<i>abstol</i>	<p>The absolute tolerance to which each eigenvalue is required. An eigenvalue (or cluster) is considered to have converged if it lies in an interval of width <i>abstol</i>.</p> <p>If <math>abstol \leq 0.0</math>, then the tolerance is taken as <math>\text{eps} *  T </math>, where <i>eps</i> is the machine precision, and <math> T </math> is the 1-norm of the matrix <math>T</math>.</p>
<i>d, e</i>	<p>Arrays:</p> <p><i>d</i> contains the diagonal elements of <math>T</math>.</p> <p>The size of <i>d</i> must be at least <math>\max(1, n)</math>.</p> <p><i>e</i> contains the off-diagonal elements of <math>T</math>.</p> <p>The size of <i>e</i> must be at least <math>\max(1, n-1)</math>.</p>

## Output Parameters

<i>m</i>	The actual number of eigenvalues found.
<i>nsplit</i>	The number of diagonal blocks detected in <i>T</i> .
<i>w</i>	Array, size at least $\max(1, n)$ . The computed eigenvalues, stored in <i>w</i> [0] to <i>w</i> [ <i>m</i> - 1].
<i>iblock, isplit</i>	Arrays, size at least $\max(1, n)$ . A positive value <i>iblock</i> [ <i>i</i> ] is the block number of the eigenvalue stored in <i>w</i> [ <i>i</i> ] (see also <i>info</i> ). The leading <i>nsplit</i> elements of <i>isplit</i> contain points at which <i>T</i> splits into blocks <i>T<sub>i</sub></i> as follows: the block <i>T<sub>1</sub></i> contains rows/columns 1 to <i>isplit</i> [0]; the block <i>T<sub>2</sub></i> contains rows/columns <i>isplit</i> [0]+1 to <i>isplit</i> [1], and so on.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = 1, for *range* = 'A' or 'V', the algorithm failed to compute some of the required eigenvalues to the desired accuracy; *iblock*[*i*] < 0 indicates that the eigenvalue stored in *w*[*i*] failed to converge.

If *info* = 2, for *range* = 'I', the algorithm failed to compute some of the required eigenvalues. Try calling the routine again with *range* = 'A'.

If *info* = 3:

for *range* = 'A' or 'V', same as *info* = 1;

for *range* = 'I', same as *info* = 2.

If *info* = 4, no eigenvalues have been computed. The floating-point arithmetic on the computer is not behaving as expected.

If *info* = -*i*, the *i*-th parameter had an illegal value.

## Application Notes

The eigenvalues of *T* are computed to high relative accuracy which means that if they vary widely in magnitude, then any small eigenvalues will be computed more accurately than, for example, with the standard QR method. However, the reduction to tridiagonal form (prior to calling the routine) may exclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix if its eigenvalues vary widely in magnitude.

*?stein*

*Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix.*

## Syntax

```
lapack_int LAPACKE_sstein( int matrix_layout, lapack_int n, const float* d, const
float* e, lapack_int m, const float* w, const lapack_int* iblock, const lapack_int*
isplit, float* z, lapack_int ldz, lapack_int* ifailv );
```

```
lapack_int LAPACKE_dstein( int matrix_layout, lapack_int n, const double* d, const
double* e, lapack_int m, const double* w, const lapack_int* iblock, const lapack_int*
isplit, double* z, lapack_int ldz, lapack_int* ifailv );
```

```
lapack_int LAPACKE_cstein( int matrix_layout, lapack_int n, const float* d, const
float* e, lapack_int m, const float* w, const lapack_int* iblock, const lapack_int*
isplit, lapack_complex_float* z, lapack_int ldz, lapack_int* ifailv );
```

```
lapack_int LAPACKE_zstein( int matrix_layout, lapack_int n, const double* d, const
double* e, lapack_int m, const double* w, const lapack_int* iblock, const lapack_int*
isplit, lapack_complex_double* z, lapack_int ldz, lapack_int* ifailv );
```

## Include Files

- mkl.h

## Description

The routine computes the eigenvectors of a real symmetric tridiagonal matrix  $T$  corresponding to specified eigenvalues, by inverse iteration. It is designed to be used in particular after the specified eigenvalues have been computed by `?stebz` with `order = 'B'`, but may also be used when the eigenvalues have been computed by other routines.

If you use this routine after `?stebz`, it can take advantage of the block structure by performing inverse iteration on each block  $T_i$  separately, which is more efficient than using the whole matrix  $T$ .

If  $T$  has been formed by reduction of a full symmetric or Hermitian matrix  $A$  to tridiagonal form, you can transform eigenvectors of  $T$  to eigenvectors of  $A$  by calling `?ormtr` or `?opmtr` (for real flavors) or by calling `?unmtr` or `?upmtr` (for complex flavors).

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>n</code>	The order of the matrix $T$ ( $n \geq 0$ ).
<code>m</code>	The number of eigenvectors to be returned.
<code>d, e, w</code>	Arrays: $d$ contains the diagonal elements of $T$ . The size of $d$ must be at least $\max(1, n)$ . $e$ contains the sub-diagonal elements of $T$ stored in elements 1 to $n-1$ . The size of $e$ must be at least $\max(1, n-1)$ . $w$ contains the eigenvalues of $T$ , stored in $w[0]$ to $w[m - 1]$ (as returned by <code>stebz</code> ). Eigenvalues of $T_1$ must be supplied first, in non-decreasing order; then those of $T_2$ , again in non-decreasing order, and so on. Constraint: if $iblock[i] = iblock[i+1]$ , $w[i] \leq w[i+1]$ . The size of $w$ must be at least $\max(1, n)$ .
<code>iblock, isplit</code>	Arrays, size at least $\max(1, n)$ . The arrays <code>iblock</code> and <code>isplit</code> , as returned by <code>?stebz</code> with <code>order = 'B'</code> .

If you did not call `?stebz` with `order = 'B'`, set all elements of `iblock` to 1, and `isplit[0]` to `n`.)

`ldz`

The leading dimension of the output array `z`;  $ldz \geq \max(1, n)$  for column major layout and  $ldz \geq \max(1, m)$  for row major layout.

## Output Parameters

`z`

Array, size at least  $\max(1, ldz * m)$  for column major layout and  $\max(1, ldz * n)$  for row major layout.

If `info = 0`, `z` contains an  $n$ -by- $n$  matrix the columns of which are orthonormal eigenvectors. (The  $i$ -th column corresponds to the  $i$ th eigenvalue.)

`ifailv`

Array, size at least  $\max(1, m)$ .

If `info = i > 0`, the first  $i$  elements of `ifailv` contain the indices of any eigenvectors that failed to converge.

## Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = i`, then  $i$  eigenvectors (as indicated by the parameter `ifailv`) each failed to converge in 5 iterations. The current iterates are stored in the corresponding columns/rows of the array `z`.

If `info = -i`, the  $i$ -th parameter had an illegal value.

## Application Notes

Each computed eigenvector  $z_i$  is an exact eigenvector of a matrix  $T + E_i$ , where  $\|E_i\|_2 = O(\epsilon) * \|T\|_2$ . However, a set of eigenvectors computed by this routine may not be orthogonal to so high a degree of accuracy as those computed by `?steqr`.

`?disna`

*Computes the reciprocal condition numbers for the eigenvectors of a symmetric/ Hermitian matrix or for the left or right singular vectors of a general matrix.*

## Syntax

```
lapack_int LAPACKE_sdisna (char job, lapack_int m, lapack_int n, const float* d, float* sep);
```

```
lapack_int LAPACKE_ddisna (char job, lapack_int m, lapack_int n, const double* d, double* sep);
```

## Include Files

- `mkl.h`

## Description

The routine computes the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general  $m$ -by- $n$  matrix.

The reciprocal condition number is the 'gap' between the corresponding eigenvalue or singular value and the nearest other one.

The bound on the error, measured by angle in radians, in the  $i$ -th computed vector is given by

$$?lamch('E') * (anorm / sep(i))$$

where  $anorm = ||A||_2 = \max(|d(j)|)$ .  $sep(i)$  is not allowed to be smaller than  $slamch('E') * anorm$  in order to limit the size of the error bound.

$?disna$  may also be used to compute error bounds for eigenvectors of the generalized symmetric definite eigenproblem.

## Input Parameters

<i>job</i>	Must be 'E', 'L', or 'R'. Specifies for which problem the reciprocal condition numbers should be computed: <i>job</i> = 'E': for the eigenvectors of a symmetric/Hermitian matrix; <i>job</i> = 'L': for the left singular vectors of a general matrix; <i>job</i> = 'R': for the right singular vectors of a general matrix.
<i>m</i>	The number of rows of the matrix ( $m \geq 0$ ).
<i>n</i>	If <i>job</i> = 'L', or 'R', the number of columns of the matrix ( $n \geq 0$ ). Ignored if <i>job</i> = 'E'.
<i>d</i>	Array, dimension at least $\max(1, m)$ if <i>job</i> = 'E', and at least $\max(1, \min(m, n))$ if <i>job</i> = 'L' or 'R'.  This array must contain the eigenvalues (if <i>job</i> = 'E') or singular values (if <i>job</i> = 'L' or 'R') of the matrix, in either increasing or decreasing order.  If singular values, they must be non-negative.

## Output Parameters

<i>sep</i>	Array, dimension at least $\max(1, m)$ if <i>job</i> = 'E', and at least $\max(1, \min(m, n))$ if <i>job</i> = 'L' or 'R'. The reciprocal condition numbers of the vectors.
------------	---

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* =  $-i$ , the  $i$ -th parameter had an illegal value.

## Generalized Symmetric-Definite Eigenvalue Problems: LAPACK Computational Routines

Generalized symmetric-definite eigenvalue problems are as follows: find the eigenvalues  $\lambda$  and the corresponding eigenvectors  $z$  that satisfy one of these equations:

$$Az = \lambda Bz, ABz = \lambda z, \text{ or } BAz = \lambda z,$$

where  $A$  is an  $n$ -by- $n$  symmetric or Hermitian matrix, and  $B$  is an  $n$ -by- $n$  symmetric positive-definite or Hermitian positive-definite matrix.

In these problems, there exist  $n$  real eigenvectors corresponding to real eigenvalues (even for complex Hermitian matrices  $A$  and  $B$ ).

Routines described in this topic allow you to reduce the above generalized problems to standard symmetric eigenvalue problem  $Cy = \lambda y$ , which you can solve by calling LAPACK routines described earlier in this chapter (see [Symmetric Eigenvalue Problems](#)).

Different routines allow the matrices to be stored either conventionally or in packed storage. Prior to reduction, the positive-definite matrix  $B$  must first be factorized using either [potrf](#) or [pptrf](#).

The reduction routine for the banded matrices  $A$  and  $B$  uses a split Cholesky factorization for which a specific routine [pbstf](#) is provided. This refinement halves the amount of work required to form matrix  $C$ .

Table "Computational Routines for Reducing Generalized Eigenproblems to Standard Problems" lists LAPACK routines that can be used to solve generalized symmetric-definite eigenvalue problems.

### Computational Routines for Reducing Generalized Eigenproblems to Standard Problems

Matrix type	Reduce to standard problems (full storage)	Reduce to standard problems (packed storage)	Reduce to standard problems (band matrices)	Factorize band matrix
real symmetric matrices	<a href="#">sygst</a>	<a href="#">spgst</a>	<a href="#">sbgst</a>	<a href="#">pbstf</a>
complex Hermitian matrices	<a href="#">hegst</a>	<a href="#">hpgst</a>	<a href="#">hbgst</a>	<a href="#">pbstf</a>

#### ?sygst

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form.

#### Syntax

```
lapack_int LAPACKE_ssygst (int matrix_layout, lapack_int itype, char uplo, lapack_int n, float* a, lapack_int lda, const float* b, lapack_int ldb);
```

```
lapack_int LAPACKE_dsygst (int matrix_layout, lapack_int itype, char uplo, lapack_int n, double* a, lapack_int lda, const double* b, lapack_int ldb);
```

#### Include Files

- mkl.h

#### Description

The routine reduces real symmetric-definite generalized eigenproblems

$$A^*z = \lambda^*B^*z, \quad A^*B^*z = \lambda^*z, \quad \text{or} \quad B^*A^*z = \lambda^*z$$

to the standard form  $C^*y = \lambda^*y$ . Here  $A$  is a real symmetric matrix, and  $B$  is a real symmetric positive-definite matrix. Before calling this routine, call [?potrf](#) to compute the Cholesky factorization:  $B = U^T*U$  or  $B = L*L^T$ .

#### Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>itype</i>	Must be 1 or 2 or 3.

If  $itype = 1$ , the generalized eigenproblem is  $A*z = lambda*B*z$

for  $uplo = 'U'$ :  $C = inv(U^T)*A*inv(U)$ ,  $z = inv(U)*y$ ;

for  $uplo = 'L'$ :  $C = inv(L)*A*inv(L^T)$ ,  $z = inv(L^T)*y$ .

If  $itype = 2$ , the generalized eigenproblem is  $A*B*z = lambda*z$

for  $uplo = 'U'$ :  $C = U*A*U^T$ ,  $z = inv(U)*y$ ;

for  $uplo = 'L'$ :  $C = L^T*A*L$ ,  $z = inv(L^T)*y$ .

If  $itype = 3$ , the generalized eigenproblem is  $B*A*z = lambda*z$

for  $uplo = 'U'$ :  $C = U*A*U^T$ ,  $z = U^T*y$ ;

for  $uplo = 'L'$ :  $C = L^T*A*L$ ,  $z = L*y$ .

Must be 'U' or 'L'.

If  $uplo = 'U'$ , the array  $a$  stores the upper triangle of  $A$ ; you must supply  $B$  in the factored form  $B = U^T*U$ .

If  $uplo = 'L'$ , the array  $a$  stores the lower triangle of  $A$ ; you must supply  $B$  in the factored form  $B = L*L^T$ .

$uplo$

The order of the matrices  $A$  and  $B$  ( $n \geq 0$ ).

