle</i>	The descriptor handle. Must be valid, that is, created in a call to <a href="#">DftiCreateDescriptorDM</a> .
<i>param</i>	Name of a parameter to be retrieved from the descriptor. See <a href="#">Table "Retrievable Configuration Parameters"</a> for the list of available parameters.

## Output Parameters

<i>value</i>	Value of the parameter.
--------------	-------------------------

## Description

This function gets the configuration value of one particular configuration parameter. The configuration parameter is one of the named constants listed in the table below, and the configuration value is the corresponding appropriate type, which can be a named constant or a native type. Possible values of the named constants can be found in [Table "Configuration Parameters"](#) and relevant subsections of the [Configuration Settings](#) section.

## Retrievable Configuration Parameters

Parameter Name	Data Type	Description
DFTI_PRECISION	Named constant	Precision of computation, input data and output data.
DFTI_DIMENSION	Integer scalar	Dimension of the transform
DFTI_LENGTHS	Array of integer values	Array of lengths of the transform. Number of lengths corresponds to the dimension of the transform.
DFTI_FORWARD_SCALE	Floating-point scalar	Scale factor of forward transform.
DFTI_BACKWARD_SCALE	Floating-point scalar	Scale factor of backward transform.
DFTI_PLACEMENT	Named constant	Placement of the computation result.
DFTI_COMMIT_STATUS	Named constant	Shows whether descriptor has been committed.
DFTI_FORWARD_DOMAIN	Named constant	Forward domain of transforms, has the value of <code>DFTI_COMPLEX</code> or <code>DFTI_REAL</code> .
DFTI_ORDERING	Named constant	Scrambling of data order.
CDFT_MPI_COMM	Type of MPI communicator	MPI communicator used for transforms.
CDFT_LOCAL_SIZE	Integer scalar	Necessary size of input, output, and buffer arrays in data elements.
CDFT_LOCAL_X_START	Integer scalar	Row/element number of the global array that corresponds to the first row/element of the local array. For more information, see <a href="#">Distributing Data among Processes</a> .
CDFT_LOCAL_NX	Integer scalar	The number of rows/elements of the global array stored in the local array. For more information, see <a href="#">Distributing Data among Processes</a> .
CDFT_LOCAL_OUT_X_START	Integer scalar	Element number of the appropriate global array that corresponds to the first element of the input or output local array in a 1D case. For details, see <a href="#">Distributing Data among Processes</a> .
CDFT_LOCAL_OUT_NX	Integer scalar	The number of elements of the appropriate global array that are stored in the input or output local array in a 1D case. For details, see <a href="#">Distributing Data among Processes</a> .

## Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to [Error Codes](#)).

## Prototype

```
MKL_LONG DftiGetValueDM(DFTI_DESCRIPTOR_DM_HANDLE handle, int param,...);
```

## Error Codes

All the cluster FFT functions return an integer value denoting the status of the operation. These values are identified by named constants. Each function returns `DFTI_NO_ERROR` if no errors were encountered during execution. Otherwise, a function generates an error code. In addition to FFT error codes, the cluster FFT interface has its own ones. The named constants specific to the cluster FFT interface have the `CDFT` prefix in their names. [Table "Error Codes that Cluster FFT Functions Return"](#) lists error codes that the cluster FFT functions may return.

### Error Codes that Cluster FFT Functions Return

Named Constants	Comments
<code>DFTI_NO_ERROR</code>	No error.
<code>DFTI_MEMORY_ERROR</code>	Usually associated with memory allocation.
<code>DFTI_INVALID_CONFIGURATION</code>	Invalid settings of one or more configuration parameters.
<code>DFTI_INCONSISTENT_CONFIGURATION</code>	Inconsistent configuration or input parameters.
<code>DFTI_NUMBER_OF_THREADS_ERROR</code>	Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function).
<code>DFTI_MULTITHREADED_ERROR</code>	Usually associated with a value that OMP routines return in case of errors.
<code>DFTI_BAD_DESCRIPTOR</code>	Descriptor is unusable for computation.
<code>DFTI_UNIMPLEMENTED</code>	Unimplemented legitimate settings; implementation dependent.
<code>DFTI_MKL_INTERNAL_ERROR</code>	Internal library error.
<code>DFTI_1D_LENGTH_EXCEEDS_INT32</code>	Length of one of the dimensions exceeds $2^{32} - 1$ (4 bytes).
<code>CDFT_SPREAD_ERROR</code>	Data cannot be distributed (For more information, see <a href="#">Distributing Data among Processes.</a> )
<code>CDFT_MPI_ERROR</code>	MPI error. Occurs when calling MPI.

## PBLAS Routines

Intel® oneAPI Math Kernel Library implements the PBLAS (Parallel Basic Linear Algebra Subprograms) routines from the ScaLAPACK package for distributed-memory architecture. PBLAS is intended for using in vector-vector, matrix-vector, and matrix-matrix operations to simplify the parallelization of linear codes. The design of PBLAS is as consistent as possible with that of the BLAS. The routine descriptions are arranged in several sections according to the PBLAS level of operation:

- [PBLAS Level 1 Routines](#) (distributed vector-vector operations)
- [PBLAS Level 2 Routines](#) (distributed matrix-vector operations)
- [PBLAS Level 3 Routines](#) (distributed matrix-matrix operations)

Each section presents the routine and function group descriptions in alphabetical order by the routine group name; for example, the `p?asum` group, the `p?axpy` group. The question mark in the group name corresponds to a character indicating the data type (`s`, `d`, `c`, and `z` or their combination); see [Routine Naming Conventions](#).

**NOTE**

PBLAS routines are provided only with Intel® oneAPI Math Kernel Library (oneMKL) versions for Linux\* and Windows\* OSs.

Generally, PBLAS runs on a network of computers using MPI as a message-passing layer and a set of prebuilt communication subprograms (BLACS), as well as a set of PBLAS optimized for the target architecture. The Intel® oneAPI Math Kernel Library (oneMKL) version of PBLAS is optimized for Intel® processors. For the detailed system and environment requirements see [Intel® oneAPI Math Kernel Library \(oneMKL\) Release Notes](#) and [Intel® oneAPI Math Kernel Library \(oneMKL\) Developer Guide](#).

For full reference on PBLAS routines and related information, see [http://www.netlib.org/scalapack/html/pblas\\_qref.html](http://www.netlib.org/scalapack/html/pblas_qref.html).

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

**PBLAS Routines Overview**

The model of the computing environment for PBLAS is represented as a one-dimensional array of processes or also a two-dimensional process grid. To use PBLAS, all global matrices or vectors must be distributed on this array or grid prior to calling the PBLAS routines.

PBLAS uses the two-dimensional block-cyclic data distribution as a layout for dense matrix computations. This distribution provides good work balance between available processors, as well as gives the opportunity to use PBLAS Level 3 routines for optimal local computations. Information about the data distribution that is required to establish the mapping between each global array and its corresponding process and memory location is contained in the so called *array descriptor* associated with each global array. [Table "Content of the array descriptor for dense matrices"](#) gives an example of an array descriptor structure.

**Content of Array Descriptor for Dense Matrices**

Array Element #	Name	Definition
1	<i>dtype</i>	Descriptor type ( =1 for dense matrices)
2	<i>ctxt</i>	BLACS context handle for the process grid
3	<i>m</i>	Number of rows in the global array
4	<i>n</i>	Number of columns in the global array
5	<i>mb</i>	Row blocking factor
6	<i>nb</i>	Column blocking factor
7	<i>rsrc</i>	Process row over which the first row of the global array is distributed
8	<i>csrc</i>	Process column over which the first column of the global array is distributed
9	<i>lld</i>	Leading dimension of the local array

The number of rows and columns of a global dense matrix that a particular process in a grid receives after data distributing is denoted by `LOCr()` and `LOCc()`, respectively. To compute these numbers, you can use the ScaLAPACK tool routine `numroc`.

After the block-cyclic distribution of global data is done, you may choose to perform an operation on a submatrix of the global matrix *A*, which is contained in the global subarray `sub(A)`, defined by the following 6 values (for dense matrices):

<i>m</i>	The number of rows of <code>sub(A)</code>
<i>n</i>	The number of columns of <code>sub(A)</code>
<i>a</i>	A pointer to the local array containing the entire global array <i>A</i>
<i>ia</i>	The row index of <code>sub(A)</code> in the global array
<i>ja</i>	The column index of <code>sub(A)</code> in the global array
<i>desca</i>	The array descriptor for the global array <i>A</i>

Intel® oneAPI Math Kernel Library (oneMKL) provides the PBLAS routines with interface similar to the interface used in the Netlib PBLAS (see [http://www.netlib.org/scalapack/html/pblas\\_qref.html](http://www.netlib.org/scalapack/html/pblas_qref.html)).

## PBLAS Routine Naming Conventions

The naming convention for PBLAS routines is similar to that used for BLAS routines (see [Routine Naming Conventions](#)). A general rule is that each routine name in PBLAS, which has a BLAS equivalent, is simply the BLAS name prefixed by initial letter *p* that stands for "parallel".

The Intel® oneAPI Math Kernel Library (oneMKL) PBLAS routine names have the following structure:

```
p <character> <name> <mod> ( )
```

The *<character>* field indicates the Fortran data type:

<i>s</i>	real, single precision
<i>c</i>	complex, single precision
<i>d</i>	real, double precision
<i>z</i>	complex, double precision
<i>i</i>	integer

Some routines and functions can have combined character codes, such as *sc* or *dz*.

For example, the function `pzcasum` uses a complex input array and returns a real value.

The *<name>* field, in PBLAS level 1, indicates the operation type. For example, the PBLAS level 1 routines `p?dot`, `p?swap`, `p?copy` compute a vector dot product, vector swap, and a copy vector, respectively.

In PBLAS level 2 and 3, *<name>* reflects the matrix argument type:

<i>ge</i>	general matrix
<i>sy</i>	symmetric matrix
<i>he</i>	Hermitian matrix
<i>tr</i>	triangular matrix

In PBLAS level 3, the *<name>=tran* indicates the transposition of the matrix.

The *<mod>* field, if present, provides additional details of the operation. The PBLAS level 1 names can have the following characters in the *<mod>* field:

<i>c</i>	conjugated vector
<i>u</i>	unconjugated vector

The PBLAS level 2 names can have the following additional characters in the *<mod>* field:

<i>mv</i>	matrix-vector product
-----------	-----------------------

sv	solving a system of linear equations with matrix-vector operations
r	rank-1 update of a matrix
r2	rank-2 update of a matrix.

The PBLAS level 3 names can have the following additional characters in the `<mod>` field:

mm	matrix-matrix product
sm	solving a system of linear equations with matrix-matrix operations
rk	rank- <i>k</i> update of a matrix
r2k	rank-2 <i>k</i> update of a matrix.

The examples below show how to interpret PBLAS routine names:

pddot	<code>&lt;p&gt; &lt;d&gt; &lt;dot&gt;</code> : double-precision real distributed vector-vector dot product
pcdotc	<code>&lt;p&gt; &lt;c&gt; &lt;dot&gt; &lt;c&gt;</code> : complex distributed vector-vector dot product, conjugated
pscasum	<code>&lt;p&gt; &lt;sc&gt; &lt;asum&gt;</code> : sum of magnitudes of distributed vector elements, single precision real output and single precision complex input
pcdotu	<code>&lt;p&gt; &lt;c&gt; &lt;dot&gt; &lt;u&gt;</code> : distributed vector-vector dot product, unconjugated, complex
psgemv	<code>&lt;p&gt; &lt;s&gt; &lt;ge&gt; &lt;mv&gt;</code> : distributed matrix-vector product, general matrix, single precision
pztrmm	<code>&lt;p&gt; &lt;z&gt; &lt;tr&gt; &lt;mm&gt;</code> : distributed matrix-matrix product, triangular matrix, double-precision complex.

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## PBLAS Level 1 Routines

PBLAS Level 1 includes routines and functions that perform distributed vector-vector operations. [Table "PBLAS Level 1 Routine Groups and Their Data Types"](#) lists the PBLAS Level 1 routine groups and the data types associated with them.

### PBLAS Level 1 Routine Groups and Their Data Types

Routine or Function Group	Data Types	Description
<a href="#">p?amax</a>	s, d, c, z	Calculates an index of the distributed vector element with maximum absolute value
<a href="#">p?asum</a>	s, d, sc, dz	Calculates sum of magnitudes of a distributed vector
<a href="#">p?axpy</a>	s, d, c, z	Calculates distributed vector-scalar product
<a href="#">p?copy</a>	s, d, c, z	Copies a distributed vector
<a href="#">p?dot</a>	s, d	Calculates a dot product of two distributed real vectors

Routine or Function Group	Data Types	Description
<code>p?dotc</code>	c, z	Calculates a dot product of two distributed complex vectors, one of them is conjugated
<code>p?dotu</code>	c, z	Calculates a dot product of two distributed complex vectors
<code>p?nrm2</code>	s, d, sc, dz	Calculates the 2-norm (Euclidean norm) of a distributed vector
<code>p?scal</code>	s, d, c, z, cs, zd	Calculates a product of a distributed vector by a scalar
<code>p?swap</code>	s, d, c, z	Swaps two distributed vectors

### **p?amax**

*Computes the global index of the element of a distributed vector with maximum absolute value.*

#### **Syntax**

```
void psamax (const MKL_INT *n , float *amax , MKL_INT *indx , const float *x , const
MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx );
void pdamax (const MKL_INT *n , double *amax , MKL_INT *indx , const double *x , const
MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx );
void pcamax (const MKL_INT *n , MKL_Complex8 *amax , MKL_INT *indx , const MKL_Complex8
*x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT
*incx );
void pzamax (const MKL_INT *n , MKL_Complex16 *amax , MKL_INT *indx , const
MKL_Complex16 *x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const
MKL_INT *incx );
```

#### **Include Files**

- `mkl_pblas.h`

#### **Description**

The functions `p?amax` compute global index of the maximum element in absolute value of a distributed vector `sub(x)`,

where `sub(x)` denotes  $X(ix, jx:jx+n-1)$  if `incx=m_x`, and  $X(ix: ix+n-1, jx)$  if `incx= 1`.

#### **Input Parameters**

<code>n</code>	(global) The length of distributed vector <code>sub(x)</code> , $n \geq 0$ .
<code>x</code>	(local) Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$ . This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively.

<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .
<i>incx</i>	(global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m_x$ . <i>incx</i> must not be zero.

## Output Parameters

<i>amax</i>	(global). Maximum absolute value (magnitude) of elements of the distributed vector only in its scope.
<i>indx</i>	(global) The global index of the maximum element in absolute value of the distributed vector $\text{sub}(x)$ only in its scope.

## p?asum

Computes the sum of magnitudes of elements of a distributed vector.

## Syntax

```
void psasum (const MKL_INT *n , float *asum , const float *x , const MKL_INT *ix ,
const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx );

void pdasum (const MKL_INT *n , double *asum , const double *x , const MKL_INT *ix ,
const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx );

void pscasum (const MKL_INT *n , float *asum , const MKL_Complex8 *x , const MKL_INT
*ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx );

void pdzasum (const MKL_INT *n , double *asum , const MKL_Complex16 *x , const MKL_INT
*ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx );
```

## Include Files

- mkl\_pblas.h

## Description

The functions p?asum compute the sum of the magnitudes of elements of a distributed vector  $\text{sub}(x)$ , where  $\text{sub}(x)$  denotes  $X(ix, jx:jx+n-1)$  if  $incx=m_x$ , and  $X(ix: ix+n-1, jx)$  if  $incx= 1$ .

## Input Parameters

<i>n</i>	(global) The length of distributed vector $\text{sub}(x)$ , $n \geq 0$ .
<i>x</i>	(local) Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$ . This array contains the entries of the distributed vector $\text{sub}(x)$ .
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix $\text{sub}(X)$ , respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .

*incx* (global) Specifies the increment for the elements of  $\text{sub}(x)$ . Only two values are supported, namely 1 and  $m_x$ . *incx* must not be zero.

## Output Parameters

*asum* (local) and *pascalum*.  
Contains the sum of magnitudes of elements of the distributed vector only in its scope.

## p?axpy

*Computes a distributed vector-scalar product and adds the result to a distributed vector.*

### Syntax

```
void psaxpy (const MKL_INT *n , const float *a , const float *x , const MKL_INT *ix ,
const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , float *y , const
MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy );

void pdaxpy (const MKL_INT *n , const double *a , const double *x , const MKL_INT *ix ,
const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , double *y , const
MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy );

void pcaxpy (const MKL_INT *n , const MKL_Complex8 *a , const MKL_Complex8 *x , const
MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx ,
MKL_Complex8 *y , const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const
MKL_INT *incy );

void pzaxpy (const MKL_INT *n , const MKL_Complex16 *a , const MKL_Complex16 *x , const
MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx ,
MKL_Complex16 *y , const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const
MKL_INT *incy );
```

### Include Files

- `mkl_pblas.h`

### Description

The `p?axpy` routines perform the following operation with distributed vectors:

```
sub(y) := sub(y) + a*sub(x)
```

where:

*a* is a scalar;

$\text{sub}(x)$  and  $\text{sub}(y)$  are *n*-element distributed vectors.

$\text{sub}(x)$  denotes  $X(ix, jx:jx+n-1)$  if  $incx=m_x$ , and  $X(ix: ix+n-1, jx)$  if  $incx= 1$ ;

$\text{sub}(y)$  denotes  $Y(iy, jy:jy+n-1)$  if  $incy=m_y$ , and  $Y(iy: iy+n-1, jy)$  if  $incy= 1$ .

### Input Parameters

*n* (global) The length of distributed vectors,  $n \geq 0$ .

*a* (local)

	Specifies the scalar $a$ .
$x$	(local) Array, size $(j_x-1)*m_x + ix+(n-1)*abs(incx)$ . This array contains the entries of the distributed vector $sub(x)$ .
$ix, jx$	(global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix $sub(X)$ , respectively.
$descx$	(global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .
$incx$	(global) Specifies the increment for the elements of $sub(x)$ . Only two values are supported, namely 1 and $m_x$ . $incx$ must not be zero.
$y$	(local) Array, size $(j_y-1)*m_y + iy+(n-1)*abs(incy)$ . This array contains the entries of the distributed vector $sub(y)$ .
$iy, jy$	(global) The row and column indices in the distributed matrix $Y$ indicating the first row and the first column of the submatrix $sub(Y)$ , respectively.
$descy$	(global and local) array of dimension 9. The array descriptor of the distributed matrix $Y$ .
$incy$	(global) Specifies the increment for the elements of $sub(y)$ . Only two values are supported, namely 1 and $m_y$ . $incy$ must not be zero.

## Output Parameters

$y$  Overwritten by  $sub(y) := sub(y) + a*sub(x)$ .

## p?copy

Copies one distributed vector to another vector.

### Syntax

```
void picopy (const MKL_INT *n , const MKL_INT *x , const MKL_INT *ix , const MKL_INT
*jx , const MKL_INT *descx , const MKL_INT *incx , MKL_INT *y , const MKL_INT *iy ,
const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy );
```

```
void pscopy (const MKL_INT *n , const float *x , const MKL_INT *ix , const MKL_INT

## Description

The `p?copy` routines perform a copy operation with distributed vectors defined as

$$\text{sub}(y) = \text{sub}(x),$$

where `sub(x)` and `sub(y)` are  $n$ -element distributed vectors.

`sub(x)` denotes  $X(ix, jx:jx+n-1)$  if  $incx=m_x$ , and  $X(ix: ix+n-1, jx)$  if  $incx= 1$ ;

`sub(y)` denotes  $Y(iy, jy:jy+n-1)$  if  $incy=m_y$ , and  $Y(iy: iy+n-1, jy)$  if  $incy= 1$ .

## Input Parameters

$n$	(global) The length of distributed vectors, $n \geq 0$ .
$x$	(local) Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$ . This array contains the entries of the distributed vector <code>sub(x)</code> .
$ix, jx$	(global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively.
$descx$	(global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .
$incx$	(global) Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and $m_x$ . $incx$ must not be zero.
$y$	(local) Array, size $(jy-1)*m_y + iy+(n-1)*abs(incy)$ . This array contains the entries of the distributed vector <code>sub(y)</code> .
$iy, jy$	(global) The row and column indices in the distributed matrix $Y$ indicating the first row and the first column of the submatrix <code>sub(Y)</code> , respectively.
$descy$	(global and local) array of dimension 9. The array descriptor of the distributed matrix $Y$ .
$incy$	(global) Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and $m_y$ . $incy$ must not be zero.

## Output Parameters

$y$	Overwritten with the distributed vector <code>sub(x)</code> .
-----	---

## p?dot

*Computes the dot product of two distributed real vectors.*

---

## Syntax

```
void psdot (const MKL_INT *n , float *dot , const float *x , const MKL_INT *ix , const
MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , const float *y , const
MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy );
```

```
void pddot (const MKL_INT *n , double *dot , const double *x , const MKL_INT *ix ,
const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , const double *y ,
const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy );
```

## Include Files

- mkl\_pblas.h

## Description

The ?dot functions compute the dot product *dot* of two distributed real vectors defined as

$$\mathit{dot} = \mathit{sub}(x) \cdot \mathit{sub}(y)$$

where *sub(x)* and *sub(y)* are *n*-element distributed vectors.

*sub(x)* denotes  $X(ix, jx:jx+n-1)$  if  $incx=m_x$ , and  $X(ix: ix+n-1, jx)$  if  $incx= 1$ ;

*sub(y)* denotes  $Y(iy, jy:jy+n-1)$  if  $incy=m_y$ , and  $Y(iy: iy+n-1, jy)$  if  $incy= 1$ .

## Input Parameters

<i>n</i>	(global) The length of distributed vectors, $n \geq 0$ .
<i>x</i>	(local) Array, size $(jx-1) * m_x + ix + (n-1) * \text{abs}(incx)$ . This array contains the entries of the distributed vector <i>sub(x)</i> .
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix <i>sub(X)</i> , respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and $m_x$ . <i>incx</i> must not be zero.
<i>y</i>	(local) Array, size $(jy-1) * m_y + iy + (n-1) * \text{abs}(incy)$ . This array contains the entries of the distributed vector <i>sub(y)</i> .
<i>iy, jy</i>	(global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <i>sub(Y)</i> , respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) Specifies the increment for the elements of <i>sub(y)</i> . Only two values are supported, namely 1 and $m_y$ . <i>incy</i> must not be zero.

## Output Parameters

*dot* (local)  
Dot product of  $\text{sub}(x)$  and  $\text{sub}(y)$  only in their scope.

### p?dotc

Computes the dot product of two distributed complex vectors, one of them is conjugated.

### Syntax

```
void pcdotc (const MKL_INT *n , MKL_Complex8 *dotc , const MKL_Complex8 *x , const
MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , const
MKL_Complex8 *y , const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const
MKL_INT *incy );
```

```
void pzdotc (const MKL_INT *n , MKL_Complex16 *dotc , const MKL_Complex16 *x , const
MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , const
MKL_Complex16 *y , const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const
MKL_INT *incy );
```

### Include Files

- mkl\_pblas.h

### Description

The `p?dotc` functions compute the dot product *dotc* of two distributed vectors, with one vector conjugated:

```
dotc = conjg(sub(x)')*sub(y)
```

where  $\text{sub}(x)$  and  $\text{sub}(y)$  are  $n$ -element distributed vectors.

$\text{sub}(x)$  denotes  $X(ix, jx:jx+n-1)$  if  $incx=m_x$ , and  $X(ix:ix+n-1, jx)$  if  $incx=1$ ;

$\text{sub}(y)$  denotes  $Y(iy, jy:jy+n-1)$  if  $incy=m_y$ , and  $Y(iy:iy+n-1, jy)$  if  $incy=1$ .

### Input Parameters

*n* (global) The length of distributed vectors,  $n \geq 0$ .

*x* (local)  
Array, size  $(jx-1)*m_x + ix+(n-1)*abs(incx)$ .  
This array contains the entries of the distributed vector  $\text{sub}(x)$ .

*ix, jx* (global) The row and column indices in the distributed matrix  $X$  indicating the first row and the first column of the submatrix  $\text{sub}(X)$ , respectively.

*descx* (global and local) array of dimension 9. The array descriptor of the distributed matrix  $X$ .

*incx* (global) Specifies the increment for the elements of  $\text{sub}(x)$ . Only two values are supported, namely 1 and  $m_x$ . *incx* must not be zero.

*y* (local)  
Array, size  $(jy-1)*m_y + iy+(n-1)*abs(incy)$ .

This array contains the entries of the distributed vector  $\text{sub}(y)$ .

<i>iy, jy</i>	(global) The row and column indices in the distributed matrix $Y$ indicating the first row and the first column of the submatrix $\text{sub}(Y)$ , respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix $Y$ .
<i>incy</i>	(global) Specifies the increment for the elements of $\text{sub}(y)$ . Only two values are supported, namely 1 and $m_y$ . <i>incy</i> must not be zero.

## Output Parameters

<i>dotc</i>	(local) Dot product of $\text{sub}(x)$ and $\text{sub}(y)$ only in their scope.
-------------	--

## p?dotu

Computes the dot product of two distributed complex vectors.

### Syntax

```
void pcdotu (const MKL_INT *n , MKL_Complex8 *dotu , const MKL_Complex8 *x , const
MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , const
MKL_Complex8 *y , const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const
MKL_INT *incy );
```

```
void pzdotu (const MKL_INT *n , MKL_Complex16 *dotu , const MKL_Complex16 *x , const
MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx , const
MKL_Complex16 *y , const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const
MKL_INT *incy );
```

### Include Files

- `mkl_pblas.h`

### Description

The `p?dotu` functions compute the dot product *dotu* of two distributed vectors defined as

$$\text{dotu} = \text{sub}(x)' * \text{sub}(y)$$

where  $\text{sub}(x)$  and  $\text{sub}(y)$  are  $n$ -element distributed vectors.

$\text{sub}(x)$  denotes  $X(ix, jx:jx+n-1)$  if  $incx=m_x$ , and  $X(ix: ix+n-1, jx)$  if  $incx= 1$ ;

$\text{sub}(y)$  denotes  $Y(iy, jy:jy+n-1)$  if  $incy=m_y$ , and  $Y(iy: iy+n-1, jy)$  if  $incy= 1$ .

### Input Parameters

<i>n</i>	(global) The length of distributed vectors, $n \geq 0$ .
<i>x</i>	(local) Array, size $(jx-1) * m_x + ix + (n-1) * \text{abs}(incx)$ . This array contains the entries of the distributed vector $\text{sub}(x)$ .

<code>ix, jx</code>	(global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix $\text{sub}(X)$ , respectively.
<code>descx</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .
<code>incx</code>	(global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m_x$ . <code>incx</code> must not be zero.
<code>y</code>	(local) Array, size $(jy-1)*m_y + iy+(n-1)*\text{abs}(incy)$ . This array contains the entries of the distributed vector $\text{sub}(y)$ .
<code>iy, jy</code>	(global) The row and column indices in the distributed matrix $Y$ indicating the first row and the first column of the submatrix $\text{sub}(Y)$ , respectively.
<code>descy</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix $Y$ .
<code>incy</code>	(global) Specifies the increment for the elements of $\text{sub}(y)$ . Only two values are supported, namely 1 and $m_y$ . <code>incy</code> must not be zero.

## Output Parameters

<code>dotu</code>	(local) Dot product of $\text{sub}(x)$ and $\text{sub}(y)$ only in their scope.
-------------------	--

## p?nrm2

Computes the Euclidean norm of a distributed vector.

### Syntax

```
void psnrm2 (const MKL_INT *n , float *norm2 , const float *x , const MKL_INT *ix ,
const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx );

void pdnrm2 (const MKL_INT *n , double *norm2 , const double *x , const MKL_INT *ix ,
const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx );

void pscnrm2 (const MKL_INT *n , float *norm2 , const MKL_Complex8 *x , const MKL_INT
*ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx );

void pdznrm2 (const MKL_INT *n , double *norm2 , const MKL_Complex16 *x , const MKL_INT
*ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx );
```

### Include Files

- `mkl_pblas.h`

### Description

The `p?nrm2` functions compute the Euclidean norm of a distributed vector  $\text{sub}(x)$ ,

where  $\text{sub}(x)$  is an  $n$ -element distributed vector.

$\text{sub}(x)$  denotes  $X(ix, jx:jx+n-1)$  if `incx=mx`, and  $X(ix: ix+n-1, jx)$  if `incx= 1`.

## Input Parameters

<i>n</i>	(global) The length of distributed vector $\text{sub}(x)$ , $n \geq 0$ .
<i>x</i>	(local) Array, size $(j_x-1)*m_x + ix+(n-1)*\text{abs}(incx)$ . This array contains the entries of the distributed vector $\text{sub}(x)$ .
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix $\text{sub}(X)$ , respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .
<i>incx</i>	(global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m_x$ . <i>incx</i> must not be zero.

## Output Parameters

<i>norm2</i>	(local) and <code>pscnrm2</code> . Contains the Euclidean norm of a distributed vector only in its scope.
--------------	--

## p?scal

Computes a product of a distributed vector by a scalar.

## Syntax

```
void psscal (const MKL_INT *n , const float *a , float *x , const MKL_INT *ix , const
MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx );

void pdscal (const MKL_INT *n , const double *a , double *x , const MKL_INT *ix , const
MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx );

void pcscal (const MKL_INT *n , const MKL_Complex8 *a , MKL_Complex8 *x , const MKL_INT
*ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx );

void pzscal (const MKL_INT *n , const MKL_Complex16 *a , MKL_Complex16 *x , const
MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx );

void pcsscal (const MKL_INT *n , const float *a , MKL_Complex8 *x , const MKL_INT *ix ,
const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx );

void pzdscale (const MKL_INT *n , const double *a , MKL_Complex16 *x , const MKL_INT
*ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx );
```

## Include Files

- `mkl_pblas.h`

## Description

The `p?scal` routines multiplies a  $n$ -element distributed vector  $\text{sub}(x)$  by the scalar  $a$ :

```
sub(x) = a*sub(x),
```

where  $\text{sub}(x)$  denotes  $X(ix, jx:jx+n-1)$  if  $incx=m_x$ , and  $X(ix: ix+n-1, jx)$  if  $incx= 1$ .

## Input Parameters

$n$	(global) The length of distributed vector $\text{sub}(x)$ , $n \geq 0$ .
$a$	(global) and <code>pssscal</code> Specifies the scalar $a$ .
$x$	(local) Array, size $(j_x-1)*m_x + ix+(n-1)*\text{abs}(incx)$ . This array contains the entries of the distributed vector $\text{sub}(x)$ .
$ix, jx$	(global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix $\text{sub}(X)$ , respectively.
$descx$	(global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .
$incx$	(global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m_x$ . $incx$ must not be zero.

## Output Parameters

$x$	Overwritten by the updated distributed vector $\text{sub}(x)$
-----	---

## p?swap

*Swaps two distributed vectors.*

### Syntax

```
void psswap (const MKL_INT *n , float *x , const MKL_INT *ix , const MKL_INT *jx ,
const MKL_INT *descx , const MKL_INT *incx , float *y , const MKL_INT *iy , const
MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy );
```

```
void pdswap (const MKL_INT *n , double *x , const MKL_INT *ix , const MKL_INT *jx ,
const MKL_INT *descx , const MKL_INT *incx , double *y , const MKL_INT *iy , const
MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy );
```

```
void pcswap (const MKL_INT *n , MKL_Complex8 *x , const MKL_INT *ix , const MKL_INT
*jx , const MKL_INT *descx , const MKL_INT *incx , MKL_Complex8 *y , const MKL_INT
*iy , const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy );
```

```
void pzswap (const MKL_INT *n , MKL_Complex16 *x , const MKL_INT *ix , const MKL_INT
*jx , const MKL_INT *descx , const MKL_INT *incx , MKL_Complex16 *y , const MKL_INT
*iy , const MKL_INT *jy , const MKL_INT *descy , const MKL_INT *incy );
```

## Include Files

- `mkl_pblas.h`

## Description

Given two distributed vectors  $\text{sub}(x)$  and  $\text{sub}(y)$ , the `p?swap` routines return vectors  $\text{sub}(y)$  and  $\text{sub}(x)$  swapped, each replacing the other.

Here  $\text{sub}(x)$  denotes  $X(ix, jx:jx+n-1)$  if  $incx=m_x$ , and  $X(ix: ix+n-1, jx)$  if  $incx= 1$ ;

$\text{sub}(y)$  denotes  $Y(iy, jy:jy+n-1)$  if  $incy=m_y$ , and  $Y(iy: iy+n-1, jy)$  if  $incy= 1$ .

## Input Parameters

<i>n</i>	(global) The length of distributed vectors, $n \geq 0$ .
<i>x</i>	(local) Array, size $(j_x-1) * m_x + i_x + (n-1) * \text{abs}(incx)$ . This array contains the entries of the distributed vector $\text{sub}(x)$ .
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix $\text{sub}(X)$ , respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m_x$ . <i>incx</i> must not be zero.
<i>y</i>	(local) Array, size $(j_y-1) * m_y + i_y + (n-1) * \text{abs}(incy)$ . This array contains the entries of the distributed vector $\text{sub}(y)$ .
<i>iy, jy</i>	(global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix $\text{sub}(Y)$ , respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) Specifies the increment for the elements of $\text{sub}(y)$ . Only two values are supported, namely 1 and $m_y$ . <i>incy</i> must not be zero.

## Output Parameters

<i>x</i>	Overwritten by distributed vector $\text{sub}(y)$ .
<i>y</i>	Overwritten by distributed vector $\text{sub}(x)$ .

## PBLAS Level 2 Routines

This section describes PBLAS Level 2 routines, which perform distributed matrix-vector operations. [Table "PBLAS Level 2 Routine Groups and Their Data Types"](#) lists the PBLAS Level 2 routine groups and the data types associated with them.

### PBLAS Level 2 Routine Groups and Their Data Types

Routine Groups	Data Types	Description
<a href="#">p?gemv</a>	s, d, c, z	Matrix-vector product using a distributed general matrix
<a href="#">p?agemv</a>	s, d, c, z	Matrix-vector product using absolute values for a distributed general matrix
<a href="#">p?ger</a>	s, d	Rank-1 update of a distributed general matrix
<a href="#">p?gerc</a>	c, z	Rank-1 update (conjugated) of a distributed general matrix

Routine Groups	Data Types	Description
<a href="#">p?geru</a>	c, z	Rank-1 update (unconjugated) of a distributed general matrix
<a href="#">p?hemv</a>	c, z	Matrix-vector product using a distributed Hermitian matrix
<a href="#">p?ahemv</a>	c, z	Matrix-vector product using absolute values for a distributed Hermitian matrix
<a href="#">p?her</a>	c, z	Rank-1 update of a distributed Hermitian matrix
<a href="#">p?her2</a>	c, z	Rank-2 update of a distributed Hermitian matrix
<a href="#">p?symv</a>	s, d	Matrix-vector product using a distributed symmetric matrix
<a href="#">p?asymv</a>	s, d	Matrix-vector product using absolute values for a distributed symmetric matrix
<a href="#">p?syr</a>	s, d	Rank-1 update of a distributed symmetric matrix
<a href="#">p?syr2</a>	s, d	Rank-2 update of a distributed symmetric matrix
<a href="#">p?trmv</a>	s, d, c, z	Distributed matrix-vector product using a triangular matrix
<a href="#">p?atrmv</a>	s, d, c, z	Distributed matrix-vector product using absolute values for a triangular matrix
<a href="#">p?trsv</a>	s, d, c, z	Solves a system of linear equations whose coefficients are in a distributed triangular matrix

## [p?gemv](#)

*Computes a distributed matrix-vector product using a general matrix.*

### Syntax

```
void psgemv (const char *trans , const MKL_INT *m , const MKL_INT *n , const float
*alpha , const float *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT

*incy );
```

## Include Files

- `mkl_pblas.h`

## Description

The `p?gemv` routines perform a distributed matrix-vector operation defined as

```
sub(y) := alpha*sub(A)*sub(x) + beta*sub(y),
```

or

```
sub(y) := alpha*sub(A)'*sub(x) + beta*sub(y),
```

or

```
sub(y) := alpha*conjg(sub(A)')*sub(x) + beta*sub(y),
```

where

*alpha* and *beta* are scalars,

*sub(A)* is a *m*-by-*n* submatrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$ ,

*sub(x)* and *sub(y)* are subvectors.

When *trans* = 'N' or 'n', *sub(x)* denotes  $X(\text{ix}, \text{jx}:\text{jx}+n-1)$  if *incx* = *m\_x*, and  $X(\text{ix}:\text{ix}+n-1, \text{jx})$  if *incx* = 1, *sub(y)* denotes  $Y(\text{iy}, \text{jy}:\text{jy}+m-1)$  if *incy* = *m\_y*, and  $Y(\text{iy}:\text{iy}+m-1, \text{jy})$  if *incy* = 1.

When *trans* = 'T' or 't', or 'C', or 'c', *sub(x)* denotes  $X(\text{ix}, \text{jx}:\text{jx}+m-1)$  if *incx* = *m\_x*, and  $X(\text{ix}:\text{ix}+m-1, \text{jx})$  if *incx* = 1, *sub(y)* denotes  $Y(\text{iy}, \text{jy}:\text{jy}+n-1)$  if *incy* = *m\_y*, and  $Y(\text{iy}:\text{iy}+m-1, \text{jy})$  if *incy* = 1.

## Input Parameters

<i>trans</i>	(global) Specifies the operation: if <i>trans</i> = 'N' or 'n', then $\text{sub}(y) := \alpha * \text{sub}(A) * \text{sub}(x) + \beta * \text{sub}(y)$ ; if <i>trans</i> = 'T' or 't', then $\text{sub}(y) := \alpha * \text{sub}(A)' * \text{sub}(x) + \beta * \text{sub}(y)$ ; if <i>trans</i> = 'C' or 'c', then $\text{sub}(y) := \alpha * \text{conjg}(\text{sub}(A)') * \text{sub}(x) + \beta * \text{sub}(y)$ .
<i>m</i>	(global) Specifies the number of rows of the distributed matrix <i>sub(A)</i> , $m \geq 0$ .
<i>n</i>	(global) Specifies the number of columns of the distributed matrix <i>sub(A)</i> , $n \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size $(\text{lld}_a, \text{LOCq}(\text{ja}+n-1))$ . Before entry this array must contain the local pieces of the distributed matrix <i>sub(A)</i> .

<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>x</i>	(local) Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$ when <i>trans</i> = 'N' or 'n', and $(jx-1)*m_x + ix+(m-1)*abs(incx)$ otherwise. This array contains the entries of the distributed vector <i>sub(x)</i> .
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix <i>sub(x)</i> , respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.
<i>beta</i>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then <i>sub(y)</i> need not be set on input.
<i>y</i>	(local) Array, size $(jy-1)*m_y + iy+(m-1)*abs(incy)$ when <i>trans</i> = 'N' or 'n', and $(jy-1)*m_y + iy+(n-1)*abs(incy)$ otherwise. This array contains the entries of the distributed vector <i>sub(y)</i> .
<i>iy, jy</i>	(global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <i>sub(y)</i> , respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) Specifies the increment for the elements of <i>sub(y)</i> . Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.

## Output Parameters

<i>y</i>	Overwritten by the updated distributed vector <i>sub(y)</i> .
----------	---

## p?agemv

Computes a distributed matrix-vector product using absolute values for a general matrix.

## Description

The p?agemv routines perform a distributed matrix-vector operation defined as

$$\text{sub}(y) := \text{abs}(\alpha) * \text{abs}(\text{sub}(A)') * \text{abs}(\text{sub}(x)) + \text{abs}(\beta * \text{sub}(y)),$$

or

$$\text{sub}(y) := \text{abs}(\alpha) * \text{abs}(\text{sub}(A)') * \text{abs}(\text{sub}(x)) + \text{abs}(\beta * \text{sub}(y)),$$

or

$$\text{sub}(y) := \text{abs}(\alpha) * \text{abs}(\text{conjg}(\text{sub}(A)')) * \text{abs}(\text{sub}(x)) + \text{abs}(\beta * \text{sub}(y)),$$

where

*alpha* and *beta* are scalars,

sub(A) is a *m*-by-*n* submatrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$ ,

sub(*x*) and sub(*y*) are subvectors.

When *trans* = 'N' or 'n',

sub(*x*) denotes  $X(\text{ix}:\text{ix}, \text{jx}:\text{jx}+n-1)$  if *incx* = *m<sub>x</sub>*, and

$X(\text{ix}:\text{ix}+n-1, \text{jx}:\text{jx})$  if *incx* = 1,

sub(*y*) denotes  $Y(\text{iy}:\text{iy}, \text{jy}:\text{jy}+m-1)$  if *incy* = *m<sub>y</sub>*, and

$Y(\text{iy}:\text{iy}+m-1, \text{jy}:\text{jy})$  if *incy* = 1.

When *trans* = 'T' or 't', or 'C', or 'c',

sub(*x*) denotes  $X(\text{ix}:\text{ix}, \text{jx}:\text{jx}+m-1)$  if *incx* = *m<sub>x</sub>*, and

$X(\text{ix}:\text{ix}+m-1, \text{jx}:\text{jx})$  if *incx* = 1,

sub(*y*) denotes  $Y(\text{iy}:\text{iy}, \text{jy}:\text{jy}+n-1)$  if *incy* = *m<sub>y</sub>*, and

$Y(\text{iy}:\text{iy}+m-1, \text{jy}:\text{jy})$  if *incy* = 1.

## Input Parameters

<i>trans</i>	<p>(global) Specifies the operation:</p> <p>if <i>trans</i> = 'N' or 'n', then <math>\text{sub}(y) :=  \alpha  * \text{sub}(A) + \text{sub}(x) + \beta * \text{sub}(y)</math></p> <p>if <i>trans</i> = 'T' or 't', then <math>\text{sub}(y) :=  \alpha  * \text{sub}(A)' + \text{sub}(x) + \beta * \text{sub}(y)</math></p> <p>if <i>trans</i> = 'C' or 'c', then <math>\text{sub}(y) :=  \alpha  * \text{sub}(A)' + \text{sub}(x) + \beta * \text{sub}(y)</math>.</p>
<i>m</i>	(global) Specifies the number of rows of the distributed matrix $\text{sub}(A)$ , $m \geq 0$ .
<i>n</i>	(global) Specifies the number of columns of the distributed matrix $\text{sub}(A)$ , $n \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size $(lld\_a, LOCq(ja+n-1))$ . Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(A)$ .
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>x</i>	(local) Array, size $(jx-1)*m\_x + ix+(n-1)*abs(incx)$ when <i>trans</i> = 'N' or 'n', and $(jx-1)*m\_x + ix+(m-1)*abs(incx)$ otherwise. This array contains the entries of the distributed vector $\text{sub}(x)$ .
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix $\text{sub}(x)$ , respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m\_x$ . <i>incx</i> must not be zero.
<i>beta</i>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then $\text{sub}(y)$ need not be set on input.
<i>y</i>	(local) Array, size $(jy-1)*m\_y + iy+(m-1)*abs(incy)$ when <i>trans</i> = 'N' or 'n', and $(jy-1)*m\_y + iy+(n-1)*abs(incy)$ otherwise. This array contains the entries of the distributed vector $\text{sub}(y)$ .

<i>iy, jy</i>	(global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <i>sub(y)</i> , respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) Specifies the increment for the elements of <i>sub(y)</i> . Only two values are supported, namely 1 and <i>m<sub>y</sub></i> . <i>incy</i> must not be zero.

## Output Parameters

<i>y</i>	Overwritten by the updated distributed vector <i>sub(y)</i> .
----------	---

## p?ger

Performs a rank-1 update of a distributed general matrix.

### Syntax

```
void psger (const MKL_INT *m , const MKL_INT *n , const float *alpha , const float *x ,
const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx ,
const float *y , const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy , const
MKL_INT *incy , float *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT
*desca );
```

### Description

The `p?ger` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha \text{sub}(x) \text{sub}(y)' + \text{sub}(A),$$

where:

*alpha* is a scalar,

*sub(A)* is a *m*-by-*n* distributed general matrix, *sub(A)*=*A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1),

*sub(x)* is an *m*-element distributed vector, *sub(y)* is an *n*-element distributed vector,

*sub(x)* denotes *X*(*ix*, *jx*:*jx*+*m*-1) if *incx* = *m<sub>x</sub>*, and *X*(*ix*: *ix*+*m*-1, *jx*) if *incx* = 1,

*sub(y)* denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m<sub>y</sub>*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

### Input Parameters

<i>m</i>	(global) Specifies the number of rows of the distributed matrix <i>sub(A)</i> , <i>m</i> ≥0.
----------	--

<i>n</i>	(global) Specifies the number of columns of the distributed matrix $\text{sub}(A)$ , $n \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) Array, size at least $(j_x-1) * m_x + i_x + (m-1) * \text{abs}(incx)$ . This array contains the entries of the distributed vector $\text{sub}(x)$ .
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix $\text{sub}(x)$ , respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m_x$ . <i>incx</i> must not be zero.
<i>y</i>	(local) Array, size at least $(j_y-1) * m_y + i_y + (n-1) * \text{abs}(incy)$ . This array contains the entries of the distributed vector $\text{sub}(y)$ .
<i>iy, jy</i>	(global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix $\text{sub}(y)$ , respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) Specifies the increment for the elements of $\text{sub}(y)$ . Only two values are supported, namely 1 and $m_y$ . <i>incy</i> must not be zero.
<i>a</i>	(local) Array, size $(lld_a, LOCq(ja+n-1))$ . Before entry this array contains the local pieces of the distributed matrix $\text{sub}(A)$ .
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .

## Output Parameters

<i>a</i>	Overwritten by the updated distributed matrix $\text{sub}(A)$ .
----------	---

## p?gerc

Performs a rank-1 update (conjugated) of a distributed general matrix.

---

## Syntax

```
void pcgerc (const MKL_INT *m , const MKL_INT *n , const MKL_Complex8 *alpha , const
MKL_Complex8 *x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const
MKL_INT *incx , const MKL_Complex8 *y , const MKL_INT *iy , const MKL_INT *jy , const
MKL_INT *descy , const MKL_INT *incy , MKL_Complex8 *a , const MKL_INT *ia , const
MKL_INT *ja , const MKL_INT *desca );
```

## Description

The p?geru routines perform a matrix-vector operation defined as

$$sub(A) := alpha * sub(x) * sub(y)' + sub(A),$$

where:

*alpha* is a scalar,

$\text{sub}(A)$  is a  $m$ -by- $n$  distributed general matrix,  $\text{sub}(A)=A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$ ,  
 $\text{sub}(x)$  is an  $m$ -element distributed vector,  $\text{sub}(y)$  is an  $n$ -element distributed vector,  
 $\text{sub}(x)$  denotes  $X(\text{ix}, \text{jx}:\text{jx}+m-1)$  if  $\text{incx} = m_x$ , and  $X(\text{ix}:\text{ix}+m-1, \text{jx})$  if  $\text{incx} = 1$ ,  
 $\text{sub}(y)$  denotes  $Y(\text{iy}, \text{jy}:\text{jy}+n-1)$  if  $\text{incy} = m_y$ , and  $Y(\text{iy}:\text{iy}+n-1, \text{jy})$  if  $\text{incy} = 1$ .

## Input Parameters

$m$	(global) Specifies the number of rows of the distributed matrix $\text{sub}(A)$ , $m \geq 0$ .
$n$	(global) Specifies the number of columns of the distributed matrix $\text{sub}(A)$ , $n \geq 0$ .
$\alpha$	(global) Specifies the scalar $\alpha$ .
$x$	(local) Array, size at least $(\text{jx}-1)*m_x + \text{ix}+(n-1)*\text{abs}(\text{incx})$ . This array contains the entries of the distributed vector $\text{sub}(x)$ .
$\text{ix}, \text{jx}$	(global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix $\text{sub}(x)$ , respectively.
$\text{descx}$	(global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .
$\text{incx}$	(global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m_x$ . $\text{incx}$ must not be zero.
$y$	(local) Array, size at least $(\text{jy}-1)*m_y + \text{iy}+(n-1)*\text{abs}(\text{incy})$ . This array contains the entries of the distributed vector $\text{sub}(y)$ .
$\text{iy}, \text{jy}$	(global) The row and column indices in the distributed matrix $Y$ indicating the first row and the first column of the submatrix $\text{sub}(y)$ , respectively.
$\text{descy}$	(global and local) array of dimension 9. The array descriptor of the distributed matrix $Y$ .
$\text{incy}$	(global) Specifies the increment for the elements of $\text{sub}(y)$ . Only two values are supported, namely 1 and $m_y$ . $\text{incy}$ must not be zero.
$a$	(local) Array, size at least $(\text{lld}_a, \text{LOCq}(\text{ja}+n-1))$ . Before entry this array contains the local pieces of the distributed matrix $\text{sub}(A)$ .
$\text{ia}, \text{ja}$	(global) The row and column indices in the distributed matrix $A$ indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.
$\text{desca}$	(global and local) array of dimension 9. The array descriptor of the distributed matrix $A$ .

## Output Parameters

*a* Overwritten by the updated distributed matrix `sub(A)`.

## p?hemv

Computes a distributed matrix-vector product using a Hermitian matrix.

## Syntax

```
void pchemv (const char *uplo , const MKL_INT *n , const MKL_Complex8 *alpha , const
MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const

## Description

The `p?hemv` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(y) := \alpha * \text{sub}(A) * \text{sub}(x) + \beta * \text{sub}(y),$$

where:

*alpha* and *beta* are scalars,

`sub(A)` is a *n*-by-*n* Hermitian distributed matrix, `sub(A)=A(ia:ia+n-1, ja:ja+n-1)`,

`sub(x)` and `sub(y)` are distributed vectors.

`sub(x)` denotes `X(ix, jx:jx+n-1)` if `incx = m_x`, and `X(ix: ix+n-1, jx)` if `incx = 1`,

`sub(y)` denotes `Y(iy, jy:jy+n-1)` if `incy = m_y`, and `Y(iy: iy+n-1, jy)` if `incy = 1`.

## Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <code>sub(A)</code> is used:  If <code>uplo = 'U'</code> or <code>'u'</code> , then the upper triangular part of the <code>sub(A)</code> is used.  If <code>uplo = 'L'</code> or <code>'l'</code> , then the low triangular part of the <code>sub(A)</code> is used.
<i>n</i>	(global) Specifies the order of the distributed matrix <code>sub(A)</code> , $n \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local)

Array, size  $(lld\_a, LOCq(ja+n-1))$ . This array contains the local pieces of the distributed matrix  $sub(A)$ .

Before entry when  $uplo = 'U'$  or  $'u'$ , the  $n$ -by- $n$  upper triangular part of the distributed matrix  $sub(A)$  must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of  $sub(A)$  is not referenced, and when  $uplo = 'L'$  or  $'l'$ , the  $n$ -by- $n$  lower triangular part of the distributed matrix  $sub(A)$  must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of  $sub(A)$  is not referenced.

*ia, ja* (global) The row and column indices in the distributed matrix  $A$  indicating the first row and the first column of the submatrix  $sub(A)$ , respectively.

*desca* (global and local) array of dimension 9. The array descriptor of the distributed matrix  $A$ .

*x* (local)  
Array, size at least  $(jx-1)*m\_x + ix+(n-1)*abs(incx)$ .  
This array contains the entries of the distributed vector  $sub(x)$ .

*ix, jx* (global) The row and column indices in the distributed matrix  $X$  indicating the first row and the first column of the submatrix  $sub(x)$ , respectively.

*descx* (global and local) array of dimension 9. The array descriptor of the distributed matrix  $X$ .

*incx* (global) Specifies the increment for the elements of  $sub(x)$ . Only two values are supported, namely 1 and  $m\_x$ .  $incx$  must not be zero.

*beta* (global)  
Specifies the scalar  $beta$ . When  $beta$  is set to zero, then  $sub(y)$  need not be set on input.

*y* (local)  
Array, size at least  $(jy-1)*m\_y + iy+(n-1)*abs(incy)$ .  
This array contains the entries of the distributed vector  $sub(y)$ .

*iy, jy* (global) The row and column indices in the distributed matrix  $Y$  indicating the first row and the first column of the submatrix  $sub(y)$ , respectively.

*descy* (global and local) array of dimension 9. The array descriptor of the distributed matrix  $Y$ .

*incy* (global) Specifies the increment for the elements of  $sub(y)$ . Only two values are supported, namely 1 and  $m\_y$ .  $incy$  must not be zero.

## Output Parameters

*y* Overwritten by the updated distributed vector  $sub(y)$ .

### **p?ahemv**

*Computes a distributed matrix-vector product using absolute values for a Hermitian matrix.*

## Syntax

```

## Description

The p?ahemv routines perform a distributed matrix-vector operation defined as

$$\text{sub}(y) := \text{abs}(\text{alpha}) * \text{abs}(\text{sub}(A)) * \text{abs}(\text{sub}(x)) + \text{abs}(\text{beta} * \text{sub}(y)),$$

where:

*alpha* and *beta* are scalars,

*sub*(*A*) is a *n*-by-*n* Hermitian distributed matrix, *sub*(*A*)=*A*(*ia:ia+n-1, ja:ja+n-1*) ,

*sub*(*x*) and *sub*(*y*) are distributed vectors.

*sub*(*x*) denotes *X*(*ix, jx:jx+n-1*) if *incx* = *m\_x*, and *X*(*ix: ix+n-1, jx*) if *incx* = 1,

*sub*(*y*) denotes *Y*(*iy, jy:jy+n-1*) if *incy* = *m\_y*, and *Y*(*iy: iy+n-1, jy*) if *incy* = 1.

## Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <i>sub</i> ( <i>A</i> ) is used:  If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub</i> ( <i>A</i> ) is used.  If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub</i> ( <i>A</i> ) is used.
<i>n</i>	(global) Specifies the order of the distributed matrix <i>sub</i> ( <i>A</i> ), $n \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size ( <i>lld_a</i> , <i>LOCq</i> ( <i>ja+n-1</i> )). This array contains the local pieces of the distributed matrix <i>sub</i> ( <i>A</i> ).  Before entry when <i>uplo</i> = 'U' or 'u', the <i>n</i> -by- <i>n</i> upper triangular part of the distributed matrix <i>sub</i> ( <i>A</i> ) must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of <i>sub</i> ( <i>A</i> ) is not referenced, and when <i>uplo</i> = 'L' or 'l', the <i>n</i> -by- <i>n</i> lower

triangular part of the distributed matrix  $\text{sub}(A)$  must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of  $\text{sub}(A)$  is not referenced.

<i>ia, ja</i>	(global) The row and column indices in the distributed matrix $A$ indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix $A$ .
<i>x</i>	(local) Array, size at least $(j_x-1)*m_x + i_x + (n-1)*\text{abs}(incx)$ . This array contains the entries of the distributed vector $\text{sub}(x)$ .
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix $\text{sub}(x)$ , respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .
<i>incx</i>	(global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m_x$ . <i>incx</i> must not be zero.
<i>beta</i>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then $\text{sub}(y)$ need not be set on input.
<i>y</i>	(local) Array, size at least $(j_y-1)*m_y + i_y + (n-1)*\text{abs}(incy)$ . This array contains the entries of the distributed vector $\text{sub}(y)$ .
<i>iy, jy</i>	(global) The row and column indices in the distributed matrix $Y$ indicating the first row and the first column of the submatrix $\text{sub}(y)$ , respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix $Y$ .
<i>incy</i>	(global) Specifies the increment for the elements of $\text{sub}(y)$ . Only two values are supported, namely 1 and $m_y$ . <i>incy</i> must not be zero.

## Output Parameters

<i>y</i>	Overwritten by the updated distributed vector $\text{sub}(y)$ .
----------	---

## p?her

Performs a rank-1 update of a distributed Hermitian matrix.

### Syntax

```
void pcher (const char *uplo , const MKL_INT *n , const float *alpha , const
MKL_Complex8 *x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const
MKL_INT *incx , MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT
*desca );
```

```
void pzher (const char *uplo , const MKL_INT *n , const double *alpha , const
MKL_Complex16 *x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const
MKL_INT *incx , MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const
MKL_INT *desca );
```

## Include Files

- mkl\_pblas.h

## Description

The `pzher` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{conjg}(\text{sub}(x)') + \text{sub}(A),$$

where:

$\alpha$  is a real scalar,

$\text{sub}(A)$  is a  $n$ -by- $n$  distributed Hermitian matrix,  $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ ,

$\text{sub}(x)$  is distributed vector.

$\text{sub}(x)$  denotes  $X(ix, jx:jx+n-1)$  if  $incx = m_x$ , and  $X(ix:ix+n-1, jx)$  if  $incx = 1$ .

## Input Parameters

<code>uplo</code>	(global) Specifies whether the upper or lower triangular part of the Hermitian distributed matrix $\text{sub}(A)$ is used:  If <code>uplo = 'U' or 'u'</code> , then the upper triangular part of the $\text{sub}(A)$ is used.  If <code>uplo = 'L' or 'l'</code> , then the low triangular part of the $\text{sub}(A)$ is used.
<code>n</code>	(global) Specifies the order of the distributed matrix $\text{sub}(A)$ , $n \geq 0$ .
<code>alpha</code>	(global) Specifies the scalar $\alpha$ .
<code>x</code>	(local) Array, size at least $(jx-1) * m_x + ix + (n-1) * \text{abs}(incx)$ .  This array contains the entries of the distributed vector $\text{sub}(x)$ .
<code>ix, jx</code>	(global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix $\text{sub}(x)$ , respectively.
<code>descx</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .
<code>incx</code>	(global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m_x$ . $incx$ must not be zero.
<code>a</code>	(local) Array, size $(lld_a, LOCq(ja+n-1))$ . This array contains the local pieces of the distributed matrix $\text{sub}(A)$ .  Before entry with <code>uplo = 'U' or 'u'</code> , the $n$ -by- $n$ upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of $\text{sub}(A)$

is not referenced, and with `uplo = 'L' or 'l'`, the  $n$ -by- $n$  lower triangular part of the distributed matrix `sub(A)` must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of `sub(A)` is not referenced.

`ia, ja` (global) The row and column indices in the distributed matrix  $A$  indicating the first row and the first column of the submatrix `sub(A)`, respectively.

`desca` (global and local) array of dimension 9. The array descriptor of the distributed matrix  $A$ .

## Output Parameters

`a` With `uplo = 'U' or 'u'`, the upper triangular part of the array  $a$  is overwritten by the upper triangular part of the updated distributed matrix `sub(A)`.

With `uplo = 'L' or 'l'`, the lower triangular part of the array  $a$  is overwritten by the lower triangular part of the updated distributed matrix `sub(A)`.

## p?her2

Performs a rank-2 update of a distributed Hermitian matrix.

## Syntax

```
void pcher2 (const char *uplo , const MKL_INT *n , const MKL_Complex8 *alpha , const
MKL_Complex8 *x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const
MKL_INT *incx , const MKL_Complex8 *y , const MKL_INT *iy , const MKL_INT *jy , const
MKL_INT *descy , const MKL_INT *incy , MKL_Complex8 *a , const MKL_INT *ia , const
MKL_INT *ja , const MKL_INT *desca );
```

```
void pzher2 (const char *uplo , const MKL_INT *n , const MKL_Complex16 *alpha , const
MKL_Complex16 *x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const
MKL_INT *incx , const MKL_Complex16 *y , const MKL_INT *iy , const MKL_INT *jy , const
MKL_INT *descy , const MKL_INT *incy , MKL_Complex16 *a , const MKL_INT *ia , const
MKL_INT *ja , const MKL_INT *desca );
```

## Include Files

- `mkl_pblas.h`

## Description

The `p?her2` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{conj}(\text{sub}(y)') + \text{conj}(\alpha) * \text{sub}(y) * \text{conj}(\text{sub}(x)') + \text{sub}(A),$$

where:

$\alpha$  is a scalar,

`sub(A)` is a  $n$ -by- $n$  distributed Hermitian matrix, `sub(A)=A(ia:ia+n-1, ja:ja+n-1)`,

`sub(x)` and `sub(y)` are distributed vectors.

`sub(x)` denotes  $X(ix, jx:jx+n-1)$  if `incx = m_x`, and  $X(ix: ix+n-1, jx)$  if `incx = 1`,

`sub(y)` denotes  $Y(iy, jy:jy+n-1)$  if `incy = m_y`, and  $Y(iy: iy+n-1, jy)$  if `incy = 1`.

## Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the distributed Hermitian matrix $\text{sub}(A)$ is used:  If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the $\text{sub}(A)$ is used.  If <i>uplo</i> = 'L' or 'l', then the low triangular part of the $\text{sub}(A)$ is used.
<i>n</i>	(global) Specifies the order of the distributed matrix $\text{sub}(A)$ , $n \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) Array, size at least $(j_x-1)*m_x + i_x + (n-1)*\text{abs}(incx)$ . This array contains the entries of the distributed vector $\text{sub}(x)$ .
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix $\text{sub}(x)$ , respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m_x$ . <i>incx</i> must not be zero.
<i>y</i>	(local) Array, size at least $(j_y-1)*m_y + i_y + (n-1)*\text{abs}(incy)$ . This array contains the entries of the distributed vector $\text{sub}(y)$ .
<i>iy, jy</i>	(global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix $\text{sub}(y)$ , respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) Specifies the increment for the elements of $\text{sub}(y)$ . Only two values are supported, namely 1 and $m_y$ . <i>incy</i> must not be zero.
<i>a</i>	(local) Array, size $(lld_a, \text{LOCq}(j_a+n-1))$ . This array contains the local pieces of the distributed matrix $\text{sub}(A)$ .  Before entry with <i>uplo</i> = 'U' or 'u', the <i>n</i> -by- <i>n</i> upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and with <i>uplo</i> = 'L' or 'l', the <i>n</i> -by- <i>n</i> lower triangular part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.

*desca* (global and local) array of dimension 9. The array descriptor of the distributed matrix *A*.

## Output Parameters

*a* With *uplo* = 'U' or 'u', the upper triangular part of the array *a* is overwritten by the upper triangular part of the updated distributed matrix *sub(A)*.

With *uplo* = 'L' or 'l', the lower triangular part of the array *a* is overwritten by the lower triangular part of the updated distributed matrix *sub(A)*.

## p?symv

*Computes a distributed matrix-vector product using a symmetric matrix.*

### Syntax

### Description

The `p?symv` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(y) := \alpha * \text{sub}(A) * \text{sub}(x) + \beta * \text{sub}(y),$$

where:

*alpha* and *beta* are scalars,

*sub(A)* is a *n*-by-*n* symmetric distributed matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ ,

*sub(x)* and *sub(y)* are distributed vectors.

*sub(x)* denotes  $X(\text{ix}, \text{jx}:\text{jx}+n-1)$  if *incx* = *m\_x*, and  $X(\text{ix}:\text{ix}+n-1, \text{jx})$  if *incx* = 1,

*sub(y)* denotes  $Y(\text{iy}, \text{jy}:\text{jy}+n-1)$  if *incy* = *m\_y*, and  $Y(\text{iy}:\text{iy}+n-1, \text{jy})$  if *incy* = 1.

### Input Parameters

*uplo* (global) Specifies whether the upper or lower triangular part of the symmetric distributed matrix *sub(A)* is used:

If *uplo* = 'U' or 'u', then the upper triangular part of the *sub(A)* is used.

	If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(A)</i> is used.
<i>n</i>	(global) Specifies the order of the distributed matrix <i>sub(A)</i> , $n \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size $(lld\_a, LOCq(ja+n-1))$ . This array contains the local pieces of the distributed matrix <i>sub(A)</i> .  Before entry when <i>uplo</i> = 'U' or 'u', the <i>n</i> -by- <i>n</i> upper triangular part of the distributed matrix <i>sub(A)</i> must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of <i>sub(A)</i> is not referenced, and when <i>uplo</i> = 'L' or 'l', the <i>n</i> -by- <i>n</i> lower triangular part of the distributed matrix <i>sub(A)</i> must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of <i>sub(A)</i> is not referenced.
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>x</i>	(local) Array, size at least $(jx-1)*m\_x + ix+(n-1)*abs(incx)$ . This array contains the entries of the distributed vector <i>sub(x)</i> .
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix <i>sub(x)</i> , respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.
<i>beta</i>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then <i>sub(y)</i> need not be set on input.
<i>y</i>	(local) Array, size at least $(jy-1)*m\_y + iy+(n-1)*abs(incy)$ . This array contains the entries of the distributed vector <i>sub(y)</i> .
<i>iy, jy</i>	(global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <i>sub(y)</i> , respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) Specifies the increment for the elements of <i>sub(y)</i> . Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.

## Output Parameters

*y* Overwritten by the updated distributed vector `sub(y)`.

### p?asymv

### Description

The `p?symv` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(y) := \text{abs}(\alpha) * \text{abs}(\text{sub}(A)) * \text{abs}(\text{sub}(x)) + \text{abs}(\beta * \text{sub}(y)),$$

where:

*alpha* and *beta* are scalars,

`sub(A)` is a *n*-by-*n* symmetric distributed matrix, `sub(A)=A(ia:ia+n-1, ja:ja+n-1)`,

`sub(x)` and `sub(y)` are distributed vectors.

`sub(x)` denotes `X(ix, jx:jx+n-1)` if `incx = m_x`, and `X(ix: ix+n-1, jx)` if `incx = 1`,

`sub(y)` denotes `Y(iy, jy:jy+n-1)` if `incy = m_y`, and `Y(iy: iy+n-1, jy)` if `incy = 1`.

### Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the symmetric distributed matrix <code>sub(A)</code> is used:  If <code>uplo = 'U'</code> or <code>'u'</code> , then the upper triangular part of the <code>sub(A)</code> is used.  If <code>uplo = 'L'</code> or <code>'l'</code> , then the low triangular part of the <code>sub(A)</code> is used.
<i>n</i>	(global) Specifies the order of the distributed matrix <code>sub(A)</code> , $n \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local)

Array, size  $(lld\_a, LOCq(ja+n-1))$ . This array contains the local pieces of the distributed matrix  $sub(A)$ .

Before entry when  $uplo = 'U'$  or  $'u'$ , the  $n$ -by- $n$  upper triangular part of the distributed matrix  $sub(A)$  must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of  $sub(A)$  is not referenced, and when  $uplo = 'L'$  or  $'l'$ , the  $n$ -by- $n$  lower triangular part of the distributed matrix  $sub(A)$  must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of  $sub(A)$  is not referenced.

*ia, ja* (global) The row and column indices in the distributed matrix  $A$  indicating the first row and the first column of the submatrix  $sub(A)$ , respectively.

*desca* (global and local) array of dimension 9. The array descriptor of the distributed matrix  $A$ .

*x* (local)  
Array, size at least  $(jx-1)*m\_x + ix+(n-1)*abs(incx)$ .  
This array contains the entries of the distributed vector  $sub(x)$ .

*ix, jx* (global) The row and column indices in the distributed matrix  $X$  indicating the first row and the first column of the submatrix  $sub(x)$ , respectively.

*descx* (global and local) array of dimension 9. The array descriptor of the distributed matrix  $X$ .

*incx* (global) Specifies the increment for the elements of  $sub(x)$ . Only two values are supported, namely 1 and  $m\_x$ . *incx* must not be zero.

*beta* (global)  
Specifies the scalar *beta*. When *beta* is set to zero, then  $sub(y)$  need not be set on input.

*y* (local)  
Array, size at least  $(jy-1)*m\_y + iy+(n-1)*abs(incy)$ .  
This array contains the entries of the distributed vector  $sub(y)$ .

*iy, jy* (global) The row and column indices in the distributed matrix  $Y$  indicating the first row and the first column of the submatrix  $sub(y)$ , respectively.

*descy* (global and local) array of dimension 9. The array descriptor of the distributed matrix  $Y$ .

*incy* (global) Specifies the increment for the elements of  $sub(y)$ . Only two values are supported, namely 1 and  $m\_y$ . *incy* must not be zero.

## Output Parameters

*y* Overwritten by the updated distributed vector  $sub(y)$ .

## p?syr

Performs a rank-1 update of a distributed symmetric matrix.

## Syntax

```
void pssyr (const char *uplo , const MKL_INT *n , const float *alpha , const float *x ,
const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT *incx ,
float *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca );
```

```
void pdsyr (const char *uplo , const MKL_INT *n , const double *alpha , const double
*x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT
*incx , double *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca );
```

## Include Files

## Description

The `p?syr` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{sub}(x)' + \text{sub}(A),$$

where:

*alpha* is a scalar,

*sub(A)* is a *n*-by-*n* distributed symmetric matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ ,

*sub(x)* is distributed vector.

*sub(x)* denotes  $X(\text{ix}, \text{jx}:\text{jx}+n-1)$  if *incx* = *m<sub>x</sub>*, and  $X(\text{ix}:\text{ix}+n-1, \text{jx})$  if *incx* = 1,

## Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the symmetric distributed matrix <i>sub(A)</i> is used:  If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(A)</i> is used.  If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(A)</i> is used.
<i>n</i>	(global) Specifies the order of the distributed matrix <i>sub(A)</i> , $n \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) Array, size at least $(\text{jx}-1) * m_x + \text{ix} + (n-1) * \text{abs}(\text{incx})$ .  This array contains the entries of the distributed vector <i>sub(x)</i> .
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix <i>sub(x)</i> , respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and <i>m<sub>x</sub></i> . <i>incx</i> must not be zero.
<i>a</i>	(local) Array, size $(l1d_a, \text{LOCq}(\text{ja}+n-1))$ . This array contains the local pieces of the distributed matrix <i>sub(A)</i> .

Before entry with `uplo = 'U' or 'u'`, the  $n$ -by- $n$  upper triangular part of the distributed matrix `sub(A)` must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of `sub(A)` is not referenced, and with `uplo = 'L' or 'l'`, the  $n$ -by- $n$  lower triangular part of the distributed matrix `sub(A)` must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of `sub(A)` is not referenced.

`ia, ja`

(global) The row and column indices in the distributed matrix  $A$  indicating the first row and the first column of the submatrix `sub(A)`, respectively.

`desca`

(global and local) array of dimension 9. The array descriptor of the distributed matrix  $A$ .

## Output Parameters

`a`

With `uplo = 'U' or 'u'`, the upper triangular part of the array `a` is overwritten by the upper triangular part of the updated distributed matrix `sub(A)`.

With `uplo = 'L' or 'l'`, the lower triangular part of the array `a` is overwritten by the lower triangular part of the updated distributed matrix `sub(A)`.

## p?syr2

Performs a rank-2 update of a distributed symmetric matrix.

## Syntax

```
void pssyr2 (const char *uplo , const MKL_INT *n , const float *alpha , const float
*x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT
*incx , const float *y , const MKL_INT *iy , const MKL_INT *jy , const MKL_INT *descy ,
const MKL_INT *incy , float *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT
*desca );
```

```
void pdsyr2 (const char *uplo , const MKL_INT *n , const double *alpha , const double
*x , const MKL_INT *ix , const MKL_INT *jx , const MKL_INT *descx , const MKL_INT
*incx , const double *y , const MKL_INT *iy , const MKL_INT *jy , const MKL_INT
*descy , const MKL_INT *incy , double *a , const MKL_INT *ia , const MKL_INT *ja ,
const MKL_INT *desca );
```

## Include Files

- `mkl_pblas.h`

## Description

The `p?syr2` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{sub}(y)' + \alpha * \text{sub}(y) * \text{sub}(x)' + \text{sub}(A),$$

where:

`alpha` is a scalar,

`sub(A)` is a  $n$ -by- $n$  distributed symmetric matrix, `sub(A) = A(ia:ia+n-1, ja:ja+n-1)`,

`sub(x)` and `sub(y)` are distributed vectors.

$\text{sub}(x)$  denotes  $X(ix, jx:jx+n-1)$  if  $incx = m_x$ , and  $X(ix:ix+n-1, jx)$  if  $incx = 1$ ,

$\text{sub}(y)$  denotes  $Y(iy, jy:jy+n-1)$  if  $incy = m_y$ , and  $Y(iy:iy+n-1, jy)$  if  $incy = 1$ .

## Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the distributed symmetric matrix $\text{sub}(A)$ is used:  If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the $\text{sub}(A)$ is used.  If <i>uplo</i> = 'L' or 'l', then the low triangular part of the $\text{sub}(A)$ is used.
<i>n</i>	(global) Specifies the order of the distributed matrix $\text{sub}(A)$ , $n \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) Array, size at least $(jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$ . This array contains the entries of the distributed vector $\text{sub}(x)$ .
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix $X$ indicating the first row and the first column of the submatrix $\text{sub}(x)$ , respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix $X$ .
<i>incx</i>	(global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m_x$ . <i>incx</i> must not be zero.
<i>y</i>	(local) Array, size at least $(jy-1)*m_y + iy+(n-1)*\text{abs}(incy)$ . This array contains the entries of the distributed vector $\text{sub}(y)$ .
<i>iy, jy</i>	(global) The row and column indices in the distributed matrix $Y$ indicating the first row and the first column of the submatrix $\text{sub}(y)$ , respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix $Y$ .
<i>incy</i>	(global) Specifies the increment for the elements of $\text{sub}(y)$ . Only two values are supported, namely 1 and $m_y$ . <i>incy</i> must not be zero.
<i>a</i>	(local) Array, size $(lld_a, \text{LOCq}(ja+n-1))$ . This array contains the local pieces of the distributed matrix $\text{sub}(A)$ .  Before entry with <i>uplo</i> = 'U' or 'u', the $n$ -by- $n$ upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the distributed symmetric matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and with <i>uplo</i> = 'L' or 'l', the $n$ -by- $n$ lower triangular part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the distributed symmetric matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .

## Output Parameters

<i>a</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of the array <i>a</i> is overwritten by the upper triangular part of the updated distributed matrix $\text{sub}(A)$ .  With <i>uplo</i> = 'L' or 'l', the lower triangular part of the array <i>a</i> is overwritten by the lower triangular part of the updated distributed matrix $\text{sub}(A)$ .

## Description

The `p?trsv` routines solve one of the systems of equations:

$\text{sub}(A) * \text{sub}(x) = b$ , or  $\text{sub}(A)' * \text{sub}(x) = b$ , or  $\text{conjg}(\text{sub}(A)') * \text{sub}(x) = b$ ,

where:

$\text{sub}(A)$  is a  $n$ -by- $n$  unit, or non-unit, upper or lower triangular distributed matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ ,

$b$  and  $\text{sub}(x)$  are  $n$ -element distributed vectors,

$\text{sub}(x)$  denotes  $X(\text{ix}, \text{jx}:\text{jx}+n-1)$  if  $\text{incx} = m_x$ , and  $X(\text{ix}:\text{ix}+n-1, \text{jx})$  if  $\text{incx} = 1$ ,

The routine does not test for singularity or near-singularity. Such tests must be performed before calling this routine.

## Input Parameters

<code>uplo</code>	(global) Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular: if <code>uplo</code> = 'U' or 'u', then the matrix is upper triangular; if <code>uplo</code> = 'L' or 'l', then the matrix is low triangular.
<code>trans</code>	(global) Specifies the form of the system of equations: if <code>transa</code> = 'N' or 'n', then $\text{sub}(A) * \text{sub}(x) = b$ ; if <code>transa</code> = 'T' or 't', then $\text{sub}(A)' * \text{sub}(x) = b$ ; if <code>transa</code> = 'C' or 'c', then $\text{conjg}(\text{sub}(A)') * \text{sub}(x) = b$ .
<code>diag</code>	(global) Specifies whether the matrix $\text{sub}(A)$ is unit triangular: if <code>diag</code> = 'U' or 'u' then the matrix is unit triangular; if <code>diag</code> = 'N' or 'n', then the matrix is not unit triangular.
<code>n</code>	(global) Specifies the order of the distributed matrix $\text{sub}(A)$ , $n \geq 0$ .
<code>a</code>	(local) Array, size at least $(\text{lld}_a, \text{LOCq}(1, \text{ja}+n-1))$ .  Before entry with <code>uplo</code> = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix $\text{sub}(A)$ , and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix $\text{sub}(A)$ is not referenced.  Before entry with <code>uplo</code> = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix $\text{sub}(A)$ , and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix $\text{sub}(A)$ is not referenced .  When <code>diag</code> = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix $\text{sub}(A)$ are not referenced either, but are assumed to be unity.

<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>x</i>	(local) Array, size at least $(j_x-1)*m_x + ix+(n-1)*\text{abs}(incx)$ . This array contains the entries of the distributed vector $\text{sub}(x)$ . Before entry, $\text{sub}(x)$ must contain the <i>n</i> -element right-hand side distributed vector <i>b</i> .
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix $\text{sub}(x)$ , respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) Specifies the increment for the elements of $\text{sub}(x)$ . Only two values are supported, namely 1 and $m_x$ . <i>incx</i> must not be zero.

## Output Parameters

<i>x</i>	Overwritten with the solution vector.
----------	---------------------------------------

## PBLAS Level 3 Routines

The PBLAS Level 3 routines perform distributed matrix-matrix operations. [Table "PBLAS Level 3 Routine Groups and Their Data Types"](#) lists the PBLAS Level 3 routine groups and the data types associated with them.

### PBLAS Level 3 Routine Groups and Their Data Types

Routine Group	Data Types	Description
<a href="#">p?geadd</a>	s, d, c, z	Distributed matrix-matrix sum of general matrices
<a href="#">p?tradd</a>	s, d, c, z	Distributed matrix-matrix sum of triangular matrices
<a href="#">p?gemm</a>	s, d, c, z	Distributed matrix-matrix product of general matrices
<a href="#">p?hemm</a>	c, z	Distributed matrix-matrix product, one matrix is Hermitian
<a href="#">p?herk</a>	c, z	Rank-k update of a distributed Hermitian matrix
<a href="#">p?her2k</a>	c, z	Rank-2k update of a distributed Hermitian matrix
<a href="#">p?symm</a>	s, d, c, z	Matrix-matrix product of distributed symmetric matrices
<a href="#">p?syrk</a>	s, d, c, z	Rank-k update of a distributed symmetric matrix
<a href="#">p?syr2k</a>	s, d, c, z	Rank-2k update of a distributed symmetric matrix
<a href="#">p?tran</a>	s, d	Transposition of a real distributed matrix
<a href="#">p?tranc</a>	c, z	Transposition of a complex distributed matrix (conjugated)
<a href="#">p?tranu</a>	c, z	Transposition of a complex distributed matrix

Routine Group	Data Types	Description
<code>p?trmm</code>	<code>s, d, c, z</code>	Distributed matrix-matrix product, one matrix is triangular
<code>p?trsm</code>	<code>s, d, c, z</code>	Solution of a distributed matrix equation, one matrix is triangular

## `p?geadd`

Performs sum operation for two distributed general matrices.

### Syntax

```
void psgeadd (const char *trans , const MKL_INT *m , const MKL_INT *n , const float
*alpha , const float *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT
*desca , const float *beta , float *c , const MKL_INT *ic , const MKL_INT *jc , const
MKL_INT *descc );
```

```
void pdgeadd (const char *trans , const MKL_INT *m , const MKL_INT *n , const double
*alpha , const double *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT
*desca , const double *beta , double *c , const MKL_INT *ic , const MKL_INT *jc , const
MKL_INT *descc );
```

```
void pcgeadd (const char *trans , const MKL_INT *m , const MKL_INT *n , const
MKL_Complex8 *alpha , const MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja ,
const MKL_INT *desca , const MKL_Complex8 *beta , MKL_Complex8 *c , const MKL_INT *ic ,
const MKL_INT *jc , const MKL_INT *descc );
```

```
void pzgeadd (const char *trans , const MKL_INT *m , const MKL_INT *n , const
MKL_Complex16 *alpha , const MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja ,
const MKL_INT *desca , const MKL_Complex16 *beta , MKL_Complex16 *c , const MKL_INT
*ic , const MKL_INT *jc , const MKL_INT *descc );
```

### Include Files

- `mkl_pblas.h`

### Description

The `p?geadd` routines perform sum operation for two distributed general matrices. The operation is defined as

$$\text{sub}(C) := \text{beta} * \text{sub}(C) + \text{alpha} * \text{op}(\text{sub}(A)),$$

where:

`op(x)` is one of `op(x) = x`, or `op(x) = x'`,

`alpha` and `beta` are scalars,

`sub(C)` is an  $m$ -by- $n$  distributed matrix, `sub(C)=C(ic:ic+m-1, jc:jc+n-1)`.

`sub(A)` is a distributed matrix, `sub(A)=A(ia:ia+n-1, ja:ja+m-1)`.

### Input Parameters

`trans` (global) Specifies the operation:  
 if `trans = 'N' or 'n'`, then `op(sub(A)) := sub(A)`;  
 if `trans = 'T' or 't'`, then `op(sub(A)) := sub(A)'`;

	if $trans = 'C'$ or $'c'$ , then $op(sub(A)) := sub(A)'$ .
<i>m</i>	(global) Specifies the number of rows of the distributed matrix $sub(C)$ and the number of columns of the submatrix $sub(A)$ , $m \geq 0$ .
<i>n</i>	(global) Specifies the number of columns of the distributed matrix $sub(C)$ and the number of rows of the submatrix $sub(A)$ , $n \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size $(lld\_a, LOCq(ja+m-1))$ . This array contains the local pieces of the distributed matrix $sub(A)$ .
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $sub(A)$ , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then $sub(C)$ need not be set on input.
<i>c</i>	(local) Array, size $(lld\_c, LOCq(jc+n-1))$ . This array contains the local pieces of the distributed matrix $sub(C)$ .
<i>ic, jc</i>	(global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix $sub(C)$ , respectively.
<i>descc</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

## Output Parameters

<i>c</i>	Overwritten by the updated submatrix.
----------	---------------------------------------

## p?tradd

Performs sum operation for two distributed triangular matrices.

### Syntax

```
void pstradd (const char *uplo , const char *trans , const MKL_INT *m , const MKL_INT
*n , const float *alpha , const float *a , const MKL_INT *ia , const MKL_INT *ja ,
const MKL_INT *desca , const float *beta , float *c , const MKL_INT *ic , const MKL_INT
*jc , const MKL_INT *descc );
```

```
void pdtradd (const char *uplo , const char *trans , const MKL_INT *m , const MKL_INT
*n , const double *alpha , const double *a , const MKL_INT *ia , const MKL_INT *ja ,
const MKL_INT *desca , const double *beta , double *c , const MKL_INT *ic , const
MKL_INT *jc , const MKL_INT *descc );
```

```
void pctradd (const char *uplo , const char *trans , const MKL_INT *m , const MKL_INT
*n , const MKL_Complex8 *alpha , const MKL_Complex8 *a , const MKL_INT *ia , const
MKL_INT *ja , const MKL_INT *desca , const MKL_Complex8 *beta , MKL_Complex8 *c , const
MKL_INT *ic , const MKL_INT *jc , const MKL_INT *descc );
```