$n$

Arrays:

$a, b$

$a$  (size  $\max(1, lda*n)$ ) contains the upper or lower triangle of  $A$ .

$b$  (size  $\max(1, ldb*n)$ ) contains the Cholesky-factored matrix  $B$ :

$B = U^T*U$  or  $B = L*L^T$  (as returned by `?potrf`).

$lda$

The leading dimension of  $a$ ; at least  $\max(1, n)$ .

$ldb$

The leading dimension of  $b$ ; at least  $\max(1, n)$ .

## Output Parameters

$a$

The upper or lower triangle of  $A$  is overwritten by the upper or lower triangle of  $C$ , as specified by the arguments  $itype$  and  $uplo$ .

## Return Values

This function returns a value  $info$ .

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

## Application Notes

Forming the reduced matrix  $C$  is a stable procedure. However, it involves implicit multiplication by  $inv(B)$  (if  $itype = 1$ ) or  $B$  (if  $itype = 2$  or  $3$ ). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if  $B$  is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is  $n^3$ .

## ?hegst

Reduces a complex Hermitian positive-definite generalized eigenvalue problem to the standard form.

### Syntax

```
lapack_int LAPACKE_chegst (int matrix_layout, lapack_int itype, char uplo, lapack_int n, lapack_complex_float* a, lapack_int lda, const lapack_complex_float* b, lapack_int ldb);
```

```
lapack_int LAPACKE_zhegst (int matrix_layout, lapack_int itype, char uplo, lapack_int n, lapack_complex_double* a, lapack_int lda, const lapack_complex_double* b, lapack_int ldb);
```

### Include Files

- mkl.h

### Description

The routine reduces a complex Hermitian positive-definite generalized eigenvalue problem to standard form.

<i>itype</i>	<b>Problem</b>	<b>Result</b>
1	$A*x = \lambda*B*x$	$A$ overwritten by $\text{inv}(U^H)*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^H)$
2	$A*B*x = \lambda*x$	$A$ overwritten by $U*A*U^H$ or $L^H*A*L$
3	$B*A*x = \lambda*x$	

Before calling this routine, you must call ?potrf to compute the Cholesky factorization:  $B = U^H*U$  or  $B = L*L^H$ .

### Input Parameters

<i>itype</i>	<p>Must be 1 or 2 or 3.</p> <p>If <i>itype</i> = 1, the generalized eigenproblem is <math>A*z = \text{lambda}*B*z</math>  for <i>uplo</i> = 'U': <math>C = (U^H)^{-1}*A*U^{-1}</math>;  for <i>uplo</i> = 'L': <math>C = L^{-1}*A*(L^H)^{-1}</math>.</p> <p>If <i>itype</i> = 2, the generalized eigenproblem is <math>A*B*z = \text{lambda}*z</math>  for <i>uplo</i> = 'U': <math>C = U*A*U^H</math>;  for <i>uplo</i> = 'L': <math>C = L^H*A*L</math>.</p> <p>If <i>itype</i> = 3, the generalized eigenproblem is <math>B*A*z = \text{lambda}*z</math>  for <i>uplo</i> = 'U': <math>C = U*A*U^H</math>;  for <i>uplo</i> = 'L': <math>C = L^H*A*L</math>.</p>
<i>uplo</i>	<p>Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangle of <i>A</i>; you must supply <i>B</i> in the factored form <math>B = U^H*U</math>.</p>

If `uplo = 'L'`, the array `a` stores the lower triangle of `A`; you must supply `B` in the factored form  $B = L^*L^H$ .

`n`

The order of the matrices `A` and `B` ( $n \geq 0$ ).

`a, b`

Arrays:

`a` (size  $\max(1, lda*n)$ ) contains the upper or lower triangle of `A`.

`b` (size  $\max(1, ldb*n)$ ) contains the Cholesky-factored matrix `B`:

$B = U^H*U$  or  $B = L^*L^H$  (as returned by `?potrf`).

`lda`

The leading dimension of `a`; at least  $\max(1, n)$ .

`ldb`

The leading dimension of `b`; at least  $\max(1, n)$ .

## Output Parameters

`a`

The upper or lower triangle of `A` is overwritten by the upper or lower triangle of `C`, as specified by the arguments `itype` and `uplo`.

## Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, the *i*-th parameter had an illegal value.

## Application Notes

Forming the reduced matrix `C` is a stable procedure. However, it involves implicit multiplication by  $B^{-1}$  (if `itype = 1`) or `B` (if `itype = 2` or `3`). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if `B` is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is  $n^3$ .

### ?spgst

*Reduces a real symmetric-definite generalized eigenvalue problem to the standard form using packed storage.*

## Syntax

<code>n</code>	The order of the matrices $A$ and $B$ ( $n \geq 0$ ).
<code>ap, bp</code>	<p>Arrays:</p> <p><code>ap</code> contains the packed upper or lower triangle of <math>A</math>.  The dimension of <code>ap</code> must be at least <math>\max(1, n*(n+1)/2)</math>.</p> <p><code>bp</code> contains the packed Cholesky factor of <math>B</math> (as returned by <code>?pptrf</code> with the same <code>uplo</code> value).  The dimension of <code>bp</code> must be at least <math>\max(1, n*(n+1)/2)</math>.</p>

## Output Parameters

<code>ap</code>	The upper or lower triangle of $A$ is overwritten by the upper or lower triangle of $C$ , as specified by the arguments <code>itype</code> and <code>uplo</code> .
-----------------	--

## Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, the  $i$ -th parameter had an illegal value.

## Application Notes

Forming the reduced matrix  $C$  is a stable procedure. However, it involves implicit multiplication by  $\text{inv}(B)$  (if  $itype = 1$ ) or  $B$  (if  $itype = 2$  or  $3$ ). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if  $B$  is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is  $n^3$ .

### ?hpgst

*Reduces a generalized eigenvalue problem with a Hermitian matrix to a standard eigenvalue problem using packed storage.*

## Syntax

```
lapack_int LAPACKE_chpgst (int matrix_layout, lapack_int itype, char uplo, lapack_int n, lapack_complex_float* ap, const lapack_complex_float* bp);
```

```
lapack_int LAPACKE_zhpgst (int matrix_layout, lapack_int itype, char uplo, lapack_int n, lapack_complex_double* ap, const lapack_complex_double* bp);
```

## Include Files

- mkl.h

## Description

The routine reduces generalized eigenproblems with Hermitian matrices

$$A^*z = \lambda^*B^*z, A^*B^*z = \lambda^*z, \text{ or } B^*A^*z = \lambda^*z.$$

to standard eigenproblems  $C^*y = \lambda^*y$ , using packed matrix storage. Here  $A$  is a complex Hermitian matrix, and  $B$  is a complex Hermitian positive-definite matrix. Before calling this routine, you must call `?pptrf` to compute the Cholesky factorization:  $B = U^H*U$  or  $B = L*L^H$ .

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<code>itype</code>	Must be 1 or 2 or 3. If $itype = 1$ , the generalized eigenproblem is $A^*z = \lambda^*B^*z$ for $uplo = 'U'$ : $C = \text{inv}(U^H)*A*\text{inv}(U)$ , $z = \text{inv}(U)*y$ ; for $uplo = 'L'$ : $C = \text{inv}(L)*A*\text{inv}(L^H)$ , $z = \text{inv}(L^H)*y$ . If $itype = 2$ , the generalized eigenproblem is $A^*B^*z = \lambda^*z$ for $uplo = 'U'$ : $C = U^*A^*U^H$ , $z = \text{inv}(U)*y$ ; for $uplo = 'L'$ : $C = L^H*A^*L$ , $z = \text{inv}(L^H)*y$ . If $itype = 3$ , the generalized eigenproblem is $B^*A^*z = \lambda^*z$ for $uplo = 'U'$ : $C = U^*A^*U^H$ , $z = U^H*y$ ; for $uplo = 'L'$ : $C = L^H*A^*L$ , $z = L*y$ .

<i>uplo</i>	<p>Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangle of <i>A</i>; you must supply <i>B</i> in the factored form <math>B = U^H * U</math>.</p> <p>If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangle of <i>A</i>; you must supply <i>B</i> in the factored form <math>B = L * L^H</math>.</p>
<i>n</i>	The order of the matrices <i>A</i> and <i>B</i> ( $n \geq 0$ ).
<i>ap, bp</i>	<p>Arrays:</p> <p><i>ap</i> contains the packed upper or lower triangle of <i>A</i>.</p> <p>The dimension of <i>a</i> must be at least <math>\max(1, n*(n+1)/2)</math>.</p> <p><i>bp</i> contains the packed Cholesky factor of <i>B</i> (as returned by <code>?pptrf</code> with the same <i>uplo</i> value).</p> <p>The dimension of <i>b</i> must be at least <math>\max(1, n*(n+1)/2)</math>.</p>

## Output Parameters

<i>ap</i>	The upper or lower triangle of <i>A</i> is overwritten by the upper or lower triangle of <i>C</i> , as specified by the arguments <i>itype</i> and <i>uplo</i> .
-----------	--

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

## Application Notes

Forming the reduced matrix *C* is a stable procedure. However, it involves implicit multiplication by  $\text{inv}(B)$  (if *itype* = 1) or *B* (if *itype* = 2 or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if *B* is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is  $n^3$ .

### ?sbgst

*Reduces a real symmetric-definite generalized eigenproblem for banded matrices to the standard form using the factorization performed by ?pbstf.*

## Syntax

```
lapack_int LAPACKE_ssbgst (int matrix_layout, char vect, char uplo, lapack_int n,
lapack_int ka, lapack_int kb, float* ab, lapack_int ldab, const float* bb, lapack_int
ldbb, float* x, lapack_int ldx);
```

```
lapack_int LAPACKE_dsbgst (int matrix_layout, char vect, char uplo, lapack_int n,
lapack_int ka, lapack_int kb, double* ab, lapack_int ldab, const double* bb, lapack_int
ldbb, double* x, lapack_int ldx);
```

## Include Files

- mkl.h

## Description

To reduce the real symmetric-definite generalized eigenproblem  $A^*z = \lambda^*B^*z$  to the standard form  $C^*y = \lambda^*y$ , where  $A$ ,  $B$  and  $C$  are banded, this routine must be preceded by a call to [pbstf](#), which computes the split Cholesky factorization of the positive-definite matrix  $B$ :  $B = S^T * S$ . The split Cholesky factorization, compared with the ordinary Cholesky factorization, allows the work to be approximately halved.

This routine overwrites  $A$  with  $C = X^T * A * X$ , where  $X = \text{inv}(S) * Q$  and  $Q$  is an orthogonal matrix chosen (implicitly) to preserve the bandwidth of  $A$ . The routine also has an option to allow the accumulation of  $X$ , and then, if  $z$  is an eigenvector of  $C$ ,  $X * z$  is an eigenvector of the original system.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>vect</i>	Must be 'N' or 'V'. If <i>vect</i> = 'N', then matrix $X$ is not returned; If <i>vect</i> = 'V', then matrix $X$ is returned.
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of $A$ . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of $A$ .
<i>n</i>	The order of the matrices $A$ and $B$ ( $n \geq 0$ ).
<i>ka</i>	The number of super- or sub-diagonals in $A$ ( $ka \geq 0$ ).
<i>kb</i>	The number of super- or sub-diagonals in $B$ ( $ka \geq kb \geq 0$ ).
<i>ab, bb</i>	<i>ab</i> (size at least $\max(1, ldab * n)$ for column major layout and at least $\max(1, ldab * (ka + 1))$ for row major layout) is an array containing either upper or lower triangular part of the symmetric matrix $A$ (as specified by <i>uplo</i> ) in band storage format. <i>bb</i> (size at least $\max(1, ldbb * n)$ for column major layout and at least $\max(1, ldbb * (kb + 1))$ for row major layout) is an array containing the banded split Cholesky factor of $B$ as specified by <i>uplo</i> , <i>n</i> and <i>kb</i> and returned by <a href="#">pbstf/pbstf</a> .
<i>ldab</i>	The leading dimension of the array <i>ab</i> ; must be at least $ka + 1$ for column major layout and $\max(1, n)$ for row major layout.
<i>ldbb</i>	The leading dimension of the array <i>bb</i> ; must be at least $kb + 1$ for column major layout and $\max(1, n)$ for row major layout.
<i>ldx</i>	The leading dimension of the output array $x$ . Constraints: if <i>vect</i> = 'N', then $ldx \geq 1$ ; if <i>vect</i> = 'V', then $ldx \geq \max(1, n)$ .

## Output Parameters

<i>ab</i>	On exit, this array is overwritten by the upper or lower triangle of <i>C</i> as specified by <i>uplo</i> .
<i>x</i>	Array. If <i>vect</i> = 'V', then <i>x</i> (size at least $\max(1, \text{ldx} * n)$ ) contains the <i>n</i> -by- <i>n</i> matrix $X = \text{inv}(S) * Q$ . If <i>vect</i> = 'N', then <i>x</i> is not referenced.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

## Application Notes

Forming the reduced matrix *C* involves implicit multiplication by  $\text{inv}(B)$ . When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if *B* is ill-conditioned with respect to inversion.

If *ka* and *kb* are much less than *n* then the total number of floating-point operations is approximately  $6n^2 * kb$ , when *vect* = 'N'. Additional  $(3/2)n^3 * (kb/ka)$  operations are required when *vect* = 'V'.

### ?hbgst

*Reduces a complex Hermitian positive-definite generalized eigenproblem for banded matrices to the standard form using the factorization performed by ?pbstf.*

## Syntax

## Description

To reduce the complex Hermitian positive-definite generalized eigenproblem  $A * z = \lambda * B * z$  to the standard form  $C * x = \lambda * y$ , where *A*, *B* and *C* are banded, this routine must be preceded by a call to [pbstf/pbstf](#), which computes the split Cholesky factorization of the positive-definite matrix *B*:  $B = S^H * S$ . The split Cholesky factorization, compared with the ordinary Cholesky factorization, allows the work to be approximately halved.