```
void pztradd (const char *uplo , const char *trans , const MKL_INT *m , const MKL_INT
*n , const MKL_Complex16 *alpha , const MKL_Complex16 *a , const MKL_INT *ia , const
MKL_INT *ja , const MKL_INT *desca , const MKL_Complex16 *beta , MKL_Complex16 *c ,
const MKL_INT *ic , const MKL_INT *jc , const MKL_INT *descc );
```

## Include Files

- mkl\_pblas.h

## Description

The `p?tradd` routines perform sum operation for two distributed triangular matrices. The operation is defined as

```
sub(C) := beta*sub(C) + alpha*op(sub(A)),
```

where:

`op(x)` is one of `op(x) = x`, or `op(x) = x'`, or `op(x) = conjg(x')`.

*alpha* and *beta* are scalars,

`sub(C)` is an *m*-by-*n* distributed matrix, `sub(C)=C(ic:ic+m-1, jc:jc+n-1)`.

`sub(A)` is a distributed matrix, `sub(A)=A(ia:ia+n-1, ja:ja+m-1)`.

## Input Parameters

<i>uplo</i>	(global) Specifies whether the distributed matrix <code>sub(C)</code> is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	(global) Specifies the operation: if <i>trans</i> = 'N' or 'n', then <code>op(sub(A)) := sub(A)</code> ; if <i>trans</i> = 'T' or 't', then <code>op(sub(A)) := sub(A)'</code> ; if <i>trans</i> = 'C' or 'c', then <code>op(sub(A)) := conjg(sub(A)')</code> .
<i>m</i>	(global) Specifies the number of rows of the distributed matrix <code>sub(C)</code> and the number of columns of the submatrix <code>sub(A)</code> , $m \geq 0$ .
<i>n</i>	(global) Specifies the number of columns of the distributed matrix <code>sub(C)</code> and the number of rows of the submatrix <code>sub(A)</code> , $n \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size ( <code>lld_a</code> , <code>LOCq(ja+m-1)</code> ). This array contains the local pieces of the distributed matrix <code>sub(A)</code> .

<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then <i>sub(C)</i> need not be set on input.
<i>c</i>	(local) Array, size ( <i>lld_c</i> , <i>LOCq(jc+n-1)</i> ). This array contains the local pieces of the distributed matrix <i>sub(C)</i> .
<i>ic, jc</i>	(global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <i>sub(C)</i> , respectively.
<i>descc</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

## Output Parameters

<i>c</i>	Overwritten by the updated submatrix.
----------	---------------------------------------

## p?gemm

*Computes a scalar-matrix-matrix product and adds the result to a scalar-matrix product for distributed matrices.*

### Syntax

```
void psgemm (const char *transa , const char *transb , const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , const float *alpha , const float *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const float *b , const MKL_INT *ib , const MKL_INT *jb , const MKL_INT *descb , const float *beta , float *c , const MKL_INT *ic , const MKL_INT *jc , const MKL_INT *descc );
```

```
void pdgemm (const char *transa , const char *transb , const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , const double *alpha , const double *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const double *b , const MKL_INT *ib , const MKL_INT *jb , const MKL_INT *descb , const double *beta , double *c , const MKL_INT *ic , const MKL_INT *jc , const MKL_INT *descc );
```

```
void pcgemm (const char *transa , const char *transb , const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , const MKL_Complex8 *alpha , const MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const MKL_Complex8 *b , const MKL_INT *ib , const MKL_INT *jb , const MKL_INT *descb , const MKL_Complex8 *beta , MKL_Complex8 *c , const MKL_INT *ic , const MKL_INT *jc , const MKL_INT *descc );
```

```
void pzgemm (const char *transa , const char *transb , const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , const MKL_Complex16 *alpha , const MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const MKL_Complex16 *b , const MKL_INT *ib , const MKL_INT *jb , const MKL_INT *descb , const MKL_Complex16 *beta , MKL_Complex16 *c , const MKL_INT *ic , const MKL_INT *jc , const MKL_INT *descc );
```

## Include Files

- `mkl_pblas.h`

## Description

The `p?gemm` routines perform a matrix-matrix operation with general distributed matrices. The operation is defined as

$$\text{sub}(C) := \alpha * \text{op}(\text{sub}(A)) * \text{op}(\text{sub}(B)) + \beta * \text{sub}(C),$$

where:

$\text{op}(x)$  is one of  $\text{op}(x) = x$ , or  $\text{op}(x) = x'$ ,

$\alpha$  and  $\beta$  are scalars,

$\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+k-1)$ ,  $\text{sub}(B) = B(\text{ib}:\text{ib}+k-1, \text{jb}:\text{jb}+n-1)$ , and  $\text{sub}(C) = C(\text{ic}:\text{ic}+m-1, \text{jc}:\text{jc}+n-1)$ , are distributed matrices.

## Input Parameters

<code>transa</code>	(global) Specifies the form of $\text{op}(\text{sub}(A))$ used in the matrix multiplication: if <code>transa</code> = 'N' or 'n', then $\text{op}(\text{sub}(A)) = \text{sub}(A)$ ; if <code>transa</code> = 'T' or 't', then $\text{op}(\text{sub}(A)) = \text{sub}(A)'$ ; if <code>transa</code> = 'C' or 'c', then $\text{op}(\text{sub}(A)) = \text{sub}(A)'$ .
<code>transb</code>	(global) Specifies the form of $\text{op}(\text{sub}(B))$ used in the matrix multiplication: if <code>transb</code> = 'N' or 'n', then $\text{op}(\text{sub}(B)) = \text{sub}(B)$ ; if <code>transb</code> = 'T' or 't', then $\text{op}(\text{sub}(B)) = \text{sub}(B)'$ ; if <code>transb</code> = 'C' or 'c', then $\text{op}(\text{sub}(B)) = \text{sub}(B)'$ .
<code>m</code>	(global) Specifies the number of rows of the distributed matrices $\text{op}(\text{sub}(A))$ and $\text{sub}(C)$ , $m \geq 0$ .
<code>n</code>	(global) Specifies the number of columns of the distributed matrices $\text{op}(\text{sub}(B))$ and $\text{sub}(C)$ , $n \geq 0$ .  The value of $n$ must be at least zero.
<code>k</code>	(global) Specifies the number of columns of the distributed matrix $\text{op}(\text{sub}(A))$ and the number of rows of the distributed matrix $\text{op}(\text{sub}(B))$ .  The value of $k$ must be greater than or equal to 0.
<code>alpha</code>	(global) Specifies the scalar $\alpha$ .  When $\alpha$ is equal to zero, then the local entries of the arrays $a$ and $b$ corresponding to the entries of the submatrices $\text{sub}(A)$ and $\text{sub}(B)$ respectively need not be set on input.
<code>a</code>	(local) Array, size <code>lld_a</code> by <code>kla</code> , where <code>kla</code> is <code>LOCc(ja+k-1)</code> when <code>transa</code> = 'N' or 'n', and is <code>LOCq(ja+m-1)</code> otherwise. Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(A)$ .

<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>b</i>	(local) Array, size <i>lld_b</i> by <i>klb</i> , where <i>klb</i> is <code>LOCc(jb+n-1)</code> when <i>transb</i> = 'N' or 'n', and is <code>LOCq(jb+k-1)</code> otherwise. Before entry this array must contain the local pieces of the distributed matrix <i>sub(B)</i> .
<i>ib, jb</i>	(global) The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix <i>sub(B)</i> , respectively
<i>descb</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>B</i> .
<i>beta</i>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then <i>sub(C)</i> need not be set on input.
<i>c</i>	(local) Array, size ( <i>lld_a</i> , <code>LOCq(jc+n-1)</code> ). Before entry this array must contain the local pieces of the distributed matrix <i>sub(C)</i> .
<i>ic, jc</i>	(global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <i>sub(C)</i> , respectively
<i>descc</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

## Output Parameters

<i>c</i>	Overwritten by the <i>m</i> -by- <i>n</i> distributed matrix $\alpha * \text{op}(\text{sub}(A)) * \text{op}(\text{sub}(B)) + \text{beta} * \text{sub}(C)$ .
----------	--

## p?hemm

Performs a scalar-matrix-matrix product (one matrix operand is Hermitian) and adds the result to a scalar-matrix product.

## Syntax

```
void pchemm (const char *side , const char *uplo , const MKL_INT *m , const MKL_INT
*n , const MKL_Complex8 *alpha , const MKL_Complex8 *a , const MKL_INT *ia , const
MKL_INT *ja , const MKL_INT *desca , const MKL_Complex8 *b , const MKL_INT *ib , const
MKL_INT *jb , const MKL_INT *descb , const MKL_Complex8 *beta , MKL_Complex8 *c , const
MKL_INT *ic , const MKL_INT *jc , const MKL_INT *descc );
```

```
void pzhemm (const char *side , const char *uplo , const MKL_INT *m , const MKL_INT
*n , const MKL_Complex16 *alpha , const MKL_Complex16 *a , const MKL_INT *ia , const
MKL_INT *ja , const MKL_INT *desca , const MKL_Complex16 *b , const MKL_INT *ib , const
MKL_INT *jb , const MKL_INT *descb , const MKL_Complex16 *beta , MKL_Complex16 *c ,
const MKL_INT *ic , const MKL_INT *jc , const MKL_INT *descc );
```

## Include Files

- `mkl_pblas.h`

## Description

The `p?hemm` routines perform a matrix-matrix operation with distributed matrices. The operation is defined as

```
sub(C) := alpha*sub(A)*sub(B) + beta*sub(C),
```

or

```
sub(C) := alpha*sub(B)*sub(A) + beta*sub(C),
```

where:

*alpha* and *beta* are scalars,

*sub(A)* is a Hermitian distributed matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+m-1)$ , if *side* = 'L', and  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ , if *side* = 'R'.

*sub(B)* and *sub(C)* are *m*-by-*n* distributed matrices.

$\text{sub}(B) = B(\text{ib}:\text{ib}+m-1, \text{jb}:\text{jb}+n-1)$ ,  $\text{sub}(C) = C(\text{ic}:\text{ic}+m-1, \text{jc}:\text{jc}+n-1)$ .

## Input Parameters

<i>side</i>	(global) Specifies whether the Hermitian distributed matrix <i>sub(A)</i> appears on the left or right in the operation:  if <i>side</i> = 'L' or 'l', then $\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B) + \beta * \text{sub}(C)$ ;  if <i>side</i> = 'R' or 'r', then $\text{sub}(C) := \alpha * \text{sub}(B) * \text{sub}(A) + \beta * \text{sub}(C)$ .
<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <i>sub(A)</i> is used:  if <i>uplo</i> = 'U' or 'u', then the upper triangular part is used; if <i>uplo</i> = 'L' or 'l', then the lower triangular part is used.
<i>m</i>	(global) Specifies the number of rows of the distribute submatrix <i>sub(C)</i> , $m \geq 0$ .
<i>n</i>	(global) Specifies the number of columns of the distribute submatrix <i>sub(C)</i> , $n \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size $(\text{lld}_a, \text{LOCq}(\text{ja}+\text{na}-1))$ .  Before entry this array must contain the local pieces of the symmetric distributed matrix <i>sub(A)</i> , such that when <i>uplo</i> = 'U' or 'u', the <i>na</i> -by- <i>na</i> upper triangular part of the distributed matrix <i>sub(A)</i> must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of <i>sub(A)</i> is not referenced, and when <i>uplo</i> = 'L' or

'1', the  $na$ -by- $na$  lower triangular part of the distributed matrix  $\text{sub}(A)$  must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of  $\text{sub}(A)$  is not referenced.

<i>ia, ja</i>	(global) The row and column indices in the distributed matrix $A$ indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix $A$ .
<i>b</i>	(local) Array, size $(lld\_b, LOCq(jb+n-1))$ . Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(B)$ .
<i>ib, jb</i>	(global) The row and column indices in the distributed matrix $B$ indicating the first row and the first column of the submatrix $\text{sub}(B)$ , respectively.
<i>descb</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix $B$ .
<i>beta</i>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then $\text{sub}(C)$ need not be set on input.
<i>c</i>	(local) Array, size $(lld\_c, LOCq(jc+n-1))$ . Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(C)$ .
<i>ic, jc</i>	(global) The row and column indices in the distributed matrix $C$ indicating the first row and the first column of the submatrix $\text{sub}(C)$ , respectively
<i>descc</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix $C$ .

## Output Parameters

<i>c</i>	Overwritten by the $m$ -by- $n$ updated distributed matrix.
----------	---

## p?herk

Performs a rank- $k$  update of a distributed Hermitian matrix.

### Syntax

```
void pcherk (const char *uplo , const char *trans , const MKL_INT *n , const MKL_INT *k , const float *alpha , const MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const float *beta , MKL_Complex8 *c , const MKL_INT *ic , const MKL_INT *jc , const MKL_INT *descc );
```

```
void pzherk (const char *uplo , const char *trans , const MKL_INT *n , const MKL_INT *k , const double *alpha , const MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const double *beta , MKL_Complex16 *c , const MKL_INT *ic , const MKL_INT *jc , const MKL_INT *descc );
```

## Include Files

- `mkl_pblas.h`

## Description

The `p?herk` routines perform a distributed matrix-matrix operation defined as

```
sub(C) := alpha*sub(A)*conjg(sub(A)') + beta*sub(C),
```

or

```
sub(C) := alpha*conjg(sub(A)')*sub(A) + beta*sub(C),
```

where:

*alpha* and *beta* are scalars,

*sub(C)* is an *n*-by-*n* Hermitian distributed matrix,  $sub(C) = C(ic:ic+n-1, jc:jc+n-1)$ .

*sub(A)* is a distributed matrix,  $sub(A) = A(ia:ia+n-1, ja:ja+k-1)$ , if *trans* = 'N' or 'n', and  $sub(A) = A(ia:ia+k-1, ja:ja+n-1)$  otherwise.

## Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <i>sub(C)</i> is used:  If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(C)</i> is used.  If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(C)</i> is used.
<i>trans</i>	(global) Specifies the operation:  if <i>trans</i> = 'N' or 'n', then $sub(C) := alpha*sub(A)*conjg(sub(A)') + beta*sub(C)$ ;  if <i>trans</i> = 'C' or 'c', then $sub(C) := alpha*conjg(sub(A)')*sub(A) + beta*sub(C)$ .
<i>n</i>	(global) Specifies the order of the distributed matrix <i>sub(C)</i> , $n \geq 0$ .
<i>k</i>	(global) On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the distributed matrix <i>sub(A)</i> , and on entry with <i>trans</i> = 'T' or 't' or 'C' or 'c', <i>k</i> specifies the number of rows of the distributed matrix <i>sub(A)</i> , $k \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size ( <i>lld_a</i> , <i>kla</i> ), where <i>kla</i> is <code>LOCq(ja+k-1)</code> when <i>trans</i> = 'N' or 'n', and is <code>LOCq(ja+n-1)</code> otherwise. Before entry with <i>trans</i> = 'N' or 'n', this array contains the local pieces of the distributed matrix <i>sub(A)</i> .
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .

<i>beta</i>	(global) Specifies the scalar <i>beta</i> .
<i>c</i>	(local) Array, size ( <i>lld_c</i> , <code>LOCq(jc+n-1)</code> ). Before entry with <i>uplo</i> = 'U' or 'u', this array contains <i>n</i> -by- <i>n</i> upper triangular part of the symmetric distributed matrix <i>sub(C)</i> and its strictly lower triangular part is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', this array contains <i>n</i> -by- <i>n</i> lower triangular part of the symmetric distributed matrix <i>sub(C)</i> and its strictly upper triangular part is not referenced.
<i>ic, jc</i>	(global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <i>sub(C)</i> , respectively.
<i>desc</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

## Output Parameters

<i>c</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of <i>sub(C)</i> is overwritten by the upper triangular part of the updated distributed matrix. With <i>uplo</i> = 'L' or 'l', the lower triangular part of <i>sub(C)</i> is overwritten by the upper triangular part of the updated distributed matrix.
----------	--

## p?her2k

Performs a rank-2k update of a Hermitian distributed matrix.

### Syntax

```
void pcher2k (const char *uplo , const char *trans , const MKL_INT *n , const MKL_INT *k , const MKL_Complex8 *alpha , const MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const MKL_Complex8 *b , const MKL_INT *ib , const MKL_INT *jb , const MKL_INT *descb , const float *beta , MKL_Complex8 *c , const MKL_INT *ic , const MKL_INT *jc , const MKL_INT *desc ) ;
```

```
void pzher2k (const char *uplo , const char *trans , const MKL_INT *n , const MKL_INT *k , const MKL_Complex16 *alpha , const MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const MKL_Complex16 *b , const MKL_INT *ib , const MKL_INT *jb , const MKL_INT *descb , const double *beta , MKL_Complex16 *c , const MKL_INT *ic , const MKL_INT *jc , const MKL_INT *desc ) ;
```

### Include Files

### Description

The `p?her2k` routines perform a distributed matrix-matrix operation defined as

```
sub(C) := alpha * sub(A) * conjg(sub(B)') + conjg(alpha) * sub(B) * conjg(sub(A)') + beta * sub(C) ,
```

or

```
sub(C) := alpha * conjg(sub(A)') * sub(A) + conjg(alpha) * conjg(sub(B)') * sub(B) + beta * sub(C) ,
```

where:

*alpha* and *beta* are scalars,

*sub(C)* is an *n*-by-*n* Hermitian distributed matrix,  $\text{sub}(C) = C(\text{ic}:\text{ic}+n-1, \text{jc}:\text{jc}+n-1)$ .

*sub(A)* is a distributed matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+k-1)$ , if *trans* = 'N' or 'n', and  $\text{sub}(A) = A(\text{ia}:\text{ia}+k-1, \text{ja}:\text{ja}+n-1)$  otherwise.

*sub(B)* is a distributed matrix,  $\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+k-1)$ , if *trans* = 'N' or 'n', and  $\text{sub}(B) = B(\text{ib}:\text{ib}+k-1, \text{jb}:\text{jb}+n-1)$  otherwise.

## Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <i>sub(C)</i> is used:  If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(C)</i> is used.  If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(C)</i> is used.
<i>trans</i>	(global) Specifies the operation:  if <i>trans</i> = 'N' or 'n', then $\text{sub}(C) := \alpha * \text{sub}(A) * \text{conjg}(\text{sub}(B)') + \text{conjg}(\alpha) * \text{sub}(B) * \text{conjg}(\text{sub}(A)') + \beta * \text{sub}(C)$ ;  if <i>trans</i> = 'C' or 'c', then $\text{sub}(C) := \alpha * \text{conjg}(\text{sub}(A)') * \text{sub}(A) + \text{conjg}(\alpha) * \text{conjg}(\text{sub}(B)') * \text{sub}(A) + \beta * \text{sub}(C)$ .
<i>n</i>	(global) Specifies the order of the distributed matrix <i>sub(C)</i> , $n \geq 0$ .
<i>k</i>	(global) On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the distributed matrices <i>sub(A)</i> and <i>sub(B)</i> , and on entry with <i>trans</i> = 'C' or 'c', <i>k</i> specifies the number of rows of the distributed matrices <i>sub(A)</i> and <i>sub(B)</i> , $k \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size ( <i>lld_a</i> , <i>kla</i> ), where <i>kla</i> is $\text{LOCq}(\text{ja}+k-1)$ when <i>trans</i> = 'N' or 'n', and is $\text{LOCq}(\text{ja}+n-1)$ otherwise. Before entry with <i>trans</i> = 'N' or 'n', this array contains the local pieces of the distributed matrix <i>sub(A)</i> .
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>b</i>	(local) Array, size ( <i>lld_b</i> , <i>kib</i> ), where <i>kib</i> is $\text{LOCq}(\text{jb}+k-1)$ when <i>trans</i> = 'N' or 'n', and is $\text{LOCq}(\text{jb}+n-1)$ otherwise. Before entry with <i>trans</i> = 'N' or 'n', this array contains the local pieces of the distributed matrix <i>sub(B)</i> .
<i>ib, jb</i>	(global) The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix <i>sub(B)</i> , respectively.

<i>descb</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>B</i> .
<i>beta</i>	(global) Specifies the scalar <i>beta</i> .
<i>c</i>	(local) Array, size ( <i>lld_c</i> , <i>LOCq(jc+n-1)</i> ). Before entry with <i>uplo</i> = 'U' or 'u', this array contains <i>n</i> -by- <i>n</i> upper triangular part of the symmetric distributed matrix <i>sub(C)</i> and its strictly lower triangular part is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', this array contains <i>n</i> -by- <i>n</i> lower triangular part of the symmetric distributed matrix <i>sub(C)</i> and its strictly upper triangular part is not referenced.
<i>ic, jc</i>	(global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <i>sub(C)</i> , respectively.
<i>descc</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

## Output Parameters

<i>c</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of <i>sub(C)</i> is overwritten by the upper triangular part of the updated distributed matrix. With <i>uplo</i> = 'L' or 'l', the lower triangular part of <i>sub(C)</i> is overwritten by the upper triangular part of the updated distributed matrix.
----------	--

## p?symm

*Performs a scalar-matrix-matrix product (one matrix operand is symmetric) and adds the result to a scalar-matrix product for distribute matrices.*

## Syntax

```
void pssymm (const char *side , const char *uplo , const MKL_INT *m , const MKL_INT
*n , const float *alpha , const float *a , const MKL_INT *ia , const MKL_INT *ja ,

## Description

The `pzsymm` routines perform a matrix-matrix operation with distributed matrices. The operation is defined as

$$\text{sub}(C) := \alpha \text{sub}(A) * \text{sub}(B) + \beta \text{sub}(C),$$

or

$$\text{sub}(C) := \alpha \text{sub}(B) * \text{sub}(A) + \beta \text{sub}(C),$$

where:

*alpha* and *beta* are scalars,

*sub(A)* is a symmetric distributed matrix, *sub(A)* = *A*(*ia:ia+m-1, ja:ja+m-1*), if *side* = 'L', and  
*sub(A)* = *A*(*ia:ia+n-1, ja:ja+n-1*), if *side* = 'R'.

*sub(B)* and *sub(C)* are *m*-by-*n* distributed matrices.

*sub(B)* = *B*(*ib:ib+m-1, jb:jb+n-1*), *sub(C)* = *C*(*ic:ic+m-1, jc:jc+n-1*).

## Input Parameters

<i>side</i>	(global) Specifies whether the symmetric distributed matrix <i>sub(A)</i> appears on the left or right in the operation: if <i>side</i> = 'L' or 'l', then $\text{sub}(C) := \alpha \text{sub}(A) * \text{sub}(B) + \beta \text{sub}(C)$ ; if <i>side</i> = 'R' or 'r', then $\text{sub}(C) := \alpha \text{sub}(B) * \text{sub}(A) + \beta \text{sub}(C)$ .
<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the symmetric distributed matrix <i>sub(A)</i> is used: if <i>uplo</i> = 'U' or 'u', then the upper triangular part is used; if <i>uplo</i> = 'L' or 'l', then the lower triangular part is used.
<i>m</i>	(global) Specifies the number of rows of the distribute submatrix <i>sub(C)</i> , $m \geq 0$ .
<i>n</i>	(global) Specifies the number of columns of the distribute submatrix <i>sub(C)</i> , $m \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size ( <i>lld<sub>a</sub></i> , <i>LOC<sub>q</sub>(ja+na-1)</i> ).

Before entry this array must contain the local pieces of the symmetric distributed matrix  $\text{sub}(A)$ , such that when  $\text{uplo} = 'U'$  or  $'u'$ , the  $na$ -by- $na$  upper triangular part of the distributed matrix  $\text{sub}(A)$  must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of  $\text{sub}(A)$  is not referenced, and when  $\text{uplo} = 'L'$  or  $'l'$ , the  $na$ -by- $na$  lower triangular part of the distributed matrix  $\text{sub}(A)$  must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of  $\text{sub}(A)$  is not referenced.

<i>ia, ja</i>	(global) The row and column indices in the distributed matrix $A$ indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix $A$ .
<i>b</i>	(local) Array, size $(lld\_b, \text{LOCq}(jb+n-1))$ . Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(B)$ .
<i>ib, jb</i>	(global) The row and column indices in the distributed matrix $B$ indicating the first row and the first column of the submatrix $\text{sub}(B)$ , respectively.
<i>descb</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix $B$ .
<i>beta</i>	(global) Specifies the scalar $\beta$ . When $\beta$ is set to zero, then $\text{sub}(C)$ need not be set on input.
<i>c</i>	(local) Array, size $(lld\_c, \text{LOCq}(jc+n-1))$ . Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(C)$ .
<i>ic, jc</i>	(global) The row and column indices in the distributed matrix $C$ indicating the first row and the first column of the submatrix $\text{sub}(C)$ , respectively.
<i>descc</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix $C$ .

## Output Parameters

<i>c</i>	Overwritten by the $m$ -by- $n$ updated matrix.
----------	---

## p?syrk

Performs a rank- $k$  update of a symmetric distributed matrix.

## Syntax

```
void pssyrk (const char *uplo , const char *trans , const MKL_INT *n , const MKL_INT
*k , const float *alpha , const float *a , const MKL_INT *ia , const MKL_INT *ja ,

## Description

The p?syr2k routines perform a distributed matrix-matrix operation defined as

$$\text{sub}(C) := \alpha \text{sub}(A) * \text{sub}(B)' + \alpha \text{sub}(B) * \text{sub}(A)' + \beta \text{sub}(C),$$

or

$$\text{sub}(C) := \alpha \text{sub}(A)' * \text{sub}(B) + \alpha \text{sub}(B)' * \text{sub}(A) + \beta \text{sub}(C),$$

where:

*alpha* and *beta* are scalars,

*sub(C)* is an *n*-by-*n* symmetric distributed matrix,  $\text{sub}(C) = C(ic:ic+n-1, jc:jc+n-1)$ .

*sub(A)* is a distributed matrix,  $\text{sub}(A) = A(ia:ia+n-1, ja:ja+k-1)$ , if *trans* = 'N' or 'n', and  $\text{sub}(A) = A(ia:ia+k-1, ja:ja+n-1)$  otherwise.

*sub(B)* is a distributed matrix,  $\text{sub}(B) = B(ib:ib+n-1, jb:jb+k-1)$ , if *trans* = 'N' or 'n', and  $\text{sub}(B) = B(ib:ib+k-1, jb:jb+n-1)$  otherwise.

## Input Parameters

*uplo* (global) Specifies whether the upper or lower triangular part of the symmetric distributed matrix *sub(C)* is used:

If *uplo* = 'U' or 'u', then the upper triangular part of the *sub(C)* is used.

If *uplo* = 'L' or 'l', then the low triangular part of the *sub(C)* is used.

*trans* (global) Specifies the operation:

if *trans* = 'N' or 'n', then  $\text{sub}(C) := \alpha \text{sub}(A) * \text{sub}(B)' + \alpha \text{sub}(B) * \text{sub}(A)' + \beta \text{sub}(C)$ ;

if *trans* = 'T' or 't', then  $\text{sub}(C) := \alpha \text{sub}(B)' * \text{sub}(A) + \alpha \text{sub}(A)' * \text{sub}(B) + \beta \text{sub}(C)$ .

<i>n</i>	(global) Specifies the order of the distributed matrix $\text{sub}(C)$ , $n \geq 0$ .
<i>k</i>	(global) On entry with $\text{trans} = 'N'$ or $'n'$ , <i>k</i> specifies the number of columns of the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$ , and on entry with $\text{trans} = 'T'$ or $'t'$ , <i>k</i> specifies the number of rows of the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$ , $k \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size $(\text{lld}_a, \text{kla})$ , where <i>kla</i> is $\text{LOCq}(ja+k-1)$ when $\text{trans} = 'N'$ or $'n'$ , and is $\text{LOCq}(ja+n-1)$ otherwise. Before entry with $\text{trans} = 'N'$ or $'n'$ , this array contains the local pieces of the distributed matrix $\text{sub}(A)$ .
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>b</i>	(local) Array, size $(\text{lld}_b, \text{kib})$ , where <i>kib</i> is $\text{LOCq}(jb+k-1)$ when $\text{trans} = 'N'$ or $'n'$ , and is $\text{LOCq}(jb+n-1)$ otherwise. Before entry with $\text{trans} = 'N'$ or $'n'$ , this array contains the local pieces of the distributed matrix $\text{sub}(B)$ .
<i>ib, jb</i>	(global) The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix $\text{sub}(B)$ , respectively.
<i>descb</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>B</i> .
<i>beta</i>	(global) Specifies the scalar <i>beta</i> .
<i>c</i>	(local) Array, size $(\text{lld}_c, \text{LOCq}(jc+n-1))$ . Before entry with $\text{uplo} = 'U'$ or $'u'$ , this array contains <i>n</i> -by- <i>n</i> upper triangular part of the symmetric distributed matrix $\text{sub}(C)$ and its strictly lower triangular part is not referenced. Before entry with $\text{uplo} = 'L'$ or $'l'$ , this array contains <i>n</i> -by- <i>n</i> lower triangular part of the symmetric distributed matrix $\text{sub}(C)$ and its strictly upper triangular part is not referenced.
<i>ic, jc</i>	(global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix $\text{sub}(C)$ , respectively.
<i>descc</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

## Output Parameters

<i>c</i>	With $\text{uplo} = 'U'$ or $'u'$ , the upper triangular part of $\text{sub}(C)$ is overwritten by the upper triangular part of the updated distributed matrix.
----------	---

With `uplo = 'L' or 'l'`, the lower triangular part of `sub(C)` is overwritten by the upper triangular part of the updated distributed matrix.

## p?tran

*Transposes a real distributed matrix.*

### Syntax

```
void pstran (const MKL_INT *m , const MKL_INT *n , const float *alpha , const float
*a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const float *beta ,
float *c , const MKL_INT *ic , const MKL_INT *jc , const MKL_INT *descc );
```

```
void pdtran (const MKL_INT *m , const MKL_INT *n , const double *alpha , const double
*a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const double
*beta , double *c , const MKL_INT *ic , const MKL_INT *jc , const MKL_INT *descc );
```

### Include Files

- `mkl_pblas.h`

### Description

The `p?tran` routines transpose a real distributed matrix. The operation is defined as

$$\text{sub}(C) := \text{beta} * \text{sub}(C) + \text{alpha} * \text{sub}(A)'$$

where:

*alpha* and *beta* are scalars,

*sub(C)* is an *m*-by-*n* distributed matrix,  $\text{sub}(C) = C(\text{ic}:\text{ic}+m-1, \text{jc}:\text{jc}+n-1)$ .

*sub(A)* is a distributed matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+m-1)$ .

### Input Parameters

<i>m</i>	(global) Specifies the number of rows of the distributed matrix <code>sub(C)</code> , $m \geq 0$ .
<i>n</i>	(global) Specifies the number of columns of the distributed matrix <code>sub(C)</code> , $n \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size $(\text{lld}_a, \text{LOCq}(\text{ja}+m-1))$ . This array contains the local pieces of the distributed matrix <code>sub(A)</code> .
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) Specifies the scalar <i>beta</i> .

When  $\beta$  is equal to zero, then  $\text{sub}(C)$  need not be set on input.

$c$	(local) Array, size $(lld_c, LOCq(jc+n-1))$ . This array contains the local pieces of the distributed matrix $\text{sub}(C)$ .
$ic, jc$	(global) The row and column indices in the distributed matrix $C$ indicating the first row and the first column of the submatrix $\text{sub}(C)$ , respectively.
$descc$	(global and local) array of dimension 9. The array descriptor of the distributed matrix $C$ .

## Output Parameters

$c$	Overwritten by the updated submatrix.
-----	---------------------------------------

## p?tranu

Transposes a distributed complex matrix.

### Syntax

```
void pctransu (const MKL_INT *m , const MKL_INT *n , const MKL_Complex8 *alpha , const
MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const
MKL_Complex8 *beta , MKL_Complex8 *c , const MKL_INT *ic , const MKL_INT *jc , const
MKL_INT *descc );
```

```
void pztranu (const MKL_INT *m , const MKL_INT *n , const MKL_Complex16 *alpha , const
MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const
MKL_Complex16 *beta , MKL_Complex16 *c , const MKL_INT *ic , const MKL_INT *jc , const
MKL_INT *descc );
```

### Include Files

- mkl\_pblas.h

### Description

The `p?tranu` routines transpose a complex distributed matrix. The operation is defined as

$$\text{sub}(C) := \beta \text{sub}(C) + \alpha \text{sub}(A)'$$

where:

$\alpha$  and  $\beta$  are scalars,

$\text{sub}(C)$  is an  $m$ -by- $n$  distributed matrix,  $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ .

$\text{sub}(A)$  is a distributed matrix,  $\text{sub}(A) = A(ia:ia+n-1, ja:ja+m-1)$ .

### Input Parameters

$m$	(global) Specifies the number of rows of the distributed matrix $\text{sub}(C)$ , $m \geq 0$ .
$n$	(global) Specifies the number of columns of the distributed matrix $\text{sub}(C)$ , $n \geq 0$ .
$\alpha$	(global)

	Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size $(lld\_a, LOCq(ja+m-1))$ . This array contains the local pieces of the distributed matrix $sub(A)$ .
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $sub(A)$ , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then $sub(C)$ need not be set on input.
<i>c</i>	(local) Array, size $(lld\_c, LOCq(jc+n-1))$ . This array contains the local pieces of the distributed matrix $sub(C)$ .
<i>ic, jc</i>	(global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix $sub(C)$ , respectively.
<i>descc</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

## Output Parameters

<i>c</i>	Overwritten by the updated submatrix.
----------	---------------------------------------

## p?tranc

Transposes a complex distributed matrix, conjugated.

### Syntax

```
void pctranc (const MKL_INT *m , const MKL_INT *n , const MKL_Complex8 *alpha , const
MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const
MKL_Complex8 *beta , MKL_Complex8 *c , const MKL_INT *ic , const MKL_INT *jc , const
MKL_INT *descc );
```

```
void pztranc (const MKL_INT *m , const MKL_INT *n , const MKL_Complex16 *alpha , const
MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const
MKL_Complex16 *beta , MKL_Complex16 *c , const MKL_INT *ic , const MKL_INT *jc , const
MKL_INT *descc );
```

### Include Files

- `mkl_pblas.h`

### Description

The `p?tranc` routines transpose a complex distributed matrix. The operation is defined as

```
sub(C) := beta*sub(C) + alpha*conjg(sub(A)'),
```

where:

*alpha* and *beta* are scalars,

$\text{sub}(C)$  is an  $m$ -by- $n$  distributed matrix,  $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ .

$\text{sub}(A)$  is a distributed matrix,  $\text{sub}(A) = A(ia:ia+n-1, ja:ja+m-1)$ .

## Input Parameters

<i>m</i>	(global) Specifies the number of rows of the distributed matrix $\text{sub}(C)$ , $m \geq 0$ .
<i>n</i>	(global) Specifies the number of columns of the distributed matrix $\text{sub}(C)$ , $n \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size $(lld\_a, LOCq(ja+m-1))$ . This array contains the local pieces of the distributed matrix $\text{sub}(A)$ .
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then $\text{sub}(C)$ need not be set on input.
<i>c</i>	(local) Array, size $(lld\_c, LOCq(jc+n-1))$ . This array contains the local pieces of the distributed matrix $\text{sub}(C)$ .
<i>ic, jc</i>	(global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix $\text{sub}(C)$ , respectively.
<i>desc</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

## Output Parameters

<i>c</i>	Overwritten by the updated submatrix.
----------	---------------------------------------

## p?trmm

Computes a scalar-matrix-matrix product (one matrix operand is triangular) for distributed matrices.

## Syntax

```
void pstrmm (const char *side , const char *uplo , const char *transa , const char
*diag , const MKL_INT *m , const MKL_INT *n , const float *alpha , const float *a ,
const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , float *b , const MKL_INT
*ib , const MKL_INT *jb , const MKL_INT *descb );
```

```
void pdtrmm (const char *side , const char *uplo , const char *transa , const char
*diag , const MKL_INT *m , const MKL_INT *n , const double *alpha , const double *a ,
const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , double *b , const
MKL_INT *ib , const MKL_INT *jb , const MKL_INT *descb );
```

```
void pctrmm (const char *side , const char *uplo , const char *transa , const char
*diag , const MKL_INT *m , const MKL_INT *n , const MKL_Complex8 *alpha , const
MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca ,
MKL_Complex8 *b , const MKL_INT *ib , const MKL_INT *jb , const MKL_INT *descb );
```

```
void pztrmm (const char *side , const char *uplo , const char *transa , const char
*diag , const MKL_INT *m , const MKL_INT *n , const MKL_Complex16 *alpha , const
MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca ,
MKL_Complex16 *b , const MKL_INT *ib , const MKL_INT *jb , const MKL_INT *descb );
```

## Include Files

- mkl\_pblas.h

## Description

The `p?trmm` routines perform a matrix-matrix operation using triangular matrices. The operation is defined as

$$\text{sub}(B) := \alpha * \text{op}(\text{sub}(A)) * \text{sub}(B)$$

or

$$\text{sub}(B) := \alpha * \text{sub}(B) * \text{op}(\text{sub}(A))$$

where:

*alpha* is a scalar,

*sub(B)* is an *m*-by-*n* distributed matrix,  $\text{sub}(B) = B(\text{ib}:\text{ib}+m-1, \text{jb}:\text{jb}+n-1)$ .

*A* is a unit, or non-unit, upper or lower triangular distributed matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+m-1)$ , if *side* = 'L' or 'l', and  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ , if *side* = 'R' or 'r'.

*op(sub(A))* is one of  $\text{op}(\text{sub}(A)) = \text{sub}(A)$ , or  $\text{op}(\text{sub}(A)) = \text{sub}(A)'$ , or  $\text{op}(\text{sub}(A)) = \text{conjg}(\text{sub}(A)')$ .

## Input Parameters

<i>side</i>	(global) Specifies whether $\text{op}(\text{sub}(A))$ appears on the left or right of <i>sub(B)</i> in the operation: if <i>side</i> = 'L' or 'l', then $\text{sub}(B) := \alpha * \text{op}(\text{sub}(A)) * \text{sub}(B)$ ; if <i>side</i> = 'R' or 'r', then $\text{sub}(B) := \alpha * \text{sub}(B) * \text{op}(\text{sub}(A))$ .
<i>uplo</i>	(global) Specifies whether the distributed matrix <i>sub(A)</i> is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>transa</i>	(global) Specifies the form of $\text{op}(\text{sub}(A))$ used in the matrix multiplication: if <i>transa</i> = 'N' or 'n', then $\text{op}(\text{sub}(A)) = \text{sub}(A)$ ; if <i>transa</i> = 'T' or 't', then $\text{op}(\text{sub}(A)) = \text{sub}(A)'$ ; if <i>transa</i> = 'C' or 'c', then $\text{op}(\text{sub}(A)) = \text{conjg}(\text{sub}(A)')$ .

<i>diag</i>	(global) Specifies whether the matrix $\text{sub}(A)$ is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>m</i>	(global) Specifies the number of rows of the distributed matrix $\text{sub}(B)$ , $m \geq 0$ .
<i>n</i>	(global) Specifies the number of columns of the distributed matrix $\text{sub}(B)$ , $n \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> . When <i>alpha</i> is zero, then the array <i>b</i> need not be set before entry.
<i>a</i>	(local) Array, size <i>lld_a</i> by <i>ka</i> , where <i>ka</i> is at least $\text{LOCq}(1, ja+m-1)$ when <i>side</i> = 'L' or 'l' and is at least $\text{LOCq}(1, ja+n-1)$ when <i>side</i> = 'R' or 'r'. Before entry with <i>uplo</i> = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix $\text{sub}(A)$ , and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix $\text{sub}(A)$ is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix $\text{sub}(A)$ , and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix $\text{sub}(A)$ is not referenced. When <i>diag</i> = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix $\text{sub}(A)$ are not referenced either, but are assumed to be unity.
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>b</i>	(local) Array, size ( <i>lld_b</i> , $\text{LOCq}(1, jb+n-1)$ ). Before entry, this array contains the local pieces of the distributed matrix $\text{sub}(B)$ .
<i>ib, jb</i>	(global) The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix $\text{sub}(B)$ , respectively.
<i>descb</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>B</i> .

## Output Parameters

<i>b</i>	Overwritten by the transformed distributed matrix.
----------	--

## p?trsm

Solves a distributed matrix equation (one matrix operand is triangular).

### Syntax

```
void pstrsm (const char *side , const char *uplo , const char *transa , const char
*diag , const MKL_INT *m , const MKL_INT *n , const float *alpha , const float *a ,
const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , float *b , const MKL_INT
*ib , const MKL_INT *jib , const MKL_INT *descb );
```

```
void pdtrsm (const char *side , const char *uplo , const char *transa , const char
*diag , const MKL_INT *m , const MKL_INT *n , const double *alpha , const double *a ,
const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , double *b , const
MKL_INT *ib , const MKL_INT *jib , const MKL_INT *descb );
```

```
void pctrsm (const char *side , const char *uplo , const char *transa , const char
*diag , const MKL_INT *m , const MKL_INT *n , const MKL_Complex8 *alpha , const
MKL_Complex8 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca ,
MKL_Complex8 *b , const MKL_INT *ib , const MKL_INT *jib , const MKL_INT *descb );
```

```
void pztrsm (const char *side , const char *uplo , const char *transa , const char
*diag , const MKL_INT *m , const MKL_INT *n , const MKL_Complex16 *alpha , const
MKL_Complex16 *a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca ,
MKL_Complex16 *b , const MKL_INT *ib , const MKL_INT *jib , const MKL_INT *descb );
```

### Include Files

- mkl\_pblas.h

### Description

The p?trsm routines solve one of the following distributed matrix equations:

$$\text{op}(\text{sub}(A)) * X = \text{alpha} * \text{sub}(B),$$

or

$$X * \text{op}(\text{sub}(A)) = \text{alpha} * \text{sub}(B),$$

where:

*alpha* is a scalar,

*X* and *sub(B)* are *m*-by-*n* distributed matrices,  $\text{sub}(B) = B(\text{ib}:\text{ib}+m-1, \text{jb}:\text{jb}+n-1)$ ;

*A* is a unit, or non-unit, upper or lower triangular distributed matrix,  $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+m-1)$ , if *side* = 'L' or 'l', and  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ , if *side* = 'R' or 'r';

*op*(*sub(A)*) is one of *op*(*sub(A)*) = *sub(A)*, or *op*(*sub(A)*) = *sub(A)*' , or *op*(*sub(A)*) = *conjg*(*sub(A)*' ).

The distributed matrix *sub(B)* is overwritten by the solution matrix *X*.

### Input Parameters

*side* (global) Specifies whether *op*(*sub(A)*) appears on the left or right of *X* in the equation:

if *side* = 'L' or 'l', then  $\text{op}(\text{sub}(A)) * X = \text{alpha} * \text{sub}(B)$ ;

if *side* = 'R' or 'r', then  $X * \text{op}(\text{sub}(A)) = \text{alpha} * \text{sub}(B)$ .

<i>uplo</i>	(global) Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>transa</i>	(global) Specifies the form of $\text{op}(\text{sub}(A))$ used in the matrix equation: if <i>transa</i> = 'N' or 'n', then $\text{op}(\text{sub}(A)) = \text{sub}(A)$ ; if <i>transa</i> = 'T' or 't', then $\text{op}(\text{sub}(A)) = \text{sub}(A)'$ ; if <i>transa</i> = 'C' or 'c', then $\text{op}(\text{sub}(A)) = \text{conjg}(\text{sub}(A)')$ .
<i>diag</i>	(global) Specifies whether the matrix $\text{sub}(A)$ is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>m</i>	(global) Specifies the number of rows of the distributed matrix $\text{sub}(B)$ , $m \geq 0$ .
<i>n</i>	(global) Specifies the number of columns of the distributed matrix $\text{sub}(B)$ , $n \geq 0$ .
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> . When <i>alpha</i> is zero, then <i>a</i> is not referenced and <i>b</i> need not be set before entry.
<i>a</i>	(local) Array, size <i>lld_a</i> by <i>ka</i> , where <i>ka</i> is at least $\text{LOCq}(1, ja+m-1)$ when <i>side</i> = 'L' or 'l' and is at least $\text{LOCq}(1, ja+n-1)$ when <i>side</i> = 'R' or 'r'. Before entry with <i>uplo</i> = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix $\text{sub}(A)$ , and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix $\text{sub}(A)$ is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix $\text{sub}(A)$ , and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix $\text{sub}(A)$ is not referenced . When <i>diag</i> = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix $\text{sub}(A)$ are not referenced either, but are assumed to be unity.
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>b</i>	(local) Array, size ( <i>lld_b</i> , $\text{LOCq}(1, jb+n-1)$ ).

Before entry, this array contains the local pieces of the distributed matrix  $\text{sub}(B)$ .

*ib, jb*

(global) The row and column indices in the distributed matrix  $B$  indicating the first row and the first column of the submatrix  $\text{sub}(B)$ , respectively.

*descb*

(global and local) array of dimension 9. The array descriptor of the distributed matrix  $B$ .

## Output Parameters

*b*

Overwritten by the solution distributed matrix  $X$ .

## Partial Differential Equations Support

The Intel® oneAPI Math Kernel Library (oneMKL) provides tools for solving Partial Differential Equations (PDE). These tools are Trigonometric Transform interface routines (see [Trigonometric Transform Routines](#)) and Poisson Solver (see [Fast Poisson Solver Routines](#)).

Poisson Solver is designed for fast solving of simple Helmholtz, Poisson, and Laplace problems. The solver is based on the Trigonometric Transform interface, which is, in turn, based on the Intel® oneAPI Math Kernel Library (oneMKL) Fast Fourier Transform (FFT) interface (refer to [Fourier Transform Functions](#)), optimized for Intel® processors.

Direct use of the Trigonometric Transform routines may be helpful to those who have already implemented their own solvers similar to the Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver. As it may be hard enough to modify the original code so as to make it work with Poisson Solver, you are encouraged to use fast (staggered) sine/cosine transforms implemented in the Trigonometric Transform interface to improve performance of your solver.

Both Trigonometric Transform and Poisson Solver routines can be called from C and Fortran.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Trigonometric Transform Routines

In addition to the Fast Fourier Transform (FFT) interface, described in [Fast Fourier Transforms](#), Intel® oneAPI Math Kernel Library (oneMKL) supports the Real Discrete Trigonometric Transforms (sometimes called real-to-real Discrete Fourier Transforms) interface. In this document, the interface is referred to as TT interface. It implements a group of routines (TT routines) used to compute sine/cosine, staggered sine/cosine, and twice staggered sine/cosine transforms (referred to as staggered2 sine/cosine transforms, for brevity). The TT interface provides much flexibility of use: you can adjust routines to your particular needs at the cost of manually tuning routine parameters or just call routines with default parameter values. The current Intel® oneAPI Math Kernel Library (oneMKL) implementation of the TT interface can be used in solving partial differential equations and contains routines that are helpful for Fast Poisson and similar solvers.

For the list of Trigonometric Transforms currently implemented in Intel® oneAPI Math Kernel Library (oneMKL) TT interface, see [Transforms Implemented](#).

If you have got used to the FFTW interface ([www.fftw.org](http://www.fftw.org)), you can call the TT interface functions through real-to-real FFTW to Intel® oneAPI Math Kernel Library (oneMKL) wrappers without changing FFTW function calls in your code (refer to [FFTW to Intel® MKL Wrappers for FFTW 3.x](#) for details). However, you are strongly encouraged to use the native TT interface for better performance. Another reason why you should use the

wrappers cautiously is that TT and the real-to-real FFTW interfaces are not fully compatible and some features of the real-to-real FFTW, such as strides and multidimensional transforms, are not available through wrappers.

## Trigonometric Transforms Implemented

TT routines allow computing the following transforms:

Forward sine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin \frac{ki\pi}{n}, k = 1, \dots, n-1$$

Backward sine transform

$$f(i) = \sum_{k=1}^{n-1} F(k) \sin \frac{ki\pi}{n}, i = 1, \dots, n-1$$

Forward staggered sine transform

$$F(k) = \frac{1}{n} \sin \frac{(2k-1)\pi}{2} f(n) + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin \frac{(2k-1)i\pi}{2n}, k = 1, \dots, n$$

Backward staggered sine transform

$$f(i) = \sum_{k=1}^n F(k) \sin \frac{(2k-1)i\pi}{2n}, i = 1, \dots, n$$

Forward staggered2 sine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^n f(i) \sin \frac{(2k-1)(2i-1)\pi}{4n}, k = 1, \dots, n$$

Backward staggered2 sine transform

$$f(i) = \sum_{k=1}^n F(k) \sin \frac{(2k-1)(2i-1)\pi}{4n}, i = 1, \dots, n$$

Forward cosine transform

$$F(k) = \frac{1}{n} [f(0) + f(n) \cos k\pi] + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \cos \frac{ki\pi}{n}, k = 0, \dots, n$$

Backward cosine transform

$$f(i) = \frac{1}{2} [F(0) + F(n) \cos i\pi] + \sum_{k=1}^{n-1} F(k) \cos \frac{ki\pi}{n}, i = 0, \dots, n$$

Forward staggered cosine transform

$$F(k) = \frac{1}{n} f(0) + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \cos \frac{(2k+1)i\pi}{2n}, k = 0, \dots, n-1$$

Backward staggered cosine transform

$$f(i) = \sum_{k=0}^{n-1} F(k) \cos \frac{(2k+1)i\pi}{2n}, i = 0, \dots, n-1$$

Forward staggered2 cosine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^n f(i) \cos \frac{(2k-1)(2i-1)\pi}{4n}, k = 1, \dots, n$$

Backward staggered2 cosine transform

$$f(i) = \sum_{k=1}^n F(k) \cos\left(\frac{(2k-1)(2i-1)\pi}{4n}\right), i = 1, \dots, n$$

---

**NOTE**

The size of the transform  $n$  can be any integer greater or equal to 2.

---

## Sequence of Invoking TT Routines

Computation of a transform using TT interface is conceptually divided into four steps, each of which is performed via a dedicated routine. [Table "TT Interface Routines"](#) lists the routines and briefly describes their purpose and use.

Most TT routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with "s" and "d". The wildcard "?" stands for either of these symbols in routine names.

### TT Interface Routines

Routine	Description
<code>?_init_trig_transform</code>	Initializes basic data structures of Trigonometric Transforms.
<code>?_commit_trig_transform</code>	Checks consistency and correctness of user-defined data and creates a data structure to be used by Intel® oneAPI Math Kernel Library (oneMKL) FFT interface <sup>1</sup> .
<code>?_forward_trig_transform</code>	Computes a forward/backward Trigonometric Transform of a specified type using the appropriate formula (see <a href="#">Transforms Implemented</a> ).
<code>?_backward_trig_transform</code>	
<code>free_trig_transform</code>	Releases the memory used by a data structure needed for calling FFT interface <sup>1</sup> .

<sup>1</sup>TT routines call Intel® oneAPI Math Kernel Library (oneMKL) FFT interface for better performance.

To find a transformed vector for a particular input vector only once, the Intel® oneAPI Math Kernel Library (oneMKL) TT interface routines are normally invoked in the order in which they are listed in [Table "TT Interface Routines"](#).

---

**NOTE**

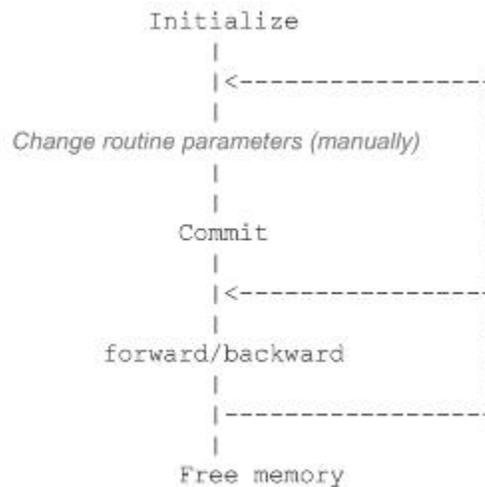

Though the order of invoking TT routines may be changed, it is highly recommended to follow the above order of routine calls.

---

The diagram in [Figure "Typical Order of Invoking TT Interface Routines"](#) indicates the typical order in which TT interface routines can be invoked in a general case (prefixes and suffixes in routine names are omitted).

\_\_border\_\_top

## Typical Order of Invoking TT Interface Routines

A general scheme of using TT routines for double-precision computations is shown below. A similar scheme holds for single-precision computations with the only difference in the initial letter of routine names.

```

...
    d_init_trig_transform(&n, &tt_type, ipar, dpar, &ir);
/* Change parameters in ipar if necessary. */
/* Note that the result of the Transform will be in f. If you want to preserve the data stored
in f,
save it to another location before the function call below */
    d_commit_trig_transform(f, &handle, ipar, dpar, &ir);
    d_forward_trig_transform(f, &handle, ipar, dpar, &ir);
    d_backward_trig_transform(f, &handle, ipar, dpar, &ir);
    free_trig_transform(&handle, ipar, &ir);
/* here the user may clean the memory used by f, dpar, ipar */
...
  
```

You can find examples of code that uses TT interface routines to solve one-dimensional Helmholtz problem in the `examples\pdettc\source` folder in your Intel® oneAPI Math Kernel Library (oneMKL) directory.

## Trigonometric Transform Interface Description

All types in this documentation are either standard C types `float` and `double` or `MKL_INT` integer type. For more information on the C types, refer to [C Datatypes Specific to oneMKL](#) and the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*. To better understand usage of the types, see examples in the `examples\pdettc\source` folder in your Intel® oneAPI Math Kernel Library (oneMKL) directory.

## Routine Options

All TT routines use parameters to pass various options to one another. These parameters are arrays `ipar`, `dpar` and `spar`. Values for these parameters should be specified very carefully (see [Common Parameters](#)). You can change these values during computations to meet your needs.

---

### WARNING

To avoid failure or incorrect results, you must provide correct and consistent parameters to the routines.

---

## User Data Arrays

TT routines take arrays of user data as input. For example, user arrays are passed to the routine `d_forward_trig_transform` to compute a forward Trigonometric Transform. To minimize storage requirements and improve the overall run-time efficiency, Intel® oneAPI Math Kernel Library (oneMKL) TT routines do not make copies of user input arrays.

---

### NOTE

If you need a copy of your input data arrays, you must save them yourself.

---

For better performance, align your data arrays as recommended in the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* (search the document for coding techniques to improve performance).

## TT Routines

The section gives detailed description of TT routines, their syntax, parameters and values they return. Double-precision and single-precision versions of the same routine are described together.

TT routines call Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (described in [FFT Functions](#)), which enhances performance of the routines.

### ?\_init\_trig\_transform

*Initializes basic data structures of a Trigonometric Transform.*

---

#### Syntax

```
void d_init_trig_transform(MKL_INT *n, MKL_INT *tt_type, MKL_INT ipar[], double dpar[],
MKL_INT *stat);
```

```
void s_init_trig_transform(MKL_INT *n, MKL_INT *tt_type, MKL_INT ipar[], float spar[],
MKL_INT *stat);
```

#### Include Files

- `mkl.h`

#### Input Parameters

<code>n</code>	MKL_INT*. Contains the size of the problem, which should be a positive integer greater than 1. Note that data vector of the transform, which other TT routines will use, must have size $n+1$ for all but staggered2 transforms. Staggered2 transforms require the vector of size $n$ .
<code>tt_type</code>	MKL_INT*. Contains the type of transform to compute, defined via a set of named constants. The following constants are available in the current implementation of TT interface: MKL_SINE_TRANSFORM, MKL_STAGGERED_SINE_TRANSFORM, MKL_STAGGERED2_SINE_TRANSFORM; MKL_COSINE_TRANSFORM, MKL_STAGGERED_COSINE_TRANSFORM, MKL_STAGGERED2_COSINE_TRANSFORM.

## Output Parameters

<i>ipar</i>	MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	double array of size $5n/2+2$ . Contains double-precision data needed for Trigonometric Transform computations.
<i>spar</i>	float array of size $5n/2+2$ . Contains single-precision data needed for Trigonometric Transform computations.
<i>stat</i>	MKL_INT*. Contains the routine completion status, which is also written to <i>ipar</i> [6]. The status should be 0 to proceed to other TT routines.

## Description

The `?_init_trig_transform` routine initializes basic data structures for Trigonometric Transforms of appropriate precision. After a call to `?_init_trig_transform`, all subsequently invoked TT routines use values of *ipar* and *dpar* (*spar*) array parameters returned by `?_init_trig_transform`. The routine initializes the entire array *ipar*. In the *dpar* or *spar* array, `?_init_trig_transform` initializes elements that do not depend upon the type of transform. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to [Common Parameters](#). You can skip a call to the initialization routine in your code. For more information, see [Caveat on Parameter Modifications](#).

## Return Values

<i>stat</i> = 0	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this <i>stat</i> value.
<i>stat</i> = -99999	The routine failed to complete the task.

## ?\_commit\_trig\_transform

*Checks consistency and correctness of user's data as well as initializes certain data structures required to perform the Trigonometric Transform.*

## Syntax

```
void d_commit_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], double dpar[], MKL_INT *stat);
```

```
void s_commit_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], float spar[], MKL_INT *stat);
```

## Include Files

- mkl.h

## Input Parameters

<i>f</i>	double for <code>d_commit_trig_transform</code> , float for <code>s_commit_trig_transform</code> ,
----------	---

array of size  $n$  for staggered2 transforms and of size  $n+1$  for all other transforms, where  $n$  is the size of the problem. Contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors:

- $f[0]$  and  $f[n]$  for sine transforms
- $f[n]$  for staggered cosine transforms
- $f[0]$  for staggered sine transforms.

Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. These restrictions meet the requirements of the Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver, which the TT interface is primarily designed for (for details, see [Fast Poisson Solver Routines](#)).

<i>ipar</i>	MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	double array of size $5n/2+2$ . Contains double-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.
<i>spar</i>	float array of size $5n/2+2$ . Contains single-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.

## Output Parameters

<i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, refer to <a href="#">FFT Functions</a> ).
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar[6]</i> is updated with the <i>stat</i> value.
<i>dpar</i>	Contains double-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.
<i>spar</i>	Contains single-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.
<i>stat</i>	MKL_INT*. Contains the routine completion status, which is also written to <i>ipar[6]</i> .

## Description

The routine `?_commit_trig_transform` checks consistency and correctness of the parameters to be passed to the transform routines `?_forward_trig_transform` and/or `?_backward_trig_transform`. The routine also initializes the following data structures: *handle*, *dpar* in case of `d_commit_trig_transform`, and *spar* in case of `s_commit_trig_transform`. The `?_commit_trig_transform` routine initializes only those elements of *dpar* or *spar* that depend upon the type of transform, defined in the `?_init_trig_transform` routine and passed to `?_commit_trig_transform` with the *ipar* array. The size of the problem  $n$ , which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called `?_init_trig_transform` routine. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to [Common Parameters](#). The routine performs only a basic check for correctness and consistency

of the parameters. If you are going to modify parameters of TT routines, see [Caveat on Parameter Modifications](#). Unlike `?_init_trig_transform`, you must call the `?_commit_trig_transform` routine in your code.

## Return Values

<code>stat= 11</code>	The routine produced some warnings and made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning <code>ipar[6]=0</code> if you are sure that the parameters are correct.
<code>stat= 10</code>	The routine made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning <code>ipar[6]=0</code> if you are sure that the parameters are correct.
<code>stat= 1</code>	The routine produced some warnings. You may proceed with computations by assigning <code>ipar[6]=0</code> if you are sure that the parameters are correct.
<code>stat= 0</code>	The routine completed the task normally.
<code>stat= -100</code>	The routine stopped for any of the following reasons: <ul style="list-style-type: none"> <li>• An error in the user's data was encountered.</li> <li>• Data in <code>ipar</code>, <code>dpar</code> or <code>spar</code> parameters became incorrect and/or inconsistent as a result of modifications.</li> </ul>
<code>stat= -1000</code>	The routine stopped because of an FFT interface error.
<code>stat= -10000</code>	The routine stopped because the initialization failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.

---

### NOTE

Although positive values of `stat` usually indicate minor problems with the input data and Trigonometric Transform computations can be continued, you are highly recommended to investigate the problem first and achieve `stat=0`.

---

## [?\\_forward\\_trig\\_transform](#)

*Computes the forward Trigonometric Transform of type specified by the parameter.*

---

### Syntax

```
void d_forward_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], double dpar[], MKL_INT *stat);
```

```
void s_forward_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], float spar[], MKL_INT *stat);
```

### Include Files

- `mkl.h`

## Input Parameters

<i>f</i>	<p>double for <code>d_forward_trig_transform</code>, float for <code>s_forward_trig_transform</code>,</p> <p>array of size <math>n</math> for staggered2 transforms and of size <math>n+1</math> for all other transforms, where <math>n</math> is the size of the problem. On input, contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors:</p> <ul style="list-style-type: none"> <li>• <math>f[0]</math> and <math>f[n]</math> for sine transforms</li> <li>• <math>f[n]</math> for staggered cosine transforms</li> <li>• <math>f[0]</math> for staggered sine transforms.</li> </ul> <p>Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. The above restrictions meet the requirements of the Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver, which the TT interface is primarily designed for (for details, see <a href="#">Fast Poisson Solver Routines</a>).</p>
<i>handle</i>	<p>FFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, see <a href="#">FFT Functions</a>).</p>
<i>ipar</i>	<p>MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.</p>
<i>dpar</i>	<p>double array of size <math>5n/2+2</math>. Contains double-precision data needed for Trigonometric Transform computations.</p>
<i>spar</i>	<p>float array of size <math>5n/2+2</math>. Contains single-precision data needed for Trigonometric Transform computations.</p>

## Output Parameters

<i>f</i>	<p>Contains the transformed vector on output.</p>
<i>ipar</i>	<p>Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar</i>[6] is updated with the <i>stat</i> value.</p>
<i>stat</i>	<p>MKL_INT*. Contains the routine completion status, which is also written to <i>ipar</i>[6].</p>

## Description

The routine computes the forward Trigonometric Transform of type defined in the `?_init_trig_transform` routine and passed to `?_forward_trig_transform` with the *ipar* array. The size of the problem  $n$ , which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called `?_init_trig_transform` routine. The other data that facilitates the computation is created by `?_commit_trig_transform` and supplied in *dpar* or *spar*. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to [Common Parameters](#). The routine has a commit step, which calls the `?_commit_trig_transform` routine. The transform is computed according to formulas given in [Transforms Implemented](#). The routine replaces the input vector *f* with the transformed vector.

<i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, see <a href="#">FFT Functions</a> ).
<i>ipar</i>	MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	double array of size $5n/2+2$ . Contains double-precision data needed for Trigonometric Transform computations.
<i>spar</i>	float array of size $5n/2+2$ . Contains single-precision data needed for Trigonometric Transform computations.

## Output Parameters

<i>f</i>	Contains the transformed vector on output.
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar</i> [6] is updated with the <i>stat</i> value.
<i>stat</i>	MKL_INT*. Contains the routine completion status, which is also written to <i>ipar</i> [6].

## Description

The routine computes the backward Trigonometric Transform of type defined in the `?_init_trig_transform` routine and passed to `?_backward_trig_transform` with the *ipar* array. The size of the problem *n*, which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called `?_init_trig_transform` routine. The other data that facilitates the computation is created by `?_commit_trig_transform` and supplied in *dpar* or *spar*. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to [Common Parameters](#). The routine has a commit step, which calls the `?_commit_trig_transform` routine. The transform is computed according to formulas given in [Transforms Implemented](#). The routine replaces the input vector *f* with the transformed vector.

---

### NOTE

If you need a copy of the data vector *f* to be transformed, make the copy before calling the `?_backward_trig_transform` routine.

---

## Return Values

<i>stat</i> = 0	The routine completed the task normally.
<i>stat</i> = -100	The routine stopped for any of the following reasons: <ul style="list-style-type: none"> <li>• An error in the user's data was encountered.</li> <li>• Data in <i>ipar</i>, <i>dpar</i> or <i>spar</i> parameters became incorrect and/or inconsistent as a result of modifications.</li> </ul>
<i>stat</i> = -1000	The routine stopped because of an FFT interface error.
<i>stat</i> = -10000	The routine stopped because its commit step failed to complete or the parameter <i>ipar</i> [0] was altered by mistake.

## free\_trig\_transform

Cleans the memory allocated for the data structure used by the FFT interface.

---

### Syntax

```
void free_trig_transform(DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], MKL_INT *stat);
```

### Include Files

- mkl.h

### Input Parameters

<i>ipar</i>	MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, refer to <a href="#">FFT Functions</a> ).

### Output Parameters

<i>handle</i>	The data structure used by Intel® oneAPI Math Kernel Library (oneMKL) FFT interface. Memory allocated for the structure is released on output.
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar[6]</i> is updated with the <i>stat</i> value.
<i>stat</i>	MKL_INT*. Contains the routine completion status, which is also written to <i>ipar[6]</i> .

### Description

The `free_trig_transform` routine cleans the memory used by the *handle* structure, needed for Intel® oneAPI Math Kernel Library (oneMKL) FFT functions. To release the memory allocated for other parameters, include cleaning of the memory in your code.

### Return Values

<i>stat</i> = 0	The routine completed the task normally.
<i>stat</i> = -1000	The routine stopped because of an FFT interface error.
<i>stat</i> = -99999	The routine failed to complete the task.

### Common Parameters of the Trigonometric Transforms

This section provides description of array parameters that hold TT routine options: *ipar*, *dpar* and *spar*.

---

**NOTE**

Initial values are assigned to the array parameters by the appropriate `?_init_trig_transform` and `?_commit_trig_transform` routines.

---

*ipar* MKL\_INT array of size 128, holds integer data needed for Trigonometric Transform computations. Its elements are described in [Table "Elements of the ipar Array"](#):

### Elements of the ipar Array

Index	Description
0	Contains the size of the problem to solve. The <code>?_init_trig_transform</code> routine sets <code>ipar[0]=n</code> , and all subsequently called TT routines use <code>ipar[0]</code> as the size of the transform.
1	<p>Contains error messaging options:</p> <ul style="list-style-type: none"> <li><code>ipar[1]=-1</code> indicates that all error messages will be printed to the file <code>MKL_Trig_Transforms_log.txt</code> in the folder from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device.</li> <li><code>ipar[1]=0</code> indicates that no error messages will be printed.</li> <li><code>ipar[1]=1</code> (default) indicates that all error messages will be printed to the preconnected default output device (usually, screen).</li> </ul> <p>In case of errors, each TT routine assigns a non-zero value to <code>stat</code> regardless of the <code>ipar[1]</code> setting.</p>
2	<p>Contains warning messaging options:</p> <ul style="list-style-type: none"> <li><code>ipar[2]=-1</code> indicates that all warning messages will be printed to the file <code>MKL_Trig_Transforms_log.txt</code> in the directory from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device.</li> <li><code>ipar[2]=0</code> indicates that no warning messages will be printed.</li> <li><code>ipar[2]=1</code> (default) indicates that all warning messages will be printed to the preconnected default output device (usually, screen).</li> </ul> <p>In case of warnings, the <code>stat</code> parameter will acquire a non-zero value regardless of the <code>ipar[2]</code> setting.</p>
3 through 4	Reserved for future use.
5	Contains the type of the transform. The <code>?_init_trig_transform</code> routine sets <code>ipar[5]=tt_type</code> , and all subsequently called TT routines use <code>ipar[5]</code> as the type of the transform.
6	Contains the <code>stat</code> value returned by the last completed TT routine. Used to check that the previous call to a TT routine completed with <code>stat=0</code> .
7	<p>Informs the <code>?_commit_trig_transform</code> routines whether to initialize data structures <code>dpar</code> (<code>spar</code>) and <code>handle</code>. <code>ipar[7]=0</code> indicates that the routine should skip the initialization and only check correctness and consistency of the parameters. Otherwise, the routine initializes the data structures. The default value is 1.</p> <p>The possibility to check correctness and consistency of input data without initializing data structures <code>dpar</code>, <code>spar</code> and <code>handle</code> enables avoiding performance losses in a repeated use of the same transform for different data vectors. Note that you can benefit from the opportunity that <code>ipar[7]</code> gives only if you are sure to have supplied proper tolerance value in the <code>dpar</code> or <code>spar</code> array. Otherwise, avoid tuning this parameter.</p>
8	Contains message style options for TT routines. Specifically, if <code>ipar[8]</code> is non-zero, TT routines print the messages in C-style notations. The default value is 1.

Index	Description
	When specifying message style options, be aware that by default, numbering of elements in C arrays starts at 0. For example, " <i>parameter ipar[0]=3 should be an even integer</i> " is a C-style message. The use of <i>ipar[8]</i> enables you to view messages in a more convenient style.
9	Specifies the number of OpenMP threads to run TT routines in the OpenMP environment of the Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver. The default value is 1. You are highly recommended not to alter this value. See also <a href="#">Caveat on Parameter Modifications</a> .
10	Specifies the mode of compatibility with FFTW. The default value is 0. Set the value to 1 to invoke compatibility with FFTW. In the latter case, results will not be normalized, because FFTW does not do this. It is highly recommended not to alter this value, but rather use real-to-real FFTW to MKL wrappers, described in <a href="#">FFTW to Intel® MKL Wrappers for FFTW 3.x</a> . See also <a href="#">Caveat on Parameter Modifications</a> .
11 through 127	Reserved for future use.

**NOTE**

While you can declare the *ipar* array as `MKL_INT ipar[11]`, for future compatibility you should declare *ipar* as `MKL_INT ipar[128]`.

Arrays *dpar* and *spar* are the same except in the data precision:

<i>dpar</i>	double array of size $5n/2+2$ , holds data needed for double-precision routines to perform TT computations. This array is initialized in the <a href="#">d_init_trig_transform</a> and <a href="#">d_commit_trig_transform</a> routines.
<i>spar</i>	float array of size $5n/2+2$ , holds data needed for single-precision routines to perform TT computations. This array is initialized in the <a href="#">s_init_trig_transform</a> and <a href="#">s_commit_trig_transform</a> routines.

As *dpar* and *spar* have similar elements in respective positions, the elements are described together in [Table "Elements of the dpar and spar Arrays"](#):

**Elements of the dpar and spar Arrays**

Index	Description
0	Contains the first absolute tolerance used by the appropriate <a href="#">?_commit_trig_transform</a> routine. For a staggered cosine or a sine transform, $f[n]$ should be equal to 0.0 and for a staggered sine or a sine transform, $f[0]$ should be equal to 0.0. The <a href="#">?_commit_trig_transform</a> routine checks whether absolute values of these parameters are below $dpar[0]*n$ or $spar[0]*n$ , depending on the routine precision. To suppress warnings resulting from tolerance checks, set $dpar[0]$ or $spar[0]$ to a sufficiently large number.
1	Reserved for future use.
2 through $5n/2+1$	Contain tabulated values of trigonometric functions. Contents of the elements depend upon the type of transform <i>tt_type</i> , set up in the <a href="#">?_commit_trig_transform</a> routine: <ul style="list-style-type: none"> <li>If <i>tt_type</i>=<code>MKL_SINE_TRANSFORM</code>, the transform uses only the first <math>n/2</math> array elements, which contain tabulated sine values.</li> <li>If <i>tt_type</i>=<code>MKL_STAGGERED_SINE_TRANSFORM</code>, the transform uses only the first <math>3n/2</math> array elements, which contain tabulated sine and cosine values.</li> </ul>

Index	Description
	<ul style="list-style-type: none"> <li>• If <code>tt_type=MKL_STAGGERED2_SINE_TRANSFORM</code>, the transform uses all the <math>5n/2</math> array elements, which contain tabulated sine and cosine values.</li> <li>• If <code>tt_type=MKL_COSINE_TRANSFORM</code>, the transform uses only the first <math>n</math> array elements, which contain tabulated cosine values.</li> <li>• If <code>tt_type=MKL_STAGGERED_COSINE_TRANSFORM</code>, the transform uses only the first <math>3n/2</math> elements, which contain tabulated sine and cosine values.</li> <li>• If <code>tt_type=MKL_STAGGERED2_COSINE_TRANSFORM</code>, the transform uses all the <math>5n/2</math> elements, which contain tabulated sine and cosine values.</li> </ul>

**NOTE**

To save memory, you can define the array size depending upon the type of transform.

**Caveat on Parameter Modifications**

Flexibility of the TT interface enables you to skip a call to the `?_init_trig_transform` routine and to initialize the basic data structures explicitly in your code. You may also need to modify the contents of `ipar`, `dpar` and `spar` arrays after initialization. When doing so, provide correct and consistent data in the arrays. Mistakenly altered arrays cause errors or wrong computation. You can perform a basic check for correctness and consistency of parameters by calling the `?_commit_trig_transform` routine; however, this does not ensure the correct result of a transform but only reduces the chance of errors or wrong results.

**NOTE**

To supply correct and consistent parameters to TT routines, you should have considerable experience in using the TT interface and good understanding of elements that the `ipar`, `spar` and `dpar` arrays contain and dependencies between values of these elements.

However, in rare occurrences, even advanced users might fail to compute a transform using TT routines after the parameter modifications. In cases like these, refer for technical support at <http://www.intel.com/software/products/support/>.

**WARNING**

The only way that ensures proper computation of the Trigonometric Transforms is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of `ipar`, `dpar` and `spar` arrays unless a strong need arises.

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

**Trigonometric Transform Implementation Details**

Several aspects of the Intel® oneAPI Math Kernel Library (oneMKL) TT interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, Intel® oneAPI Math Kernel Library (oneMKL) provides you with the TT language-specific header file to include in your code:

- `mkl_trig_transforms.h`, to be used together with `mkl_dfti.h`.

---

**NOTE**

- Use of the Intel® oneAPI Math Kernel Library (oneMKL) TT software without including the above language-specific header files is not supported.
- 

## Header File

The header file below defines the following function prototypes:

```
void d_init_trig_transform(MKL_INT *, MKL_INT *, MKL_INT *, double *, MKL_INT *);
void d_commit_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, double *, MKL_INT
*);
void d_forward_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, double *, MKL_INT
*);
void d_backward_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, double *, MKL_INT
*);

void s_init_trig_transform(MKL_INT *, MKL_INT *, MKL_INT *, float *, MKL_INT *);
void s_commit_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, float *, MKL_INT *);
void s_forward_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, float *, MKL_INT *);
void s_backward_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, float *, MKL_INT
*);

void free_trig_transform(DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, MKL_INT *);
```

## Fast Poisson Solver Routines

In addition to the Real Discrete Trigonometric Transforms (TT) interface (refer to [Trigonometric Transform Routines](#)), Intel® oneAPI Math Kernel Library (oneMKL) supports the Poisson Solver interface. This interface implements a group of routines (Poisson Solver routines) used to compute a solution of Laplace, Poisson, and Helmholtz problems of a special kind using discrete Fourier transforms. Laplace and Poisson problems are special cases of a more general Helmholtz problem. The problems that are solved by the Poisson Solver interface are defined more exactly in [Poisson Solver Implementation](#). The Poisson Solver interface provides much flexibility of use: you can call routines with the default parameter values or adjust routines to your particular needs by manually tuning routine parameters. You can adjust the style of error and warning messages to a C notation by setting up a dedicated parameter. This adds convenience to debugging, because you can read information in the way that is natural for your code. The Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver interface currently contains only routines that implement the following solvers:

- Fast Laplace, Poisson and Helmholtz solvers in a Cartesian coordinate system
- Fast Poisson and Helmholtz solvers in a spherical coordinate system.

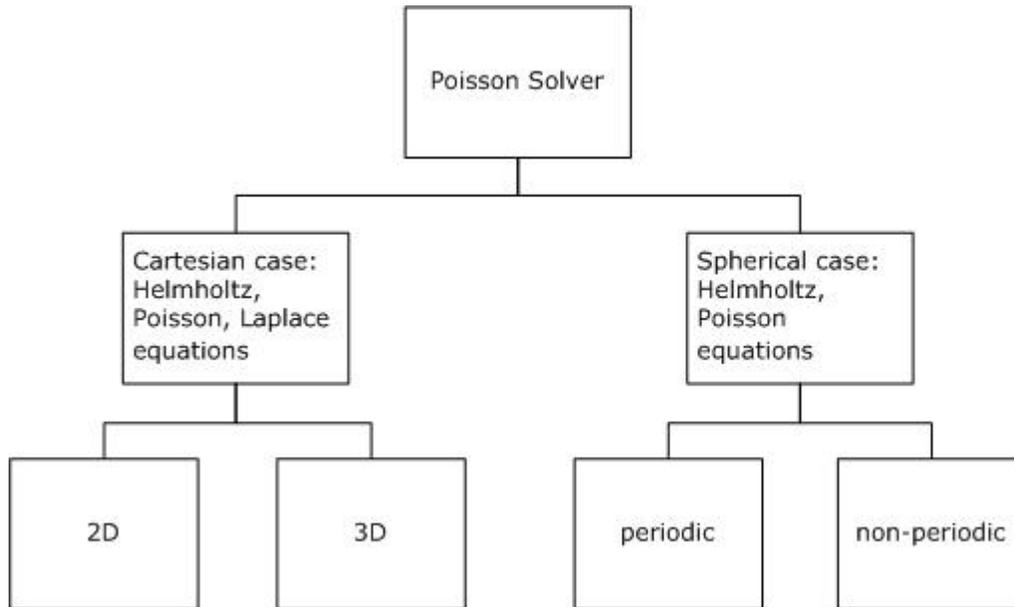

## Poisson Solver Implementation

Poisson Solver routines enable approximate solving of certain two-dimensional and three-dimensional problems. [Figure "Structure of the Poisson Solver"](#) shows the general structure of the Poisson Solver.

---

\_\_border\_\_top

## Structure of the Poisson Solver

---

### NOTE

Although in the Cartesian case, both periodic and non-periodic solvers are also supported, they use the same interfaces.

---

Sections below provide details of the problems that can be solved using Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver.

## Two-Dimensional Problems

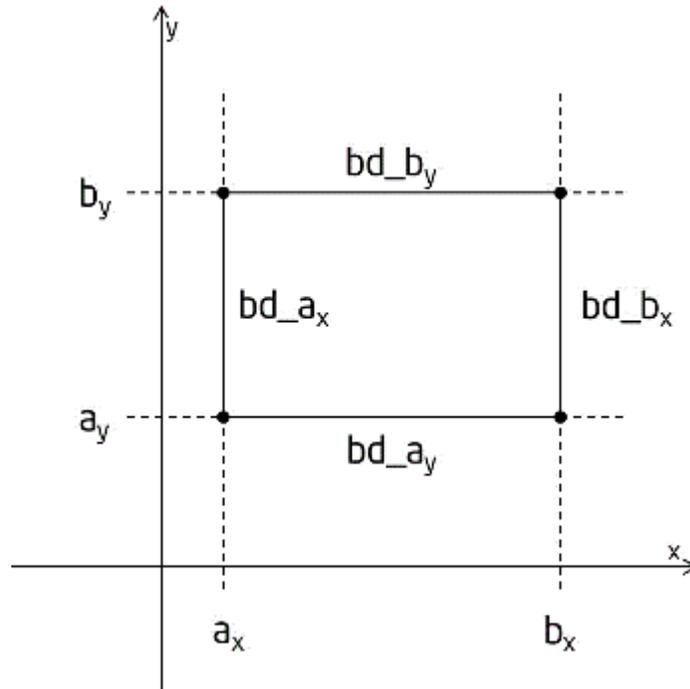

### Notational Conventions

The Poisson Solver interface description uses the following notation for boundaries of a rectangular domain  $a_x < x < b_x$ ,  $a_y < y < b_y$  on a Cartesian plane:

$$bd\_a_x = \{x = a_x, a_y \leq y \leq b_y\}, \quad bd\_b_x = \{x = b_x, a_y \leq y \leq b_y\}$$

$$bd\_a_y = \{a_x \leq x \leq b_x, y = a_y\}, \quad bd\_b_y = \{a_x \leq x \leq b_x, y = b_y\}.$$

The following figure shows these boundaries:

The wildcard "+" may stand for any of the symbols  $a_x, b_x, a_y, b_y$ , so  $bd_+$  denotes any of the above boundaries.

The Poisson Solver interface description uses the following notation for boundaries of a rectangular domain  $a_\varphi < \varphi < b_\varphi, a_\theta < \theta < b_\theta$  on a sphere  $0 \leq \varphi \leq 2\pi, 0 \leq \theta \leq \pi$ :

$$bd_{a_\varphi} = \{\varphi = a_\varphi, a_\theta \leq \theta \leq b_\theta\}, \quad bd_{b_\varphi} = \{\varphi = b_\varphi, a_\theta \leq \theta \leq b_\theta\},$$

$$bd_{a_\theta} = \{a_\varphi \leq \varphi \leq b_\varphi, \theta = a_\theta\}, \quad bd_{b_\theta} = \{a_\varphi \leq \varphi \leq b_\varphi, \theta = b_\theta\}.$$

The wildcard "~" may stand for any of the symbols  $a_\varphi, b_\varphi, a_\theta, b_\theta$ , so  $bd_{\sim}$  denotes any of the above boundaries.

### Two-dimensional Helmholtz problem on a Cartesian plane

The two-dimensional (2D) Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} + qu = f(x, y), \quad q = const \geq 0$$

in a rectangle, that is, a rectangular domain  $a_x < x < b_x, a_y < y < b_y$ , with one of the following boundary conditions on each boundary  $bd_+$ :

- The Dirichlet boundary condition

$$u(x, y) = G(x, y)$$

- The Neumann boundary condition

$$\frac{\partial u}{\partial n}(x, y) = g(x, y)$$

where

$$n = -x \text{ on } bd_{a_x}, \quad n = x \text{ on } bd_{b_x},$$

$$n = -y \text{ on } bd_{a_y}, \quad n = y \text{ on } bd_{b_y}.$$

- Periodic boundary conditions

$$u(a_x, y) = u(b_x, y), \quad \frac{\partial}{\partial x} u(a_x, y) = \frac{\partial}{\partial x} u(b_x, y),$$

$$u(x, a_y) = u(x, b_y), \quad \frac{\partial}{\partial y} u(x, a_y) = \frac{\partial}{\partial y} u(x, b_y).$$

### Two-dimensional Poisson problem on a Cartesian plane

The Poisson problem is a special case of the Helmholtz problem, when  $q=0$ . The 2D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} = f(x, y)$$

in a rectangle  $a_x < x < b_x$ ,  $a_y < y < b_y$  with the Dirichlet, Neumann, or periodic boundary conditions on each boundary  $bd_+$ . In case of a problem with the Neumann boundary condition on the entire boundary, you can find the solution of the problem only up to a constant. In this case, the Poisson Solver will compute the solution that provides the minimal Euclidean norm of a residual.

### Two-dimensional (2D) Laplace problem on a Cartesian plane

The Laplace problem is a special case of the Helmholtz problem, when  $q=0$  and  $f(x, y)=0$ . The 2D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$$

in a rectangle  $a_x < x < b_x$ ,  $a_y < y < b_y$  with the Dirichlet, Neumann, or periodic boundary conditions on each boundary  $bd_+$ .

### Helmholtz problem on a sphere

The Helmholtz problem on a sphere is to find an approximate solution of the Helmholtz equation

$$-\Delta_s u + qu = f, \quad q = \text{const} \geq 0,$$

$$\Delta_s = \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \phi^2} + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left( \sin \theta \frac{\partial}{\partial \theta} \right)$$

in a domain bounded by angles  $a_\phi \leq \phi \leq b_\phi$ ,  $a_\theta \leq \theta \leq b_\theta$  (spherical rectangle), with boundary conditions for particular domains listed in [Table "Details of Helmholtz Problem on a Sphere"](#).

#### Details of Helmholtz Problem on a Sphere

Domain on a sphere	Boundary condition	Periodic/non-periodic case
Rectangular, that is, $b_\phi - a_\phi < 2\pi$ and $b_\theta - a_\theta < \pi$	Homogeneous Dirichlet boundary conditions on each boundary $bd_+$	<i>non-periodic</i>
Where $a_\phi = 0$ , $b_\phi = 2\pi$ , and $b_\theta - a_\theta < \pi$	Homogeneous Dirichlet boundary conditions on the boundaries $bd_{a_\theta}$ and $bd_{b_\theta}$	<i>periodic</i>
Entire sphere, that is, $a_\phi = 0$ , $b_\phi = 2\pi$ , $a_\theta = 0$ , and $b_\theta = \pi$	Boundary condition $\left( \sin \theta \frac{\partial u}{\partial \theta} \right) = 0$ at $\theta \rightarrow 0$ and $\theta \rightarrow \pi$ at the poles	<i>periodic</i>

### Poisson problem on a sphere

The Poisson problem is a special case of the Helmholtz problem, when  $q=0$ . The Poisson problem on a sphere is to find an approximate solution of the Poisson equation

$$-\Delta_s u = f, \quad \Delta_s = \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \phi^2} + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left( \sin \theta \frac{\partial}{\partial \theta} \right)$$

in a spherical rectangle  $a_\phi \leq \phi \leq b_\phi$ ,  $a_\theta \leq \theta \leq b_\theta$  in cases listed in [Table "Details of Helmholtz Problem on a Sphere"](#). The solution to the Poisson problem on the entire sphere can be found up to a constant only. In this case, Poisson Solver will compute the solution that provides the minimal Euclidean norm of a residual.

### Approximation of 2D problems

To find an approximate solution for any of the 2D problems, in the rectangular domain a uniform mesh can be defined for the Cartesian case as:

$$\{x_i = a_x + ih_x, y_j = a_y + jh_y\},$$

$$i = 0, \dots, n_x, j = 0, \dots, n_y, h_x = \frac{b_x - a_x}{n_x}, h_y = \frac{b_y - a_y}{n_y}$$

and for the spherical case as:

$$\{\phi_i = a_\phi + ih_\phi, \theta_j = a_\theta + jh_\theta\},$$

$$i = 0, \dots, n_\phi, j = 0, \dots, n_\theta, h_\phi = \frac{b_\phi - a_\phi}{n_\phi}, h_\theta = \frac{b_\theta - a_\theta}{n_\theta}.$$

The Poisson Solver uses the standard five-point finite difference approximation on this mesh to compute the approximation to the solution:

- In the Cartesian case, the values of the approximate solution will be computed in the mesh points  $(x_i, y_j)$  provided that you can supply the values of the right-hand side  $f(x, y)$  in these points and the values of the appropriate boundary functions  $G(x, y)$  and/or  $g(x, y)$  in the mesh points laying on the boundary of the rectangular domain.
- In the spherical case, the values of the approximate solution will be computed in the mesh points  $(\phi_i, \theta_j)$  provided that you can supply the values of the right-hand side  $f(\phi, \theta)$  in these points.

---

#### NOTE

The number of mesh intervals  $n_\phi$  in the  $\phi$  direction of a spherical mesh must be even in the periodic case. The Poisson Solver does not support spherical meshes that do not meet this condition.

---

## Three-Dimensional Problems

### Notational Conventions

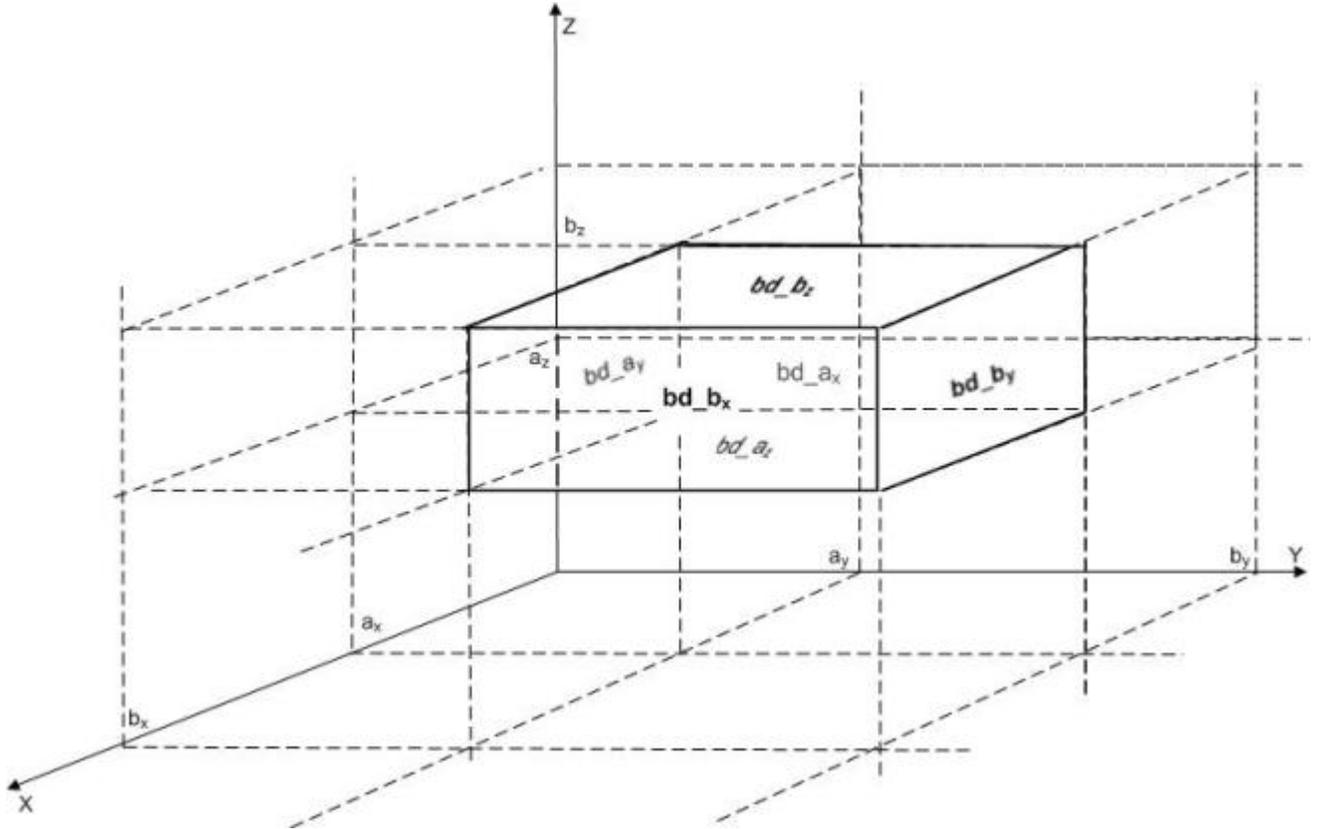

The Poisson Solver interface description uses the following notation for boundaries of a parallelepiped domain  $a_x < x < b_x$ ,  $a_y < y < b_y$ ,  $a_z < z < b_z$ :

$$bd_{a_x} = \{x = a_x, a_y \leq y \leq b_y, a_z \leq z \leq b_z\}, bd_{b_x} = \{x = b_x, a_y \leq y \leq b_y, a_z \leq z \leq b_z\},$$

$$bd_{a_y} = \{a_x \leq x \leq b_x, y = a_y, a_z \leq z \leq b_z\}, bd_{b_y} = \{a_x \leq x \leq b_x, y = b_y, a_z \leq z \leq b_z\},$$

$$bd_{a_z} = \{a_x \leq x \leq b_x, a_y \leq y \leq b_y, z = a_z\}, bd_{b_z} = \{a_x \leq x \leq b_x, a_y \leq y \leq b_y, z = b_z\}.$$

The following figure shows these boundaries:

The wildcard "+" may stand for any of the symbols  $a_x$ ,  $b_x$ ,  $a_y$ ,  $b_y$ ,  $a_z$ ,  $b_z$ , so  $bd_+$  denotes any of the above boundaries.

### Three-dimensional (3D) Helmholtz problem

The 3D Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} - \frac{\partial^2 u}{\partial z^2} + qu = f(x, y, z), \quad q = \text{const} \geq 0$$

in a parallelepiped, that is, a parallelepiped domain  $a_x < x < b_x$ ,  $a_y < y < b_y$ ,  $a_z < z < b_z$ , with one of the following boundary conditions on each boundary  $bd_+$ :

- The Dirichlet boundary condition
- The Neumann boundary condition

$$u(x, y, z) = G(x, y, z)$$

$$\frac{\partial u}{\partial n}(x, y, z) = g(x, y, z)$$

where

$$n = -x \text{ on } bd_{a_x}, \quad n = x \text{ on } bd_{b_x},$$

$$n = -y \text{ on } bd_{a_y}, \quad n = y \text{ on } bd_{b_y},$$

$$n = -z \text{ on } bd_{a_z}, \quad n = z \text{ on } bd_{b_z}.$$

- Periodic boundary conditions

$$u(a_x, y, z) = u(b_x, y, z), \quad \frac{\partial}{\partial x} u(a_x, y, z) = \frac{\partial}{\partial x} u(b_x, y, z),$$

$$u(x, a_y, z) = u(x, b_y, z), \quad \frac{\partial}{\partial y} u(x, a_y, z) = \frac{\partial}{\partial y} u(x, b_y, z),$$

$$u(x, y, a_z) = u(x, y, b_z), \frac{\partial}{\partial z} u(x, y, a_z) = \frac{\partial}{\partial z} u(x, y, b_z).$$

### Three-dimensional (3D) Poisson problem

The Poisson problem is a special case of the Helmholtz problem, when  $q=0$ . The 3D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} - \frac{\partial^2 u}{\partial z^2} = f(x, y, z)$$

in a parallelepiped  $a_x < x < b_x$ ,  $a_y < y < b_y$ ,  $a_z < z < b_z$  with the Dirichlet, Neumann, or periodic boundary conditions on each boundary  $bd_{-+}$ .

### Three-dimensional (3D) Laplace problem

The Laplace problem is a special case of the Helmholtz problem, when  $q=0$  and  $f(x, y, z)=0$ . The 3D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0$$

in a parallelepiped  $a_x < x < b_x$ ,  $a_y < y < b_y$ ,  $a_z < z < b_z$  with the Dirichlet, Neumann, or periodic boundary conditions on each boundary  $bd_{-+}$ .

### Approximation of 3D problems

To find an approximate solution for each of the 3D problems, a uniform mesh can be defined in the parallelepiped domain as:

$$\{x_i = a_x + ih_x, y_j = a_y + jh_y, z_k = a_z + kh_z\},$$

where

$$i = 0, \dots, n_x, j = 0, \dots, n_y, k = 0, \dots, n_z,$$

$$h_x = \frac{b_x - a_x}{n_x}, h_y = \frac{b_y - a_y}{n_y}, h_z = \frac{b_z - a_z}{n_z}.$$

The Poisson Solver uses the standard seven-point finite difference approximation on this mesh to compute the approximation to the solution. The values of the approximate solution will be computed in the mesh points  $(x_i, y_j, z_k)$ , provided that you can supply the values of the right-hand side  $f(x, y, z)$  in these points and the values of the appropriate boundary functions  $G(x, y, z)$  and/or  $g(x, y, z)$  in the mesh points laying on the boundary of the parallelepiped domain.

## Sequence of Invoking Poisson Solver Routines

---

### NOTE

This description always shows the solution process for the Helmholtz problem, because Fast Poisson Solvers and Fast Laplace Solvers are special cases of Fast Helmholtz Solvers (see [Poisson Solver Implementation](#)).

---

The Poisson Solver interface enables you to compute a solution of the Helmholtz problem in four steps. Each step is performed by a dedicated routine. [Table "Poisson Solver Interface Routines"](#) lists the routines and briefly describes their purpose.

Most Poisson Solver routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with "s" and "d". The wildcard "?" stands for either of these symbols in routine names. The routines for the Cartesian coordinate system have 2D and 3D versions. Their names end respectively in "2D" and "3D". The routines for spherical coordinate system have periodic and non-periodic versions. Their names end respectively in "p" and "np".

## Poisson Solver Interface Routines

Routine	Description
<code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/ ?_init_sph_p/?_init_sph_np</code>	Initializes basic data structures for Fast Helmholtz Solver in the 2D/3D/periodic/non-periodic case, respectively.
<code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/ ?_commit_sph_p/?_commit_sph_np</code>	Checks consistency and correctness of input data and initializes data structures for the solver, including those used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface <sup>1</sup> .
<code>?_Helmholtz_2D/?_Helmholtz_3D/?_sph_p/?_sph_np</code>	Computes an approximate solution of the 2D/3D/periodic/non-periodic Helmholtz problem (see <a href="#">Poisson Solver Implementation</a> ) specified by the parameters.
<code>free_Helmholtz_2D/free_Helmholtz_3D/ free_sph_p/free_sph_np</code>	Releases the memory used by the data structures needed for calling the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface <sup>1</sup> .

<sup>1</sup>Poisson Solver routines call the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface for better performance.

To find an approximate solution of Helmholtz problem only once, the Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver interface routines are normally invoked in the order in which they are listed in [Table "Poisson Solver Interface Routines"](#).

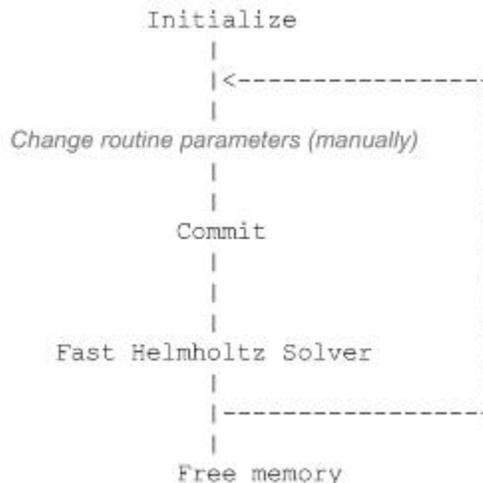

### NOTE

Though the order of invoking Poisson Solver routines may be changed, it is highly recommended to follow the above order of routine calls.

The diagram in [Figure "Typical Order of Invoking Poisson Solver Routines"](#) indicates the typical order in which Poisson Solver routines can be invoked in a general case.

[\\_\\_border\\_\\_ top](#)

### Typical Order of Invoking Poisson Solver Routines

A general scheme of using Poisson Solver routines for double-precision computations in a 3D Cartesian case is shown below. You can change this scheme to a scheme for single-precision computations by changing the initial letter of the Poisson Solver routine names from "d" to "s". You can also change the scheme below from the 3D to 2D case by changing the ending of the Poisson Solver routine names.

```
...
d_init_Helmholtz_3D(&ax, &bx, &ay, &by, &az, &bz, &nx, &ny, &nz, BCtype, ipar, dpar, &stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f. If you want to keep the data
that is stored in f, save it to another location before the function call below */
d_commit_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar,
dpar, &stat);
d_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar, dpar,
&stat);
free_Helmholtz_3D (&xhandle, &yhandle, ipar, &stat);
/* here you may clean the memory used by f, dpar, ipar */
...
```

A general scheme of using Poisson Solver routines for double-precision computations in a spherical periodic case is shown below. You can change this scheme to a scheme for single-precision computations by changing the initial letter of the Poisson Solver routine names from "d" to "s". You can also change the scheme below to a scheme for a non-periodic case by changing the ending of the Poisson Solver routine names from "p" to "np".

```
...
d_init_sph_p(&ap, &bp, &at, &bt, &np, &nt, &q, ipar, dpar, &stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f. If you want to keep the data
that is stored in f, save it to another location before the function call below */
d_commit_sph_p(f, &handle_s, &handle_c, ipar, dpar, &stat);
d_sph_p(f, &handle_s, &handle_c, ipar, dpar, &stat);
free_sph_p(&handle_s, &handle_c, ipar, &stat);
/* here you may clean the memory used by f, dpar, ipar */
...
```

You can find examples of code that uses Poisson Solver routines to solve Helmholtz problem (in both Cartesian and spherical cases) in the `examples\pdepoissonc\source` folder in your Intel® oneAPI Math Kernel Library (oneMKL) directory.

## Fast Poisson Solver Interface Description

All numerical types in this section are either standard C types `float` and `double` or `MKL_INT` integer type. For more information on the C types, refer to [C Datatypes Specific to oneMKL](#) and the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*. To better understand usage of the types, see examples in the `examples\pdepoissonc\source` folder in your Intel® oneAPI Math Kernel Library (oneMKL) directory.

## Routine Options

All Poisson Solver routines use parameters for passing various options to the routines. These parameters are arrays `ipar`, `dpar`, and `spar`. Values for these parameters should be specified very carefully (see [Common Parameters](#)). You can change these values during computations to meet your needs. For more details, see the descriptions of specific routines.

---

### WARNING

To avoid failure or incorrect results, you must provide correct and consistent parameters to the routines.

---

	float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D.
	The coordinate of the leftmost boundary of the domain along the x-axis.
<i>bx</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D.
	The coordinate of the rightmost boundary of the domain along the x-axis.
<i>ay</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D.
	The coordinate of the leftmost boundary of the domain along the y-axis.
<i>by</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D.
	The coordinate of the rightmost boundary of the domain along the y-axis.
<i>az</i>	double* for d_init_Helmholtz_3D, float* for s_init_Helmholtz_3D.
	The coordinate of the leftmost boundary of the domain along the z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
<i>bz</i>	double* for d_init_Helmholtz_3D, float* for s_init_Helmholtz_3D.
	The coordinate of the rightmost boundary of the domain along the z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
<i>nx</i>	MKL_INT*. The number of mesh intervals along the x-axis.
<i>ny</i>	MKL_INT*. The number of mesh intervals along the y-axis.
<i>nz</i>	MKL_INT*. The number of mesh intervals along the z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
<i>BCtype</i>	char*. Contains the type of boundary conditions on each boundary. Must contain four characters for ?_init_Helmholtz_2D and six characters for ?_init_Helmholtz_3D. Each of the characters can be 'N' (Neumann boundary condition), 'D' (Dirichlet boundary condition), or 'P' (periodic boundary conditions). Specify the types of boundary conditions for the boundaries in the following order: <i>bd_ax</i> , <i>bd_bx</i> , <i>bd_ay</i> , <i>bd_by</i> , <i>bd_az</i> , and <i>bd_bz</i> . Specify periodic boundary conditions on the respective boundaries in pairs (for example, 'PPDD' or 'NNPP' in the 2D case). The types of boundary conditions for the last two boundaries are needed only in the 3D case.
<i>q</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D.

The constant Helmholtz coefficient. Note that to solve Poisson or Laplace problem, you should set the value of  $q$  to 0.

## Output Parameters

<i>ipar</i>	MKL_INT array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to <a href="#">ipar</a> ).
<i>dpar</i>	double array of size $5 \cdot nx/2 + 7$ in the 2D case or $5 \cdot (nx + ny)/2 + 9$ in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to <a href="#">dpar</a> and <a href="#">spar</a> ).
<i>spar</i>	float array of size $5 \cdot nx/2 + 7$ in the 2D case or $5 \cdot (nx + ny)/2 + 9$ in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to <a href="#">dpar</a> and <a href="#">spar</a> ).
<i>stat</i>	MKL_INT*. Routine completion status, which is also written to <i>ipar</i> [0]. Continue to call other Poisson Solver routines only if the status is 0.

## Description

The `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routines initialize basic data structures for Poisson Solver computations of the appropriate precision. All routines invoked after a call to a `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine use values of the *ipar*, *dpar* and *spar* array parameters returned by the routine. Detailed description of the array parameters can be found in [Common Parameters](#).

---

### Caution

Data structures initialized and created by 2D flavors of the routine cannot be used by 3D flavors of any Poisson Solver routines, and vice versa.

---

You can skip calls to these routines in your code. However, see [Caveat on Parameter Modifications](#) for information on initializing the data structures.

## Return Values

<i>stat</i> = 0	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this <i>stat</i> value.
<i>stat</i> = -99999	The routine failed to complete the task because of a fatal error.

### [\\_commit\\_Helmholtz\\_2D/?\\_commit\\_Helmholtz\\_3D](#)

*Checks consistency and correctness of input data and initializes certain data structures required to solve 2D/3D Helmholtz problem.*

```

```
void s_commit_Helmholtz_3D (float * f, const float * bd_ax, const float * bd_bx, const
float * bd_ay, const float * bd_by, const float * bd_az, const float * bd_bz,
DFTI_DESCRIPTOR_HANDLE * xhandle, DFTI_DESCRIPTOR_HANDLE * yhandle, MKL_INT * ipar,
float * spar, MKL_INT * stat );
```

## Include Files

- mkl.h

## Input Parameters

<i>f</i>	<p>double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.</p> <p>Contains the right-hand side of the problem packed in a single vector:</p> <ul style="list-style-type: none"> <li>• 2D problem: The size of the vector for the is <math>(n_x+1)*(n_y+1)</math>. The value of the right-hand side in the mesh point <math>(i, j)</math> is stored in <math>f[i+j*(n_x+1)]</math>.</li> <li>• 3D problem: The size of the vector for the is <math>(n_x+1)*(n_y+1)*(n_z+1)</math>. The value of the right-hand side in the mesh point <math>(i, j, k)</math> is stored in <math>f[i+j*(n_x+1)+k*(n_x+1)*(n_y+1)]</math>.</li> </ul> <p>Note that to solve the Laplace problem, you should set all the elements of the array <i>f</i> to 0.</p> <p>Note also that the array <i>f</i> may be altered by the routine. To preserve the <i>f</i> vector, save it to another memory location.</p>
<i>ipar</i>	<p>MKL_INT array of size 128. Contains integer data to be used by the Fast Helmholtz Solver (for details, refer to <a href="#">ipar</a>).</p>
<i>dpar</i>	<p>double array of size depending on the dimension of the problem:</p> <ul style="list-style-type: none"> <li>• 2D problem: <math>5*n_x/2+7</math></li> <li>• 3D problem: <math>5*(n_x+n_y)/2+9</math></li> </ul> <p>Contains double-precision data to be used by the Fast Helmholtz Solver (for details, refer to <a href="#">dpar</a> and <a href="#">spar</a>).</p>
<i>spar</i>	<p>float array of size depending on the dimension of the problem:</p> <ul style="list-style-type: none"> <li>• 2D problem: <math>5*n_x/2+7</math></li> <li>• 3D problem: <math>5*(n_x+n_y)/2+9</math></li> </ul> <p>Contains single-precision data to be used by the Fast Helmholtz Solver (for details, refer to <a href="#">dpar</a> and <a href="#">spar</a>).</p>
<i>bd_ax</i>	<p>double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.</p>

Contains values of the boundary condition on the leftmost boundary of the domain along the  $x$ -axis (for more information, refer to [a detailed description of `bd\_ax`](#)).

`bd_bx` double\* for `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D`,  
float\* for `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D`.

Contains values of the boundary condition on the rightmost boundary of the domain along the  $x$ -axis (for more information, refer to [a detailed description of `bd\_bx`](#)).

`bd_ay` double\* for `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D`,  
float\* for `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D`.

Contains values of the boundary condition on the leftmost boundary of the domain along the  $y$ -axis (for more information, refer to [a detailed description of `bd\_ay`](#)).

`bd_by` double\* for `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D`,  
float\* for `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D`.

Contains values of the boundary condition on the rightmost boundary of the domain along the  $y$ -axis (for more information, refer to [a detailed description of `bd\_by`](#)).

`bd_az` double\* for `d_commit_Helmholtz_3D`,  
float\* for `s_commit_Helmholtz_3D`.

Used only by `?_commit_Helmholtz_3D`. Contains values of the boundary condition on the leftmost boundary of the domain along the  $z$ -axis (for more information, refer to [a detailed description of `bd\_az`](#)).

`bd_bz` double\* for `d_commit_Helmholtz_3D`,  
float\* for `s_commit_Helmholtz_3D`.

Used only by `?_commit_Helmholtz_3D`. Contains values of the boundary condition on the rightmost boundary of the domain along the  $z$ -axis (for more information, refer to [a detailed description of `bd\_bz`](#)).

## Output Parameters

`f` Contains right-hand side of the problem, possibly altered on output.

`ipar` Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in [ipar](#).

`dpar` Contains double-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in [dpar](#) and [spar](#).

`spar` Contains single-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in [dpar](#) and [spar](#).

`xhandle, yhandle` `DFTI_DESCRIPTOR_HANDLE*`. Data structures used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, refer to [FFT Functions](#)). `yhandle` is used only by `?_commit_Helmholtz_3D`.

*stat* MKL\_INT\*. Routine completion status, which is also written to *ipar[0]*. Continue to call other Poisson Solver routines only if the status is 0.

## Description

The `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routines check the consistency and correctness of the parameters to be passed to the solver routines `?_Helmholtz_2D/?_Helmholtz_3D`. They also initialize the *xhandle* and *yhandle* data structures, *ipar* array, and *dpar* or *spar* array, depending upon the routine precision. Refer to [Common Parameters](#) to find out which particular array elements the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routines initialize and to what values these elements are initialized.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of Poisson Solver routines, see [Caveat on Parameter Modifications](#).

Unlike `?_init_Helmholtz_2D/?_init_Helmholtz_3D`, you must call

the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routines in your code. Values of *ax*, *bx*, *ay*, *by*, *az*, and *bz* are passed to the routines with the *spar/dpar* array, and values of *nx*, *ny*, *nz*, and *BCtype* are passed with the *ipar* array.

## Return Values

<i>stat</i> = 1	The routine completed without errors but with warnings.
<i>stat</i> = 0	The routine successfully completed the task.
<i>stat</i> = -100	The routine stopped because an error in the input data was found, or the data in the <i>dpar</i> , <i>spar</i> , or <i>ipar</i> array was altered by mistake.
<i>stat</i> = -1000	The routine stopped because of an Intel® oneAPI Math Kernel Library (oneMKL) FFT or TT interface error.
<i>stat</i> = -10000	The routine stopped because the initialization failed to complete or the parameter <i>ipar[0]</i> was altered by mistake.
<i>stat</i> = -99999	The routine failed to complete the task because of a fatal error.

## `?_Helmholtz_2D/?_Helmholtz_3D`

*Computes the solution of the 2D/3D Helmholtz problem specified by the parameters.*

---

## Syntax

```
void d_Helmholtz_2D (double * f, const double * bd_ax, const double * bd_bx, const
double * bd_ay, const double *bd_by, DFTI_DESCRIPTOR_HANDLE * xhandle, MKL_INT * ipar,
const double * dpar, MKL_INT * stat );
```

```
void s_Helmholtz_2D (float * f, const float * bd_ax, const float * bd_bx, const float *
bd_ay, const float * bd_by, DFTI_DESCRIPTOR_HANDLE * xhandle, MKL_INT * ipar, const
float * spar, MKL_INT * stat );
```

```
void d_Helmholtz_3D (double * f, const double * bd_ax, const double * bd_bx, const
double * bd_ay, const double *bd_by, const double * bd_az, const double * bd_bz,
DFTI_DESCRIPTOR_HANDLE * xhandle, DFTI_DESCRIPTOR_HANDLE * yhandle, MKL_INT * ipar,
const double * dpar, MKL_INT * stat );
```

```
void s_Helmholtz_3D (float * f, const float * bd_ax, const float * bd_bx, const float *
bd_ay, const float * bd_by, const float * bd_az, const float * bd_bz,
DFTI_DESCRIPTOR_HANDLE * xhandle, DFTI_DESCRIPTOR_HANDLE * yhandle, MKL_INT * ipar,
const float * spar, MKL_INT * stat );
```

## Include Files

- mkl.h

## Input Parameters

<i>f</i>	<p>double* for d_Helmholtz_2D/d_Helmholtz_3D, float* for s_Helmholtz_2D/s_Helmholtz_3D.</p> <p>Contains the right-hand side of the problem packed in a single vector and modified by the appropriate <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. Note that an attempt to substitute the original right-hand side vector, which was passed to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine, at this point results in an incorrect solution.</p> <ul style="list-style-type: none"> <li>• 2D problem: the size of the vector is <math>(nx+1)*(ny+1)</math>. The value of the modified right-hand side in the mesh point <math>(i, j)</math> is stored in <math>f[i+j*(nx+1)]</math>.</li> <li>• 3D problem: the size of the vector is <math>(nx+1)*(ny+1)*(nz+1)</math>. The value of the modified right-hand side in the mesh point <math>(i, j, k)</math> is stored in <math>f[i+j*(nx+1)+k*(nx+1)*(ny+1)]</math>.</li> </ul>
<i>xhandle, yhandle</i>	<p>DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, refer to <a href="#">FFT Functions</a>). <i>yhandle</i> is used only by <code>?_Helmholtz_3D</code>.</p>
<i>ipar</i>	<p>MKL_INT array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to <a href="#">ipar</a>).</p>
<i>dpar</i>	<p>double array of size depending on the dimension of the problem:</p> <ul style="list-style-type: none"> <li>• 2D problem: <math>5*nx/2+7</math></li> <li>• 3D problem: <math>5*(nx+ny)/2+9</math></li> </ul> <p>Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to <a href="#">dpar and spar</a>).</p>
<i>spar</i>	<p>float array of size depending on the dimension of the problem:</p> <ul style="list-style-type: none"> <li>• 2D problem: <math>5*nx/2+7</math></li> <li>• 3D problem: <math>5*(nx+ny)/2+9</math></li> </ul> <p>Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to <a href="#">dpar and spar</a>).</p>
<i>bd_ax</i>	<p>double* for d_Helmholtz_2D/d_Helmholtz_3D, float* for s_Helmholtz_2D/s_Helmholtz_3D.</p> <p>Contains values of the boundary condition on the leftmost boundary of the domain along the x-axis (for more information, refer to <a href="#">a detailed description of bd_ax</a>).</p>

<code>bd_bx</code>	<p>double* for <code>d_Helmholtz_2D/d_Helmholtz_3D</code>, float* for <code>s_Helmholtz_2D/s_Helmholtz_3D</code>.</p> <p>Contains values of the boundary condition on the rightmost boundary of the domain along the <i>x</i>-axis (for more information, refer to <a href="#">a detailed description of <code>bd_bx</code></a>).</p>
<code>bd_ay</code>	<p>double* for <code>d_Helmholtz_2D/d_Helmholtz_3D</code>, float* for <code>s_Helmholtz_2D/s_Helmholtz_3D</code>.</p> <p>Contains values of the boundary condition on the leftmost boundary of the domain along the <i>y</i>-axis for more information, refer to <a href="#">a detailed description of <code>bd_ay</code></a>).</p>
<code>bd_by</code>	<p>double* for <code>d_Helmholtz_2D/d_Helmholtz_3D</code>, float* for <code>s_Helmholtz_2D/s_Helmholtz_3D</code>.</p> <p>Contains values of the boundary condition on the rightmost boundary of the domain along the <i>y</i>-axis (for more information, refer to <a href="#">a detailed description of <code>bd_by</code></a>).</p>
<code>bd_az</code>	<p>double* for <code>d_Helmholtz_3D</code>, float* for <code>s_Helmholtz_3D</code>.</p> <p>Used only by <code>?_Helmholtz_3D</code>. Contains values of the boundary condition on the leftmost boundary of the domain along the <i>z</i>-axis (for more information, refer to <a href="#">a detailed description of <code>bd_az</code></a>).</p>
<code>bd_bz</code>	<p>double* for <code>d_Helmholtz_3D</code>, float* for <code>s_Helmholtz_3D</code>.</p> <p>Used only by <code>?_Helmholtz_3D</code>. Contains values of the boundary condition on the rightmost boundary of the domain along the <i>z</i>-axis (for more information, refer to <a href="#">a detailed description of <code>bd_bz</code></a>).</p>

**NOTE**

To avoid incorrect computation results, do not change arrays `bd_ax`, `bd_bx`, `bd_ay`, `bd_by`, `bd_az`, `bd_bz` between a call to the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine and a subsequent call to the appropriate `?_Helmholtz_2D/?_Helmholtz_3D` routine.

**Output Parameters**

<code>f</code>	On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input.
<code>xhandle, yhandle</code>	Data structures used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface. Although the addresses do not change, the structures are modified on output.
<code>ipar</code>	Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in <a href="#">ipar</a> .

*stat* MKL\_INT\*. Routine completion status, which is also written to *ipar[0]*. Continue to call other Poisson Solver routines only if the status is 0.

## Description

The `?_Helmholtz_2D/?_Helmholtz_3D` routines compute the approximate solution of the Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to formulas given in [Poisson Solver Implementation](#). The  $f$  parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of  $ax$ ,  $bx$ ,  $ay$ ,  $by$ ,  $az$ , and  $bz$  are passed to the routines with the *spar/dpar* array, and values of  $nx$ ,  $ny$ ,  $nz$ , and *BCTYPE* are passed with the *ipar* array.

## Return Values

<i>stat</i> = 1	The routine completed without errors but with some warnings.
<i>stat</i> = 0	The routine successfully completed the task.
<i>stat</i> = -2	The routine stopped because division by zero occurred. It usually happens if the data in the <i>dpar</i> or <i>spar</i> array was altered by mistake.
<i>stat</i> = -3	The routine stopped because the sufficient memory was unavailable for the computations.
<i>stat</i> = -100	The routine stopped because an error in the input data was found or the data in the <i>dpar</i> , <i>spar</i> , or <i>ipar</i> array was altered by mistake.
<i>stat</i> = -1000	The routine stopped because of the Intel® oneAPI Math Kernel Library (oneMKL) FFT or TT interface error.
<i>stat</i> = -10000	The routine stopped because the initialization failed to complete or the parameter <i>ipar[0]</i> was altered by mistake.
<i>stat</i> = -99999	The routine failed to complete the task because of a fatal error.

## `free_Helmholtz_2D/free_Helmholtz_3D`

*Releases the memory allocated for the data structures used by the FFT interface.*

## Syntax

```
void free_Helmholtz_2D(DFTI_DESCRIPTOR_HANDLE* xhandle, MKL_INT* ipar, MKL_INT* stat);
void free_Helmholtz_3D(DFTI_DESCRIPTOR_HANDLE* xhandle, DFTI_DESCRIPTOR_HANDLE*
yhandle, MKL_INT* ipar, MKL_INT* stat);
```

## Include Files

- `mkL.h`

## Input Parameters

<i>xhandle, yhandle</i>	DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, refer to <a href="#">FFT Functions</a> ). The structure <i>yhandle</i> is used only by <code>free_Helmholtz_3D</code> .
<i>ipar</i>	MKL_INT array of size 128. Contains integer data used by Fast Helmholtz Solver (for details, refer to <a href="#">ipar</a> ).

## Output Parameters

<i>xhandle, yhandle</i>	Data structures used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface. Memory allocated for the structures is released on output.
<i>ipar</i>	Contains integer data used by Fast Helmholtz Solver. On output, the status of the routine call is written to <i>ipar[0]</i> .
<i>stat</i>	MKL_INT*. Routine completion status, which is also written to <i>ipar[0]</i> .

## Description

The `free_Helmholtz_2D-free_Helmholtz_3D` routine releases the memory used by the *xhandle* and *yhandle* structures, which are needed for calling the Intel® oneAPI Math Kernel Library (oneMKL) FFT functions. To release memory allocated for other parameters, include memory release statements in your code.

## Return Values

<i>stat</i> = 0	The routine successfully completed the task.
<i>stat</i> = -1000	The routine stopped because of an Intel® oneAPI Math Kernel Library (oneMKL) FFT or TT interface error.
<i>stat</i> = -99999	The routine failed to complete the task because of a fatal error.

## Routines for the Spherical Solver

The section describes Poisson Solver routines for the spherical case, their syntax, parameters, and return values. All flavors of the same routine are described together: single- and double-precision and periodic (having names ending in "p") and non-periodic (having names ending in "np").

These Poisson Solver routines also call the Intel® oneAPI Math Kernel Library (oneMKL) FFT routines (described in [FFT Functions](#)), which enhance the performance of the Poisson Solver routines.

### [?\\_init\\_sph\\_p/?\\_init\\_sph\\_np](#)

*Initializes basic data structures of the periodic and non-periodic Fast Helmholtz Solver on a sphere.*

### Syntax

```
void d_init_sph_p (const double * ap, const double * at, const double * bp, const
double * bt, const MKL_INT * np, const MKL_INT * nt, const double * q, MKL_INT * ipar,
double * dpar, MKL_INT * stat );
```

```
void s_init_sph_p (const float * ap, const float * at, const float * bp, const float *
bt, const MKL_INT * np, const MKL_INT * nt, const float * q, MKL_INT * ipar, float *
spar, MKL_INT * stat );
```

```
void d_init_sph_np (const double * ap, const double * at, const double * bp, const
double * bt, const MKL_INT * np, const MKL_INT *nt, const double * q, MKL_INT * ipar,
double * dpar, MKL_INT * stat );
```

```
void s_init_sph_np (const float * ap, const float * at, const float * bp, const float *
bt, const MKL_INT * np, const MKL_INT * nt, const float * q, MKL_INT * ipar, float *
spar, MKL_INT * stat );
```

## Include Files

- mkl.h

## Input Parameters

<i>ap</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The coordinate (angle) of the leftmost boundary of the domain along the $\phi$ -axis.
<i>bp</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The coordinate (angle) of the rightmost boundary of the domain along the $\phi$ -axis.
<i>at</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The coordinate (angle) of the leftmost boundary of the domain along the $\theta$ -axis.
<i>bt</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The coordinate (angle) of the rightmost boundary of the domain along the $\theta$ -axis.
<i>np</i>	MKL_INT*. The number of mesh intervals along the $\phi$ -axis. Must be even in the periodic case.
<i>nt</i>	MKL_INT*. The number of mesh intervals along the $\theta$ -axis.
<i>q</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The constant Helmholtz coefficient. To solve the Poisson problem, set the value of <i>q</i> to 0.

## Output Parameters

<i>ipar</i>	MKL_INT array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to <a href="#">ipar</a> ).
-------------	---

<i>dpar</i>	double array of size $5*np/2+nt+10$ . Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to <a href="#">dpar and spar</a> ).
<i>spar</i>	float array of size $5*np/2+nt+10$ . Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to <a href="#">dpar and spar</a> ).
<i>stat</i>	MKL_INT*. Routine completion status, which is also written to <i>ipar[0]</i> . Continue to call other Poisson Solver routines only if the status is 0.

## Description

The `?_init_sph_p/?_init_sph_np` routines initialize basic data structures for Poisson Solver computations. All routines invoked after a call to a `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine use values of the *ipar*, *dpar*, and *spar* array parameters returned by the routine. A detailed description of the array parameters can be found in [Common Parameters](#).

---

### Caution

Data structures initialized and created by periodic flavors of the routine cannot be used by non-periodic flavors of any Poisson Solver routines for Helmholtz Solver on a sphere, and vice versa.

---

You can skip calls to these routines in your code. However, see [Caveat on Parameter Modifications](#) for information on initializing the data structures.

## Return Values

<i>stat</i> = 0	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this <i>stat</i> value.
<i>stat</i> = -99999	The routine failed to complete the task because of fatal error.

## [?\\_commit\\_sph\\_p/?\\_commit\\_sph\\_np](#)

*Checks consistency and correctness of input data and initializes certain data structures required to solve the periodic/non-periodic Helmholtz problem on a sphere.*

## Syntax

```
void d_commit_sph_p(double* f, DFTI_DESCRIPTOR_HANDLE* handle_s,
DFTI_DESCRIPTOR_HANDLE* handle_c, MKL_INT* ipar, double* dpar, MKL_INT* stat);

void s_commit_sph_p(float* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE*
handle_c, MKL_INT* ipar, float* spar, MKL_INT* stat);

void d_commit_sph_np(double* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, double*
dpar, MKL_INT* stat);

void s_commit_sph_np(float* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, float*
spar, MKL_INT* stat);
```

## Include Files

- `mkl.h`

## Input Parameters

<i>f</i>	double* for <code>d_commit_sph_p/d_commit_sph_np</code> , float* for <code>s_commit_sph_p/s_commit_sph_np</code> .  Contains the right-hand side of the problem packed in a single vector. The size of the vector is $(np+1)*(nt+1)$ and value of the right-hand side in the mesh point $(i, j)$ is stored in $f[i+j*(np+1)]$ .  Note that the array <i>f</i> may be altered by the routine. Save this vector to another memory location if you want to preserve it.
<i>ipar</i>	MKL_INT array of size 128. Contains integer data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to <a href="#">ipar</a> ).
<i>dpar</i>	double array of size $5*np/2+nt+10$ . Contains double-precision data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to <a href="#">dpar and spar</a> ).
<i>spar</i>	float array of size $5*np/2+nt+10$ . Contains single-precision data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to <a href="#">dpar and spar</a> ).

## Output Parameters

<i>f</i>	Contains the right-hand side of the problem, possibly altered on output.
<i>ipar</i>	Contains integer data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in <a href="#">ipar</a> .
<i>dpar</i>	Contains double-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in <a href="#">dpar and spar</a> .
<i>spar</i>	Contains single-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in <a href="#">dpar and spar</a> .
<i>handle_s, handle_c, handle</i>	DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, refer to <a href="#">FFT Functions</a> ). <i>handle_s</i> and <i>handle_c</i> are used only in <code>?_commit_sph_p</code> and <i>handle</i> is used only in <code>?_commit_sph_np</code> .
<i>stat</i>	MKL_INT*. Routine completion status, which is also written to <i>ipar[0]</i> . Continue to call other Poisson Solver routines only if the status is 0.

## Description

The `?_commit_sph_p/?_commit_sph_np` routines check consistency and correctness of the parameters to be passed to the solver routines `?_sph_p/?_sph_np`, respectively. They also initialize certain data structures. The routine `?_commit_sph_p` initializes structures *handle\_s* and *handle\_c*, and `?_commit_sph_np` initializes *handle*. The routines also initialize the *ipar* array and *dpar* or *spar* array,

depending upon the routine precision. Refer to [Common Parameters](#) to find out which particular array elements the `?_commit_sph_p/?_commit_sph_np` routines initialize and to what values these elements are initialized.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of Poisson Solver routines, see [Caveat on Parameter Modifications](#).

Unlike `?_init_sph_p/?_init_sph_np`, you must call the `?_commit_sph_p/?_commit_sph_np` routines. Values of `np` and `nt` are passed to each of the routines with the `ipar` array.

## Return Values

<code>stat= 1</code>	The routine completed without errors but with warnings.
<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -100</code>	The routine stopped because an error in the input data was found or the data in the <code>dpar</code> , <code>spar</code> , or <code>ipar</code> array was altered by mistake.
<code>stat= -1000</code>	The routine stopped because of an Intel® oneAPI Math Kernel Library (oneMKL) FFT or TT interface error.
<code>stat= -10000</code>	The routine stopped because the initialization failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

## `?_sph_p/?_sph_np`

*Computes the solution of the spherical Helmholtz problem specified by the parameters.*

---

## Syntax

```
void d_sph_p(double* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE* handle_c, MKL_INT* ipar, double* dpar, MKL_INT* stat);
```

```
void s_sph_p(float* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE* handle_c, MKL_INT* ipar, float* spar, MKL_INT* stat);
```

```
void d_sph_np(double* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, double* dpar, MKL_INT* stat);
```

```
void s_sph_np(float* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, float* spar, MKL_INT* stat);
```

- `mkl.h`

## Input Parameters

`f` double\* for `d_sph_p/d_sph_np`,  
float\* for `s_sph_p/s_sph_np`.

Contains the right-hand side of the problem packed in a single vector and modified by the appropriate `?_commit_sph_p/?_commit_sph_np` routine. Note that an attempt to substitute the original right-hand side vector, which was passed to the `?_commit_sph_p/?_commit_sph_np` routine, at this point results in an incorrect solution.

The size of the vector is  $(np+1)*(nt+1)$  and the value of the modified right-hand side in the mesh point  $(i, j)$  is stored in  $f[j+j*(np+1)]$ .

`handle_s, handle_c, handle`

DFTI\_DESCRIPTOR\_HANDLE\*. Data structures used by Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, refer to [FFT Functions](#)). `handle_s` and `handle_c` are used only in `?_sph_p` and `handle` is used only in `?_sph_np`.

`ipar`

MKL\_INT array of size 128. Contains integer data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to [ipar](#)).

`dpar`

double array of size  $5*np/2+nt+10$ . Contains double-precision data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to [dpar and spar](#)).

`spar`

float array of size  $5*np/2+nt+10$ . Contains single-precision data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to [dpar and spar](#)).

## Output Parameters

`f`

On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input.

`handle_s, handle_c, handle`

Data structures used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface.

`ipar`

Contains integer data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in [ipar](#).

`dpar`

Contains double-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in [dpar and spar](#).

`spar`

Contains single-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in [dpar and spar](#).

`stat`

MKL\_INT\*. Routine completion status, which is also written to `ipar[0]`. Continue to call other Poisson Solver routines only if the status is 0.

## Description

The `sph_p/sph_np` routines compute the approximate solution on a sphere of the Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to the formulas given in [Poisson Solver Implementation](#). The `f` parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of `np` and `nt` are passed to each of the routines with the `ipar` array.

## Return Values

<code>stat= 1</code>	The routine completed without errors but with warnings.
<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -2</code>	The routine stopped because division by zero occurred. It usually happens if the data in the <code>dpar</code> or <code>spar</code> array was altered by mistake.
<code>stat= -3</code>	The routine stopped because the memory was insufficient to complete the computations.
<code>stat= -100</code>	The routine stopped because an error in the input data was found or the data in the <code>dpar</code> , <code>spar</code> , or <code>ipar</code> array was altered by mistake.
<code>stat= -1000</code>	The routine stopped because of an Intel® oneAPI Math Kernel Library (oneMKL) FFT or TT interface error.
<code>stat= -10000</code>	The routine stopped because the initialization failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

## free\_sph\_p/free\_sph\_np

Releases the memory allocated for the data structures used by the FFT interface.

### Syntax

```
void free_sph_p(DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE* handle_c,
MKL_INT* ipar, MKL_INT* stat);
```

```
void free_sph_np(DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, MKL_INT* stat);
```

### Include Files

- `mkl.h`

### Input Parameters

<code>handle_s</code> , <code>handle_c</code> , <code>handle</code>	DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface (for details, refer to <a href="#">FFT Functions</a> ). The structures <code>handle_s</code> and <code>handle_c</code> are used only in <code>free_sph_p</code> , and <code>handle</code> is used only in <code>free_sph_np</code> .
<code>ipar</code>	MKL_INT array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to <a href="#">ipar</a> ).

### Output Parameters

<code>handle_s</code> , <code>handle_c</code> , <code>handle</code>	Data structures used by the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface. Memory allocated for the structures is released on output.
---	--

<i>ipar</i>	Contains integer data to be used by Fast Helmholtz Solver on a sphere. On output, the status of the routine call is written to <i>ipar[0]</i> .
<i>stat</i>	MKL_INT*. Routine completion status, which is also written to <i>ipar[0]</i> .

## Description

The `free_sph_p/free_sph_np` routine releases the memory used by the `handle_s`, `handle_c` or `handle` structures, needed for calling the Intel® oneAPI Math Kernel Library (oneMKL) FFT functions. To release memory allocated for other parameters, include memory release statements in your code.

## Return Values

<i>stat</i> = 0	The routine successfully completed the task.
<i>stat</i> = -1000	The routine stopped because of an Intel® oneAPI Math Kernel Library (oneMKL) FFT or TT interface error.
<i>stat</i> = -99999	The routine failed to complete the task because of a fatal error.

## Common Parameters for the Poisson Solver

### *ipar*

<i>ipar</i>	MKL_INT array of size 128, holds integer data needed for Fast Helmholtz Solver (both for Cartesian and spherical coordinate systems). Its elements are described in <a href="#">Table "Elements of the ipar Array"</a> :
-------------	--

---

#### NOTE

Initial values can be assigned to the array parameters by the appropriate `?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np` and `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np` routines.

---

## Elements of the ipar Array

Index	Description
0	<p>Contains status value of the last Poisson Solver routine called. In general, it should be 0 on exit from a routine to proceed with the Fast Helmholtz Solver. The element has no predefined values. This element can also be used to inform the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np</code> routines of how the Commit step of the computation should be carried out (see <a href="#">Figure "Typical Order of Invoking Poisson Solver Routines"</a>). A non-zero value of <i>ipar[0]</i> with decimal representation</p> $\overline{abc} = 100a + 10b + c$ <p>=100a+10b+c, where each of <i>a</i>, <i>b</i>, and <i>c</i> is equal to 0 or 9, indicates that some parts of the Commit step should be omitted.</p> <ul style="list-style-type: none"> <li>• If <i>c</i>=9, the routine omits checking of parameters and initialization of the data structures.</li> <li>• If <i>b</i>=9,</li> </ul>

Index	Description
	<ul style="list-style-type: none"> <li>In the Cartesian case, the routine omits the adjustment of the right-hand side vector <math>f</math> to the Neumann boundary condition (multiplication of boundary values by 0.5 as well as incorporation of the boundary function <math>g</math>) and/or the Dirichlet boundary condition (setting boundary values to 0 as well as incorporation of the boundary function <math>G</math>).</li> <li>For the Helmholtz solver on a sphere, the routine omits computation of the spherical weights for the <math>dpar/spar</math> array.</li> <li>If <math>a=9</math>, the routine omits the normalization of the right-hand side vector <math>f</math>. Depending on the solver, the normalization means: <ul style="list-style-type: none"> <li>2D Cartesian case: multiplication by <math>h_y^2</math>, where <math>h_y</math> is the mesh size in the <math>y</math> direction (for details, see <a href="#">Poisson Solver Implementation</a>).</li> <li>3D (Cartesian) case: multiplication by <math>h_z^2</math>, where <math>h_z</math> is the mesh size in the <math>z</math> direction.</li> <li>Helmholtz solver on a sphere: multiplication by <math>h_\theta^2</math>, where <math>h_\theta</math> is the mesh size in the <math>\theta</math> direction (for details, see <a href="#">Poisson Solver Implementation</a>).</li> </ul> </li> </ul> <p>Using <code>ipar[0]</code> you can adjust the routine to your needs and improve efficiency in solving multiple Helmholtz problems that differ only in the right-hand side. You must be cautious when using this method, because any misunderstanding of the commit process may cause incorrect results or program failure (see also <a href="#">Caveat on Parameter Modifications</a>).</p>
1	<p>Contains error messaging options:</p> <ul style="list-style-type: none"> <li><code>ipar[1]=-1</code> indicates that all error messages are printed to the <code>MKL_Poisson_Library_log.txt</code> file in the folder from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device (usually, screen).</li> <li><code>ipar[1]=0</code> indicates that no error messages will be printed.</li> <li><code>ipar[1]=1</code> is the default value. It indicates that all error messages are printed to the standard output device.</li> </ul> <p>In case of errors, the <code>stat</code> parameter contains a non-zero value on exit from a routine regardless of the <code>ipar[1]</code> setting.</p>
2	<p>Contains warning messaging options:</p> <ul style="list-style-type: none"> <li><code>ipar[2]=-1</code> indicates that all warning messages are printed to the <code>MKL_Poisson_Library_log.txt</code> file in the directory from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device.</li> <li><code>ipar[2]=0</code> indicates that no warning messages will be printed.</li> <li><code>ipar[2]=1</code> is the default value. It indicates that all warning messages are printed to the standard output device.</li> </ul> <p>In case of warnings, the <code>stat</code> parameter contains a non-zero value on exit from a routine regardless of the <code>ipar[2]</code> setting.</p>
3 through 5	Internal parameters.
Parameters 6 through 11 are used only in the Cartesian case.	
6	<p>Takes this value:</p> <ul style="list-style-type: none"> <li>2, if <code>BCTYPE[0]='P'</code></li> <li>1, if <code>BCTYPE[0]='N'</code></li> <li>0, if <code>BCTYPE[0]='D'</code></li> <li>-1, otherwise</li> </ul>
7	<p>Takes this value:</p> <ul style="list-style-type: none"> <li>2, if <code>BCTYPE[1]='P'</code></li> </ul>

Index	Description
	<ul style="list-style-type: none"> <li>• 1, if <math>BCtype[1]='N'</math></li> <li>• 0, if <math>BCtype[1]='D'</math></li> <li>• -1, otherwise</li> </ul>
8	<p>Takes this value:</p> <ul style="list-style-type: none"> <li>• 2, if <math>BCtype[2]='P'</math></li> <li>• 1, if <math>BCtype[2]='N'</math></li> <li>• 0, if <math>BCtype[2]='D'</math></li> <li>• -1, otherwise</li> </ul>
9	<p>Takes this value:</p> <ul style="list-style-type: none"> <li>• 2, if <math>BCtype[3]='P'</math></li> <li>• 1, if <math>BCtype[3]='N'</math></li> <li>• 0, if <math>BCtype[3]='D'</math></li> <li>• -1, otherwise</li> </ul>
10	<p>Takes this value:</p> <ul style="list-style-type: none"> <li>• 2, if <math>BCtype[4]='P'</math></li> <li>• 1, if <math>BCtype[4]='N'</math></li> <li>• 0, if <math>BCtype[4]='D'</math></li> <li>• -1, otherwise</li> </ul>
11	<p>Takes this value:</p> <ul style="list-style-type: none"> <li>• 2, if <math>BCtype[5]='P'</math></li> <li>• 1, if <math>BCtype[5]='N'</math></li> <li>• 0, if <math>BCtype[5]='D'</math></li> <li>• -1, otherwise</li> </ul>
12	<p>Takes the value of</p> <ul style="list-style-type: none"> <li>• <math>nx</math>, that is, the number of intervals along the <math>x</math>-axis, in the Cartesian case.</li> <li>• <math>np</math>, that is, the number of intervals along the <math>\varphi</math>-axis, in the spherical case.</li> </ul>
13	<p>Takes the value of</p> <ul style="list-style-type: none"> <li>• <math>ny</math>, that is, the number of intervals along the <math>y</math>-axis, in the Cartesian case</li> <li>• <math>nt</math>, that is, the number of intervals along the <math>\theta</math>-axis, in the spherical case.</li> </ul>
14	<p>Takes the value of <math>nz</math>, the number of intervals along the <math>z</math>-axis. This parameter is used only in the 3D case (Cartesian).</p>
15 through 22	<p>Internal parameters which define the internal partitioning of the <math>dpar/spar</math> array.</p>
	<p>The values of <math>ipar[21] - ipar[119]</math> are assigned regardless of the dimension of the problem for the Cartesian solver or of whether the solver on a sphere is periodic.</p>
23	<p>Contains message style options. Specifically:</p> <ul style="list-style-type: none"> <li>• <math>ipar[21]=0</math> indicates that Poisson Solver routines prints the messages in Fortran-style notations.</li> <li>• <math>ipar[21]=1</math> (default) indicates that Poisson Solver routines prints the messages in C-style notations.</li> </ul>

- For the Cartesian solver, double array of size  $5*n_x/2+7$  in the 2D case or  $5*(n_x+n_y)/2+9$  in the 3D case; initialized in the `d_init_Helmholtz_2D/d_init_Helmholtz_3D` and `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D` routines.
- For the spherical solver, double array of size  $5*n_p/2+nt+10$ ; initialized in the `d_init_sph_p/d_init_sph_np` and `d_commit_sph_p/d_commit_sph_np` routines.

*spar*

Holds data needed for single-precision Fast Helmholtz Solver computations.

- For the Cartesian solver, float array of size  $5*n_x/2+7$  in the 2D case or  $5*(n_x+n_y)/2+9$  in the 3D case; initialized in the `s_init_Helmholtz_2D/s_init_Helmholtz_3D` and `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D` routines.
- For the spherical solver, float array of size  $5*n_p/2+nt+10$ ; initialized in the `s_init_sph_p/s_init_sph_np` and `s_commit_sph_p/s_commit_sph_np` routines.

Because *dpar* and *spar* have similar elements in each position, the elements are described together in [Table "Elements of the dpar and spar Arrays"](#):

### Elements of the dpar and spar Arrays

Index	Description
0	<p>In the Cartesian case, contains the length of the interval along the x-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size <math>h_x</math> in the x direction (for details, see <a href="#">Poisson Solver Implementation</a>) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine.</p> <p>In the spherical case, contains the length of the interval along the <math>\phi</math>-axis right after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine or the mesh size <math>h_\phi</math> in the <math>\phi</math> direction (for details, see <a href="#">Poisson Solver Implementation</a>) after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.</p>
1	<p>In the Cartesian case, contains the length of the interval along the y-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size <math>h_y</math> in the y direction (for details, see <a href="#">Poisson Solver Implementation</a>) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine.</p> <p>In the spherical case, contains the length of the interval along the <math>\theta</math>-axis right after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine or the mesh size <math>h_\theta</math> in the <math>\theta</math> direction (for details, see <a href="#">Poisson Solver Implementation</a>) after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.</p>
2	<p>In the Cartesian case, contains the length of the interval along the z-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size <math>h_z</math> in the z direction (for details, see <a href="#">Poisson Solver Implementation</a>) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. In the Cartesian solver, this parameter is used only in the 3D case.</p> <p>In the spherical solver, contains the coordinate of the leftmost boundary along the <math>\theta</math>-axis after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine.</p>
3	<p>Contains the value of the coefficient <math>q</math> after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np</code> routine.</p>

Index	Description
4	<p>Contains the tolerance parameter after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np</code> routine.</p> <ul style="list-style-type: none"> <li>In the Cartesian case, this value is used only for the pure Neumann boundary conditions (<math>BCType="NNNN"</math> in the 2D case; <math>BCType="NNNNNN"</math> in the 3D case). This is a special case, because the right-hand side of the problem cannot be arbitrary if the coefficient <math>q</math> is zero. The Poisson Solver verifies that the classical solution exists (up to rounding errors) using this tolerance. In any case, the Poisson Solver computes the normal solution, that is, the solution that has the minimal Euclidean norm of residual. Nevertheless, the <code>?_Helmholtz_2D/?_Helmholtz_3D</code> routine informs you that the solution may not exist in a classical sense (up to rounding errors).</li> <li>In the spherical case, the value is used for the special case of a periodic problem on the entire sphere. This special case is similar to the Cartesian case with pure Neumann boundary conditions. Here the Poisson Solver computes the normal solution as well. The parameter is also used to detect whether the problem is periodic up to rounding errors.</li> </ul> <p>The default value for this parameter is 1.0E-10 in case of double-precision computations or 1.0E-4 in case of single-precision computations. You can increase the value of the tolerance, for instance, to avoid the warnings that may appear.</p>
<code>ipar[15]-1</code> through <code>ipar[16]-1</code>	<p>In the Cartesian case, contain the spectrum of the one-dimensional (1D) problem along the <math>x</math>-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine.</p> <p>In the spherical case, contains the spectrum of the 1D problem along the <math>\phi</math>-axis after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.</p>
<code>ipar[17]-1</code> through <code>ipar[18]-1</code>	<p>In the Cartesian case, contain the spectrum of the 1D problem along the <math>y</math>-axis after a call to the <code>?_commit_Helmholtz_3D</code> routine. These elements are used only in the 3D case.</p> <p>In the spherical case, contains the spherical weights after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.</p>
<code>ipar[19]-1</code> through <code>ipar[20]-1</code>	<p>Take the values of the (staggered) sine/cosine in the mesh points:</p> <ul style="list-style-type: none"> <li>along the <math>x</math>-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine for a Cartesian solver</li> <li>along the <math>\phi</math>-axis after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine for a spherical solver.</li> </ul>
<code>ipar[21]-1</code> through <code>ipar[22]-1</code>	<p>Take the values of the (staggered) sine/cosine in the mesh points:</p> <ul style="list-style-type: none"> <li>along the <math>y</math>-axis after a call to the <code>?_commit_Helmholtz_3D</code> routine for a Cartesian 3D solver</li> <li>along the <math>\phi</math>-axis after a call to the <code>?_commit_sph_p</code> routine for a spherical periodic solver.</li> </ul> <p>These elements are not used in the 2D Cartesian case and in the non-periodic spherical case.</p>
<code>ipar[25]-1</code> through <code>ipar[26]-1</code>	<p>Take the values of the (staggered) sine/cosine in the mesh points along the <math>x</math>-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. These elements are used only in the periodic Cartesian case.</p>

Index	Description
<i>ipar</i> [27]-1 through <i>ipar</i> [28]	Take the values of the (staggered) sine/cosine in the mesh points along the x-axis after a call to the <code>?_commit_Helmholtz_3D</code> routine. These elements are used only in the periodic 3D Cartesian case.

**NOTE**

You may define the array size depending upon the type of the problem to solve.

**Caveat on Parameter Modifications**

Flexibility of the Poisson Solver interface enables you to skip calls to the `?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np` routine and to initialize the basic data structures explicitly in your code. You may also need to modify contents of the *ipar*, *dpar*, and *spar* arrays after initialization. When doing so, provide correct and consistent data in the arrays. Mistakenly altered arrays cause errors or incorrect results. You can perform a basic check for correctness and consistency of parameters by calling the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine; however, this does not ensure the correct solution but only reduces the chance of errors or wrong results.

**NOTE**

To supply correct and consistent parameters to Poisson Solver routines, you should have considerable experience in using the Poisson Solver interface and good understanding of the solution process, as well as elements contained in the *ipar*, *spar*, and *dpar* arrays and dependencies between values of these elements.

In rare occurrences when you fail in tuning parameters for the Fast Helmholtz Solver, refer for technical support at <http://www.intel.com/software/products/support/>.

**WARNING**

The only way that ensures a proper solution of a Helmholtz problem is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of *ipar*, *dpar*, and *spar* arrays unless it is necessary.

**Parameters That Define Boundary Conditions**

Poisson Solver routines for the Cartesian solver use the following common parameters to define the boundary conditions.

**Parameters to Define Boundary Conditions for the Cartesian Solver**

Parameter	Description
<i>bd_ax</i>	<p>double* for <code>d_commit_Helmholtz_2D/d_commit_Helmholtz_3D</code> and <code>d_Helmholtz_2D/d_Helmholtz_3D</code>,</p> <p>float* for <code>s_commit_Helmholtz_2D/s_commit_Helmholtz_3D</code> and <code>s_Helmholtz_2D/s_Helmholtz_3D</code>.</p> <p>Contains values of the boundary condition on the leftmost boundary of the domain along the x-axis.</p> <ul style="list-style-type: none"> <li>2D problem: the size of the array is <math>n_y+1</math>. Its contents depend on the boundary conditions as follows:</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>Dirichlet boundary condition (value of <code>BCtype[0]</code> is 'D'): values of the function <math>G(ax, y_j), j=0, \dots, ny</math>.</li> <li>Neumann boundary condition (value of <code>BCtype[0]</code> is 'N'): values of the function <math>g(ax, y_j), j=0, \dots, ny</math>.</li> </ul> <p>The value corresponding to the index <math>j</math> is placed in <code>bd_ax[j]</code>.</p> <ul style="list-style-type: none"> <li>3D problem: the size of the array is <math>(ny+1)*(nz+1)</math>. Its contents depend on the boundary conditions as follows: <ul style="list-style-type: none"> <li>Dirichlet boundary condition (value of <code>BCtype[0]</code> is 'D'): values of the function <math>G(ax, y_j, z_k), j=0, \dots, ny, k=0, \dots, nz</math>.</li> <li>Neumann boundary condition (value of <code>BCtype[0]</code> is 'N'): the values of the function <math>g(ax, y_j, z_k), j=0, \dots, ny, k=0, \dots, nz</math>.</li> </ul> <p>The values are packed in the array so that the value corresponding to indices <math>(j, k)</math> is placed in <code>bd_ax[j+k*(ny+1)]</code>.</p> </li> </ul> <p>For periodic boundary conditions (the value of <code>BCtype[0]</code> is 'P'), this parameter is not used, so it can accept a dummy pointer.</p>
<code>bd_bx</code>	<pre>double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D and d_Helmholtz_2D/d_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D and s_Helmholtz_2D/s_Helmholtz_3D.</pre> <p>Contains values of the boundary condition on the rightmost boundary of the domain along the <math>x</math>-axis.</p> <ul style="list-style-type: none"> <li>2D problem: the size of the array is <math>ny+1</math>. Its contents depend on the boundary conditions as follows: <ul style="list-style-type: none"> <li>Dirichlet boundary condition (value of <code>BCtype[1]</code> is 'D'): values of the function <math>G(bx, y_j), j=0, \dots, ny</math>.</li> <li>Neumann boundary condition (value of <code>BCtype[1]</code> is 'N'): values of the function <math>g(bx, y_j), j=0, \dots, ny</math>.</li> </ul> <p>The value corresponding to the index <math>j</math> is placed in <code>bd_bx[j]</code>.</p> </li> <li>3D problem: the size of the array is <math>(ny+1)*(nz+1)</math>. ## Poisson Solver Implementation Details

Several aspects of the Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver interface are platform-specific and language-specific. To promote portability of the Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver interface across platforms and ease of use across different languages, Intel® oneAPI Math Kernel Library (oneMKL) provides you with the Poisson Solver language-specific header file to include in your code:

- `mkl_poisson.h`, to be used together with `mkl_dfti.h`.

---

### NOTE

- Use of the Intel® oneAPI Math Kernel Library (oneMKL) Poisson Solver software without including the above language-specific header files is not supported.
- 

## Header File

The header file defines the function prototypes for the Cartesian and spherical solver available in specific function descriptions.

## Nonlinear Optimization Problem Solvers

---

Intel® oneAPI Math Kernel Library (oneMKL) provides tools for solving nonlinear least squares problems using the Trust-Region (TR) algorithms. The general nonlinear solver workflow and naming conventions are described here:

- [Nonlinear Solver Organization and Implementation](#)
- [Nonlinear Solver Routine Naming Conventions](#)

The solver routines are grouped according to their purpose as follows:

- [Nonlinear Least Squares Problem without Constraints](#)
- [Nonlinear Least Squares Problem with Linear \(Boundary\) Constraints](#)
- [Jacobian Matrix Calculation Routines](#)

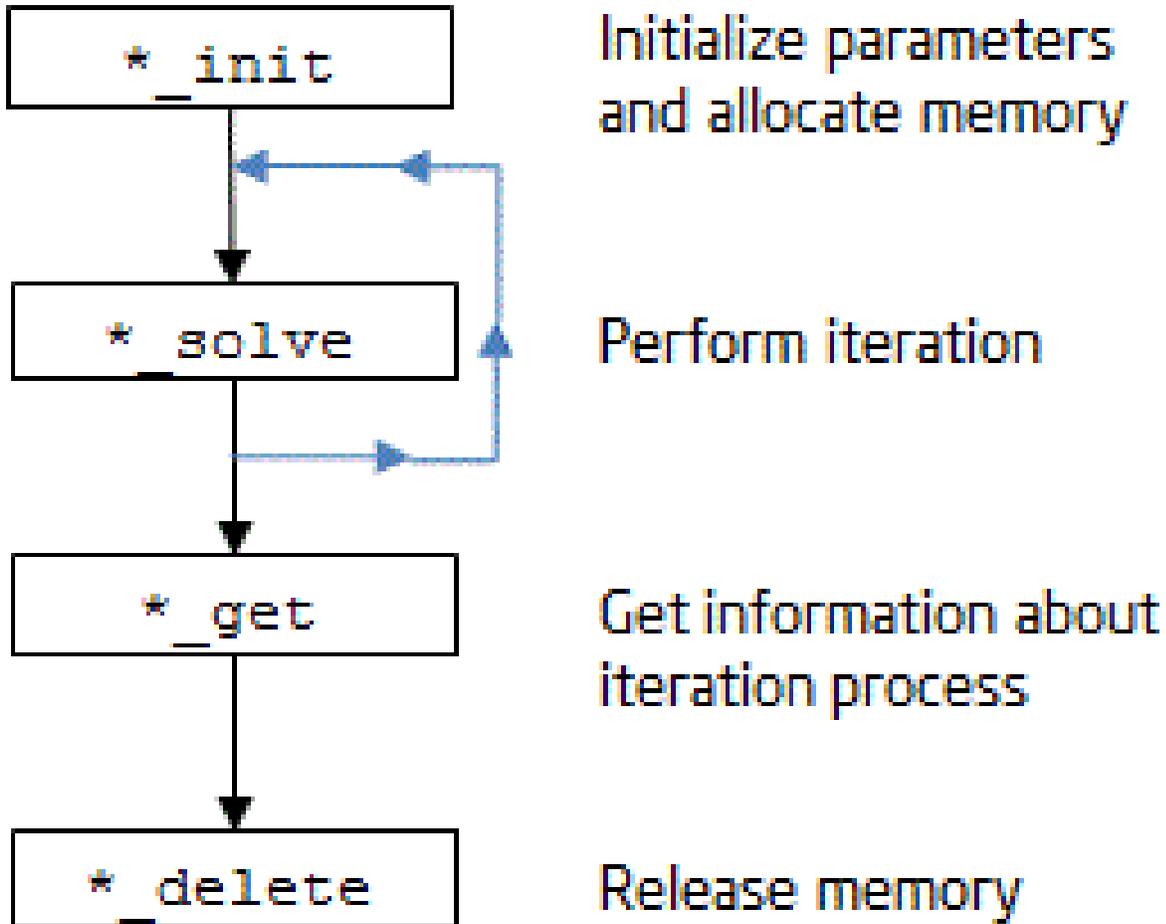

For more information on the key concepts required to understand the use of the Intel® oneAPI Math Kernel Library (oneMKL) nonlinear least squares problem solver routines, see [[Conn00](#)].

### Nonlinear Solver Organization and Implementation

The Intel® oneAPI Math Kernel Library (oneMKL) solver routines for nonlinear least squares problems use reverse communication interfaces (RCI). That means you need to provide the solver with information required for the iteration process, for example, the corresponding Jacobian matrix, or values of the objective function. RCI removes the dependency of the solver on specific implementation of the operations. However, it does require that you organize a computational loop.

\_\_border\_\_top

**Typical order for invoking RCI solver routines**

The nonlinear least squares problem solver routines, or Trust-Region (TR) solvers, are implemented with threading support. You can manage the threads using [Threading Control Functions](#). The TR solvers use BLAS and LAPACK routines, and offer the same parallelism as those domains. The `?jacobi` and `?jacobix` routines of Jacobi matrix calculations are parallel. These routines (`?jacobi` and `?jacobix`) make calls to the user-supplied functions with different `x` parameters for multiple threads.

**Memory Allocation and Handles**

To make the TR solver routines easy to use, you are not required to allocate temporary working storage. The solver allocates all temporary memory internally. To allow multiple users to access the solver simultaneously, the solver keeps track of the storage allocated for a particular application by using a data object called a handle. Each TR solver routine creates, uses, or deletes a handle. The handle datatype definition can be found in `mk1.h` (or `mk1_rci.h/mk1_rci_win.h`).

Include one of the mentioned headers and declare the handle as :

```
TRNSP_HANDLE_t handle;
```

or

```
TRNSPBC_HANDLE_t handle;
```

The first declaration is used for nonlinear least squares problems without boundary constraints, and the second is used for nonlinear least squares problems with boundary constraints.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.intel.com/PerformanceIndex](http://www.intel.com/PerformanceIndex).

Notice revision #20201201

## Nonlinear Solver Routine Naming Conventions

The TR routine names have the following structure:

```
<character><name>_<action>( )
```

where

- *<character>* indicates the data type:

s	float
d	double

- *<name>* indicates the task type:

trnlsp	nonlinear least squares problem without constraints
trnlspbc	nonlinear least squares problem with boundary constraints
jacobi	computation of the Jacobian matrix using central differences

- *<action>* indicates an action on the task:

init	initializes the solver
check	checks correctness of the input parameters
solve	solves the problem
get	retrieves the number of iterations, the stop criterion, the initial residual, and the final residual
delete	releases the allocated data

## Nonlinear Least Squares Problem without Constraints

The nonlinear least squares problem without constraints can be described as follows:

$$\min_{x \in \mathbb{R}^n} \|F(x)\|_2^2 = \min_{x \in \mathbb{R}^n} \|y - f(x)\|_2^2, y \in \mathbb{R}^m, x \in \mathbb{R}^n, f: \mathbb{R}^n \rightarrow \mathbb{R}^m, m \geq n,$$

where

$F(x) : \mathbb{R}^n \rightarrow \mathbb{R}^m$  is a twice differentiable function in  $\mathbb{R}^n$ .

Solving a nonlinear least squares problem means searching for the best approximation to the vector  $y$  with the model function  $f_i(x)$  and nonlinear variables  $x$ . The best approximation means that the sum of squares of residuals  $y_i - f_i(x)$  is the minimum.

See usage examples in the `examples\c\nonlinear_solvers` folder of your Intel® oneAPI Math Kernel Library (oneMKL) directory. Specifically, see `ex_nlsqp_f.fex_nlsqp_c.c`.

## RCI TR Routines

Routine Name	Operation
<code>?trnlsp_init</code>	Initializes the solver.
<code>?trnlsp_check</code>	Checks correctness of the input parameters.
<code>?trnlsp_solve</code>	Solves a nonlinear least squares problem using the Trust-Region algorithm.
<code>?trnlsp_get</code>	Retrieves the number of iterations, stop criterion, initial residual, and final residual.
<code>?trnlsp_delete</code>	Releases allocated data.

### ?trnlsp\_init

Initializes the solver of a nonlinear least squares problem.

### Syntax

```
MKL_INT strnlsp_init (_TRNSP_HANDLE_t* handle, const MKL_INT* n, const MKL_INT* m,
const float* x, const float* eps, const MKL_INT* iter1, const MKL_INT* iter2, const
float* rs);
```

```
MKL_INT dtrnlsp_init (_TRNSP_HANDLE_t* handle, const MKL_INT* n, const MKL_INT* m,
const double* x, const double* eps, const MKL_INT* iter1, const MKL_INT* iter2, const
double* rs);
```

### Include Files

- `mkl.h`

### Description

The `?trnlsp_init` routine initializes the solver.

After initialization, all subsequent invocations of the `?trnlsp_solve` routine should use the values of the `handle` returned by `?trnlsp_init`. This handle stores internal data, including pointers to the arrays `x` and `eps`. It is important to not move or deallocate these arrays until after calling the `?trnlsp_delete` routine.

The `eps` array contains a number indicating the stopping criteria:

<code>eps</code> Value	Description
0	$\Delta < eps[0]$
1	$\ F(x)\ _2 < eps[1]$
2	The Jacobian matrix is singular. $\ J(x)_{[m*(j-1)...m*j-1]}\ _2 < eps[2], j = 1, \dots, n$
3	$\ s\ _2 < eps[3]$
4	$\ F(x)\ _2 - \ F(x) - J(x)s\ _2 < eps[4]$

<i>eps</i> Value	Description
5	The trial step precision. If $eps[5] = 0$ , then the trial step meets the required precision ( $\leq 1.0 \cdot 10^{-10}$ ).

Note:

- $J(x)$  is the Jacobian matrix.
- $\Delta$  is the trust-region area.
- $F(x)$  is the value of the functional.
- $s$  is the trial step.

## Input Parameters

<i>n</i>	Length of $x$ .
<i>m</i>	Length of $F(x)$ .
<i>x</i>	Array of size $n$ . Initial guess. A reference to this array is stored in <i>handle</i> for later use and modification by <code>?trnlsp_solve</code> .
<i>eps</i>	Array of size 6; contains stopping criteria. See the values in the Description section. A reference to this array is stored in <i>handle</i> for later use by <code>?trnlsp_solve</code> .
<i>iter1</i>	Specifies the maximum number of iterations.
<i>iter2</i>	Specifies the maximum number of iterations of trial step calculation.
<i>rs</i>	Definition of initial size of the trust region (boundary of the trial step). The recommend minimum value is 0.1, and the recommended maximum value is 100.0. Based on your knowledge of the objective function and initial guess you can increase or decrease the initial trust region. It can influence the iteration process, for example, the direction of the iteration process and the number of iterations. If you set <i>rs</i> to 0.0, the solver uses the default value, which is 100.0.

## Output Parameters

<i>handle</i>	Type <code>_TRNSP_HANDLE_t</code> .
<i>res</i>	Indicates task completion status. <ul style="list-style-type: none"> <li>• <i>res</i> = <code>TR_SUCCESS</code> - the routine completed the task normally.</li> <li>• <i>res</i> = <code>TR_INVALID_OPTION</code> - there was an error in the input parameters.</li> <li>• <i>res</i> = <code>TR_OUT_OF_MEMORY</code> - there was a memory error.</li> </ul> <p><code>TR_SUCCESS</code>, <code>TR_INVALID_OPTION</code>, and <code>TR_OUT_OF_MEMORY</code> are defined in the <code>mkl_rci.h</code> include file.</p>

## See Also

[?trnlsp\\_solve](#)

## ?trnlsp\_check

Checks the correctness of *handle* and arrays containing Jacobian matrix, objective function, and stopping criteria.

### Syntax

```
MKL_INT strnlsp_check (_TRNSP_HANDLE_t* handle, const MKL_INT* n, const MKL_INT* m,
const float* fjac, const float* fvec, const float* eps, MKL_INT* info);
```

```
MKL_INT dtrnlsp_check (_TRNSP_HANDLE_t* handle, const MKL_INT* n, const MKL_INT* m,
const double* fjac, const double* fvec, const double* eps, MKL_INT* info);
```

### Include Files

- mkl.h

### Description

The ?trnlsp\_check routine checks the arrays passed into the solver as input parameters. If an array contains any INF or NaN values, the routine sets the flag in output array *info* (see the description of the values returned in the Output Parameters section for the *info* array).

### Input Parameters

<i>handle</i>	Type <code>_TRNSP_HANDLE_t</code> .
<i>n</i>	Length of <i>x</i> .
<i>m</i>	Length of $F(x)$ .
<i>fjac</i>	Array of size <i>m</i> by <i>n</i> . Contains the Jacobian matrix of the function.
<i>fvec</i>	Array of size <i>m</i> . Contains the function values at <i>x</i> , where $fvec[i] = (y_i - \hat{f}_i(x))$ .
<i>eps</i>	Array of size 6; contains stopping criteria. See the values in the Description section of the ?trnlsp_init.

### Output Parameters

*info* Array of size 6.  
Results of input parameter checking:

Parameter	Used for	Value	Description
<i>info</i> [0]	Flags for <i>handle</i>	0	The <i>handle</i> is valid.
		1	The <i>handle</i> is not allocated.
<i>info</i> [1]	Flags for <i>fjac</i>	0	The <i>fjac</i> array is valid.
		1	The <i>fjac</i> array is not allocated
		2	The <i>fjac</i> array contains NaN.
		3	The <i>fjac</i> array contains Inf.

Parameter	Used for	Value	Description
<i>info</i> [2]	Flags for <i>fvec</i>	0	The <i>fvec</i> array is valid.
		1	The <i>fvec</i> array is not allocated
		2	The <i>fvec</i> array contains NaN.
		3	The <i>fvec</i> array contains Inf.
<i>info</i> [3]	Flags for <i>eps</i>	0	The <i>eps</i> array is valid.
		1	The <i>eps</i> array is not allocated
		2	The <i>eps</i> array contains NaN.
		3	The <i>eps</i> array contains Inf.
		4	The <i>eps</i> array contains a value less than or equal to zero.

*res*

Information about completion of the task.

*res* = TR\_SUCCESS - the routine completed the task normally.

TR\_SUCCESS is defined in the `mkl_rci.h` include file.

## ?trnlsp\_solve

Solves a nonlinear least squares problem using the TR algorithm.

### Syntax

```
MKL_INT strnlsp_solve (_TRNSP_HANDLE_t* handle, float* fvec, float* fjac, MKL_INT* RCI_Request);
```

```
MKL_INT dtrnlsp_solve (_TRNSP_HANDLE_t* handle, double* fvec, double* fjac, MKL_INT* RCI_Request);
```

### Include Files

- `mkl.h`

### Description

The ?trnlsp\_solve routine uses the TR algorithm to solve nonlinear least squares problems.

The problem is stated as follows:

$$\min_{x \in \mathbb{R}^n} \|F(x)\|_2^2 = \min_{x \in \mathbb{R}^n} \|y - f(x)\|_2^2, y \in \mathbb{R}^m, x \in \mathbb{R}^n, f: \mathbb{R}^n \rightarrow \mathbb{R}^m, m \geq n,$$

where

- $F(x): \mathbb{R}^n \rightarrow \mathbb{R}^m$
- $m \geq n$

From a current point  $x_{current}$ , the algorithm uses the trust-region approach:

$$\min_{x \in \mathbb{R}^n} \left\| F(x_{\text{current}}) + J(x_{\text{current}})(x_{\text{new}} - x_{\text{current}}) \right\|_2^2 \quad \text{subject to } \|x_{\text{new}} - x_{\text{current}}\| \leq \Delta_{\text{current}}$$

to get  $x_{\text{new}} = x_{\text{current}} + s$  that satisfies

$$\min_{x \in \mathbb{R}^n} \left\| J^T(x) J(x) s + J^T F(x) \right\|_2^2$$

where

- $J(x)$  is the Jacobian matrix
- $s$  is the trial step
- $\|s\|_2 \leq \Delta_{\text{current}}$
- $\Delta$  is the trust-region area.

The `RCI_Request` parameter provides additional information:

<code>RCI_Request</code> Value	Description
2	Request to calculate the Jacobian matrix and put the result into <code>fjac</code>
1	Request to recalculate the function at vector <code>x</code> and put the result into <code>fvec</code>
0	One successful iteration step on the current trust-region radius (that does not mean that the value of <code>x</code> has changed)
-1	The algorithm has exceeded the maximum number of iterations
-2	$\Delta < \text{eps}[0]$
-3	$\ F(x)\ _2 < \text{eps}[1]$
-4	The Jacobian matrix is singular. $\ J(x)_{[m*(j-1)...m*j-1]}\ _2 < \text{eps}[2], j = 1, \dots, n$
-5	$\ s\ _2 < \text{eps}[3]$
-6	$\ F(x)\ _2 - \ F(x) - J(x)s\ _2 < \text{eps}[4]$

**NOTE**

If it is possible to combine computations of the function and the jacobian (`RCI_Request = 1` and `2`), you can do that and provide both updated values for `fvec` and `fjac` as fulfillment of `RCI_Request = 1` (and do nothing for `RCI_Request = 2`).

**Input Parameters**

- `handle` Type `_TRNSP_HANDLE_t`.
- `fvec` Array of size `m`. Contains the function values at `x`, where `fvec[i] = (yi - fi(x))`.

*fjac* Array of size  $m$  by  $n$ . Contains the Jacobian matrix of the function.