This routine overwrites *A* with  $C = X^H * A * X$ , where  $X = \text{inv}(S) * Q$ , and *Q* is a unitary matrix chosen (implicitly) to preserve the bandwidth of *A*. The routine also has an option to allow the accumulation of *X*, and then, if *z* is an eigenvector of *C*,  $X * z$  is an eigenvector of the original system.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<i>vect</i>	Must be 'N' or 'V'. If <i>vect</i> = 'N', then matrix <i>X</i> is not returned; If <i>vect</i> = 'V', then matrix <i>X</i> is returned.
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	The order of the matrices <i>A</i> and <i>B</i> ( $n \geq 0$ ).
<i>ka</i>	The number of super- or sub-diagonals in <i>A</i> ( $ka \geq 0$ ).
<i>kb</i>	The number of super- or sub-diagonals in <i>B</i> ( $ka \geq kb \geq 0$ ).
<i>ab, bb</i>	<i>ab</i> (size at least $\max(1, ldab*n)$ for column major layout and at least $\max(1, ldab*(ka + 1))$ for row major layout) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> (as specified by <i>uplo</i> ) in band storage format. <i>bb</i> (size at least $\max(1, ldbb*n)$ for column major layout and at least $\max(1, ldbb*(kb + 1))$ for row major layout) is an array containing the banded split Cholesky factor of <i>B</i> as specified by <i>uplo</i> , <i>n</i> and <i>kb</i> and returned by <a href="#">pbstf/pbstf</a> .
<i>ldab</i>	The leading dimension of the array <i>ab</i> ; must be at least $ka+1$ for column major layout and $\max(1, n)$ for row major layout.
<i>ldbb</i>	The leading dimension of the array <i>bb</i> ; must be at least $kb+1$ for column major layout and $\max(1, n)$ for row major layout.
<i>ldx</i>	The leading dimension of the output array <i>x</i> . Constraints: if <i>vect</i> = 'N', then $ldx \geq 1$ ; if <i>vect</i> = 'V', then $ldx \geq \max(1, n)$ .

## Output Parameters

<i>ab</i>	On exit, this array is overwritten by the upper or lower triangle of <i>C</i> as specified by <i>uplo</i> .
<i>x</i>	Array. If <i>vect</i> = 'V', then <i>x</i> (size at least $\max(1, ldx*n)$ ) contains the $n$ -by- $n$ matrix $X = \text{inv}(S) * Q$ . If <i>vect</i> = 'N', then <i>x</i> is not referenced.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

## Application Notes

Forming the reduced matrix *C* involves implicit multiplication by  $\text{inv}(B)$ . When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if *B* is ill-conditioned with respect to inversion. The total number of floating-point operations is approximately  $20n^2*kb$ , when *vect* = 'N'. Additional  $5n^3*(kb/ka)$  operations are required when *vect* = 'V'. All these estimates assume that both *ka* and *kb* are much less than *n*.

### ?pbstf

Computes a split Cholesky factorization of a real symmetric or complex Hermitian positive-definite banded matrix used in ?sbgst/?hbgst .

## Syntax

```
lapack_int LAPACKE_spbstf (int matrix_layout, char uplo, lapack_int n, lapack_int kb,
float* bb, lapack_int ldbb);
```

```
lapack_int LAPACKE_dpbstf (int matrix_layout, char uplo, lapack_int n, lapack_int kb,
double* bb, lapack_int ldbb);
```

```
lapack_int LAPACKE_cpbstf (int matrix_layout, char uplo, lapack_int n, lapack_int kb,
lapack_complex_float* bb, lapack_int ldbb);
```

```
lapack_int LAPACKE_zpbstf (int matrix_layout, char uplo, lapack_int n, lapack_int kb,
lapack_complex_double* bb, lapack_int ldbb);
```

## Include Files

- mkl.h

## Description

The routine computes a split Cholesky factorization of a real symmetric or complex Hermitian positive-definite band matrix *B*. It is to be used in conjunction with [sbgst/hbgst](#).

The factorization has the form  $B = S^T * S$  (or  $B = S^H * S$  for complex flavors), where *S* is a band matrix of the same bandwidth as *B* and the following structure: *S* is upper triangular in the first  $(n+kb)/2$  rows and lower triangular in the remaining rows.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>bb</i> stores the upper triangular part of <i>B</i> . If <i>uplo</i> = 'L', <i>bb</i> stores the lower triangular part of <i>B</i> .

$n$	The order of the matrix $B$ ( $n \geq 0$ ).
$kb$	The number of super- or sub-diagonals in $B$ ( $kb \geq 0$ ).
$bb$	$bb$ (size at least $\max(1, ldbb * n)$ for column major layout and at least $\max(1, ldbb * (kb + 1))$ for row major layout) is an array containing either upper or lower triangular part of the matrix $B$ (as specified by <i>uplo</i> ) in band storage format.
$ldbb$	The leading dimension of $bb$ ; must be at least $kb+1$ for column major and at least $\max(1, n)$ for row major.

## Output Parameters

$bb$	On exit, this array is overwritten by the elements of the split Cholesky factor $S$ .
------	---

## Return Values

This function returns a value *info*.

If  $info=0$ , the execution is successful.

If  $info = i$ , then the factorization could not be completed, because the updated element  $b_{ii}$  would be the square root of a negative number; hence the matrix  $B$  is not positive-definite.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

## Application Notes

The computed factor  $S$  is the exact factor of a perturbed matrix  $B + E$ , where

$$|E| \leq c(kb + 1)\epsilon |S^H| |S|, \quad |e_{ij}| \leq c(kb + 1)\epsilon \sqrt{b_{ii} b_{jj}}$$

$c(n)$  is a modest linear function of  $n$ , and  $\epsilon$  is the machine precision.

The total number of floating-point operations for real flavors is approximately  $n(kb+1)^2$ . The number of operations for complex flavors is 4 times greater. All these estimates assume that  $kb$  is much less than  $n$ .

After calling this routine, you can call [sbgst/hbgst](#) to solve the generalized eigenproblem  $Az = \lambda Bz$ , where  $A$  and  $B$  are banded and  $B$  is positive-definite.

## Nonsymmetric Eigenvalue Problems: LAPACK Computational Routines

This topic describes LAPACK routines for solving nonsymmetric eigenvalue problems, computing the Schur factorization of general matrices, as well as performing a number of related computational tasks.

A *nonsymmetric eigenvalue problem* is as follows: given a nonsymmetric (or non-Hermitian) matrix  $A$ , find the *eigenvalues*  $\lambda$  and the corresponding *eigenvectors*  $z$  that satisfy the equation

$$Az = \lambda z \text{ (right eigenvectors } z)$$

or the equation

$$z^H A = \lambda z^H \text{ (left eigenvectors } z).$$

Nonsymmetric eigenvalue problems have the following properties:

- The number of eigenvectors may be less than the matrix order (but is not less than the number of *distinct eigenvalues* of  $A$ ).

- Eigenvalues may be complex even for a real matrix  $A$ .
- If a real nonsymmetric matrix has a complex eigenvalue  $a+bi$  corresponding to an eigenvector  $z$ , then  $a-bi$  is also an eigenvalue. The eigenvalue  $a-bi$  corresponds to the eigenvector whose elements are complex conjugate to the elements of  $z$ .

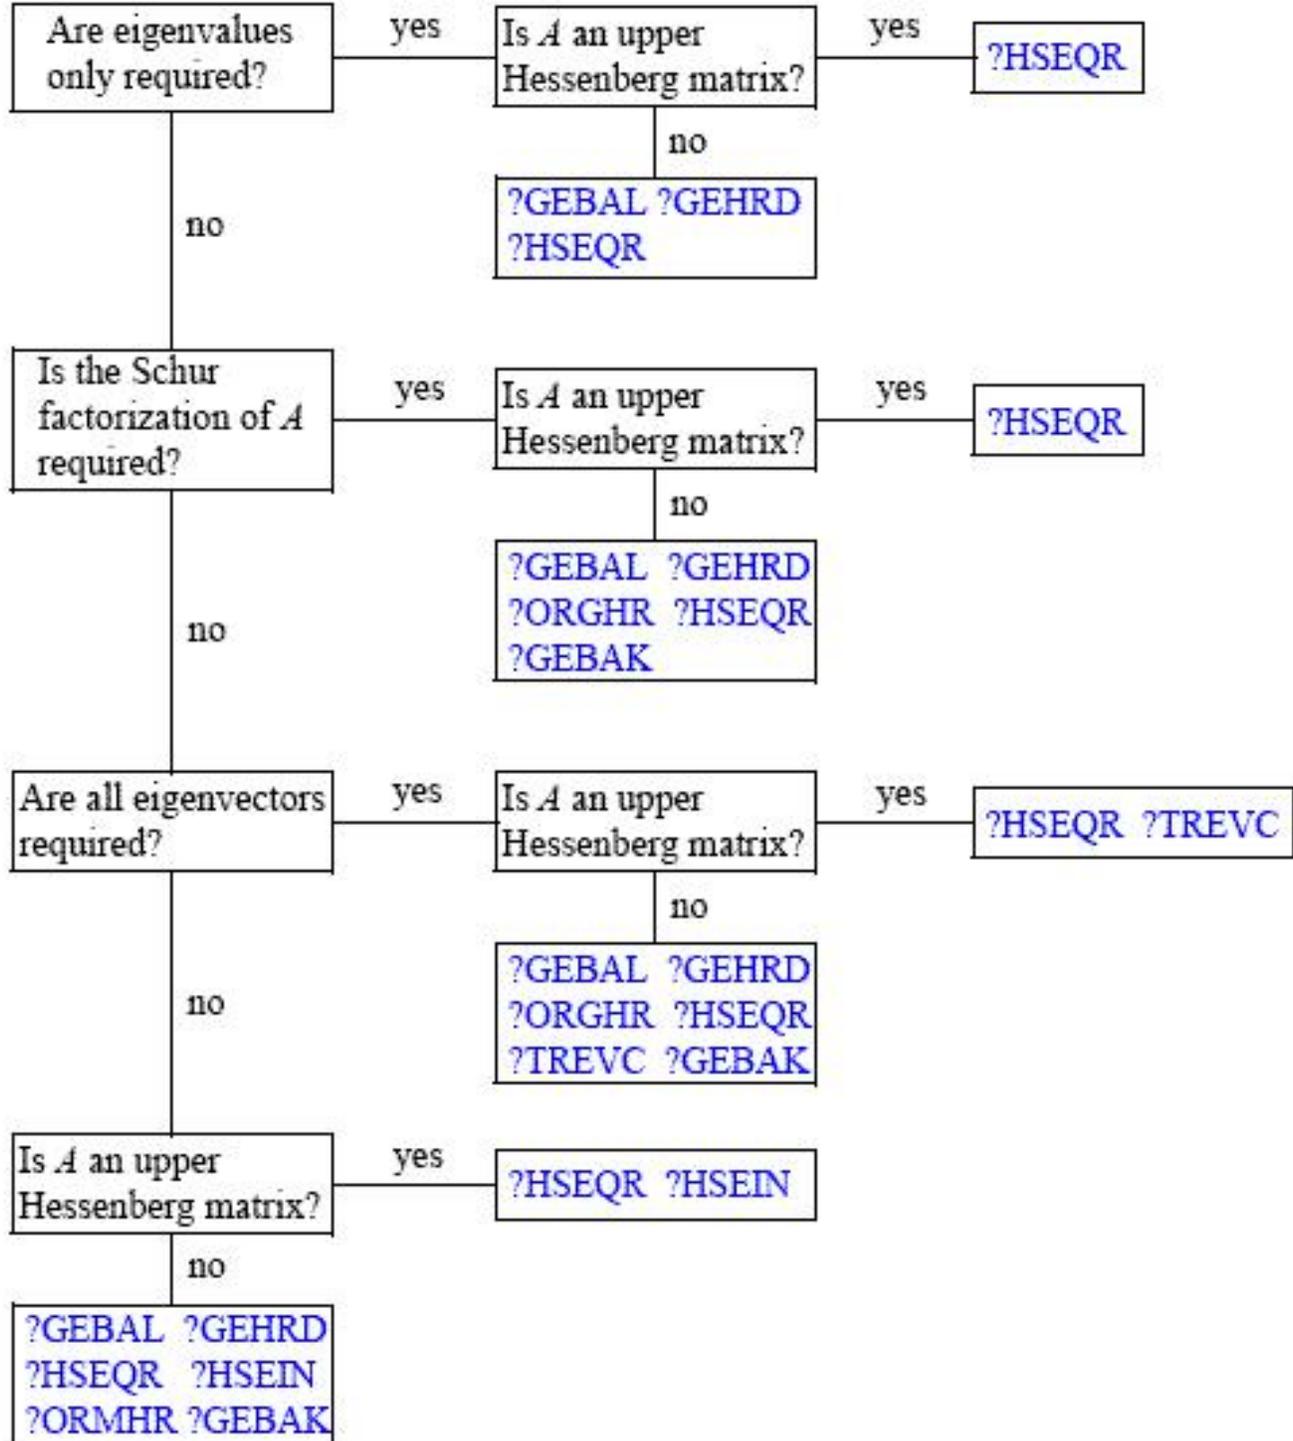

To solve a nonsymmetric eigenvalue problem with LAPACK, you usually need to reduce the matrix to the upper Hessenberg form and then solve the eigenvalue problem with the Hessenberg matrix obtained. [Table "Computational Routines for Solving Nonsymmetric Eigenvalue Problems"](#) lists LAPACK routines to reduce the matrix to the upper Hessenberg form by an orthogonal (or unitary) similarity transformation  $A = QHQ^H$  as well as routines to solve eigenvalue problems with Hessenberg matrices, forming the Schur factorization of such matrices and computing the corresponding condition numbers.

The decision tree in [Figure "Decision Tree: Real Nonsymmetric Eigenvalue Problems"](#) helps you choose the right routine or sequence of routines for an eigenvalue problem with a real nonsymmetric matrix. If you need to solve an eigenvalue problem with a complex non-Hermitian matrix, use the decision tree shown in [Figure "Decision Tree: Complex Non-Hermitian Eigenvalue Problems"](#).

## Decision Tree: Real Nonsymmetric Eigenvalue Problems

**Decision Tree: Complex Non-Hermitian Eigenvalue Problems**

?gehrd  
Reduces a general matrix to upper Hessenberg form.

## Syntax

```
lapack_int LAPACKE_sgehrd (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int ihi, float* a, lapack_int lda, float* tau);
```

```
lapack_int LAPACKE_dgehrd (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int ihi, double* a, lapack_int lda, double* tau);
```

```
lapack_int LAPACKE_cgehrd (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int ihi, lapack_complex_float* a, lapack_int lda, lapack_complex_float* tau);
```

```
lapack_int LAPACKE_zgehrd (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int ihi, lapack_complex_double* a, lapack_int lda, lapack_complex_double* tau);
```

## Include Files

- mkl.h

## Description

The routine reduces a general matrix  $A$  to upper Hessenberg form  $H$  by an orthogonal or unitary similarity transformation  $A = Q^*H^*Q^H$ . Here  $H$  has real subdiagonal elements.

The routine does not form the matrix  $Q$  explicitly. Instead,  $Q$  is represented as a product of *elementary reflectors*. Routines are provided to work with  $Q$  in this representation.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>n</i>	The order of the matrix $A$ ( $n \geq 0$ ).
<i>ilo</i> , <i>ihi</i>	If $A$ is an output by <code>?gebal</code> , then <i>ilo</i> and <i>ihi</i> must contain the values returned by that routine. Otherwise $ilo = 1$ and $ihi = n$ . (If $n > 0$ , then $1 \leq ilo \leq ihi \leq n$ ; if $n = 0$ , $ilo = 1$ and $ihi = 0$ .)
<i>a</i>	Arrays: <i>a</i> (size $\max(1, lda*n)$ ) contains the matrix $A$ .
<i>lda</i>	The leading dimension of <i>a</i> ; at least $\max(1, n)$ .

## Output Parameters

<i>a</i>	The elements on and above the subdiagonal contain the upper Hessenberg matrix $H$ . The subdiagonal elements of $H$ are real. The elements below the subdiagonal, with the array <i>tau</i> , represent the orthogonal matrix $Q$ as a product of $n$ elementary reflectors.
<i>tau</i>	Array, size at least $\max(1, n-1)$ . Contains scalars that define elementary reflectors for the matrix $Q$ .

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

### Application Notes

The computed Hessenberg matrix  $H$  is exactly similar to a nearby matrix  $A + E$ , where  $\|E\|_2 < c(n)\epsilon\|A\|_2$ ,  $c(n)$  is a modestly increasing function of  $n$ , and  $\epsilon$  is the machine precision.

The approximate number of floating-point operations for real flavors is  $(2/3) * (ihi - ilo)^2 (2ihi + 2ilo + 3n)$ ; for complex flavors it is 4 times greater.

`?orghr`

Generates the real orthogonal matrix  $Q$  determined by `?gehrd`.

### Syntax

```
lapack_int LAPACKE_sorghr (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int
ihi, float* a, lapack_int lda, const float* tau);
```

```
lapack_int LAPACKE_dorghr (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int
ihi, double* a, lapack_int lda, const double* tau);
```

### Include Files

- `mkl.h`

### Description

The routine explicitly generates the orthogonal matrix  $Q$  that has been determined by a preceding call to `sgehrd/dgehrd`. (The routine `?gehrd` reduces a real general matrix  $A$  to upper Hessenberg form  $H$  by an orthogonal similarity transformation,  $A = Q^*H^*Q^T$ , and represents the matrix  $Q$  as a product of  $ihi-ilo$  elementary reflectors. Here  $ilo$  and  $ihi$  are values determined by `sgebal/dgebal` when balancing the matrix; if the matrix has not been balanced,  $ilo = 1$  and  $ihi = n$ .)

The matrix  $Q$  generated by `?orghr` has the structure:

$$Q = \begin{bmatrix} I & 0 & 0 \\ 0 & Q_{22} & 0 \\ 0 & 0 & I \end{bmatrix}$$

where  $Q_{22}$  occupies rows and columns  $ilo$  to  $ihi$ .

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>n</i>	The order of the matrix $Q$ ( $n \geq 0$ ).
<i>ilo, ihi</i>	These must be the same parameters <i>ilo</i> and <i>ihi</i> , respectively, as supplied to ?gehrd. (If $n > 0$ , then $1 \leq ilo \leq ihi \leq n$ ; if $n = 0$ , $ilo = 1$ and $ihi = 0$ .)
<i>a, tau</i>	Arrays: <i>a</i> (size $\max(1, lda * n)$ ) contains details of the vectors which define the elementary reflectors, as returned by ?gehrd.  <i>tau</i> contains further details of the elementary reflectors, as returned by ?gehrd.  The dimension of <i>tau</i> must be at least $\max(1, n-1)$ .
<i>lda</i>	The leading dimension of <i>a</i> ; at least $\max(1, n)$ .

## Output Parameters

<i>a</i>	Overwritten by the $n$ -by- $n$ orthogonal matrix $Q$ .
----------	---

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* =  $-i$ , the  $i$ -th parameter had an illegal value.

## Application Notes

The computed matrix  $Q$  differs from the exact result by a matrix  $E$  such that  $\|E\|_2 = O(\epsilon)$ , where  $\epsilon$  is the machine precision.

The approximate number of floating-point operations is  $(4/3)(ihi-ilo)^3$ .

The complex counterpart of this routine is [unghr](#).

### ?ormhr

*Multiplies an arbitrary real matrix C by the real orthogonal matrix Q determined by ?gehrd.*

## Syntax

```
lapack_int LAPACKE_sormhr (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int ilo, lapack_int ihi, const float* a, lapack_int lda, const
float* tau, float* c, lapack_int ldc);
```

```
lapack_int LAPACKE_dormhr (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int ilo, lapack_int ihi, const double* a, lapack_int lda, const
double* tau, double* c, lapack_int ldc);
```

## Include Files

- mkl.h

## Description

The routine multiplies a matrix  $C$  by the orthogonal matrix  $Q$  that has been determined by a preceding call to `sgehrd/dgehrd`. (The routine `?gehrd` reduces a real general matrix  $A$  to upper Hessenberg form  $H$  by an orthogonal similarity transformation,  $A = Q^*H^*Q^T$ , and represents the matrix  $Q$  as a product of *ihi-ilo* elementary reflectors. Here *ilo* and *ihi* are values determined by `sgebal/dgebal` when balancing the matrix; if the matrix has not been balanced,  $ilo = 1$  and  $ihi = n$ .)

With `?ormhr`, you can form one of the matrix products  $Q^*C$ ,  $Q^T*C$ ,  $C*Q$ , or  $C*Q^T$ , overwriting the result on  $C$  (which may be any real rectangular matrix).

A common application of `?ormhr` is to transform a matrix  $V$  of eigenvectors of  $H$  to the matrix  $QV$  of eigenvectors of  $A$ .

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>side</code>	Must be 'L' or 'R'. If <code>side= 'L'</code> , then the routine forms $Q^*C$ or $Q^T*C$ . If <code>side= 'R'</code> , then the routine forms $C*Q$ or $C*Q^T$ .
<code>trans</code>	Must be 'N' or 'T'. If <code>trans= 'N'</code> , then $Q$ is applied to $C$ . If <code>trans= 'T'</code> , then $Q^T$ is applied to $C$ .
<code>m</code>	The number of rows in $C$ ( $m \geq 0$ ).
<code>n</code>	The number of columns in $C$ ( $n \geq 0$ ).
<code>ilo, ihi</code>	These must be the same parameters <i>ilo</i> and <i>ihi</i> , respectively, as supplied to <code>?gehrd</code> . If $m > 0$ and <code>side = 'L'</code> , then $1 \leq ilo \leq ihi \leq m$ . If $m = 0$ and <code>side = 'L'</code> , then $ilo = 1$ and $ihi = 0$ . If $n > 0$ and <code>side = 'R'</code> , then $1 \leq ilo \leq ihi \leq n$ . If $n = 0$ and <code>side = 'R'</code> , then $ilo = 1$ and $ihi = 0$ .
<code>a, tau, c</code>	Arrays: <code>a</code> (size $\max(1, lda*n)$ for <code>side='R'</code> and size $\max(1, lda*m)$ for <code>side='L'</code> ) contains details of the vectors which define the <i>elementary reflectors</i> , as returned by <code>?gehrd</code> . <code>tau</code> contains further details of the <i>elementary reflectors</i> , as returned by <code>?gehrd</code> . The dimension of <code>tau</code> must be at least $\max(1, m-1)$ if <code>side = 'L'</code> and at least $\max(1, n-1)$ if <code>side = 'R'</code> . <code>c</code> (size $\max(1, ldc*n)$ for column major layout and $\max(1, ldc*m)$ for row major layout) contains the $m$ by $n$ matrix $C$ .

<code>lda</code>	The leading dimension of $a$ ; at least $\max(1, m)$ if $side = 'L'$ and at least $\max(1, n)$ if $side = 'R'$ .
<code>ldc</code>	The leading dimension of $c$ ; at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout .

## Output Parameters

<code>c</code>	$C$ is overwritten by product $Q^*C$ , $Q^T C$ , $C^*Q$ , or $C^*Q^T$ as specified by $side$ and $trans$ .
----------------	--

## Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, the  $i$ -th parameter had an illegal value.

## Application Notes

The computed matrix  $Q$  differs from the exact result by a matrix  $E$  such that  $\|E\|_2 = O(\epsilon) \|C\|_2$ , where  $\epsilon$  is the machine precision.

The approximate number of floating-point operations is

$2n(ihi-ilo)^2$  if  $side = 'L'$ ;

$2m(ihi-ilo)^2$  if  $side = 'R'$ .

The complex counterpart of this routine is [unmhr](#).

### ?unghr

Generates the complex unitary matrix  $Q$  determined by ?gehrd.

## Syntax

```
lapack_int LAPACKE_cunghr (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int
ihi, lapack_complex_float* a, lapack_int lda, const lapack_complex_float* tau);
```

```
lapack_int LAPACKE_zunghr (int matrix_layout, lapack_int n, lapack_int ilo, lapack_int
ihi, lapack_complex_double* a, lapack_int lda, const lapack_complex_double* tau);
```

## Include Files

- `mkl.h`

## Description

The routine is intended to be used following a call to `cgehrd/zgehrd`, which reduces a complex matrix  $A$  to upper Hessenberg form  $H$  by a unitary similarity transformation:  $A = Q^*H^*Q^H$ . `?gehrd` represents the matrix  $Q$  as a product of  $ihi-ilo$  elementary reflectors. Here  $ilo$  and  $ihi$  are values determined by `cgebal/zgebal` when balancing the matrix; if the matrix has not been balanced,  $ilo = 1$  and  $ihi = n$ .

Use the routine [unghr](#) to generate  $Q$  explicitly as a square matrix. The matrix  $Q$  has the structure:

$$Q = \begin{bmatrix} I & 0 & 0 \\ 0 & Q_{22} & 0 \\ 0 & 0 & I \end{bmatrix}$$

where  $Q_{22}$  occupies rows and columns  $ilo$  to  $ihi$ .

### Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>n</code>	The order of the matrix $Q$ ( $n \geq 0$ ).
<code>ilo, ihi</code>	These must be the same parameters $ilo$ and $ihi$ , respectively, as supplied to <code>?gehrd</code> . (If $n > 0$ , then $1 \leq ilo \leq ihi \leq n$ . If $n = 0$ , then $ilo = 1$ and $ihi = 0$ .)
<code>a, tau</code>	Arrays: $a$ (size $\max(1, lda * n)$ ) contains details of the vectors which define the <i>elementary reflectors</i> , as returned by <code>?gehrd</code> . $tau$ contains further details of the <i>elementary reflectors</i> , as returned by <code>?gehrd</code> . The dimension of $tau$ must be at least $\max(1, n-1)$ .
<code>lda</code>	The leading dimension of $a$ ; at least $\max(1, n)$ .

### Output Parameters

<code>a</code>	Overwritten by the $n$ -by- $n$ unitary matrix $Q$ .
----------------	--

### Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, the  $i$ -th parameter had an illegal value.

## Application Notes

The computed matrix  $Q$  differs from the exact result by a matrix  $E$  such that  $\|E\|_2 = O(\varepsilon)$ , where  $\varepsilon$  is the machine precision.

The approximate number of real floating-point operations is  $(16/3)(ihi-ilo)^3$ .

The real counterpart of this routine is [orghr](#).

### ?unmhr

*Multiplies an arbitrary complex matrix  $C$  by the complex unitary matrix  $Q$  determined by ?gehrd.*

## Syntax

```
lapack_int LAPACKE_cunmhr (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int ilo, lapack_int ihi, const lapack_complex_float* a, lapack_int
lda, const lapack_complex_float* tau, lapack_complex_float* c, lapack_int ldc);
```

```
lapack_int LAPACKE_zunmhr (int matrix_layout, char side, char trans, lapack_int m,
lapack_int n, lapack_int ilo, lapack_int ihi, const lapack_complex_double* a,
lapack_int lda, const lapack_complex_double* tau, lapack_complex_double* c, lapack_int
ldc);
```

## Include Files

- mkl.h

## Description

The routine multiplies a matrix  $C$  by the unitary matrix  $Q$  that has been determined by a preceding call to `cgehrd/zgehrd`. (The routine `?gehrd` reduces a real general matrix  $A$  to upper Hessenberg form  $H$  by an orthogonal similarity transformation,  $A = Q^H H Q$ , and represents the matrix  $Q$  as a product of *ihi-ilo elementary reflectors*. Here *ilo* and *ihi* are values determined by `cgebal/zgebal` when balancing the matrix; if the matrix has not been balanced, *ilo* = 1 and *ihi* = *n*.)