## Output Parameters

*fvec* Array of size  $m$ . Updated function evaluated at  $x$ .

*RCI\_Request* Informs about the task stage.

See the Description section for the parameter values and their meaning.

*res* Indicates the task completion.

*res* = TR\_SUCCESS - the routine completed the task normally.

TR\_SUCCESS is defined in the `mkl_rci.h` include file.

## ?trnlsp\_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

### Syntax

```
MKL_INT strnlsp_get(_TRNSP_HANDLE_t* handle, MKL_INT* iter, MKL_INT* st_cr, float* r1, float* r2);
```

```
MKL_INT dtrnlsp_get (_TRNSP_HANDLE_t* handle, MKL_INT* iter, MKL_INT* st_cr, double* r1, double* r2);
```

### Include Files

- `mkl.h`

### Description

The routine retrieves the current number of iterations, the stop criterion, the initial residual, and final residual.

The initial residual is the value of the functional ( $||y - f(x)||$ ) of the initial  $x$  values provided by the user.

The final residual is the value of the functional ( $||y - f(x)||$ ) of the final  $x$  resulting from the algorithm operation.

The *st\_cr* parameter contains a number indicating the stop criterion:

<i>st_cr</i> Value	Description
1	The algorithm has exceeded the maximum number of iterations
2	$\Delta < eps[0]$
3	$  F(x)  _2 < eps[1]$
4	The Jacobian matrix is singular. $  J(x)_{[m*(j-1)...m*j-1]}  _2 < eps[2], j = 1, \dots, n$
5	$  s  _2 < eps[3]$
6	$  F(x)  _2 -   F(x) - J(x)s  _2 < eps[4]$

Note:

- $J(x)$  is the Jacobian matrix.
- $\Delta$  is the trust-region area.
- $F(x)$  is the value of the functional.
- $s$  is the trial step.

## Input Parameters

*handle*                      Type `_TRNSP_HANDLE_t`.

## Output Parameters

*iter*                      Contains the current number of iterations.

*st\_cr*                      Contains the stop criterion.  
See the Description section for the parameter values and their meanings.

*r1*                        Contains the residual,  $(\|y - f(x)\|)$  given the initial  $x$ .

*r2*                        Contains the final residual, that is, the value of the functional  $(\|y - f(x)\|)$  of the final  $x$  resulting from the algorithm operation.

*res*                        Indicates the task completion.  
*res* = `TR_SUCCESS` - the routine completed the task normally.  
`TR_SUCCESS` is defined in the `mkl_rci.h` include file.

## ?trnlsp\_delete

*Releases allocated data.*

---

### Syntax

```
MKL_INT strnlsp_delete(_TRNSP_HANDLE_t* handle);
MKL_INT dtrnlsp_delete(_TRNSP_HANDLE_t* handle);
```

### Include Files

- `mkl.h`

### Description

The `?trnlsp_delete` routine releases all memory allocated for the handle. Only after calling this routine is it safe for the user to move or deallocate the memory referenced by  $x$  and  $eps$ .

This routine flags memory as not used, but to actually release all memory you must call the support function [mkl\\_free\\_buffers](#).

### Input Parameters

*handle*                      Type `_TRNSP_HANDLE_t`.

### Output Parameters

*res*                        Indicates the task completion.  
*res* = `TR_SUCCESS` means the routine completed the task normally.  
`TR_SUCCESS` is defined in the `mkl_rci.h` include file.

## Nonlinear Least Squares Problem with Linear (Bound) Constraints

The nonlinear least squares problem with linear bound constraints is very similar to the [nonlinear least squares problem without constraints](#) but it has the following constraints:

$$l_i \leq x_i \leq u_i, i = 1, \dots, N, \quad l, u \in R^n.$$

See usage examples in the `examples\c\nonlinear_solvers` folder of your Intel® oneAPI Math Kernel Library (oneMKL) directory. Specifically, see `ex_nlsqp_bc_c.c`.

---

**NOTE** There are two options for handling the boundary constraints enabled through the parameter array, see the description of [eps\[4\]](#)

---

### RCI TR Routines for Problem with Bound Constraints

Routine Name	Operation
<code>?trnlsqbc_init</code>	Initializes the solver.
<code>?trnlsqbc_check</code>	Checks correctness of the input parameters.
<code>?trnlsqbc_solve</code>	Solves a nonlinear least squares problem using RCI and the Trust-Region algorithm.
<code>?trnlsqbc_get</code>	Retrieves the number of iterations, stop criterion, initial residual, and final residual.
<code>?trnlsqbc_delete</code>	Releases allocated data.

#### `?trnlsqbc_init`

*Initializes the solver of nonlinear least squares problem with linear (boundary) constraints.*

#### Syntax

```
MKL_INT strnlsqbc_init (_TRNSQBC_HANDLE_t* handle, const MKL_INT* n, const MKL_INT* m,
const float* x, const float* LW, const float* UP, const float* eps, const MKL_INT*
iter1, const MKL_INT* iter2, const float* rs);
```

```
MKL_INT dtrnlsqbc_init (_TRNSQBC_HANDLE_t* handle, const MKL_INT* n, const MKL_INT* m,
const double* x, const double* LW, const double* UP, const double* eps, const MKL_INT*
iter1, const MKL_INT* iter2, const double* rs);
```

#### Description

The `?trnlsqbc_init` routine initializes the solver.

After initialization, all subsequent invocations of the `?trnlsqbc_solve` routine should use the values of the `handle` returned by `?trnlsqbc_init`. This `handle` stores internal data, including pointers to the arrays `x`, `LW`, `UP`, and `eps`. It is important to not move or deallocate these arrays until after calling the `?trnlsqbc_delete` routine.

The `eps` array contains a number indicating the stopping criteria:

<i>eps</i> Value	Description
0	$\Delta < eps[0]$
1	$  F(x)  _2 < eps[1]$
2	The Jacobian matrix is singular. $  J(x)_{[m*(j-1)...m*j-1]}  _2 < eps[2], j = 1, \dots, n$
3	$  s  _2 < eps[3]$
4	$  F(x)  _2 -   F(x) - J(x)s  _2 <  eps[4] $
<hr/> <p><b>NOTE</b></p> <p>If <math>eps[4] &gt; 0</math>, an extra scaling is applied to 's' after it has been selected, to ensure that it does not leave the specified domain, but scales it down to not cross the boundary. This preserves the solution inside the boundary, but may result in getting stuck in a local minimum on the boundary and exiting early due to this stopping criteria</p> <p>If <math>eps[4] &lt; 0</math>, extra scaling is not applied, which may result in the solution, <math>x</math>, leaving the domain. If this occurs, try starting over with a different initial condition.</p> <hr/>	
5	The trial step precision. If $eps[5] = 0$ , then the trial step meets the required precision ( $\leq 1.0*10^{-10}$ ).

**Note:**

- $J(x)$  is the Jacobian matrix.
- $\Delta$  is the trust-region area.
- $F(x)$  is the value of the functional.
- $s$  is the trial step.

**Input Parameters**

$n$	Length of $x$ .
$m$	Length of $F(x)$ .
$x$	Array of size $n$ . Initial guess. A reference to this array is stored in handle for later use and modification by <code>?trnlspbc_solve</code> .
$LW$	Array of size $n$ . Contains low bounds for $x$ ( $lw_i < x_i$ ). A reference to this array is stored in handle for later use by <code>?trnlspbc_solve</code> .
$UP$	Array of size $n$ . Contains upper bounds for $x$ ( $up_i > x_i$ ). A reference to this array is stored in handle for later use by <code>?trnlspbc_solve</code> .
$eps$	Array of size 6; contains stopping criteria. See the values in the Description section. A reference to this array is stored in handle for later use by <code>?trnlspbc_solve</code> .

<code>iter1</code>	Specifies the maximum number of iterations.
<code>iter2</code>	Specifies the maximum number of iterations of trial step calculation.
<code>rs</code>	Definition of initial size of the trust region (boundary of the trial step). The recommended minimum value is 0.1, and the recommended maximum value is 100.0. Based on your knowledge of the objective function and initial guess you can increase or decrease the initial trust region. It can influence the iteration process, for example, the direction of the iteration process and the number of iterations. If you set <code>rs</code> to 0.0, the solver uses the default value, which is 100.0.

## Output Parameters

<code>handle</code>	Type <code>_TRNSPBC_HANDLE_t</code> .
<code>res</code>	<p>Informs about the task completion.</p> <ul style="list-style-type: none"> <li>• <code>res = TR_SUCCESS</code> - the routine completed the task normally.</li> <li>• <code>res = TR_INVALID_OPTION</code> - there was an error in the input parameters.</li> <li>• <code>res = TR_OUT_OF_MEMORY</code> - there was a memory error.</li> </ul> <p><code>TR_SUCCESS</code>, <code>TR_INVALID_OPTION</code>, and <code>TR_OUT_OF_MEMORY</code> are defined in the <code>mkl_rci.h</code> include file.</p>

## ?trnlspsc\_check

*Checks the correctness of `handle` and arrays containing Jacobian matrix, objective function, lower and upper bounds, and stopping criteria.*

### Syntax

```
MKL_INT strnlspsc_check (_TRNSPBC_HANDLE_t* handle, const MKL_INT* n, const MKL_INT* m,
const float* fjac, const float* fvec, const float* LW, const float* UP, const float*
eps, MKL_INT* info);
```

```
MKL_INT dtrnlspsc_check (_TRNSPBC_HANDLE_t* handle, const MKL_INT* n, const MKL_INT* m,
const double* fjac, const double* fvec, const double* LW, const double* UP, const
double* eps, MKL_INT* info);
```

### Include Files

- `mkl.h`

### Description

The `?trnlspsc_check` routine checks the arrays passed into the solver as input parameters. If an array contains any `INF` or `NaN` values, the routine sets the flag in output array `info` (see the description of the values returned in the Output Parameters section for the `info` array).

### Input Parameters

<code>handle</code>	Type <code>_TRNSPBC_HANDLE_t</code> .
<code>n</code>	Length of <code>x</code> .
<code>m</code>	Length of <code>F(x)</code> .

<i>fjac</i>	Array of size $m$ by $n$ . Contains the Jacobian matrix of the function.
<i>fvec</i>	Array of size $m$ . Contains the function values at $x$ , where $fvec[i] = (y_i - f_i(x))$ .
<i>LW</i>	Array of size $n$ . Contains low bounds for $x$ ( $lw_i < x_i$ ).
<i>UP</i>	Array of size $n$ . Contains upper bounds for $x$ ( $up_i > x_i$ ).
<i>eps</i>	Array of size 6; contains stopping criteria. See the values in the Description section of the <a href="#">?trnlspsc_init</a> .

## Output Parameters

*info* Array of size 6.  
Results of input parameter checking:

Parameter	Used for	Value	Description
<i>info</i> [0]	Flags for <i>handle</i>	0	The handle is valid.
		1	The handle is not allocated.
<i>info</i> [1]	Flags for <i>fjac</i>	0	The <i>fjac</i> array is valid.
		1	The <i>fjac</i> array is not allocated
		2	The <i>fjac</i> array contains NaN.
		3	The <i>fjac</i> array contains Inf.
<i>info</i> [2]	Flags for <i>fvec</i>	0	The <i>fvec</i> array is valid.
		1	The <i>fvec</i> array is not allocated
		2	The <i>fvec</i> array contains NaN.
		3	The <i>fvec</i> array contains Inf.
<i>info</i> [3]	Flags for <i>LW</i>	0	The <i>LW</i> array is valid.
		1	The <i>LW</i> array is not allocated
		2	The <i>LW</i> array contains NaN.
		3	The <i>LW</i> array contains Inf.
		4	The lower bound is greater than the upper bound.
<i>info</i> [4]	Flags for <i>up</i>	0	The <i>up</i> array is valid.
		1	The <i>up</i> array is not allocated

Parameter	Used for	Value	Description
		2	The <i>up</i> array contains NaN.
		3	The <i>up</i> array contains Inf.
		4	The upper bound is less than the lower bound.
<i>info</i> [5]	Flags for <i>eps</i>	0	The <i>eps</i> array is valid.
		1	The <i>eps</i> array is not allocated
		2	The <i>eps</i> array contains NaN.
		3	The <i>eps</i> array contains Inf.
		4	The <i>eps</i> array contains a value less than or equal to zero.

*res*

Information about completion of the task.

*res* = TR\_SUCCESS - the routine completed the task normally.

TR\_SUCCESS is defined in the `mkl_rci.h` include file.

## ?trnlspbc\_solve

*Solves a nonlinear least squares problem with linear (bound) constraints using the Trust-Region algorithm.*

### Syntax

```
MKL_INT strnlspbc_solve (_TRNSPBC_HANDLE_t* handle, float* fvec, float* fjac, MKL_INT* RCI_Request);
```

```
MKL_INT dtrnlspbc_solve (_TRNSPBC_HANDLE_t* handle, double* fvec, double* fjac, MKL_INT* RCI_Request);
```

### Include Files

- `mkl.h`

### Description

The ?trnlspbc\_solve routine, based on RCI, uses the Trust-Region algorithm to solve nonlinear least squares problems with linear (bound) constraints. The problem is stated as follows:

$$\min_{x \in \mathcal{K}^n} \|F(x)\|_2^2 = \min_{x \in \mathcal{K}^n} \|y - f(x)\|_2^2, y \in \mathbb{R}^m, x \in \mathbb{R}^n, f: \mathbb{R}^n \rightarrow \mathbb{R}^m, m \geq n$$

where

$$l_i \leq x_i \leq u_i$$

$$i = 1, \dots, n.$$

The *RCI\_Request* parameter provides additional information:

<i>RCI_Request</i> Value	Description
2	Request to calculate the Jacobian matrix and put the result into <i>fjac</i>
1	Request to recalculate the function at vector <i>x</i> and put the result into <i>fvec</i>
0	One successful iteration step on the current trust-region radius (that does not mean that the value of <i>x</i> has changed)
-1	The algorithm has exceeded the maximum number of iterations
-2	$\Delta < eps[0]$
-3	$\ F(x)\ _2 < eps[1]$
-4	The Jacobian matrix is singular. $\ J(x)_{[m*(j-1)...m*j-1]}\ _2 < eps[2], j = 1, \dots, n$
-5	$\ s\ _2 < eps[3]$
-6	$\ F(x)\ _2 - \ F(x) - J(x)s\ _2 <  eps[4] $

Note:

- $J(x)$  is the Jacobian matrix.
- $\Delta$  is the trust-region area.
- $F(x)$  is the value of the functional.
- $s$  is the trial step.

### Input Parameters

<i>handle</i>	Type <code>_TRNSPBC_HANDLE_t</code> .
<i>fvec</i>	Array of size $m$ . Contains the function values at $x$ , where $fvec[i] = (y_i - f_i(x))$ .
<i>fjac</i>	Array of size $m$ by $n$ . Contains the Jacobian matrix of the function.

### Output Parameters

<i>fvec</i>	Array of size $m$ . Updated function evaluated at $x$ .
<i>RCI_Request</i>	<p>Informs about the task stage.</p> <p>See the Description section for the parameter values and their meaning.</p>
<i>res</i>	<p>Informs about the task completion.</p> <p><code>res = TR_SUCCESS</code> means the routine completed the task normally.</p> <p><code>TR_SUCCESS</code> is defined in the <code>mkl_rci.h</code> include file.</p>

### ?trnlspsc\_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

## Syntax

```
MKL_INT strnlspbc_get (_TRNSPBC_HANDLE_t* handle, MKL_INT* iter, MKL_INT* st_cr, float* r1, float* r2);
```

```
MKL_INT dtrnlspbc_get (_TRNSPBC_HANDLE_t* handle, MKL_INT* iter, MKL_INT* st_cr, double* r1, double* r2);
```

## Include Files

- mkl.h

## Description

The routine retrieves the current number of iterations, the stop criterion, the initial residual, and final residual.

The *st\_cr* parameter contains a number indicating the stop criterion:

<i>st_cr</i> Value	Description
1	The algorithm has exceeded the maximum number of iterations
2	$\Delta < eps[0]$
3	$\ F(x)\ _2 < eps[1]$
4	The Jacobian matrix is singular. $\ J(x)_{[m*(j-1)...m*j-1]}\ _2 < eps[2], j = 1, \dots, n$
5	$\ s\ _2 < eps[3]$
6	$\ F(x)\ _2 - \ F(x) - J(x)s\ _2 < eps[4]$

Note:

- $J(x)$  is the Jacobian matrix.
- $\Delta$  is the trust-region area.
- $F(x)$  is the value of the functional.
- $s$  is the trial step.

## Input Parameters

*handle* Type `_TRNSPBC_HANDLE_t`.

## Output Parameters

*iter* Contains the current number of iterations.

*st\_cr* Contains the stop criterion.

See the Description section for the parameter values and their meanings.

*r1* Contains the residual,  $(\|y - f(x)\|)$  given the initial  $x$ .

*r2* Contains the final residual, that is, the value of the function  $(\|y - f(x)\|)$  of the final  $x$  resulting from the algorithm operation.

*res* Informs about the task completion.

*res* = `TR_SUCCESS` - the routine completed the task normally.

TR\_SUCCESS is defined in the `mkl_rci.h` include file.

## ?trnlspsc\_delete

Releases allocated data.

### Syntax

```
MKL_INT strnlspsc_delete (_TRNSPBC_HANDLE_t* handle);
MKL_INT dtrnlspsc_delete (_TRNSPBC_HANDLE_t* handle);
```

### Include Files

- `mkl.h`

### Description

The `?trnlspsc_delete` routine releases all memory allocated for the handle. Only after calling this routine is it safe for the user to move or deallocate the memory referenced by *x*, *LW*, *UP*, and *eps*.

#### NOTE

This routine flags memory as not used, but to actually release all memory you must call the support function [mkl\\_free\\_buffers](#).

### Input Parameters

*handle* Type `_TRNSPBC_HANDLE_t`.

### Output Parameters

*res* Informs about the task completion.  
*res* = TR\_SUCCESS means the routine completed the task normally.  
 TR\_SUCCESS is defined in the `mkl_rci.h` include file.

## Jacobian Matrix Calculation Routines

This section describes routines that compute the Jacobian matrix using the central difference algorithm. Jacobian matrix calculation is required to solve a nonlinear least squares problem and systems of nonlinear equations (with or without linear bound constraints). Routines for calculation of the Jacobian matrix have the "Black-Box" interfaces, where you pass the objective function via parameters. Your objective function must have a fixed interface.

### Jacobian Matrix Calculation Routines

Routine Name	Operation
<code>?jacobi_init</code>	Initializes the solver.
<code>?jacobi_solve</code>	Computes the Jacobian matrix of the function on the basis of RCI using the central difference algorithm.
<code>?jacobi_delete</code>	Removes data.

Routine Name	Operation
<code>?jacobi</code>	Computes the Jacobian matrix of the <code>fcn</code> function using the central difference algorithm.
<code>?jacobix</code>	Presents an alternative interface for the <code>?jacobi</code> function enabling you to pass additional data into the objective function.

## `?jacobi_init`

*Initializes the solver for Jacobian calculations.*

### Syntax

```
MKL_INT sjacobi_init (_JACOBIHANDLE_t* handle, const MKL_INT* n, const MKL_INT* m, const float* x, const float* fjac, const float* eps);
```

```
MKL_INT djacobi_init (_JACOBIHANDLE_t* handle, const MKL_INT* n, const MKL_INT* m, const double* x, const double* fjac, const double* eps);
```

### Include Files

- `mkl.h`

### Description

The routine initializes the solver.

### Input Parameters

<code>n</code>	Length of <code>x</code> .
<code>m</code>	Length of <code>F</code> .
<code>x</code>	Array of size <code>n</code> . Vector, at which the function is evaluated. A reference to this array is stored in <code>handle</code> for later use and modification by <code>?jacobi_solve</code> .
<code>eps</code>	Precision of the Jacobian matrix calculation.
<code>fjac</code>	Array of size <code>m</code> by <code>n</code> . Contains the Jacobian matrix of the function. A reference to this array is stored in <code>handle</code> for later use and modification by <code>?jacobi_solve</code> .

### Output Parameters

<code>handle</code>	Data object of the <code>_JACOBIHANDLE_t</code> type. Stores internal data, including pointers to the user-provided arrays <code>x</code> and <code>fjac</code> . It is important that the user does not move or deallocate these arrays until after calling the <code>?jacobi_delete</code> routine.
<code>res</code>	Indicates task completion status. <ul style="list-style-type: none"> <li>• <code>res = TR_SUCCESS</code> - the routine completed the task normally.</li> <li>• <code>res = TR_INVALID_OPTION</code> - there was an error in the input parameters.</li> <li>• <code>res = TR_OUT_OF_MEMORY</code> - there was a memory error.</li> </ul>

TR\_SUCCESS, TR\_INVALID\_OPTION, and TR\_OUT\_OF\_MEMORY are defined in the mkl\_rci.h include file.

## ?jacobi\_solve

Computes the Jacobian matrix of the function using RCI and the central difference algorithm.

### Syntax

```
MKL_INT sjacobi_solve (_JACOBI_MATRIX_HANDLE_t* handle, float* f1, float* f2, MKL_INT* RCI_Request);
```

```
MKL_INT djacobi_solve (_JACOBI_MATRIX_HANDLE_t* handle, double* f1, double* f2, MKL_INT* RCI_Request);
```

### Include Files

- mkl.h

### Description

The ?jacobi\_solve routine computes the Jacobian matrix of the function using RCI and the central difference algorithm.

See usage examples in the examples\solverc\source folder of your Intel® oneAPI Math Kernel Library (oneMKL) directory. Specifically, see sjacobi\_rci\_c.c and djacobi\_rci\_c.c.

### Input Parameters

<i>handle</i>	Type <code>_JACOBI_MATRIX_HANDLE_t</code> .
<i>RCI_Request</i>	Set to 0 before the first call to ?jacobi_solve.

### Output Parameters

<i>f1</i>	Contains the updated function values at $x + eps$ .
<i>f2</i>	Array of size $m$ . Contains the updated function values at $x - eps$ .
<i>RCI_Request</i>	Provides information about the task completion. When equal to 0, the task has completed successfully.  <i>RCI_Request</i> = 1 indicates that you should compute the function values at the current $x$ point and put the results into <i>f1</i> .  <i>RCI_Request</i> = 2 indicates that you should compute the function values at the current $x$ point and put the results into <i>f2</i> .
<i>res</i>	Indicates the task completion status. <ul style="list-style-type: none"> <li>• <i>res</i> = TR_SUCCESS - the routine completed the task normally.</li> <li>• <i>res</i> = TR_INVALID_OPTION - there was an error in the input parameters.</li> </ul> TR_SUCCESS and TR_INVALID_OPTION are defined in the mkl_rci.h include file.

### See Also

?jacobi\_init

## Input Parameters

*fcn*

User-supplied subroutine to evaluate the function that defines the least squares problem. Called as *fcn* (*m*, *n*, *x*, *f*) with the following parameters:

Parameter	Type	Description
Input Parameters		
<i>m</i>		Pointer to the length of <i>f</i> .
<i>n</i>		Pointer to the length of <i>x</i> .
<i>x</i>		Array of size <i>n</i> . Vector, at which the function is evaluated. The <i>fcn</i> function should not change this parameter.
Output Parameters		
<i>f</i>		Array of size <i>m</i> ; contains the function values at <i>x</i> .

You need to declare *fcn* as `extern` in the calling program.

*n*

Length of *X*.

*m*

Length of *F*.

*x*

Array of size *n*. Vector at which the function is evaluated.

*eps*

Precision of the Jacobian matrix calculation.

## Output Parameters

*fjac*

Array of size *m* by *n*. Contains the Jacobian matrix of the function.

*res*

Indicates task completion status.

- *res* = TR\_SUCCESS - the routine completed the task normally.
- *res* = TR\_INVALID\_OPTION - there was an error in the input parameters.
- *res* = TR\_OUT\_OF\_MEMORY - there was a memory error.

TR\_SUCCESS, TR\_INVALID\_OPTION, and TR\_OUT\_OF\_MEMORY are defined in the `mkl_rci.h` include file.

## See Also

[?jacobix](#)

## ?jacobix

*Alternative interface for ?jacobi function for passing additional data into the objective function.*

## Syntax

```
MKL_INT sjacobix (USRFCNXS fcn, const MKL_INT* n, const MKL_INT * m, float* fjac,
float* x, float* eps, void* user_data);
```

```
MKL_INT djacobix (USRFCNXD fcn, const MKL_INT* n, const MKL_INT * m, double* fjac,
double* x, double* eps, void* user_data);
```

## Include Files

- `mkl.h`

## Description

The `?jacobix` routine presents an alternative interface for the `?jacobi` function that enables you to pass additional data into the objective function `fcn`.

See calling and usage examples in the `examples\solverc\source` folder of your Intel® oneAPI Math Kernel Library (oneMKL) directory. Specifically, see `ex_nlsqp_c_x.c` and `ex_nlsqp_bc_c_x.c`.

## Input Parameters

`fcn` User-supplied subroutine to evaluate the function that defines the least squares problem. Called as `fcn(m, n, x, f, user_data)` with the following parameters:

Parameter	Description
Input Parameters	
<code>m</code>	Pointer to the length of <code>f</code> .
<code>n</code>	Pointer to the length of <code>x</code> .
<code>x</code>	Array of size <code>n</code> . Vector, at which the function is evaluated. The <code>fcn</code> function should not change this parameter.
<code>user_data</code>	Pointer to your additional data, if any. Otherwise, a dummy argument.
Output Parameters	
<code>f</code>	Array of size <code>m</code> ; contains the function values at <code>x</code> .

You need to declare `fcn` as `extern` in the calling program.

<code>n</code>	Length of <code>X</code> .
<code>m</code>	Length of <code>F</code> .
<code>x</code>	Array of size <code>n</code> . Vector at which the function is evaluated.
<code>eps</code>	Precision of the Jacobian matrix calculation.
<code>user_data</code>	Pointer to your additional data. If there is no additional data, this is a dummy argument.

## Output Parameters

`fjac` Array of size `m` by `n`). Contains the Jacobian matrix of the function.

`res` Indicates task completion status.

- `res = TR_SUCCESS` - the routine completed the task normally.
- `res = TR_INVALID_OPTION` - there was an error in the input parameters.
- `res = TR_OUT_OF_MEMORY` - there was a memory error.

TR\_SUCCESS, TR\_INVALID\_OPTION, and TR\_OUT\_OF\_MEMORY are defined in the `mkl_rci.h` include file.

## Support Functions

Intel® oneAPI Math Kernel Library (oneMKL) support functions are subdivided into the following groups according to their purpose:

[Version Information](#)

[Threading Control](#)

[Error Handling](#)

[Character Equality Testing](#)

[Timing](#)

[Memory Management](#)

[Single Dynamic Library Control](#)

[Conditional Numerical Reproducibility Control](#)

[Miscellaneous](#)

The following table lists Intel® oneAPI Math Kernel Library (oneMKL) support functions.

### oneMKL Support Functions

Function Name	Operation
Version Information	
<code>mkl_get_version</code>	Returns the Intel® oneAPI Math Kernel Library (oneMKL) version.
<code>mkl_get_version_string</code>	Returns the Intel® oneAPI Math Kernel Library (oneMKL) version in a character string.
Threading Control	
<code>mkl_set_num_threads</code>	Specifies the number of OpenMP* threads to use.
<code>mkl_domain_set_num_threads</code>	Specifies the number of OpenMP* threads for a particular function domain.
<code>mkl_set_num_threads_local</code>	Specifies the number of OpenMP* threads for all Intel® oneAPI Math Kernel Library (oneMKL) functions on the current execution thread.
<code>mkl_set_dynamic</code>	Enables Intel® oneAPI Math Kernel Library (oneMKL) to dynamically change the number of OpenMP* threads.
<code>mkl_get_max_threads</code>	Gets the number of OpenMP* threads targeted for parallelism.
<code>mkl_domain_get_max_threads</code>	Gets the number of OpenMP* threads targeted for parallelism for a particular function domain.
<code>mkl_get_dynamic</code>	Determines whether Intel® oneAPI Math Kernel Library (oneMKL) is enabled to dynamically change the number of OpenMP* threads.

Function Name	Operation
<code>mkl_set_num_stripes</code>	Specifies the number of partitions along the leading dimension of the output matrix for parallel ?gemm functions.
<code>mkl_get_num_stripes</code>	Gets the number of partitions along the leading dimension of the output matrix for parallel ?gemm functions.
<b>Error Handling</b>	
<code>xerbla</code>	Error handling function called by BLAS, LAPACK, Vector Math, and Vector Statistics functions.
<code>pxerbla</code>	Handles error conditions for the ScaLAPACK routines.
<code>LAPACKE_xerbla</code>	Error handling function called by the C interface to LAPACK functions.
<code>mkl_set_exit_handler</code>	Sets the custom handler of fatal errors.
<b>Character Equality Testing</b>	
<code>lsame</code>	Tests two characters for equality regardless of the case.
<code>lsamen</code>	Tests two character strings for equality regardless of the case.
<b>Timing</b>	
<code>second/dsecnd</code>	Returns elapsed time in seconds. Use to estimate real time between two calls to this function.
<code>mkl_get_cpu_clocks</code>	Returns elapsed CPU clocks.
<code>mkl_get_cpu_frequency</code>	Returns CPU frequency value in GHz.
<code>mkl_get_max_cpu_frequency</code>	Returns the maximum CPU frequency value in GHz.
<code>mkl_get_clocks_frequency</code>	Returns the frequency value in GHz based on constant-rate Time Stamp Counter.
<b>Memory Management</b>	
<code>mkl_free_buffers</code>	Frees unused memory allocated by the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator.
<code>mkl_thread_free_buffers</code>	Frees unused memory allocated by the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator in the current thread.
<code>mkl_mem_stat</code>	Reports the status of the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator.
<code>mkl_peak_mem_usage</code>	Reports the peak memory allocated by the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator.
<code>mkl_disable_fast_mm</code>	Turns off the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator for Intel® oneAPI Math Kernel Library (oneMKL) functions to directly use the <code>systemmalloc/free</code> functions.
<code>mkl_malloc</code>	Allocates an aligned memory buffer.

Function Name	Operation
<code>mkl_malloc</code>	Allocates and initializes an aligned memory buffer.
<code>mkl_realloc</code>	Changes the size of memory buffer allocated by <code>mkl_malloc/mkl_malloc</code> .
<code>mkl_free</code>	Frees the aligned memory buffer allocated by <code>mkl_malloc/mkl_malloc</code> .
<code>mkl_set_memory_limit</code>	On Linux, sets the limit of memory that Intel® oneAPI Math Kernel Library (oneMKL) can allocate for a specified type of memory.
<b>Single Dynamic Library (SDL) Control</b>	
<code>mkl_set_interface_layer</code>	Sets the interface layer for Intel® oneAPI Math Kernel Library (oneMKL) at run time.
<code>mkl_set_threading_layer</code>	Sets the threading layer for Intel® oneAPI Math Kernel Library (oneMKL) at run time.
<code>mkl_set_xerbla</code>	Replaces the error handling routine. Use with the Single Dynamic Library .
<code>mkl_set_progress</code>	Replaces the progress information routine.
<code>mkl_set_pardiso_pivot</code>	Replaces the routine handling Intel® oneAPI Math Kernel Library (oneMKL) PARDISO pivots with a user-defined routine. Use with the Single Dynamic Library (SDL).
<b>Conditional Numerical Reproducibility (CNR) Control</b>	
<code>mkl_cbwr_set</code>	Configures the CNR mode of Intel® oneAPI Math Kernel Library (oneMKL).
<code>mkl_cbwr_get</code>	Returns the current CNR settings.
<code>mkl_cbwr_get_auto_branch</code>	Automatically detects the CNR code branch for your platform.
<b>Miscellaneous</b>	
<code>mkl_progress</code>	Provides progress information.
<code>mkl_enable_instructions</code>	
<code>mkl_set_env_mode</code>	Set up the mode that ignores environment settings specific to Intel® oneAPI Math Kernel Library (oneMKL).
<code>mkl_verbose</code>	Enable or disable Intel® oneAPI Math Kernel Library (oneMKL) Verbose mode.
<code>mkl_verbose_output_file</code>	Write output in Intel® oneAPI Math Kernel Library (oneMKL) Verbose mode to a file.
<code>mkl_set_mpi</code>	Sets the implementation of the message-passing interface to be used by Intel® oneAPI Math Kernel Library (oneMKL).
<code>mkl_finalize</code>	Terminates Intel® oneAPI Math Kernel Library (oneMKL) execution environment and frees resources allocated by the library.

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

**Version Information**

Intel® oneAPI Math Kernel Library (oneMKL) provides two methods for extracting information about the library version number:

- extracting a version string using the `mkl_get_version_string` function
- using the `mkl_get_version` function to obtain an `MKLVersion` structure that contains the version information

A makefile is also provided to automatically build the examples and output summary files containing the version information for the current library.

**mkl\_get\_version**

Returns the Intel® oneAPI Math Kernel Library (oneMKL) version.

**Syntax**

```
void mkl_get_version( MKLVersion* pVersion );
```

**Include Files**

- `mkl.h`

**Output Parameters**

`pVersion`                      Pointer to the `MKLVersion` structure.

**Description**

The `mkl_get_version` function collects information about the active C version of the Intel® oneAPI Math Kernel Library (oneMKL) software and returns this information in a structure of `MKLVersion` type by the `pVersion` address. The `MKLVersion` structure type is defined in the `mkl_types.h` file. The following fields of the `MKLVersion` structure are available:

<code>MajorVersion</code>	is the major number of the current library version.
<code>MinorVersion</code>	is the minor number of the current library version.
<code>UpdateVersion</code>	is the update number of the current library version.
<code>ProductStatus</code>	is the status of the current library version. Possible variants are "Beta" or "Product".
<code>Build</code>	is the string that contains the build date and the internal build number.
<code>Platform</code>	is the string that contains the current architecture. Possible variants are "IA-32 architecture" or "Intel(R) 64 architecture".

Processor

is the processor optimization. Normally it is targeted for the processor installed on your system and based on the detection of the Intel® oneAPI Math Kernel Library (oneMKL) library that is optimal for the installed processor. In the Conditional Numerical Reproducibility (CNR) mode, the processor optimization matches the selected CNR branch.

Notice revision #20201201

## mkl\_get\_version Usage

---

```
#include <stdio.h>
#include <stdlib.h>
#include "mkl.h"

int main(void)
{
    MKLVersion Version;

    mkl_get_version(&Version);

    printf("Major version:          %d\n", Version.MajorVersion);
    printf("Minor version:           %d\n", Version.MinorVersion);
    printf("Update version:            %d\n", Version.UpdateVersion);
    printf("Product status:           %s\n", Version.ProductStatus);
    printf("Build:                     %s\n", Version.Build);
    printf("Platform:                  %s\n", Version.Platform);
    printf("Processor optimization:    %s\n", Version.Processor);
    printf("=====\n");
    printf("\n");

    return 0;
}
```

Output:

Major Version	11
Minor Version	0
Update Version	2
Product status	Product
Build	20121113
Platform	Intel(R) 64 architecture
Processor optimization	Intel(R) Core(TM) i7 Processor

## mkl\_get\_version\_string

Returns the Intel® oneAPI Math Kernel Library (oneMKL) version in a character string.

### Syntax

```
void mkl_get_version_string (char* buf, int len);
```

### Include Files

- mkl.h

### Output Parameters

Name	Type	Description
<i>buf</i>	char*	Source string
<i>len</i>	int	Length of the source string

### Description

The function returns a string that contains the Intel® oneAPI Math Kernel Library (oneMKL) version.

For usage details, see the code example below:

### Example

```
#include <stdio.h>
#include "mkl.h"

int main(void)
{
    int len=198;
    char buf[198];
    mkl_get_version_string(buf, len);
    printf("%s\n",buf);
    printf("\n");
    return 0;
}
```

## Threading Control

Intel® oneAPI Math Kernel Library (oneMKL) provides functions for OpenMP\* threading control, discussed in this section.

### Important

If Intel® oneAPI Math Kernel Library (oneMKL) operates within the Intel® Threading Building Blocks (Intel® TBB) execution environment, the environment variables for OpenMP\* threading control, such as `asomp_num_threads`, and Intel® oneAPI Math Kernel Library (oneMKL) functions discussed in this section have no effect. If the Intel TBB threading technology is used, control the number of threads through the Intel TBB application programming interface. Read the documentation for the `tbb::task_scheduler_init` class at <https://www.threadingbuildingblocks.org/docs/doxygen/a00150.html> to find out how to specify the number of Intel TBB threads.

If Intel® oneAPI Math Kernel Library (oneMKL) operates within an OpenMP\* execution environment, you can control the number of threads for Intel® oneAPI Math Kernel Library (oneMKL) using OpenMP\* runtime library routines and environment variables (see the OpenMP\* specification for details). Additionally Intel® oneAPI

Math Kernel Library (oneMKL) provides *optional* threading control functions and environment variables that enable you to specify the number of threads for Intel® oneAPI Math Kernel Library (oneMKL) and to control dynamic adjustment of the number of threads *independently* of the OpenMP\* settings. The settings made with the Intel® oneAPI Math Kernel Library (oneMKL) threading control functions and environment variables do not affect OpenMP\* settings but take precedence over them.

If functions are used, Intel® oneAPI Math Kernel Library (oneMKL) environment variables may control Intel® oneAPI Math Kernel Library (oneMKL) threading. For details of those environment variables, see the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*.

You can specify the number of threads for Intel® oneAPI Math Kernel Library (oneMKL) function domains with the `mkl_set_num_threads` or `mkl_domain_set_num_threads` function. While `mkl_set_num_threads` specifies the number of threads for the entire Intel® oneAPI Math Kernel Library (oneMKL), `mkl_domain_set_num_threads` does it for a specific function domain. The following table lists the function domains that support independent threading control. The table also provides named constants to pass to threading control functions as a parameter that specifies the function domain.

### oneMKL Function Domains

Function Domain	Named Constant
Basic Linear Algebra Subroutines (BLAS)	MKL_DOMAIN_BLAS
Fast Fourier Transform (FFT) functions, except Cluster FFT functions	MKL_DOMAIN_FFT
Vector Math (VM) functions	MKL_DOMAIN_VML
Parallel Direct Solver (PARDISO) functions	MKL_DOMAIN_PARDISO
All Intel® oneAPI Math Kernel Library (oneMKL) functions except the functions from the domains where the number of threads is set explicitly.	MKL_DOMAIN_ALL

#### Warning

Do not increase the number of OpenMP threads used for `cluster_sparse_solver` between the first call and the factorization or solution phase. Because the minimum amount of memory required for out-of-core execution depends on the number of OpenMP threads, increasing it after the initial call can cause incorrect results.

Both `mkl_set_num_threads` and `mkl_domain_set_num_threads` functions set the number of threads for all subsequent calls to Intel® oneAPI Math Kernel Library (oneMKL) from all applications threads. Use the `mkl_set_num_threads_local` function to specify different numbers of threads for Intel® oneAPI Math Kernel Library (oneMKL) on different execution threads of your application. The thread-local settings take precedence over the global settings. However, the thread-local settings may have undesirable side effects (see the description of the `mkl_set_num_threads_local` function for details).

By default, Intel® oneAPI Math Kernel Library (oneMKL) can adjust the specified number of threads dynamically. For example, Intel® oneAPI Math Kernel Library (oneMKL) may use fewer threads if the size of the computation is not big enough or not create parallel regions when running within an OpenMP\* parallel region. Although Intel® oneAPI Math Kernel Library (oneMKL) may actually use a different number of threads from the number specified, the library does not create parallel regions with more threads than specified. If dynamic adjustment of the number of threads is disabled, Intel® oneAPI Math Kernel Library (oneMKL) attempts to use the specified number of threads in internal parallel regions (for more information, see the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*). Use the `mkl_set_dynamic` function to control dynamic adjustment of the number of threads.

### `mkl_set_num_threads`

*Specifies the number of OpenMP\* threads to use.*

---

## Syntax

```
void mkl_set_num_threads( int nt );
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>nt</i>	int	<i>nt</i> > 0 - The number of threads suggested by the user. <i>nt</i> ≤ 0 - Invalid value, which is ignored.

## Description

This function enables you to specify how many OpenMP threads Intel® oneAPI Math Kernel Library (oneMKL) should use for internal parallel regions. If this number is not set (default), Intel® oneAPI Math Kernel Library (oneMKL) functions use the default number of threads for the OpenMP run-time library. The specified number of threads applies:

- To all Intel® oneAPI Math Kernel Library (oneMKL) functions except the functions from the domains where the number of threads is set with [mkl\\_domain\\_set\\_num\\_threads](#)
- To all execution threads except the threads where the number of threads is set with [mkl\\_set\\_num\\_threads\\_local](#)

The number specified is a hint, and Intel® oneAPI Math Kernel Library (oneMKL) may actually use a smaller number.

### NOTE

This function takes precedence over the `MKL_NUM_THREADS` environment variable.

## Example

```
#include "mkl.h"
...
mkl_set_num_threads(4);
my_compute_using_mkl(); // Intel MKL uses up to 4 OpenMP threads
```

## mkl\_domain\_set\_num\_threads

*Specifies the number of OpenMP\* threads for a particular function domain.*

## Syntax

```
int mkl_domain_set_num_threads (int nt, int domain);
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<i>nt</i>	int	<i>nt</i> > 0 - The number of threads suggested by the user.

Name	Type	Description
		<p><i>nt</i> = 0 - The default number of threads for the OpenMP run-time library.</p> <p><i>nt</i> &lt; 0 - Invalid value, which is ignored.</p>
<i>domain</i>	int	The named constant that defines the targeted domain.

## Description

This function specifies how many OpenMP threads a particular function domain of Intel® oneAPI Math Kernel Library (oneMKL) should use. If this number is not set (default) or if it is set to zero in a call to this function, Intel® oneAPI Math Kernel Library (oneMKL) uses the default number of threads for the OpenMP run-time library. The number of threads specified applies to the specified function domain on all execution threads except the threads where the number of threads is set with `mkl_set_num_threads_local`. For a list of supported values of the *domain* argument, see [Table "Intel MKL Function Domains"](#).

The number of threads specified is only a hint, and Intel® oneAPI Math Kernel Library (oneMKL) may actually use a smaller number.

---

### NOTE

This function takes precedence over the `MKL_DOMAIN_NUM_THREADS` environment variable.

---

## Return Values

Name	Type	Description
<i>ierr</i>	int	<p>1 - Indicates no error, execution is successful.</p> <p>0 - Indicates a failure, possibly because of invalid input parameters.</p>

## Example

```
#include "mkl.h"
...
mkl_domain_set_num_threads(4, MKL_DOMAIN_BLAS);
my_compute_using_mkl_blas(); // Intel MKL BLAS functions use up to 4 threads
my_compute_using_mkl_dft(); // Intel MKL FFT functions use the default number of threads
```

## `mkl_set_num_threads_local`

*Specifies the number of OpenMP\* threads for all Intel® oneAPI Math Kernel Library (oneMKL) functions on the current execution thread.*

---

### Syntax

```
int mkl_set_num_threads_local( int nt );
```

### Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>nt</code>	<code>int</code>	<p><code>nt &gt; 0</code> - The number of threads for Intel® oneAPI Math Kernel Library (oneMKL) functions to use on the current execution thread.</p> <p><code>nt = 0</code> - A request to reset the thread-local number of threads and use the global number.</p>

## Description

This function sets the number of OpenMP threads that Intel® oneAPI Math Kernel Library (oneMKL) functions should request for parallel computation. The number of threads is thread-local, which means that it only affects the current execution thread of the application. If the thread-local number is not set or if this number is set to zero in a call to this function, Intel® oneAPI Math Kernel Library (oneMKL) functions use the global number of threads. You can set the global number of threads using the [mkl\\_set\\_num\\_threads](#) or [mkl\\_domain\\_set\\_num\\_threads](#) function.

The thread-local number of threads takes precedence over the global number: if the thread-local number is non-zero, changes to the global number of threads have no effect on the current thread.

### Caution

If your application is threaded with OpenMP\* and parallelization of Intel® oneAPI Math Kernel Library (oneMKL) is based on nested OpenMP parallelism, different OpenMP parallel regions reuse OpenMP threads. Therefore a thread-local setting in one OpenMP parallel region may continue to affect not only the master thread after the parallel region ends, but also subsequent parallel regions. To avoid performance implications of this side effect, reset the thread-local number of threads before leaving the OpenMP parallel region (see [Examples](#) for how to do it).

## Return Values

Name	Type	Description
<code>save_nt</code>	<code>int</code>	The value of the thread-local number of threads that was used before this function call. Zero means that the global number of threads was used.

## Examples

This example shows how to avoid the side effect of a thread-local number of threads by reverting to the global setting:

```
#include "omp.h"
#include "mkl.h"
...
mkl_set_num_threads(16);
my_compute_using_mkl();          // Intel MKL functions use up to 16 threads
#pragma omp parallel num_threads(2)
{
    if (0 == omp_get_thread_num())
        mkl_set_num_threads_local(4);
    else
        mkl_set_num_threads_local(12);
}
```

```
my_compute_using_mkl();          // Intel MKL functions use up to 4 threads on thread 0
// and up to 12 threads on thread 1
}
my_compute_using_mkl();          // Intel MKL functions use up to 4 threads (!)
mkl_set_num_threads_local( 0 ); // make master thread use global setting
my_compute_using_mkl();          // Intel MKL functions use up to 16 threads
```

This example shows how to avoid the side effect of a thread-local number of threads by saving and restoring the existing setting:

```
#include "mkl.h"
void my_compute( int nt )
{
    int save = mkl_set_num_threads_local( nt ); // save the Intel® oneAPI Math Kernel Library
(oneMKL) number of threads
    my_compute_using_mkl(); // Intel MKL functions use up to nt threads on this thread
    mkl_set_num_threads_local( save ); // restore the Intel® oneAPI Math Kernel Library (oneMKL)
number of threads
}
```

## mkl\_set\_dynamic

Enables Intel® oneAPI Math Kernel Library (oneMKL) to dynamically change the number of OpenMP\* threads.

### Syntax

```
void mkl_set_dynamic (int flag);
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>flag</i>	int	<i>flag</i> = 0 - Requests disabling dynamic adjustment of the number of threads. <i>flag</i> ≠ 0 - Requests enabling dynamic adjustment of the number of threads.

### Description

This function indicates whether Intel® oneAPI Math Kernel Library (oneMKL) can dynamically change the number of OpenMP threads or should avoid doing this. The setting applies to all Intel® oneAPI Math Kernel Library (oneMKL) functions on all execution threads. This function takes precedence over the `MKL_DYNAMIC` environment variable.

Dynamic adjustment of the number of threads is enabled by default. Specifically, Intel® oneAPI Math Kernel Library (oneMKL) may use fewer threads in parallel regions than the number returned by the `mkl_get_max_threads` function. Disabling dynamic adjustment of the number of threads does not ensure that Intel® oneAPI Math Kernel Library (oneMKL) actually uses the specified number of threads, although the library attempts to use that number.

**Tip**

If you call Intel® oneAPI Math Kernel Library (oneMKL) from within an OpenMP parallel region and want to create internal parallel regions, either disable dynamic adjustment of the number of threads or set the thread-local number of threads ([seemkl\\_set\\_num\\_threads\\_local](#) for how to do it).

**Example**

```
#include "mkl.h"
...
mkl_set_num_threads( 8 );
#pragma omp parallel
{
    my_compute_with_mkl();    // Intel MKL uses 1 thread, being called from OpenMP parallel
region
    mkl_set_dynamic( 0 );    // disable adjustment of the number of threads
    my_compute_with_mkl();    // Intel MKL uses 8 threads
}
```

**mkl\_get\_max\_threads**

*Gets the number of OpenMP\* threads targeted for parallelism.*

**Syntax**

```
int mkl_get_max_threads (void);
```

**Include Files**

- mkl.h

**Description**

This function returns the number of OpenMP threads available for Intel® oneAPI Math Kernel Library (oneMKL) to use in internal parallel regions.

**Return Values**

Name	Type	Description
<i>nt</i>	int	The maximum number of threads for Intel® oneAPI Math Kernel Library (oneMKL) functions to use in internal parallel regions.

**Example**

```
#include "mkl.h"
...
if (1 == mkl_get_max_threads()) puts("Intel MKL does not employ threading");
```

**See Also**

[mkl\\_set\\_dynamic](#)

[mkl\\_get\\_dynamic](#)

## mkl\_domain\_get\_max\_threads

Gets the number of OpenMP\* threads targeted for parallelism for a particular function domain.

### Syntax

```
int mkl_domain_get_max_threads (int domain);
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>domain</i>	int	The named constant that defines the targeted domain.

### Description

Computational functions of the Intel® oneAPI Math Kernel Library (oneMKL) function domain defined by the *domain* parameter use the value returned by this function as a limit of the number of OpenMP threads they should request for parallel computations. The `mkl_domain_get_max_threads` function returns the thread-local number of threads or, if that value is zero or not set, the global number of threads. To determine this number, the function inspects the environment settings and return values of the function calls below in the order they are listed until it finds a non-zero value:

- A call to `mkl_set_num_threads_local`
- The last of the calls to `mkl_set_num_threads` or `mkl_domain_set_num_threads( ..., MKL_DOMAIN_ALL)`
- A call to `mkl_domain_set_num_threads( ..., domain)`
- The `MKL_DOMAIN_NUM_THREADS` environment variable with the `MKL_DOMAIN_ALL` tag
- The `MKL_DOMAIN_NUM_THREADS` environment variable (with the specific domain tag)
- The `MKL_NUM_THREADS` environment variable
- A call to `omp_set_num_threads`
- The `OMP_NUM_THREADS` environment variable

Actual number of threads used by the Intel® oneAPI Math Kernel Library (oneMKL) computational functions may vary depending on the problem size and on whether dynamic adjustment of the number of threads is enabled (see the description of `mkl_set_dynamic`). For a list of supported values of the *domain* argument, see [Table "Intel MKL Function Domains"](#).

### Return Values

Name	Type	Description
<i>nt</i>	int	The maximum number of threads for Intel® oneAPI Math Kernel Library (oneMKL) functions from a given domain to use in internal parallel regions.  If an invalid value of <i>domain</i> is supplied, the function returns the number of threads for <code>MKL_DOMAIN_ALL</code>

### Example

```
#include "mkl.h"
...
if (1 < mkl_domain_get_max_threads(MKL_DOMAIN_BLAS))
puts("Intel MKL BLAS functions employ threading");
```

## mkl\_get\_dynamic

Determines whether Intel® oneAPI Math Kernel Library (oneMKL) is enabled to dynamically change the number of OpenMP\* threads.

---

### Syntax

```
int mkl_get_dynamic(void);
```

### Include Files

- `mkl.h`

### Description

This function returns the status of dynamic adjustment of the number of OpenMP\* threads. To determine this status, the function inspects the return value of the following function call and if it is undefined, inspects the environment setting below:

- A call to `mkl_set_dynamic`
- The `MKL_DYNAMIC` environment variable

---

#### NOTE

Dynamic adjustment of the number of threads is enabled by default.

---

The dynamic adjustment works as follows. Suppose that the `mkl_get_max_threads` function returns the number of threads equal to  $N$ . If dynamic adjustment is enabled, Intel® oneAPI Math Kernel Library (oneMKL) may request up to  $N$  threads, depending on the size of the problem. If dynamic adjustment is disabled, Intel® oneAPI Math Kernel Library (oneMKL) requests exactly  $N$  threads for internal parallel regions (provided it uses a threaded algorithm with at least  $N$  computations that can be done in parallel). However, the OpenMP\* run-time library may be configured to supply fewer threads than Intel® oneAPI Math Kernel Library (oneMKL) requests, depending on the OpenMP\* setting of dynamic adjustment.

### Return Values

Name	Type	Description
<code>ret</code>	<code>int</code>	0 - Dynamic adjustment of the number of threads is disabled. 1 - Dynamic adjustment of the number of threads is enabled.

### Example

```
#include "mkl.h"
...
int nt = mkl_get_max_threads();
if (1 == mkl_get_dynamic())
printf("Intel MKL may use less than %i threads for a large problem", nt);
else
printf("Intel MKL should use %i threads for a large problem", nt);
```

## mkl\_set\_num\_stripes

Specifies the number of partitions along the leading dimension of the output matrix for parallel ?gemm functions.

---

### Syntax

```
void mkl_set_num_stripes( int ns );
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>ns</i>	int	<i>ns</i> > 0 - Specifies the number of partitions to use. <i>ns</i> = 0 - Instructs Intel® oneAPI Math Kernel Library (oneMKL) ?gemm functions to use the default partitioning algorithm. <i>ns</i> < 0 - Invalid value; ignored.

### Description

This function enables you to specify the number of stripes, or partitions along the leading dimension of the output matrix, for parallel ?gemm functions. If this number is not set (default) or if it is set to zero, Intel® oneAPI Math Kernel Library (oneMKL) ?gemm functions use the default partitioning algorithm. The specified number of partitions only applies to ?gemm functions.

The number specified is a hint, and Intel® oneAPI Math Kernel Library (oneMKL) may actually use a smaller number.

---

#### NOTE

This function takes precedence over the MKL\_NUM\_STRIPES environment variable.

---

### Example

```
#include "mkl.h"
...
mkl_set_num_stripes(4);
dgemm(...); // Intel MKL uses up to 4 stripes for dgemm
```

### See Also

[mkl\\_get\\_num\\_stripes](#)

## mkl\_get\_num\_stripes

Gets the number of partitions along the leading dimension of the output matrix for parallel ?gemm functions.

---

### Syntax

```
int mkl_get_num_stripes(void);
```

## Include Files

- `mkl.h`

## Description

This function returns the number of stripes, that is, partitions along the leading dimension of the output matrix, for parallel `?gemm` functions. The number of partitions only applies to `?gemm` functions.

The number returned is a hint, and Intel® oneAPI Math Kernel Library (oneMKL) may actually use a smaller number.

## Return Values

Name	Type	Description
<code>ns</code>	<code>int</code>	The number of stripes for Intel® oneAPI Math Kernel Library (oneMKL) <code>?gemm</code> functions to use.

## Example

```
#include "mkl.h"
...
int ns = mkl_get_num_stripes();
if (ns > 0) printf("Intel MKL uses %d number of stripes\n", ns);
```

## See Also

[mkl\\_set\\_num\\_stripes](#)

## Error Handling

### Error Handling for Linear Algebra Routines

#### **xerbla**

*Error handling function called by BLAS, LAPACK, Vector Math, and Vector Statistics functions.*

#### Syntax

```
void xerbla( const char * sname, const int* info, const int len );
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>sname</code>	<code>const char*</code>	The name of the routine that called <code>xerbla</code>
<code>info</code>	<code>const int*</code>	The position of the invalid parameter in the parameter list of the calling function or an error code
<code>len</code>	<code>const int</code>	Length of the source string

## Description

The `xerbla` function is an error handler for Intel® oneAPI Math Kernel Library (oneMKL) BLAS, LAPACK, Vector Math, and Vector Statistics functions. These functions call `xerbla` if an issue is encountered on entry or during the function execution.

`xerbla` operates as follows:

1. Prints a message that depends on the value of the `info` parameter as explained in the following table.

---

**NOTE**

A specific message can differ from the listed messages in numeric values and/or function names.

---

2. Returns to the calling application.

## Error Messages Printed by `xerbla`

Value of <code>info</code>	Error Message
1001	Intel MKL ERROR: Incompatible optional parameters on entry to DGEMM.
1000 or 1089	Intel MKL INTERNAL ERROR: Insufficient workspace available in function CGELSD.
< 0	Intel MKL INTERNAL ERROR: Condition 1 detected in function DLASD8.
Other	The position of the invalid parameter in the parameter list of the calling function.

Note that `xerbla` is an internal function. You can change or disable printing of an error message by providing your own `xerbla` function. The following examples illustrate usage of `xerbla`.

## Example

```
void xerbla(char* sname, int* info, int len){
// sname - name of the function that called xerbla
// info - position of the invalid parameter in the parameter list
// len - length of the name in bytes
printf("\nXERBLA is called :%s: %d\n",sname,*info);
}
```

## See Also

[mkl\\_set\\_xerbla](#)

## `pxerbla`

*Error handling routine called by ScaLAPACK routines.*

## Syntax

```
void pxerbla (MKL_INT* ictxt, char* sname, MKL_INT* info, MKL_INT sname_len);
```

## Include Files

- `mkl_scalapack.h`

## Input Parameters

`ictxt` (local)

	MKL_INT*	
		The BLACS context handle, indicating the global context of the operation. The context itself is global.
<i>sname</i>	(global) char*	The name of the routine that called <code>p_xerbla</code> .
<i>info</i>	(global) MKL_INT*	The position of the invalid parameter in the parameter list of the calling routine.
<i>sname_len</i>	(global) MKL_INT	The length of the calling routine name.

## Description

This routine is an error handler for the *ScaLAPACK* routines. It is called if an input parameter has an invalid value. A message is printed and program execution continues. For *ScaLAPACK* driver and computational routines, a `RETURN` statement is issued following the call to `p_xerbla`.

Control returns to the higher-level calling routine, and you can determine how the program should proceed. However, in the specialized low-level *ScaLAPACK* routines (auxiliary routines that are Level 2 equivalents of computational routines), the call to `p_xerbla()` is immediately followed by a call to `BLACS_ABORT()` to terminate program execution since recovery from an error at this level in the computation is not possible.

It is always good practice to check for a non-zero value of *info* on return from a *ScaLAPACK* routine. Installers may consider modifying this routine in order to call system-specific exception-handling facilities.

## LAPACKE\_xerbla

*Error handling function called by the C interface to LAPACK functions.*

## Syntax

```
void LAPACKE_xerbla( const char * name, lapack_int info );
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<i>name</i>	<code>const char*</code>	The name of the routine that called <code>LAPACKE_xerbla</code>
<i>info</i>	<code>lapack_int</code>	The position of the invalid parameter in the parameter list of the calling function or an error code

## Description

The `LAPACKE_xerbla` function is an error handler for Intel® oneAPI Math Kernel Library (oneMKL) LAPACKE functions (the C interface to LAPACK functionality). If a LAPACKE function encounters an issue on entry or during the function execution, it calls `LAPACKE_xerbla` to print an error message and return an error code.

---

### NOTE

The `LAPACKE_xerbla` routine does not replace the `xerbla` routine. For instance, if an issue occurs when a LAPACK function is called by a LAPACKE function, the LAPACK function calls `xerbla`.

---

## Error Messages Printed by LAPACKE\_xerbla

Value of <i>info</i>	Example Error Message
<code>LAPACK_WORK_MEMORY_ERROR</code>	Not enough memory to allocate work array in <code>LAPACKE_dgees</code>
<code>LAPACK_TRANSPOSE_MEMORY_ERROR</code>	Not enough memory to transpose matrix in <code>LAPACKE_dgetrf_work</code>
<code>&lt; 0</code>	Wrong parameter 1 in <code>LAPACKE_dgetrf</code>

---

### NOTE

`LAPACKE_xerbla` is an internal function. You can change or disable printing of an error message by providing your own `LAPACKE_xerbla` function. Intel® oneAPI Math Kernel Library (oneMKL) does not provide functionality for dynamic replacement of `LAPACKE_xerbla`.

---

## See Also

[xerbla](#)

## Handling Fatal Errors

A fatal error is a circumstance under which Intel® oneAPI Math Kernel Library (oneMKL) cannot continue the computation. For example, a fatal error occurs when Intel® oneAPI Math Kernel Library (oneMKL) cannot load a dynamic library or confronts an unsupported CPU type. In case of a fatal error, the default Intel® oneAPI Math Kernel Library (oneMKL) behavior is to print an explanatory message to the console and call an internal function that terminates the application with a call to the `system_exit()` function. Intel® oneAPI Math Kernel Library (oneMKL) enables you to override this behavior by setting a custom handler of fatal errors. The custom error handler can be configured to throw a C++ exception, set a global variable indicating the failure, or otherwise handle cannot-continue situations. It is not necessary for the custom error handler to call the `system_exit()` function. Once execution of the error handler completes, a call to Intel® oneAPI Math Kernel Library (oneMKL) returns to the calling program without performing any computations and leaves no memory allocated by Intel® oneAPI Math Kernel Library (oneMKL) and no thread synchronization pending on return.

To specify a custom fatal error handler, call the `mkl_set_exit_handler` function.

### `mkl_set_exit_handler`

*Sets the custom handler of fatal errors.*

---

### Syntax

```
int mkl_set_exit_handler (MKLExitHandler myexit);
```

## Include Files

- mkl.h

## Input Parameters

Name	Prototype	Description
<code>myexit</code>	<code>void (*myexit)(int why);</code>	The error handler to set.

## Description

This function sets the custom handler of fatal errors. If the input parameter is `NULL`, the system `exit()` function is set.

The following example shows how to use a custom handler of fatal errors in your C++ application:

```
#include "mkl.h"
void my_exit(int why){
    throw my_exception();
}
int ComputationFunction()
{
    mkl_set_exit_handler( my_exit );
    try {
        compute_using_mkl();
    }
    catch (const my_exception& e) {
        handle_exception();
    }
}
```

## Character Equality Testing

### lsame

*Tests two characters for equality regardless of the case.*

### Syntax

```
int lsame( const char* ca, const char* cb, int lca, int lcb );
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<code>ca, cb</code>	<code>const char*</code>	Pointers to the single characters to be compared
<code>lca, lcb</code>	<code>int</code>	Lengths of the input character strings, equal to one.

## Description

This logical function checks whether two characters are equal regardless of the case.

## Return Values

Name	Type	Description
<code>val</code>	<code>int</code>	Result of the comparison: <ul style="list-style-type: none"> <li>a non-zero value if <code>ca</code> is the same letter as <code>cb</code>, maybe except for the case.</li> <li>zero if <code>ca</code> and <code>cb</code> are different letters for whatever cases.</li> </ul>

## lsamen

Tests two character strings for equality regardless of the case.

---

## Syntax

```
MKL_INT lsamen( const MKL_INT* n, const char* ca, const char* cb );
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>n</code>	<code>const MKL_INT*</code>	Pointer to the number of characters in <code>ca</code> and <code>cb</code> to be compared.
<code>ca, cb</code>	<code>const char*</code>	Character strings of length at least <code>n</code> to be compared. Only the first <code>n</code> characters of each string will be accessed.

## Description

This logical function tests whether the first `n` letters of one string are the same as the first `n` letters of the other string, regardless of the case.

## Return Values

Name	Type	Description
<code>val</code>	<code>MKL_INT</code>	Result of the comparison: <ul style="list-style-type: none"> <li>a non-zero value if the first <code>n</code> letters in <code>ca</code> and <code>cb</code> character strings are equal, maybe except for the case, or if the length of character string <code>ca</code> or <code>cb</code> is less than <code>n</code>.</li> <li>zero if the first <code>n</code> letters in <code>ca</code> and <code>cb</code> character strings are different for whatever cases.</li> </ul>

## Timing

### second/dsecnd

Returns elapsed time in seconds. Use to estimate real time between two calls to this function.

---

## Syntax

```
float second( void );
double dsecnd( void );
```

## Include Files

- `mkl.h`

## Description

The `second/dsecnd` function returns time in seconds to be used to estimate real time between two calls to the function. The difference between these functions is in the precision of the floating-point type of the result: while `second` returns the single-precision type, `dsecnd` returns the double-precision type.

Use these functions to measure durations. To do this, call each of these functions twice. For example, to measure performance of a routine, call the appropriate function directly before a call to the routine to be measured, and then after the call of the routine. The difference between the returned values shows real time spent in the routine.

Initializations may take some time when the `second/dsecnd` function runs for the first time. To eliminate the effect of this extra time on your measurements, make the first call to `second/dsecnd` in advance.

Do not use `second` to measure short time intervals because the single-precision format is not capable of holding sufficient timer precision.

## Return Values

Name	Type	Description
<code>val</code>	float for <code>second</code> double for <code>dsecnd</code>	Elapsed real time in seconds

## `mkl_get_cpu_clocks`

*Returns elapsed CPU clocks.*

## Syntax

```
void mkl_get_cpu_clocks (unsigned MKL_INT64 *clocks);
```

## Include Files

- `mkl.h`

## Output Parameters

Name	Type	Description
<code>clocks</code>	unsigned MKL_INT64	Elapsed CPU clocks

## Description

The `mkl_get_cpu_clocks` function returns the elapsed CPU clocks.

This may be useful when timing short intervals with high resolution. The `mkl_get_cpu_clocks` function is also applied in pairs like `second/dsecnd`. Note that out-of-order code execution on IA-32 or Intel® 64 architecture processors may disturb the exact elapsed CPU clocks value a little bit, which may be important while measuring extremely short time intervals.

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

**mkl\_get\_cpu\_frequency**

Returns the current CPU frequency value in GHz.

---

**Syntax**

```
double mkl_get_cpu_frequency(void);
```

**Include Files**

- `mkl.h`

**Description**

The function `mkl_get_cpu_frequency` returns the current CPU frequency in GHz.

**NOTE**

The returned value may vary from run to run if power management or Intel® Turbo Boost Technology is enabled.

---

**Return Values**

Name	Type	Description
<code>freq</code>	double	Current CPU frequency value in GHz

**mkl\_get\_max\_cpu\_frequency**

Returns the maximum CPU frequency value in GHz.

---

**Syntax**

```
double mkl_get_max_cpu_frequency(void);
```

**Include Files**

- `mkl.h`

**Description**

The function `mkl_get_max_cpu_frequency` returns the maximum CPU frequency in GHz.

**Return Values**

Name	Type	Description
<code>freq</code>	double	Maximum CPU frequency value in GHz

## mkl\_get\_clocks\_frequency

Returns the frequency value in GHz based on constant-rate Time Stamp Counter.

---

### Syntax

```
double mkl_get_clocks_frequency (void);
```

### Include Files

- mkl.h

### Description

The function `mkl_get_clocks_frequency` returns the CPU frequency value (in GHz) based on constant-rate Time Stamp Counter (TSC). Use of the constant-rate TSC ensures that each clock tick is constant even if the CPU frequency changes. Therefore, the returned frequency is constant.

---

#### NOTE

Obtaining the frequency may take some time when `mkl_get_clocks_frequency` is called for the first time. The same holds for functions `second/dsecnd`, which call `mkl_get_clocks_frequency`.

---

### Return Values

Name	Type	Description
<code>freq</code>	double	Frequency value in GHz

### See Also

`second/dsecnd`

## Memory Management

This section describes the Intel® oneAPI Math Kernel Library (oneMKL) memory functions. See the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for more memory usage information.

## mkl\_free\_buffers

Frees unused memory allocated by the Intel® oneAPI Math Kernel Library (oneMKL) on the Host.

---

### Syntax

```
void mkl_free_buffers (void);
```

### Include Files

- mkl.h

### Description

To improve performance of Intel® oneAPI Math Kernel Library (oneMKL) on CPU, the Memory Allocator uses per-thread memory pools where buffers may be collected for fast reuse. Intel® oneAPI Math Kernel Library (oneMKL) also allocates temporary buffers on the host memory to improve performance of GPU kernels. The `mkl_free_buffers` function frees both types of memory.

See the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for details.

You should call `mkl_free_buffers` after the last call to Intel® oneAPI Math Kernel Library (oneMKL) functions. In large applications, if you suspect that the memory may get insufficient, you may call this function earlier, but anticipate a drop in performance that may occur due to reallocation of buffers for subsequent calls to Intel® oneAPI Math Kernel Library (oneMKL) functions.

## Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Usage of `mkl_free_buffers` with FFT Functions

```
DFTI_DESCRIPTOR_HANDLE hand1;
DFTI_DESCRIPTOR_HANDLE hand2;
void mkl_free_buffers(void);
. . . . .
/* Using Intel MKL FFT */
Status = DftiCreateDescriptor(&hand1, DFTI_SINGLE, DFTI_COMPLEX, dim, m1);
Status = DftiCommitDescriptor(hand1);
Status = DftiComputeForward(hand1, s_array1);
. . . . .
Status = DftiCreateDescriptor(&hand2, DFTI_SINGLE, DFTI_COMPLEX, dim, m2);
Status = DftiCommitDescriptor(hand2);
. . . . .
Status = DftiFreeDescriptor(&hand1);
. . . . .
Status = DftiComputeBackward(hand2, s_array2);
Status = DftiFreeDescriptor(&hand2);
/* Here you finish using Intel MKL FFT */
/* Memory leak will be triggered by any memory control tool */
/* Use mkl_free_buffers() to avoid memory leaking */
mkl_free_buffers();
```

## `mkl_thread_free_buffers`

*Frees unused memory allocated by the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator in the current thread.*

### Syntax

```
void mkl_thread_free_buffers (void);
```

### Include Files

- `mkl.h`

### Description

To improve performance of Intel® oneAPI Math Kernel Library (oneMKL), the Memory Allocator uses per-thread memory pools where buffers may be collected for fast reuse. The `mkl_thread_free_buffers` function frees unused memory allocated by the Memory Allocator in the current thread only.

You should call `mkl_thread_free_buffers` after the last call to Intel® oneAPI Math Kernel Library (oneMKL) functions in the current thread. In large applications, if you suspect that the memory may get insufficient, you may call this function earlier, but anticipate a drop in performance that may occur due to reallocation of buffers for subsequent calls to Intel® oneAPI Math Kernel Library (oneMKL) functions.

## See Also

[mkl\\_free\\_buffers](#)

## mkl\_disable\_fast\_mm

Turns off the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator for Intel® oneAPI Math Kernel Library (oneMKL) functions to directly use the `systemmalloc/free` functions.

---

## Syntax

```
int mkl_disable_fast_mm (void);
```

## Include Files

- `mkl.h`

## Description

The `mkl_disable_fast_mm` function turns the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator off for Intel® oneAPI Math Kernel Library (oneMKL) functions to directly use the `systemmalloc/free` functions. Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator uses per-thread memory pools where buffers may be collected for fast reuse. The Memory Allocator is turned on by default for better performance. To turn it off, you can use the `mkl_disable_fast_mm` function or the `MKL_DISABLE_FAST_MM` environment variable (See the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for details.) Call `mkl_disable_fast_mm` before calling any Intel® oneAPI Math Kernel Library (oneMKL) functions that require allocation of memory buffers.

---

### NOTE

Turning the Memory Allocator off negatively impacts performance of some Intel® oneAPI Math Kernel Library (oneMKL) routines, especially for small problem sizes.

---

## Return Values

Name	Type	Description
<code>mm</code>	<code>int</code>	1 - The Memory Allocator is successfully turned off. 0 - Turning the Memory Allocator off failed.

## mkl\_mem\_stat

Reports the status of the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator.

---

## Syntax

```
MKL_INT64 mkl_mem_stat (int* AllocatedBuffers);
```

## Include Files

- `mkl.h`

## Output Parameters

Name	Type	Description
<i>AllocatedBuffers</i>	int	The number of buffers allocated by Intel® oneAPI Math Kernel Library (oneMKL).

## Description

The function returns the number of buffers allocated by Intel® oneAPI Math Kernel Library (oneMKL) and the amount of memory in these buffers. Intel® oneAPI Math Kernel Library (oneMKL) can allocate the memory buffers internally or in a call to `mkl_malloc/mkl_calloc`. If no buffers are allocated at the moment, the `mkl_mem_stat` function returns 0. Call `mkl_mem_stat` to check the Intel® oneAPI Math Kernel Library (oneMKL) memory status.

### NOTE

If you free all the memory allocated in calls to `mkl_malloc` or `mkl_calloc` and then call `mkl_free_buffers`, a subsequent call to `mkl_mem_stat` normally returns 0.

## Return Values

Name	Type	Description
<i>AllocatedBytes</i>	MKL_INT64	The amount of allocated memory (in bytes).

## See Also

[Usage Example for the Memory Functions](#)

### `mkl_peak_mem_usage`

*Reports the peak memory allocated by the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator.*

## Syntax

```
MKL_INT64 mkl_peak_mem_usage (int mode);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<i>mode</i>	int	Requested mode of the function's operation. Possible values: <ul style="list-style-type: none"> <li>• <code>MKL_PEAK_MEM_ENABLE</code> - start gathering the peak memory data</li> <li>• <code>MKL_PEAK_MEM_DISABLE</code> - stop gathering the peak memory data</li> <li>• <code>MKL_PEAK_MEM</code> - return the peak memory</li> </ul>

Name	Type	Description
		<ul style="list-style-type: none"> <li>MKL_PEAK_MEM_RESET - return the peak memory and reset the counter to start gathering the peak memory data from scratch</li> </ul>

## Description

The `mkl_peak_mem_usage` function reports the peak memory allocated by the Intel® oneAPI Math Kernel Library (oneMKL) Memory Allocator.

Gathering the peak memory data is turned off by default. If you need to know the peak memory, explicitly turn the data gathering mode on by calling the function with the `MKL_PEAK_MEM_ENABLE` value of the parameter. Use the `MKL_PEAK_MEM` and `MKL_PEAK_MEM_RESET` values only when the data gathering mode is turned on. Otherwise the function returns -1. The data gathering mode leads to performance degradation, so when the mode is turned on, you can turn it off by calling the function with the `MKL_PEAK_MEM_DISABLE` value of the parameter.

---

### NOTE

- If Intel® oneAPI Math Kernel Library (oneMKL) is running in a threaded mode, the `mkl_peak_mem_usage` function may return different amounts of memory from run to run.
  - The function reports the peak memory for the entire application, not just for the calling thread.
- 

## Return Values

Name	Type	Description
<i>AllocatedBytes</i>	MKL_INT64	The peak memory allocated by the Memory Allocator (in bytes) or -1 in case of errors.

## See Also

[Usage Example for the Memory Functions](#)

## `mkl_malloc`

*Allocates an aligned memory buffer.*

---

### Syntax

```
void* mkl_malloc (size_t alloc_size, int alignment);
```

### Include Files

- `mkl.h`

### Input Parameters

Name	Type	Description
<i>alloc_size</i>	<code>size_t</code>	Size of the buffer to be allocated.
<i>alignment</i>	<code>int</code>	Alignment of the buffer.

### Description

The function allocates an `alloc_size`-byte buffer aligned on the `alignment`-byte boundary.

If *alignment* is not a power of 2, the 64-byte alignment is used.

## Return Values

Name	Type	Description
<i>a_ptr</i>	void*	Pointer to the allocated buffer if <i>alloc_size</i> ≥ 1, NULL if <i>alloc_size</i> < 1.

## See Also

[mkl\\_free](#)

[Usage Example for the Memory Functions](#)

## mkl\_calloc

*Allocates and initializes an aligned memory buffer.*

## Syntax

```
void* mkl_calloc (size_t num, size_t size, int alignment);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<i>num</i>	size_t	The number of elements in the buffer to be allocated.
<i>size</i>	size_t	The size of the element.
<i>alignment</i>	int	Alignment of the buffer.

## Description

The function allocates a *num*\**size*-byte buffer, aligned on the *alignment*-byte boundary, and initializes the buffer with zeros.

If *alignment* is not a power of 2, the 64-byte alignment is used.

## Return Values

Name	Type	Description
<i>a_ptr</i>	void*	Pointer to the allocated buffer if <i>size</i> ≥ 1, NULL if <i>size</i> < 1.

## See Also

[mkl\\_malloc](#)

[mkl\\_realloc](#)

[mkl\\_free](#)

[Usage Example for the Memory Functions](#)

## mkl\_realloc

*Changes the size of memory buffer allocated by mkl\_malloc/mkl\_calloc.*

---

### Syntax

```
void* mkl_realloc (void *ptr, size_t size);
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>ptr</i>	void*	Pointer to the memory buffer allocated by the mkl_malloc or mkl_calloc function or a NULL pointer.
<i>size</i>	size_t	New size of the buffer.

### Description

The function changes the size of the memory buffer allocated by the mkl\_malloc or mkl\_calloc function to *size* bytes. The first bytes of the returned buffer up to the minimum of the old and new sizes keep the content of the input buffer. The returned memory buffer can have a different location than the input one. If *ptr* is NULL, the function works as mkl\_malloc.

### Return Values

Name	Type	Description
<i>a_ptr</i>	void*	<ul style="list-style-type: none"><li>• Pointer to the re-allocated buffer if re-allocation is successful.</li><li>• NULL if re-allocation is unsuccessful.</li></ul>

### See Also

mkl\_malloc

mkl\_calloc

mkl\_free

[Usage Example for the Memory Functions](#)

## mkl\_free

*Frees the aligned memory buffer allocated by mkl\_malloc/mkl\_calloc.*

---

### Syntax

```
void mkl_free (void *a_ptr);
```

### Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<code>a_ptr</code>	<code>void*</code>	Pointer to the buffer to be freed.

## Description

The function frees the buffer pointed by `a_ptr` and allocated by the `mkl_malloc()` or `mkl_calloc()` function and does nothing if `a_ptr` is `NULL`.

## See Also

[mkl\\_malloc](#)

[mkl\\_calloc](#)

[Usage Example for the Memory Functions](#)

## **mkl\_set\_memory\_limit**

*On Linux, sets the limit of memory that Intel® oneAPI Math Kernel Library (oneMKL) can allocate for a specified type of memory.*

---

## Syntax

```
int mkl_set_memory_limit (int mem_type, size_t limit);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>mem_type</code>	<code>int</code>	Type of memory to limit. Possible values:  <code>MKL_MEM_MCDRAM</code> - Multi-Channel Dynamic Random Access Memory (MCDRAM).
<code>limit</code>	<code>size_t</code>	Memory limit in megabytes.

## Description

This function sets the limit for the amount of memory that Intel® oneAPI Math Kernel Library (oneMKL) can allocate for the specified memory type. The limit bounds both internal allocations (inside Intel® oneAPI Math Kernel Library (oneMKL) computation routines) and external allocations (in a call to `mkl_malloc`, `mkl_calloc`, or `mkl_realloc`). By default no limit is set for memory allocation.

Call `mkl_set_memory_limit` at most once, prior to calling any other Intel® oneAPI Math Kernel Library (oneMKL) function in your application except [mkl\\_set\\_interface\\_layer](#) and [mkl\\_set\\_threading\\_layer](#).

---

### NOTE

- Allocation in MCDRAM requires `libmemkind` and `libjemalloc` dynamic libraries which are a part of Intel® Manycore Platform Software Package (Intel® MPSP) for Linux\*.
  - The `mkl_set_memory_limit` function takes precedence over the `MKL_FAST_MEMORY_LIMIT` environment variable.
-

## Return Values

Type	Description
int	Status of the function completion: <ul style="list-style-type: none"> <li>• 1 - the limit is set</li> <li>• 0 - the limit is not set</li> </ul>

## See Also

## Usage Example for the Memory Functions

```
#include <stdio.h>
#include <mkl.h>

int main(void) {
    double *a, *b, *c;
    int n, i;
    double alpha, beta;
    MKL_INT64 AllocatedBytes;
    int N_AllocatedBuffers;

    alpha = 1.1; beta = -1.2;
    n = 1000;
    mkl_peak_mem_usage(MKL_PEAK_MEM_ENABLE);
    a = (double*)mkl_malloc(n*n*sizeof(double), 64);
    b = (double*)mkl_malloc(n*n*sizeof(double), 64);
    c = (double*)mkl_calloc(n*n, sizeof(double), 64);
    for (i=0; i<(n*n); i++) {
        a[i] = (double)(i+1);
        b[i] = (double)(-i-1);
    }

    dgemv("N", "N", &n, &n, &n, &alpha, a, &n, b, &n, &beta, c, &n);
    AllocatedBytes = mkl_mem_stat(&N_AllocatedBuffers);
    printf("\nDGEMV uses %d bytes in %d buffers", AllocatedBytes, N_AllocatedBuffers);

    mkl_free_buffers();
    mkl_free(a);
    mkl_free(b);
    mkl_free(c);

    AllocatedBytes = mkl_mem_stat(&N_AllocatedBuffers);
    if (AllocatedBytes > 0) {
        printf("\nMKL memory leak!");
        printf("\nAfter mkl_free_buffers there are %d bytes in %d buffers",
            AllocatedBytes, N_AllocatedBuffers);
    }
    printf("\nPeak memory allocated by Intel MKL memory allocator %d bytes. Start to count new
memory peak",
        mkl_peak_mem_usage(MKL_PEAK_MEM_RESET));
    a = (double*)mkl_malloc(n*n*sizeof(double), 64);
    a = (double*)mkl_realloc(a, 2*n*n*sizeof(double));
```

```
mkl_free(a);
printf("\nPeak memory allocated by Intel MKL memory allocator after reset of peak memory
counter %d bytes\n",
      mkl_peak_mem_usage(MKL_PEAK_MEM));

return 0;
}
```

## Single Dynamic Library Control

Intel® oneAPI Math Kernel Library (oneMKL) provides the Single Dynamic Library (SDL), which enables setting the interface and threading layer for Intel® oneAPI Math Kernel Library (oneMKL) at run time. See *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for details of SDL and layered model concept. This section describes the functions supporting SDL.

### `mkl_set_interface_layer`

*Sets the interface layer for Intel® oneAPI Math Kernel Library (oneMKL) at run time. Use with the Single Dynamic Library.*

#### Syntax

```
int mkl_set_interface_layer (int required_interface);
```

#### Include Files

- `mkl.h`

#### Input Parameters

Name	Type	Description
<code>required_interface</code>	int	Determines the interface layer. Possible values depend on the system architecture. Some of the values are only available on Linux* OS: <ul style="list-style-type: none"><li>• Intel® 64 architecture:<ul style="list-style-type: none"><li><code>MKL_INTERFACE_LP64</code> for the Intel LP64 interface.</li><li><code>MKL_INTERFACE_ILP64</code> for the Intel ILP64 interface.</li><li><code>MKL_INTERFACE_LP64+MKL_INTERFACE_GNU</code> for the GNU* LP64 interface on Linux OS.</li><li><code>MKL_INTERFACE_ILP64+MKL_INTERFACE_GNU</code> for the GNU ILP64 interface on Linux OS.</li></ul></li><li>• IA-32 architecture:<ul style="list-style-type: none"><li><code>MKL_INTERFACE_LP64</code> for the Intel interface on Linux OS.</li><li><code>MKL_INTERFACE_LP64+MKL_INTERFACE_GNU</code> or <code>MKL_INTERFACE_GNU</code> for the GNU interface on Linux OS.</li></ul></li></ul>

#### Description

If you are using the Single Dynamic Library (SDL), the `mkl_set_interface_layer` function sets the specified interface layer for Intel® oneAPI Math Kernel Library (oneMKL) at run time.

Call this function prior to calling any other Intel® oneAPI Math Kernel Library (oneMKL) function in your application except `mkl_set_threading_layer`. You can call `mkl_set_interface_layer` and `mkl_set_threading_layer` in any order.

The `mkl_set_interface_layer` function takes precedence over the `MKL_INTERFACE_LAYER` environment variable.

See *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for the layered model concept and usage details of the SDL.

## Return Values

Type	Description
<code>int</code>	<ul style="list-style-type: none"> <li>Current interface layer if it is set in a call to <code>mkl_set_interface_layer</code> or specified by environment variables or defaults.</li> </ul> <p>Possible values are specified in <a href="#">Input Parameters</a>.</p> <ul style="list-style-type: none"> <li>-1, if the layer was not specified prior to the call and the input parameter is incorrect.</li> </ul>

## `mkl_set_threading_layer`

*Sets the threading layer for Intel® oneAPI Math Kernel Library (oneMKL) at run time. Use with the Single Dynamic Library (SDL).*

## Syntax

```
int mkl_set_threading_layer (int required_threading);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>required_threading</code>	<code>int</code>	<p>Determines the threading layer. Possible values:</p> <p><code>MKL_THREADING_INTEL</code> for Intel threading.</p> <p><code>MKL_THREADING_SEQUENTIAL</code> for the sequential mode of Intel® oneAPI Math Kernel Library (oneMKL).</p> <p><code>MKL_THREADING_TBB</code> for threading with the Intel® Threading Building Blocks.</p> <p><code>MKL_THREADING_PGI</code> for PGI threading on Windows* or Linux* operating system only. Do not use this value with the SDL for Intel® Many Integrated Core (Intel® MIC) Architecture.</p>

---

**NOTE** PGI\* support is deprecated and will be removed in the oneMKL 2025.0 release.

---

Name	Type	Description
		MKL_THREADING_GNU for GNU threading on Linux* operating system only. Do not use this value with the SDL for Intel MIC Architecture.

## Description

If you are using the Single Dynamic Library (SDL), the `mkl_set_threading_layer` function sets the specified threading layer for Intel® oneAPI Math Kernel Library (oneMKL) at run time.

Call this function prior to calling any other Intel® oneAPI Math Kernel Library (oneMKL) function in your application except `mkl_set_interface_layer`.

You can call `mkl_set_threading_layer` and `mkl_set_interface_layer` in any order.

The `mkl_set_threading_layer` function takes precedence over the `MKL_THREADING_LAYER` environment variable.

See *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for the layered model concept and usage details of the SDL.

## Return Values

Type	Description
<code>int</code>	<ul style="list-style-type: none"> <li>Current threading layer if it is set in a call to <code>mkl_set_threading_layer</code> or specified by environment variables or defaults. Possible values are specified in <a href="#">Input Parameters</a>.</li> <li>-1, if the layer was not specified prior to the call and the input parameter is incorrect.</li> </ul>

## `mkl_set_xerbla`

*Replaces the error handling routine. Use with the Single Dynamic Library .*

## Syntax

```
XerblaEntry mkl_set_xerbla (XerblaEntry new_xerbla_ptr);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>new_xerbla_ptr</code>	<code>XerblaEntry</code>	Pointer to the error handling routine to be used.

## Description

The `mkl_set_xerbla` function replaces the error handling routine that is called by Intel® oneAPI Math Kernel Library (oneMKL) functions with the routine specified by the parameter.

See *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for details about SDL.

## Return Values

The function returns the pointer to the replaced error handling routine.

## See Also

[xerbla](#)

## **mkl\_set\_progress**

*Replaces the progress information routine.*

---

### Syntax

```
ProgressEntry mkl_set_progress (ProgressEntry new_progress_ptr);
```

### Include Files

- `mkl.h`

### Input Parameters

Name	Type	Description
<code>new_progress_ptr</code>	<code>ProgressEntry</code>	Pointer to the progress information routine to be used.

### Description

The `mkl_set_progress` function replaces the currently used progress information routine with the routine specified by the parameter.

Usually a user-supplied `mkl_progress` function redefines the default `mkl_progress` function automatically. However, you must call `mkl_set_progress` to replace the default `mkl_progress` on Windows\* in any of the following cases:

- You are using the Single Dynamic Library (SDL) `mkl_rt.lib`.
- You link dynamically with ScaLAPACK.

See *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for details of SDL.

### Return Values

The function returns the pointer to the replaced progress information routine.

## See Also

[mkl\\_progress](#)

## **mkl\_set\_pardiso\_pivot**

*Replaces the routine handling Intel® oneAPI Math Kernel Library (oneMKL) PARDISO pivots with a user-defined routine. Use with the Single Dynamic Library (SDL).*

---

### Syntax

```
PardisopivotEntry mkl_set_pardiso_pivot (PardisopivotEntry new_pardiso_pivot_ptr);
```

### Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>new_pardiso_pivot_ptr</code>	<code>PardisoPivotEntry</code>	Pointer to the pivot setting routine to be used.

## Description

If you are using the Single Dynamic Library (SDL), the `mkl_set_pardiso_pivot` function replaces the pivot setting routine that is called by Intel® oneAPI Math Kernel Library (oneMKL) functions with the routine specified by the parameter.

See *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for usage details of the SDL.

## Return Values

Type	Description
<code>PardisoPivotEntry</code>	Pointer to the replaced pivot setting routine.

## See Also

[mkl\\_pardiso\\_pivot](#)

## Conditional Numerical Reproducibility Control

The CNR mode of Intel® oneAPI Math Kernel Library (oneMKL) ensures bitwise reproducible results from run to run of Intel® oneAPI Math Kernel Library (oneMKL) functions on a fixed number of threads for a specific Intel instruction set architecture (ISA) under the following conditions:

- Calls to Intel® oneAPI Math Kernel Library (oneMKL) occur in a single executable
- The number of computational threads used by the library does not change in the run

Intel® oneAPI Math Kernel Library (oneMKL) offers both functions and environment variables to support conditional numerical reproducibility. See the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide* for more information on bitwise reproducible results of computations and for details about the environment variables.

The support functions enable you to configure the CNR mode and also provide information on the current and optimal CNR branch on your system. [Usage Examples for CNR Support Functions](#) illustrate usage of these functions.

---

### Important

Call the functions that define the behavior of CNR before any of the math library functions that they control.

---

Intel® oneAPI Math Kernel Library (oneMKL) provides named constants for use as input and output parameters of the functions instead of integer values. See [Named Constants for CNR Control](#) for a list of the named constants.

Although you can configure the CNR mode using either the support functions or the environment variables, the functions offer more flexible configuration and control than the environment variables. Settings specified by the functions take precedence over the settings specified by the environment variables.

Use Intel® oneAPI Math Kernel Library (oneMKL) in the CNR mode only in case a need for bitwise reproducible results is critical. Otherwise, run Intel® oneAPI Math Kernel Library (oneMKL) as usual to avoid performance degradation.

While you can supply unaligned input and output data to Intel® oneAPI Math Kernel Library (oneMKL) functions running in the CNR mode, use of aligned data is recommended. Refer to [Reproducibility Conditions](#) for more details.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## mkl\_cbwr\_set

Configures the CNR mode of Intel® oneAPI Math Kernel Library (oneMKL).

### Syntax

```
int mkl_cbwr_set (int setting);
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>setting</i>	int	CNR branch to set. See <a href="#">Named Constants for CNR Control</a> for a list of named constants that specify the settings.

### Description

The `mkl_cbwr_set` function configures the CNR mode. In this release, it sets the CNR branch and turns on the CNR mode.

#### NOTE

Settings specified by the `mkl_cbwr_set` function take precedence over the settings specified by the `MKL_CBWR` environment variable.

### Return Values

Name	Type	Description
<i>status</i>	int	<p>The status of the function completion:</p> <ul style="list-style-type: none"> <li>• <code>MKL_CBWR_SUCCESS</code> - the function completed successfully.</li> <li>• <code>MKL_CBWR_ERR_INVALID_INPUT</code> - an invalid setting is requested.</li> <li>• <code>MKL_CBWR_ERR_UNSUPPORTED_BRANCH</code> - the input value of the branch does not match the instruction set architecture (ISA) of your system. See <a href="#">Named Constants for CNR Control</a> for more details.</li> </ul>

Name	Type	Description
		<ul style="list-style-type: none"> <li>MKL_CBWR_ERR_MODE_CHANGE_FAILURE - the <code>mkl_cbwr_set</code> function requested to change the current CNR branch after a call to some Intel® oneAPI Math Kernel Library (oneMKL) function other than a CNR function.</li> </ul>

## See Also

Usage Examples for CNR Support Functions

### `mkl_cbwr_get`

Returns the current CNR settings.

### Syntax

```
int mkl_cbwr_get (int option);
```

### Include Files

- `mkl.h`

### Input Parameters

Name	Type	Description
<code>option</code>	<code>int</code>	Specifies the CNR settings requested. Named constants define possible values of <code>option</code> : <ul style="list-style-type: none"> <li>• MKL_CBWR_BRANCH - returns the current CNR branch only.</li> <li>• MKL_CBWR_ALL - returns all CNR settings including strict CNR setting.</li> </ul>

### Description

The `mkl_cbwr_get` function returns the requested CNR settings. The function returns `MKL_CBWR_ERR_INVALID_INPUT` if an invalid option is specified.

#### NOTE

To enable CNR mode, use the `mkl_cbwr_set` function or environment variables. For more details, see the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*.

### Return Values

Name	Type	Description
<code>setting</code>	<code>int</code>	Requested CNR settings. See <a href="#">Named Constants for CNR Control</a> for a list of named constants that specify the settings.  If the value of the <code>option</code> parameter is not permitted, contains the <code>MKL_CBWR_ERR_INVALID_INPUT</code> error code.

## See Also

Usage Examples for CNR Support Functions

`mkl_cbwr_set`

## `mkl_cbwr_get_auto_branch`

Automatically detects the CNR code branch for your platform.

## Syntax

```
int mkl_cbwr_get_auto_branch (void);
```

## Include Files

- `mkl.h`

## Description

The `mkl_cbwr_get_auto_branch` function uses a run-time CPU check to return a CNR branch that is optimized for the processor where the program is currently running.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Return Values

Name	Type	Description
<code>setting</code>	<code>int</code>	Automatically detected CNR branch. May be any <i>specific</i> branch listed in <a href="#">Named Constants for CNR Control</a> .

## See Also

Usage Examples for CNR Support Functions

## Named Constants for CNR Control

Use the conditional numerical reproducibility (CNR) functionality in Intel® oneAPI Math Kernel Library (oneMKL) to obtain reproducible results from MKL routines. When enabling CNR, you choose a specific code branch of Intel® oneAPI Math Kernel Library (oneMKL) that corresponds to the instruction set architecture (ISA) that you target. Use these named constants to specify the code branch and other CNR options.

Named Constant	Value	Description
<b>CNR Branches</b>		
<code>MKL_CBWR_OFF</code>	0	Disable CNR mode
<code>MKL_CBWR_BRANCH_OFF</code>	1	CNR mode is disabled
<code>MKL_CBWR_AUTO</code>	2	Choose branch automatically. CNR mode uses the standard ISA-based dispatching model while ensuring fixed cache sizes, deterministic reductions, and static scheduling
<code>MKL_CBWR_COMPATIBLE</code>	3	Intel® Streaming SIMD Extensions 2 (Intel® SSE2) without <code>rcpps/rsqrtps</code> instructions

Named Constant	Value	Description
MKL_CBWR_SSE2	4	Intel SSE2
MKL_CBWR_SSE3	5	DEPRECATED. Intel® Streaming SIMD Extensions 3 (Intel® SSE3). This setting is kept for backward compatibility and is equivalent to MKL_CBWR_SSE2.
MKL_CBWR_SSSE3	6	Supplemental Streaming SIMD Extensions 3 (SSSE3)
MKL_CBWR_SSE4_1	7	Intel® Streaming SIMD Extensions 4-1 (SSE4-1)
MKL_CBWR_SSE4_2	8	Intel® Streaming SIMD Extensions 4-2 (SSE4-2)
MKL_CBWR_AVX	9	Intel® Advanced Vector Extensions (Intel® AVX)
MKL_CBWR_AVX2	10	Intel® Advanced Vector Extensions 2 (Intel® AVX2)
MKL_CBWR_AVX512_MIC	11	DEPRECATED. Intel® Advanced Vector Extensions 512 (Intel® AVX-512) on Intel® Xeon Phi™ processors. This setting is kept for backward compatibility and is equivalent to MKL_CBWR_AVX2.
MKL_CBWR_AVX512	12	Intel AVX-512 on Intel® Xeon® processors
MKL_CBWR_AVX512_MIC_E1	13	DEPRECATED. Intel® Advanced Vector Extensions 512 (Intel® AVX-512) for Intel® Many Integrated Core Architecture (Intel® MIC Architecture) with support of AVX512_4FMAPS and AVX512_4VNNIW instruction groups enabled processors. This setting is kept for backward compatibility and is equivalent to MKL_CBWR_AVX2.
MKL_CBWR_AVX512_E1	14	Intel® Advanced Vector Extensions 512 (Intel® AVX-512) with support of Vector Neural Network Instructions enabled processors
<b>CNR Flags</b>		
MKL_CBWR_STRICT	65536 or 0x10000	Strict CNR mode enabled. See <a href="#">Reproducibility Conditions</a> for more information.

When specifying the CNR branch with the named constants, be aware of the following:

- Reproducible results are provided under [Reproducibility Conditions](#).
- Settings other than MKL\_CBWR\_AUTO or MKL\_CBWR\_COMPATIBLE are available only for Intel processors.
- Intel and Intel compatible CPUs have a few instructions, such as approximation instructions rcpps/rsqrtps, that may return different results. Setting the branch to MKL\_CBWR\_COMPATIBLE ensures that Intel® oneAPI Math Kernel Library (oneMKL) does not use these instructions and forces a single Intel SSE2-only code path to be executed.

#### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

[Usage Examples for CNR Support Functions](#)

## Reproducibility Conditions

To get reproducible results from run to run, ensure that the number of threads is fixed and constant. Specifically:

- If you are running your program with OpenMP\* parallelization on different processors, explicitly specify the number of threads.
- To ensure that your application has deterministic behavior with OpenMP\* parallelization and does not adjust the number of threads dynamically at run time, set `MKL_DYNAMIC` and `OMP_DYNAMIC` to `FALSE`. This is especially needed if you are running your program on different systems.
- If you are running your program with the Intel® Threading Building Blocks parallelization, numerical reproducibility is not guaranteed.

## Strict CNR Mode

In strict CNR mode, oneAPI Math Kernel Library provides bitwise reproducible results for a limited set of functions and code branches even when the number of threads changes. These routines and branches support strict CNR mode (64-bit libraries only):

- `?gemm`, `?symm`, `?hemm`, `?trsm`, and their CBLAS equivalents (`cblas_?gemm`, `cblas_?symm`, `cblas_?hemm`, and `cblas_?trsm`).
- Intel® Advanced Vector Extensions 2 (Intel® AVX2) or Intel® Advanced Vector Extensions 512 (Intel® AVX-512).

When using other routines or CNR branches, oneAPI Math Kernel Library operates in standard (non-strict) CNR mode, subject to the restrictions described above. Enabling strict CNR mode can reduce performance.

### NOTE

- As usual, you should align your data, even in CNR mode, to obtain the best possible performance. While CNR mode also fully supports unaligned input and output data, the use of it might reduce the performance of some oneAPI Math Kernel Library functions on earlier Intel processors. To ensure proper alignment of arrays, allocate memory for them using `mkl_malloc/mkl_calloc`.
- Conditional Numerical Reproducibility does not ensure that bitwise-identical NaN values are generated when the input data contains NaN values.
- If dynamic memory allocation fails on one run but succeeds on another run, you may fail to get reproducible results between these two runs.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

## Usage Examples for CNR Support Functions

The following examples illustrate usage of support functions for conditional numerical reproducibility.

## Setting Automatically Detected CNR Branch

```
#include <mkl.h>
int main(void) {
    int my_cbwr_branch;
```

```
/* Find the available MKL_CBWR_BRANCH automatically */
my_cbwr_branch = mkl_cbwr_get_auto_branch();
/* User code without Intel MKL calls */
/* Piece of the code where CNR of Intel MKL is needed */
/* The performance of Intel MKL functions might be reduced for CNR mode */
if (mkl_cbwr_set(my_cbwr_branch)!=MKL_CBWR_SUCCESS) {
    printf("Error in setting MKL_CBWR_BRANCH! Aborting...\n");
    return;
}
/* CNR calls to Intel MKL + any other code */
}
```

## Use of the `mkl_cbwr_get` Function

```
#include <mkl.h>
int main(void) {
    int my_cbwr_branch;
    /* Piece of the code where CNR of Intel MKL is analyzed */
    my_cbwr_branch = mkl_cbwr_get(MKL_CBWR_BRANCH);
    switch (my_cbwr_branch) {
        case MKL_CBWR_AUTO:
            /* actions in case of automatic mode */
            break;
        case MKL_CBWR_SSSE3:
            /* actions for SSSE3 code */
            break;
        default:
            /* all other cases */
    }
    /* User code */
}
```

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Miscellaneous

### `mkl_progress`

*Provides progress information.*

#### Syntax

```
int mkl_progress (int* thread_process, int* step, char* stage, int lstage);
```

#### Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>thread_process</code>	<code>const int*</code>	Indicates the number of thread or process the progress routine is called from: <ul style="list-style-type: none"> <li>• The thread number for non-cluster components linked with OpenMP threading layer</li> <li>• Zero for non-cluster components linked with sequential threading layer</li> <li>• The process number (MPI rank) for cluster components</li> </ul>
<code>step</code>	<code>const int*</code>	Pointer to the linear progress indicator that shows the amount of work done. Increases from 0 to the linear size of the problem during the computation.
<code>stage</code>	<code>const char*</code>	Message indicating the name of the routine or the name of the computation stage the progress routine is called from.
<code>lstage</code>	<code>int</code>	The length of a stage string excluding the trailing NULL character.

## Description

The `mkl_progress` function is intended to track progress of a lengthy computation and/or interrupt the computation. By default this routine does nothing but the user application can redefine it to obtain the computation progress information. You can set it to perform certain operations during the routine computation, for instance, to print a progress indicator. A non-zero return value may be supplied by the redefined function to break the computation.

---

### NOTE

The user-defined `mkl_progress` function must be thread-safe.

---

Some Intel® oneAPI Math Kernel Library (oneMKL) functions from LAPACK, ScaLAPACK, DSS/PARDISO, and Parallel Direct Sparse Solver for Clusters regularly call the `mkl_progress` function during the computation. Refer to the description of a specific function from those domains to see whether the function supports this feature or not.

If a LAPACK function returns `info=-1002`, the function was interrupted by `mkl_progress`. Because ScaLAPACK does not support interruption of the computation, Intel® oneAPI Math Kernel Library (oneMKL) ignores any value returned by `mkl_progress`.

While a user-supplied `mkl_progress` function usually redefines the default `mkl_progress` function automatically, some configurations require calling the `mkl_set_progress` function to replace the default `mkl_progress` function. Call `mkl_set_progress` to replace the default `mkl_progress` on Windows\* in any of the following cases:

- You are using the Single Dynamic Library (SDL) `mkl_rt.lib`.
- You link dynamically with ScaLAPACK.

---

### Warning

The `mkl_progress` function supports OpenMP\*/TBB threading and sequential execution for specific routines.

---

## Return Values

Name	Type	Description
<code>stopflag</code>	<code>int</code>	The stopping flag. A non-zero flag forces the routine to be interrupted. The zero flag is the default return value.

## Example

The following example prints the progress information to the standard output device:

```
#include <stdio.h>
#include <string.h>
#define BUFLLEN 16
int mkl_progress( int* thread_process, int* step, char* stage, int lstage )
{
    char buf[BUFLLEN];
    if( lstage >= BUFLLEN ) lstage = BUFLLEN-1;
    strncpy( buf, stage, lstage );
    buf[lstage] = '\0';
    printf( "In thread %i, at stage %s, steps passed %i\n", *thread_process, buf, *step );
    return 0;
}
```

## mkl\_enable\_instructions

*Enables dispatching for new Intel® architectures or restricts the set of Intel® instruction sets available for dispatching. The `mkl_enable_instructions` function must be called only once, before any other Intel® oneAPI Math Kernel Library (oneMKL) functions.*

### Syntax

```
int mkl_enable_instructions (int isa);
```

### Input Parameters

Name	Type	Description
<code>isa</code>	<code>int</code>	The latest Intel® instruction-set architecture (ISA) for Intel® oneAPI Math Kernel Library (oneMKL) to dispatch.
<code>MKL_ENABLE_AVX512</code>		Intel® Advanced Vector Extensions 512 (Intel® AVX-512)
<code>MKL_ENABLE_AVX512_E1</code>		Intel® Advanced Vector Extensions 512 (Intel® AVX-512) with support for Intel® Deep Learning Boost (Intel® DL Boost).
<code>MKL_ENABLE_AVX512_E2</code>		Intel® Advanced Vector Extensions 512 (Intel® AVX-512) with support for Intel® Deep Learning Boost (Intel® DL Boost).

Name	Type	Description
		Boost), EVEX-encoded AES, and Carry-Less Multiplication Quadword instructions
MKL_ENABLE_AVX512_E3		Intel® Advanced Vector Extensions 512 (Intel® AVX-512) with support for Intel® Deep Learning Boost (Intel® DL Boost) and bfloat16
MKL_ENABLE_AVX512_E4		Intel® Advanced Vector Extensions 512 (Intel® AVX-512) with support for INT8, BF16, FP16 (limited) instructions, and Intel® Advanced Matrix Extensions (Intel® AMX) with INT8 and BF16
MKL_ENABLE_AVX512_E5		Intel® Advanced Vector Extensions 512 (Intel® AVX-512) with support for INT8, BF16, FP16 (limited) instructions, and Intel® Advanced Matrix Extensions (Intel® AMX) with INT8, BF16, and FP16
<b>NOTE</b> Not dispatched by default.		
MKL_ENABLE_AVX2		Intel® Advanced Vector Extensions 2 (Intel® AVX2)
MKL_ENABLE_AVX2_E1		Intel® Advanced Vector Extensions 2 (Intel® AVX2) with support for Intel® Deep Learning Boost (Intel® DL Boost)
MKL_ENABLE_SSE4_2		Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2)

## Description

Intel® oneAPI Math Kernel Library (oneMKL) does run-time processor dispatching to identify appropriate internal code paths to traverse for Intel® oneAPI Math Kernel Library (oneMKL) functions called by the application. The `mkl_enable_instructions` function controls the behavior of the dispatcher to do either of the following:

- Enable dispatching for new Intel architectures.

Intel® oneAPI Math Kernel Library (oneMKL) does not dispatch instruction sets that do not have silicon available at time of the product launch. Call `mkl_enable_instructions` to enable dispatching the code path for such an ISA in a simulator environment or on hardware that supports this ISA.

- Restrict the set of Intel instruction sets available for dispatching.

Call `mkl_enable_instructions` to restrict dispatching to code paths for earlier ISA. For example, if the hardware supports Intel AVX, a call to `mkl_enable_instructions` with the `MKL_ENABLE_SSE4_2` parameter forces the dispatcher to use the Intel SSE4-2 code path.

If the system does not support the instruction set specified by the `isa` parameter or if the system is based on a non-Intel architecture, `mkl_enable_instructions` does nothing and returns zero.

Settings specified by the `mkl_enable_instructions` function set an upper limit to settings specified by the `mkl_cbwr_set` function.

You can use the `MKL_ENABLE_INSTRUCTIONS` environment variable instead of calling `mkl_enable_instructions` (for more details, see the [Intel® oneAPI Math Kernel Library \(oneMKL\) Developer Guide](#)); however, the settings specified by the function take precedence over the settings specified by the environment variable.

## Return Values

Name	Type	Description
<code>irc</code>	<code>int</code>	Function completion status:  1 - Intel® oneAPI Math Kernel Library (oneMKL) dispatches the code path for the specified ISA by default.  0 - The request is rejected. Usually this occurs if <code>mkl_enable_instructions</code> was called: <ul style="list-style-type: none"><li>• After another Intel® oneAPI Math Kernel Library (oneMKL) function</li><li>• On a non-Intel architecture</li><li>• With an incompatible ISA specified</li></ul>

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## `mkl_set_env_mode`

*Sets up the mode that ignores environment settings specific to Intel® oneAPI Math Kernel Library (oneMKL).*

### Syntax

```
int mkl_set_env_mode(int mode);
```

### Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>mode</code>	<code>int</code>	Specifies what mode to set. For details, see <a href="#">Description</a> . Possible values: <ul style="list-style-type: none"> <li>0 - Do nothing.</li> <li>Use this value to query the current environment mode.</li> <li>1 - Make Intel® oneAPI Math Kernel Library (oneMKL) ignore environment settings specific to the library.</li> </ul>

## Description

In the default *environment mode*, Intel® oneAPI Math Kernel Library (oneMKL) can control its behavior using environment variables for threading, memory management, Conditional Numerical Reproducibility, automatic offload, and so on. The `mkl_set_env_mode` function sets up the environment mode that ignores all settings specified by Intel® oneAPI Math Kernel Library (oneMKL) environment variables except `MIC_LD_LIBRARY_PATH` and `MKLROOT`.

## Return Values

Name	Type	Description
<code>current_mode</code>	<code>int</code>	Environment mode that was used before the function call: <ul style="list-style-type: none"> <li>0 - Default</li> <li>1 - Ignore environment settings specific to Intel® oneAPI Math Kernel Library (oneMKL).</li> </ul>

## `mkl_verbose`

*Enables or disables Intel® oneAPI Math Kernel Library (oneMKL) Verbose mode.*

## Syntax

```
int mkl_verbose (int enable);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>enable</code>	<code>int</code>	Desired state of the Intel® oneAPI Math Kernel Library (oneMKL) Verbose mode. Indicates whether printing Intel® oneAPI Math Kernel Library (oneMKL) function call information should be turned on or off. Possible values: <ul style="list-style-type: none"> <li>0 – disable the Verbose mode</li> <li>1 – enable the Verbose mode (GPU application: enable the Verbose mode without timing)</li> <li>2 – enable the Verbose mode (GPU application: enable the Verbose mode with synchronous timing)</li> </ul>

## Description

This function enables or disables the Intel® oneAPI Math Kernel Library (oneMKL) Verbose mode, in which computational functions print call description information. For details of the Verbose mode, see the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*, available in the Intel® Software Documentation Library.

### NOTE

The setting for the Verbose mode specified by the `mkl_verbose` function takes precedence over the setting specified by the `MKL_VERBOSE` environment variable.

## Return Values

Name	Type	Description
<code>status</code>	<code>int</code>	<ul style="list-style-type: none"> <li>If the requested operation completed successfully, contains previous state of the verbose mode: <ul style="list-style-type: none"> <li>0 – Verbose mode was disabled</li> <li>1 – Verbose mode was enabled (GPU application: Verbose mode was enabled without timing)</li> <li>2 – Verbose mode was enabled (GPU application: Verbose mode was enabled with synchronous timing)</li> </ul> </li> <li>If the function failed to complete the operation because of an incorrect input parameter, equals -1.</li> </ul>

### `mkl_verbose_output_file`

*Write output in Intel® oneAPI Math Kernel Library (oneMKL) Verbose mode to a file.*

## Syntax

```
int mkl_verbose_output_file (const char*filename);
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>filename</code>	<code>char</code>	Name of file. Specify the complete path of the output file.

## Description

This function writes the output in Verbose mode to the file specified in the path.

If the write operation is successful, the function returns 0.

If the file does not exist or cannot be opened, the write operation is unsuccessful. The function returns 1 and defaults to `mkl_verbose` behavior by printing to `stdout`.

**NOTE**

You can alternatively use `MKL_VERBOSE_OUTPUT_FILE` environment variable instead of calling the `mkl_verbose_output_file` function. If you want to use the environment variable option, you must set it to the complete path of the output file.

---

**Important** The setting for the verbose output file specified by the `mkl_verbose_output_file` function takes precedence over the setting specified by the `MKL_VERBOSE_OUTPUT_FILE` environment variable.

---

For more information on the Verbose mode, see the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*, available in the Intel® Software Documentation Library.

---

**Return Values**

Name	Type	Description
<code>status</code>	<code>int</code>	<ul style="list-style-type: none"> <li>0 indicates that the write operation was successful.</li> <li>1 indicates that the write operation was unsuccessful.</li> </ul>

**See Also**

[Intel Software Documentation Library](#)

**mkl\_set\_mpi**

*Sets the implementation of the message-passing interface to be used by Intel® oneAPI Math Kernel Library (oneMKL).*

---

**Syntax**

```
int mkl_set_mpi (int vendor, const char *custom_library_name);
```

**Include Files**

- `mkl.h`

**Input Parameters**

Name	Type	Description
<code>vendor</code>	<code>int</code>	<p>Specifies the implementation of the message-passing interface (MPI) to use:</p> <p>Possible values:</p> <ul style="list-style-type: none"> <li>• <code>MKL_BLACS_CUSTOM</code> - a custom MPI library. Requires a prebuilt custom MPI BLACS library.</li> <li>• <code>MKL_BLACS_MSMPPI</code> - Microsoft MPI library.</li> <li>• <code>MKL_BLACS_INTELMPI</code> - Intel® MPI library.</li> <li>• <code>MKL_BLACS_MPICH</code> - MPICH MPI library.</li> </ul>

Name	Type	Description
<code>custom_library_name</code>	<code>const char *</code>	The filename (without a directory name) of the custom BLACS dynamic library to use. This library must be located in the directory with your application executable or with Intel® oneAPI Math Kernel Library (oneMKL) dynamic libraries. Can be <code>NULL</code> or an empty string.

## Description

Call this function to set the MPI implementation to be used by Intel® oneAPI Math Kernel Library (oneMKL) on Windows\* OS when dynamic Intel® oneAPI Math Kernel Library (oneMKL) libraries are used. For all other configurations, the function returns an error indicating that you cannot set the MPI implementation. You can specify your own prebuilt dynamic BLACS library for a custom MPI by setting `vendor` to `MKL_BLACS_CUSTOM` and optionally passing the name of the custom BLACS dynamic library. If the `custom_library_path` parameter is `NULL` or an empty string, Intel® oneAPI Math Kernel Library (oneMKL) uses the default platform-specific library name: `mkl_blacs_custom_lp64.dll` or `mkl_blacs_custom_ilp64.dll`, depending on whether the BLACS interface linked against your application is LP64 or ILP64.

## Return Values

Name	Type	Description
<code>status</code>	<code>int</code>	The return status: <ul style="list-style-type: none"> <li>• 0 - The function completed successfully.</li> <li>• -1 - The <code>vendor</code> parameter is invalid.</li> <li>• -2 - The <code>custom_library_name</code> parameter is invalid.</li> <li>• -3 - The MPI library cannot be set at this point.</li> </ul>

Notice revision #20201201

## mkl\_finalize

*Terminates Intel® oneAPI Math Kernel Library (oneMKL) execution environment and frees resources allocated by the library.*

### Syntax

```
void mkl_finalize(void);
```

### Include Files

- `mkl.h`

### Description

This function frees resources allocated by Intel® oneAPI Math Kernel Library (oneMKL). Once this function is called, the application can no longer call Intel® oneAPI Math Kernel Library (oneMKL) functions other than `mkl_finalize`.

In particular, the `mkl_finalize` function enables you to free resources when a third-party shared library is statically linked to Intel® oneAPI Math Kernel Library (oneMKL). To avoid resource leaks that may happen when a shared library is loaded and unloaded multiple times, call `mkl_finalize` each time the library is unloaded. The recommended method to do this depends on the operating system:

- On Linux\* or macOS\*, place the call into a shared library destructor.
- On Windows\*, call `mkl_finalize` from the `DLL_PROCESS_DETACH` handler of `DllMain`.

---

**NOTE**

Intel® oneAPI Math Kernel Library (oneMKL) shared libraries automatically perform finalization when they are unloaded. If an application is statically linked to Intel® oneAPI Math Kernel Library (oneMKL), the operating system frees all resources allocated by Intel® oneAPI Math Kernel Library (oneMKL) during termination of the process associated with the application.

---

## BLACS Routines

---

Intel® oneAPI Math Kernel Library implements FORTRAN 77 routines from the BLACS (Basic Linear Algebra Communication Subprograms) package. These routines are used to support a linear algebra oriented message passing interface that may be implemented efficiently and uniformly across a large range of distributed memory platforms.

The BLACS routines make linear algebra applications both easier to program and more portable. For this purpose, they are used in Intel® oneAPI Math Kernel Library (oneMKL) intended for the Linux\* and Windows\* OSs as the communication layer of ScaLAPACK and Cluster FFT.

On computers, a linear algebra matrix is represented by a two dimensional array (2D array), and therefore the BLACS operate on 2D arrays. See description of the basic [matrix shapes](#) in a special topic.

The BLACS routines implemented in Intel® oneAPI Math Kernel Library (oneMKL) are of four categories:

- Combines
- Point to Point Communication
- Broadcast
- Support.

The [Combines](#) take data distributed over processes and combine the data to produce a result. The [Point to Point](#) routines are intended for point-to-point communication and [Broadcast](#) routines send data possessed by one process to all processes within a scope.

The [Support routines](#) perform distinct tasks that can be used for initialization, destruction, information, and miscellaneous tasks.

Notice revision #20201201

## Matrix Shapes

The BLACS routines recognize the two most common classes of matrices for dense linear algebra. The first of these classes consists of general rectangular matrices, which in machine storage are 2D arrays consisting of  $m$  rows and  $n$  columns, with a leading dimension,  $lda$ , that determines the distance between successive columns in memory.

The *general rectangular* matrices take the following parameters as input when determining what array to operate on:

*m* (input) INTEGER. The number of matrix rows to be operated on.

*n* (input) INTEGER. The number of matrix columns to be operated on.

*a* (input/output) TYPE (depends on routine), array of dimension  $(lda, n)$ .  
A pointer to the beginning of the (sub)array to be sent.

*lda* (input) INTEGER. The distance between two elements in matrix row.

The second class of matrices recognized by the BLACS are *trapezoidal* matrices (triangular matrices are a sub-class of trapezoidal). Trapezoidal arrays are defined by *m*, *n*, and *lda*, as above, but they have two additional parameters as well. These parameters are:

*uplo* (input) CHARACTER\*1 . Indicates whether the matrix is upper or lower trapezoidal, as discussed below.

*diag* (input) CHARACTER\*1 . Indicates whether the diagonal of the matrix is unit diagonal (will not be operated on) or otherwise (will be operated on).

The shape of the trapezoidal arrays is determined by these parameters as follows:

\_\_border\_\_top

**Trapezoidal Arrays Shapes**

<i>uplo</i>	$m \leq n$	$m > n$
"U"		
"L"		

The packing of arrays, if required, so that they may be sent efficiently is hidden, allowing the user to concentrate on the logical matrix, rather than on how the data is organized in the system memory.

## Repeatability and Coherence

Floating point computations are not exact on almost all modern architectures. This lack of precision is particularly problematic in parallel operations. Since floating point computations are inexact, algorithms are classified according to whether they are *repeatable* and to what degree they guarantee *coherence*.

- Repeatable: a routine is repeatable if it is guaranteed to give the same answer if called multiple times with the same parallel configuration and input.
- Coherent: a routine is coherent if all processes selected to receive the answer get identical results.

---

### NOTE

Repeatability and coherence do not effect correctness. A routine may be both incoherent and non-repeatable, and still give correct output. But inaccuracies in floating point calculations may cause the routine to return differing values, all of which are equally valid.

---

## Repeatability

Because the precision of floating point arithmetic is limited, it is not truly associative:  $(a + b) + c$  might not be the same as  $a + (b + c)$ . The lack of exact arithmetic can cause problems whenever the possibility for reordering of floating point calculations exists. This problem becomes prevalent in parallel computing due to race conditions in message passing. For example, consider a routine which sums numbers stored on different processes. Assume this routine runs on four processes, with the numbers to be added being the process numbers themselves. Therefore, process 0 has the value 0:0, process 1 has the value 1:0, and so on.

One algorithm for the computation of this result is to have all processes send their process numbers to process 0; process 0 adds them up, and sends the result back to all processes. So, process 0 would add a number to 0:0 in the first step. If receiving the process numbers is ordered so that process 0 always receives the message from process 1 first, then 2, and finally 3, this results in a repeatable algorithm, which evaluates the expression  $((0:0 + 1:0) + 2:0) + 3:0$ .

However, to get the best parallel performance, it is better not to require a particular ordering, and just have process 0 add the first available number to its value and continue to do so until all numbers have been added in. Using this method, a race condition occurs, because the order of the operation is determined by the order in which process 0 receives the messages, which can be effected by any number of things. This implementation is not repeatable, because the answer can vary between invocations, even if the input is the same. For instance, one run might produce the sequence  $((0:0 + 1:0) + 2:0) + 3:0$ , while a subsequent run could produce  $((0:0 + 2:0) + 1:0) + 3:0$ . Both of these results are correct summations of the given numbers, but because of floating point roundoff, they might be different.

## Coherence

A routine produces coherent output if all processes are guaranteed to produce the exact same results. Obviously, almost no algorithm involving communication is coherent if communication can change the values being communicated. Therefore, if the parallel system being studied cannot guarantee that communication between processes preserves values, no routine is guaranteed to produce coherent results.

If communication is assumed to be coherent, there are still various levels of coherent algorithms. Some algorithms guarantee coherence only if floating point operations are done in the exact same order on every node. This is *homogeneous coherence*: the result will be coherent if the parallel machine is homogeneous in its handling of floating point operations.

A stronger assertion of coherence is *heterogeneous coherence*, which does not require all processes to have the same handling of floating point operations.

In general, a routine that is homogeneous coherent performs computations redundantly on all nodes, so that all processes get the same answer only if all processes perform arithmetic in the exact same way, whereas a routine which is heterogeneous coherent is usually constrained to having one process calculate the final result, and broadcast it to all other processes.

## Example of Incoherence

An incoherent algorithm is one which does not guarantee that all processes get the same result even on a homogeneous system with coherent communication. The previous example of summing the process numbers demonstrates this kind of behavior. One way to perform such a sum is to have every process broadcast its number to all other processes. Each process then adds these numbers, starting with its own. The calculations performed by each process receives would then be:

- Process 0 :  $((0:0 + 1:0) + 2:0) + 3:0$
- Process 1 :  $((1:0 + 2:0) + 3:0) + 0:0$
- Process 2 :  $((2:0 + 3:0) + 0:0) + 1:0$
- Process 3 :  $((3:0 + 0:0) + 1:0) + 0:0$

All of these results are equally valid, and since all the results might be different from each other, this algorithm is incoherent. Notice, however, that this algorithm is repeatable: each process will get the same result if the algorithm is called again on the same data.

## Example of Homogeneous Coherence

Another way to perform this summation is for all processes to send their data to all other processes, and to ensure the result is not incoherent, enforce the ordering so that the calculation each node performs is  $((0:0 + 1:0) + 2:0) + 3:0$ . This answer is the same for all processes only if all processes do the floating point arithmetic in the same way. Otherwise, each process may make different floating point errors during the addition, leading to incoherence of the output. Notice that since there is a specific ordering to the addition, this algorithm is repeatable.

## Example of Heterogeneous Coherence

In the final example, all processes send the result to process 0, which adds the numbers and broadcasts the result to the rest of the processes. Since one process does all the computation, it can perform the operations in any order and it will give coherent results as long as communication is itself coherent. If a particular order is not forced on the the addition, the algorithm will not be repeatable. If a particular order is forced, it will be repeatable.

## Summary

Repeatability and coherence are separate issues which may occur in parallel computations. These concepts may be summarized as:

- Repeatability: The routine will yield the exact same result if it run multiple times on an identical problem. Each process may get a different result than the others (i.e., repeatability does not imply coherence), but that value will not change if the routine is invoked multiple times.
- Homogeneous coherence: All processes selected to possess the result will receive the exact same answer if:
  - Communication does not change the value of the communicated data.
  - All processes perform floating point arithmetic exactly the same.
- Heterogeneous coherence: All processes will receive the exact same answer if communication does not change the value of the communicated data.

In general, lack of the associative property for floating point calculations may cause both incoherence and non-repeatability. Algorithms that rely on redundant computations are at best homogeneous coherent, and algorithms in which one process broadcasts the result are heterogeneous coherent. Repeatability does not imply coherence, nor does coherence imply repeatability.

Since these issues do not effect the correctness of the answer, they can usually be ignored. However, in very specific situations, these issues may become very important. A stopping criteria should not be based on incoherent results, for instance. Also, a user creating and debugging a parallel program may wish to enforce repeatability so the exact same program sequence occurs on every run.

In the BLACS, coherence and repeatability apply only in the context of the combine operations. As mentioned above, it is possible to have communication which is incoherent (for instance, two machines which store floating point numbers differently may easily produce incoherent communication, since a number stored on machine A may not have a representation on machine B). However, the BLACS cannot control this issue. Communication is assumed to be coherent, which for communication implies that it is also repeatable.

For combine operations, the BLACS allow you to set flags indicating that you would like combines to be repeatable and/or heterogeneous coherent (see `blacs_get` and `blacs_set` for details on setting these flags).

If the BLACS are instructed to guarantee heterogeneous coherency, the BLACS restrict the topologies which can be used so that one process calculates the final result of the combine, and if necessary, broadcasts the answer to all other processes.

If the BLACS are instructed to guarantee repeatability, orderings will be enforced in the topologies which are selected. This may result in loss of performance which can range from negligible to serious depending on the application.

A couple of additional notes are in order. Incoherence and nonrepeatability can arise as a result of floating point errors, as discussed previously. This might lead you to suspect that integer calculations are always repeatable and coherent, since they involve exact arithmetic. This is true if overflow is ignored. With overflow taken into consideration, even integer calculations can display incoherence and non-repeatability. Therefore, if the repeatability or coherence flags are set, the BLACS treats integer combines the same as floating point combines in enforcing repeatability and coherence guards.

By their nature, maximization and minimization should always be repeatable. In the complex precisions, however, the real and imaginary parts must be combined in order to obtain a magnitude value used to do the comparison (this is typically  $|r| + |i|$  or  $\text{sqr}(r^2 + i^2)$ ). This allows for the possibility of heterogeneous incoherence. The BLACS therefore restrict which topologies are used for maximization and minimization in the complex routines when the heterogeneous coherence flag is set.

## BLACS Combine Operations

This topic describes BLACS routines that combine the data to produce a result.

In a combine operation, each participating process contributes data that is combined with other processes' data to produce a result. This result can be given to a particular process (called the *destination* process), or to all participating processes. If the result is given to only one process, the operation is referred to as a *leave-on-one* combine, and if the result is given to all participating processes the operation is referenced as a *leave-on-all* combine.

At present, three kinds of combines are supported. They are:

- element-wise summation
- element-wise absolute value maximization
- element-wise absolute value minimization

of general rectangular arrays.

Note that a combine operation combines data between processes. By definition, a combine performed across a scope of only one process does not change the input data. This is why the operations (`max/min/sum`) are specified as *element-wise*. Element-wise indicates that each element of the input array will be combined with the corresponding element from all other processes' arrays to produce the result. Thus, a 4 x 2 array of inputs produces a 4 x 2 answer array.

When the `max/min` comparison is being performed, absolute value is used. For example, -5 and 5 are equivalent. However, the returned value is unchanged; that is, it is not the absolute value, but is a signed value instead. Therefore, if you performed a BLACS absolute value maximum combine on the numbers -5, 3, 1, 8 the result would be -8.

The initial symbol ? in the routine names below masks the data type:

i	integer
s	single precision real
d	double precision real
c	single precision complex
z	double precision complex.

## BLACS Combines

Routine name	Results of operation
<a href="#">gamx2d</a>	Entries of result matrix will have the value of the greatest absolute value found in that position.
<a href="#">gamn2d</a>	Entries of result matrix will have the value of the smallest absolute value found in that position.
<a href="#">gsum2d</a>	Entries of result matrix will have the summation of that position.

### ?gamx2d

*Performs element-wise absolute value maximization.*

### Syntax

```
call igamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rflag, rdest, cdest )
call sgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rflag, rdest, cdest )
call dgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rflag, rdest, cdest )
call cgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rflag, rdest, cdest )
call zgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rflag, rdest, cdest )
```

### Input Parameters

<code>icontxt</code>	INTEGER. Integer handle that indicates the context.
<code>scope</code>	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
<code>top</code>	CHARACTER*1. Communication pattern to use during the combine operation.
<code>m</code>	INTEGER. The number of matrix rows to be combined.
<code>n</code>	INTEGER. The number of matrix columns to be combined.

<i>a</i>	TYPE array ( <i>lda</i> , <i>n</i> ). Matrix to be compared with to produce the maximum.
<i>lda</i>	INTEGER. The leading dimension of the matrix <i>A</i> , that is, the distance between two successive elements in a matrix row.
<i>rcflag</i>	INTEGER.  If <i>rcflag</i> = -1, the arrays <i>ra</i> and <i>ca</i> are not referenced and need not exist. Otherwise, <i>rcflag</i> indicates the leading dimension of these arrays, and so must be $\geq m$ .
<i>rdest</i>	INTEGER.  The process row coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.
<i>cdest</i>	INTEGER.  The process column coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.

## Output Parameters

<i>a</i>	TYPE array ( <i>lda</i> , <i>n</i> ). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.
<i>ra</i>	INTEGER array ( <i>rcflag</i> , <i>n</i> ).  If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> × <i>n</i> ) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.
<i>ca</i>	INTEGER array ( <i>rcflag</i> , <i>n</i> ).  If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> × <i>n</i> ) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

## Description

This routine performs element-wise absolute value maximization, that is, each element of matrix *A* is compared with the corresponding element of the other process's matrices. Note that the value of *A* is returned, but the absolute value is used to determine the maximum (the 1-norm is used for complex numbers). Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

## See Also

## ?gamn2d

Performs element-wise absolute value minimization.

### Syntax

```
call igamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call sgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call dgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call cgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call zgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
```

### Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
<i>top</i>	CHARACTER*1. Communication pattern to use during the combine operation.
<i>m</i>	INTEGER. The number of matrix rows to be combined.
<i>n</i>	INTEGER. The number of matrix columns to be combined.
<i>a</i>	TYPE array ( <i>lda</i> , <i>n</i> ). Matrix to be compared with to produce the minimum.
<i>lda</i>	INTEGER. The leading dimension of the matrix <i>A</i> , that is, the distance between two successive elements in a matrix row.
<i>rcflag</i>	INTEGER. If <i>rcflag</i> = -1, the arrays <i>ra</i> and <i>ca</i> are not referenced and need not exist. Otherwise, <i>rcflag</i> indicates the leading dimension of these arrays, and so must be $\geq m$ .
<i>rdest</i>	INTEGER. The process row coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.
<i>cdest</i>	INTEGER. The process column coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.

### Output Parameters

<i>a</i>	TYPE array ( <i>lda</i> , <i>n</i> ). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.
<i>ra</i>	INTEGER array ( <i>rcflag</i> , <i>n</i> ).

If  $rcflag = -1$ , this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least  $rcflag \times n$ ) indicating the row index of the process that provided the minimum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

*ca*

INTEGER array ( $rcflag, n$ ).

If  $rcflag = -1$ , this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least  $rcflag \times n$ ) indicating the row index of the process that provided the minimum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

## Description

This routine performs element-wise absolute value minimization, that is, each element of matrix  $A$  is compared with the corresponding element of the other process's matrices. Note that the value of  $A$  is returned, but the absolute value is used to determine the minimum (the 1-norm is used for complex numbers). Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

## See Also

[Examples of BLACS Routines Usage](#)

## ?gsum2d

*Performs element-wise summation.*

## Syntax

```
call igsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
```

```
call sgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
```

```
call dgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
```

```
call cgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
```

```
call zgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
```

## Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
<i>top</i>	CHARACTER*1. Communication pattern to use during the combine operation.
<i>m</i>	INTEGER. The number of matrix rows to be combined.
<i>n</i>	INTEGER. The number of matrix columns to be combined.
<i>a</i>	TYPE array ( $lda, n$ ). Matrix to be added to produce the sum.
<i>lda</i>	INTEGER. The leading dimension of the matrix $A$ , that is, the distance between two successive elements in a matrix row.

*rdest*

INTEGER.

The process row coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.

*cdest*

INTEGER.

The process column coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.

## Output Parameters

*a*

TYPE array (*lda*, *n*). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.

## Description

This routine performs element-wise summation, that is, each element of matrix *A* is summed with the corresponding element of the other process's matrices. Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

[Examples of BLACS Routines Usage](#)

## BLACS Point To Point Communication

This topic describes BLACS routines for point to point communication.

Point to point communication requires two complementary operations. The *send* operation produces a message that is then consumed by the *receive* operation. These operations have various resources associated with them. The main such resource is the buffer that holds the data to be sent or serves as the area where the incoming data is to be received. The level of *blocking* indicates what correlation the return from a send/receive operation has with the availability of these resources and with the status of message.

## Non-blocking

The return from the *send* or *receive* operations does not imply that the resources may be reused, that the message has been sent/received or that the complementary operation has been called. Return means only that the send/receive has been started, and will be completed at some later date. Polling is required to determine when the operation has finished.

In non-blocking message passing, the concept of *communication/computation overlap* (abbreviated C/C overlap) is important. If a system possesses C/C overlap, independent computation can occur at the same time as communication. That means a nonblocking operation can be posted, and unrelated work can be done while the message is sent/received in parallel. If C/C overlap is not present, after returning from the routine call, computation will be interrupted at some later date when the message is actually sent or received.

## Locally-blocking

Return from the *send* or *receive* operations indicates that the resources may be reused. However, since this only depends on local information, it is unknown whether the complementary operation has been called. There are no locally-blocking receives: the send must be completed before the receive buffer is available for re-use.

If a receive has not been posted at the time a locally-blocking send is issued, buffering will be required to avoid losing the message. Buffering can be done on the sending process, the receiving process, or not done at all, losing the message.

## Globally-blocking

Return from a globally-blocking procedure indicates that the operation resources may be reused, and that complement of the operation has at least been posted. Since the receive has been posted, there is no buffering required for globally-blocking sends: the message is always sent directly into the user's receive buffer.

Almost all processors support non-blocking communication, as well as some other level of blocking sends. What level of blocking the send possesses varies between platforms. For instance, the Intel® processors support locally-blocking sends, with buffering done on the receiving process. This is a very important distinction, because codes written assuming locally-blocking sends will hang on platforms with globally-blocking sends. Below is a simple example of how this can occur:

```
IAM = MY_PROCESS_ID()
IF (IAM .EQ. 0) THEN
  SEND TO PROCESS 1
  RECV FROM PROCESS 1
ELSE IF (IAM .EQ. 1) THEN
  SEND TO PROCESS 0
  RECV FROM PROCESS 0
END IF
```

If the send is globally-blocking, process 0 enters the send, and waits for process 1 to start its receive before continuing. In the meantime, process 1 starts to send to 0, and waits for 0 to receive before continuing. Both processes are now waiting on each other, and the program will never continue.

The solution for this case is obvious. One of the processes simply reverses the order of its communication calls and the hang is avoided. However, when the communication is not just between two processes, but rather involves a hierarchy of processes, determining how to avoid this kind of difficulty can become problematic.

For this reason, it was decided the BLACS would support locally-blocking sends. On systems natively supporting globally-blocking sends, non-blocking sends coupled with buffering is used to simulate locally-blocking sends. The BLACS support globally-blocking receives.

In addition, the BLACS specify that point to point messages between two given processes will be strictly ordered. If process 0 sends three messages (label them *A*, *B*, and *C*) to process 1, process 1 must receive *A* before it can receive *B*, and message *C* can be received only after both *A* and *B*. The main reason for this restriction is that it allows for the computation of message identifiers.

Note, however, that messages from different processes are not ordered. If processes 0, . . . , 3 send messages *A*, . . . , *D* to process 4, process 4 may receive these messages in any order that is convenient.

## Convention

The convention used in the communication routine names follows the template  $?_{xx}yy2d$ , where the letter in the ? position indicates the data type being sent, *xx* is replaced to indicate the shape of the matrix, and the *yy* positions are used to indicate the type of communication to perform:

i	integer
s	single precision real
d	double precision real
c	single precision complex

z	double precision complex
ge	The data to be communicated is stored in a general rectangular matrix.
tr	The data to be communicated is stored in a trapezoidal matrix.
sd	Send. One process sends to another.
rv	Receive. One process receives from another.

### BLACS Point To Point Communication

Routine name	Operation performed
<a href="#">gesd2d</a>	Take the indicated matrix and send it to the destination process.
<a href="#">trsd2d</a>	
<a href="#">gerv2d</a>	Receive a message from the process into the matrix.
<a href="#">trrv2d</a>	

As a simple example, the pseudo code given above is rewritten below in terms of the BLACS. It is further specified that the data being exchanged is the double precision vector  $X$ , which is 5 elements long.

```
CALL GRIDINFO(NPROW, NPCOL, MYPROW, MYPCOL)

IF (MYPROW.EQ.0 .AND. MYPCOL.EQ.0) THEN
  CALL DGESD2D(5, 1, X, 5, 1, 0)
  CALL DGERV2D(5, 1, X, 5, 1, 0)
ELSE IF (MYPROW.EQ.1 .AND. MYPCOL.EQ.0) THEN
  CALL DGESD2D(5, 1, X, 5, 0, 0)
  CALL DGERV2D(5, 1, X, 5, 0, 0)
END IF
```

### [?gesd2d](#)

*Takes a general rectangular matrix and sends it to the destination process.*

### Syntax

```
call igesd2d( icontxt, m, n, a, lda, rdest, cdest )
call sgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call dgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call cgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call zgesd2d( icontxt, m, n, a, lda, rdest, cdest )
```

### Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>m, n, a, lda</i>	Describe the matrix to be sent. See <a href="#">Matrix Shapes</a> for details.
<i>rdest</i>	INTEGER. The process row coordinate of the process to send the message to.
<i>cdest</i>	INTEGER. The process column coordinate of the process to send the message to.

## Description

This routine takes the indicated general rectangular matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix A) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

## See Also

[Examples of BLACS Routines Usage](#)

### ?trsd2d

*Takes a trapezoidal matrix and sends it to the destination process.*

## Syntax

```
call itrtd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call strtd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call dtrtd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call ctrtd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call ztrtd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
```

## Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>uplo, diag, m, n, a, lda</i>	Describe the matrix to be sent. See <a href="#">Matrix Shapes</a> for details.
<i>rdest</i>	INTEGER. The process row coordinate of the process to send the message to.
<i>cdest</i>	INTEGER. The process column coordinate of the process to send the message to.

## Description

This routine takes the indicated trapezoidal matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix A) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

### ?gerv2d

*Receives a message from the process into the general rectangular matrix.*

## Syntax

```
call igerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call sgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call dgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call cgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call zgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
```

## Input Parameters

<code>icontxt</code>	INTEGER. Integer handle that indicates the context.
<code>m, n, lda</code>	Describe the matrix to be sent. See <a href="#">Matrix Shapes</a> for details.
<code>rsrc</code>	INTEGER. The process row coordinate of the source of the message.
<code>csrc</code>	INTEGER. The process column coordinate of the source of the message.

## Output Parameters

<code>a</code>	An array of dimension $(lda, n)$ to receive the incoming message into.
----------------	--

## Description

This routine receives a message from process {RSRC, CSRC} into the general rectangular matrix *A*. This routine is globally-blocking, that is, return from the routine indicates that the message has been received into *A*.

## See Also

[Examples of BLACS Routines Usage](#)

## ?trrv2d

*Receives a message from the process into the trapezoidal matrix.*

## Syntax

```
call itrsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call strsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call dtrsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call ctrsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call ztrsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
```

## Input Parameters

<code>icontxt</code>	INTEGER. Integer handle that indicates the context.
<code>uplo, diag, m, n, lda</code>	Describe the matrix to be sent. See <a href="#">Matrix Shapes</a> for details.
<code>rsrc</code>	INTEGER. The process row coordinate of the source of the message.
<code>csrc</code>	INTEGER. The process column coordinate of the source of the message.

## Output Parameters

<code>a</code>	An array of dimension $(lda, n)$ to receive the incoming message into.
----------------	--

## Description

This routine receives a message from process {RSRC, CSRC} into the trapezoidal matrix  $A$ . This routine is globally-blocking, that is, return from the routine indicates that the message has been received into  $A$ .

## BLACS Broadcast Routines

This topic describes BLACS broadcast routines.

A broadcast sends data possessed by one process to all processes within a scope. Broadcast, much like point to point communication, has two complementary operations. The process that owns the data to be broadcast issues a *broadcast/send*. All processes within the same scope must then issue the complementary *broadcast/receive*.

The BLACS define that both broadcast/send and broadcast/receive are *globally-blocking*. Broadcasts/receives cannot be locally-blocking since they must post a receive. Note that receives cannot be locally-blocking. When a given process can leave, a broadcast/receive operation is topology dependent, so, to avoid a hang as topology is varied, the broadcast/receive must be treated as if no process can leave until all processes have called the operation.

Broadcast/sends could be defined to be *locally-blocking*. Since no information is being received, as long as locally-blocking point to point sends are used, the broadcast/send will be locally blocking. However, defining one process within a scope to be locally-blocking while all other processes are globally-blocking adds little to the programmability of the code. On the other hand, leaving the option open to have globally-blocking broadcast/sends may allow for optimization on some platforms.

The fact that broadcasts are defined as globally-blocking has several important implications. The first is that scoped operations (broadcasts or combines) must be strictly ordered, that is, all processes within a scope must agree on the order of calls to separate scoped operations. This constraint falls in line with that already in place for the computation of message IDs, and is present in point to point communication as well.

A less obvious result is that scoped operations with `SCOPE = 'ALL'` must be ordered with respect to any other scoped operation. This means that if there are two broadcasts to be done, one along a column, and one involving the entire process grid, all processes within the process column issuing the column broadcast must agree on which broadcast will be performed first.

The convention used in the communication routine names follows the template `?xxyy2d`, where the letter in the `?` position indicates the data type being sent, `xx` is replaced to indicate the shape of the matrix, and the `yy` positions are used to indicate the type of communication to perform:

i	integer
s	single precision real
d	double precision real
c	single precision complex
z	double precision complex
ge	The data to be communicated is stored in a general rectangular matrix.
tr	The data to be communicated is stored in a trapezoidal matrix.
bs	Broadcast/send. A process begins the broadcast of data within a scope.
br	Broadcast/receive A process receives and participates in the broadcast of data within a scope.

## BLACS Broadcast Routines

Routine name	Operation performed
<code>gebs2d</code>	Start a broadcast along a scope.

Routine name	Operation performed
<a href="#">trbs2d</a>	
<a href="#">gebr2d</a>	Receive and participate in a broadcast along a scope.
<a href="#">trbr2d</a>	

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

### ?gebs2d

*Starts a broadcast along a scope for a general rectangular matrix.*

### Syntax

```
call igebs2d( icontxt, scope, top, m, n, a, lda )
call sgebs2d( icontxt, scope, top, m, n, a, lda )
call dgebs2d( icontxt, scope, top, m, n, a, lda )
call cgebs2d( icontxt, scope, top, m, n, a, lda )
call zgebs2d( icontxt, scope, top, m, n, a, lda )
```

### Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>m, n, a, lda</i>	Describe the matrix to be sent. See <a href="#">Matrix Shapes</a> for details.

### Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix *A*.

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

### ?trbs2d

*Starts a broadcast along a scope for a trapezoidal matrix.*

### Syntax

```
call itrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
```

```
call strbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call dtrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call ctrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call ztrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
```

## Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>uplo, diag, m, n, a, lda</i>	Describe the matrix to be sent. See <a href="#">Matrix Shapes</a> for details.

## Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix A.

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

## ?gebr2d

*Receives and participates in a broadcast along a scope for a general rectangular matrix.*

## Syntax

```
call igebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call sgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call dgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call cgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call zgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
```

## Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>m, n, lda</i>	Describe the matrix to be sent. See <a href="#">Matrix Shapes</a> for details.
<i>rsrc</i>	INTEGER. The process row coordinate of the process that called broadcast/send.

*csrc* INTEGER.  
The process column coordinate of the process that called broadcast/send.

## Output Parameters

*a* An array of dimension  $(lda, n)$  to receive the incoming message into.

## Description

This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix *A*. Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

### ?trbr2d

*Receives and participates in a broadcast along a scope for a trapezoidal matrix.*

## Syntax

```
call itrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call strbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call dtrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call ctrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call ztrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
```

## Input Parameters

*icontxt* INTEGER. Integer handle that indicates the context.

*scope* CHARACTER\*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.

*top* CHARACTER\*1. Indicates the communication pattern to use for the broadcast.

*uplo, diag, m, n, lda* Describe the matrix to be sent. See [Matrix Shapes](#) for details.

*rsrc* INTEGER.  
The process row coordinate of the process that called broadcast/send.

*csrc* INTEGER.  
The process column coordinate of the process that called broadcast/send.

## Output Parameters

*a* An array of dimension  $(lda, n)$  to receive the incoming message into.

## Description

This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix  $A$ . Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

## BLACS Support Routines

The support routines perform distinct tasks that can be used for:

Initialization

Destruction

Information Purposes

Miscellaneous Tasks.

## Initialization Routines

This topic describes BLACS routines that deal with grid/context creation, and processing before the grid/context has been defined.

### BLACS Initialization Routines

Routine name	Operation performed
<a href="#">blacs_pinfo</a>	Returns the number of processes available for use.
<a href="#">blacs_setup</a>	Allocates virtual machine and spawns processes.
<a href="#">blacs_get</a>	Gets values that BLACS use for internal defaults.
<a href="#">blacs_set</a>	Sets values that BLACS use for internal defaults.
<a href="#">blacs_gridinit</a>	Assigns available processes into BLACS process grid.
<a href="#">blacs_gridmap</a>	Maps available processes into BLACS process grid.

### [blacs\\_pinfo](#)

*Returns the number of processes available for use.*

### Syntax

```
call blacs_pinfo( mypnum, nprocs )
```

### Output Parameters

<i>mypnum</i>	INTEGER. An integer between 0 and ( <i>nprocs</i> - 1) that uniquely identifies each process.
<i>nprocs</i>	INTEGER. The number of processes available for BLACS use.

## Description

This routine is used when some initial system information is required before the BLACS are set up. On all platforms except PVM, *nprocs* is the actual number of processes available for use, that is,  $nrows * ncols \leq nprocs$ . In PVM, the virtual machine may not have been set up before this call, and therefore no parallel machine exists. In this case, *nprocs* is returned as less than one. If a process has been spawned via the

## Syntax

```
call blacs_get( icontxt, what, val )
```

## Input Parameters

<i>icontxt</i>	INTEGER. On values of <i>what</i> that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.
<i>what</i>	INTEGER. Indicates what BLACS internal(s) should be returned in <i>val</i> . Present options are: <ul style="list-style-type: none"><li>• <i>what</i> = 0 : Handle indicating default system context.</li><li>• <i>what</i> = 1 : The BLACS message ID range.</li><li>• <i>what</i> = 2 : The BLACS debug level the library was compiled with.</li><li>• <i>what</i> = 10 : Handle indicating the system context used to define the BLACS context whose handle is <i>icontxt</i>.</li><li>• <i>what</i> = 11 : Number of rings multiring broadcast topology is presently using.</li><li>• <i>what</i> = 12 : Number of branches general tree broadcast topology is presently using.</li><li>• <i>what</i> = 13 : Number of rings multiring combine topology is presently using.</li><li>• <i>what</i> = 14 : Number of branches general tree combine topology is presently using.</li><li>• <i>what</i> = 15 : Whether topologies are forced to be repeatable or not. A non-zero return value indicates that topologies are being forced to be repeatable. See <a href="#">Repeatability and Coherence</a> for more information about repeatability.</li><li>• <i>what</i> = 16 : Whether topologies are forced to be heterogenous coherent or not. A non-zero return value indicates that topologies are being forced to be heterogenous coherent. See <a href="#">Repeatability and Coherence</a> for more information about coherence.</li></ul>

## Output Parameters

<i>val</i>	INTEGER. The value of the BLACS internal.
------------	---

## Description

This routine gets the values that the BLACS are using for internal defaults. Some values are tied to a BLACS context, and some are more general. The most common use is in retrieving a default system context for input into [blacs\\_gridinit](#) or [blacs\\_gridmap](#).

Some systems, such as MPI\*, supply their own version of context. For those users who mix system code with BLACS code, a BLACS context should be formed in reference to a system context. Thus, the grid creation routines take a system context as input. If you wish to have strictly portable code, you may use [blacs\\_get](#) to retrieve a default system context that will include all available processes. This value is not tied to a BLACS context, so the parameter *icontxt* is unused.

[blacs\\_get](#) returns information on three quantities that are tied to an individual BLACS context, which is passed in as *icontxt*. The information that may be retrieved is:

- The handle of the system context upon which this BLACS context was defined
- The number of rings for TOP = 'M' (multiring broadcast/combine)

- The number of branches for `TOP = 'T'` (general tree broadcast/general tree gather).
- Whether topologies are being forced to be repeatable or heterogenous coherent.

## See Also

### Examples of BLACS Routines Usage

#### `blacs_set`

Sets values that BLACS use for internal defaults.

#### Syntax

```
call blacs_set( icontxt, what, val )
```

#### Input Parameters

<i>icontxt</i>	INTEGER. For values of <i>what</i> that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.
<i>what</i>	<p>INTEGER. Indicates what BLACS internal(s) should be set. Present values are:</p> <ul style="list-style-type: none"> <li>• 1 = Set the BLACS message ID range</li> <li>• 11 = Number of rings for multiring broadcast topology to use</li> <li>• 12 = Number of branches for general tree broadcast topology to use</li> <li>• 13 = Number of rings for multiring combine topology to use</li> <li>• 14 = Number of branches for general tree combine topology to use</li> <li>• 15 = Force topologies to be repeatable or not</li> <li>• 16 = Force topologies to be heterogenous coherent or not</li> </ul>
<i>val</i>	INTEGER. Array of dimension (*). Indicates the value(s) the internals should be set to. The specific meanings depend on <i>what</i> values, as discussed in Description below.

#### Description

This routine sets the BLACS internal defaults depending on *what* values:

<i>what</i> = 1	<p>Setting the BLACS message ID range.</p> <p>If you wish to mix the BLACS with other message-passing packages, restrict the BLACS to a certain message ID range not to be used by the non-BLACS routines. The message ID range must be set before the first call to <code>blacs_gridinit</code> or <code>blacs_gridmap</code>. Subsequent calls will have no effect. Because the message ID range is not tied to a particular context, the parameter <i>icontxt</i> is ignored, and <i>val</i> is defined as:</p> <pre>VAL (input) INTEGER array of dimension (2)</pre> <p><code>VAL(1)</code> : The smallest message ID (also called message type or message tag) the BLACS should use.</p> <p><code>VAL(2)</code> : The largest message ID (also called message type or message tag) the BLACS should use.</p>
<i>what</i> = 11	<p>Set number of rings for <code>TOP = 'M'</code> (multiring broadcast). This quantity is tied to a context, so <i>icontxt</i> is used, and <i>val</i> is defined as:</p>

	VAL (input) INTEGER array of dimension (1)	
	VAL(1) :	The number of rings for multiring topology to use.
<i>what</i> = 12		Set number of branches for TOP = 'T' (general tree broadcast). This quantity is tied to a context, so <i>icontxt</i> is used, and <i>val</i> is defined as:
	VAL (input) INTEGER array of dimension (1)	
	VAL(1) :	The number of branches for general tree topology to use.
<i>what</i> = 13		Set number of rings for TOP = 'M' (multiring combine). This quantity is tied to a context, so <i>icontxt</i> is used, and <i>val</i> is defined as:
	VAL (input) INTEGER array of dimension (1)	
	VAL(1) :	The number of rings for multiring topology to use.
<i>what</i> = 14		Set number of branches for TOP = 'T' (general tree gather). This quantity is tied to a context, so <i>icontxt</i> is used, and <i>val</i> is defined as:
	VAL (input) INTEGER array of dimension (1)	
	VAL(1) :	The number of branches for general tree topology to use.
<i>what</i> = 15		Force topologies to be repeatable or not (see <a href="#">Repeatability and Coherence</a> for more information about repeatability).
	VAL (input) INTEGER array of dimension (1)	
	VAL(1) = 0 (default)	Topologies are not required to be repeatable.
	VAL(1) ≠ 0	All used topologies are required to be repeatable, which might degrade performance.
<i>what</i> = 16		Force topologies to be heterogenous coherent or not (see <a href="#">Repeatability and Coherence</a> for more information about coherence).
	VAL (input) INTEGER array of dimension (1)	
	VAL(1) = 0 (default)	Topologies are not required to be heterogenous coherent.
	VAL(1) ≠ 0	All used topologies are required to be heterogenous coherent, which might degrade performance.

**blacs\_gridinit**

*Assigns available processes into BLACS process grid.*

**Syntax**

```
call blacs_gridinit( icontxt, layout, nprow, npcol )
```

**Input Parameters**

<i>icontxt</i>	INTEGER. Integer handle indicating the system context to be used in creating the BLACS context. Call <code>blacs_get</code> to obtain a default system context.
<i>layout</i>	CHARACTER*1. Indicates how to map processes to BLACS grid. Options are:

- 'R' : Use row-major natural ordering
- 'C' : Use column-major natural ordering
- ELSE : Use row-major natural ordering

<i>nprow</i>	INTEGER. Indicates how many process rows the process grid should contain.
<i>npcol</i>	INTEGER. Indicates how many process columns the process grid should contain.

## Output Parameters

<i>icontxt</i>	INTEGER. Integer handle to the created BLACS context.
----------------	---

## Description

All BLACS codes must call this routine, or its sister routine `blacs_gridmap`. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine `blacs_setup` should be used to create the virtual machine.

This routine creates a simple  $nprow \times npcold$  process grid. This process grid uses the first  $nprow * npcold$  processes, and assigns them to the grid in a row- or column-major natural ordering. If these process-to-grid mappings are unacceptable, call `blacs_gridmap`.

`blacs_gridmap`  
`blacs_setup`

### **blacs\_gridmap**

*Maps available processes into BLACS process grid.*

## Syntax

```
call blacs_gridmap( icontxt, usermap, ldumap, nprow, npcold )
```

## Input Parameters

<i>icontxt</i>	INTEGER. Integer handle indicating the system context to be used in creating the BLACS context. Call <code>blacs_get</code> to obtain a default system context.
----------------	---

<i>usermap</i>	INTEGER. Array, dimension ( <i>ldumap</i> , <i>npcol</i> ), indicating the process-to-grid mapping.
<i>ldumap</i>	INTEGER. Leading dimension of the 2D array <i>usermap</i> . $ldumap \geq nprow$ .
<i>nprow</i>	INTEGER. Indicates how many process rows the process grid should contain.
<i>npcol</i>	INTEGER. Indicates how many process columns the process grid should contain.

## Output Parameters

<i>icontxt</i>	INTEGER. Integer handle to the created BLACS context.
----------------	---

## Description

All BLACS codes must call this routine, or its sister routine `blacs_gridinit`. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are actual processors (hardware), and they are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine `blacs_setup` should be used to create the virtual machine.

This routine allows the user to map processes to the process grid in an arbitrary manner. `usermap(i, j)` holds the process number of the process to be placed in  $\{i, j\}$  of the process grid. On most distributed systems, this process number is a machine defined number between  $0 \dots nprow-1$ . For PVM, these node numbers are the PVM TIDS (Task IDs). The `blacs_gridmap` routine is intended for an experienced user. The `blacs_gridinit` routine is much simpler. `blacs_gridinit` simply performs a `gridmap` where the first  $nprow * npcold$  processes are mapped into the current grid in a row-major natural ordering. If you are an experienced user, `blacs_gridmap` allows you to take advantage of your system's actual layout. That is, you can map nodes that are physically connected to be neighbors in the BLACS grid, etc. The `blacs_gridmap` routine also opens the way for *multigridding*: you can separate your nodes into arbitrary grids, join them together at some later date, and then re-split them into new grids. `blacs_gridmap` also provides the ability to make arbitrary grids or subgrids (for example, a "nearest neighbor" grid), which can greatly facilitate operations among processes that do not fall on a row or column of the main process grid.

## Destruction Routines

This topic describes BLACS routines that destroy grids, abort processes, and free resources.

### BLACS Destruction Routines

Routine name	Operation performed
<a href="#">blacs_freebuff</a>	Frees BLACS buffer.
<a href="#">blacs_gridexit</a>	Frees a BLACS context.
<a href="#">blacs_abort</a>	Aborts all processes.
<a href="#">blacs_exit</a>	Frees all BLACS contexts and releases all allocated memory.

#### [blacs\\_freebuff](#)

*Frees BLACS buffer.*

#### Syntax

```
call blacs_freebuff( icontxt, wait )
```

#### Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the BLACS context.
<i>wait</i>	INTEGER. Parameter indicating whether to wait for non-blocking operations or not. If equals 0, the operations should not be waited for; free only unused buffers. Otherwise, wait in order to free all buffers.

#### Description

This routine releases the BLACS buffer.

The BLACS have at least one internal buffer that is used for packing messages. The number of internal buffers depends on what platform you are running the BLACS on. On systems where memory is tight, keeping this buffer or buffers may become expensive. Call `freebuff` to release the buffer. However, the next call of a communication routine that requires packing reallocates the buffer.

The *wait* parameter determines whether the BLACS should wait for any non-blocking operations to be completed or not. If *wait* = 0, the BLACS free any buffers that can be freed without waiting. If *wait* is not 0, the BLACS free all internal buffers, even if non-blocking operations must be completed first.

#### [blacs\\_gridexit](#)

*Frees a BLACS context.*

#### Syntax

```
call blacs_gridexit( icontxt )
```

#### Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the BLACS context to be freed.
----------------	---

#### Description

This routine frees a BLACS context.

Release the resources when contexts are no longer needed. After freeing a context, the context no longer exists, and its handle may be re-used if new contexts are defined.

## **blacs\_abort**

*Aborts all processes.*

---

### **Syntax**

```
call blacs_abort( icontxt, errornum )
```

### **Input Parameters**

<i>icontxt</i>	INTEGER. Integer handle that indicates the BLACS context to be aborted.
<i>errornum</i>	INTEGER. User-defined integer error number.

### **Description**

This routine aborts all the BLACS processes, not only those confined to a particular context.

Use `blacs_abort` to abort all the processes in case of a serious error. Note that both parameters are input, but the routine uses them only in printing out the error message. The context handle passed in is not required to be a valid context handle.

## **blacs\_exit**

*Frees all BLACS contexts and releases all allocated memory.*

---

### **Syntax**

```
call blacs_exit( continue )
```

### **Input Parameters**

<i>continue</i>	INTEGER. Flag indicating whether message passing continues after the BLACS are done. If <i>continue</i> is non-zero, the user is assumed to continue using the machine after completing the BLACS. Otherwise, no message passing is assumed after calling this routine.
-----------------	---

### **Description**

This routine frees all BLACS contexts and releases all allocated memory.

This routine should be called when a process has finished all use of the BLACS. The *continue* parameter indicates whether the user will be using the underlying communication platform after the BLACS are finished. This information is most important for the PVM BLACS. If *continue* is set to 0, then `pvm_exit` is called; otherwise, it is not called. Setting *continue* not equal to 0 indicates that explicit PVM `send/recvs` will be called after the BLACS routines are used. Make sure your code calls `pvm_exit`. PVM users should either call `blacs_exit` or explicitly call `pvm_exit` to avoid PVM problems.

[Examples of BLACS Routines Usage](#)

### **Informational Routines**

This topic describes BLACS routines that return information involving the process grid.

## BLACS Informational Routines

Routine name	Operation performed
<code>blacs_gridinfo</code>	Returns information on the current grid.
<code>blacs_pnum</code>	Returns the system process number of the process in the process grid.
<code>blacs_pcoord</code>	Returns the row and column coordinates in the process grid.

### `blacs_gridinfo`

Returns information on the current grid.

#### Syntax

```
call blacs_gridinfo( ictxt, nrow, ncol, myrow, mycol )
```

#### Input Parameters

`ictxt` INTEGER. Integer handle that indicates the context.

#### Output Parameters

`nrow` INTEGER. Number of process rows in the current process grid.

`ncol` INTEGER. Number of process columns in the current process grid.

`myrow` INTEGER. Row coordinate of the calling process in the process grid.

`mycol` INTEGER. Column coordinate of the calling process in the process grid.

#### Description

This routine returns information on the current grid. If the context handle does not point at a valid context, all quantities are returned as -1.

#### See Also

[Examples of BLACS Routines Usage](#)

### `blacs_pnum`

Returns the system process number of the process in the process grid.

#### Syntax

```
call blacs_pnum( ictxt, prow, pcol )
```

#### Input Parameters

`ictxt` INTEGER. Integer handle that indicates the context.

`prow` INTEGER. Row coordinate of the process the system process number of which is to be determined.

`pcol` INTEGER. Column coordinate of the process the system process number of which is to be determined.

#### Description

This function returns the system process number of the process at {`PROW`, `PCOL`} in the process grid.

## See Also

[Examples of BLACS Routines Usage](#)

### **blacs\_pcoord**

Returns the row and column coordinates in the process grid.

---

### Syntax

```
call blacs_pcoord( ictxt, pnum, prow, pcol )
```

### Input Parameters

<i>ictxt</i>	INTEGER. Integer handle that indicates the context.
<i>pnum</i>	INTEGER. Process number the coordinates of which are to be determined. This parameter stand for the process number of the underlying machine, that is, it is a <code>tid</code> for PVM.

### Output Parameters

<i>prow</i>	INTEGER. Row coordinates of the <i>pnum</i> process in the BLACS grid.
<i>pcol</i>	INTEGER. Column coordinates of the <i>pnum</i> process in the BLACS grid.

### Description

Given the system process number, this function returns the row and column coordinates in the BLACS process grid.

[Examples of BLACS Routines Usage](#)

### Miscellaneous Routines

This topic describes `blacs_barrier` routine.

### BLACS Informational Routines

---

Routine name	Operation performed
<code>blacs_barrier</code>	Holds up execution of all processes within the indicated scope until they have all called the routine.

---

### **blacs\_barrier**

Holds up execution of all processes within the indicated scope.

---

### Syntax

```
call blacs_barrier( ictxt, scope )
```

### Input Parameters

<i>ictxt</i>	INTEGER. Integer handle that indicates the context.
--------------	---

*scope*

CHARACTER\*1. Parameter that indicates whether a process row (*scope='R'*), column ('C'), or entire grid ('A') will participate in the barrier.

## Description

This routine holds up execution of all processes within the indicated scope until they have all called the routine.

## Examples of BLACS Routines Usage

## Data Fitting Functions

---

Data Fitting functions in Intel® oneAPI Math Kernel Library (oneMKL) provide spline-based interpolation capabilities that you can use to approximate functions, function derivatives or integrals, and perform cell search operations.

The Data Fitting component is task based. The task is a data structure or descriptor that holds the parameters related to a specific Data Fitting operation. You can modify the task parameters using the task editing functionality of the library.

For definition of the implemented operations, see [Mathematical Conventions](#).

Data Fitting routines use the following workflow to process a task:

1. Create a task or multiple tasks.
2. Modify the task parameters.
3. Perform a Data Fitting computation.
4. Destroy the task or tasks.

All Data Fitting functions fall into the following categories:

[Task Creation and Initialization Routines](#) - routines that create a new Data Fitting task descriptor and initialize the most common parameters, such as partition of the interpolation interval, values of the vector-valued function, and the parameters describing their structure.

[Task Configuration Routines](#) - routines that set, modify, or query parameters in an existing Data Fitting task.

[Computational Routines](#) - routines that perform Data Fitting computations, such as construction of a spline, interpolation, computation of derivatives and integrals, and search.

[Task Destructors](#) - routines that delete Data Fitting task descriptors and deallocate resources.

You can access the Data Fitting routines through the Fortran and C89/C99 language interfaces. You can also use the C89 interface with more recent versions of C/C++, or the Fortran 90 interface with programs written in Fortran 95.

The `$(MKL)/includedirectory` of the Intel® oneAPI Math Kernel Library (oneMKL) contains the following Data Fitting header files:

- `mkl_df.h`

You can find examples that demonstrate usage of Data Fitting routines in the `$(MKL)/examples/datafittingc` directory .

## Data Fitting Function Naming Conventions

The interface of the Data Fitting functions, types, and constants are case-sensitive and can be in lowercase, uppercase, and mixed case.

The names of all routines have the following structure:

`df[datatype]<base_name>`

where

- `df` is a prefix indicating that the routine belongs to the Data Fitting component of Intel® oneAPI Math Kernel Library (oneMKL).
- `[datatype]` field specifies the type of the input and/or output data and can be `s` (for the single precision real type), `d` (for the double precision real type), or `i` (for the integer type). This field is omitted in the names of the routines that are not data type dependent.
- `<base_name>` field specifies the functionality the routine performs. For example, this field can be `NewTask1D`, `Interpolate1D`, or `DeleteTask`

## Data Fitting Function Data Types

The Data Fitting component provides routines for processing single and double precision real data types. The results of cell search operations are returned as a generic integer data type.

All Data Fitting routines use the following data type:

Type	Data Object
<code>DFTaskPtr</code>	Pointer to a task

### NOTE

The actual size of the generic integer type is platform-dependent. Before compiling your application, you need to set an appropriate byte size for integers. For details, see section *Using the ILP64 Interface vs. LP64 Interface of the Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*.

## Mathematical Conventions for Data Fitting Functions

This section explains the notation used for Data Fitting function descriptions. Spline notations are based on the terminology and definitions of [deBoor2001]. The Subbotin quadratic spline definition follows the conventions of [StechSub76]. The quasi-uniform partition definition is based on [Schumaker2007].