With `?unmhr`, you can form one of the matrix products  $Q^H C$ ,  $Q C$ ,  $C^H Q$ , or  $C Q^H$ , overwriting the result on  $C$  (which may be any complex rectangular matrix). A common application of this routine is to transform a matrix  $V$  of eigenvectors of  $H$  to the matrix  $QV$  of eigenvectors of  $A$ .

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>side</i>	Must be 'L' or 'R'. If <i>side</i> = 'L', then the routine forms $Q^H C$ or $Q C$ . If <i>side</i> = 'R', then the routine forms $C^H Q$ or $C Q^H$ .
<i>trans</i>	Must be 'N' or 'T'. If <i>trans</i> = 'N', then $Q$ is applied to $C$ . If <i>trans</i> = 'T', then $Q^H$ is applied to $C$ .
<i>m</i>	The number of rows in $C$ ( $m \geq 0$ ).

$n$	The number of columns in $C$ ( $n \geq 0$ ).
$ilo, ihi$	These must be the same parameters $ilo$ and $ihi$ , respectively, as supplied to <code>?gehrd</code> . If $m > 0$ and $side = 'L'$ , then $1 \leq ilo \leq ihi \leq m$ . If $m = 0$ and $side = 'L'$ , then $ilo = 1$ and $ihi = 0$ . If $n > 0$ and $side = 'R'$ , then $1 \leq ilo \leq ihi \leq n$ . If $n = 0$ and $side = 'R'$ , then $ilo = 1$ and $ihi = 0$ .
$a, tau, c$	Arrays: $a$ (size $\max(1, lda * n)$ for $side='R'$ and size $\max(1, lda * m)$ for $side='L'$ ) contains details of the vectors which define the elementary reflectors, as returned by <code>?gehrd</code> . $tau$ contains further details of the elementary reflectors, as returned by <code>?gehrd</code> . The dimension of $tau$ must be at least $\max(1, m-1)$ if $side = 'L'$ and at least $\max(1, n-1)$ if $side = 'R'$ . $c$ (size $\max(1, ldc * n)$ for column major layout and $\max(1, ldc * m)$ for row major layout) contains the $m$ -by- $n$ matrix $C$ .
$lda$	The leading dimension of $a$ ; at least $\max(1, m)$ if $side = 'L'$ and at least $\max(1, n)$ if $side = 'R'$ .
$ldc$	The leading dimension of $c$ ; at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout.

## Output Parameters

$c$	$C$ is overwritten by $Q * C$ , or $Q^H * C$ , or $C * Q^H$ , or $C * Q$ as specified by $side$ and $trans$ .
-----	---

## Return Values

This function returns a value  $info$ .

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

## Application Notes

The computed matrix  $Q$  differs from the exact result by a matrix  $E$  such that  $\|E\|_2 = O(\epsilon) * \|C\|_2$ , where  $\epsilon$  is the machine precision.

The approximate number of floating-point operations is

$8n(ihi-ilo)^2$  if  $side = 'L'$ ;

$8m(ihi-ilo)^2$  if  $side = 'R'$ .

The real counterpart of this routine is [ormhr](#).

## *sgebal*

Balances a general matrix to improve the accuracy of computed eigenvalues and eigenvectors.

### Syntax

```
lapack_int LAPACKE_sgebal( int matrix_layout, char job, lapack_int n, float* a,
lapack_int lda, lapack_int* ilo, lapack_int* ihi, float* scale );

lapack_int LAPACKE_dgebal( int matrix_layout, char job, lapack_int n, double* a,
lapack_int lda, lapack_int* ilo, lapack_int* ihi, double* scale );

lapack_int LAPACKE_cgebal( int matrix_layout, char job, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_int* ilo, lapack_int* ihi, float*
scale );

lapack_int LAPACKE_zgebal( int matrix_layout, char job, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_int* ilo, lapack_int* ihi, double*
scale );
```

### Include Files

- mkl.h

### Description

The routine *balances* a matrix *A* by performing either or both of the following two similarity transformations:

(1) The routine first attempts to permute *A* to block upper triangular form:

$$PAP^T = A' = \begin{bmatrix} A'_{11} & A'_{12} & A'_{13} \\ 0 & A'_{22} & A'_{23} \\ 0 & 0 & A'_{33} \end{bmatrix}$$

where *P* is a permutation matrix, and *A'*<sub>11</sub> and *A'*<sub>33</sub> are upper triangular. The diagonal elements of *A'*<sub>11</sub> and *A'*<sub>33</sub> are eigenvalues of *A*. The rest of the eigenvalues of *A* are the eigenvalues of the central diagonal block *A'*<sub>22</sub>, in rows and columns *ilo* to *ihi*. Subsequent operations to compute the eigenvalues of *A* (or its Schur factorization) need only be applied to these rows and columns; this can save a significant amount of work if *ilo* > 1 and *ihi* < *n*.

If no suitable permutation exists (as is often the case), the routine sets *ilo* = 1 and *ihi* = *n*, and *A'*<sub>22</sub> is the whole of *A*.

(2) The routine applies a diagonal similarity transformation to *A'*, to make the rows and columns of *A'*<sub>22</sub> as close in norm as possible:

$$A'' = DA'D^{-1} = \begin{bmatrix} I & 0 & 0 \\ 0 & D_{22} & 0 \\ 0 & 0 & I \end{bmatrix} \times \begin{bmatrix} A'_{11} & A'_{12} & A'_{13} \\ 0 & A'_{22} & A'_{23} \\ 0 & 0 & A'_{33} \end{bmatrix} \times \begin{bmatrix} I & 0 & 0 \\ 0 & D_{22}^{-1} & 0 \\ 0 & 0 & I \end{bmatrix}$$

This scaling can reduce the norm of the matrix (that is,  $\|A''_{22}\| < \|A'_{22}\|$ ), and hence reduce the effect of rounding errors on the accuracy of computed eigenvalues and eigenvectors.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>job</i>	Must be 'N' or 'P' or 'S' or 'B'. If <i>job</i> = 'N', then <i>A</i> is neither permuted nor scaled (but <i>ilo</i> , <i>ihi</i> , and <i>scale</i> get their values). If <i>job</i> = 'P', then <i>A</i> is permuted but not scaled. If <i>job</i> = 'S', then <i>A</i> is scaled but not permuted. If <i>job</i> = 'B', then <i>A</i> is both scaled and permuted.
<i>n</i>	The order of the matrix <i>A</i> ( $n \geq 0$ ).
<i>a</i>	Array <i>a</i> (size $\max(1, lda * n)$ ) contains the matrix <i>A</i> .
<i>lda</i>	The leading dimension of <i>a</i> ; at least $\max(1, n)$ .

## Output Parameters

<i>a</i>	Overwritten by the balanced matrix ( <i>a</i> is not referenced if <i>job</i> = 'N').
<i>ilo</i> , <i>ihi</i>	The values <i>ilo</i> and <i>ihi</i> such that on exit $a(i,j)$ is zero if $i > j$ and $1 \leq j < ilo$ or $ihi < j \leq n$ . If <i>job</i> = 'N' or 'S', then <i>ilo</i> = 1 and <i>ihi</i> = <i>n</i> .
<i>scale</i>	Array, size at least $\max(1, n)$ . Contains details of the permutations and scaling factors. More precisely, if $p_j$ is the index of the row and column interchanged with row and column <i>j</i> , and $d_j$ is the scaling factor used to balance row and column <i>j</i> , then $scale[j - 1] = p_j$ for $j = 1, 2, \dots, ilo-1, ihi+1, \dots, n$ ; $scale[j - 1] = d_j$ for $j = ilo, ilo + 1, \dots, ihi$ . The order in which the interchanges are made is <i>n</i> to <i>ihi+1</i> , then 1 to <i>ilo-1</i> .

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

## Application Notes

The errors are negligible, compared with those in subsequent computations.

If the matrix  $A$  is balanced by this routine, then any eigenvectors computed subsequently are eigenvectors of the matrix  $A''$  and hence you must call [gebak](#) to transform them back to eigenvectors of  $A$ .

If the Schur vectors of  $A$  are required, do not call this routine with  $job = 'S'$  or  $'B'$ , because then the balancing transformation is not orthogonal (not unitary for complex flavors).

If you call this routine with  $job = 'P'$ , then any Schur vectors computed subsequently are Schur vectors of the matrix  $A''$ , and you need to call [gebak](#) (with  $side = 'R'$ ) to transform them back to Schur vectors of  $A$ .

The total number of floating-point operations is proportional to  $n^2$ .

### ?gebak

*Transforms eigenvectors of a balanced matrix to those of the original nonsymmetric matrix.*

### Syntax

```
lapack_int LAPACKE_sgebak( int matrix_layout, char job, char side, lapack_int n,
lapack_int ilo, lapack_int ihi, const float* scale, lapack_int m, float* v, lapack_int
ldv );
```

```
lapack_int LAPACKE_dgebak( int matrix_layout, char job, char side, lapack_int n,
lapack_int ilo, lapack_int ihi, const double* scale, lapack_int m, double* v,
lapack_int ldv );
```

```
lapack_int LAPACKE_cgebak( int matrix_layout, char job, char side, lapack_int n,
lapack_int ilo, lapack_int ihi, const float* scale, lapack_int m, lapack_complex_float*
v, lapack_int ldv );
```

```
lapack_int LAPACKE_zgebak( int matrix_layout, char job, char side, lapack_int n,
lapack_int ilo, lapack_int ihi, const double* scale, lapack_int m,
lapack_complex_double* v, lapack_int ldv );
```

### Include Files

- mkl.h

### Description

The routine is intended to be used after a matrix  $A$  has been balanced by a call to [gebal](#), and eigenvectors of the balanced matrix  $A''_{22}$  have subsequently been computed. For a description of balancing, see [gebal](#). The balanced matrix  $A''$  is obtained as  $A'' = D * P * A * P^T * \text{inv}(D)$ , where  $P$  is a permutation matrix and  $D$  is a diagonal scaling matrix. This routine transforms the eigenvectors as follows:

if  $x$  is a right eigenvector of  $A''$ , then  $P^T * \text{inv}(D) * x$  is a right eigenvector of  $A$ ; if  $y$  is a left eigenvector of  $A''$ , then  $P^T * D * y$  is a left eigenvector of  $A$ .

### Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>job</i>	Must be 'N' or 'P' or 'S' or 'B'. The same parameter <i>job</i> as supplied to <a href="#">gebal</a> .

<i>side</i>	Must be 'L' or 'R'. If <i>side</i> = 'L', then left eigenvectors are transformed. If <i>side</i> = 'R', then right eigenvectors are transformed.
<i>n</i>	The number of rows of the matrix of eigenvectors ( $n \geq 0$ ).
<i>ilo, ihi</i>	The values <i>ilo</i> and <i>ihi</i> , as returned by ?gebal. (If $n > 0$ , then $1 \leq ilo \leq ihi \leq n$ ; if $n = 0$ , then $ilo = 1$ and $ihi = 0$ .)
<i>scale</i>	Array, size at least $\max(1, n)$ . Contains details of the permutations and/or the scaling factors used to balance the original general matrix, as returned by ?gebal.
<i>m</i>	The number of columns of the matrix of eigenvectors ( $m \geq 0$ ).
<i>v</i>	Arrays: <i>v</i> (size $\max(1, ldv * n)$ for column major layout and $\max(1, ldv * m)$ for row major layout) contains the matrix of left or right eigenvectors to be transformed.
<i>ldv</i>	The leading dimension of <i>v</i> ; at least $\max(1, n)$ for column major layout and at least $\max(1, m)$ for row major layout .

## Output Parameters

<i>v</i>	Overwritten by the transformed eigenvectors.
----------	--

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

## Application Notes

The errors in this routine are negligible.

The approximate number of floating-point operations is approximately proportional to  $m * n$ .

### ?hseqr

Computes all eigenvalues and (optionally) the Schur factorization of a matrix reduced to Hessenberg form.

## Syntax

```
lapack_int LAPACKE_shseqr( int matrix_layout, char job, char compz, lapack_int n,
lapack_int ilo, lapack_int ihi, float* h, lapack_int ldh, float* wr, float* wi, float*
z, lapack_int ldz );
```

```
lapack_int LAPACKE_dhseqr( int matrix_layout, char job, char compz, lapack_int n,
lapack_int ilo, lapack_int ihi, double* h, lapack_int ldh, double* wr, double* wi,
double* z, lapack_int ldz );
```

```
lapack_int LAPACKE_chseqr( int matrix_layout, char job, char compz, lapack_int n,
lapack_int ilo, lapack_int ihi, lapack_complex_float* h, lapack_int ldh,
lapack_complex_float* w, lapack_complex_float* z, lapack_int ldz );

lapack_int LAPACKE_zhseqr( int matrix_layout, char job, char compz, lapack_int n,
lapack_int ilo, lapack_int ihi, lapack_complex_double* h, lapack_int ldh,
lapack_complex_double* w, lapack_complex_double* z, lapack_int ldz );
```

## Include Files

- mkl.h

## Description

The routine computes all the eigenvalues, and optionally the Schur factorization, of an upper Hessenberg matrix  $H$ :  $H = Z^* T^* Z^H$ , where  $T$  is an upper triangular (or, for real flavors, quasi-triangular) matrix (the Schur form of  $H$ ), and  $Z$  is the unitary or orthogonal matrix whose columns are the Schur vectors  $z_i$ .

You can also use this routine to compute the Schur factorization of a general matrix  $A$  which has been reduced to upper Hessenberg form  $H$ :

$A = Q^* H^* Q^H$ , where  $Q$  is unitary (orthogonal for real flavors);

$A = (QZ)^* T^* (QZ)^H$ .

In this case, after reducing  $A$  to Hessenberg form by [ghehrd](#), call [orghr](#) to form  $Q$  explicitly and then pass  $Q$  to `?hseqr` with `compz = 'V'`.