### Mathematical Notation in the Data Fitting Component

Concept	Mathematical Notation
Partition of interpolation interval $[a, b]$ , where <ul style="list-style-type: none"> <li>• <math>x_i</math> denotes breakpoints.</li> <li>• <math>[x_i, x_{i+1})</math> denotes a sub-interval (cell) of size <math>\Delta_i = x_{i+1} - x_i</math>.</li> </ul>	$\{x_i\}_{i=1,\dots,n}$ , where $a = x_1 < x_2 < \dots < x_n = b$
Quasi-uniform partition of interpolation interval $[a, b]$	Partition $\{x_i\}_{i=1,\dots,n}$ which meets the constraint with a constant $C$ defined as $1 \leq M / m \leq C,$ where <ul style="list-style-type: none"> <li>• <math>M = \max_{i=1,\dots,n-1} (\Delta_i)</math></li> <li>• <math>m = \min_{i=1,\dots,n-1} (\Delta_i)</math></li> <li>• <math>\Delta_i = x_{i+1} - x_i</math></li> </ul>
Vector-valued function of dimension $p$ being fit	$f(x) = (f_1(x), \dots, f_p(x))$
Piecewise polynomial (PP) function $f$ of order $k+1$	$f(x) = P_i(x)$ , if $x \in [x_i, x_{i+1})$ , $i = 1, \dots, n-1$ where

Concept	Mathematical Notation
Function $p$ agrees with function $f$ at the points $\{x_i\}_{i=1,\dots,n}$ .	<ul style="list-style-type: none"> <li><math>\{x_i\}_{i=1,\dots,n}</math> is a strictly increasing sequence of breakpoints.</li> <li><math>P_i(x) = c_{i,0} + c_{i,1}(x - x_i) + \dots + c_{i,k}(x - x_i)^k</math> is a polynomial of degree <math>k</math> (order <math>k+1</math>) over the interval <math>x \in [x_i, x_{i+1})</math>.</li> </ul>
The $k$ -th divided difference of function $f$ at points $x_i, \dots, x_{i+k}$ . This difference is the leading coefficient of the polynomial of order $k+1$ that agrees with $f$ at $x_i, \dots, x_{i+k}$ .	$[x_i, \dots, x_{i+k}] f$ In particular, <ul style="list-style-type: none"> <li><math>[x_1] f = f(x_1)</math></li> <li><math>[x_1, x_2] f = (f(x_1) - f(x_2)) / (x_1 - x_2)</math></li> </ul>
A $k$ -order derivative of interpolant $f(x)$ at interpolation site $\tau$ .	$f^{(k)}(\tau)$

### Interpolants to the Function $f$ at $x_1, \dots, x_n$ and Boundary Conditions

Concept	Mathematical Notation
Linear interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i)$ , where <ul style="list-style-type: none"> <li><math>x \in [x_i, x_{i+1})</math></li> <li><math>c_{1,i} = f(x_i)</math></li> <li><math>c_{2,i} = [x_i, x_{i+1}] f</math></li> <li><math>i = 1, \dots, n-1</math></li> </ul>
Piecewise parabolic interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2$ , $x \in [x_i, x_{i+1})$ Coefficients $c_{1,i}$ , $c_{2,i}$ , and $c_{3,i}$ depend on the conditions: <ul style="list-style-type: none"> <li><math>P_i(x_i) = f(x_i)</math></li> <li><math>P_i(x_{i+1}) = f(x_{i+1})</math></li> <li><math>P_i((x_{i+1} + x_i) / 2) = v_{i+1}</math></li> </ul> where parameter $v_{i+1}$ depends on the interpolant being continuously differentiable: $P_{i-1}^{(1)}(x_i) = P_i^{(1)}(x_i)$
Piecewise parabolic Subbotin interpolant	$P(x) = P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + d_{3,i}((x - t_i)_+)^2$ , where <ul style="list-style-type: none"> <li><math>x \in [t_i, t_{i+1})</math></li> <li><math>\{t_i\}_{i=1,\dots,n+1}</math> is a sequence of knots such that               <ul style="list-style-type: none"> <li><math>t_1 = x_1, t_{n+1} = x_n</math></li> <li><math>t_i \in (x_{i-1}, x_i), i = 2, \dots, n</math></li> </ul> </li> </ul> $x_+ = f(x) = \begin{cases} 0, & \text{if } x < 0 \\ x, & \text{if } x \geq 0 \end{cases}$ Coefficients $c_{1,i}$ , $c_{2,i}$ , $c_{3,i}$ , and $d_{3,i}$ depend on the following conditions:

Concept	Mathematical Notation
	<ul style="list-style-type: none"> <li>• <math>P_i(x_i) = f(x_i), P_i(x_{i+1}) = f(x_{i+1})</math></li> <li>• <math>P(x)</math> is a continuously differentiable polynomial of the second degree on <math>[t_i, t_{i+1}), i = 1, \dots, n</math>.</li> </ul>
Piecewise cubic Hermite interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3,$ <p>where</p> <ul style="list-style-type: none"> <li>• <math>x \in [x_i, x_{i+1})</math></li> <li>• <math>c_{1,i} = f(x_i)</math></li> <li>• <math>c_{2,i} = s_i</math></li> <li>• <math>c_{3,i} = ([x_i, x_{i+1}]f - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)</math></li> <li>• <math>c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]f) / (\Delta x_i)^2</math></li> <li>• <math>i = 1, \dots, n-1</math></li> <li>• <math>s_i = f^{(1)}(x_i)</math></li> </ul>
Piecewise cubic Bessel interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3,$ <p>where</p> <ul style="list-style-type: none"> <li>• <math>x \in [x_i, x_{i+1})</math></li> <li>• <math>c_{1,i} = f(x_i)</math></li> <li>• <math>c_{2,i} = s_i</math></li> <li>• <math>c_{3,i} = ([x_i, x_{i+1}]f - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)</math></li> <li>• <math>c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]f) / (\Delta x_i)^2</math></li> <li>• <math>i = 1, \dots, n-1</math></li> <li>• <math>s_i = (\Delta x_i[x_{i-1}, x_i]f + \Delta x_{i-1}[x_i, x_{i+1}]f) / (\Delta x_i + \Delta x_{i+1})</math></li> </ul>
Piecewise cubic Akima interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3,$ <p>where</p> <ul style="list-style-type: none"> <li>• <math>x \in [x_i, x_{i+1})</math></li> <li>• <math>c_{1,i} = f(x_i)</math></li> <li>• <math>c_{2,i} = s_i</math></li> <li>• <math>c_{3,i} = ([x_i, x_{i+1}]f - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)</math></li> <li>• <math>c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]f) / (\Delta x_i)^2</math></li> <li>• <math>i = 1, \dots, n-1</math></li> <li>• <math>s_i = (w_{i+1}[x_{i-1}, x_i]f + w_{i-1}[x_i, x_{i+1}]f) / (w_{i+1} + w_{i-1}),</math></li> </ul> <p>where</p> $w_i =  [x_i, x_{i+1}]f - [x_{i-1}, x_i]f $
Piecewise natural cubic interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3,$ <p>where</p> <ul style="list-style-type: none"> <li>• <math>x \in [x_i, x_{i+1})</math></li> <li>• <math>c_{1,i} = f(x_i)</math></li> <li>• <math>c_{2,i} = s_i</math></li> <li>• <math>c_{3,i} = ([x_i, x_{i+1}]f - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)</math></li> <li>• <math>c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]f) / (\Delta x_i)^2</math></li> <li>• <math>i = 1, \dots, n-1</math></li> <li>• Parameter <math>s_i</math> depends on the condition that the interpolant is twice continuously differentiable: <math>P_{i-1}^{(2)}(x_i) = P_i^{(2)}(x_i)</math>.</li> </ul>
Not-a-knot boundary condition.	Parameters $s_1$ and $s_n$ provide $P_1 = P_2$ and $P_{n-1} = P_n$ , so that the first and the last interior breakpoints are inactive.
Free-end boundary condition.	$f''(x_1) = f''(x_n) = 0$

Concept	Mathematical Notation
Look-up interpolator for discrete set of points $(x_1, y_1), \dots, (x_n, y_n)$ .	$y(x) = \begin{cases} y_1, & \text{if } x = x_1 \\ y_2, & \text{if } x = x_2 \\ \dots & \\ y_n, & \text{if } x = x_n \\ \text{error,} & \text{otherwise} \end{cases}$
Step-wise constant continuous right interpolator.	$y(x) = \begin{cases} y_1, & \text{if } x_1 \leq x < x_2 \\ y_2, & \text{if } x_2 \leq x < x_3 \\ \dots & \\ y_{n-1}, & \text{if } x_{n-1} \leq x < x_n \\ y_n, & \text{if } x = x_n \end{cases}$
Step-wise constant continuous left interpolator.	$y(x) = \begin{cases} y_1, & \text{if } x = x_1 \\ y_2, & \text{if } x_1 < x \leq x_2 \\ y_3, & \text{if } x_2 < x \leq x_3 \\ \dots & \\ y_n, & \text{if } x_{n-1} < x \leq x_n \end{cases}$

## Data Fitting Usage Model

Consider an algorithm that uses the Data Fitting functions. Typically, such algorithms consist of four steps or stages:

1. Create a task. You can call the Data Fitting function several times to create multiple tasks.

```
status = dfdNewTask1D( &task, nx, x, xhint, ny, y, yhint );
```

2. Modify the task parameters.

```
status = dfdEditPPSpline1D( task, s_order, c_type, bc_type, bc, ic_type, ic,
scoeff, scoeffhint );
```

3. Perform Data Fitting spline-based computations. You may reiterate steps 2-3 as needed.

```
status = dfdInterpolate1D(task, estimate, method, nsite, site, sitehint, ndorder,
dorder, datahint, r, rhint, cell );
```

4. Destroy the task or tasks.

```
status = dfDeleteTask( &task );
```

## Data Fitting Usage Examples

The examples below illustrate several operations that you can perform with Data Fitting routines.

You can get source code for similar examples in the `.\examples\datafittingc` subdirectory of the Intel® oneAPI Math Kernel Library (oneMKL) installation directory.

The following example demonstrates the construction of a linear spline using Data Fitting routines. The spline approximates a scalar function defined on non-uniform partition. The coefficients of the spline are returned as a one-dimensional array:

## Example of Linear Spline Construction

```
#include "mkl.h"
#define N 500 /* Size of partition, number of breakpoints */
#define SPLINE_ORDER DF_PP_LINEAR /* Linear spline to construct */

int main()
{
    int status; /* Status of a Data Fitting operation */
    DFTaskPtr task; /* Data Fitting operations are task based */

    /* Parameters describing the partition */
    MKL_INT nx; /* The size of partition x */
    double x[N]; /* Partition x */
    MKL_INT xhint; /* Additional information about the structure of breakpoints */

    /* Parameters describing the function */
    MKL_INT ny; /* Function dimension */
    double y[N]; /* Function values at the breakpoints */
    MKL_INT yhint; /* Additional information about the function */

    /* Parameters describing the spline */
    MKL_INT s_order; /* Spline order */
    MKL_INT s_type; /* Spline type */
    MKL_INT ic_type; /* Type of internal conditions */
    double* ic; /* Array of internal conditions */
    MKL_INT bc_type; /* Type of boundary conditions */
    double* bc; /* Array of boundary conditions */

    double scoeff[(N-1)*SPLINE_ORDER]; /* Array of spline coefficients */
    MKL_INT scoeffhint; /* Additional information about the coefficients */

    /* Initialize the partition */
    nx = N;
    /* Set values of partition x */
    ...
    xhint = DF_NO_HINT; /* No additional information about the function is provided.
                        By default, the partition is non-uniform. */
    /* Initialize the function */
    ny = 1; /* The function is scalar. */

    /* Set function values */
    ...
    yhint = DF_NO_HINT; /* No additional information about the function is provided. */

    /* Create a Data Fitting task */
    status = dfdNewTask1D( &task, nx, x, xhint, ny, y, yhint );

    /* Check the Data Fitting operation status */
    ...

    /* Initialize spline parameters */
    s_order = DF_PP_LINEAR; /* Spline is of the second order. */
    s_type = DF_PP_DEFAULT; /* Spline is of the default type. */
}
```

```

/* Define internal conditions for linear spline construction (none in this example) */
ic_type = DF_NO_IC;
ic = NULL;

/* Define boundary conditions for linear spline construction (none in this example) */
bc_type = DF_NO_BC;
bc = NULL;
scoeffhint = DF_NO_HINT;    /* No additional information about the spline. */

/* Set spline parameters in the Data Fitting task */
status = dfdEditPPSpline1D( task, s_order, s_type, bc_type, bc, ic_type,
                           ic, scoeff, scoeffhint );

/* Check the Data Fitting operation status */
...

/* Use a standard computation method to construct a linear spline: */
/*  $P_i(x) = c_{i,0} + c_{i,1}(x-x_i)$ ,  $i=0, \dots, N-2$  */
/* The library packs spline coefficients to array scoeff. */
/*  $scoeff[2*i+0]=c_{i,0}$  and  $scoeff[2*i+1]=c_{i,1}$ ,  $i=0, \dots, N-2$  */
status = dfdConstruct1D( task, DF_PP_SPLINE, DF_METHOD_STD );

/* Check the Data Fitting operation status */
...

/* Process spline coefficients */
...

/* Deallocate Data Fitting task resources */
status = dfDeleteTask( &task );

/* Check the Data Fitting operation status */
...
return 0 ;
}

```

The following example demonstrates cubic spline-based interpolation using Data Fitting routines. In this example, a scalar function defined on non-uniform partition is approximated by Bessel cubic spline using not-a-knot boundary conditions. Once the spline is constructed, you can use the spline to compute spline values at the given sites. Computation results are packed by the Data Fitting routine in row-major format.

## Example of Cubic Spline-Based Interpolation

```

#include "mkl.h"

#define NX 100                /* Size of partition, number of breakpoints */
#define NSITE 1000           /* Number of interpolation sites */
#define SPLINE_ORDER DF_PP_CUBIC /* A cubic spline to construct */

int main()
{
    int status;                /* Status of a Data Fitting operation */
    DFTaskPtr task;           /* Data Fitting operations are task based */

    /* Parameters describing the partition */
    MKL_INT nx;                /* The size of partition x */
    double x[NX];              /* Partition x */
    MKL_INT xhint;             /* Additional information about the structure of breakpoints */
}

```

```
/* Parameters describing the function */
MKL_INT ny;          /* Function dimension */
double y[NX];       /* Function values at the breakpoints */
MKL_INT yhint;      /* Additional information about the function */

/* Parameters describing the spline */
MKL_INT s_order;    /* Spline order */
MKL_INT s_type;     /* Spline type */
MKL_INT ic_type;    /* Type of internal conditions */

    nsite = NSITE;

    /* Set sites in the ascending order */
    ...
    sitehint = DF_SORTED_DATA; /* Sites are provided in the ascending order. */
    datahint = DF_NO_APRIORI_INFO; /* No additional information

```

```

        about breakpoints/sites is provided.*/

/* Use a standard method to compute indices of the cells that contain
   interpolation sites. The library places the index of the cell containing
   site(i) to the cell(i), i=0,...,nsite-1 */
status = dfsSearchCells1D( task, DF_METHOD_STD, nsite, site, sitehint,
                          datahint, cell );
/* Check Data Fitting operation status */
...

/* Process cell indices */
...

/* Deallocate Data Fitting task resources */
status = dfDeleteTask( &task );

/* Check Data Fitting operation status */
...
return 0;
}

```

## Data Fitting Function Task Status and Error Reporting

The Data Fitting routines report a task status through integer values. Negative status values indicate errors, while positive values indicate warnings. An error can be caused by invalid parameter values or a memory allocation failure.

The status codes have symbolic names predefined in the header file as macros via the `#define` statements.

If no error occurred, the function returns the `DF_STATUS_OK` code defined as zero:

```
#define DF_STATUS_OK 0
```

In case of an error, the function returns a non-zero error code that specifies the origin of the failure. Header files define the following status codes:

### Status Codes in the Data Fitting Component

Status Code	Description
<b>Common Status Codes</b>	
<code>DF_STATUS_OK</code>	Operation completed successfully.
<code>DF_ERROR_NULL_TASK</code>	Data Fitting task is a <code>NULL</code> pointer.
<code>DF_ERROR_MEM_FAILURE</code>	Memory allocation failure.
<code>DF_ERROR_METHOD_NOT_SUPPORTED</code>	Requested method is not supported.
<code>DF_ERROR_COMP_TYPE_NOT_SUPPORTED</code>	Requested computation type is not supported.
<code>DF_ERROR_NULL_PTR</code>	Pointer to parameter is null.
<b>Data Fitting Task Creation and Initialization, and Generic Editing Operations</b>	
<code>DF_ERROR_BAD_NX</code>	Invalid number of breakpoints.
<code>DF_ERROR_BAD_X</code>	Array of breakpoints is invalid.
<code>DF_ERROR_BAD_X_HINT</code>	Invalid hint describing the structure of the partition.

Status Code	Description
DF_ERROR_BAD_NY	Invalid dimension of vector-valued function $y$ .
DF_ERROR_BAD_Y	Array of function values is invalid.
DF_ERROR_BAD_Y_HINT	Invalid flag describing the structure of function $y$
<b>Data Fitting Task-Specific Editing Operations</b>	
DF_ERROR_BAD_SPLINE_ORDER	Invalid spline order.
DF_ERROR_BAD_SPLINE_TYPE	Invalid spline type.
DF_ERROR_BAD_IC_TYPE	Type of internal conditions used for spline construction is invalid.
DF_ERROR_BAD_IC	Array of internal conditions for spline construction is not defined.
DF_ERROR_BAD_BC_TYPE	Type of boundary conditions used in spline construction is invalid.
DF_ERROR_BAD_BC	Array of boundary conditions for spline construction is not defined.
DF_ERROR_BAD_PP_COEFF	Array of piecewise polynomial spline coefficients is not defined.
DF_ERROR_BAD_PP_COEFF_HINT	Invalid flag describing the structure of the piecewise polynomial spline coefficients.
DF_ERROR_BAD_PERIODIC_VAL	Function values at the endpoints of the interpolation interval are not equal as required in periodic boundary conditions.
DF_ERROR_BAD_DATA_ATTR	Invalid attribute of the pointer to be set or modified in Data Fitting task descriptor with the <code>df?</code> <code>EditIdxPtr</code> task editor.
DF_ERROR_BAD_DATA_IDX	Index of the pointer to be set or modified in the Data Fitting task descriptor with the <code>df?</code> <code>EditIdxPtr</code> task editor is out of the pre-defined range.
<b>Data Fitting Computation Operations</b>	
DF_ERROR_BAD_NSITE	Invalid number of interpolation sites.
DF_ERROR_BAD_SITE	Array of interpolation sites is not defined.
DF_ERROR_BAD_SITE_HINT	Invalid flag describing the structure of interpolation sites.
DF_ERROR_BAD_NDORDER	Invalid size of the array defining derivative orders to be computed at interpolation sites.
DF_ERROR_BAD_DORDER	Array defining derivative orders to be computed at interpolation sites is not defined.
DF_ERROR_BAD_DATA_HINT	Invalid flag providing additional information about partition or interpolation sites.

Status Code	Description
DF_ERROR_BAD_INTERP	Array of spline-based interpolation results is not defined.
DF_ERROR_BAD_INTERP_HINT	Invalid flag defining the structure of spline-based interpolation results.
DF_ERROR_BAD_CELL_IDX	Array of indices of partition cells containing interpolation sites is not defined.
DF_ERROR_BAD_NLIM	Invalid size of arrays containing integration limits.
DF_ERROR_BAD_LLM	Array of the left-side integration limits is not defined.
DF_ERROR_BAD_RLM	Array of the right-side integration limits is not defined.
DF_ERROR_BAD_INTEGR	Array of spline-based integration results is not defined.
DF_ERROR_BAD_INTEGR_HINT	Invalid flag providing the structure of the array of spline-based integration results.
DF_ERROR_BAD_LOOKUP_INTERP_SITE	Bad site provided for interpolation with look-up interpolator.

**NOTE**

The routine that estimates piecewise polynomial cubic spline coefficients can return internal error codes related to the specifics of the implementation. Such error codes indicate invalid input data or other issues unrelated to Data Fitting routines.

## Data Fitting Task Creation and Initialization Routines

Task creation and initialization routines are functions used to create a new task descriptor and initialize its parameters. The Data Fitting component provides the `df?NewTask1D` routine that creates and initializes a new task descriptor for a one-dimensional Data Fitting task.

### `df?NewTask1D`

*Creates and initializes a new task descriptor for a one-dimensional Data Fitting task.*

### Syntax

```
status = dfsNewTask1D(&task, nx, x, xhint, ny, y, yhint)
```

```
status = dfdNewTask1D(&task, nx, x, xhint, ny, y, yhint)
```

### Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<i>nx</i>	const MKL_INT	Number of breakpoints representing partition of interpolation interval $[a, b]$ .
<i>x</i>	const float* for dfsNewTask1D const double* for dfdNewTask1D	One-dimensional array containing the strictly sorted breakpoints from interpolation interval $[a, b]$ . The structure of the array is defined by parameter <i>xhint</i> : <ul style="list-style-type: none"> <li>If partition is non-uniform or quasi-uniform, the array should contain <i>nx</i> strictly ordered values.</li> <li>If partition is uniform, the array should contain two entries that represent endpoints of interpolation interval <math>[a, b]</math>.</li> </ul> <hr/> <p><b>Caution</b> The array must be strictly sorted. If it is unordered, the results of data fitting routines are not correct.</p> <hr/>
<i>xhint</i>	const MKL_INT	A flag describing the structure of partition <i>x</i> . For the list of possible values of <i>xhint</i> , see table " <a href="#">Hint Values for Partition x</a> ". If you set the flag to the DF_NO_HINT value, the library interprets the partition as non-uniform.
<i>ny</i>	const MKL_INT	Dimension of vector-valued function <i>y</i> .
<i>y</i>	const float* for dfsNewTask const double* for dfdNewTask	Vector-valued function <i>y</i> , array of size $nx \times ny$ . The storage format of function values in the array is defined by the value of flag <i>yhint</i> .
<i>yhint</i>	const MKL_INT	A flag describing the structure of array <i>y</i> . Valid hint values are listed in table " <a href="#">Hint Values for Vector-Valued Function y</a> ". If you set the flag to the DF_NO_HINT value, the library assumes that all <i>ny</i> coordinates of the vector-valued function <i>y</i> are provided and stored in row-major format.

## Output Parameters

Name	Type	Description
<i>task</i>	DFTaskPtr	Descriptor of the task.
<i>status</i>	int	Status of the routine: <ul style="list-style-type: none"> <li>DF_STATUS_OK if the task is created successfully.</li> <li>Non-zero error code if the task creation failed. See "<a href="#">Task Status and Error Reporting</a>" for error code definitions.</li> </ul>

## Description

The `df?NewTask1D` routine creates and initializes a new Data Fitting task descriptor with user-specified parameters for a one-dimensional Data Fitting task. The  $x$  and  $nx$  parameters representing the partition of interpolation interval  $[a, b]$  are mandatory. If you provide invalid values for these parameters, such as a `NULL` pointer  $x$  or the number of breakpoints smaller than two, the routine does not create the Data Fitting task and returns an error code.

If you provide a vector-valued function  $y$ , make sure that the function dimension  $ny$  and the array of function values  $y$  are both valid. If any of these parameters are invalid, the routine does not create the Data Fitting task and returns an error code.

If you store coordinates of the vector-valued function  $y$  in non-contiguous memory locations, you can set the `yhint` flag to `DF_1ST_COORDINATE`, and pass only the first coordinate of the function into the task creation routine. After successful creation of the Data Fitting task, you can pass the remaining coordinates using the `df?EditIdxPtr` task editor.

If the routine fails to create the task descriptor, it returns a `NULL` task pointer.

The routine supports the following hint values for partition  $x$ :

### Hint Values for Partition $x$

Value	Description
<code>DF_NON_UNIFORM_PARTITION</code>	Partition is non-uniform.
<code>DF_QUASI_UNIFORM_PARTITION</code>	Partition is quasi-uniform.
<code>DF_UNIFORM_PARTITION</code>	Partition is uniform.
<code>DF_NO_HINT</code>	No hint is provided. By default, partition is interpreted as non-uniform.

The routine supports the following hint values for the vector-valued function:

### Hint Values for Vector-Valued Function $y$

Value	Description
<code>DF_MATRIX_STORAGE_ROWS</code>	Data is stored in row-major format according to C conventions.
<code>DF_MATRIX_STORAGE_COLS</code>	Data is stored in column-major format according to Fortran conventions.
<code>DF_1ST_COORDINATE</code>	The first coordinate of vector-valued data is provided.
<code>DF_NO_HINT</code>	No hint is provided. By default, the coordinates of vector-valued function $y$ are provided and stored in row-major format.

#### NOTE

You must preserve the arrays  $x$  (breakpoints) and  $y$  (vector-valued functions) through the entire workflow of the Data Fitting computations for a task, as the task stores the addresses of the arrays for spline-based computations.

## Task Configuration Routines

In order to configure tasks, you can use task editors and task query routines.

Task editors initialize or change the predefined Data Fitting task parameters. You can use task editors to initialize or modify pointers to arrays or parameter values.

Task editors can be task-specific or generic. Task-specific editors can modify more than one parameter related to a specific task. Generic editors modify a single parameter at a time.

The Data Fitting component of Intel® oneAPI Math Kernel Library (oneMKL) provides the following task editors:

### Data Fitting Task Editors

Editor	Description	Type
<code>df?</code> <code>EditPPSpline1D</code>	Changes parameters of the piecewise polynomial spline.	Task-specific
<code>df?EditPtr</code>	Changes a pointer in the task descriptor.	Generic
<code>dfiEditVal</code>	Changes a value in the task descriptor.	Generic
<code>df?EditIdxPtr</code>	Changes a coordinate of data represented in matrix format, such as a vector-valued function or spline coefficients.	Generic

Task query routines are used to read the predefined Data Fitting task parameters. You can use task query routines to read the values of pointers or parameters.

Task query routines are generic (not task-specific), allowing you to read a single parameter at a time.

The Data Fitting component of the Intel® oneAPI Math Kernel Library (oneMKL) provides the following task query routines:

### Data Fitting Task Query Routines

Editor	Description	Type
<code>df?QueryPtr</code>	Queries a pointer in the task descriptor.	Generic
<code>dfiQueryVal</code>	Queries a value in the task descriptor.	Generic
<code>df?QueryIdxPtr</code>	Queries a coordinate of data represented in matrix format, such as a vector-valued function or spline coefficients.	Generic

#### `df?EditPPSpline1D`

*Modifies parameters representing a spline in a Data Fitting task descriptor.*

#### Syntax

```
status = dfsEditPPSpline1D(task, s_order, s_type, bc_type, bc, ic_type, ic, scoeff,
scoeffhint)
```

```
status = dfdEditPPSpline1D(task, s_order, s_type, bc_type, bc, ic_type, ic, scoeff,
scoeffhint)
```

#### Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<i>task</i>	DFTaskPtr	Descriptor of the task.
<i>s_order</i>	const MKL_INT	Spline order. The parameter takes one of the values described in table " <a href="#">Spline Orders Supported by Data Fitting Functions</a> ".
<i>s_type</i>	const MKL_INT	Spline type. The parameter takes one of the values described in table " <a href="#">Spline Types Supported by Data Fitting Functions</a> ".
<i>bc_type</i>	const MKL_INT	Type of boundary conditions. The parameter takes one of the values described in table " <a href="#">Boundary Conditions Supported by Data Fitting Functions</a> ".
<i>bc</i>	const float* for dfsEditPPSpline1D  const double* for dfdEditPPSpline1D	Pointer to boundary conditions. The size of the array is defined by the value of parameter <i>bc_type</i> : <ul style="list-style-type: none"> <li>• If you set free-end or not-a-knot boundary conditions, pass the NULL pointer to this parameter.</li> <li>• If you combine boundary conditions at the endpoints of the interpolation interval, pass an array of two elements.</li> <li>• If you set a boundary condition for the default quadratic spline or a periodic condition for Hermite or the default cubic spline, pass an array of one element.</li> </ul>
<i>ic_type</i>	const MKL_INT	Type of internal conditions. The parameter takes one of the values described in table " <a href="#">Internal Conditions Supported by Data Fitting Functions</a> ".
<i>ic</i>	const float* for dfsEditPPSpline1D  const double* for dfdEditPPSpline1D	A non-NULL pointer to the array of internal conditions. The size of the array is defined by the value of parameter <i>ic_type</i> : <ul style="list-style-type: none"> <li>• If you set first derivatives or second derivatives internal conditions (<i>ic_type</i>=DF_IC_1ST_DER or <i>ic_type</i>=DF_IC_2ND_DER), pass an array of <math>n-1</math> derivative values at the internal points of the interpolation interval.</li> <li>• If you set the knot values internal condition for Subbotin spline (<i>ic_type</i>=DF_IC_Q_KNOT) and the knot partition is non-uniform, pass an array of <math>n+1</math> elements.</li> <li>• If you set the knot values internal condition for Subbotin spline (<i>ic_type</i>=DF_IC_Q_KNOT) and the knot partition is uniform, pass an array of four elements.</li> </ul>
<i>scoeff</i>	const float* for dfsEditPPSpline1D  const double* for dfdEditPPSpline1D	Spline coefficients. An array of size $ny*s\_order*(nx-1)$ . The storage format of the coefficients in the array is defined by the value of flag <i>scoeffhint</i> .

Name	Type	Description
<code>scoeffhint</code>	<code>const MKL_INT</code>	A flag describing the structure of the array of spline coefficients. For valid hint values, see table " <a href="#">Hint Values for Spline Coefficients</a> ". The library stores the coefficients in row-major format. The default value is <code>DF_NO_HINT</code> .

## Output Parameters

Name	Type	Description
<code>status</code>	<code>int</code>	Status of the routine: <ul style="list-style-type: none"> <li><code>DF_STATUS_OK</code> if the routine execution completed successfully.</li> <li>Non-zero error code if the routine execution failed. See "<a href="#">Task Status and Error Reporting</a>" for error code definitions.</li> </ul>

## Description

The editor modifies parameters that describe the order, type, boundary conditions, internal conditions, and coefficients of a spline. The spline order definition is provided in the "[Mathematical Conventions](#)" section. You can set the spline order to any value supported by Data Fitting functions. The table below lists the available values:

### Spline Orders Supported by the Data Fitting Functions

Order	Description
<code>DF_PP_STD</code>	Artificial value. Use this value for look-up and step-wise constant interpolants only.
<code>DF_PP_LINEAR</code>	Piecewise polynomial spline of the second order (linear spline).
<code>DF_PP_QUADRATIC</code>	Piecewise polynomial spline of the third order (quadratic spline).
<code>DF_PP_CUBIC</code>	Piecewise polynomial spline of the fourth order (cubic spline).

To perform computations with a spline not supported by Data Fitting routines, set the parameter defining the spline order and pass the spline coefficients to the library in the supported format. For format description, see figure "[Row-major Coefficient Storage Format](#)".

The table below lists the supported spline types:

### Spline Types Supported by Data Fitting Functions

Type	Description
<code>DF_PP_DEFAULT</code>	The default spline type. You can use this type with linear, quadratic, or user-defined splines.
<code>DF_PP_SUBBOTIN</code>	Quadratic splines based on Subbotin algorithm, [ <a href="#">TechSub76</a> ].
<code>DF_PP_NATURAL</code>	Natural cubic spline.

Type	Description
DF_PP_HERMITE	Hermite cubic spline.
DF_PP_BESSEL	Bessel cubic spline.
DF_PP_AKIMA	Akima cubic spline.
DF_LOOKUP_INTERPOLANT	Look-up interpolant.
DF_CR_STEPWISE_CONST_INTERPOLANT	Continuous right step-wise constant interpolant.
DF_CL_STEPWISE_CONST_INTERPOLANT	Continuous left step-wise constant interpolant.

If you perform computations with look-up or step-wise constant interpolants, set the spline order to the `DF_PP_STD` value.

Construction of specific splines may require boundary or internal conditions. To compute coefficients of such splines, you should pass boundary or internal conditions to the library by specifying the type of the conditions and providing the necessary values. For splines that do not require additional conditions, such as linear splines, set condition types to `DF_NO_BC` and `DF_NO_IC`, and pass `NULL` pointers to the conditions. The table below defines the supported boundary conditions:

#### Boundary Conditions Supported by Data Fitting Functions

Boundary Condition	Description	Spline
DF_NO_BC	No boundary conditions provided.	All
DF_BC_NOT_A_KNOT	Not-a-knot boundary conditions.	Akima, Bessel, Hermite, natural cubic
DF_BC_FREE_END	Free-end boundary conditions.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_1ST_LEFT_DER	The first derivative at the left endpoint.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_1ST_RIGHT_DER	The first derivative at the right endpoint.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_2ST_LEFT_DER	The second derivative at the left endpoint.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_2ND_RIGHT_DER	The second derivative at the right endpoint.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_PERIODIC	Periodic boundary conditions.	Linear, all cubic splines
DF_BC_Q_VAL	Function value at point $(x_0 + x_1)/2$	Default quadratic

**NOTE**

To construct a natural cubic spline, pass these settings to the editor:

- `DF_PP_CUBIC` as the spline order,
- `DF_PP_NATURAL` as the spline type, and
- `DF_BC_FREE_END` as the boundary condition.

To construct a cubic spline with other boundary conditions, pass these settings to the editor:

- `DF_PP_CUBIC` as the spline order,
- `DF_PP_NATURAL` as the spline type, and
- the required type of boundary condition.

For Akima, Hermite, Bessel, and default cubic splines use the corresponding type defined in [Table Spline Types Supported by Data Fitting Functions](#).

You can combine the values of boundary conditions with a bitwise `OR` operation. This permits you to pass combinations of first and second derivatives at the endpoints of the interpolation interval into the library. To pass a first derivative at the left endpoint and a second derivative at the right endpoint, set the boundary conditions to `DF_BC_1ST_LEFT_DER OR DF_BC_2ND_RIGHT_DER`.

You should pass the combined boundary conditions as an array of two elements. The first entry of the array contains the value of the boundary condition for the left endpoint of the interpolation interval, and the second entry - for the right endpoint. Pass other boundary conditions as arrays of one element.

For the conditions defined as a combination of valid values, the library applies the following rules to identify the boundary condition type:

- If not required for spline construction, the value of boundary conditions is ignored.
- Not-a-knot condition has the highest priority. If set, other boundary conditions are ignored.
- Free-end condition has the second priority after the not-a-knot condition. If set, other boundary conditions are ignored.
- Periodic boundary condition has the next priority after the free-end condition.
- The first derivative has higher priority than the second derivative at the right and left endpoints.

If you set the periodic boundary condition, make sure that function values at the endpoints of the interpolation interval are identical. Otherwise, the library returns an error code. The table below specifies the values to be provided for each type of spline if the periodic boundary condition is set.

**Boundary Requirements for Periodic Conditions**

Spline Type	Periodic Boundary Condition Support	Boundary Value
Linear	Yes	Not required
Default quadratic	No	
Subbotin quadratic	No	
Natural cubic	Yes	Not required
Bessel	Yes	Not required
Akima	Yes	Not required
Hermite cubic	Yes	First derivative
Default cubic	Yes	Second derivative

Internal conditions supported in the Data Fitting domain that you can use for the *ic\_type* parameter are the following:

## Internal Conditions Supported by Data Fitting Functions

Internal Condition	Description	Spline
DF_NO_IC	No internal conditions provided.	
DF_IC_1ST_DER	Array of first derivatives of size $n-2$ , where $n$ is the number of breakpoints. Derivatives are applicable to each coordinate of the vector-valued function.	Hermite cubic
DF_IC_2ND_DER	Array of second derivatives of size $n-2$ , where $n$ is the number of breakpoints. Derivatives are applicable to each coordinate of the vector-valued function.	Default cubic
DF_IC_Q_KNOT	Knot array of size $n+1$ , where $n$ is the number of breakpoints.	Subbotin quadratic

To construct a Subbotin quadratic spline, you have three options to get the array of knots in the library:

- If you do not provide the knots, the library uses the default values of knots  $t = \{t_i\}$ ,  $i = 0, \dots, n$  according to the rule:

$$t_0 = x_0, t_n = x_{n-1}, t_i = (x_i + x_{i-1})/2, i = 1, \dots, n - 1.$$

- If you provide the knots in an array of size  $n + 1$ , the knots form a non-uniform partition. Make sure that the knot values you provide meet the following conditions:

$$t_0 = x_0, t_n = x_{n-1}, t_i \in (x_{i-1}, x_i), i = 1, \dots, n - 1.$$

- If you provide the knots in an array of size 4, the knots form a uniform partition

$$t_0 = x_0, t_1 = l, t_2 = r, t_3 = x_{n-1}, \text{ where } l \in (x_0, x_1) \text{ and } r \in (x_{n-2}, x_{n-1}).$$

In this case, you need to set the value of the *ic\_type* parameter holding the type of internal conditions to DF\_IC\_Q\_KNOT OR DF\_UNIFORM\_PARTITION.

### NOTE

Since the partition is uniform, perform an OR operation with the DF\_UNIFORM\_PARTITION partition hint value described in [Table Hint Values for Partition x](#).

For computations based on look-up and step-wise constant interpolants, you can avoid calling the `df?EditPPSpline1D` editor and directly call one of the routines for spline-based computation of spline values, derivatives, or integrals. For example, you can call the `df?Construct1D` routine to construct the required spline with the given attributes, such as order or type.

The memory location of the spline coefficients is defined by the *scoeff* parameter. Make sure that the size of the array is sufficient to hold  $n_y * s\_order * (n_x - 1)$  values.

The `df?EditPPSpline1D` routine supports the following hint values for spline coefficients:

## Hint Values for Spline Coefficients

Order	Description
DF_1ST_COORDINATE	The first coordinate of vector-valued data is provided.
DF_NO_HINT	No hint is provided. By default, all sets of spline coefficients are stored in row-major format.

The coefficients for all coordinates of the vector-valued function are packed in memory one by one in successive order, from function  $y_1$  to function  $y_{NY}$ .

Within each coordinate, the library stores the coefficients as an array, in row-major format:

$$c_{1,0}, c_{1,1}, \dots, c_{1,k}, c_{2,0}, c_{2,1}, \dots, c_{2,k}, \dots, c_{n-1,0}, c_{n-1,1}, \dots, c_{n-1,k}$$

Mapping of the coefficients to storage in the *scoeff* array is described below, where  $c_{i,j}$  is the  $j$ th coefficient of the function

$$P_i(x) = c_{i,0} + c_{i,1}(x - x_i) + \dots + c_{i,k}(x - x_i)^k$$

See [Mathematical Conventions](#) for more details on nomenclature and interpolants.

### Row-major Coefficient Storage Format

$$\begin{aligned}
 P_1(x) &= \overrightarrow{c_{1,0}} + \overrightarrow{c_{1,1}(x-x_1)} + \overrightarrow{\dots} + \overrightarrow{c_{1,k}(x-x_1)^k} \\
 P_2(x) &= \overrightarrow{c_{2,0}} + \overrightarrow{c_{2,1}(x-x_2)} + \overrightarrow{\dots} + \overrightarrow{c_{2,k}(x-x_2)^k} \\
 &\quad \vdots \qquad \qquad \qquad \vdots \qquad \qquad \qquad \vdots \\
 P_{n-1}(x) &= \overrightarrow{c_{n-1,0}} + \overrightarrow{c_{n-1,1}(x-x_{n-1})} + \overrightarrow{\dots} + \overrightarrow{c_{n-1,k}(x-x_{n-1})^k}
 \end{aligned}$$

If you store splines corresponding to different coordinates of the vector-valued function at non-contiguous memory locations, do the following:

1. Set the *scoeffhint* flag to DF\_1ST\_COORDINATE and provide the spline for the first coordinate.
2. Pass the spline coefficients for the remaining coordinates into the Data Fitting task using the *df?EditIdxPtr* task editor.

Using the *df?EditPPSpline1D* task editor, you can provide to the Data Fitting task an already constructed spline that you want to use in computations. To ensure correct interpretation of the memory content, you should set the following parameters:

- Spline order and type, if appropriate. If the spline is not supported by the library, set the *s\_type* parameter to DF\_PP\_DEFAULT.
- Pointer to the array of spline coefficients in row-major format.
- The *scoeffhint* parameter describing the structure of the array:
  - Set the *scoeffhint* flag to the DF\_1ST\_COORDINATE value to pass spline coefficients stored at different memory locations. In this case, you can set the parameters that describe boundary and internal conditions to zero.

- Use the default value `DF_NO_HINT` for all other cases.

Before passing an already constructed spline into the library, you should call the `dfiEditVal` task editor to provide the dimension of the spline `DF_NY`. See table "[Parameters Supported by the `dfiEditVal` Task Editor](#)" for details.

After you provide the spline to the Data Fitting task, you can run computations that use this spline.

---

#### NOTE

You must preserve the arrays `bc` (boundary conditions), `ic` (internal conditions), and `scoeff` (spline coefficients) through the entire workflow of the Data Fitting computations for a task, as the task stores the addresses of the arrays for spline-based computations.

---

#### `df?EditPtr`

Modifies a pointer to an array held in a Data Fitting task descriptor.

---

#### Syntax

```
status = dfsEditPtr(task, ptr_attr, ptr)
```

```
status = dfdEditPtr(task, ptr_attr, ptr)
```

#### Include Files

- `mkl.h`

#### Input Parameters

Name	Type	Description
<code>task</code>	<code>DFTaskPtr</code>	Descriptor of the task.
<code>ptr_attr</code>	<code>const MKL_INT</code>	The parameter to change. For details, see the <i>Pointer Attribute</i> column in table " <a href="#">Pointers Supported by the <code>df?EditPtr</code> Task Editor</a> ".
<code>ptr</code>	<code>const float*</code> for <code>dfsEditPtr</code> <code>const double*</code> for <code>dfdEditPtr</code>	New pointer. For details, see the <i>Purpose</i> column in table " <a href="#">Pointers Supported by the <code>df?EditPtr</code> Task Editor</a> ".

#### Output Parameters

Name	Type	Description
<code>status</code>	<code>int</code>	Status of the routine: <ul style="list-style-type: none"> <li>• <code>DF_STATUS_OK</code> if the routine execution completed successfully.</li> <li>• Non-zero error code otherwise. See "<a href="#">Task Status and Error Reporting</a>" for error code definitions.</li> </ul>

#### Description

The `df?EditPtr` editor replaces the pointer of type `ptr_attr` stored in a Data Fitting task descriptor with a new pointer `ptr`. The table below describes types of pointers supported by the editor:

## Pointers Supported by the `df?EditPtr` Task Editor

Pointer Attribute	Purpose
<code>DF_X</code>	Partition $x$ of the interpolation interval, an array of strictly sorted breakpoints.
	<hr/> <b>Caution</b> The array must be strictly sorted. If it is unordered, the results of data fitting routines are not correct. <hr/>
<code>DF_Y</code>	Vector-valued function $y$
<code>DF_IC</code>	Internal conditions for spline construction. For details, see table " <a href="#">Internal Conditions Supported by Data Fitting Functions</a> ".
<code>DF_BC</code>	Boundary conditions for spline construction. For details, see table " <a href="#">Boundary Conditions Supported by Data Fitting Functions</a> ".
<code>DF_PP_SCOEFF</code>	Spline coefficients

You can use `df?EditPtr` to modify different types of pointers including pointers to the vector-valued function and spline coefficients stored in contiguous memory. Use the `df?EditIdxPtr` editor if you need to modify pointers to coordinates of the vector-valued function or spline coefficients stored at non-contiguous memory locations.

If you modify a partition of the interpolation interval, then you should call the `dfiEditVal` task editor with the corresponding value of `DF_XHINT`, even if the structure of the partition remains the same.

If you pass a `NULL` pointer to the `df?EditPtr` task editor, the task remains unchanged and the routine returns an error code. For the predefined error codes, please see "[Task Status and Error Reporting](#)".

### NOTE

You must preserve the arrays  $x$  (breakpoints),  $y$  (vector-valued functions),  $bc$  (boundary conditions),  $ic$  (internal conditions), and  $scoeff$  (spline coefficients) through the entire workflow of the Data Fitting computations which use those arrays, as the task stores the addresses of the arrays for spline-based computations.

### `dfiEditVal`

*Modifies a parameter value in a Data Fitting task descriptor.*

### Syntax

```
status = dfiEditVal(task, val_attr, val)
```

### Include Files

- `mkl.h`

### Input Parameters

Name	Type	Description
<code>task</code>	<code>DFTaskPtr</code>	Descriptor of the task.

Name	Type	Description
<code>val_attr</code>	<code>const MKL_INT</code>	The parameter to change. See table "Parameters Supported by the <code>dfiEditVal</code> Task Editor".
<code>val</code>	<code>const MKL_INT</code>	A new parameter value. See table "Parameters Supported by the <code>dfiEditVal</code> Task Editor".

## Output Parameters

Name	Type	Description
<code>status</code>	<code>int</code>	Status of the routine: <ul style="list-style-type: none"> <li>• <code>DF_STATUS_OK</code> if the routine execution completed successfully.</li> <li>• Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.</li> </ul>

## Description

The `dfiEditVal` task editor replaces the parameter of type `val_attr` stored in a Data Fitting task descriptor with a new value `val`. The table below describes valid types of parameter `val_attr` supported by the editor:

### Parameters Supported by the `dfiEditVal` Task Editor

Parameter Attribute	Purpose
<code>DF_NX</code>	Number of breakpoints
<code>DF_XHINT</code>	A flag describing the structure of partition. See table "Hint Values for Partition <i>x</i> " for the list of available values.
<code>DF_NY</code>	Dimension of the vector-valued function
<code>DF_YHINT</code>	A flag describing the structure of the vector-valued function. See table "Hint Values for Vector Function <i>y</i> " for the list of available values.
<code>DF_SPLINE_ORDER</code>	Spline order. See table "Spline Orders Supported by Data Fitting Functions" for the list of available values.
<code>DF_SPLINE_TYPE</code>	Spline type. See table "Spline Types Supported by Data Fitting Functions" for the list of available values.
<code>DF_BC_TYPE</code>	Type of boundary conditions used in spline construction. See table "Boundary Conditions Supported by Data Fitting Functions" for the list of available values.
<code>DF_IC_TYPE</code>	Type of internal conditions used in spline construction. See table "Internal Conditions Supported by Data Fitting Functions" for the list of available values.
<code>DF_PP_COEFF_HINT</code>	A flag describing the structure of spline coefficients. See table "Hint Values for Spline Coefficients" for the list of available values.
<code>DF_CHECK_FLAG</code>	A flag which controls checking of Data Fitting parameters. See table "Possible Values for the <code>DF_CHECK_FLAG</code> Parameter" for the list of available values.

If you pass a zero value for the parameter describing the size of the arrays that hold coefficients for a partition, a vector-valued function, or a spline, the parameter held in the Data fitting task remains unchanged and the routine returns an error code. For the predefined error codes, see ["Task Status and Error Reporting"](#).

### Possible Values for the `DF_CHECK_FLAG` Parameter

Value	Description
<code>DF_ENABLE_CHECK_FLAG</code>	Checks the correctness of parameters of Data Fitting computational routines (default mode).
<code>DF_DISABLE_CHECK_FLAG</code>	Disables checking of the correctness of parameters of Data Fitting computational routines.

Use `DF_CHECK_FLAG` for `val_attr` in order to control validation of parameters of Data Fitting computational routines such as `df?Construct1D`, `df?Interpolate1D`/`df?InterpolateEx1D`, and `df?SearchCells1D`/`df?SearchCellsEx1D`, which can perform better with a small number of interpolation sites or integration limits (fewer than one dozen). The default mode, with checking of parameters enabled, should be used as you develop a Data Fitting-based application. After you complete development you can disable parameter checking in order to improve the performance of your application.

If you modify the parameter describing dimensions of the arrays that hold the vector-valued function or spline coefficients in contiguous memory, you should call the `df?EditPtr` task editor with the corresponding pointers to the vector-valued function or spline coefficients even when this pointer remains unchanged. Call the `df?EditIdxPtr` editor if those arrays are stored in non-contiguous memory locations.

You must call the `dfiEditVal` task editor to edit the structure of the partition `DF_XHINT` every time you modify a partition using `df?EditPtr`, even if the structure of the partition remains the same.

#### `df?EditIdxPtr`

*Modifies a pointer to the memory representing a coordinate of the data stored in matrix format.*

### Syntax

```
status = dfsEditIdxPtr(task, ptr_attr, idx, ptr)
```

```
status = dfdEditIdxPtr(task, ptr_attr, idx, ptr)
```

### Include Files

- `mkl.h`

### Input Parameters

Name	Type	Description
<code>task</code>	<code>DFTaskPtr</code>	Descriptor of the task.
<code>ptr_attr</code>	<code>const MKL_INT</code>	Type of the data to be modified. The parameter takes one of the values described in <a href="#">"Data Attributes Supported by the <code>df?EditIdxPtr</code> Task Editor"</a> .
<code>idx</code>	<code>const MKL_INT</code>	Index of the coordinate whose pointer is to be modified.
<code>ptr</code>	<code>const float*</code> for <code>dfsEditIdxPtr</code>	Pointer to the data that holds values of coordinate <code>idx</code> . For details, see table <a href="#">"Data Attributes Supported by the <code>df?EditIdxPtr</code> Task Editor"</a> .

Name	Type	Description
------	------	-------------

	const double* for dfdEditIdxPtr	
--	------------------------------------	--

## Output Parameters

Name	Type	Description
------	------	-------------

<i>status</i>	int	
---------------	-----	--

Status of the routine:

- `DF_STATUS_OK` if the routine execution completed successfully.
- Non-zero error code otherwise. See ["Task Status and Error Reporting"](#) for error code definitions.

## Description

The routine modifies a pointer to the array that holds the *idx* coordinate of vector-valued function *y* or the pointer to the array of spline coefficients corresponding to the given coordinate.

You can use the editor if you need to pass into a Data Fitting task or modify the pointer to coordinates of the vector-valued function or spline coefficients held at non-contiguous memory locations. Do not use the editor for coordinates at contiguous memory locations in row-major format.

Before calling this editor, make sure that you have created and initialized the task using a task creation function or a relevant editor such as the generic or specific `df?EditPPSpline1D` editor.

### Data Attributes Supported by the `df?EditIdxPtr` Task Editor

Data Attribute	Description
<code>DF_Y</code>	Vector-valued function <i>y</i>
<code>DF_PP_SCOEFF</code>	Piecewise polynomial spline coefficients

When using `df?EditIdxPtr`, you might receive an error code in the following cases:

- You passed an unsupported parameter value into the editor.
- The value of the index exceeds the predefined value that equals the dimension *ny* of the vector-valued function.
- You pass a `NULL` pointer to the editor. In this case, the task remains unchanged.
- You pass a pointer to the *idx* coordinate of the vector-valued function you provided to contiguous memory in column-major format.

The code example below demonstrates how to use the editor for providing values of a vector-valued function stored in two non-contiguous arrays:

```
#define NX 1000 /* number of break points */
#define NY 2 /* dimension of vector-valued function */
int main()
{
    DFTaskPtr task;
    double x[NX];
    double y1[NX], y2[NX]; /* vector-valued function is stored as two arrays */
    /* Provide first coordinate of two-dimensional function y into creation routine */
    status = dfdNewTask1D( &task, NX, x, DF_NON_UNIFORM_PARTITION, NY, y1,
                          DF_1ST_COORDINATE );
    /* Provide second coordiante of two-dimensional function */
}
```

```

status = dfdEditIdxPtr(task, DF_Y, 1, y2 );
...
}

```

### df?QueryPtr

Reads a pointer to an array held in a Data Fitting task descriptor.

### Syntax

```
status = dfsQueryPtr(task, ptr_attr, ptr)
```

```
status = dfdQueryPtr(task, ptr_attr, ptr)
```

### Include Files

- mkl.h

### Input Parameters

Name	Type	Description
<i>task</i>	DFTaskPtr	Descriptor of the task.
<i>ptr_attr</i>	const MKL_INT	The parameter to query. The query routine supports pointer attributes described in the table "Pointers Supported by the df?EditPtr Task Editor". For details, see the <i>Pointer Attribute</i> column in the table.

### Output Parameters

Name	Type	Description
<i>ptr</i>	float** for dfsQueryPtr double** for dfdQueryPtr	Pointer to array returned by the query routine. For details, see the <i>Purpose</i> column in table "Pointers Supported by the df?EditPtr Task Editor".
<i>status</i>	int	Status of the routine: <ul style="list-style-type: none"> <li>• DF_STATUS_OK if the routine execution completed successfully.</li> <li>• Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.</li> </ul>

### Description

The df?QueryPtr routine returns the pointer of type *ptr\_attr* stored in a Data Fitting task descriptor as parameter *ptr*. Attributes of the pointers supported by the query function are identical to those supported by the editor df?EditPtr editor in the table "Pointers Supported by the df?EditPtr Task Editor".

You can use df?QueryPtr to read different types of pointers including pointers to the vector-valued function and spline coefficients stored in contiguous memory.

### dfiQueryVal

Reads a parameter value in a Data Fitting task descriptor.

## Syntax

```
status = dfiQueryVal(task, val_attr, val)
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<code>task</code>	<code>DFTaskPtr</code>	Descriptor of the task.
<code>val_attr</code>	<code>const MKL_INT</code>	The parameter to query. The query function supports the parameter attributes described in <a href="#">"Parameters Supported by the dfiEditVal Task Editor"</a> .

## Output Parameters

Name	Type	Description
<code>val</code>	<code>MKL_INT</code>	The parameter value returned by the query function. See table <a href="#">"Parameters Supported by the dfiEditVal Task Editor"</a> .
<code>status</code>	<code>int</code>	Status of the routine: <ul style="list-style-type: none"> <li>• <code>DF_STATUS_OK</code> if the routine execution completed successfully.</li> <li>• Non-zero error code otherwise. See <a href="#">"Task Status and Error Reporting"</a> for error code definitions.</li> </ul>

## Description

The `dfiQueryVal` routine returns a parameter of type `val_attr` stored in a Data Fitting task descriptor as parameter `val`. The query function supports the parameter attributes described in ["Parameters Supported by the dfiEditVal Task Editor"](#).

### **df?QueryIdxPtr**

*Reads a pointer to the memory representing a coordinate of the data stored in matrix format.*

## Syntax

```
status = dfsQueryIdxPtr(task, ptr_attr, idx, ptr)
```

```
status = dfdQueryIdxPtr(task, ptr_attr, idx, ptr)
```

## Include Files

- mkl.h

## Input Parameters

Name	Type	Description
<code>task</code>	<code>DFTaskPtr</code>	Descriptor of the task.

Name	Type	Description
<code>ptr_attr</code>	<code>const MKL_INT</code>	Pointer attribute to query. The parameter takes one of the attributes described in <a href="#">"Data Attributes Supported by the <code>df?EditIdxPtr</code> Task Editor"</a> .
<code>idx</code>	<code>const MKL_INT</code>	Index of the coordinate of the pointer to query.

## Output Parameters

Name	Type	Description
<code>ptr</code>	<code>float*</code> for <code>dfsQueryIdxPtr</code> <code>double*</code> for <code>dfdQueryIdxPtr</code>	Pointer to the data that holds values of coordinate <code>idx</code> returned. For details, see table <a href="#">"Data Attributes Supported by the <code>df?EditIdxPtr</code> Task Editor"</a> .
<code>status</code>	<code>int</code>	Status of the routine: <ul style="list-style-type: none"> <li>• <code>DF_STATUS_OK</code> if the routine execution completed successfully.</li> <li>• Non-zero error code otherwise. See <a href="#">"Task Status and Error Reporting"</a> for error code definitions.</li> </ul>

## Description

The routine returns a pointer to the array that holds the `idx` coordinate of vector-valued function `y` or the pointer to the array of spline coefficients corresponding to the given coordinate.

You can use the query routine if you need the pointer to coordinates of the vector-valued function or spline coefficients held at non-contiguous memory locations or at a contiguous memory location in row-major format (the default storage format for spline coefficients).

Before calling this query routine, make sure that you have created and initialized the task using a task creation function or a relevant editor such as the generic or specific `df?EditPPSpline1D` editor.

When using `df?QueryIdxPtr`, you might receive an error code in the following cases:

- You passed an unsupported parameter value into the editor.
- The value of the index exceeds the predefined value that equals the dimension `ny` of the vector-valued function.
- You request the pointer to the `idx` coordinate of the vector-valued function you provided to contiguous memory in column-major format.

## Data Fitting Computational Routines

Data Fitting computational routines are functions used to perform spline-based computations, such as:

- spline construction
- computation of values, derivatives, and integrals of the predefined order
- cell search

Once you create a Data Fitting task and initialize the required parameters, you can call computational routines as many times as necessary.

The table below lists the available computational routines:

## Data Fitting Computational Routines

Routine	Description
<code>df?Construct1D</code>	Constructs a spline for a one-dimensional Data Fitting task.
<code>df?Interpolate1D</code>	Computes spline values and derivatives.
<code>df?InterpolateEx1D</code>	Computes spline values and derivatives by calling user-provided interpolants.
<code>df?Integrate1D</code>	Computes spline-based integrals.
<code>df?IntegrateEx1D</code>	Computes spline-based integrals by calling user-provided integrators.
<code>df?SearchCells1D</code>	Finds indices of cells containing interpolation sites.
<code>df?SearchCellsEx1D</code>	Finds indices of cells containing interpolation sites by calling user-provided cell searchers.

If a Data Fitting computation completes successfully, the computational routines return the `DF_STATUS_OK` code. If an error occurs, the routines return an error code specifying the origin of the failure. Some possible errors are the following:

- The task pointer is `NULL`.
- Memory allocation failed.
- The computation failed for another reason.

For the list of available status codes, see "[Task Status and Error Reporting](#)".

### NOTE

Data Fitting computational routines do not control errors for floating-point conditions, such as overflow, gradual underflow, or operations with Not a Number (NaN) values.

### `df?Construct1D`

#### Syntax

Constructs a spline of the given type.

```
status = dfsConstruct1D(task, s_format, method)
```

```
status = dfdConstruct1D(task, s_format, method)
```

#### Include Files

- `mkl.h`

#### Input Parameters

Name	Type	Description
<i>task</i>	<code>DFTaskPtr</code>	Descriptor of the task.
<i>s_format</i>	<code>const MKL_INT</code>	Spline format. The supported value is <code>DF_PP_SPLINE</code> .
<i>method</i>	<code>const MKL_INT</code>	Construction method. The supported value is <code>DF_METHOD_STD</code> .

## Output Parameters

Name	Type	Description
<i>status</i>	int	Status of the routine: <ul style="list-style-type: none"> <li>DF_STATUS_OK if the routine execution completed successfully.</li> <li>Non-zero error code if the routine execution failed. See "<a href="#">Task Status and Error Reporting</a>" for error code definitions.</li> </ul>

## Description

Before calling `df?Construct1D`, you need to create and initialize the task, and set the parameters representing the spline. Then you can call the `df?Construct1D` routine to construct the spline. The format of the spline is defined by parameter *s\_format*. The method for spline construction is defined by parameter *method*. Upon successful construction, the spline coefficients are available in the user-provided memory location in the format you set through the Data Fitting editor. For the available storage formats, see table "[Hint Values for Spline Coefficients](#)".

### `df?Interpolate1D/df?InterpolateEx1D`

*Runs data fitting computations.*

## Syntax

```
status = dfsInterpolate1D(task, type, method, nsite, site, sitehint, ndorder, dorder,  
datahint, r, rhint, cell)
```

```
status = dfdInterpolate1D(task, type, method, nsite, site, sitehint, ndorder, dorder,  
datahint, r, rhint, cell)
```

```
status = dfsInterpolateEx1D(task, type, method, nsite, site, sitehint, ndorder, dorder,  
datahint, r, rhint, cell, le_cb, le_params, re_cb, re_params, i_cb, i_params, search_cb,  
search_params)
```

```
status = dfdInterpolateEx1D(task, type, method, nsite, site, sitehint, ndorder, dorder,  
datahint, r, rhint, cell, le_cb, le_params, re_cb, re_params, i_cb, i_params, search_cb,  
search_params)
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<i>task</i>	DFTaskPtr	Descriptor of the task.
<i>type</i>	const MKL_INT	Type of spline-based computations. The parameter takes one or more values combined with an OR operation. For the list of possible values, see table " <a href="#">Computation Types Supported by the df?Interpolate1D/ df?Interpolate1D Routines</a> ".
<i>method</i>	const MKL_INT	Computation method. The supported value is DF_METHOD_PP.

Name	Type	Description
<i>nsite</i>	const MKL_INT	Number of interpolation sites.
<i>site</i>	const float* for dfsInterpolate1D/ dfsInterpolateEx1D  const double* for dfdInterpolate1D/ dfdInterpolateEx1D	<p>Array of interpolation sites of size <i>nsite</i>. The structure of the array is defined by the <i>sitehint</i> parameter:</p> <ul style="list-style-type: none"> <li>• If sites form a non-uniform partition, the array should contain <i>nsite</i> values.</li> <li>• If sites form a uniform partition, the array should contain two entries that represent the left and the right interpolation sites. The first entry of the array contains the left-most interpolation point. The second entry of the array contains the right-most interpolation point.</li> </ul>
<i>sitehint</i>	const MKL_INT	A flag describing the structure of the interpolation sites. For the list of possible values of <i>sitehint</i> , see table " <a href="#">Hint Values for Interpolation Sites</a> ". If you set the flag to DF_NO_HINT, the library interprets the site-defined partition as non-uniform.
<i>ndorder</i>	const MKL_INT	Maximal derivative order increased by one to be computed at interpolation sites.
<i>dorder</i>	const MKL_INT*	Array of size <i>ndorder</i> that defines the order of the derivatives to be computed at the interpolation sites. If all the elements in <i>dorder</i> are zero, the library computes the spline values only. If you do not need interpolation computations, set <i>ndorder</i> to zero and pass a NULL pointer to <i>dorder</i> .
<i>datahint</i>	const float* for dfsInterpolate1D/ dfsInterpolateEx1D  const double* for dfdInterpolate1D/ dfdInterpolateEx1D	Array that contains additional information about the structure of partition <i>x</i> and interpolation sites. This data helps to speed up the computation. If you provide a NULL pointer, the routine uses the default settings for computations. For details on the <i>datahint</i> array, see table " <a href="#">Structure of the datahint Array</a> ".
<i>r</i>	float* for dfsInterpolate1D/ dfsInterpolateEx1D  double* for dfdInterpolate1D/ dfdInterpolateEx1D	Array for results. If you do not need spline-based interpolation, set this pointer to NULL.
<i>rhint</i>	const MKL_INT	A flag describing the structure of the results. For the list of possible values of <i>rhint</i> , see table " <a href="#">Hint Values for the rhint Parameter</a> ". If you set the flag to DF_NO_HINT, the library stores the result in row-major format.
<i>cell</i>	MKL_INT*	Array of cell indices in partition <i>x</i> that contain the interpolation sites. Provide this parameter as input if <i>type</i> is DF_INTERP_USER_CELL. If you do not need cell indices, set this parameter to NULL.

Name	Type	Description
<i>le_cb</i>	constdfsInterpCallback for dfsInterpolateEx1D	User-defined callback function for extrapolation at the sites to the left of the interpolation interval.
	constdfdInterpCallback for dfdInterpolateEx1D	Set to NULL if you are not supplying a callback function.
<i>le_params</i>	const void*	Pointer to additional user-defined parameters passed by the library to the <i>le_cb</i> function.  Set to NULL if there are no additional parameters or if you are not supplying a callback function.
<i>re_cb</i>	constdfsInterpCallback for dfsInterpolateEx1D	User-defined callback function for extrapolation at the sites to the right of the interpolation interval.
	constdfdInterpCallback for dfdInterpolateEx1D	Set to NULL if you are not supplying a callback function.
<i>re_params</i>	const void*	Pointer to additional user-defined parameters passed by the library to the <i>re_cb</i> function.  Set to NULL if there are no additional parameters or if you are not supplying a callback function.
<i>i_cb</i>	constdfsInterpCallback for dfsInterpolateEx1D	User-defined callback function for interpolation within the interpolation interval.
	constdfdInterpCallback for dfdInterpolateEx1D	Set to NULL if you are not supplying a callback function.
<i>i_params</i>	const void*	Pointer to additional user-defined parameters passed by the library to the <i>i_cb</i> function.  Set to NULL if there are no additional parameters or if you are not supplying a callback function.
<i>search_cb</i>	constdfsSearchCellsCal lBack for dfsInterpolateEx1D	User-defined callback function for computing indices of cells that can contain interpolation sites.
	constdfdSearchCellsCal lBack for dfdInterpolateEx1D	Set to NULL if you are not supplying a callback function.
<i>search_params</i>	const void*	Pointer to additional user-defined parameters passed by the library to the <i>search_cb</i> function.  Set to NULL if there are no additional parameters or if you are not supplying a callback function.

## Output Parameters

Name	Type	Description
<i>status</i>	int	Status of the routine:

Name	Type	Description
		<ul style="list-style-type: none"> <li>DF_STATUS_OK if the routine execution completed successfully.</li> <li>Non-zero error code if the routine execution failed. See <a href="#">"Task Status and Error Reporting"</a> for error code definitions.</li> </ul>
<i>r</i>		Contains results of computations at the interpolation sites.
		<hr/> <p><b>Caution</b> The <code>df?Interpolate1D/df?InterpolateEx1D</code> routines do not support in-place computations. You must provide non-aliasing memory locations for the <i>site</i> input parameter and the <i>r</i> output parameter.</p> <hr/>
<i>cell</i>		Array of cell indices in partition <i>x</i> that contain the interpolation sites, which is computed if <i>type</i> is DF_CELL.

## Description

The `df?Interpolate1D/df?InterpolateEx1D` routine performs spline-based computations with user-defined settings. The routine supports two types of computations for interpolation sites provided in array *site*:

### Computation Types Supported by the `df?Interpolate1D/df?InterpolateEx1D` Routines

Type	Description
DF_INTERP	Compute derivatives of predefined order. The derivative of the zero order is the spline value.
DF_INTERP_USER_CELL	<p>Compute derivatives of predefined order given user-provided cell indices. The derivative of the zero order is the spline value.</p> <p>For this type of the computations you should provide a valid <i>cell</i> array, which holds the indices of cells in the <i>site</i> array containing relevant interpolation sites.</p>
DF_CELL	Compute indices of cells in partition <i>x</i> that contain the sites.

If the indices of cells which contain interpolation types are available before the call to `df?Interpolate1D/df?InterpolateEx1D`, you can improve performance by using the DF\_INTERP\_USER\_CELL computation type.

**NOTE**

If you pass any combination of `DF_INTERP`, `DF_INTERP_USER_CELL`, and `DF_CELL` computation types to the routine, the library uses the `DF_INTERP_USER_CELL` computation mode.

If you specify `DF_INTERP_USER_CELL` computation mode and a user-defined callback function for computing cell indices to `df?InterpolateEx1D`, the library uses the `DF_INTERP_USER_CELL` computation mode, and the call-back function is not called.

If the sites do not belong to interpolation interval  $[a, b]$ , the library uses:

- polynomial  $P_0$  of the spline constructed on interval  $[x_0, x_1]$  for computations at the sites to the left of  $a$ .
- polynomial  $P_{n-2}$  of the spline constructed on interval  $[x_{n-2}, x_{n-1}]$  for computations at the sites to the right of  $b$ .

Interpolation sites support the following hints:

**Hint Values for Interpolation Sites**

Value	Description
<code>DF_NON_UNIFORM_PARTITION</code>	Partition is non-uniform.
<code>DF_UNIFORM_PARTITION</code>	Partition is uniform.
<code>DF_SORTED_DATA</code>	Interpolation sites are sorted in the ascending order and define a non-uniform partition.
<code>DF_NO_HINT</code>	No hint is provided. By default, the partition defined by interpolation sites is interpreted as non-uniform.

**NOTE**

If you pass a sorted array of interpolation sites to the Intel® oneAPI Math Kernel Library (oneMKL), set the `sitehint` parameter to the `DF_SORTED_DATA` value. The library uses this information when choosing the search algorithm and ignores any other data hints about the structure of the interpolation sites.

Data Fitting computation routines can use the following hints to speed up the computation:

- `DF_UNIFORM_PARTITION` describes the structure of breakpoints and the interpolation sites.
- `DF_QUASI_UNIFORM_PARTITION` describes the structure of breakpoints.

Pass the above hints to the library when appropriate.

For spline-based interpolation, you should set the derivatives whose values are required for the computation. You can provide the derivatives by setting the `dorder` array of size `ndorder` as follows:

$$dorder[i] = \begin{cases} 1, & \text{if derivative of the } i\text{-th order is required} \\ 0, & \text{otherwise} \end{cases} \quad i = 0, \dots, ndorder - 1$$

Orders of derivatives  $i_d (d = 0, 1, \dots, nder - 1)$ , corresponding to non-zero derivatives to be calculated, form the array  $\{i_d\}$  of length  $nder \leq ndorder$ .

The storage format for the interpolation results is specified using the `rhint` parameter values. For each storage format, Table [Hint Values for the `rhint` Parameter](#) describes how to get the result  $R(j, s, i_d)$  from array  $r$ , for function index  $j (0 \leq j \leq yn - 1)$ , site number  $s (0 \leq s \leq nsite - 1)$ , and derivative index  $i_d (0 \leq i_d \leq nder - 1)$ , where  $yn$  is the number of functions,  $nsite$  is the number of sites, and  $nder$  is the total number of non-zero derivatives for interpolation. The array  $r$  can be either a one-dimensional array of size  $ny * nder * nsite$  or a three-dimensional array with the dimensions described in the table.

## Hint Values for the *rhint* Parameter

Value	Location of $R(j, s, i_d)$ , One-dimensional Array Storage	Location of $R(j, s, i_d)$ , Three-dimensional Array Storage
DF_MATRIX_STORAGE_FU NCS_SITES_DERS (DF_MATRIX_STORAGE_ROWS)	$r[d + nder*(s + nsite*j)]$	$r[j][s][d]$ $r$ declared as $r[ny][nsite][nder]$ .
DF_MATRIX_STORAGE_FU NCS_DERS_SITES (DF_MATRIX_STORAGE_COLS)	$r[s + nsite*(d + nder*j)]$	$r[j][d][s]$ $r$ declared as $r[ny][nder][nsite]$ .
DF_MATRIX_STORAGE_SI TES_FUNCS_DERS	$r[d + nder*(j + ny*s)]$	$r[s][j][d]$ $r$ declared as $r[nsite][ny][nder]$ .
DF_MATRIX_STORAGE_SI TES_DERS_FUNCS	$r[j + ny*(d + nder*s)]$	$r[s][d][j]$ $r$ declared as $r[nsite][nder][ny]$ .
DF_NO_HINT	No hint is provided. By default, the results are stored as in $rhint = DF\_MATRIX\_STORAGE\_FUNCS\_SITES\_DERS$ .	

The following figures show the structure of the storage formats. Each shows sequential memory layout line by line, left to right.

- Storage in  $r$  for  $rhint = DF\_MATRIX\_STORAGE\_FUNCS\_SITES\_DERS$  ( $DF\_MATRIX\_STORAGE\_ROWS$ ):

$R(0, 0, i_0)$	$R(0, 0, i_1)$	...	$R(0, 0, i_{nder-1})$
$R(0, 1, i_0)$	$R(0, 1, i_1)$	...	$R(0, 1, i_{nder-1})$
...	...	...	...
$R(0, nsite - 1, i_0)$	$R(0, nsite - 1, i_1)$	...	$R(0, nsite - 1, i_{nder-1})$
$R(1, 0, i_0)$	$R(1, 0, i_1)$	...	$R(1, 0, i_{nder-1})$
$R(1, 1, i_0)$	$R(1, 1, i_1)$	...	$R(1, 1, i_{nder-1})$
...	...	...	...
$R(1, nsite - 1, i_0)$	$R(1, nsite - 1, i_1)$	...	$R(1, nsite - 1, i_{nder-1})$
...	...	...	...

- Storage in  $r$  for  $rhint = DF\_MATRIX\_STORAGE\_FUNCS\_DERS\_SITES$  ( $DF\_MATRIX\_STORAGE\_COLS$ ):

$R(0,0,i_0)$	$R(0,1,i_0)$	...	$R(0,nsite-1,i_0)$
$R(0,0,i_1)$	$R(0,1,i_1)$	...	$R(0,nsite-1,i_1)$
...	...	...	...
$R(0,0,i_{nder-1})$	$R(0,1,i_{nder-1})$	...	$R(0,nsite-1,i_{nder-1})$

$R(1,0,i_0)$	$R(1,1,i_0)$	...	$R(1,nsite-1,i_0)$
$R(1,0,i_1)$	$R(1,1,i_1)$	...	$R(1,nsite-1,i_1)$
...	...	...	...
$R(1,0,i_{nder-1})$	$R(1,1,i_{nder-1})$	...	$R(1,nsite-1,i_{nder-1})$

...	...	...	...
-----	-----	-----	-----

- Storage in  $r$  for  $rhint = DF\_MATRIX\_STORAGE\_SITES\_FUNCS\_DERS$ :

$R(0,0,i_0)$	$R(0,0,i_1)$	...	$R(0,0,i_{nder-1})$
$R(1,0,i_0)$	$R(1,0,i_1)$	...	$R(1,0,i_{nder-1})$
...	...	...	...
$R(ny-1,0,i_0)$	$R(ny-1,0,i_1)$	...	$R(ny-1,0,i_{nder-1})$

$R(0,1,i_0)$	$R(0,1,i_1)$	...	$R(0,1,i_{nder-1})$
$R(1,1,i_0)$	$R(1,1,i_1)$	...	$R(1,1,i_{nder-1})$
...	...	...	...
$R(ny-1,1,i_0)$	$R(ny-1,1,i_1)$	...	$R(ny-1,1,i_{nder-1})$

...	...	...	...
-----	-----	-----	-----

- Storage in  $r$  for  $rhint = DF\_MATRIX\_STORAGE\_SITES\_DERS\_FUNCS$ :

$R(0,0,i_0)$	$R(1,0,i_0)$	...	$R(ny-1,0,i_0)$
$R(0,0,i_1)$	$R(1,0,i_1)$	...	$R(ny-1,0,i_1)$
...	...	...	...
$R(0,0,i_{nder-1})$	$R(1,0,i_{nder-1})$	...	$R(ny-1,0,i_{nder-1})$

$R(0, 1, i_0)$	$R(1, 1, i_0)$	...	$R(ny - 1, 1, i_0)$
$R(0, 1, i_1)$	$R(1, 1, i_1)$	...	$R(ny - 1, 1, i_1)$
...	...	...	...
$R(0, 1, i_{nder-1})$	$R(1, 1, i_{nder-1})$	...	$R(ny - 1, 1, i_{nder-1})$
...	...	...	...

To speed up Data Fitting computations, use the `datahint` parameter that provides additional information about the structure of the partition and interpolation sites. This data represents a floating-point or a double array with the following structure:

### Structure of the `datahint` Array

Element Number	Description
0	Task dimension
1	Type of additional information
2	Reserved field
3	The total number $q$ of elements containing additional information.
4	Element (1)
...	...
$q+3$	Element ( $q$ )

Data Fitting computation functions support the following types of additional information for `datahint[1]`:

### Types of Additional Information

Type	Element Number	Parameter
DF_NO_APRIORI_INFO	0	No parameters are provided. Information about the data structure is absent.
DF_APRIORI_MOST_LIKELY_CELL	1	Index of the cell that is likely to contain interpolation sites.

To compute indices of the cells that contain interpolation sites, provide the pointer to the array of size `nsite` for the results. The library supports the following scheme of cell indexing for the given partition  $\{x_i\}$ ,  $i=1, \dots, nx$ :

$$cell[j] = i, \text{ if } site[j] \in [x_i, x_{i+1}), i = 0, \dots, nx - 2,$$

$$cell[j] = nx - 1, \text{ if } site[j] \in [x_{nx-1}, x_{nx}],$$

$$cell[j] = nx, \text{ if } site[j] \in (x_{nx}, x_{nx+1}],$$

where

- $x_0 = -\infty$
- $x_{nx+1} = +\infty$
- $j = 0, \dots, nsite-1$

To perform interpolation computations with spline types unsupported in the Data Fitting component, use the extended version of the routine `df?InterpolateEx1D`. With this routine, you can provide user-defined callback functions for computations within, to the left of, or to the right of interpolation interval  $[a, b]$ . The callback functions compute indices of the cells that contain the specified interpolation sites or can serve as an approximation for computing the exact indices of such cells.

If you do not pass any function for computations at the sites outside the interval  $[a, b]$ , the routine uses the default settings.

## Include Files

- `mk1.h`

## Input Parameters

Name	Type	Description
<code>task</code>	<code>DFTaskPtr</code>	Descriptor of the task.
<code>method</code>	<code>const MKL_INT</code>	Integration method. The supported value is <code>DF_METHOD_PP</code> .
<code>nlim</code>	<code>const MKL_INT</code>	Number of pairs of integration limits.
<code>llim</code>	<code>const float*</code> for <code>dfsIntegrate1D/</code> <code>dfsIntegrateEx1D</code>  <code>const double*</code> for <code>dfdIntegrate1D/</code> <code>dfdIntegrateEx1D</code>	Array of size <code>nlim</code> that defines the left-side integration limits.

Name	Type	Description
<i>llimhint</i>	const MKL_INT	A flag describing the structure of the left-side integration limits <i>llim</i> . For the list of possible values of <i>llimhint</i> , see table <a href="#">"Hint Values for Integration Limits"</a> . If you set the flag to the DF_NO_HINT value, the library assumes that the left-side integration limits define a non-uniform partition.
<i>rlim</i>	const float* for dfsIntegrate1D/ dfsIntegrateEx1D  const double* for dfdIntegrate1D/ dfdIntegrateEx1D	Array of size <i>nlim</i> that defines the right-side integration limits.
<i>rlimhint</i>	const MKL_INT	A flag describing the structure of the right-side integration limits <i>rlim</i> . For the list of possible values of <i>rlimhint</i> , see table <a href="#">"Hint Values for Integration Limits"</a> . If you set the flag to the DF_NO_HINT value, the library assumes that the right-side integration limits define a non-uniform partition.
<i>ldatahint</i>	const float* for dfsIntegrate1D/ dfsIntegrateEx1D  const double* for dfdIntegrate1D/ dfdIntegrateEx1D	Array that contains additional information about the structure of partition <i>x</i> and left-side integration limits. For details on the <i>ldatahint</i> array, see table <a href="#">"Structure of the datahint Array"</a> in the description of the df? Interpolate1D function.
<i>rdatahint</i>	const float* for dfsIntegrate1D/ dfsIntegrateEx1D  const double* for dfdIntegrate1D/ dfdIntegrateEx1D	Array that contains additional information about the structure of partition <i>x</i> and right-side integration limits. For details on the <i>rdatahint</i> array, see table <a href="#">"Structure of the datahint Array"</a> in the description of the df? Interpolate1D function.
<i>rhint</i>	const MKL_INT	A flag describing the structure of the results. For the list of possible values of <i>rhint</i> , see table <a href="#">"Hint Values for Integration Results"</a> . If you set the flag to the DF_NO_HINT value, the library stores the results in row-major format.
<i>le_cb</i>	constdfsIntegrCallback for dfsIntegrateEx1D  constdfdIntegrCallback for dfdIntegrateEx1D	User-defined callback function for integration on interval $[llim[i], \min(rlim[i], a))$ for $llim[i] < a$ .  Set to NULL if you are not supplying a callback function.
<i>le_params</i>	const void*	Pointer to additional user-defined parameters passed by the library to the <i>le_cb</i> function.  Set to NULL if there are no additional parameters or if you are not supplying a callback function.

Name	Type	Description
<i>re_cb</i>	constdfsInterpCallBack for dfsIntegrateEx1D	User-defined callback function for integration on interval $[\max(llim[i], b), rlim[i])$ for $rlim[i] \geq b$ .
	constdfdInterpCallBack for dfdIntegrateEx1D	Set to NULL if you are not supplying a callback function.
<i>re_params</i>	const void*	Pointer to additional user-defined parameters passed by the library to the <i>re_cb</i> function.
		Set to NULL if there are no additional parameters or if you are not supplying a callback function.
<i>i_cb</i>	constdfsIntegrCallBack for dfsIntegrateEx1D	User-defined callback function for integration on interval $[\max(a, llim[i], ), \min(rlim[i], b))$ .
	constdfdIntegrCallBack for dfdIntegrateEx1D	Set to NULL if you are not supplying a callback function.
<i>i_params</i>	const void*	Pointer to additional user-defined parameters passed by the library to the <i>i_cb</i> function.
		Set to NULL if there are no additional parameters or if you are not supplying a callback function.
<i>search_cb</i>	constdfsSearchCellsCal lBack for dfsIntegrateEx1D	User-defined callback function for computing indices of cells that can contain interpolation sites.
	constdfdSearchCellsCal lBack for dfdIntegrateEx1D	Set to NULL if you are not supplying a callback function.
	const void*	Pointer to additional user-defined parameters passed by the library to the <i>search_cb</i> function.
<i>search_params</i>	const void*	Pointer to additional user-defined parameters passed by the library to the <i>search_cb</i> function.
		Set to NULL if there are no additional parameters or if you are not supplying a callback function.

## Output Parameters

Name	Type	Description
<i>status</i>	int	Status of the routine: <ul style="list-style-type: none"> <li>DF_STATUS_OK if the routine execution completed successfully.</li> <li>Non-zero error code if the routine execution failed. See <a href="#">"Task Status and Error Reporting"</a> for error code definitions.</li> </ul>
<i>r</i>	float* for dfsIntegrate1D/ dfsIntegrateEx1D  double* for dfdIntegrate1D/ dfdIntegrateEx1D	Array of integration results. The size of the array should be sufficient to hold $nlim * ny$ values, where $ny$ is the dimension of the vector-valued function. The integration results are packed according to the settings in <i>rhint</i> .

Name	Type	Description
------	------	-------------

**Caution**

The `df?Integrate1D/df?IntegrateEx1D` routines do not support in-place computations. You must provide non-aliasing memory locations for the `llim` and `rlim` input parameters and the `r` output parameter.

**Description**

The `df?Integrate1D/df?IntegrateEx1D` routine computes spline-based integral on user-defined intervals

$$I(i, j) = \int_{ll_i}^{rl_i} f_j(x) dx$$

where  $rl_i = rlim[i]$ ,  $ll_i = llim[i]$ , and  $i = 0, \dots, ny - 1$ .

If  $rlim[i] < llim[i]$ , the routine returns

$$I(i, j) = -\int_{rl_i}^{ll_i} f_j(x) dx$$

The routine supports the following hint values for integration results:

**Hint Values for Integration Results**

Value	Description
DF_MATRIX_STORAGE_ROWS	Data is stored in row-major format according to C conventions.
DF_MATRIX_STORAGE_COLS	Data is stored in column-major format according to Fortran conventions.
DF_NO_HINT	No hint is provided. By default, the coordinates of vector-valued function $y$ are provided and stored in row-major format.

A common structure of the storage formats for the integration results is as follows:

- Row-major format

$I(0, 0)$	...	$I(0, nlim - 1)$
...	...	...
$I(ny - 1, 0)$	...	$I(ny - 1, nlim - 1)$

- Column-major format

$I(0, 0)$	...	$I(ny - 1, 0)$
...	...	...
$I(0, nlim - 1)$	...	$I(ny - 1, nlim - 1)$

Using the `llimhint` and `rlimhint` parameters, you can provide the following hint values for integration limits:

### Hint Values for Integration Limits

Value	Description
<code>DF_SORTED_DATA</code>	Integration limits are sorted in the ascending order and define a non-uniform partition.
<code>DF_NON_UNIFORM_PARTITION</code>	Partition defined by integration limits is non-uniform.
<code>DF_UNIFORM_PARTITION</code>	Partition defined by integration limits is uniform.
<code>DF_NO_HINT</code>	No hint is provided. By default, partition defined by integration limits is interpreted as non-uniform.

To compute integration with splines unsupported in the Data Fitting component, use the extended version of the routine `df?IntegrateEx1D`. With this routine, you can provide user-defined callback functions that compute:

- integrals within, to the left of, or to the right of the interpolation interval  $[a, b]$
- indices of cells that contain the provided integration limits or can serve as an approximation for computing the exact indices of such cells

If you do not pass callback functions, the routine uses the default settings.

## Output Parameters

Name	Type	Description
<i>status</i>	int	<p>Status of the routine:</p> <ul style="list-style-type: none"> <li>• DF_STATUS_OK if the routine execution completed successfully.</li> <li>• Non-zero error code if the routine execution failed. See "<a href="#">Task Status and Error Reporting</a>" for error code definitions.</li> </ul>
<i>cell</i>	MKL_INT*	Array of cell indices in the partition that contain the interpolation sites.

## Description

The `df?SearchCells1D/df?SearchCellsEx1D` routines return array `cell` of indices of sub-intervals (cells) in the partition that contain interpolation sites available in array `site`. For details on the cell indexing scheme, see the description of the `df?Interpolate1D/df?InterpolateEx1D` computation routines.

Use the `datahint` parameter to provide additional information about the structure of the partition and/or interpolation sites. The definition of the `datahint` parameter is available in the description of the `df?Interpolate1D/df?InterpolateEx1D` computation routines.

For description of the user-defined callback for computation of cell indices, see `df?SearchCellsCallBack`.

### df?InterpCallBack

A callback function for user-defined interpolation to be passed into `df?InterpolateEx1D`.

## Syntax

```
status = dfsInterpCallBack(n, cell, site, r, user_params, library_params)
```

```
status = dfdInterpCallBack(n, cell, site, r, user_params, library_params)
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>n</code>	<code>long long*</code>	Number of interpolation sites.
<code>cell</code>	<code>long long*</code>	Array of size <code>n</code> containing indices of the cells to which the interpolation sites in array <code>site</code> belong.
<code>site</code>	<code>float*</code> for <code>dfsInterpCallBack</code> <code>double*</code> for <code>dfdInterpCallBack</code>	Array of interpolation sites of size <code>n</code> .
<code>user_params</code>	<code>void*</code>	Pointer to user-defined parameters of the callback function.
<code>library_params</code>	<code>dfInterpCallBackLibraryParams*</code>	Pointer to library-defined parameters of the callback function.

## Output Parameters

Name	Type	Description
<code>status</code>	<code>int</code>	The status returned by the callback function: <ul style="list-style-type: none"> <li>• Zero indicates successful completion of the callback operation.</li> <li>• A negative value indicates an error.</li> <li>• A positive value indicates a warning.</li> </ul> See " <a href="#">Task Status and Error Reporting</a> " for error code definitions.
<code>r</code>	<code>float*</code> for <code>dfsInterpCallback</code> <code>double*</code> for <code>dfdInterpCallback</code>	Array of the computed interpolation results packed in row-major format.

## Description

When passed into the `df?InterpolateEx1D` routine, this function performs user-defined interpolation operation.

The `library_params` parameter allows the library to provide extra parameters. Currently no parameters are provided.

## `df?IntegrCallback`

*A callback function that you can pass into `df?IntegrateEx1D` to define integration computations.*

## Syntax

```
status = dfsIntegrCallback(n, lcell, llim, rcell, rlim, r, user_params, library_params)
```

```
status = dfdIntegrCallback(n, lcell, llim, rcell, rlim, r, user_params, library_params)
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>n</code>	<code>long long*</code>	Number of pairs of integration limits.
<code>lcell</code>	<code>long long*</code>	Array of size <code>n</code> with indices of the cells that contain the left-side integration limits in array <code>llim</code> .
<code>llim</code>	<code>float*</code> for <code>dfsIntegrCallback</code> <code>double*</code> for <code>dfdIntegrCallback</code>	Array of size <code>n</code> that holds the left-side integration limits.

Name	Type	Description
<i>rcell</i>	long long*	Array of size <i>n</i> with indices of the cells that contain the right-side integration limits in array <i>rlim</i> .
<i>rlim</i>	float* for <code>dfsIntegrCallback</code> double* for <code>dfdIntegrCallback</code>	Array of size <i>n</i> that holds the right-side integration limits.
<i>user_params</i>	void*	Pointer to user-defined parameters of the callback function.
<i>library_params</i>	<code>dfIntegrCallbackLibraryParams*</code>	Pointer to library-defined parameters of the callback function.

## Output Parameters

Name	Type	Description
<i>status</i>	int	The status returned by the callback function: <ul style="list-style-type: none"> <li>• Zero indicates successful completion of the callback operation.</li> <li>• A negative value indicates an error.</li> <li>• A positive value indicates a warning.</li> </ul> See " <a href="#">Task Status and Error Reporting</a> " for error code definitions.
<i>r</i>	float* for <code>dfsIntegrCallback</code> double* for <code>dfdIntegrCallback</code>	Array of integration results. For packing the results in row-major format, follow the instructions described in <a href="#">df?Interpolate1D/df?InterpolateEx1D</a> .

## Description

When passed into the `df?IntegrateEx1D` routine, this function defines integration computations. If at least one of the integration limits is outside the interpolation interval  $[a, b]$ , the library decomposes the integration into sub-intervals that belong to the extrapolation range to the left of *a*, the extrapolation range to the right of *b*, and the interpolation interval  $[a, b]$ , as follows:

- If the left integration limit is to the left of the interpolation interval ( $l_{lim} < a$ ), the `df?IntegrateEx1D` routine passes *l<sub>lim</sub>* as the left integration limit and  $\min(r_{lim}, a)$  as the right integration limit to the user-defined callback function.
- If the right integration limit is to the right of the interpolation interval ( $r_{lim} > b$ ), the `df?IntegrateEx1D` routine passes  $\max(l_{lim}, b)$  as the left integration limit and *r<sub>lim</sub>* as the right integration limit to the user-defined callback function.
- If the left and the right integration limits belong to the interpolation interval, the `df?IntegrateEx1D` routine passes them to the user-defined callback function unchanged.

The value of the integral is the sum of integral values obtained on the sub-intervals.

The *library\_params* parameter allows the library to provide extra parameters. Currently no parameters are provided.

## Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

### [df?SearchCellsCallback](#)

A callback function for user-defined search to be passed into [df?InterpolateEx1D](#), [df?IntegrateEx1D](#), or [df?SearchCellsEx1D](#).

## Syntax

```
status = dfsSearchCellsCallback(n, site, cell, flag, user_params, library_params)
```

```
status = dfdSearchCellsCallback(n, site, cell, flag, user_params, library_params)
```

## Include Files

- `mk1.h`

## Input Parameters

Name	Type	Description
<i>n</i>	long long*	Number of interpolation sites or integration limits.
<i>site</i>	float* for dfsSearchCellsCallback  double* for dfdSearchCellsCallback	Array, size <i>n</i> , of interpolation sites or integration limits.
<i>flag</i>	int*	Array of size <i>n</i> , with values set as follows: <ul style="list-style-type: none"> <li>• If the cell with index <i>cell</i>[<i>i</i>] contains <i>site</i>[<i>i</i>], set <i>flag</i>[<i>i</i>] to 1.</li> <li>• Otherwise, set <i>flag</i>[<i>i</i>] to zero. In this case, the library interprets the index as an approximation and computes the index of the cell containing <i>site</i>[<i>i</i>] by using the provided index as a starting point for the search.</li> </ul>
<i>user_params</i> <i>ms</i>	void*	Pointer to user-defined parameters of the callback function.

Name	Type	Description
<code>library_params</code>	<code>dfSearchCallBackLibraryParams*</code>	Pointer to library-defined parameters of the callback function.

## Output Parameters

Name	Type	Description
<code>status</code>	<code>int</code>	<p>The status returned by the callback function:</p> <ul style="list-style-type: none"> <li>• Zero indicates successful completion of the callback operation.</li> <li>• A negative value indicates an error.</li> <li>• The <code>DF_STATUS_EXACT_RESULT</code> status indicates that cell indices returned by the callback function are exact. In this case, you do not need to initialize entries of the <code>flag</code> array.</li> <li>• A positive value indicates a warning.</li> </ul> <p>See "Task Status and Error Reporting" for error code definitions.</p>
<code>cell</code>	<code>long long*</code>	Array of size $n$ that returns indices of the cells computed by the callback function.

## Description

When passed into the `df?InterpolateEx1D`, `df?IntegrateEx1D`, or `df?SearchCellsEx1D` routine, this function performs a user-defined search.

The `library_params` parameter allows the library to provide extra parameters. The `df?InterpolateEx1D`, and `df?SearchCellsEx1D` routines do not provide extra parameters and set `library_params` to `NULL`. The `df?IntegrateEx1D` routines use this parameter to specify which type of integration limits, left or right, are provided for the callback. To do this the library declares the `dfSearchCallBackLibraryParams` structure. It currently contains one field, `limit_type_flag`, of type `int`. The field is set by the library to one of two possible values: `DF_INTEGR_SEARCH_CB_LLIM_FLAG` if the left integration limits are provided, or `DF_INTEGR_SEARCH_CB_RLIM_FLAG` if the right integration limits are provided.

## Data Fitting Task Destructors

Task destructors are routines used to delete task descriptors and deallocate the corresponding memory resources. The Data Fitting task destructor `dfDeleteTask` destroys a Data Fitting task and frees the memory.

### `dfDeleteTask`

*Destroys a Data Fitting task object and frees the memory.*

---

## Syntax

```
status = dfDeleteTask(&task)
```

## Include Files

- `mkl.h`

## Input Parameters

Name	Type	Description
<code>task</code>	<code>DFTaskPtr</code>	Descriptor of the task to destroy.

## Output Parameters

Name	Type	Description
<code>status</code>	<code>int</code>	Status of the routine: <ul style="list-style-type: none"> <li>• <code>DF_STATUS_OK</code> if the task is deleted successfully.</li> <li>• Non-zero error code if the operation failed. See "<a href="#">Task Status and Error Reporting</a>" for error code definitions.</li> </ul>

## Description

Given a pointer to a task descriptor, this routine deletes the Data Fitting task descriptor and frees the memory allocated for the structure. If the task is deleted successfully, the routine sets the task pointer to `NULL`. Otherwise, the routine returns an error code.

# Appendix A: Linear Solvers Basics

Many applications in science and engineering require the solution of a system of linear equations. This problem is usually expressed mathematically by the matrix-vector equation,  $Ax = b$ , where  $A$  is an  $m$ -by- $n$  matrix,  $x$  is the  $n$  element column vector and  $b$  is the  $m$  element column vector. The matrix  $A$  is usually referred to as the coefficient matrix, and the vectors  $x$  and  $b$  are referred to as the solution vector and the right-hand side, respectively.

Basic concepts related to solving linear systems with sparse matrices are described in [Sparse Linear Systems](#) and various storage schemes for sparse matrices are described in [Sparse Matrix Storage Formats](#).

## Sparse Linear Systems

In many real-life applications, most of the elements in  $A$  are zero. Such a matrix is referred to as sparse. Conversely, matrices with very few zero elements are called dense. For sparse matrices, computing the solution to the equation  $Ax = b$  can be made much more efficient with respect to both storage and computation time, if the sparsity of the matrix can be exploited. The more an algorithm can exploit the sparsity without sacrificing the correctness, the better the algorithm.

Generally speaking, computer software that finds solutions to systems of linear equations is called a solver. A solver designed to work specifically on sparse systems of equations is called a sparse solver. Solvers are usually classified into two groups - direct and iterative.

**Iterative Solvers** start with an initial approximation to a solution and attempt to estimate the difference between the approximation and the true result. Based on the difference, an iterative solver calculates a new approximation that is closer to the true result than the initial approximation. This process is repeated until the difference between the approximation and the true result is sufficiently small. The main drawback to iterative solvers is that the rate of convergence depends greatly on the values in the matrix  $A$ . Consequently, it is not possible to predict how long it will take for an iterative solver to produce a solution. In fact, for ill-

conditioned matrices, the iterative process will not converge to a solution at all. However, for well-conditioned matrices it is possible for iterative solvers to converge to a solution very quickly. Consequently, if an application involves well-conditioned matrices iterative solvers can be very efficient.

**Direct Solvers**, on the other hand, factor the matrix  $A$  into the product of two triangular matrices and then perform a forward and backward triangular solve.

This approach makes the time required to solve a systems of linear equations relatively predictable, based on the size of the matrix. In fact, for sparse matrices, the solution time can be predicted based on the number of non-zero elements in the array  $A$ .

## Matrix Fundamentals

A matrix is a rectangular array of either real or complex numbers. A matrix is denoted by a capital letter; its elements are denoted by the same lower case letter with row/column subscripts. Thus, the value of the element in row  $i$  and column  $j$  in matrix  $A$  is denoted by  $a(i, j)$ . For example, a 3 by 4 matrix  $A$ , is written as follows:

$$A = \begin{bmatrix} a(1, 1) & a(1, 2) & a(1, 3) & a(1, 4) \\ a(2, 1) & a(2, 2) & a(2, 3) & a(2, 4) \\ a(3, 1) & a(3, 2) & a(3, 3) & a(3, 4) \end{bmatrix}$$

Note that with the above notation, we assume the standard Fortran programming language convention of starting array indices at 1 rather than the C programming language convention of starting them at 0.

A matrix in which all of the elements are real numbers is called a real matrix. A matrix that contains at least one complex number is called a complex matrix. A real or complex matrix  $A$  with the property that  $a(i, j) = a(j, i)$ , is called a symmetric matrix. A complex matrix  $A$  with the property that  $a(i, j) = \text{conj}(a(j, i))$ , is called a Hermitian matrix. Note that programs that manipulate symmetric and Hermitian matrices need only store half of the matrix values, since the values of the non-stored elements can be quickly reconstructed from the stored values.

A matrix that has the same number of rows as it has columns is referred to as a square matrix. The elements in a square matrix that have same row index and column index are called the diagonal elements of the matrix, or simply the diagonal of the matrix.

The transpose of a matrix  $A$  is the matrix obtained by "flipping" the elements of the array about its diagonal. That is, we exchange the elements  $a(i, j)$  and  $a(j, i)$ . For a complex matrix, if we both flip the elements about the diagonal and then take the complex conjugate of the element, the resulting matrix is called the Hermitian transpose or conjugate transpose of the original matrix. The transpose and Hermitian transpose of a matrix  $A$  are denoted by  $A^T$  and  $A^H$  respectively.

A column vector, or simply a vector, is a  $n \times 1$  matrix, and a row vector is a  $1 \times n$  matrix. A real or complex matrix  $A$  is said to be positive definite if the vector-matrix product  $x^T A x$  is greater than zero for all non-zero vectors  $x$ . A matrix that is not positive definite is referred to as indefinite.

An upper (or lower) triangular matrix, is a square matrix in which all elements below (or above) the diagonal are zero. A unit triangular matrix is an upper or lower triangular matrix with all 1's along the diagonal.

A matrix  $P$  is called a permutation matrix if, for any matrix  $A$ , the result of the matrix product  $PA$  is identical to  $A$  except for interchanging the rows of  $A$ . For a square matrix, it can be shown that if  $PA$  is a permutation of the rows of  $A$ , then  $AP^T$  is the same permutation of the columns of  $A$ . Additionally, it can be shown that the inverse of  $P$  is  $P^T$ .

In order to save space, a permutation matrix is usually stored as a linear array, called a permutation vector, rather than as an array. Specifically, if the permutation matrix maps the  $i$ -th row of a matrix to the  $j$ -th row, then the  $i$ -th element of the permutation vector is  $j$ .

A matrix with non-zero elements only on the diagonal is called a diagonal matrix. As is the case with a permutation matrix, it is usually stored as a vector of values, rather than as a matrix.

## Direct Method

For solvers that use the direct method, the basic technique employed in finding the solution of the system  $Ax = b$  is to first factor  $A$  into triangular matrices. That is, find a lower triangular matrix  $L$  and an upper triangular matrix  $U$ , such that  $A = LU$ . Having obtained such a factorization (usually referred to as an  $LU$  decomposition or  $LU$  factorization), the solution to the original problem can be rewritten as follows.

$$\begin{aligned} Ax &= b \\ \Rightarrow LUx &= b \\ \Rightarrow L(Ux) &= b \end{aligned}$$

This leads to the following two-step process for finding the solution to the original system of equations:

1. Solve the systems of equations  $Ly = b$ .
2. Solve the system  $Ux = y$ .

Solving the systems  $Ly = b$  and  $Ux = y$  is referred to as a forward solve and a backward solve, respectively.

If a symmetric matrix  $A$  is also positive definite, it can be shown that  $A$  can be factored as  $LL^T$  where  $L$  is a lower triangular matrix. Similarly, a Hermitian matrix,  $A$ , that is positive definite can be factored as  $A = LL^H$ . For both symmetric and Hermitian matrices, a factorization of this form is called a Cholesky factorization.

In a Cholesky factorization, the matrix  $U$  in an  $LU$  decomposition is either  $L^T$  or  $L^H$ . Consequently, a solver can increase its efficiency by only storing  $L$ , and one-half of  $A$ , and not computing  $U$ . Therefore, users who can express their application as the solution of a system of positive definite equations will gain a significant performance improvement over using a general representation.

For matrices that are symmetric (or Hermitian) but not positive definite, there are still some significant efficiencies to be had. It can be shown that if  $A$  is symmetric but not positive definite, then  $A$  can be factored as  $A = LDL^T$ , where  $D$  is a diagonal matrix and  $L$  is a lower unit triangular matrix. Similarly, if  $A$  is Hermitian, it can be factored as  $A = LDL^H$ . In either case, we again only need to store  $L$ ,  $D$ , and half of  $A$  and we need not compute  $U$ . However, the backward solve phases must be amended to solving  $L^T x = D^{-1}y$  rather than  $L^T x = y$ .

## Fill-In and Reordering of Sparse Matrices

Two important concepts associated with the solution of sparse systems of equations are fill-in and reordering. The following example illustrates these concepts.

Consider the system of linear equation  $Ax = b$ , where  $A$  is a symmetric positive definite sparse matrix, and  $A$  and  $b$  are defined by the following:

$$A = \begin{bmatrix} 9 & \frac{3}{2} & 6 & \frac{3}{4} & 3 \\ \frac{3}{2} & \frac{1}{2} & * & * & * \\ 6 & * & 12 & * & * \\ \frac{3}{4} & * & * & \frac{5}{8} & * \\ 3 & * & * & * & 16 \end{bmatrix}, b = \begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{bmatrix}$$

A star (\*) is used to represent zeros and to emphasize the sparsity of  $A$ . The Cholesky factorization of  $A$  is:  $A = LL^T$ , where  $L$  is the following:

$$L = \begin{bmatrix} 3 & * & * & * & * \\ 1 & 1 & * & * & * \\ 2 & 2 & & & \\ 2 & -2 & 2 & * & * \\ 1 & 1 & 1 & 1 & * \\ 4 & -4 & -2 & 2 & \\ 1 & -1 & -2 & -3 & 1 \end{bmatrix}$$

Notice that even though the matrix  $A$  is relatively sparse, the lower triangular matrix  $L$  has no zeros below the diagonal. If we computed  $L$  and then used it for the forward and backward solve phase, we would do as much computation as if  $A$  had been dense.

The situation of  $L$  having non-zeros in places where  $A$  has zeros is referred to as fill-in. Computationally, it would be more efficient if a solver could exploit the non-zero structure of  $A$  in such a way as to reduce the fill-in when computing  $L$ . By doing this, the solver would only need to compute the non-zero entries in  $L$ . Toward this end, consider permuting the rows and columns of  $A$ . As described in [Matrix Fundamentals](#), the permutations of the rows of  $A$  can be represented as a permutation matrix,  $P$ . The result of permuting the rows is the product of  $P$  and  $A$ . Suppose, in the above example, we swap the first and fifth row of  $A$ , then swap the first and fifth columns of  $A$ , and call the resulting matrix  $B$ . Mathematically, we can express the process of permuting the rows and columns of  $A$  to get  $B$  as  $B = PAP^T$ . After permuting the rows and columns of  $A$ , we see that  $B$  is given by the following:

$$B = \begin{bmatrix} 16 & * & * & * & 3 \\ * & 1 & * & * & 3 \\ * & 2 & * & * & 2 \\ * & * & 12 & * & 6 \\ * & * & * & 5 & 3 \\ 3 & 3 & 6 & 8 & 4 \\ 2 & 3 & 4 & 3 & 9 \end{bmatrix}$$

Since  $B$  is obtained from  $A$  by simply switching rows and columns, the numbers of non-zero entries in  $A$  and  $B$  are the same. However, when we find the Cholesky factorization,  $B = LL^T$ , we see the following:

$$L = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{\sqrt{5}} \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix}$$

The fill-in associated with  $B$  is much smaller than the fill-in associated with  $A$ . Consequently, the storage and computation time needed to factor  $B$  is much smaller than to factor  $A$ . Based on this, we see that an efficient sparse solver needs to find permutation  $P$  of the matrix  $A$ , which minimizes the fill-in for factoring  $B = PAP^T$ , and then use the factorization of  $B$  to solve the original system of equations.

Although the above example is based on a symmetric positive definite matrix and a Cholesky decomposition, the same approach works for a general  $LU$  decomposition. Specifically, let  $P$  be a permutation matrix,  $B = PAP^T$  and suppose that  $B$  can be factored as  $B = LU$ . Then

$$Ax = b \Rightarrow PA(P^{-1}P)x = Pb$$

$$\Rightarrow PA(P^T P)x = Pb$$

$$\Rightarrow (PAP^T)(Px) = Pb$$

$$\Rightarrow B(Px) = Pb$$

$$\Rightarrow LU(Px) = Pb$$

It follows that if we obtain an  $LU$  factorization for  $B$ , we can solve the original system of equations by a three step process:

1. Solve  $Ly = Pb$ .
2. Solve  $Uz = y$ .
3. Set  $x = P^Tz$ .

If we apply this three-step process to the current example, we first need to perform the forward solve of the systems of equation  $Ly = Pb$ :

$$Ly = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix} * \begin{bmatrix} y1 \\ y2 \\ y3 \\ y4 \\ y5 \end{bmatrix} = \begin{bmatrix} 5 \\ 2 \\ 3 \\ 4 \\ 1 \end{bmatrix}$$

This gives:

$$y^T = \frac{5}{4}, 2\sqrt{2}, \frac{\sqrt{3}}{2}, \frac{16}{\sqrt{10}}, \frac{-979\sqrt{3}}{12}.$$

The second step is to perform the backward solve,  $Uz = y$ . Or, in this case, since a Cholesky factorization is used,  $L^Tz = y$ .

$$\begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix}^T * \begin{bmatrix} z1 \\ z2 \\ z3 \\ z4 \\ z5 \end{bmatrix} = \begin{bmatrix} \frac{5}{4} \\ 2(\sqrt{2}) \\ \frac{\sqrt{3}}{2} \\ \frac{16}{\sqrt{10}} \\ \frac{-979\sqrt{3}}{12\sqrt{5}} \end{bmatrix}$$

This gives

$$z^T = \frac{123}{2}, 983, \frac{1961}{12}, 398, \frac{-979}{3}.$$

The third and final step is to set  $x = P^T z$ . This gives

$$X^T = \frac{-979}{3}, 983, \frac{1961}{12}, 398, \frac{123}{2}.$$

## Sparse Matrix Storage Formats

It is more efficient to store only the non-zero elements of a sparse matrix. There are a number of common storage formats used for sparse matrices, but most of them employ the same basic technique. That is, store all non-zero elements of the matrix into a linear array and provide auxiliary arrays to describe the locations of the non-zero elements in the original matrix.

### Storage Formats for the Direct Sparse Solvers

Storing the non-zero elements of a sparse matrix into a linear array is done by walking down each column (column-major format) or across each row (row-major format) in order, and writing the non-zero elements to a linear array in the order they appear in the walk.

## DSS Symmetric Matrix Storage

For symmetric matrices, it is necessary to store only the upper triangular half of the matrix (upper triangular format) or the lower triangular half of the matrix (lower triangular format).

The Intel® oneAPI Math Kernel Library (oneMKL) direct sparse solvers use a row-major upper triangular storage format: the matrix is compressed row-by-row and for symmetric matrices only non-zero elements in the upper triangular half of the matrix are stored.

The Intel® oneAPI Math Kernel Library (oneMKL) sparse matrix storage format for direct sparse solvers is specified by three arrays: *values*, *columns*, and *rowIndex*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix.

<i>values</i>	A real or complex array that contains the non-zero elements of a sparse matrix. The non-zero elements are mapped into the <i>values</i> array using the row-major upper triangular storage mapping described above.
<i>columns</i>	Element <i>i</i> of the integer array <i>columns</i> is the number of the column that contains the <i>i</i> -th element in the <i>values</i> array.
<i>rowIndex</i>	Element <i>j</i> of the integer array <i>rowIndex</i> gives the index of the element in the <i>values</i> array that is first non-zero element in a row <i>j</i> .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in the matrix.

As the *rowIndex* array gives the location of the first non-zero element within a row, and the non-zero elements are stored consecutively, the number of non-zero elements in the *i*-th row is equal to the difference of *rowIndex*[*i*] and *rowIndex*[*i*+1].

To have this relationship hold for the last row of the matrix, an additional entry (dummy entry) is added to the end of *rowIndex*. Its value is equal to the number of non-zero elements plus one. This makes the total length of the *rowIndex* array one larger than the number of rows in the matrix.

---

### NOTE

The Intel® oneAPI Math Kernel Library (oneMKL) sparse storage scheme for the direct sparse solvers supports both one-based indexing and zero-based indexing.

---

Consider the symmetric matrix *A*:

$$A = \begin{pmatrix} 1 & -1 & * & -3 & * \\ -1 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -3 & * & 6 & 7 & * \\ * & * & 4 & * & -5 \end{pmatrix}$$

Only elements from the upper triangle are stored. The actual arrays for the matrix *A* are as follows:

### Storage Arrays for a Symmetric Matrix

#### one-based indexing

<i>values</i>	=	(1	-1	-3	5	4	6	4	7	-5)
<i>columns</i>	=	(1	2	4	2	3	4	5	4	5)
<i>rowIndex</i>	=	(1	4	5	8	9	10)			

#### zero-based indexing

<i>values</i>	=	(1	-1	-3	5	4	6	4	7	-5)
<i>columns</i>	=	(0	1	3	1	2	3	4	3	4)
<i>rowIndex</i>	=	(0	3	4	7	8	9)			

## Storage Format Restrictions

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
- no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

## DSS Nonsymmetric Matrix Storage

For a non-symmetric or non-Hermitian matrix, all non-zero elements need to be stored. Consider the non-symmetric matrix *B*:

$$\begin{pmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{pmatrix}$$

The matrix *B* has 13 non-zero elements, and all of them are stored as follows:

### Storage Arrays for a Non-Symmetric Matrix

#### one-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>columns</i>	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
<i>rowIndex</i>	=	(1	4	6	9	12	14)							

#### zero-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>columns</i>	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
<i>rowIndex</i>	=	(0	3	5	8	11	13)							

## Storage Format Restrictions

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
- no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

## DSS Structurally Symmetric Matrix Storage

Direct sparse solvers can also solve symmetrically structured systems of equations. A symmetrically structured system of equations is one where the pattern of non-zero elements is symmetric. That is, a matrix has a symmetric structure if  $a_{j,i}$  is not zero if and only if  $a_{i,j}$  is not zero. From the point of view of the solver software, a "non-zero" element of a matrix is any element stored in the *values* array, even if its value is

equal to 0. In that sense, any non-symmetric matrix can be turned into a symmetrically structured matrix by carefully adding zeros to the *values* array. For example, the above matrix *B* can be turned into a symmetrically structured matrix by adding two non-zero entries:

$$B = \begin{pmatrix} 1 & -1 & * & 3 & * \\ -2 & 5 & * & * & 0 \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & 0 & * & -5 \end{pmatrix}$$

The matrix *B* can be considered to be symmetrically structured with 15 non-zero elements and represented as:

### Storage Arrays for a Symmetrically Structured Matrix

#### one-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	0	4	6	4	-4	2	7	8	0	-5)	
<i>columns</i>	=	(1	2	4	1	2	5	3	4	5	1	3	4	2	3	5)	
<i>rowIndex</i>	=	(1	4	7	10	13	16)										

#### zero-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	0	4	6	4	-4	2	7	8	0	-5)	
<i>columns</i>	=	(0	1	3	0	1	4	2	3	4	0	2	3	1	2	4)	
<i>rowIndex</i>	=	(0	3	6	9	12	15)										

### Storage Format Restrictions

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
- no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

### DSS Distributed Symmetric Matrix Storage

The distributed assembled matrix input format can be used by the Parallel Direct Sparse Solver for Clusters Interface.

In this format, the symmetric input matrix *A* is divided into sequential row subsets, or domains. Each domain belongs to an MPI process. Neighboring domains can overlap. For such intersection between two domains, the element values of the full matrix can be obtained by summing the respective elements of both domains.

As in the centralized format, the distributed format uses three arrays to describe the input data, but the *values*, *columns*, and *rowIndex* arrays on each processor only describe the domain belonging to that particular processor and not the entire matrix.

For example, consider a symmetric matrix *A*:

$$A = \begin{pmatrix} 6 & -1 & * & -3 & * \\ -1 & 5 & * & * & * \\ * & * & 11 & 5 & 4 \\ -3 & * & 5 & 10 & * \\ * & * & 4 & * & 5 \end{pmatrix}$$

This array could be distributed between two domains corresponding to two MPI processes, with the first containing rows 1 through 3, and the second containing rows 3 through 5.

**NOTE**

For the symmetric input matrix, it is not necessary to store the values from the lower triangle.

$$A_{Domain1} = \begin{pmatrix} 6 & -1 & * & -3 & * \\ -1 & 5 & * & * & * \\ * & * & 3 & * & 2 \end{pmatrix}$$

**Distributed Storage Arrays for a Symmetric Matrix, Domain 1**

**one-based indexing**

<i>values</i>	=	(6	-1	-3	5	3	2)
<i>columns</i>	=	(1	2	4	2	3	5)
<i>rowIndex</i>	=	(1	4	5	7)		

**zero-based indexing**

<i>values</i>	=	(6	-1	-3	5	3	2)
<i>columns</i>	=	(0	1	3	1	2	4)
<i>rowIndex</i>	=	(0	3	4	6)		

$$A_{Domain2} = \begin{pmatrix} * & * & 8 & 5 & 2 \\ -3 & * & 5 & 10 & * \\ * & * & 4 & * & 5 \end{pmatrix}$$

**Distributed Storage Arrays for a Symmetric Matrix, Domain 2**

**one-based indexing**

<i>values</i>	=	(8	5	2	10	5)
<i>columns</i>	=	(3	4	5	4	5)
<i>rowIndex</i>	=	(1	4	5	6)	

**zero-based indexing**

<i>values</i>	=	(8	5	2	10	5)
<i>columns</i>	=	(2	3	4	3	4)
<i>rowIndex</i>	=	(0	3	4	5)	

The third row of matrix A is common between domain 1 and domain 2. The values of row 3 of matrix A are the sums of the respective elements of row 3 of matrix  $A_{Domain1}$  and row 1 of matrix  $A_{Domain2}$ .

**Storage Format Restrictions**

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
- no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

Notice revision #20201201

**Sparse BLAS CSR Matrix Storage Format**

The Intel® oneAPI Math Kernel Library (oneMKL) Sparse BLAS compressed sparse row (CSR) format is specified by four arrays:

- *values*

- *columns*
- *pointerB*
- *pointerE*

In addition, each sparse matrix has an associated variable *indexing*, which specifies if the matrix indices are 0-based (*indexing=0*) or 1-based (*indexing=1*). These are descriptions of the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

<i>values</i>	A real or complex array that contains the non-zero elements of <i>A</i> . Values of the non-zero elements of <i>A</i> are mapped into the <i>values</i> array using the row-major storage mapping described above.
<i>columns</i>	Element <i>i</i> of the integer array <i>columns</i> is the number of the column in <i>A</i> that contains the <i>i</i> -th value in the <i>values</i> array.
<i>pointerB</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>values</i> array that is first non-zero element in a row <i>j</i> of <i>A</i> . Note that this index is equal to <i>pointerB[j]-indexing</i> .
<i>pointerE</i>	An integer array that contains row indices, such that <i>pointerE[j]-1-indexing</i> is the index of the element in the <i>values</i> array that is last non-zero element in a row <i>j</i> of <i>A</i> .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in *A*. The length of the *pointerB* and *pointerE* arrays is equal to the number of rows in *A*.

---

#### NOTE

Note that the Intel® oneAPI Math Kernel Library (oneMKL) Sparse BLAS routines support the CSR format both with one-based indexing and zero-based indexing.

---

You can represent the matrix *B*

$$B = \begin{pmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{pmatrix}$$

in the CSR format as:

#### Storage Arrays for a Matrix in CSR Format

##### one-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>columns</i>	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
<i>pointerB</i>	=	(1	4	6	9	12)								
<i>pointerE</i>	=	(4	6	9	12	14)								

##### zero-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>columns</i>	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
<i>pointerB</i>	=	(0	3	5	8	11)								
<i>pointerE</i>	=	(3	5	8	11	13)								

Additionally, you can define submatrices with different *pointerB* and *pointerE* arrays that share the same *values* and *columns* arrays of a CSR matrix. For example, you can represent the lower right 3x3 submatrix of *B* as:

#### Storage Arrays for a Matrix in CSR Format

##### one-based indexing

<i>subpointerB</i>	=	(6	10	13)
<i>subpointerE</i>	=	(9	12	14)

##### zero-based indexing

<i>subpointerB</i>	=	(5	9	12)
<i>subpointerE</i>	=	(8	11	13)

**NOTE** The CSR matrix must have a monotonically increasing row index. That is,  $pointerB[i] \leq pointerB[j]$  and  $pointerE[i] \leq pointerE[j]$  for all indices  $i < j$ .

This storage format is used in the NIST Sparse BLAS library [Rem05].

### Three Array Variation of CSR Format

The storage format accepted for the direct sparse solvers is a variation of the CSR format. It also is used in the Intel® oneAPI Math Kernel Library (oneMKL) Sparse BLAS Level 2 both with one-based indexing and zero-based indexing. The above matrix *B* can be represented in this format (referred to as the 3-array variation of the CSR format or CSR3) as:

#### Storage Arrays for a Matrix in CSR Format (3-Array Variation)

##### one-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>columns</i>	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
<i>rowIndex</i>	=	(1	4	6	9	12	14)							

##### zero-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>columns</i>	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
<i>rowIndex</i>	=	(0	3	5	8	11	13)							

The 3-array variation of the CSR format has a restriction: all non-zero elements are stored continuously, that is the set of non-zero elements in the row *J* goes just after the set of non-zero elements in the row *J-1*.

There are no such restrictions in the general (NIST) CSR format. This may be useful, for example, if there is a need to operate with different submatrices of the matrix at the same time. In this case, it is enough to define the arrays *pointerB* and *pointerE* for each needed submatrix so that all these arrays are pointers to the same array *values*.

By definition, the array *rowIndex* from the Table "Storage Arrays for a Non-Symmetric Example Matrix" is related to the arrays *pointerB* and *pointerE* from the Table "Storage Arrays for an Example Matrix in CSR Format", and you can see that

```
pointerB[i] = rowIndex[i] for i=0, ..4;
pointerE[i] = rowIndex[i+1] for i=0, ..4.
```

This enables calling a routine that has *values*, *columns*, *pointerB* and *pointerE* as input parameters for a sparse matrix stored in the format accepted for the direct sparse solvers. For example, a routine with the interface:

```
void name_routine(..., double *values, MKL_INT *columns, MKL_INT *pointerB, MKL_INT *pointerE, ...)
```

can be called with parameters *values*, *columns*, *rowIndex* as follows:

```
name_routine(..., values, columns, rowIndex, rowIndex+1, ...).
```

### Sparse BLAS CSC Matrix Storage Format

The compressed sparse column format (CSC) is similar to the CSR format, but the columns are used instead the rows. In other words, the CSC format is identical to the CSR format for the transposed matrix. The CSR format is specified by four arrays: *values*, *columns*, *pointerB*, and *pointerE*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

<i>values</i>	A real or complex array that contains the non-zero elements of <i>A</i> . Values of the non-zero elements of <i>A</i> are mapped into the <i>values</i> array using the column-major storage mapping.
<i>rows</i>	Element <i>i</i> of the integer array <i>rows</i> is the number of the row in <i>A</i> that contains the <i>i</i> -th value in the <i>values</i> array.
<i>pointerB</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>values</i> array that is first non-zero element in a column <i>j</i> of <i>A</i> . Note that this index is equal to <i>pointerB[j]-indexing</i> for Inspector-executor Sparse BLAS CSC arrays.
<i>pointerE</i>	An integer array that contains column indices, such that <i>pointerE[j]-indexing</i> is the index of the element in the <i>values</i> array that is last non-zero element in a column <i>j</i> of <i>A</i> .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in *A*. The length of the *pointerB* and *pointerE* arrays is equal to the number of columns in *A*.

**NOTE**

Note that the Intel® oneAPI Math Kernel Library (oneMKL) Sparse BLAS routines support the CSC format both with one-based indexing and zero-based indexing.

For example, consider matrix *B*:

$$B = \begin{pmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{pmatrix}$$

It can be represented in the CSC format as:

**Storage Arrays for a Matrix in CSC Format****one-based indexing**

<i>values</i>	=	(1	-2	-4	-1	5	8	4	2	-3	6	7	4	-5)
<i>rows</i>	=	(1	2	4	1	2	5	3	4	1	3	4	3	5)
<i>pointerB</i>	=	(1	4	7	9	12)								
<i>pointerE</i>	=	(4	7	9	12	14)								

**zero-based indexing**

<i>values</i>	=	(1	-2	-4	-1	5	8	4	2	-3	6	7	4	-5)
<i>rows</i>	=	(0	1	3	0	1	4	2	3	0	2	3	2	4)
<i>pointerB</i>	=	(0	3	6	8	11)								
<i>pointerE</i>	=	(3	6	8	11	13)								

**Sparse BLAS Coordinate Matrix Storage Format**

The coordinate format is the most flexible and simplest format for the sparse matrix representation. Only non-zero elements are stored, and the coordinates of each non-zero element are given explicitly. Many commercial libraries support the matrix-vector multiplication for the sparse matrices in the coordinate format.

The Intel® oneAPI Math Kernel Library (oneMKL) coordinate format is specified by three arrays: *values*, *rows*, and *column*, and a parameter *nnz* which is number of non-zero elements in *A*. All three arrays have dimension *nnz*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

<i>values</i>	A real or complex array that contains the non-zero elements of <i>A</i> in any order.
---------------	---

<i>rows</i>	Element <i>i</i> of the integer array <i>rows</i> is the number of the row in <i>A</i> that contains the <i>i</i> -th value in the <i>values</i> array.
<i>columns</i>	Element <i>i</i> of the integer array <i>columns</i> is the number of the column in <i>A</i> that contains the <i>i</i> -th value in the <i>values</i> array.

**NOTE**

Note that the Intel® oneAPI Math Kernel Library (oneMKL) Sparse BLAS routines support the coordinate format both with one-based indexing and zero-based indexing.

For example, the sparse matrix *C*

$$C = \begin{pmatrix} 1 & -1 & -3 & 0 & 0 \\ -2 & 5 & 0 & 0 & 0 \\ 0 & 0 & 4 & 6 & 4 \\ -4 & 0 & 2 & 7 & 0 \\ 0 & 8 & 0 & 0 & -5 \end{pmatrix}$$

can be represented in the coordinate format as follows:

**Storage Arrays for an Example Matrix in case of the coordinate format**

one-based indexing														
<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>rows</i>	=	(1	1	1	2	2	3	3	3	4	4	4	5	5)
<i>columns</i>	=	(1	2	3	1	2	3	4	5	1	3	4	2	5)
zero-based indexing														
<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>rows</i>	=	(0	0	0	1	1	2	2	2	3	3	3	4	4)
<i>columns</i>	=	(0	1	2	0	1	2	3	4	0	2	3	1	4)

**Sparse BLAS Diagonal Matrix Storage Format**

If the sparse matrix has diagonals containing only zero elements, then the diagonal storage format can be used to reduce the amount of information needed to locate the non-zero elements. This storage format is particularly useful in many applications where the matrix arises from a finite element or finite difference discretization. The Intel® oneAPI Math Kernel Library (oneMKL) diagonal storage format is specified by two arrays: *values* and *distance*, and two parameters: *ndiag*, which is the number of non-empty diagonals, and *lval*, which is the declared leading dimension in the calling (sub)programs. The following table describes the arrays *values* and *distance*:

<i>values</i>	A real or complex two-dimensional array is dimensioned as <i>lval</i> by <i>ndiag</i> . Each column of it contains the non-zero elements of certain diagonal of <i>A</i> . The key point of the storage is that each element in <i>values</i> retains the row number of the original matrix. To achieve this diagonals in the lower triangular part of the matrix are padded from the top, and those in the upper triangular part are padded from the bottom. Note that the value of <i>distance</i> [ <i>i</i> ] is the number of elements to be padded for diagonal <i>i</i> .
<i>distance</i>	An integer array with dimension <i>ndiag</i> . Element <i>i</i> of the array <i>distance</i> is the distance between <i>i</i> -diagonal and the main diagonal. The distance is positive if the diagonal is above the main diagonal, and negative if the diagonal is below the main diagonal. The main diagonal has a distance equal to zero.

The above matrix *C* can be represented in the diagonal storage format as follows:

$$distance = (-3 \ -1 \ 0 \ 1 \ 2)$$

$$values = \begin{pmatrix} * & * & 1 & -1 & -3 \\ * & -2 & 5 & 0 & 0 \\ * & 0 & 4 & 6 & 4 \\ -4 & 2 & 7 & 0 & * \\ 8 & 0 & -5 & * & * \end{pmatrix}$$

where the asterisks denote padded elements.

When storing symmetric, Hermitian, or skew-symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For the Intel® oneAPI Math Kernel Library (oneMKL) triangular solver routines elements of the array *distance* must be sorted in increasing order. In all other cases the diagonals and distances can be stored in arbitrary order.

### Sparse BLAS Skyline Matrix Storage Format

The skyline storage format is important for the direct sparse solvers, and it is well suited for Cholesky or LU decomposition when no pivoting is required.

The skyline storage format accepted in Intel® oneAPI Math Kernel Library (oneMKL) can store only triangular matrix or triangular part of a matrix. This format is specified by two arrays: *values* and *pointers*. The following table describes these arrays:

<i>values</i>	A scalar array. For a lower triangular matrix it contains the set of elements from each row of the matrix starting from the first non-zero element to and including the diagonal element. For an upper triangular matrix it contains the set of elements from each column of the matrix starting with the first non-zero element down to and including the diagonal element. Encountered zero elements are included in the sets.
<i>pointers</i>	An integer array with dimension $(m+1)$ , where $m$ is the number of rows for lower triangle (columns for the upper triangle). $pointers[i] - pointers[0]+1$ gives the index of element in <i>values</i> that is first non-zero element in row (column) $i$ . The value of $pointers[m]$ is set to $nnz+pointers[0]$ , where $nnz$ is the number of elements in the array <i>values</i> .

For example, consider the matrix  $C$ :

$$C = \begin{pmatrix} 1 & -1 & -3 & 0 & 0 \\ -2 & 5 & 0 & 0 & 0 \\ 0 & 0 & 4 & 6 & 4 \\ -4 & 0 & 2 & 7 & 0 \\ 0 & 8 & 0 & 0 & -5 \end{pmatrix}$$

The low triangle of the matrix  $C$  given above can be stored as follows:

```
values = [ 1  -2  5  4  -4  0  2  7  8  0  0  -5 ]
pointers = [ 0  1  3  4  8  12 ]
```

and the upper triangle of this matrix  $C$  can be stored as follows:

```
values = [ 1  -1  5  -3  0  4  6  7  4  0  -5 ]
pointers = [ 0  1  3  6  8  11 ]
```

This storage format is supported by the NIST Sparse BLAS library [[Rem05](#)].

Note that the Intel® oneAPI Math Kernel Library (oneMKL) Sparse BLAS routines operating with the skyline storage format do not support general matrices.

## Sparse BLAS BSR Matrix Storage Format

The Intel® oneAPI Math Kernel Library (oneMKL) block compressed sparse row (BSR) format for sparse matrices is specified by four arrays: *values*, *columns*, *pointerB*, and *pointerE*. The following table describes these arrays.

<i>values</i>	A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block-by-block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of them are equal to zero. Within each non-zero block elements are stored in column-major order in the case of one-based indexing, and in row-major order in the case of the zero-based indexing.
<i>columns</i>	Element <i>i</i> of the integer array <i>columns</i> is the number of the column in the block matrix that contains the <i>i</i> -th non-zero block.
<i>pointerB</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>columns</i> array that is first non-zero block in a row <i>j</i> of the block matrix.
<i>pointerE</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>columns</i> array that contains the last non-zero block in a row <i>j</i> of the block matrix plus 1.

The length of the *values* array is equal to the number of all elements in the non-zero blocks, the length of the *columns* array is equal to the number of non-zero blocks. The length of the *pointerB* and *pointerE* arrays is equal to the number of block rows in the block matrix.

---

### NOTE

Note that the Intel® oneAPI Math Kernel Library (oneMKL) Sparse BLAS routines support BSR format both with one-based indexing and zero-based indexing.

---

For example, consider the sparse matrix *D*

$$D = \begin{pmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ * & * & 1 & 4 & * & * \\ * & * & 5 & 1 & * & * \\ * & * & 4 & 3 & 7 & 2 \\ * & * & 0 & 0 & 0 & 0 \end{pmatrix}$$

If the size of the block equals 2, then the sparse matrix *D* can be represented as a 3x3 block matrix *E* with the following structure:

$$E = \begin{pmatrix} L & M & * \\ * & N & * \\ * & P & Q \end{pmatrix}$$

where

$$L = \begin{pmatrix} 1 & 0 \\ 2 & 1 \end{pmatrix}, \quad M = \begin{pmatrix} 6 & 7 \\ 8 & 2 \end{pmatrix}, \quad N = \begin{pmatrix} 1 & 4 \\ 5 & 1 \end{pmatrix}, \quad P = \begin{pmatrix} 4 & 3 \\ 0 & 0 \end{pmatrix}, \quad Q = \begin{pmatrix} 7 & 2 \\ 0 & 0 \end{pmatrix}$$

The matrix *D* can be represented in the BSR format as follows:

one-based indexing

```
values = (1 2 0 1 6 8 7 2 1 5 4 1 4 0 3 0 7 0 2 0)
columns = (1 2 2 2 3)
pointerB = (1 3 4)
pointerE = (3 4 6)
```

## zero-based indexing

```
values = [1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0]
columns = [0 1 1 1 2]
pointerB = [0 2 3]
pointerE = [2 3 5]
```

This storage format is supported by the NIST Sparse BLAS library [[Rem05](#)].

**Three Array Variation of BSR Format**

Intel® oneAPI Math Kernel Library (oneMKL) supports the variation of the BSR format that is specified by three arrays: *values*, *columns*, and *rowIndex*. The following table describes these arrays.

<i>values</i>	A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block by block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of them is equal to zero. Within each non-zero block the elements are stored in column major order in the case of the one-based indexing, and in row major order in the case of the zero-based indexing.
<i>columns</i>	Element <i>i</i> of the integer array <i>columns</i> is the number of the column in the block matrix that contains the <i>i</i> -th non-zero block.
<i>rowIndex</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>columns</i> array that is first non-zero block in a row <i>j</i> of the block matrix.

The length of the *values* array is equal to the number of all elements in the non-zero blocks, the length of the *columns* array is equal to the number of non-zero blocks.

As the *rowIndex* array gives the location of the first non-zero block within a row, and the non-zero blocks are stored consecutively, the number of non-zero blocks in the *i*-th row is equal to the difference of *rowIndex*[*i*] and *rowIndex*[*i*+1].

To retain this relationship for the last row of the block matrix, an additional entry (dummy entry) is added to the end of *rowIndex* with value equal to the number of non-zero blocks plus one. This makes the total length of the *rowIndex* array one larger than the number of rows of the block matrix.

The above matrix *D* can be represented in this 3-array variation of the BSR format as follows:

## one-based indexing

```
values = [1 2 0 1 6 8 7 2 1 5 4 2 4 0 3 0 7 0 2 0]
columns = [1 2 2 2 3]
rowIndex = [1 3 4 6]
```

## zero-based indexing

```
values = [1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0]
columns = [0 1 1 1 2]
rowIndex = [0 2 3 5]
```

When storing symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For example, consider the symmetric sparse matrix *F*:

$$F = \begin{pmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ 6 & 8 & 1 & 4 & * & * \\ 7 & 2 & 5 & 2 & * & * \\ * & * & * & * & 7 & 2 \\ * & * & * & * & 0 & 0 \end{pmatrix}$$

If the size of the block equals 2, then the sparse matrix  $F$  can be represented as a 3x3 block matrix  $G$  with the following structure:

$$G = \begin{pmatrix} L & M & * \\ M' & N & * \\ * & * & Q \end{pmatrix}$$

where

$$L = \begin{pmatrix} 1 & 0 \\ 2 & 1 \end{pmatrix}, M = \begin{pmatrix} 6 & 7 \\ 8 & 2 \end{pmatrix}, M' = \begin{pmatrix} 6 & 8 \\ 7 & 2 \end{pmatrix}, N = \begin{pmatrix} 1 & 4 \\ 5 & 2 \end{pmatrix}, \text{ and } Q = \begin{pmatrix} 7 & 2 \\ 0 & 0 \end{pmatrix}$$

The symmetric matrix  $F$  can be represented in this 3-array variation of the BSR format (storing only the upper triangular part) as follows:

one-based indexing

```
values = [1 2 0 1 6 8 7 2 1 5 4 2 7 0 2 0]
columns = [1 2 2 3]
rowIndex = [1 3 4 5]
```

zero-based indexing

```
values = [1 0 2 1 6 7 8 2 1 4 5 2 7 2 0 0]
columns = [0 1 1 2]
rowIndex = [0 2 3 4]
```

## Variable BSR Format

A variation of BSR3 is variable block compressed sparse row format. For a trust level  $t$ ,  $0 \leq t \leq 100$ , rows similar up to  $t$  percent are placed in one supernode.

## Appendix B: Routine and Function Arguments

---

The major arguments in the BLAS routines are vector and matrix, whereas VM functions work on vector arguments only. The sections that follow discuss each of these arguments and provide examples.

### Vector Arguments in BLAS

Vector arguments are passed in one-dimensional arrays. The array dimension (length) and vector increment are passed as integer variables. The length determines the number of elements in the vector. The increment (also called stride) determines the spacing between vector elements and the order of the elements in the array in which the vector is passed.

A vector of length  $n$  and increment  $incx$  is passed in a one-dimensional array  $x$  whose values are defined as

```
x[0], x[|incx|], ..., x[(n-1)* |incx|]
```

If *incx* is positive, then the elements in array *x* are stored in increasing order. If *incx* is negative, the elements in array *x* are stored in decreasing order with the first element defined as  $x[(n-1) * |incx|]$ . If *incx* is zero, then all elements of the vector have the same value,  $x[0]$ . The size of the one-dimensional array that stores the vector must always be at least

```
idimx = 1 + (n-1)* |incx |
```

### Example. One-dimensional Real Array

Let  $x[0:6]$  be the one-dimensional real array

```
x = [1.0, 3.0, 5.0, 7.0, 9.0, 11.0, 13.0].
```

If *incx* = 2 and *n* = 3, then the vector argument with elements in order from first to last is [1.0, 5.0, 9.0].

If *incx* = -2 and *n* = 4, then the vector elements in order from first to last is [13.0, 9.0, 5.0, 1.0].

If *incx* = 0 and *n* = 4, then the vector elements in order from first to last is [1.0, 1.0, 1.0, 1.0].

One-dimensional substructures of a matrix, such as the rows, columns, and diagonals, can be passed as vector arguments with the starting address and increment specified.

Storage of the *m*-by-*n* matrix can be based on either column-major ordering where the increment between elements in the same column is 1, the increment between elements in the same row is *m*, and the increment between elements on the same diagonal is *m* + 1; or row-major ordering where the increment between elements in the same row is 1, the increment between elements in the same column is *n*, and the increment between elements on the same diagonal is *n* + 1.

### Example. Two-dimensional Real Matrix

Let *a* be a real 5 x 4 matrix declared as .

To scale the third column of *a* by 2.0, use the BLAS routine `sscal` with the following calling sequence:

```
cblas_sscal (5, 2.0, a[2], 4)
```

To scale the second row, use the statement:

```
cblas_sscal (4, 2.0, a[4], 1)
```

To scale the main diagonal of *a* by 2.0, use the statement:

```
cblas_sscal (4, 2.0, a[0], 5)
```

#### NOTE

The default vector argument is assumed to be 1.

### Vector Arguments in Vector Math

Vector arguments of classic VM mathematical functions are passed in one-dimensional arrays with unit vector increment. It means that a vector of length *n* is passed contiguously in an array *a* whose values are defined as

```
a[0], a[1], ..., a[n-1].
```

Strided VM mathematical functions allow using positive increments for all input and output vector arguments.

To accommodate for arrays with other increments, or more complicated indexing, VM contains auxiliary Pack/Unpack functions that gather the array elements into a contiguous vector and then scatter them after the computation is complete.

Generally, if the vector elements are stored in a one-dimensional array  $a$  as

$$a[m0], a[m1], \dots, a[mn-1]$$

and need to be regrouped into an array  $y$  as

$$y[k0], y[k1], \dots, y[kn-1],$$

VM Pack/Unpack functions can use one of the following indexing methods:

### Positive Increment Indexing

$$kj = incy * j, mj = inca * j, j = 0, \dots, n-1.$$

Constraint:  $incy > 0$  and  $inca > 0$ .

For example, setting  $incy = 1$  specifies gathering array elements into a contiguous vector.

This method is similar to that used in BLAS, with the exception that negative and zero increments are not permitted.

### Index Vector Indexing

$$kj = iy[j], mj = ia[j], j = 0, \dots, n-1.$$

where  $ia$  and  $iy$  are arrays of length  $n$  that contain index vectors for the input and output arrays  $a$  and  $y$ , respectively.

### Mask Vector Indexing

Indices  $kj, mj$  are such that:

$$my[kj] \neq 0, ma[mj] \neq 0, j = 0, \dots, n-1.$$

where  $ma$  and  $my$  are arrays that contain mask vectors for the input and output arrays  $a$  and  $y$ , respectively.

## Vector Mathematical Functions

### Matrix Arguments

Matrix arguments of the Intel® oneAPI Math Kernel Library routines can be stored in arrays, using the following storage schemes:

- [conventional full storage](#)
- [packed storage](#) for Hermitian, symmetric, or triangular matrices
- [band storage](#) for band matrices
- [rectangular full packed storage](#) for symmetric, Hermitian, or triangular matrices as compact as the Packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels.

**Full storage** is the simplest scheme. A matrix  $A$  is stored in a one-dimensional array  $a$ , with the matrix element  $a_{ij}$  stored in the array element  $a[i - 1 + (j - 1) * lda]$ , where  $lda$  is the leading dimension of array  $a$ .

If a matrix is triangular (upper or lower, as specified by the argument  $uplo$ ), only the elements of the relevant triangle are stored; the remaining elements of the array need not be set.

Routines that handle symmetric or Hermitian matrices allow for either the upper or lower triangle of the matrix to be stored in the corresponding elements of the array:

if  $uplo = 'U'$ ,  $a_{ij}$  is stored as described for  $i \leq j$ , other elements of  $a$  need not be set.

if  $uplo = 'L'$ ,  $a_{ij}$  is stored as described for  $j \leq i$ , other elements of  $a$  need not be set.

**Packed storage** allows you to store symmetric, Hermitian, or triangular matrices more compactly: the relevant triangle (again, as specified by the argument  $uplo$ ) is packed by columns in a one-dimensional array  $ap$ :

if  $uplo = 'U'$ ,  $a_{ij}$  is stored in  $ap[i - 1 + j(j - 1)/2]$  for  $i \leq j$

if  $uplo = 'L'$ ,  $a_{ij}$  is stored in  $ap[i - 1 + (2*n - j)*(j - 1)/2]$  for  $j \leq i$ .

In descriptions of LAPACK routines, arrays with packed matrices have names ending in  $p$ .

**Band storage** is as follows: an  $m$ -by- $n$  band matrix with  $kl$  non-zero sub-diagonals and  $ku$  non-zero super-diagonals is stored compactly in an array  $ab$  with  $(kl+ku + 1)*n$  elements. Thus,

$a_{ij}$  is stored in  $ab(ku+1+i-j,j)$  for  $\max(1, j-ku) \leq i \leq \min(n, j+kl)$ .

Use the band storage scheme only when  $kl$  and  $ku$  are much less than the matrix size  $n$ . Although the routines work correctly for all values of  $kl$  and  $ku$ , using the band storage is inefficient if your matrices are not really banded.

The band storage scheme is illustrated by the following example, when

$$m = n = 6, kl = 2, ku = 1$$

Array elements marked \* are not used by the routines:

Banded matrix A	Band storage of A																								
$\begin{bmatrix} a_{11} & a_{12} & 0 & 0 & 0 & 0 \\ a_{21} & a_{22} & a_{23} & 0 & 0 & 0 \\ a_{31} & a_{32} & a_{33} & a_{34} & 0 & 0 \\ 0 & a_{42} & a_{43} & a_{44} & a_{45} & 0 \\ 0 & 0 & a_{53} & a_{54} & a_{55} & a_{56} \\ 0 & 0 & 0 & a_{64} & a_{65} & a_{66} \end{bmatrix}$	<table style="border-collapse: collapse; margin-left: auto; margin-right: auto;"> <tr> <td style="padding: 0 10px;">*</td> <td style="padding: 0 10px;"><math>a_{12}</math></td> <td style="padding: 0 10px;"><math>a_{23}</math></td> <td style="padding: 0 10px;"><math>a_{34}</math></td> <td style="padding: 0 10px;"><math>a_{45}</math></td> <td style="padding: 0 10px;"><math>a_{56}</math></td> </tr> <tr> <td style="padding: 0 10px;"><math>a_{11}</math></td> <td style="padding: 0 10px;"><math>a_{22}</math></td> <td style="padding: 0 10px;"><math>a_{33}</math></td> <td style="padding: 0 10px;"><math>a_{44}</math></td> <td style="padding: 0 10px;"><math>a_{55}</math></td> <td style="padding: 0 10px;"><math>a_{66}</math></td> </tr> <tr> <td style="padding: 0 10px;"><math>a_{21}</math></td> <td style="padding: 0 10px;"><math>a_{32}</math></td> <td style="padding: 0 10px;"><math>a_{43}</math></td> <td style="padding: 0 10px;"><math>a_{54}</math></td> <td style="padding: 0 10px;"><math>a_{65}</math></td> <td style="padding: 0 10px;">*</td> </tr> <tr> <td style="padding: 0 10px;"><math>a_{31}</math></td> <td style="padding: 0 10px;"><math>a_{42}</math></td> <td style="padding: 0 10px;"><math>a_{53}</math></td> <td style="padding: 0 10px;"><math>a_{64}</math></td> <td style="padding: 0 10px;">*</td> <td style="padding: 0 10px;">*</td> </tr> </table>	*	$a_{12}$	$a_{23}$	$a_{34}$	$a_{45}$	$a_{56}$	$a_{11}$	$a_{22}$	$a_{33}$	$a_{44}$	$a_{55}$	$a_{66}$	$a_{21}$	$a_{32}$	$a_{43}$	$a_{54}$	$a_{65}$	*	$a_{31}$	$a_{42}$	$a_{53}$	$a_{64}$	*	*
*	$a_{12}$	$a_{23}$	$a_{34}$	$a_{45}$	$a_{56}$																				
$a_{11}$	$a_{22}$	$a_{33}$	$a_{44}$	$a_{55}$	$a_{66}$																				
$a_{21}$	$a_{32}$	$a_{43}$	$a_{54}$	$a_{65}$	*																				
$a_{31}$	$a_{42}$	$a_{53}$	$a_{64}$	*	*																				

When a general band matrix is supplied for *LU factorization*, space must be allowed to store  $kl$  additional super-diagonals generated by fill-in as a result of row interchanges. This means that the matrix is stored according to the above scheme, but with  $kl + ku$  super-diagonals. Thus,

$a_{ij}$  is stored in  $ab(kl+ku+1+i-j, j)$  for  $\max(1, j-ku) \leq i \leq \min(n, j+kl)$ .

The band storage scheme for LU factorization is illustrated by the following example, when  $m = n = 6$ ,  $kl = 2$ ,  $ku = 1$ :

Banded matrix A	Band storage of A																																				
$\begin{bmatrix} a_{11} & a_{12} & 0 & 0 & 0 & 0 \\ a_{21} & a_{22} & a_{23} & 0 & 0 & 0 \\ a_{31} & a_{32} & a_{33} & a_{34} & 0 & 0 \\ 0 & a_{42} & a_{43} & a_{44} & a_{45} & 0 \\ 0 & 0 & a_{53} & a_{54} & a_{55} & a_{56} \\ 0 & 0 & 0 & a_{64} & a_{65} & a_{66} \end{bmatrix}$	<table style="border-collapse: collapse; width: 100%; text-align: center;"> <tr><td>*</td><td>*</td><td>*</td><td>+</td><td>+</td><td>+</td></tr> <tr><td>*</td><td>*</td><td>+</td><td>+</td><td>+</td><td>+</td></tr> <tr><td>*</td><td><math>a_{12}</math></td><td><math>a_{23}</math></td><td><math>a_{34}</math></td><td><math>a_{45}</math></td><td><math>a_{56}</math></td></tr> <tr><td><math>a_{11}</math></td><td><math>a_{22}</math></td><td><math>a_{33}</math></td><td><math>a_{44}</math></td><td><math>a_{55}</math></td><td><math>a_{66}</math></td></tr> <tr><td><math>a_{21}</math></td><td><math>a_{32}</math></td><td><math>a_{43}</math></td><td><math>a_{54}</math></td><td><math>a_{65}</math></td><td>*</td></tr> <tr><td><math>a_{31}</math></td><td><math>a_{42}</math></td><td><math>a_{53}</math></td><td><math>a_{64}</math></td><td>*</td><td>*</td></tr> </table>	*	*	*	+	+	+	*	*	+	+	+	+	*	$a_{12}$	$a_{23}$	$a_{34}$	$a_{45}$	$a_{56}$	$a_{11}$	$a_{22}$	$a_{33}$	$a_{44}$	$a_{55}$	$a_{66}$	$a_{21}$	$a_{32}$	$a_{43}$	$a_{54}$	$a_{65}$	*	$a_{31}$	$a_{42}$	$a_{53}$	$a_{64}$	*	*
*	*	*	+	+	+																																
*	*	+	+	+	+																																
*	$a_{12}$	$a_{23}$	$a_{34}$	$a_{45}$	$a_{56}$																																
$a_{11}$	$a_{22}$	$a_{33}$	$a_{44}$	$a_{55}$	$a_{66}$																																
$a_{21}$	$a_{32}$	$a_{43}$	$a_{54}$	$a_{65}$	*																																
$a_{31}$	$a_{42}$	$a_{53}$	$a_{64}$	*	*																																

Array elements marked \* are not used by the routines; elements marked + need not be set on entry, but are required by the LU factorization routines to store the results. The input array will be overwritten on exit by the details of the LU factorization as follows:

*	*	*	$U_{14}$	$U_{25}$	$U_{36}$
*	*	$U_{13}$	$U_{24}$	$U_{35}$	$U_{46}$
*	$U_{12}$	$U_{23}$	$U_{34}$	$U_{45}$	$U_{56}$
$U_{11}$	$U_{22}$	$U_{33}$	$U_{44}$	$U_{55}$	$U_{66}$
$m_{21}$	$m_{32}$	$m_{43}$	$m_{54}$	$m_{65}$	*
$m_{31}$	$m_{42}$	$m_{53}$	$m_{64}$	*	*

where  $u_{ij}$  are the elements of the upper triangular matrix U, and  $m_{ij}$  are the multipliers used during factorization.

Triangular band matrices are stored in the same format, with either  $kl = 0$  if upper triangular, or  $ku = 0$  if lower triangular. For symmetric or Hermitian band matrices with  $k$  sub-diagonals or super-diagonals, you need to store only the upper or lower triangle, as specified by the argument *uplo*:

if *uplo* = 'U',  $a_{ij}$  is stored in  $ab(k+1+i-j,j)$  for  $\max(1,j-k) \leq i \leq j$

if *uplo* = 'L',  $a_{ij}$  is stored in  $ab(1+i-j,j)$  for  $j \leq i \leq \min(n,j+k)$ .

In descriptions of LAPACK routines, arrays that hold matrices in band storage have names ending in *b*.

In Fortran, column-major ordering of storage is assumed. This means that elements of the same column occupy successive storage locations.

Three quantities are usually associated with a two-dimensional array argument: its leading dimension, which specifies the number of storage locations between elements in the same row, its number of rows, and its number of columns. For a matrix in full storage, the leading dimension of the array must be at least as large as the number of rows in the matrix.

A character transposition parameter is often passed to indicate whether the matrix argument is to be used in normal or transposed form or, for a complex matrix, if the conjugate transpose of the matrix is to be used.

The values of the transposition parameter for these three cases are the following:

'N' or 'n'	normal (no conjugation, no transposition)
'T' or 't'	transpose
'C' or 'c'	conjugate transpose.

### Example. Two-Dimensional Complex Array

Suppose  $A$  (1:5, 1:4) is the complex two-dimensional array presented by matrix

$$\begin{bmatrix} (1.1, 0.11) & (1.2, 0.12) & (1.3, 0.13) & (1.4, 0.14) \\ (2.1, 0.21) & (2.2, 0.22) & (2.3, 0.23) & (1.4, 0.24) \\ (3.1, 0.31) & (3.2, 0.32) & (3.3, 0.33) & (1.4, 0.34) \\ (4.1, 0.41) & (4.2, 0.42) & (4.3, 0.43) & (1.4, 0.44) \\ (5.1, 0.51) & (5.2, 0.52) & (5.3, 0.53) & (1.4, 0.54) \end{bmatrix}$$

Let *transa* be the transposition parameter, *m* be the number of rows, *n* be the number of columns, and *lda* be the leading dimension. Then if

*transa* = 'N', *m* = 4, *n* = 2, and *lda* = 5, the matrix argument would be

$$\begin{bmatrix} (1.1, 0.11) & (1.2, 0.12) \\ (2.1, 0.21) & (2.2, 0.22) \\ (3.1, 0.31) & (3.2, 0.32) \\ (4.1, 0.41) & (4.2, 0.42) \end{bmatrix}$$

If *transa* = 'T', *m* = 4, *n* = 2, and *lda* = 5, the matrix argument would be

$$\begin{bmatrix} (1.1, 0.11) & (2.1, 0.21) & (3.1, 0.31) & (4.1, 0.41) \\ (1.2, 0.12) & (2.2, 0.22) & (3.2, 0.32) & (4.2, 0.42) \end{bmatrix}$$

If  $transa = 'C'$ ,  $m = 4$ ,  $n = 2$ , and  $lda = 5$ , the matrix argument would be

$$\begin{bmatrix} (1.1, -0.11) & (2.1, -0.21) & (3.1, -0.31) & (4.1, -0.41) \\ (1.2, -0.12) & (2.2, -0.22) & (3.2, -0.32) & (4.2, -0.42) \end{bmatrix}$$

Note that care should be taken when using a leading dimension value which is different from the number of rows specified in the declaration of the two-dimensional array. For example, suppose the array  $A$  above is declared as a complex 5-by-4 matrix.

Then if  $transa = 'N'$ ,  $m = 3$ ,  $n = 4$ , and  $lda = 4$ , the matrix argument will be

$$\begin{bmatrix} (1.1, 0.11) & (5.1, 0.51) & (4.2, 0.42) & (3.3, 0.33) \\ (2.1, 0.21) & (1.2, 0.12) & (5.2, 0.52) & (4.3, 0.43) \\ (3.1, 0.31) & (2.2, 0.22) & (1.3, 0.13) & (5.3, 0.53) \end{bmatrix}$$

**Rectangular Full Packed storage** allows you to store symmetric, Hermitian, or triangular matrices as compact as the Packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels. To store an  $n$ -by- $n$  triangle (and suppose for simplicity that  $n$  is even), you partition the triangle into three parts: two  $n/2$ -by- $n/2$  triangles and an  $n/2$ -by- $n/2$  square, then pack this as an  $n$ -by- $n/2$  rectangle (or  $n/2$ -by- $n$  rectangle), by transposing (or transpose-conjugating) one of the triangles and packing it next to the other triangle. Since the two triangles are stored in full storage, you can use existing efficient routines on them.

There are eight cases of RFP storage representation: when  $n$  is even or odd, the packed matrix is transposed or not, the triangular matrix is lower or upper. See below for all the eight storage schemes illustrated:

$n$  is odd,  $A$  is lower triangular

Full format	RFP (not transposed)	RFP (transposed)
$a_{11}$ X X X X X X	$a_{11}$ $a_{55}$ $a_{65}$ $a_{75}$	
$a_{21}$ $a_{22}$ X X X X X	$a_{21}$ $a_{22}$ $a_{66}$ $a_{76}$

Intel® oneAPI Math Kernel Library (oneMKL) provides a number of routines such as `?hfrk`, `?sfrk` performing BLAS operations working directly on RFP matrices, as well as some conversion routines, for instance, `?tpttf` goes from the standard packed format to RFP and `?trttf` goes from the full format to RFP.

Please refer to the Netlib site for more information.

Note that in the descriptions of LAPACK routines, arrays with RFP matrices have names ending in `fp`.

## Appendix C: FFTW Interface to Intel® Math Kernel Library

Intel® oneAPI Math Kernel Library (oneMKL) offers FFTW2 and FFTW3 interfaces to Intel® oneAPI Math Kernel Library (oneMKL) Fast Fourier Transform and Trigonometric Transform functionality. The purpose of these interfaces is to enable applications using FFTW ([www.fftw.org](http://www.fftw.org)) to gain performance with Intel® oneAPI Math Kernel Library (oneMKL) without changing the program source code.

Both FFTW2 and FFTW3 interfaces are provided in open source as FFTW wrappers to Intel® oneAPI Math Kernel Library (oneMKL). For ease of use, FFTW3 interface is also integrated in Intel® oneAPI Math Kernel Library (oneMKL).

### FFTW Notational Conventions

This appendix typically employs path notations for Windows\* OS.

### FFTW2 Interface to Intel® oneAPI Math Kernel Library

This section describes a collection of C and Fortran wrappers providing FFTW 2.x interface to Intel® oneAPI Math Kernel Library (oneMKL). The wrappers translate calls to FFTW 2.x functions into the calls of the Intel® oneAPI Math Kernel Library (oneMKL) Fast Fourier Transform interface (FFT interface).

Note that Intel® oneAPI Math Kernel Library (oneMKL) FFT interface operates on both single- and double-precision floating-point data types.

Because of differences between FFTW and Intel® oneAPI Math Kernel Library (oneMKL) FFT functionalities, there are restrictions on using wrappers instead of the FFTW functions. Some FFTW functions have empty wrappers. However, many typical FFTs can be computed using these wrappers.

Refer to [Fourier Transform Functions](#), for better understanding the effects from the use of the wrappers.

## Wrappers Reference

The section provides a brief reference for the FFTW 2.x C interface. For details please refer to the original FFTW 2.x documentation available at [www.fftw.org](http://www.fftw.org).

Each FFTW function has its own wrapper. Some of them, which are *not* expressly listed in this section, are empty and do nothing, but they are provided to avoid link errors and satisfy the function calls.

### One-dimensional Complex-to-complex FFTs

The following functions compute a one-dimensional complex-to-complex Fast Fourier transform.

```
fftw_plan fftw_create_plan(int n, fftw_direction dir, int flags);
fftw_plan fftw_create_plan_specific(int n, fftw_direction dir, int flags, fftw_complex
*in, int istride, fftw_complex *out, int ostride);

void fftw(fftw_plan plan, int howmany, fftw_complex *in, int istride, int idist,
fftw_complex *out, int ostride, int odist);
void fftw_one(fftw_plan plan, fftw_complex *in , fftw_complex *out);

void fftw_destroy_plan(fftw_plan plan);
```

### Multi-dimensional Complex-to-complex FFTs

The following functions compute a multi-dimensional complex-to-complex Fast Fourier transform.

```
fftwnd_plan fftwnd_create_plan(int rank, const int *n, fftw_direction dir, int flags);
fftwnd_plan fftw2d_create_plan(int nx, int ny, fftw_direction dir, int flags);
fftwnd_plan fftw3d_create_plan(int nx, int ny, int nz, fftw_direction dir, int flags);
fftwnd_plan fftwnd_create_plan_specific(int rank, const int *n, fftw_direction dir, int
flags, fftw_complex *in, int istride, fftw_complex *out, int ostride);
fftwnd_plan fftw2d_create_plan_specific(int nx, int ny, fftw_direction dir, int flags,
fftw_complex *in, int istride, fftw_complex *out, int ostride);
fftwnd_plan fftw3d_create_plan_specific(int nx, int ny, int nz, fftw_direction dir, int
flags, fftw_complex *in, int istride, fftw_complex *out, int ostride);

void fftwnd(fftwnd_plan plan, int howmany, fftw_complex *in, int istride, int idist,
fftw_complex *out, int ostride, int odist);
void fftwnd_one(fftwnd_plan plan, fftw_complex *in, fftw_complex *out);

void fftwnd_destroy_plan(fftwnd_plan plan);
```

### One-dimensional Real-to-half-complex/Half-complex-to-real FFTs

Half-complex representation of a conjugate-even symmetric vector of size  $N$  in a real array of the same size  $N$  consists of  $N/2+1$  real parts of the elements of the vector followed by non-zero imaginary parts in the reverse order. Because the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface does not currently support this representation, all wrappers of this kind are empty and do nothing.