You can also call [gebal](#) to balance the original matrix before reducing it to Hessenberg form by `?hseqr`, so that the Hessenberg matrix  $H$  will have the structure:

$$\begin{bmatrix} H_{11} & H_{12} & H_{13} \\ 0 & H_{22} & H_{23} \\ 0 & 0 & H_{33} \end{bmatrix}$$

where  $H_{11}$  and  $H_{33}$  are upper triangular.

If so, only the central diagonal block  $H_{22}$  (in rows and columns  $ilo$  to  $ihi$ ) needs to be further reduced to Schur form (the blocks  $H_{12}$  and  $H_{23}$  are also affected). Therefore the values of  $ilo$  and  $ihi$  can be supplied to `?hseqr` directly. Also, after calling this routine you must call `gebak` to permute the Schur vectors of the balanced matrix to those of the original matrix.

If `?gebal` has not been called, however, then  $ilo$  must be set to 1 and  $ihi$  to  $n$ . Note that if the Schur factorization of  $A$  is required, `?gebal` must not be called with  $job = 'S'$  or  $'B'$ , because the balancing transformation is not unitary (for real flavors, it is not orthogonal).

`?hseqr` uses a multishift form of the upper Hessenberg  $QR$  algorithm. The Schur vectors are normalized so that  $\|z_i\|_2 = 1$ , but are determined only to within a complex factor of absolute value 1 (for the real flavors, to within a factor  $\pm 1$ ).

## Input Parameters

<code>job</code>	Must be 'E' or 'S'. If $job = 'E'$ , then eigenvalues only are required. If $job = 'S'$ , then the Schur form $T$ is required.
<code>compz</code>	Must be 'N' or 'I' or 'V'. If $compz = 'N'$ , then no Schur vectors are computed (and the array $z$ is not referenced). If $compz = 'I'$ , then the Schur vectors of $H$ are computed (and the array $z$ is initialized by the routine). If $compz = 'V'$ , then the Schur vectors of $A$ are computed (and the array $z$ must contain the matrix $Q$ on entry).
<code>n</code>	The order of the matrix $H$ ( $n \geq 0$ ).
<code>ilo, ihi</code>	If $A$ has been balanced by <code>?gebal</code> , then $ilo$ and $ihi$ must contain the values returned by <code>?gebal</code> . Otherwise, $ilo$ must be set to 1 and $ihi$ to $n$ .
<code>h, z</code>	Arrays: $h$ (size $\max(1, ldh*n)$ ) The $n$ -by- $n$ upper Hessenberg matrix $H$ . $z$ (size $\max(1, ldz*n)$ ) If $compz = 'V'$ , then $z$ must contain the matrix $Q$ from the reduction to Hessenberg form. If $compz = 'I'$ , then $z$ need not be set. If $compz = 'N'$ , then $z$ is not referenced.
<code>ldh</code>	The leading dimension of $h$ ; at least $\max(1, n)$ .
<code>ldz</code>	The leading dimension of $z$ ; If $compz = 'N'$ , then $ldz \geq 1$ . If $compz = 'V'$ or $'I'$ , then $ldz \geq \max(1, n)$ .

## Output Parameters

<code>w</code>	Array, size at least $\max(1, n)$ . Contains the computed eigenvalues, unless $info > 0$ . The eigenvalues are stored in the same order as on the diagonal of the Schur form $T$ (if computed).
----------------	---

$wr, wi$	Arrays, size at least $\max(1, n)$ each.  Contain the real and imaginary parts, respectively, of the computed eigenvalues, unless $info > 0$ . Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first. The eigenvalues are stored in the same order as on the diagonal of the Schur form $T$ (if computed).
$h$	If $info = 0$ and $job = 'S'$ , $h$ contains the upper quasi-triangular matrix $T$ from the Schur decomposition (the Schur form).  If $info = 0$ and $job = 'E'$ , the contents of $h$ are unspecified on exit. (The output value of $h$ when $info > 0$ is given under the description of $info$ below.)
$z$	If $compz = 'V'$ and $info = 0$ , then $z$ contains $Q^*Z$ .  If $compz = 'I'$ and $info = 0$ , then $z$ contains the unitary or orthogonal matrix $Z$ of the Schur vectors of $H$ .  If $compz = 'N'$ , then $z$ is not referenced.

## Return Values

This function returns a value  $info$ .

If  $info = 0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = i$ , `?hseqr` failed to compute all of the eigenvalues. Elements  $1, 2, \dots, ilo-1$  and  $i+1, i+2, \dots, n$  of the eigenvalue arrays ( $wr$  and  $wi$  for real flavors and  $w$  for complex flavors) contain the real and imaginary parts of those eigenvalues that have been successfully found.

If  $info > 0$ , and  $job = 'E'$ , then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns  $ilo$  through  $info$  of the final output value of  $H$ .

If  $info > 0$ , and  $job = 'S'$ , then on exit (initial value of  $H$ )\* $U = U$ \*(final value of  $H$ ), where  $U$  is a unitary matrix. The final value of  $H$  is upper Hessenberg and triangular in rows and columns  $info+1$  through  $ihl$ .

If  $info > 0$ , and  $compz = 'V'$ , then on exit (final value of  $Z$ ) = (initial value of  $Z$ )\* $U$ , where  $U$  is the unitary matrix (regardless of the value of  $job$ ).

If  $info > 0$ , and  $compz = 'I'$ , then on exit (final value of  $Z$ ) =  $U$ , where  $U$  is the unitary matrix (regardless of the value of  $job$ ).

If  $info > 0$ , and  $compz = 'N'$ , then  $Z$  is not accessed.

## Application Notes

The computed Schur factorization is the exact factorization of a nearby matrix  $H + E$ , where  $\|E\|_2 < O(\epsilon) \|H\|_2 / s_i$ , and  $\epsilon$  is the machine precision.

If  $\lambda_j$  is an exact eigenvalue, and  $\mu_j$  is the corresponding computed value, then  $|\lambda_j - \mu_j| \leq c(n) * \epsilon * \|H\|_2 / s_j$ , where  $c(n)$  is a modestly increasing function of  $n$ , and  $s_j$  is the reciprocal condition number of  $\lambda_j$ . The condition numbers  $s_j$  may be computed by calling `trsna`.

The total number of floating-point operations depends on how rapidly the algorithm converges; typical numbers are as follows.

If only eigenvalues are computed:  $7n^3$  for real flavors  
 $25n^3$  for complex flavors.

If the Schur form is computed:	$10n^3$ for real flavors $35n^3$ for complex flavors.
If the full Schur factorization is computed:	$20n^3$ for real flavors $70n^3$ for complex flavors.

### ?hsein

Computes selected eigenvectors of an upper Hessenberg matrix that correspond to specified eigenvalues.

### Syntax

```
lapack_int LAPACKE_shsein( int matrix_layout, char side, char eigsrc, char initv,

### Description

The routine computes left and/or right eigenvectors of an upper Hessenberg matrix  $H$ , corresponding to selected eigenvalues.

The right eigenvector  $x$  and the left eigenvector  $y$ , corresponding to an eigenvalue  $\lambda$ , are defined by:  $H^*x = \lambda^*x$  and  $y^H H = \lambda y^H$  (or  $H^H y = \lambda^* y$ ). Here  $\lambda^*$  denotes the conjugate of  $\lambda$ .

The eigenvectors are computed by inverse iteration. They are scaled so that, for a real eigenvector  $x$ ,  $\max |x_i| = 1$ , and for a complex eigenvector,  $\max (|\text{Re}x_i| + |\text{Im}x_i|) = 1$ .

If  $H$  has been formed by reduction of a general matrix  $A$  to upper Hessenberg form, then eigenvectors of  $H$  may be transformed to eigenvectors of  $A$  by [ormhr](#) or [unmhr](#).

## Input Parameters

<i>side</i>	<p>Must be 'R' or 'L' or 'B'.</p> <p>If <i>side</i> = 'R', then only right eigenvectors are computed.</p> <p>If <i>side</i> = 'L', then only left eigenvectors are computed.</p> <p>If <i>side</i> = 'B', then all eigenvectors are computed.</p>
<i>eigsrc</i>	<p>Must be 'Q' or 'N'.</p> <p>If <i>eigsrc</i> = 'Q', then the eigenvalues of <i>H</i> were found using <a href="#">hseqr</a>; thus if <i>H</i> has any zero sub-diagonal elements (and so is block triangular), then the <i>j</i>-th eigenvalue can be assumed to be an eigenvalue of the block containing the <i>j</i>-th row/column. This property allows the routine to perform inverse iteration on just one diagonal block. If <i>eigsrc</i> = 'N', then no such assumption is made and the routine performs inverse iteration using the whole matrix.</p>
<i>initv</i>	<p>Must be 'N' or 'U'.</p> <p>If <i>initv</i> = 'N', then no initial estimates for the selected eigenvectors are supplied.</p> <p>If <i>initv</i> = 'U', then initial estimates for the selected eigenvectors are supplied in <i>vl</i> and/or <i>vr</i>.</p>
<i>select</i>	<p>Array, size at least <math>\max(1, n)</math>. Specifies which eigenvectors are to be computed.</p> <p><i>For real flavors:</i></p> <p>To obtain the real eigenvector corresponding to the real eigenvalue <math>wr[j]</math>, set <i>select</i>[<i>j</i>] to 1</p> <p>To select the complex eigenvector corresponding to the complex eigenvalue (<math>wr[j - 1]</math>, <math>wi[j - 1]</math>) with complex conjugate (<math>wr[j]</math>, <math>wi[j]</math>), set <i>select</i>[<i>j</i> - 1] and/or <i>select</i>[<i>j</i>] to 1; the eigenvector corresponding to the first eigenvalue in the pair is computed.</p> <p><i>For complex flavors:</i></p> <p>To select the eigenvector corresponding to the eigenvalue <math>w[j]</math>, set <i>select</i>[<i>j</i>] to 1</p>
<i>n</i>	The order of the matrix <i>H</i> ( $n \geq 0$ ).
<i>h, vl, vr</i>	<p>Arrays:</p> <p><i>h</i> (size <math>\max(1, ldh*n)</math>) The <i>n</i>-by-<i>n</i> upper Hessenberg matrix <i>H</i>. If an NAN value is detected in <i>h</i>, the routine returns with <i>info</i> = -6.</p> <p><i>vl</i>(size <math>\max(1, ldvl*mm)</math> for column major layout and <math>\max(1, ldvl*n)</math> for row major layout)</p> <p>If <i>initv</i> = 'V' and <i>side</i> = 'L' or 'B', then <i>vl</i> must contain starting vectors for inverse iteration for the left eigenvectors. Each starting vector must be stored in the same column or columns as will be used to store the corresponding eigenvector.</p> <p>If <i>initv</i> = 'N', then <i>vl</i> need not be set.</p>

The array  $vl$  is not referenced if  $side = 'R'$ .

$vr(\text{size } \max(1, ldvr * mm)$  for column major layout and  $\max(1, ldvr * n)$  for row major layout)

If  $initv = 'V'$  and  $side = 'R'$  or  $'B'$ , then  $vr$  must contain starting vectors for inverse iteration for the right eigenvectors. Each starting vector must be stored in the same column or columns as will be used to store the corresponding eigenvector.

If  $initv = 'N'$ , then  $vr$  need not be set.

The array  $vr$  is not referenced if  $side = 'L'$ .

$ldh$

The leading dimension of  $h$ ; at least  $\max(1, n)$ .

$w$

Array, size at least  $\max(1, n)$ .

Contains the eigenvalues of the matrix  $H$ .

If  $eigsrc = 'Q'$ , the array must be exactly as returned by `?hseqr`.

$wr, wi$

Arrays, size at least  $\max(1, n)$  each.

Contain the real and imaginary parts, respectively, of the eigenvalues of the matrix  $H$ . Complex conjugate pairs of values must be stored in consecutive elements of the arrays. If  $eigsrc = 'Q'$ , the arrays must be exactly as returned by `?hseqr`.

$ldvl$

The leading dimension of  $vl$ .

If  $side = 'L'$  or  $'B'$ ,  $ldvl \geq \max(1, n)$  for column major layout and  $ldvl \geq \max(1, mm)$  for row major layout .

If  $side = 'R'$ ,  $ldvl \geq 1$ .

$ldvr$

The leading dimension of  $vr$ .

If  $side = 'R'$  or  $'B'$ ,  $ldvr \geq \max(1, n)$  for column major layout and  $ldvr \geq \max(1, mm)$  for row major layout .

If  $side = 'L'$ ,  $ldvr \geq 1$ .

$mm$

The number of columns in  $vl$  and/or  $vr$ .

Must be at least  $m$ , the actual number of columns required (see *Output Parameters* below).

*For real flavors*,  $m$  is obtained by counting 1 for each selected real eigenvector and 2 for each selected complex eigenvector (see *select*).

*For complex flavors*,  $m$  is the number of selected eigenvectors (see *select*).

Constraint:

$$0 \leq mm \leq n.$$

## Output Parameters

$select$

Overwritten for real flavors only.

If a complex eigenvector was selected as specified above, then  $select[j - 1]$  is set to 1 and  $select[j]$  to 0

<i>w</i>	The real parts of some elements of <i>w</i> may be modified, as close eigenvalues are perturbed slightly in searching for independent eigenvectors.
<i>wr</i>	Some elements of <i>wr</i> may be modified, as close eigenvalues are perturbed slightly in searching for independent eigenvectors.
<i>vl, vr</i>	<p>If <i>side</i> = 'L' or 'B', <i>vl</i> contains the computed left eigenvectors (as specified by <i>select</i>).</p> <p>If <i>side</i> = 'R' or 'B', <i>vr</i> contains the computed right eigenvectors (as specified by <i>select</i>).</p> <p>The eigenvectors treated column-wise form a rectangular <i>n</i>-by-<i>mm</i> matrix.</p> <p><i>For real flavors</i>: a real eigenvector corresponding to a real eigenvalue occupies one column of the matrix; a complex eigenvector corresponding to a complex eigenvalue occupies two columns: the first column holds the real part of the eigenvector and the second column holds the imaginary part of the eigenvector. The matrix is stored in a one-dimensional array as described by <i>matrix_layout</i> (using either column major or row major layout).</p>
<i>m</i>	<p><i>For real flavors</i>: the number of columns of <i>vl</i> and/or <i>vr</i> required to store the selected eigenvectors.</p> <p><i>For complex flavors</i>: the number of selected eigenvectors.</p>
<i>ifaill, ifailr</i>	<p>Arrays, size at least <math>\max(1, mm)</math> each.</p> <p><i>ifaill</i>[<i>i</i> - 1] = 0 if the <i>i</i>th column of <i>vl</i> converged;</p> <p><i>ifaill</i>[<i>i</i> - 1] = <i>j</i> &gt; 0 if the eigenvector stored in the <i>i</i>-th column of <i>vl</i> (corresponding to the <i>j</i>th eigenvalue) failed to converge.</p> <p><i>ifailr</i>[<i>i</i> - 1] = 0 if the <i>i</i>th column of <i>vr</i> converged;</p> <p><i>ifailr</i>[<i>i</i> - 1] = <i>j</i> &gt; 0 if the eigenvector stored in the <i>i</i>-th column of <i>vr</i> (corresponding to the <i>j</i>th eigenvalue) failed to converge.</p> <p><i>For real flavors</i>: if the <i>i</i>th and (<i>i</i>+1)th columns of <i>vl</i> contain a selected complex eigenvector, then <i>ifaill</i>[<i>i</i> - 1] and <i>ifaill</i>[<i>i</i>] are set to the same value. A similar rule holds for <i>vr</i> and <i>ifailr</i>.</p> <p>The array <i>ifaill</i> is not referenced if <i>side</i> = 'R'. The array <i>ifailr</i> is not referenced if <i>side</i> = 'L'.</p>

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, then *i* eigenvectors (as indicated by the parameters *ifaill* and/or *ifailr* above) failed to converge. The corresponding columns of *vl* and/or *vr* contain no useful information.

## Application Notes

Each computed right eigenvector  $x_i$  is the exact eigenvector of a nearby matrix  $A + E_i$ , such that  $\|E_i\| < O(\epsilon) \|A\|$ . Hence the residual is small:

$$\|Ax_i - \lambda_i x_i\| = O(\epsilon) \|A\|.$$

However, eigenvectors corresponding to close or coincident eigenvalues may not accurately span the relevant subspaces.

Similar remarks apply to computed left eigenvectors.

*?strevc*

*Computes selected eigenvectors of an upper (quasi-) triangular matrix computed by ?hseqr.*

## Description

The routine computes some or all of the right and/or left eigenvectors of an upper triangular matrix  $T$  (or, for real flavors, an upper quasi-triangular matrix  $T$ ). Matrices of this type are produced by the Schur factorization of a general matrix:  $A = Q^* T^* Q^H$ , as computed by [hseqr](#).

The right eigenvector  $x$  and the left eigenvector  $y$  of  $T$  corresponding to an eigenvalue  $w$ , are defined by:

$$T^* x = w^* x, y^H T = w^* y^H, \text{ where } y^H \text{ denotes the conjugate transpose of } y.$$

The eigenvalues are not input to this routine, but are read directly from the diagonal blocks of  $T$ .

This routine returns the matrices  $X$  and/or  $Y$  of right and left eigenvectors of  $T$ , or the products  $Q^* X$  and/or  $Q^* Y$ , where  $Q$  is an input matrix.

If  $Q$  is the orthogonal/unitary factor that reduces a matrix  $A$  to Schur form  $T$ , then  $Q^* X$  and  $Q^* Y$  are the matrices of right and left eigenvectors of  $A$ .

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>side</i>	Must be 'R' or 'L' or 'B'. If <i>side</i> = 'R', then only right eigenvectors are computed.

If *side* = 'L', then only left eigenvectors are computed.

If *side* = 'B', then all eigenvectors are computed.

*howmny*

Must be 'A' or 'B' or 'S'.

If *howmny* = 'A', then all eigenvectors (as specified by *side*) are computed.

If *howmny* = 'B', then all eigenvectors (as specified by *side*) are computed and backtransformed by the matrices supplied in *vl* and *vr*.

If *howmny* = 'S', then selected eigenvectors (as specified by *side* and *select*) are computed.

*select*

Array, size at least  $\max(1, n)$ .

If *howmny* = 'S', *select* specifies which eigenvectors are to be computed.

If *howmny* = 'A' or 'B', *select* is not referenced.

*For real flavors:*

If *omega*[*j*] is a real eigenvalue, the corresponding real eigenvector is computed if *select*[*j*] is 1.

If *omega*[*j* - 1] and *omega*[*j*] are the real and imaginary parts of a complex eigenvalue, the corresponding complex eigenvector is computed if either *select*[*j* - 1] or *select*[*j*] is 1, and on exit *select*[*j* - 1] is set to 1 and *select*[*j*] is set to 0.

*For complex flavors:*

The eigenvector corresponding to the *j*-th eigenvalue is computed if *select*[*j* - 1] is 1.

*n*

The order of the matrix *T* ( $n \geq 0$ ).

*t, vl, vr*

Arrays:

*t* (size  $\max(1, ldt * n)$ ) contains the *n*-by-*n* matrix *T* in Schur canonical form. For complex flavors *ctrevc* and *ztrevc*, contains the upper triangular matrix *T*.

*vl* (size  $\max(1, ldvl * mm)$  for column major layout and  $\max(1, ldvl * n)$  for row major layout)

If *howmny* = 'B' and *side* = 'L' or 'B', then *vl* must contain an *n*-by-*n* matrix *Q* (usually the matrix of Schur vectors returned by *?hseqr*).

If *howmny* = 'A' or 'S', then *vl* need not be set.

The array *vl* is not referenced if *side* = 'R'.

*vr* (size  $\max(1, ldvr * mm)$  for column major layout and  $\max(1, ldvr * n)$  for row major layout)

If *howmny* = 'B' and *side* = 'R' or 'B', then *vr* must contain an *n*-by-*n* matrix *Q* (usually the matrix of Schur vectors returned by *?hseqr*). .

If *howmny* = 'A' or 'S', then *vr* need not be set.

The array *vr* is not referenced if *side* = 'L'.

<code>ldt</code>	The leading dimension of <code>t</code> ; at least $\max(1, n)$ .
<code>ldvl</code>	The leading dimension of <code>vl</code> . If <code>side = 'L' or 'B'</code> , $ldvl \geq n$ . If <code>side = 'R'</code> , $ldvl \geq 1$ .
<code>ldvr</code>	The leading dimension of <code>vr</code> . If <code>side = 'R' or 'B'</code> , $ldvr \geq n$ . If <code>side = 'L'</code> , $ldvr \geq 1$ .
<code>mm</code>	The number of columns in the arrays <code>vl</code> and/or <code>vr</code> . Must be at least $m$ (the precise number of columns required). If <code>howmny = 'A' or 'B'</code> , $mm = n$ . If <code>howmny = 'S'</code> : for real flavors, $mm$ is obtained by counting 1 for each selected real eigenvector and 2 for each selected complex eigenvector; for complex flavors, $mm$ is the number of selected eigenvectors (see <code>select</code> ). Constraint: $0 \leq mm \leq n$ .

## Output Parameters

<code>select</code>	If a complex eigenvector of a real matrix was selected as specified above, then <code>select[j]</code> is set to 1 and <code>select[j + 1]</code> to 0
<code>t</code>	<code>ctrevc/ztrevc</code> modify the <code>t</code> array, which is restored on exit.
<code>vl, vr</code>	If <code>side = 'L' or 'B'</code> , <code>vl</code> contains the computed left eigenvectors (as specified by <code>howmny</code> and <code>select</code> ). If <code>side = 'R' or 'B'</code> , <code>vr</code> contains the computed right eigenvectors (as specified by <code>howmny</code> and <code>select</code> ). The eigenvectors treated column-wise form a rectangular $n$ -by- $mm$ matrix. <i>For real flavors</i> : a real eigenvector corresponding to a real eigenvalue occupies one column of the matrix; a complex eigenvector corresponding to a complex eigenvalue occupies two columns: the first column holds the real part of the eigenvector and the second column holds the imaginary part of the eigenvector. The matrix is stored in a one-dimensional array as described by <code>matrix_layout</code> (using either column major or row major layout).
<code>m</code>	<i>For complex flavors</i> : the number of selected eigenvectors. If <code>howmny = 'A' or 'B'</code> , $m$ is set to $n$ . <i>For real flavors</i> : the number of columns of <code>vl</code> and/or <code>vr</code> actually used to store the selected eigenvectors. If <code>howmny = 'A' or 'B'</code> , $m$ is set to $n$ .

## Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, the *i*-th parameter had an illegal value.

## Application Notes

If  $x_i$  is an exact right eigenvector and  $y_i$  is the corresponding computed eigenvector, then the angle  $\theta(y_i, x_i)$  between them is bounded as follows:  $\theta(y_i, x_i) \leq (c(n)\epsilon \|T\|_2) / \text{sep}_i$  where  $\text{sep}_i$  is the reciprocal condition number of  $x_i$ . The condition number  $\text{sep}_i$  may be computed by calling `?trsna`.

### ?trevc3

Computes selected eigenvectors of an upper (quasi-) triangular matrix computed by `?hseqr` using Level 3

BLAS

---

## Syntax

```

## Include Files

- `mkl.fi`

## Description

This routine computes some or all of the right and left eigenvectors of an upper triangular matrix  $T$  (or, for real flavors, an upper quasi-triangular matrix  $T$ ) using Level 3 BLAS. Matrices of this type are produced by the Schur factorization of a general matrix:  $A = Q^*T^*QH$ , as computed by `hseqr`.

The right eigenvector  $x$  and the left eigenvector  $y$  of  $T$  corresponding to an eigenvalue  $w$  are defined by the following:

$$T^*x = w^*x, \quad y^H T = w^*y^H$$

where  $y^H$  denotes the conjugate transpose of  $y$ .

The eigenvalues are not passed to this routine but are read directly from the diagonal blocks of  $T$ .

This routine returns one or both of the matrices  $X$  and  $Y$  of the right and left eigenvectors of  $T$ , or one or both of the products  $Q^*X$  and  $Q^*Y$ , where  $Q$  is an input matrix.

If  $Q$  is the orthogonal/unitary factor that reduces a matrix  $A$  to Schur form  $T$ , then  $Q^*X$  and  $Q^*Y$  are the matrices of the right and left eigenvectors of  $A$ .

## Input Parameters

*side*

CHARACTER\*1

Must be 'R', 'L', or 'B'.

- If `side = 'R'`, only right eigenvectors are computed.
- If `side = 'L'`, only left eigenvectors are computed.

	<ul style="list-style-type: none"> <li>• If <i>side</i> = 'B', all eigenvectors are computed.</li> </ul>
<i>howmny</i>	<p>CHARACTER*1</p> <p>Must be 'A', 'B', or 'S'.</p> <ul style="list-style-type: none"> <li>• If <i>howmny</i> = 'A', all eigenvectors (as specified by <i>side</i>) are computed.</li> <li>• If <i>howmny</i> = 'B', all eigenvectors (as specified by <i>side</i>) are computed and back-transformed by the matrices supplied in <i>vl</i> and <i>vr</i>.</li> <li>• If <i>howmny</i> = 'S', selected eigenvectors (as specified by <i>side</i> and <i>select</i>) are computed.</li> </ul>
<i>select</i>	<p>Array with a size of at least <math>\max(1, n)</math></p> <p>If <i>howmny</i> = 'S', <i>select</i> specifies which eigenvectors are to be computed. If <i>howmny</i> = 'A' or <i>howmny</i> = 'B', <i>select</i> is not referenced.</p> <p>For real flavors:</p> <ul style="list-style-type: none"> <li>• If <math>\omega(j)</math> is a real eigenvalue and <i>select</i>(<i>j</i>) is .TRUE., the corresponding real eigenvector is computed.</li> <li>• If <math>\omega(j)</math> and <math>\omega(j + 1)</math> are the real and imaginary parts of a complex eigenvalue and either <i>select</i>(<i>j</i>) or <i>select</i>(<i>j + 1</i>) is .TRUE., the corresponding complex eigenvector is computed, and on exit <i>select</i>(<i>j</i>) is set to .TRUE. and <i>select</i>(<i>j + 1</i>) is set to .FALSE..</li> </ul> <p>For complex flavors:</p> <ul style="list-style-type: none"> <li>• If <i>select</i>(<i>j</i>) is .TRUE., the eigenvector corresponding to the <i>j</i><sup>th</sup> eigenvalue is computed.</li> </ul>
<i>n</i>	<p>INTEGER</p> <p>The order of the matrix <i>T</i> (<math>n \geq 0</math>).</p>
<i>t, vl, vr, work</i>	<ul style="list-style-type: none"> <li>• REAL for <i>strevc3</i></li> <li>• DOUBLE PRECISION for <i>dtrevc3</i></li> <li>• COMPLEX for <i>ctrevc3</i></li> <li>• DOUBLE COMPLEX for <i>ztrevc3</i></li> </ul> <p>Arrays:</p> <ul style="list-style-type: none"> <li>• <i>t</i>(<i>ldt</i>,*) contains the <i>n</i>-by-<i>n</i> matrix <i>T</i> in Schur canonical form. For complex flavors <i>ctrevc3</i> and <i>ztrevc3</i>, the array contains the upper triangular matrix <i>T</i>. The second dimension of <i>t</i> must be at least <math>\max(1, n)</math>.</li> <li>• <i>vl</i>(<i>ldvl</i>,*) If <i>howmny</i> = 'B' and <i>side</i> = 'L' or 'B', then <i>vl</i> must contain an <i>n</i>-by-<i>n</i> matrix <i>Q</i> (usually the matrix of Schur vectors returned by ?hseqr). If <i>howmny</i> = 'A' or 'S', <i>vl</i> need not be set.</li> </ul>

The second dimension of  $vl$  must be at least  $\max(1, mm)$  if  $side = 'L'$  or  $'B'$ , and at least 1 if  $side = 'R'$ .