Nevertheless, you can perform one-dimensional real-to-complex and complex-to-real transforms using `rfftwnd` functions with `rank=1`.

void rfftwnd_destroy_plan(rfftwnd_plan plan);

```

#### Multi-threaded FFTW

This section discusses multi-threaded FFTW wrappers only. MPI FFTW wrappers, available only with Intel® oneAPI Math Kernel Library (oneMKL) for the Linux\* and Windows\* operating systems, are described in [a separate section](#).

Unlike the original FFTW interface, every computational function in the FFTW2 interface to Intel® oneAPI Math Kernel Library (oneMKL) provides multithreaded computation by default, with the maximum number of threads permitted in FFT functions (see "Techniques to Set the Number of Threads" in *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*). To limit the number of threads, call the threaded FFTW computational functions:

```

void fftw_threads(int nthreads, fftw_plan plan, int howmany, fftw_complex *in, int
istride, int idist, fftw_complex *out, int ostride, int odist);
void fftw_threads_one(int nthreads, rfftwnd_plan plan, fftw_complex *in, fftw_complex
*out);
...
void rfftwnd_threads_real_to_complex( int nthreads, rfftwnd_plan plan, int howmany,
fftw_real *in, int istride, int idist, fftw_complex *out, int ostride, int odist);

```

Compared to its non-threaded counterpart, every threaded computational function has `threads_` as the second part of its name and additional first parameter `nthreads`. Set the `nthreads` parameter to the thread limit to ensure that the computation requires at most that number of threads.

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

**FFTW Support Functions**

The FFTW wrappers provide memory allocation functions to be used with FFTW:

```
void* fftw_malloc(size_t n);
void fftw_free(void* x);
```

The `fftw_malloc` wrapper aligns the memory on a 16-byte boundary.

If `fftw_malloc` fails to allocate memory, it aborts the application. To override this behavior, set a global variable `fftw_malloc_hook` and optionally the complementary variable `fftw_free_hook`:

```
void *(*fftw_malloc_hook) (size_t n);
void (*fftw_free_hook) (void *p);
```

The wrappers use the function `fftw_die` to abort the application in cases when a caller cannot be informed of an error otherwise (for example, in computational functions that return `void`). To override this behavior, set a global variable `fftw_die_hook`:

```
void (*fftw_die_hook) (const char *error_string);
void fftw_die(const char *s);
```

**Limitations of the FFTW2 Interface to Intel® oneAPI Math Kernel Library (oneMKL)**

The FFTW2 wrappers implement the functionality of only those FFTW functions that Intel® oneAPI Math Kernel Library (oneMKL) can reasonably support. Other functions are provided as no-operation functions, whose only purpose is to satisfy link-time symbol resolution. Specifically, no-operation functions include:

- Real-to-half-complex and respective backward transforms
- Print plan functions
- Functions for importing/exporting/forgetting wisdom
- Most of the FFTW functions not covered by the original FFTW2 documentation

Because the Intel® oneAPI Math Kernel Library (oneMKL) implementation of FFTW2 wrappers does not use plan and plan node structures declared in `fftw.h`, the behavior of an application that relies on the internals of the plan structures defined in that header file is undefined.

FFTW2 wrappers define plan as a set of attributes, such as strides, used to commit the Intel® oneAPI Math Kernel Library (oneMKL) FFT descriptor structure. If an FFTW2 computational function is called with attributes different from those recorded in the plan, the function attempts to adjust the attributes of the plan and recommit the descriptor. So, repeated calls of a computational function with the same plan but different strides, distances, and other parameters may be performance inefficient.

Plan creation functions disregard most planner flags passed through the `flags` parameter. These functions take into account only the following values of `flags`:

- `FFTW_IN_PLACE`

If this value of `flags` is supplied, the plan is marked so that computational functions using that plan ignore the parameters related to output (`out`, `ostride`, and `odist`). Unlike the original FFTW interface, the wrappers never use the `out` parameter as a scratch space for in-place transforms.

- `FFTW_THREADSAFE`

If this value of `flags` is supplied, the plan is marked read-only. An attempt to change attributes of a read-only plan aborts the application.

FFTW wrappers are generally not thread safe. Therefore, do not use the same plan in parallel user threads simultaneously.

## Installing FFTW2 Interface Wrappers

Wrappers are delivered as source code, which you must compile to build the wrapper library. Then you can substitute the wrapper and Intel® oneAPI Math Kernel Library (oneMKL) libraries for the FFTW library. The source code for the wrappers, makefiles, and files with lists of wrappers are located in the `.\interfaces\fftw2xc` subdirectory in the Intel® oneAPI Math Kernel Library (oneMKL) directory.

## Creating the Wrapper Library

Two header files are used to compile the C wrapper library: `fftw2_mkl.h` and `fftw.h`. The `fftw2_mkl.h` file is located in the `.\interfaces\fftw2xc\wrappers` subdirectory in the Intel® oneAPI Math Kernel Library (oneMKL) directory.

The file `fftw.h`, used to compile libraries and located in the `.\include\fftw` subdirectory in the Intel® oneAPI Math Kernel Library (oneMKL) directory, slightly differs from the original FFTW ([www.fftw.org](http://www.fftw.org)) header file `fftw.h`.

The source code for the wrappers, makefiles, and files with lists of functions are located in the `.\interfaces\fftw2xc` subdirectory in the Intel® oneAPI Math Kernel Library (oneMKL) directory.

A wrapper library contains wrappers for complex and real transforms in a serial and multi-threaded mode for double- or single-precision floating-point data types. A makefile parameter manages the data type.

Parameters of a makefile also specify the platform (required), compiler, and data precision. The makefile comment heading provides the exact description of these parameters.

To build the library, run the `make` command on Linux\* OS and macOS\* or the `nmake` command on Windows\* OS with appropriate parameters.

For example, on Linux OS the command

```
make libintel64
```

builds a double-precision wrapper library for Intel® 64 architecture based applications using the Intel® oneAPI DPC++/C++ Compiler or the Intel® Fortran Compiler (Compilers and data precision are chosen by default.)

Each makefile creates the library in the directory with Intel® oneAPI Math Kernel Library (oneMKL) libraries corresponding to the platform used. For example, `./lib/ia32` (on Linux OS and macOS) or `.\lib\ia32` (on Windows\* OS).

In the names of a wrapper library, the suffix corresponds to the compiler used and the letter preceding the underscore is "c" for the C programming language.

For example,

```
fftw2xc_intel.lib (on Windows OS); libfftw2xc_intel.a (on Linux OS and macOS);
```

```
fftw2xc_ms.lib (on Windows OS); libfftw2xc_gnu.a (on Linux OS and macOS).
```

## Application Assembling

Use the necessary original FFTW ([www.fftw.org](http://www.fftw.org)) header files without any modifications. Use the created wrapper library and the Intel® oneAPI Math Kernel Library (oneMKL) library instead of the FFTW library.

## Running FFTW2 Interface Wrapper Examples

Intel® oneAPI Math Kernel Library (oneMKL) provides examples to demonstrate how to use the MPI FFTW wrapper library. The source code for the examples, makefiles used to run them, and files with lists of examples are located in the `.\examples\fftw2xc` subdirectory in the Intel® oneAPI Math Kernel Library (oneMKL) directory. To build examples, several additional files are needed: `fftw.h`, `fftw_threads.h`,

`rfftw.h`, and `rfftw_threads.h`. These files are distributed with permission from FFTW and are available in `.\include\rfftw`. The original files can also be found in FFTW 2.1.5 at <http://www.fftw.org/download.html>.

An example makefile uses the `function` parameter in addition to the parameters of the corresponding wrapper library makefile (see [Creating a Wrapper Library](#)). The makefile comment heading provides the exact description of these parameters.

An example makefile normally invokes examples. However, if the appropriate wrapper library is not yet created, the makefile first builds the library the same way as the wrapper library makefile does and then proceeds to examples.

If the parameter `function=<example_name>` is defined, only the specified example runs. Otherwise, all examples from the appropriate subdirectory run. The subdirectory `.\_results` is created, and the results are stored there in the `<example_name>.res` files.

## Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## MPI FFTW2 Wrappers

MPI FFTW wrappers for FFTW 2 are available only with Intel® oneAPI Math Kernel Library (oneMKL) for the Linux\* and Windows\* operating systems.

## MPI FFTW Wrappers Reference

The section provides a reference for MPI FFTW C interface.

### Complex MPI FFTW

## Complex One-dimensional MPI FFTW Transforms

```
fftw_mpi_plan fftw_mpi_create_plan(MPI_Comm comm, int n, fftw_direction dir, int
flags);

void fftw_mpi(fftw_mpi_plan p, int n_fields, fftw_complex *local_data, fftw_complex
*work);

void fftw_mpi_local_sizes(fftw_mpi_plan p, int *local_n, int *local_start, int
*local_n_after_transform, int *local_start_after_transform, int *total_local_size);

void fftw_mpi_destroy_plan(fftw_mpi_plan plan);
```

### Argument restrictions:

- Supported values of `flags` are `FFTW_ESTIMATE`, `FFTW_MEASURE`, `FFTW_SCRAMBLED_INPUT` and `FFTW_SCRAMBLED_OUTPUT`. The same algorithm corresponds to all these values of the flags parameter. If any other `flags` value is supplied, the wrapper library reports an error '`CDFT error in wrapper: unknown flags`'.
- The only supported value of `n_fields` is 1.

## Complex Multi-dimensional MPI FFTW Transforms

```

fftwnd_mpi_plan fftw2d_mpi_create_plan(MPI_Comm comm, int nx, int ny, fftw_direction
dir, int flags);

fftwnd_mpi_plan fftw3d_mpi_create_plan(MPI_Comm comm, int nx, int ny, int nz,
fftw_direction dir, int flags);

fftwnd_mpi_plan fftwnd_mpi_create_plan(MPI_Comm comm, int dim, int *n, fftw_direction
dir, int flags);

void fftwnd_mpi(fftwnd_mpi_plan p, int n_fields, fftw_complex *local_data, fftw_complex
*work, fftwnd_mpi_output_order output_order);

void fftwnd_mpi_local_sizes(fftwnd_mpi_plan p, int *local_nx, int *local_x_start, int
*local_ny_after_transpose, int *local_y_start_after_transpose, int *total_local_size);

void fftwnd_mpi_destroy_plan(fftwnd_mpi_plan plan);

```

**Argument restrictions:**

- Supported values of *flags* are FFTW\_ESTIMATE and FFTW\_MEASURE. If any other value of *flags* is supplied, the wrapper library reports an error '*CDFT error in wrapper: unknown flags*'.
- The only supported value of *n\_fields* is 1.

**Real MPI FFTW****Real-to-Complex MPI FFTW Transforms**

```

rfftwnd_mpi_plan rfftw2d_mpi_create_plan(MPI_Comm comm, int nx, int ny, fftw_direction
dir, int flags);

rfftwnd_mpi_plan rfftw3d_mpi_create_plan(MPI_Comm comm, int nx, int ny, int nz,
fftw_direction dir, int flags);

rfftwnd_mpi_plan rfftwnd_mpi_create_plan(MPI_Comm comm, int dim, int *n, fftw_direction
dir, int flags);

void rfftwnd_mpi(rfftwnd_mpi_plan p, int n_fields, fftw_real *local_data, fftw_real
*work, fftwnd_mpi_output_order output_order);

void rfftwnd_mpi_local_sizes(rfftwnd_mpi_plan p, int *local_nx, int *local_x_start, int
*local_ny_after_transpose, int *local_y_start_after_transpose, int *total_local_size);

void rfftwnd_mpi_destroy_plan(rfftwnd_mpi_plan plan);

```

**Argument restrictions:**

- Supported values of *flags* are FFTW\_ESTIMATE and FFTW\_MEASURE. If any other value of *flags* is supplied, the wrapper library reports an error '*CDFT error in wrapper: unknown flags*'.
- The only supported value of *n\_fields* is 1.

**NOTE**

- Function *rfftwnd\_mpi\_create\_plan* can be used for both one-dimensional and multi-dimensional transforms.
- Both values of the *output\_order* parameter are supported: FFTW\_NORMAL\_ORDER and FFTW\_TRANSPOSED\_ORDER.

## Creating MPI FFTW2 Wrapper Library

The source code for the wrappers, makefiles, and files with lists of wrappers are located in the `.\interfaces\fftw2x_cdft` subdirectory in the Intel® oneAPI Math Kernel Library (oneMKL) directory.

A wrapper library contains C wrappers for Complex One-dimensional MPI FFTW Transforms and Complex Multi-dimensional MPI FFTW Transforms. The library also contains empty C wrappers for Real Multi-dimensional MPI FFTW Transforms. For details, see [MPI FFTW Wrappers Reference](#).

Parameters of a makefile specify the platform (required), compiler, and data precision. Specifying the platform is required. The makefile comment heading provides the exact description of these parameters.

To build the library, run the `make` command on Linux\* OS and macOS\* or the `nmake` command on Windows\* OS with appropriate parameters.

For example, on Linux OS the command

```
make libintel64
```

builds a double-precision wrapper library for Intel® 64 architecture based applications using Intel MPI and the Intel® oneAPI DPC++/C++ Compiler (compilers and data precision are chosen by default.).

A makefile creates the wrapper library in the directory with the Intel® oneAPI Math Kernel Library (oneMKL) libraries corresponding to the used platform. For example, `./lib/ia32` (on Linux OS) or `.\lib\ia32` (on Windows\* OS).

In the wrapper library names, the suffix corresponds to the used data precision. For example,

`fftw2x_cdft_SINGLE.lib` on Windows OS;

`libfftw2x_cdft_DOUBLE.a` on Linux OS.

## Application Assembling with MPI FFTW Wrapper Library

Use the necessary original FFTW ([www.fftw.org](http://www.fftw.org)) header files without any modifications. Use the created MPI FFTW wrapper library and the Intel® oneAPI Math Kernel Library (oneMKL) library instead of the FFTW library.

## Running MPI FFTW2 Wrapper Examples

There are some examples that demonstrate how to use the MPI FFTW wrapper library for FFTW2. The source C code for the examples, makefiles used to run them, and files with lists of examples are located in the `.\examples\fftw2x_cdft` subdirectory in the Intel® oneAPI Math Kernel Library (oneMKL) directory. To build examples, one additional file, `fftw_mpi.h`, is needed. This file is distributed with permission from FFTW and is available in `.\include\fftw`. The original file can also be found in FFTW 2.1.5 at <http://www.fftw.org/download.html>.

Parameters for the example makefiles are described in the makefile comment headings and are similar to the parameters of the wrapper library makefiles (see [Creating MPI FFTW Wrapper Library](#)).

The table below lists examples available in the `.\examples\fftw2x_cdft\source` subdirectory.

### Examples of MPI FFTW Wrappers

Source file for the example	Description
<code>wrappers_c1d.c</code>	One-dimensional Complex MPI FFTW transform, using <code>plan = fftw_mpi_create_plan(...)</code>
<code>wrappers_c2d.c</code>	Two-dimensional Complex MPI FFTW transform, using <code>plan = fftw2d_mpi_create_plan(...)</code>
<code>wrappers_c3d.c</code>	Three-dimensional Complex MPI FFTW transform, using <code>plan = fftw3d_mpi_create_plan(...)</code>
<code>wrappers_c4d.c</code>	Four-dimensional Complex MPI FFTW transform, using <code>plan = fftwnd_mpi_create_plan(...)</code>

Source file for the example	Description
<code>wrappers_r1d.c</code>	One-dimensional Real MPI FFTW transform, using <code>plan = rfftw_mpi_create_plan(...)</code>
<code>wrappers_r2d.c</code>	Two-dimensional Real MPI FFTW transform, using <code>plan = rfftw2d_mpi_create_plan(...)</code>
<code>wrappers_r3d.c</code>	Three-dimensional Real MPI FFTW transform, using <code>plan = rfftw3d_mpi_create_plan(...)</code>
<code>wrappers_r4d.c</code>	Four-dimensional Real MPI FFTW transform, using <code>plan = rfftwnd_mpi_create_plan(...)</code>

## FFTW3 Interface to Intel® oneAPI Math Kernel Library

This section describes a collection of FFTW3 wrappers to Intel® oneAPI Math Kernel Library (oneMKL). The wrappers translate calls of FFTW3 functions to the calls of the Intel® oneAPI Math Kernel Library (oneMKL) Fourier transform (FFT) or Trigonometric Transform (TT) functions. The purpose of FFTW3 wrappers is to enable developers whose programs currently use the FFTW3 library to gain performance with the Intel® oneAPI Math Kernel Library (oneMKL) Fourier transforms without changing the program source code.

The FFTW3 wrappers provide a limited functionality compared to the original FFTW 3.x library, because of differences between FFTW and Intel® oneAPI Math Kernel Library (oneMKL) FFT and TT functionality. This section describes limitations of the FFTW3 wrappers and hints for their usage. Nevertheless, many typical FFT tasks can be performed using the FFTW3 wrappers to Intel® oneAPI Math Kernel Library (oneMKL).

The FFTW3 wrappers are integrated in Intel® oneAPI Math Kernel Library (oneMKL). The only change required to use Intel® oneAPI Math Kernel Library (oneMKL) through the FFTW3 wrappers is to link your application using FFTW3 against Intel® oneAPI Math Kernel Library (oneMKL).

A reference implementation of the FFTW3 wrappers is also provided in open source. You can find it in the `interfaces` directory of the Intel® oneAPI Math Kernel Library (oneMKL) distribution. You can use the reference implementation to create your own wrapper library (see [Building Your Own Wrapper Library](#))

See also these resources:

<a href="#">Fourier Transform Functions</a>	for a description of the Intel® oneAPI Math Kernel Library (oneMKL) FFT interface.
<a href="#">Trigonometric Transform Routines</a>	for a description of Intel® oneAPI Math Kernel Library (oneMKL) TT interface.

## Using FFTW3 Wrappers

The FFTW3 wrappers are a set of functions and data structures depending on one another. The wrappers are not designed to provide the interface on a function-per-function basis. Some FFTW3 wrapper functions are empty and do nothing, but they are present to avoid link errors and satisfy function calls.

This document does not list the declarations of the functions that the FFTW3 wrappers provide (you can find the declarations in the `fftw3.h` header file). Instead, this section comments on particular limitations of the wrappers and provides usage hints: . These are some known limitations of FFTW3 wrappers and their usage in Intel® oneAPI Math Kernel Library (oneMKL).

- The FFTW3 wrappers do not support long double precision because Intel® oneAPI Math Kernel Library (oneMKL) FFT functions operate only on single- and double-precision floating-point data types (`float` and `double`, respectively). Therefore the functions with prefix `fftwl_`, supporting the long double data type, are not provided.

- The wrappers provide equivalent implementation for double- and single-precision functions (those with prefixes `fftw_` and `fftwf_`, respectively). So, all these comments equally apply to the double- and single-precision functions and will refer to functions with prefix `fftw_`, that is, double-precision functions, for brevity.
- The FFTW3 interface that the wrappers provide is defined in the `fftw3.h` header file. This file is borrowed from the FFTW3.x package and distributed within Intel® oneAPI Math Kernel Library (oneMKL) with permission. Additionally, the `fftw3_mkl.h` header file defines supporting structures and supplementary constants and macros.
- Actual functionality of the plan creation wrappers is implemented in `guru64` set of functions. Basic interface, advanced interface, and `guru` interface plan creation functions call the `guru64` interface functions. So, all types of the FFTW3 plan creation interface in the wrappers are functional.
- Plan creation functions may return a `NULL` plan, indicating that the functionality is not supported. So, please carefully check the result returned by plan creation functions in your application. In particular, the following problems return a `NULL` plan:
  - `c2r` and `r2c` problems with a split storage of complex data.
  - `r2r` problems with `kind` values `FFTW_R2HC`, `FFTW_HC2R`, and `FFTW_DHT`. The only supported `r2r` kinds are even/odd DFTs (sine/cosine transforms).
  - Multidimensional `r2r` transforms.
  - Transforms of multidimensional vectors. That is, the only supported values for parameter `howmany_rank` in `guru` and `guru64` plan creation functions are 0 and 1.
  - Multidimensional transforms with `rank > MKL_MAXRANK`.
- The `MKL_RODFT00` value of the `kind` parameter is introduced by the FFTW3 wrappers. For better performance, you are strongly encouraged to use this value rather than `FFTW_RODFT00`. To use this `kind` value, provide an extra first element equal to 0.0 for the input/output vectors. Consider the following example:

```
plan1 = fftw_plan_r2r_1d(n, in1, out1, FFTW_RODFT00, FFTW_ESTIMATE);
plan2 = fftw_plan_r2r_1d(n, in2, out2, MKL_RODFT00, FFTW_ESTIMATE);
```

Both plans perform the same transform, except that the `in2/out2` arrays have one extra zero element at location 0. For example, if `n=3`, `in1={x,y,z}` and `out1={u,v,w}`, then `in2={0,x,y,z}` and `out2={0,u,v,w}`.

- The `flags` parameter in plan creation functions is always ignored. The same algorithm is used regardless of the value of this parameter. In particular, `flags` values `FFTW_ESTIMATE`, `FFTW_MEASURE`, etc. have no effect.
- For multithreaded plans, use normal sequence of calls to the `fftw_init_threads()` and `fftw_plan_with_nthreads()` functions (refer to FFTW documentation).
- Memory allocation function `fftw_malloc` returns memory aligned at a 16-byte boundary. You must free the memory with `fftw_free`.
- The FFTW3 wrappers to Intel® oneAPI Math Kernel Library (oneMKL) use the 32-bit `int` type in both LP64 and ILP64 interfaces of Intel® oneAPI Math Kernel Library (oneMKL). Use `guru64` FFTW3 interfaces for 64-bit sizes.
- The wrappers typically indicate a problem by returning a `NULL` plan. In a few cases, the wrappers may report a descriptive message of the problem detected. By default the reporting is turned off. To turn it on, set variable `fftw3_mkl.verbose` to a non-zero value, for example:

```
#include "fftw3.h"
#include "fftw3_mkl.h"
fftw3_mkl.verbose = 0;
plan = fftw_plan_r2r(...);
```

- The following functions are empty:
  - For saving, loading, and printing plans
  - For saving and loading wisdom
  - For estimating arithmetic cost of the transforms.
- Do not use macro `FFTW_DLL` with the FFTW3 wrappers to Intel® oneAPI Math Kernel Library (oneMKL).

- Do not use negative stride values. Though FFTW3 wrappers support negative strides in the part of advanced and guru FFTW interface, the underlying implementation does not.
- Do not set a FFTW2 wrapper library before a FFTW3 wrapper library or Intel® oneAPI Math Kernel Library (oneMKL) in your link line application. All libraries define "fftw\_destroy\_plan" symbol and linkage in incorrect order results into expected errors.

## Building Your Own FFTW3 Interface Wrapper Library

The FFTW3 wrappers to Intel® oneAPI Math Kernel Library (oneMKL) are delivered both integrated in Intel® oneAPI Math Kernel Library (oneMKL) and as source code, which can be compiled to build a standalone wrapper library with exactly the same functionality. Normally you do not need to build the wrappers yourself.

The source code for the wrappers, makefiles, and files with lists of functions are located in the `.\interfaces\fftw3xc` subdirectory in the Intel® oneAPI Math Kernel Library (oneMKL) directory.

To build the wrappers,

1. Change the current directory to the wrapper directory
2. Run the `make` command on Linux\* OS and macOS\* or the `nmake` command on Windows\* OS with a required target and optionally several parameters.

The target `libia32` or `libintel64` defines the platform architecture, and the other parameters specify the compiler, size of the default integer type, and placement of the resulting wrapper library. You can find a detailed and up-to-date description of the parameters in the makefile.

In the following example, the `make` command is used to build the FFTW3 C wrappers to Intel® oneAPI Math Kernel Library (oneMKL) for use from the GNU `gcc`\* compiler on Linux OS based on Intel® 64 architecture:

```
cd interfaces/fftw3xc
make libintel64 compiler=gnu INSTALL_DIR=/my/path
```

This command builds the wrapper library and places the result, named `libfftw3xc_gnu.a`, into the `/my/path` directory. The name of the resulting library is composed of the name of the compiler used and may be changed by an optional parameter `INSTALL_LIBNAME`.

## Building an Application With FFTW3 Interface Wrappers

Normally, the only change needed to build your application with FFTW3 wrappers replacing original FFTW library is to add Intel® oneAPI Math Kernel Library (oneMKL) at the link stage (see section "*Linking Your Application with Intel® oneAPI Math Kernel Library*" in the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*).

If you recompile your application, add subdirectory `include\fftw` to the search path for header files to avoid FFTW3 version conflicts.

Sometimes, you may have to modify your application according to the following recommendations:

- The application requires

```
#include "fftw3.h",
```

which it probably already includes.

- The application does not require

```
#include "mkl_dfti.h" .
```

- The application does not require

```
#include "fftw3_mkl.h" .
```

It is required only in case you want to use the `MKL_RODFT00` constant.

- If the application does not check whether a `NULL` plan is returned by plan creation functions, this check must be added, because the FFTW3 to Intel® oneAPI Math Kernel Library (oneMKL) wrappers do not provide 100% of FFTW3 functionality.

## Running FFTW3 Interface Wrapper Examples

There are some examples that demonstrate how to use the wrapper library. The source code for the examples, makefiles used to run them, and files with lists of examples are located in the `.\examples\fftw3xc` subdirectory in the Intel® oneAPI Math Kernel Library (oneMKL) directory.

Parameters of the example makefiles are similar to the parameters of the wrapper library makefiles. Example makefiles normally build and invoke the examples. If the parameter `function=<example_name>` is defined, then only the specified example will run. Otherwise, all examples will be executed. Results of running the examples are saved in subdirectory `.\_results` in files with extension `.res`.

For detailed information about options for the example makefile, refer to the makefile.

## MPI FFTW3 Wrappers

This section describes a collection of MPI FFTW wrappers to Intel® oneAPI Math Kernel Library (oneMKL).

MPI FFTW wrappers are available only with Intel® oneAPI Math Kernel Library (oneMKL) for the Linux\* and Windows\* operating systems.

These wrappers translate calls of MPI FFTW functions to the calls of the Intel® oneAPI Math Kernel Library (oneMKL) cluster Fourier transform (CFFT) functions. The purpose of the wrappers is to enable users of MPI FFTW functions improve performance of the applications without changing the program source code.

Although the MPI FFTW wrappers provide less functionality than the original FFTW3 because of differences between MPI FFTW and Intel® oneAPI Math Kernel Library (oneMKL) CFFT, the wrappers cover many typical CFFT use cases.

The MPI FFTW wrappers are provided as source code. To use the wrappers, you need to build your own wrapper library (see [Building Your Own Wrapper Library](#)).

See also these resources:

Intel® oneAPI Math Kernel Library (oneMKL) Release Notes	for the version of the FFTW3 library supported by the wrappers.
<a href="http://www.fftw.org">www.fftw.org</a>	for a description of the MPI FFTW interface.
<a href="#">Cluster FFT Functions</a>	for a description of the Intel® oneAPI Math Kernel Library (oneMKL) CFFT interface.

## Building Your Own Wrapper Library

The MPI FFTW wrappers for FFTW3 are delivered as source code, which can be compiled to build a wrapper library.

The source code for the wrappers, makefiles, and files with lists of functions are located in subdirectory `.\interfaces\fftw3x_cdft` in the Intel® oneAPI Math Kernel Library (oneMKL) directory.

To build the wrappers,

1. Change the current directory to the wrapper directory
2. Run the `make` command on Linux\* OS or the `nmake` command on Windows\* OS with a required target and optionally several parameters.

The target `libia32` or `libintel64` defines the platform architecture, and the other parameters specify the compiler, size of the default `INTEGER` type, as well as the name and placement of the resulting wrapper library. You can find a detailed and up-to-date description of the parameters in the makefile.

In the following example, the `make` command is used to build the MPI FFTW wrappers to Intel® oneAPI Math Kernel Library (oneMKL) for use from the GNU C compiler on Linux OS based on Intel® 64 architecture:

```
cd interfaces/fftw3x_cdft
make libintel64 compiler=gnu mpi=openmpi INSTALL_DIR=/my/path
```

This command builds the wrapper library using the GNU gcc compiler so that the final executable can use Open MPI, and places the result, named `libfftw3x_cdft_DOUBLE.a`, into directory `/my/path`.

## Building an Application

Normally, the only change needed to build your application with MPI FFTW wrappers replacing original FFTW3 library is to add Intel® oneAPI Math Kernel Library (oneMKL) and the wrapper library at the link stage (see section "[Linking Your Application with Intel® oneAPI Math Kernel Library](#)" in the *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*).

When you are recompiling your application, add subdirectory `include\fftw` to the search path for header files to avoid FFTW3 version conflicts.

## Running Examples

There are some examples that demonstrate how to use the MPI FFTW wrapper library for FFTW3. The source code for the examples, makefiles used to run them, and files with lists of examples are located in the `.\examples\fftw3x_cdft` subdirectory in the Intel® oneAPI Math Kernel Library (oneMKL) directory.

Parameters of the example makefiles are similar to the parameters of the wrapper library makefiles. Example makefiles normally build and invoke the examples. Results of running the examples are saved in subdirectory `.\_results` in files with extension `.res`.

For detailed information about options for the example makefile, refer to the makefile.

# Appendix D: Code Examples

This appendix presents code examples of using some Intel® oneAPI Math Kernel Library (oneMKL) routines and functions.

Please refer to respective sections in the document for detailed descriptions of function parameters and operation.

## BLAS Code Examples

### Example. Using BLAS Level 1 Function

The following example illustrates a call to the BLAS Level 1 function `sdot`. This function performs a vector-vector operation of computing a scalar product of two single-precision real vectors `x` and `y`.

#### Parameters

<code>n</code>	Specifies the number of elements in vectors <code>x</code> and <code>y</code> .
<code>incx</code>	Specifies the increment for the elements of <code>x</code> .
<code>incy</code>	Specifies the increment for the elements of <code>y</code> .

```
#include <stdio.h>
#include <stdlib.h>

#include "mkl_example.h"

int main()
{
    MKL_INT n, incx, incy, i;
```

```

float  *x, *y;
float  res;
MKL_INT len_x, len_y;

n = 5;
incx = 2;
incy = 1;

len_x = 1+(n-1)*abs(incx);
len_y = 1+(n-1)*abs(incy);
x = (float *)calloc( len_x, sizeof( float ) );
y = (float *)calloc( len_y, sizeof( float ) );
if( x == NULL || y == NULL ) {
    printf( "\n Can't allocate memory for arrays\n");
    return 1;
}

for (i = 0; i < n; i++) {
    x[i*abs(incx)] = 2.0;
    y[i*abs(incy)] = 1.0;
}

res = cblas_sdot(n, x, incx, y, incy);

printf("\n      SDOT = %7.3f", res);

free(x);
free(y);

return 0;
}

```

As a result of this program execution, the following line is printed:

```
SDOT = 10.000
```

### Example. Using BLAS Level 1 Routine

The following example illustrates a call to the BLAS Level 1 routine `scopy`. This routine performs a vector-vector operation of copying a single-precision real vector  $x$  to a vector  $y$ .

#### Parameters

$n$	Specifies the number of elements in vectors $x$ and $y$ .
$incx$	Specifies the increment for the elements of $x$ .
$incy$	Specifies the increment for the elements of $y$ .

```

#include <stdio.h>
#include <stdlib.h>

#include "mkl_example.h"

int main()
{
    MKL_INT n, incx, incy, i;
    float  *x, *y;

```

```

MKL_INT len_x, len_y;
n = 3;
incx = 3;
incy = 1;

len_x = 10;
len_y = 10;
x = (float *)calloc( len_x, sizeof( float ) );
y = (float *)calloc( len_y, sizeof( float ) );
if( x == NULL || y == NULL ) {
    printf( "\n Can't allocate memory for arrays\n");
    return 1;
}
for (i = 0; i < 10; i++) {
    x[i] = i + 1;
}

cblas_scopy(n, x, incx, y, incy);

/*      Print output data      */

printf("\n\n      OUTPUT DATA");
PrintVectorS(FULLPRINT, n, y, incy, "Y");

free(x);
free(y);
return 0;
}

```

As a result of this program execution, the following line is printed:

Y = 1.00000 4.00000 7.00000

### Example. Using BLAS Level 2 Routine

The following example illustrates a call to the BLAS Level 2 routine `sger`. This routine performs a matrix-vector operation

$$a := \alpha x y^T + a.$$

#### Parameters

<i>alpha</i>	Specifies a scalar <i>alpha</i> .
<i>x</i>	<i>m</i> -element vector.
<i>y</i>	<i>n</i> -element vector.
<i>a</i>	<i>m</i> -by- <i>n</i> matrix.

```

#include <stdio.h>
#include <stdlib.h>

#include "mkl_example.h"

int main()
{
    MKL_INT      m, n, lda, incx, incy, i, j;
    MKL_INT      rmaxa, cmaxa;

```

```
float      alpha;
float      *a, *x, *y;
CBLAS_LAYOUT layout;
MKL_INT    len_x, len_y;

m = 2;
n = 3;
lda = 5;
incx = 2;
incy = 1;
alpha = 0.5;

                layout = CblasRowMajor;

len_x = 10;
len_y = 10;
rmaxa = m + 1;
cmaxa = n;
a = (float *)calloc( rmaxa*cmaxa, sizeof(float) );
x = (float *)calloc( len_x, sizeof(float) );
y = (float *)calloc( len_y, sizeof(float) );
if( a == NULL || x == NULL || y == NULL ) {
    printf( "\n Can't allocate memory for arrays\n");
    return 1;
}
if( layout == CblasRowMajor )
    lda=cmaxa;
else
    lda=rmaxa;

for (i = 0; i < 10; i++) {
    x[i] = 1.0;
    y[i] = 1.0;
}

for (i = 0; i < m; i++) {
    for (j = 0; j < n; j++) {
        a[i + j*lda] = j + 1;
    }
}

cblas_sger(layout, m, n, alpha,x, incx, y, incy, a, lda);

PrintArrayS(&layout, FULLPRINT, GENERAL_MATRIX, &m, &n, a, &lda, "A");

free(a);
free(x);
free(y);

return 0;
}
```

As a result of this program execution, matrix *a* is printed as follows:

Matrix A:

```
1.50000 2.50000 3.50000
1.50000 2.50000 3.50000
```

## Example. Using BLAS Level 3 Routine

The following example illustrates a call to the BLAS Level 3 routine `ssymm`. This routine performs a matrix-matrix operation

$$c := \alpha * a * b' + \beta * c.$$

### Parameters

<i>alpha</i>	Specifies a scalar <i>alpha</i> .
<i>beta</i>	Specifies a scalar <i>beta</i> .
<i>a</i>	Symmetric matrix
<i>b</i>	<i>m</i> -by- <i>n</i> matrix
<i>c</i>	<i>m</i> -by- <i>n</i> matrix

```
#include <stdio.h>
#include <stdlib.h>

#include "mkl_example.h"

int main(int argc, char *argv[])
{
    MKL_INT      m, n, i, j;
    MKL_INT      lda, ldb, ldc;
    MKL_INT      rmaxa, cmaxa, rmaxb, cmaxb, rmaxc, cmaxc;
    float        alpha, beta;
    float        *a, *b, *c;
    CBLAS_LAYOUT layout;
    CBLAS_SIDE   side;
    CBLAS_UPLO   uplo;
    MKL_INT      ma, na, typeA;
    uplo = 'u';
    side = 'l';
    layout = CblasRowMajor;
    m = 3;
    n = 2;
    lda = 3;
    ldb = 3;
    ldc = 3;
    alpha = 0.5;
    beta = 2.0;

    if( side == CblasLeft ) {
        rmaxa = m + 1;
        cmaxa = m;
        ma    = m;
        na    = m;
    } else {
        rmaxa = n + 1;
        cmaxa = n;
        ma    = n;
        na    = n;
    }

    rmaxb = m + 1;
    cmaxb = n;
    rmaxc = m + 1;
    cmaxc = n;
}
```

```

a = (float *)calloc( rmaxa*cmaxa, sizeof(float) );
b = (float *)calloc( rmaxb*cmaxb, sizeof(float) );
c = (float *)calloc( rmaxc*cmaxc, sizeof(float) );
if ( a == NULL || b == NULL || c == NULL ) {
    printf("\n Can't allocate memory arrays");
    return 1;
}
if( layout == CblasRowMajor ) {
    lda=cmaxa;
    ldb=cmaxb;
    ldc=cmaxc;
} else {
    lda=rmaxa;
    ldb=rmaxb;
    ldc=rmaxc;
}
if (uplo == CblasUpper) typeA = UPPER_MATRIX;
else typeA = LOWER_MATRIX;
for (i = 0; i < m; i++) {
    for (j = 0; j < m; j++) {
        a[i + j*lda] = 1.0;
    }
}
for (i = 0; i < m; i++) {
    for (j = 0; j < n; j++) {
        c[i + j*ldc] = 1.0;
        b[i + j*ldb] = 2.0;
    }
}

cblas_ssymm(layout, side, uplo, m, n, alpha, a, lda,
            b, ldb, beta, c, ldc);

printf("\n\n      OUTPUT DATA");
PrintArrayS(&layout, FULLPRINT, GENERAL_MATRIX, &m, &n, c, &ldc, "C");

free(a);
free(b);
free(c);

return 0;
}

```

As a result of this program execution, matrix c is printed as follows:

Matrix C:

```

5.00000 5.00000
5.00000 5.00000
5.00000 5.00000

```

The following example illustrates a call from a C program to the Fortran version of the complex BLAS Level 1 function `zdotc()`. This function computes the dot product of two double-precision complex vectors.

## Example. Calling a Complex BLAS Level 1 Function from C

In this example, the complex dot product is returned in the structure `c`.

```
#include <stdio>
#include "mkl_blas.h"
#define N 5
void main()
{
    int n, inca = 1, incb = 1, i;
    MKL_Complex16 a[N], b[N], c;
    void zdotc();
    n = N;
    for( i = 0; i < n; i++ ){
        a[i].real = (double)i; a[i].imag = (double)i * 2.0;
        b[i].real = (double)(n - i); b[i].imag = (double)i * 2.0;
    }
    zdotc( &c, &n, a, &inca, b, &incb );
    printf( "The complex dot product is: ( %6.2f, %6.2f )\n", c.real, c.imag );
}
```

### NOTE

Instead of calling BLAS directly from C programs, you might wish to use the C interface to the Basic Linear Algebra Subprograms (CBLAS) implemented in Intel® oneAPI Math Kernel Library (oneMKL). See [C Interface Conventions](#) for more information.

## Fourier Transform Functions Code Examples

This section presents code examples for functions described in the “[FFT Functions](#)” and “[Cluster FFT Functions](#)” subsections in the “[Fourier Transform Functions](#)” section. The examples are grouped in subsections

- [Examples for FFT Functions](#), including [Examples of Using Multi-Threading for FFT Computation](#)
- [Examples for Cluster FFT Functions](#)
- [Auxiliary data transformations](#).

### FFT Code Examples

This section presents examples of using the FFT interface functions described in “[Fourier Transform Functions](#)”.

Here are the examples of two one-dimensional computations. These examples use the default settings for all of the configuration parameters, which are specified in “[Configuration Settings](#)”.

### One-dimensional In-place FFT

```
/* C example, float _Complex is defined in C9X */
#include "mkl_dfti.h"

float _Complex c2c_data[32];
float r2c_data[34];
DFTI_DESCRIPTOR_HANDLE my_desc1_handle = NULL;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle = NULL;
MKL_LONG status;

/* ...put values into c2c_data[i] 0<=i<=31 */
/* ...put values into r2c_data[i] 0<=i<=31 */
```

```
status = DftiCreateDescriptor(&my_desc1_handle, DFTI_SINGLE,
                             DFTI_COMPLEX, 1, 32);
status = DftiCommitDescriptor(my_desc1_handle);
status = DftiComputeForward(my_desc1_handle, c2c_data);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is c2c_data[i] 0<=i<=31 */
status = DftiCreateDescriptor(&my_desc2_handle, DFTI_SINGLE,
                             DFTI_REAL, 1, 32);
status = DftiCommitDescriptor(my_desc2_handle);
status = DftiComputeForward(my_desc2_handle, r2c_data);
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is the complex value r2c_data[i] 0<=i<=31 */
/* and is stored in CCS format*/
```

## One-dimensional Out-of-place FFT

```
/* C example, float _Complex is defined in C9X */
#include "mkl_dfti.h"

float _Complex c2c_input[32];
float _Complex c2c_output[32];
float r2c_input[32];
float r2c_output[34];
DFTI_DESCRIPTOR_HANDLE my_desc1_handle = NULL;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle = NULL;
MKL_LONG status;

/* ...put values into c2c_input[i] 0<=i<=31 */
/* ...put values into r2c_input[i] 0<=i<=31 */

status = DftiCreateDescriptor(&my_desc1_handle, DFTI_SINGLE,
                             DFTI_COMPLEX, 1, 32);
status = DftiSetValue(my_desc1_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor(my_desc1_handle);
status = DftiComputeForward(my_desc1_handle, c2c_input, c2c_output);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is c2c_output[i] 0<=i<=31 */
status = DftiCreateDescriptor(&my_desc2_handle, DFTI_SINGLE,
                             DFTI_REAL, 1, 32);
Status = DftiSetValue(my_desc1_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor(my_desc2_handle);
status = DftiComputeForward(my_desc2_handle, r2c_input, r2c_output);
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is the complex r2c_data[i] 0<=i<=31 and is stored in CCS format*/
```

## Two-dimensional FFT

```
/* C99 example */
#include "mkl_dfti.h"

/* complex data in, complex data out */
float _Complex c2c_data[32][100];
/* real data in, complex data out */
float r2c_data[34][102];
```

```

DFTI_DESCRIPTOR_HANDLE my_desc1_handle = NULL;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle = NULL;
MKL_LONG status;MKL_LONG dim_sizes[2] = {32, 100};

/* ...put values into c2c_data[i][j] 0<=i<=31, 0<=j<=99 */
/* ...put values into r2c_data[i][j] 0<=i<=31, 0<=j<=99 */

status = DftiCreateDescriptor(&my_desc1_handle, DFTI_SINGLE,
                             DFTI_COMPLEX, 2, dim_sizes);
status = DftiCommitDescriptor(my_desc1_handle);
status = DftiComputeForward(my_desc1_handle, c2c_data);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is the complex value c2c_data[i][j], 0<=i<=31, 0<=j<=99 */
status = DftiCreateDescriptor(&my_desc2_handle, DFTI_SINGLE,
                             DFTI_REAL, 2, dim_sizes);
status = DftiCommitDescriptor(my_desc2_handle);
status = DftiComputeForward(my_desc2_handle, r2c_data);
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is the complex r2c_data[i][j] 0<=i<=31, 0<=j<=99
   and is stored in CCS format*/

```

The following example demonstrates how you can change the default configuration settings by using the `DftiSetValue` function.

For instance, to preserve the input data after the FFT computation, the configuration of `DFTI_PLACEMENT` should be changed to "not in place" from the default choice of "in place."

The code below illustrates how this can be done:

## Changing Default Settings

```

/* C99 example */
#include "mkl_dfti.h"

float _Complex x_in[32], x_out[32];
DFTI_DESCRIPTOR_HANDLE my_desc_handle = NULL;
MKL_LONG status;

/* ...put values into x_in[i] 0<=i<=31 */

status = DftiCreateDescriptor(&my_desc_handle, DFTI_SINGLE,
                             DFTI_COMPLEX, 1, 32);
status = DftiSetValue(my_desc_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor(my_desc_handle);
status = DftiComputeForward(my_desc_handle, x_in, x_out);
status = DftiFreeDescriptor(&my_desc_handle);
/* result is the complex value x_out[i], 0<=i<=31 */

```

## Using Status Checking Functions

This example illustrates the use of status checking functions described in "[Fourier Transform Functions](#)".

```

/* C99 example */
#include "mkl_dfti.h"

DFTI_DESCRIPTOR_HANDLE desc = NULL;

```

```
MKL_LONG status;

/* ...descriptor creation and other code */

status = DftiCommitDescriptor(desc);
if (status && !DftiErrorClass(status, DFTI_NO_ERROR))
{
    printf('Error: %s\n', DftiErrorMessage(status));
}
```

## Computing 2D FFT by One-Dimensional Transforms

Below is an example where a 20-by-40 two-dimensional FFT is computed explicitly using one-dimensional transforms.

```
/* C */
#include "mkl_dfti.h"

float _Complex data[20][40];
MKL_LONG status;
DFTI_DESCRIPTOR_HANDLE desc_handle_dim1 = NULL;
DFTI_DESCRIPTOR_HANDLE desc_handle_dim2 = NULL;

/* ...put values into data[i][j] 0<=i<=19, 0<=j<=39 */

status = DftiCreateDescriptor(&desc_handle_dim1, DFTI_SINGLE,
                             DFTI_COMPLEX, 1, 20);
status = DftiCreateDescriptor(&desc_handle_dim2, DFTI_SINGLE,
                             DFTI_COMPLEX, 1, 40);

/* perform 40 one-dimensional transforms along 1st dimension */
/* note that the 1st dimension data are not unit-stride */
MKL_LONG stride[2] = {0, 40};

status = DftiSetValue(desc_handle_dim1, DFTI_NUMBER_OF_TRANSFORMS, 40);
status = DftiSetValue(desc_handle_dim1, DFTI_INPUT_DISTANCE, 1);
status = DftiSetValue(desc_handle_dim1, DFTI_OUTPUT_DISTANCE, 1);
status = DftiSetValue(desc_handle_dim1, DFTI_INPUT_STRIDES, stride);
status = DftiSetValue(desc_handle_dim1, DFTI_OUTPUT_STRIDES, stride);
status = DftiCommitDescriptor(desc_handle_dim1);
status = DftiComputeForward(desc_handle_dim1, data);
/* perform 20 one-dimensional transforms along 2nd dimension */
/* note that the 2nd dimension is unit stride */
status = DftiSetValue(desc_handle_dim2, DFTI_NUMBER_OF_TRANSFORMS, 20);
status = DftiSetValue(desc_handle_dim2, DFTI_INPUT_DISTANCE, 40);
status = DftiSetValue(desc_handle_dim2, DFTI_OUTPUT_DISTANCE, 40);
status = DftiCommitDescriptor(desc_handle_dim2);
status = DftiComputeForward(desc_handle_dim2, data);
status = DftiFreeDescriptor(&desc_handle_dim1);
status = DftiFreeDescriptor(&desc_handle_dim2);
```

The following code illustrates real multi-dimensional transforms with CCE format storage of conjugate-even complex matrix. [Example "Three-Dimensional REAL FFT \(C Interface\)"](#) is three-dimensional out-of-place transform in C interface.

## Three-Dimensional REAL FFT

```

/* C99 example */
#include "mkl_dfti.h"

float input[32][100][19];
float _Complex output[32][100][10]; /* 10 = 19/2 + 1 */
DFTI_DESCRIPTOR_HANDLE my_desc_handle = NULL;
MKL_LONG status;
MKL_LONG dim_sizes[3] = {32, 100, 19};
MKL_LONG strides_out[4] = {0, 100*10*1, 10*1, 1};

//...put values into input[i][j][k] 0<=i<=31; 0<=j<=99, 0<=k<=9

status = DftiCreateDescriptor(&my_desc_handle,
                             DFTI_SINGLE, DFTI_REAL, 3, dim_sizes);
status = DftiSetValue(my_desc_handle,
                     DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX);
status = DftiSetValue(my_desc_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiSetValue(my_desc_handle, DFTI_OUTPUT_STRIDES, strides_out);

status = DftiCommitDescriptor(my_desc_handle);
status = DftiComputeForward(my_desc_handle, input, output);
status = DftiFreeDescriptor(&my_desc_handle);
/* result is the complex output[i][j][k] 0<=i<=31; 0<=j<=99, 0<=k<=9
   and is stored in CCE format. */

```

### Examples of Using OpenMP\* Threading for FFT Computation

The following sample program shows how to employ internal OpenMP\* threading in Intel® oneAPI Math Kernel Library (oneMKL) for FFT computation.

To specify the number of threads inside Intel® oneAPI Math Kernel Library (oneMKL), use the following settings:

set `MKL_NUM_THREADS = 1` for one-threaded mode;

set `MKL_NUM_THREADS = 4` for multi-threaded mode.

### Using oneMKL Internal Threading Mode (C Example)

```

/* C99 example */
#include "mkl_dfti.h"

float data[200][100];
DFTI_DESCRIPTOR_HANDLE fft = NULL;
MKL_LONG dim_sizes[2] = {200, 100};

/* ...put values into data[i][j] 0<=i<=199, 0<=j<=99 */

DftiCreateDescriptor(&fft, DFTI_SINGLE, DFTI_REAL, 2, dim_sizes);
DftiCommitDescriptor(fft);
DftiComputeForward(fft, data);
DftiFreeDescriptor(&fft);

```

The following [Example "Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region"](#) and [Example "Using Parallel Mode with Multiple Descriptors Initialized in One Thread"](#) illustrate a parallel customer program with each descriptor instance used only in a single thread.

Specify the number of OpenMP threads for [Example “Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region”](#) like this:

set `MKL_NUM_THREADS = 1` for Intel® oneAPI Math Kernel Library (oneMKL) to work in the single-threaded mode (recommended);

set `OMP_NUM_THREADS = 4` for the customer program to work in the multi-threaded mode.

## Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region

Note that in this example, the program can be transformed to become single-threaded at the customer level but using parallel mode within Intel® oneAPI Math Kernel Library (oneMKL). To achieve this, you must set the parameter `DFTI_NUMBER_OF_TRANSFORMS = 4` and to set the corresponding parameter `DFTI_INPUT_DISTANCE = 5000`.

```
/* C99 example */
#include "mkl_dfti.h"
#include <omp.h>
#define ARRAY_LEN(a) sizeof(a)/sizeof(a[0])

// 4 OMP threads, each does 2D FFT 50x100 points
MKL_Complex8 data[4][50][100];
int nth = ARRAY_LEN(data);
MKL_LONG dim_sizes[2] = {
    ARRAY_LEN(data[0]),
    ARRAY_LEN(data[0][0])
}; /* {50, 100} */
int th;

/* ...put values into data[i][j][k] 0<=i<=3, 0<=j<=49, 0<=k<=99 */

// assume data is initialized and do 2D FFTs
#pragma omp parallel for shared(dim_sizes, data)
for (th = 0; th < nth; ++th)
{
    DFTI_DESCRIPTOR_HANDLE myFFT = NULL;

    DftiCreateDescriptor(&myFFT, DFTI_SINGLE, DFTI_COMPLEX, 2, dim_sizes);
    DftiCommitDescriptor(myFFT);
    DftiComputeForward(myFFT, data[th]);
    DftiFreeDescriptor(&myFFT);
}
```

Specify the number of OpenMP threads for [Example “Using Parallel Mode with Multiple Descriptors Initialized in One Thread”](#) like this:

set `MKL_NUM_THREADS = 1` for Intel® oneAPI Math Kernel Library (oneMKL) to work in the single-threaded mode (obligatory);

set `OMP_NUM_THREADS = 4` for the customer program to work in the multi-threaded mode.

## Using Parallel Mode with Multiple Descriptors Initialized in One Thread

```
/* C99 example */
#include "mkl_dfti.h"
#include <omp.h>#
define ARRAY_LEN(a) sizeof(a)/sizeof(a[0])

// 4 OMP threads, each does 2D FFT 50x100 points
MKL_Complex8 data[4][50][100];
int nth = ARRAY_LEN(data);
MKL_LONG dim_sizes[2] = {
```

```

    ARRAY_LEN(data[0]),
    ARRAY_LEN(data[0][0])
}; /* {50, 100} */
DFTI_DESCRIPTOR_HANDLE FFT[ARRAY_LEN(data)];
int th;

/* ...put values into data[i][j][k] 0<=i<=3, 0<=j<=49, 0<=k<=99 */

for (th = 0; th < nth; ++th)
    DftiCreateDescriptor(&FFT[th], DFTI_SINGLE, DFTI_COMPLEX, 2, dim_sizes);
for (th = 0; th < nth; ++th)
    DftiCommitDescriptor(FFT[th]);

// assume data is initialized and do 2D FFTs
#pragma omp parallel for shared(FFT, data)
for (th = 0; th < nth; ++th)
    DftiComputeForward(FFT[th], data[th]);

for (th = 0; th < nth; ++th)
    DftiFreeDescriptor(&FFT[th]);

```

The following [Example “Using Parallel Mode with a Common Descriptor”](#) illustrates a parallel customer program with a common descriptor used in several threads.

## Using Parallel Mode with a Common Descriptor

```

#include "mkl_dfti.h"
#include <omp.h>
#define ARRAY_LEN(a) sizeof(a)/sizeof(a[0])

// 4 OMP threads, each does 2D FFT 50x100 points
MKL_Complex8 data[4][50][100];
int nth = ARRAY_LEN(data);
MKL_LONG len[2] = {ARRAY_LEN(data[0]), ARRAY_LEN(data[0][0])};
DFTI_DESCRIPTOR_HANDLE FFT;
int th;

/* ...put values into data[i][j][k] 0<=i<=3, 0<=j<=49, 0<=k<=99 */

DftiCreateDescriptor(&FFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len);
DftiCommitDescriptor(FFT);

// assume data is initialized and do 2D FFTs
#pragma omp parallel for shared(FFT, data)
for (th = 0; th < nth; ++th)
    DftiComputeForward(FFT, data[th]);
DftiFreeDescriptor(&FFT);

```

## Examples for Cluster FFT Functions

The following C example computes a 2-dimensional out-of-place FFT using the cluster FFT interface:

### 2D Out-of-place Cluster FFT Computation

```

/* C99 example */
#include "mpi.h"
#include "mkl_cdft.h"

DFTI_DESCRIPTOR_DM_HANDLE desc = NULL;

```

```

MKL_LONG v, i, j, n, s;
Complex *in, *out;
MKL_LONG dim_sizes[2] = {nx, ny};

MPI_Init(...);

/* Create descriptor for 2D FFT */
DftiCreateDescriptorDM(MPI_COMM_WORLD,
                      &desc, DFTI_DOUBLE, DFTI_COMPLEX, 2, dim_sizes);
/* Ask necessary length of in and out arrays and allocate memory */
DftiGetValueDM(desc, CDFT_LOCAL_SIZE, &v);
in = (Complex*) malloc(v*sizeof(Complex));
out = (Complex*) malloc(v*sizeof(Complex));
/* Fill local array with initial data. Current process performs n rows,
   0 row of in corresponds to s row of virtual global array */
DftiGetValueDM(desc, CDFT_LOCAL_NX, &n);
DftiGetValueDM(desc, CDFT_LOCAL_X_START, &s);
/* Virtual global array globalIN is defined by function f as
   globalIN[i*ny+j]=f(i,j) */
for(i = 0; i < n; ++i)
    for(j = 0; j < ny; ++j) in[i*ny+j] = f(i+s,j);
/* Set that we want out-of-place transform (default is DFTI_INPLACE) */
DftiSetValueDM(desc, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
/* Commit descriptor, calculate FFT, free descriptor */
DftiCommitDescriptorDM(desc);
DftiComputeForwardDM(desc, in, out);
/* Virtual global array globalOUT is defined by function g as
   globalOUT[i*ny+j]=g(i,j)   Now out contains result of FFT. out[i*ny+j]=g(i+s,j) */
DftiFreeDescriptorDM(&desc);
free(in);
free(out);
MPI_Finalize();

```

## 1D In-place Cluster FFT Computations

The C example below illustrates one-dimensional in-place cluster FFT computations effected with a user-defined workspace:

```

/* C99 example */
#include "mpi.h"
#include "mkl_cdft.h"

DFTI_DESCRIPTOR_DM_HANDLE desc = NULL;
MKL_LONG N, v, i, n_out, s_out;
Complex *in, *work;

MPI_Init(...);
/* Create descriptor for 1D FFT */
DftiCreateDescriptorDM(MPI_COMM_WORLD, &desc, DFTI_DOUBLE, DFTI_COMPLEX, 1, N);
/* Ask necessary length of array and workspace and allocate memory */
DftiGetValueDM(desc, CDFT_LOCAL_SIZE, &v);
in = (Complex*) malloc(v*sizeof(Complex));
work = (Complex*) malloc(v*sizeof(Complex));
/* Fill local array with initial data. Local array has n elements,
   0 element of in corresponds to s element of virtual global array */
DftiGetValueDM(desc, CDFT_LOCAL_NX, &n);
DftiGetValueDM(desc, CDFT_LOCAL_X_START, &s);
/* Set work array as a workspace */

```

```

DftiSetValueDM(desc, CDFT_WORKSPACE, work);
/* Virtual global array globalIN is defined by function f as globalIN[i]=f(i) */
for(i = 0; i < n; ++i) in[i] = f(i+s);
/* Commit descriptor, calculate FFT, free descriptor */
DftiCommitDescriptorDM(desc);
DftiComputeForwardDM(desc,in);
DftiGetValueDM(desc, CDFT_LOCAL_OUT_NX, &n_out);
DftiGetValueDM(desc, CDFT_LOCAL_OUT_X_START, &s_out);
/* Virtual global array globalOUT is defined by function g as globalOUT[i]=g(i)
   Now in contains result of FFT. Local array has n_out elements,
   0 element of in corresponds to s_out element of virtual global array.
   in[i]==g(i+s_out) */
DftiFreeDescriptorDM(&desc);
free(in);
free(work);
MPI_Finalize();

```

## Auxiliary Data Transformations

This section presents C examples for conversion from the Cartesian to polar representation of complex data and vice versa.

### Conversion from Cartesian to polar representation of complex data

```

// Cartesian->polar conversion of complex data
// Cartesian representation: z = re + I*im
// Polar representation: z = r * exp( I*phi )
#include <mkl_vml.h>

void
variant1_Cartesian2Polar(int n,const double *re,const double *im,
                        double *r,double *phi)
{
    vdHypot(n,re,im,r);          // compute radii r[]
    vdAtan2(n,im,re,phi);       // compute phases phi[]
}

void
variant2_Cartesian2Polar(int n,const MKL_Complex16 *z,double *r,double *phi,
                        double *temp_re,double *temp_im)
{
    vzAbs(n,z,r);               // compute radii r[]
    vdPackI(n, (double*)z + 0, 2, temp_re);
    vdPackI(n, (double*)z + 1, 2, temp_im);
    vdAtan2(n,temp_im,temp_re,phi); // compute phases phi[]
}

```

### Conversion from polar to Cartesian representation of complex data

```

// Polar->Cartesian conversion of complex data.
// Polar representation: z = r * exp( I*phi )
// Cartesian representation: z = re + I*im
#include <mkl_vml.h>

void

```

```

variant1_Polar2Cartesian(int n,const double *r,const double *phi,
                        double *re,double *im)
{
    vdSinCos(n,phi,im,re);    // compute direction, i.e. z[]/abs(z[])
    vdMul(n,r,re,re);        // scale real part
    vdMul(n,r,im,im);        // scale imaginary part
}

void
variant2_Polar2Cartesian(int n,const double *r,const double *phi,
                        MKL_Complex16 *z,
                        double *temp_re,double *temp_im)
{
    vdSinCos(n,phi,temp_im,temp_re); // compute direction, i.e. z[]/abs(z[])
    vdMul(n,r,temp_im,temp_im); // scale imaginary part
    vdMul(n,r,temp_re,temp_re); // scale real part
    vdUnpackI(n,temp_re,(double*)z + 0, 2); // fill in result.re
    vdUnpackI(n,temp_im,(double*)z + 1, 2); // fill in result.im
}

```

## Appendix F: oneMKL Functionality

This appendix provides an overview of the Intel® oneAPI Math Kernel Library (oneMKL) functionality on the different devices.

### BLAS Functionality

C

Functionality	CPU	OpenMP Offload Intel GPU
Level 1 BLAS (standard)	All	All
Level 2 BLAS (standard)	All	All
Level 3 BLAS (standard)	All	All
BLAS Extensions and Specializations	{AXPY,GEMM,TRSM}_BATCH (group and strided)	{AXPY,GEMM,TRSM}_BATCH (group and strided)
	GEMMT, AXPBY, GEMM3M	GEMMT
	Integer GEMM (s8u8)	N/A
	Bfloat16 GEMM	N/A
	JIT GEMM API	N/A
	PACK GEMM API	N/A
	COMPACT GEMM API	N/A

## Transposition Functionality

Functionality	CPU	OpenMP Offload Intel GPU
In-place dense matrix transpose	Yes	No
Out-of-place dense matrix transpose	Yes	No
In-place dense matrix add	Yes	No
Out-of-place dense matrix copy	Yes	No

## LAPACK Functionality

**NOTE** All of the DPC++ LAPACK computational routines have a corresponding `*_scratchpad_size` function for calculating the required amount of scratchpad space.

### LU Factorization Routines

Functionality	CPU	OpenMP Offload Intel GPU
getrf	Yes	Yes
getrs	Yes	Yes
getri	Yes	Yes

### Cholesky Factorization Routines

Functionality	CPU	OpenMP Offload Intel GPU
potrf	Yes	Yes
potrs	Yes	Yes
potri	Yes	Yes

### Orthogonal Factorization Routines

Functionality	CPU	OpenMP Offload Intel GPU
geqrf	Yes	Yes
{or,un}gqr	Yes	Yes
{or,un}mqr	Yes	Yes
gerqf	Yes	No
{or,un}mrq	Yes	No

### Other Linear Equation Routines

Functionality	CPU	OpenMP Offload Intel GPU
trtrs	Yes	Yes
{sy,he}trf	Yes	No

### Symmetric Eigenvalue Routines

Functionality	CPU	OpenMP Offload Intel GPU
{sy,he}ev	Yes	Yes

Functionality	CPU	OpenMP Offload Intel GPU

### Other LAPACK Routines

CPU	OpenMP Offload Intel GPU
Yes	No

## DFT Functionality

### DFTI Interfaces

Functionality	CPU	OpenMP Offload Intel GPU
Complex-to-Complex FFT transformations	Yes, 1D through 7D	Yes, 1D through 3D

Functionality	CPU	OpenMP Offload Intel GPU
Real-to-Complex FFT transformations	Yes, 1D through 7D	Yes, 1D through 3D

### FFTW3 Interfaces

Functionality	CPU	OpenMP Offload Intel GPU
Complex-to-Complex FFT transformations	Yes, 1D through 7D	Yes, 1D through 3D
Real-to-Complex FFT transformations	Yes, 1D through 7D	No

### FFTW2 Interfaces

Functionality	CPU	OpenMP Offload Intel GPU
Complex-to-Complex FFT transformations	Yes, 1D through 7D	No
Real-to-Complex FFT transformations	Yes, 1D through 7D	No

## Sparse BLAS Functionality

In the following table for functionality, sm = sparse matrix, dm = dense matrix, sv = sparse vector, dv = dense vector, sc = scalar.

In the following table for operations, dense vectors = x, y, sparse vectors = w,v, dense matrices = X,Y, sparse matrices = A, B, C, and scalars = alpha, beta, d.

### Level 1

Functionality	Operations	CPU	OpenMP Offload Intel GPU
Sparse Vector - Dense Vector addition (AXPY)	$y \leftarrow \alpha * w + y$	Yes	No
Sparse Vector - Sparse Vector Dot product (SPDOT) (sv.sv -> sc)	$d \leftarrow \text{dot}(w,v)$	N/A	N/A
	$\text{dot}(w,v) = \sum(w_i * v_i)$	No	No
	$\text{dot}(w,v) = \sum(\text{conj}(w_i) * v_i)$	No	No
Sparse Vector - Dense Vector Dot product (SPDOT) (sv.dv -> sc)	$d \leftarrow \text{dot}(w,x)$	N/A	N/A
	$\text{dot}(w,v) = \sum(w_i * v_i)$	Yes	No
	$\text{dot}(w,v) = \sum(\text{conj}(w_i) * v_i)$	Yes	No
Dense Vector - Sparse Vector Conversion (sv <-> dv)	—	N/A	N/A
	$x = \text{scatter}(w)$	Yes	No
	$w = \text{gather}(x, \text{windx})$	Yes	No

In the following table for functionality, sm = sparse matrix, dm = dense matrix, sv = sparse vector, dv = dense vector, sc = scalar.

In the following table for operations, dense vectors = x, y, sparse vectors = w,v, dense matrices = X,Y, sparse matrices = A, B, C, and scalars = alpha, beta, d.

**Level 2**

Functionality	Operations	CPU	OpenMP Offload Intel GPU
General Matrix-Vector multiplication (GEMV) (sm*dv->dv)	$y \leftarrow \beta * y + \alpha * \text{op}(A) * x$	N/A	N/A
	$\text{op}(A) = A$	Yes	No
	$\text{op}(A) = A^T$	Yes	No
	$\text{op}(A) = A^H$	Yes	No
Symmetric Matrix-Vector multiplication (SYMV) (sm*dv->dv)	$y \leftarrow \beta * y + \alpha * \text{op}(A) * x$	N/A	N/A
	$\text{op}(A) = A$	Yes	No
	$\text{op}(A) = A^T$	Yes	No
	$\text{op}(A) = A^H$	Yes	No
Triangular Matrix-Vector multiplication (TRMV) (sm*dv->dv)	$y \leftarrow \beta * y + \alpha * \text{op}(A) * x$	N/A	N/A
	$\text{op}(A) = A$	Yes	No
	$\text{op}(A) = A^T$	Yes	No
	$\text{op}(A) = A^H$	Yes	No
General Matrix-Vector mult with dot product (GEMV DOT) (sm*dv -> dv, dv.dv->sc)	$y \leftarrow \beta * y + \alpha * \text{op}(A) * x, d = \text{dot}(x, y)$	N/A	N/A
	$\text{op}(A) = A$	Yes	No
	$\text{op}(A) = A^T$	Yes	No
	$\text{op}(A) = A^H$	Yes	No
Triangular Solve (TRSV) (inv(sm)*dv -> dv)	solve for $y, \text{op}(A) * y = \alpha * x$	N/A	N/A
	$\text{op}(A) = A$	Yes	No
	$\text{op}(A) = A^T$	Yes	No
	$\text{op}(A) = A^H$	Yes	No

In the following table for functionality, sm = sparse matrix, dm = dense matrix, sv = sparse vector, dv = dense vector, sc = scalar.

In the following table for operations, dense vectors =  $x, y$ , sparse vectors =  $w, v$ , dense matrices =  $X, Y$ , sparse matrices =  $A, B, C$ , and scalars =  $\alpha, \beta, d$ .

**Level 3**

Functionality	Operations	CPU	OpenMP Offload Intel GPU
General Sparse Matrix - Dense Matrix Multiplication (GEMM) (sm*dm->dm)	$Y \leftarrow \alpha * \text{op}(A) * \text{op}(X) + \beta * Y$	N/A	N/A
	$\text{op}(A) = A, \text{op}(X) = X$	Yes	No
	$\text{op}(A) = A^T, \text{op}(X) = X$	Yes	No
	$\text{op}(A) = A^H, \text{op}(X) = X$	Yes	No

Functionality	Operations	CPU	OpenMP Offload Intel GPU
General Dense Matrix - Sparse Matrix Multiplication (GEMM) (dm*sm->dm)	$op(A) = A, op(X) = X^T$	No	No
	$op(A) = A^T, op(X) = X^T$	No	No
	$op(A) = A, op(X) = X^H$	No	No
	$op(A) = A^H$	No	No
	$op(A) = A^T, op(X) = X^H$	No	No
	$op(A) = A^H, op(X) = X^H$	No	No
	$Y <- \alpha * op(X) * op(A) + \beta * Y$	N/A	N/A
	$op(X) = X, op(A) = A$	No	No
	$op(X) = X^H, op(A) = A$	No	No
	$op(X) = X^H, op(A) = A$	No	No
General Sparse Matrix - Sparse Matrix Multiplication (GEMM) (sm*sm->sm)	$op(X) = X, op(A) = A^H$	No	No
	$op(X) = X^H, op(A) = A^H$	No	No
	$op(X) = X^H, op(A) = A^H$	No	No
	$op(X) = X, op(A) = A^H$	No	No
	$op(X) = X^H, op(A) = A^H$	No	No
	$op(X) = X, op(A) = A^H$	No	No
	$op(X) = X^H, op(A) = A^H$	No	No
	$op(X) = X^H, op(A) = A^H$	No	No
	$C <- \alpha * op(A) * op(B) + \beta * C$	N/A	N/A
	$op(A) = A, op(B) = B$	Yes	No
General Sparse Matrix - Sparse Matrix Multiplication (GEMM) (sm*sm->dm)	$op(A) = A^T, op(B) = B$	Yes	No
	$op(A) = A^H, op(B) = B$	Yes	No
	$op(A) = A, op(B) = B^T$	Yes	No
	$op(A) = A^T, op(B) = B^T$	Yes	No
	$op(A) = A^H, op(B) = B^T$	Yes	No
	$op(A) = A, op(B) = B^H$	Yes	No
	$op(A) = A^T, op(B) = B^H$	Yes	No
	$op(A) = A^H, op(B) = B^H$	Yes	No
	$Y <- \alpha * op(A) * op(B) + \beta * Y$	N/A	N/A
	$op(A) = A, op(B) = B$	Yes	No
$op(A) = A^T, op(B) = B$	Yes	No	
$op(A) = A^H, op(B) = B$	Yes	No	
$op(A) = A, op(B) = B^T$	No	No	

Functionality	Operations	CPU	OpenMP Offload Intel GPU
	$op(A)=A^T, op(B)=B^T$	No	No
	$op(A)=A^H, op(B)=B^T$	No	No
	$op(A)=A, op(B)=B^H$	No	No
	$op(A)=A^T, op(B)=B^H$	No	No
	$op(A)=A^H, op(B)=B^H$	No	No
Symmetric Rank-K update (SYRK) (sm*sm->sm)	$C \leftarrow op(A)*op(A)^H$	N/A	N/A
	$op(A)=A$	Yes	No
	$op(A)=A^T$	Yes	No
	$op(A)=A^H$	Yes	No
Symmetric Rank-K update (SYRK) (sm*sm->dm)	$Y \leftarrow op(A)*op(A)^H$	N/A	N/A
	$op(A)=A$	Yes	No
	$op(A)=A^T$	Yes	No
	$op(A)=A^H$	Yes	No
Symmetric Triple Product (SYPR) (op(sm)*sm*sm -> sm)	$C \leftarrow op(A)*B*op(A)^H$	N/A	N/A
	$op(A)=A$	Yes	No
	$op(A)=A^T$	Yes	No
	$op(A)=A^H$	Yes	No
Triangular Solve (TRSM) (inv(sm)*dm -> dm)	solve for Y, $op(A)*Y = alpha*X$	N/A	N/A
	$op(A)=A$	Yes	No
	$op(A)=A^T$	Yes	No
	$op(A)=A^H$	Yes	No

In the following table for functionality, sm = sparse matrix, dm = dense matrix, sv = sparse vector, dv = dense vector, sc = scalar.

In the following table for operations, dense vectors = x, y, sparse vectors = w, v, dense matrices = X, Y, sparse matrices = A, B, C, and scalars = alpha, beta, d.

### Other

Functionality	Operations	CPU	OpenMP Offload Intel GPU
Symmetric Gauss-Seidel Preconditioner (SYMGS) (update $A*x=b, A=L+D+U$ )	$x0 \leftarrow x*alpha; (L+D)*x1=b-U*x0; (U+D)*x=b-L*x1$	Yes	No
Symmetric Gauss-Seidel Preconditioner with Matrix-Vector product (SYMGS_MV) (update $A*x=b,$ $A=L+D+U$ )	$x0 \leftarrow x*alpha; (L+D)*x1=b-U*x0; (U+D)*x=b-L*x1; y=A*x$	Yes	No
LU Smoother (LU_SMOOTHER) (update $A*x=b, A=L+D+U,$ $E \sim inv(D)$ )	$r=b-A*x; (L+D)*E*(U+D)*dx=r; y=x+dr$	Yes	No

Functionality	Operations	CPU	OpenMP Offload Intel GPU
Sparse Matrix Add (ADD)	$C \leftarrow \alpha * \text{op}(A) + B$	Yes	No
	$\text{op}(A) = A^T$	Yes	No
	$\text{op}(A) = A^H$	Yes	No

In the following table for operations, dense vectors =  $x, y$ , sparse vectors =  $w, v$ , dense matrices =  $X, Y$ , sparse matrices =  $A, B, C$ , and scalars =  $\alpha, \beta, d$ .

### Helper Functions

Functionality	Operations	CPU	OpenMP Offload Intel GPU
Sort Indices of Matrix (ORDER)	N/A	Yes	No
Transpose of Sparse Matrix (TRANSPPOSE)	$A \leftarrow \text{op}(A)$ with $\text{op}=\text{trans}$ or $\text{conjtrans}$	N/A	N/A
	transpose CSR/CSC matrix	Yes	No
	transpose BSR matrix	Yes	No
Sparse Matrix Format Converter (CONVERT)	N/A	Yes	No
Dense to Sparse Matrix Format Converter (CONVERT)	N/A	Yes	No
Copy Matrix Handle (COPY)	N/A	Yes	No
Create CSR Matrix Handle	N/A	Yes	No
Create CSC Matrix Handle	N/A	Yes	No
Create COO Matrix Handle	N/A	Yes	No
Create BSR Matrix Handle	N/A	Yes	No
Export CSR Matrix	Allows access to internal data in the CSR Matrix handle	Yes	No
Export CSC Matrix	Allows access to internal data in the CSC Matrix handle	Yes	No
Export COO Matrix	Allows access to internal data in the COO Matrix handle	Yes	No
Export BSR Matrix	Allows access to internal data in the BSR Matrix handle	Yes	No
Set Value in Matrix	N/A	Yes	No

In the following table for functionality,  $sm$  = sparse matrix,  $dm$  = dense matrix,  $sv$  = sparse vector,  $dv$  = dense vector,  $sc$  = scalar.

In the following table for operations, dense vectors =  $x, y$ , sparse vectors =  $w, v$ , dense matrices =  $X, Y$ , sparse matrices =  $A, B, C$ , and scalars =  $\alpha, \beta, d$ .

### Optimize Stages

Functionality	Operations	CPU	OpenMP Offload Intel GPU
add MEMORY hint and optimize	Chooses to allow larger memory requiring optimizations or not.	Yes	No

Functionality	Operations	CPU	OpenMP Offload Intel GPU
Add GEMV hint and optimize	N/A	Yes	No
Add SYMV hint and optimize	N/A	Yes	No
Add TRMV hint and optimize	N/A	Yes	No
add TRSV hint and optimize	N/A	Yes	No
add GEMM hint and optimize	N/A	Yes	No
add TRSM hint and optimize	N/A	Yes	No
add DOTMV hint and optimize	N/A	Yes	No
add SYMGS hint and optimize	N/A	Yes	No
add SYMGS_MV hint and optimize	N/A	Yes	No
add LU_SMOOTHING hint and optimize	N/A	Yes	No

## Sparse Solvers Functionality

Functionality	CPU	OpenMP Offload Intel GPU
Sparse Cholesky Factorization	Yes	No
Sparse LU Factorization	Yes	No
Sparse QR factorization	Yes	No
Hermitian/Symmetric Eigensolver on intervals for Sparse Matrices	Yes	No
Extremal Eigensolvers for Sparse Matrix	Yes	No
Poisson Solver	Yes	No
Trust Region Solver	Yes	No

## Random Number Generators Functionality

### Engines

Functionality	CPU	OpenMP Offload Intel GPU
MRG32K3A	Yes	Yes
MT2203	Yes	Yes
MT19937	Yes	Yes
PHILOX4X32X10	Yes	Yes
SOBOL	Yes	Yes
ARS5	Yes	No
MCG59	Yes	Yes
NIEDERR	Yes	No

Functionality	CPU	OpenMP Offload Intel GPU
MCG31	Yes	Yes
WH	Yes	No
SFMT19937	Yes	No
R250	Yes	No
NONDETERM	Yes	No
DABSTRACT	Yes	No
SABSTRACT	Yes	No
IABSTRACT	Yes	No

### Distributions

Functionality	CPU	OpenMP Offload Intel GPU
Uniform (single/double/integer)	Yes	Yes
UniformBits32	Yes	Yes
UniformBits64		
Lognormal (single/double)	Yes	Yes
Gaussian (single/double)	Yes	Yes
Poisson	Yes	Yes
UniformBits	Yes	Yes
Bernoulli	Yes	Yes
Beta (single/double)	Yes	No
Binomial	Yes	No
ChiSquare (single/double)	Yes	No
Exponential (single/double)	Yes	Yes
Gamma (single/double)	Yes	No
Geometric	Yes	Yes
Gumbel (single/double)	Yes	Yes
Hyper Geometric	Yes	No
Laplace (single/double)	Yes	Yes
Multinomial	Yes	No
Negative Binomial	Yes	No
PoissonV	Yes	No
Rayleigh (single/double)	Yes	Yes
Weibull (single/double)	Yes	Yes
Cauchy (single/double)	Yes	Yes

Functionality	CPU	OpenMP Offload Intel GPU
GaussianMV (single/double)	Yes	Yes

## Vector Math Functionality

Functionality	CPU	OpenMP Offload Intel GPU
Vector Math Functions, Single Precision	Yes	Yes*
Vector Math Functions, Double Precision	Yes	Yes*
Vector Math Functions, Single Precision Complex	Yes	No
Vector Math Functions, Double Precision Complex	Yes	No

\*OpenMP offload to the GPU is implemented in the Linux\* OS, but not in the Windows\* OS. The Windows OS implementation will be available in a future release.

## Data Fitting Functionality

### Splines, Spline Type

Functionality	CPU	OpenMP Offload Intel GPU
default (linear/quadratic/cubic)	Yes	No
subbotin	Yes	No
natural	Yes	No
hermite	Yes	No
akima	Yes	No
bessel	Yes	No
hyman	Yes	No
lookup interpolant	Yes	No
cr stepwise const interpolant	Yes	No
cl stepwise const interpolant	Yes	No

### Computation Routines

Functionality	CPU	OpenMP Offload Intel GPU
Construct1D	Yes	No
Interpolate1D/Interpolate1DEx	Yes	No
Integrate1D/Integrate1DEx	Yes	No
SearchCells1D/SearchCells1DEx	Yes	No
InterpolationCallBack	Yes	No
IntegrateCallBack	Yes	No

Functionality	CPU	OpenMP Offload Intel GPU
SearchCellsCallBack	Yes	No

## Summary Statistics Functionality

Functionality	CPU	OpenMP Offload Intel GPU
min	Yes	No
max	Yes	No
raw sum	Yes	No
2nd order raw sum		
3rd order raw sum		
4th order raw sum		
2nd order central sum	Yes	No
3rd order central sum		
4th order central sum		
mean	Yes	No
2nd order raw moment		
3rd order raw moment		
4th order raw moment		
2nd order central moment	Yes	No
3rd order central moment		
4th order central moment		
kurtosis	Yes	No
skewness	Yes	No
variation coefficient	Yes	No
covariance matrix	Yes	No
correlation matrix	Yes	No
cross-product matrix	Yes	No
pooled covariance matrix	Yes	No
pooled mean	Yes	No
group covariance matrix	Yes	No
group mean	Yes	No
quantiles	Yes	No
order statistics	Yes	No
robust covariance matrix	Yes	No
ouliers detection	Yes	No

Functionality	CPU	OpenMP Offload Intel GPU
partial covariance matrix	Yes	No
partial covariance matrix	Yes	No
missing values	Yes	No
parameterized correlation matrix	Yes	No
stream quantiles	Yes	No
mean absolute deviation	Yes	No
median absolute deviation	Yes	No
sorted observations	Yes	No

## Glossary

---

$A^H$	Denotes the conjugate transpose of a general matrix $A$ . See also conjugate matrix.
$A^T$	Denotes the transpose of a general matrix $A$ . See also transpose.
band matrix	A general $m$ -by- $n$ matrix $A$ such that $a_{ij} = 0$ for $ i - j  > l$ , where $1 < l < \min(m, n)$ . For example, any tridiagonal matrix is a band matrix.
band storage	A special storage scheme for band matrices. A matrix is stored in a two-dimensional array: columns of the matrix are stored in the corresponding columns of the array, and <i>diagonals</i> of the matrix are stored in rows of the array.
BLAS	Abbreviation for Basic Linear Algebra Subprograms. These subprograms implement vector, matrix-vector, and matrix-matrix operations.

BRNG	Abbreviation for Basic Random Number Generator. Basic random number generators are pseudorandom number generators imitating i.i.d. random number sequences of uniform distribution. Distributions other than uniform are generated by applying different transformation techniques to the sequences of random numbers of uniform distribution.
BRNG registration	Standardized mechanism that allows a user to include a user-designed BRNG into the VSL and use it along with the predefined VSL basic generators.
Bunch-Kaufman factorization	Representation of a real symmetric or complex Hermitian matrix $A$ in the form $A = PUDU^H P^T$ (or $A = PLDL^H P^T$ ) where $P$ is a permutation matrix, $U$ and $L$ are upper and lower triangular matrices with unit diagonal, and $D$ is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. $U$ and $L$ have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of $D$ .
c	When found as the first letter of routine names, $c$ indicates the use of the single-precision complex data type.
CBLAS	C interface to the BLAS. See BLAS.
CDF	Cumulative Distribution Function. The function that determines probability distribution for univariate or multivariate random variable $X$ . For univariate distribution the cumulative distribution function is the function of real argument $x$ , which for every $x$ takes a value equal to probability of the event $A: X \leq x$ . For multivariate distribution the cumulative distribution function is the function of a real vector $x = (x_1, x_2, \dots, x_n)$ , which, for every $x$ , takes a value equal to probability of the event $A = (X_1 \leq x_1 \ \& \ X_2 \leq x_2, \ \& \ \dots, \ \& \ X_n \leq x_n)$ .
Cholesky factorization	Representation of a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix $A$ in the form $A = U^H U$ or $A = LL^H$ , where $L$ is a lower triangular matrix and $U$ is an upper triangular matrix.
condition number	The number $\kappa(A)$ defined for a given square matrix $A$ as follows: $\kappa(A) = \ A\  \ A^{-1}\ $ .
conjugate matrix	The matrix $A^H$ defined for a given general matrix $A$ as follows: $(A^H)_{ij} = (a_{ji})^*$ .
conjugate number	The conjugate of a complex number $z = a + bi$ is $z^* = a - bi$ .
d	When found as the first letter of routine names, $d$ indicates the use of the double-precision real data type.
dot product	The number denoted $x \cdot y$ and defined for given vectors $x$ and $y$ as follows: $x \cdot y = \sum_i x_i y_i$ . Here $x_i$ and $y_i$ stand for the $i$ -th elements of $x$ and $y$ , respectively.
double precision	A floating-point data type. On Intel® processors, this data type allows you to store real numbers $x$ such that $2.23 \cdot 10^{-308} <  x  < 1.79 \cdot 10^{308}$ . For this data type, the machine precision $\epsilon$ is approximately $10^{-15}$ , which means that double-precision numbers usually contain no more than 15 significant decimal digits. For more information, refer to <i>Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture</i> .
eigenvalue	See eigenvalue problem.

eigenvalue problem	A problem of finding non-zero vectors $x$ and numbers $\lambda$ (for a given square matrix $A$ ) such that $Ax = \lambda x$ . Here the numbers $\lambda$ are called the eigenvalues of the matrix $A$ and the vectors $x$ are called the eigenvectors of the matrix $A$ .
eigenvector	See eigenvalue problem.
elementary reflector(Householder matrix)	Matrix of a general form $H = I - \tau v v^T$ , where $v$ is a column vector and $\tau$ is a scalar. In LAPACK elementary reflectors are used, for example, to represent the matrix $Q$ in the $QR$ factorization (the matrix $Q$ is represented as a product of elementary reflectors).
factorization	Representation of a matrix as a product of matrices. See also Bunch-Kaufman factorization, Cholesky factorization, $LU$ factorization, $LQ$ factorization, $QR$ factorization, Schur factorization.
FFTs	Abbreviation for Fast Fourier Transforms. See "Fourier Transform Functions".
full storage	A storage scheme allowing you to store matrices of any kind. A matrix $A$ is stored in a two-dimensional array $a$ , with the matrix element $a_{ij}$ stored in the array element $a(i, j)$ .
Hermitian matrix	A square matrix $A$ that is equal to its conjugate matrix $A^H$ . The conjugate $A^H$ is defined as follows: $(A^H)_{ij} = (a_{ji})^*$ .
I	See identity matrix.
identity matrix	A square matrix $I$ whose diagonal elements are 1, and off-diagonal elements are 0. For any matrix $A$ , $AI = A$ and $IA = A$ .
i.i.d.	Independent Identically Distributed.
in-place	Qualifier of an operation. A function that performs its operation in-place takes its input from an array and returns its output to the same array.
Intel® oneAPI Math Kernel Library (oneMKL)	Abbreviation for Intel® oneAPI Math Kernel Library.
inverse matrix	The matrix denoted as $A^{-1}$ and defined for a given square matrix $A$ as follows: $AA^{-1} = A^{-1}A = I$ . $A^{-1}$ does not exist for singular matrices $A$ .
$LQ$ factorization	Representation of an $m$ -by- $n$ matrix $A$ as $A = LQ$ or $A = (L \ 0)Q$ . Here $Q$ is an $n$ -by- $n$ orthogonal (unitary) matrix. For $m \leq n$ , $L$ is an $m$ -by- $m$ lower triangular matrix with real diagonal elements; for $m > n$ ,

$$I = \begin{bmatrix} I_1 & & \\ & & \\ & & I_2 \end{bmatrix}$$

	where $L_1$ is an $n$ -by- $n$ lower triangular matrix, and $L_2$ is a rectangular matrix.
LU factorization	Representation of a general $m$ -by- $n$ matrix $A$ as $A = PLU$ , where $P$ is a permutation matrix, $L$ is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$ ) and $U$ is upper triangular (upper trapezoidal if $m < n$ ).
machine precision	The number $\varepsilon$ determining the precision of the machine representation of real numbers. For Intel® architecture, the machine precision is approximately $10^{-7}$ for single-precision data, and approximately $10^{-15}$ for double-precision data. The precision also determines the number of significant decimal digits in the machine representation of real numbers. See also double precision and single precision.
MPI	Message Passing Interface. This standard defines the user interface and functionality for a wide range of message-passing capabilities in parallel computing.
MPICH	A freely available, portable implementation of MPI standard for message-passing libraries.
orthogonal matrix	A real square matrix $A$ whose transpose and inverse are equal, that is, $A^T = A^{-1}$ , and therefore $AA^T = A^T A = I$ . All eigenvalues of an orthogonal matrix have the absolute value 1.
packed storage	A storage scheme allowing you to store symmetric, Hermitian, or triangular matrices more compactly. The upper or lower triangle of a matrix is packed by columns in a one-dimensional array.
PDF	Probability Density Function. The function that determines probability distribution for univariate or multivariate continuous random variable $X$ . The probability density function $f(x)$ is closely related with the cumulative distribution function $F(x)$ . For univariate distribution the relation is
	$F(x) = \int_{-\infty}^x f(t) dt .$
	For multivariate distribution the relation is
	$F(x_1, x_2, \dots, x_n) = \int_{-\infty}^{x_1} \int_{-\infty}^{x_2} \dots \int_{-\infty}^{x_n} f(t_1, t_2, \dots, t_n) dt_1 dt_2 \dots dt_n .$
positive-definite matrix	A square matrix $A$ such that $Ax \cdot x > 0$ for any non-zero vector $x$ . Here $\cdot$ denotes the dot product.
pseudorandom number generator	A completely deterministic algorithm that imitates truly random sequences.
QR factorization	Representation of an $m$ -by- $n$ matrix $A$ as $A = QR$ , where $Q$ is an $m$ -by- $m$ orthogonal (unitary) matrix, and $R$ is $n$ -by- $n$ upper triangular with real diagonal elements (if $m \geq n$ ) or trapezoidal (if $m < n$ ) matrix.

random stream	An abstract source of independent identically distributed random numbers of uniform distribution. In this manual a random stream points to a structure that uniquely defines a random number sequence generated by a basic generator associated with a given random stream.
RNG	Abbreviation for Random Number Generator. In this manual the term "random number generators" stands for pseudorandom number generators, that is, generators based on completely deterministic algorithms imitating truly random sequences.
Rectangular Full Packed (RFP) storage	A storage scheme combining the full and packed storage schemes for the upper or lower triangle of the matrix. This combination enables using half of the full storage as packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels as the full storage.
s	When found as the first letter of routine names, <i>s</i> indicates the use of the single-precision real data type.
ScaLAPACK	Stands for Scalable Linear Algebra PACKage.
Schur factorization	Representation of a square matrix $A$ in the form $A = ZTZ^H$ . Here $T$ is an upper quasi-triangular matrix (for complex $A$ , triangular matrix) called the Schur form of $A$ ; the matrix $Z$ is orthogonal (for complex $A$ , unitary). Columns of $Z$ are called Schur vectors.
single precision	A floating-point data type. On Intel® processors, this data type allows you to store real numbers $x$ such that $1.18*10^{-38} <  x  < 3.40*10^{38}$ . For this data type, the machine precision ( $\epsilon$ ) is approximately $10^{-7}$ , which means that single-precision numbers usually contain no more than 7 significant decimal digits. For more information, refer to <i>Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture</i> .
singular matrix	A matrix whose determinant is zero. If $A$ is a singular matrix, the inverse $A^{-1}$ does not exist, and the system of equations $Ax = b$ does not have a unique solution (that is, there exist no solutions or an infinite number of solutions).
singular value	The numbers defined for a given general matrix $A$ as the eigenvalues of the matrix $AA^H$ . See <i>also</i> SVD.
SMP	Abbreviation for Symmetric MultiProcessing. Intel® oneAPI Math Kernel Library (oneMKL) offers performance gains through parallelism provided by the SMP feature.
sparse BLAS	Routines performing basic vector operations on sparse vectors. Sparse BLAS routines take advantage of vectors' sparsity: they allow you to store only non-zero elements of vectors. See BLAS.
sparse vectors	Vectors in which most of the components are zeros.
storage scheme	The way of storing matrices. See full storage, packed storage, and band storage.
SVD	Abbreviation for Singular Value Decomposition. See <i>also</i> Singular value decomposition section in "LAPACK Auxiliary and Utility Routines".
symmetric matrix	A square matrix $A$ such that $a_{ij} = a_{ji}$ .

transpose	The transpose of a given matrix $A$ is a matrix $A^T$ such that $(A^T)_{ij} = a_{ji}$ (rows of $A$ become columns of $A^T$ , and columns of $A$ become rows of $A^T$ ).
trapezoidal matrix	A matrix $A$ such that $A = (A_1 A_2)$ , where $A_1$ is an upper triangular matrix, $A_2$ is a rectangular matrix.
triangular matrix	A matrix $A$ is called an upper (lower) triangular matrix if all its subdiagonal elements (superdiagonal elements) are zeros. Thus, for an upper triangular matrix $a_{ij} = 0$ when $i > j$ ; for a lower triangular matrix $a_{ij} = 0$ when $i < j$ .
tridiagonal matrix	A matrix whose non-zero elements are in three diagonals only: the leading diagonal, the first subdiagonal, and the first super-diagonal.
unitary matrix	A complex square matrix $A$ whose conjugate and inverse are equal, that is, that is, $A^H = A^{-1}$ , and therefore $AA^H = A^H A = I$ . All eigenvalues of a unitary matrix have the absolute value 1.
VML	Abbreviation for Vector Mathematical Library. See "Vector Mathematical Functions".
VSL	Abbreviation for Vector Statistical Library. See "Statistical Functions".
z	When found as the first letter of routine names, $z$ indicates the use of the double-precision complex data type.

THIS SOFTWARE IS PROVIDED BY THE AUTHOR "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE AUTHOR BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

- Some Fast Fourier Transform (FFT) functions in this release of Intel® oneAPI Math Kernel Library have been generated by the SPIRAL software generation system (<http://www.spiral.net/>) under license from Carnegie Mellon University. The authors of SPIRAL are Markus Puschel, Jose Moura, Jeremy Johnson, David Padua, Manuela Veloso, Bryan Singer, Jianxin Xiong, Franz Franchetti, Aca Gacic, Yevgen Voronenko, Kang Chen, Robert W. Johnson, and Nick Rizzolo.
- Open MPI is distributed under the New BSD license, listed below.

Most files in this release are marked with the copyrights of the organizations who have edited them. The copyrights below are in no particular order and generally reflect members of the Open MPI core team who have contributed code to this release. The copyrights for code used under license from other parties are included in the corresponding files.