The array  $vl$  is not referenced if  $side = 'R'$ .

- $vr(ldvr, *)$

If  $howmny = 'B'$  and  $side = 'R'$  or  $'B'$ ,  $vr$  must contain an  $n$ -by- $n$  matrix  $Q$  (usually the matrix of Schur vectors returned by `?hseqr`).

If  $howmny = 'A'$  or  $'S'$ ,  $vr$  need not be set.

The second dimension of  $vr$  must be at least  $\max(1, mm)$  if  $side = 'R'$  or  $'B'$ , and at least 1 if  $side = 'L'$ .

The array  $vr$  is not referenced if  $side = 'L'$ .

- $work(*)$  is a workspace array, and its dimension is  $\max(1, lwork)$ .

$lwork$

INTEGER

The size of the work array. Must be at least  $\max(1, 3*n)$  for real flavors, and at least  $\max(1, 2*n)$  for complex flavors.

If  $lwork = -1$ , a workspace query is assumed; the routine calculates only the optimal size of the work array and returns this value as the first entry of the work array, and no error message related to  $lwork$  is issued by xerbla. For details, see "Application Notes" below.

$ldt$

INTEGER

The leading dimension of  $t$ . It is at least  $\max(1, n)$ .

$ldvl$

INTEGER

The leading dimension of  $vl$ .

- If  $side = 'L'$  or  $'B'$ ,  $ldvl \geq n$ .
- If  $side = 'R'$ ,  $ldvl \geq 1$ .

$ldvr$

INTEGER

The leading dimension of  $vr$ .

- If  $side = 'R'$  or  $'B'$ ,  $ldvr \geq n$ .
- If  $side = 'L'$ ,  $ldvr \geq 1$ .

$mm$

INTEGER

The number of columns in one or both of the arrays  $vl$  and  $vr$ . Must be at least  $m$  (the precise number of columns required).

- If  $howmny = 'A'$  or  $'B'$ ,  $mm = n$ .
- If  $howmny = 'S'$ : for real flavors,  $mm$  is obtained by counting 1 for each selected real eigenvector and 2 for each selected complex eigenvector; for complex flavors,  $mm$  is the number of selected eigenvectors (see `select`).

Constraint:  $0 \leq mm \leq n$ .

$rwork$

- REAL for `ctrevc3`

- DOUBLE PRECISION for `ztrevc3`

The workspace array is used in complex flavors only. Its dimension is  $\max(1, lrwork)$ .

*lrwork*

INTEGER

The size of the *rwork* array. It must be at least  $\max(1, n)$ .

If *lrwork* = -1, a workspace query is assumed; the routine calculates only the optimal size of the work array and returns this value as the first entry of the *rwork* array, and no error message related to *lrwork* is issued by xerbla. For details, see "Application Notes" below.

## Output Parameters

*select*

If a complex eigenvector of a real matrix was selected as specified above, then `select(j)` is set to `.TRUE.` and `select(j + 1)` is set to `.FALSE.`.

*t*

COMPLEX for `ctrevc3`

DOUBLE COMPLEX for `ztrevc3`

`ctrevc3` or `ztrevc3` modifies the `t(ldt,*)` array, which is restored on exit.

*vl, vr*

If *side* = 'L' or 'B', *vl* contains the computed left eigenvectors (as specified by *howmny* and *select*).

If *side* = 'R' or 'B', *vr* contains the computed right eigenvectors (as specified by *howmny* and *select*).

Treated column-wise, the eigenvectors form a rectangular *n*-by-*mm* matrix.

---

**For real flavors** A real eigenvector corresponding to a real eigenvalue occupies one column of the matrix; a complex eigenvector corresponding to a complex eigenvalue occupies two columns. The first column holds the real part of the eigenvector, and the second column holds the imaginary part of the eigenvector. The matrix is stored in a one-dimensional array as described by `matrix_layout` (using either column major or row major layout).

---

*m*

INTEGER

---

**For complex flavors** The number of selected eigenvectors. If *howmny* = 'A' or 'B', *m* is set to *n*.

---

---

**For real flavors** The number of columns of one or both of *vl* and *vr* actually used to store the selected eigenvectors. If *howmny* = 'A' or 'B', *m* is set to *n*.

---

<code>work(l)</code>	On exit, if <code>info = 0</code> , <code>work(l)</code> returns the required optimal size of <code>lwork</code> .
<code>rwork(l)</code>	On exit, if <code>info = 0</code> , then <code>rwork(l)</code> returns the required optimal size of <code>lrwork</code> .
<code>info</code>	INTEGER If <code>info = 0</code> , the execution is successful. If <code>info = -i</code> , the $i^{\text{th}}$ parameter contained an illegal value.

## Application Notes

If  $x_i$  is an exact right eigenvector and  $y_i$  is the corresponding computed eigenvector, the angle  $\theta(y_i, x_i)$  between them is bounded as follows:

$$\theta(y_i, x_i) \leq (c(n) \varepsilon \|T\|_2) / \text{sepi}$$

where  $\text{sepi}$  is the reciprocal condition number of  $x_i$ . You can compute the condition number  $\text{sepi}$  by calling `?trsna`.

## Description

The routine estimates condition numbers for specified eigenvalues and/or right eigenvectors of an upper triangular matrix  $T$  (or, for real flavors, upper quasi-triangular matrix  $T$  in canonical Schur form). These are the same as the condition numbers of the eigenvalues and right eigenvectors of an original matrix  $A = Z^* T^* Z^H$  (with unitary or, for real flavors, orthogonal  $Z$ ), from which  $T$  may have been derived.

The routine computes the reciprocal of the condition number of an eigenvalue  $\lambda_i$  as  $s_i = |v^{T*}u| / (||u||_E ||v||_E)$  for real flavors and  $s_i = |v^{H*}u| / (||u||_E ||v||_E)$  for complex flavors,

where:

- $u$  and  $v$  are the right and left eigenvectors of  $T$ , respectively, corresponding to  $\lambda_i$ .
- $v^T/v^H$  denote transpose/conjugate transpose of  $v$ , respectively.

This reciprocal condition number always lies between zero (ill-conditioned) and one (well-conditioned).

An approximate error estimate for a computed eigenvalue  $\lambda_i$  is then given by  $\epsilon^* ||T|| / s_i$ , where  $\epsilon$  is the *machine precision*.

To estimate the reciprocal of the condition number of the right eigenvector corresponding to  $\lambda_i$ , the routine first calls [trexc](#) to reorder the diagonal elements of matrix  $T$  so that  $\lambda_i$  is in the leading position:

$$T = Q \begin{bmatrix} \lambda_i & C^H \\ 0 & T_{22} \end{bmatrix} Q^H$$

The reciprocal condition number of the eigenvector is then estimated as  $sep_i$ , the smallest singular value of the matrix  $T_{22} - \lambda_i I$ .

An approximate error estimate for a computed right eigenvector  $u$  corresponding to  $\lambda_i$  is then given by  $\epsilon^* ||T|| / sep_i$ .

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>job</code>	Must be 'E' or 'V' or 'B'. If <code>job = 'E'</code> , then condition numbers for eigenvalues only are computed. If <code>job = 'V'</code> , then condition numbers for eigenvectors only are computed. If <code>job = 'B'</code> , then condition numbers for both eigenvalues and eigenvectors are computed.
<code>howmny</code>	Must be 'A' or 'S'. If <code>howmny = 'A'</code> , then the condition numbers for all eigenpairs are computed. If <code>howmny = 'S'</code> , then condition numbers for selected eigenpairs (as specified by <code>select</code> ) are computed.

<i>select</i>	<p>Array, size at least <math>\max(1, n)</math> if <i>howmny</i> = 'S' and at least 1 otherwise.</p> <p>Specifies the eigenpairs for which condition numbers are to be computed if <i>howmny</i> = 'S'.</p> <p><i>For real flavors:</i></p> <p>To select condition numbers for the eigenpair corresponding to the real eigenvalue <math>\lambda_j</math>, <i>select</i>[<i>j</i>] must be set 1;</p> <p>to select condition numbers for the eigenpair corresponding to a complex conjugate pair of eigenvalues <math>\lambda_j</math> and <math>\lambda_{j+1}</math>, <i>select</i>[<i>j</i> - 1] and/or <i>select</i>[<i>j</i>] must be set 1</p> <p><i>For complex flavors</i></p> <p>To select condition numbers for the eigenpair corresponding to the eigenvalue <math>\lambda_j</math>, <i>select</i>[<i>j</i>] must be set 1 <i>select</i> is not referenced if <i>howmny</i> = 'A'.</p>
<i>n</i>	The order of the matrix <i>T</i> ( $n \geq 0$ ).
<i>t, vl, vr</i>	<p>Arrays:</p> <p><i>t</i> (size <math>\max(1, ldt * n)</math>) contains the <i>n</i>-by-<i>n</i> matrix <i>T</i>.</p> <p><i>vl</i> (size <math>\max(1, ldvl * mm)</math> for column major layout and <math>\max(1, ldvl * n)</math> for row major layout)</p> <p>If <i>job</i> = 'E' or 'B', then <i>vl</i> must contain the left eigenvectors of <i>T</i> (or of any matrix <math>Q * T * Q^H</math> with <i>Q</i> unitary or orthogonal) corresponding to the eigenpairs specified by <i>howmny</i> and <i>select</i>. The eigenvectors must be stored in consecutive columns of <i>vl</i>, as returned by <a href="#">trevc</a> or <a href="#">hsein</a>.</p> <p>The array <i>vl</i> is not referenced if <i>job</i> = 'V'.</p> <p><i>vr</i> (size <math>\max(1, ldvr * mm)</math> for column major layout and <math>\max(1, ldvr * n)</math> for row major layout)</p> <p>If <i>job</i> = 'E' or 'B', then <i>vr</i> must contain the right eigenvectors of <i>T</i> (or of any matrix <math>Q * T * Q^H</math> with <i>Q</i> unitary or orthogonal) corresponding to the eigenpairs specified by <i>howmny</i> and <i>select</i>. The eigenvectors must be stored in consecutive columns of <i>vr</i>, as returned by <a href="#">trevc</a> or <a href="#">hsein</a>.</p> <p>The array <i>vr</i> is not referenced if <i>job</i> = 'V'.</p>
<i>ldt</i>	The leading dimension of <i>t</i> ; at least $\max(1, n)$ .
<i>ldvl</i>	<p>The leading dimension of <i>vl</i>.</p> <p>If <i>job</i> = 'E' or 'B', <math>ldvl \geq \max(1, n)</math> for column major layout and <math>ldvl \geq \max(1, mm)</math> for row major layout .</p> <p>If <i>job</i> = 'V', <math>ldvl \geq 1</math>.</p>
<i>ldvr</i>	<p>The leading dimension of <i>vr</i>.</p> <p>If <i>job</i> = 'E' or 'B', <math>ldvr \geq \max(1, n)</math> for column major layout and <math>ldvr \geq \max(1, mm)</math> for row major layout .</p> <p>If <i>job</i> = 'R', <math>ldvr \geq 1</math>.</p>

*mm* The number of elements in the arrays *s* and *sep*, and the number of columns in *vl* and *vr* (if used). Must be at least *m* (the precise number required).

If *howmny* = 'A',  $mm = n$ ;

if *howmny* = 'S', for *real flavors* *mm* is obtained by counting 1 for each selected real eigenvalue and 2 for each selected complex conjugate pair of eigenvalues.

for *complex flavors* *mm* is the number of selected eigenpairs (see *select*).  
Constraint:  
 $0 \leq mm \leq n$ .

## Output Parameters

*s* Array, size at least  $\max(1, mm)$  if *job* = 'E' or 'B' and at least 1 if *job* = 'V'.  
Contains the reciprocal condition numbers of the selected eigenvalues if *job* = 'E' or 'B', stored in consecutive elements of the array. Thus *s*[*j* - 1], *sep*[*j* - 1] and the *j*-th columns of *vl* and *vr* all correspond to the same eigenpair (but not in general the *j* th eigenpair unless all eigenpairs have been selected).  
For *real flavors*: for a complex conjugate pair of eigenvalues, two consecutive elements of *s* are set to the same value. The array *s* is not referenced if *job* = 'V'.

*sep* Array, size at least  $\max(1, mm)$  if *job* = 'V' or 'B' and at least 1 if *job* = 'E'. Contains the estimated reciprocal condition numbers of the selected right eigenvectors if *job* = 'V' or 'B', stored in consecutive elements of the array.  
For *real flavors*: for a complex eigenvector, two consecutive elements of *sep* are set to the same value; if the eigenvalues cannot be reordered to compute *sep*[*j* - 1], then *sep*[*j* - 1] is set to zero; this can only occur when the true value would be very small anyway. The array *sep* is not referenced if *job* = 'E'.

*m* For *complex flavors*: the number of selected eigenpairs.  
If *howmny* = 'A', *m* is set to *n*.  
For *real flavors*: the number of elements of *s* and/or *sep* actually used to store the estimated condition numbers.  
If *howmny* = 'A', *m* is set to *n*.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

## Application Notes

The computed values *sep<sub>i</sub>* may overestimate the true value, but seldom by a factor of more than 3.

?trexc

Reorders the Schur factorization of a general matrix.

## Syntax

```
lapack_int LAPACKE_strexc( int matrix_layout, char compq, lapack_int n, float* t,
lapack_int ldt, float* q, lapack_int ldq, lapack_int* ifst, lapack_int* ilst );

lapack_int LAPACKE_dtrexc( int matrix_layout, char compq, lapack_int n, double* t,
lapack_int ldt, double* q, lapack_int ldq, lapack_int* ifst, lapack_int* ilst );

lapack_int LAPACKE_ctrexc( int matrix_layout, char compq, lapack_int n,
lapack_complex_float* t, lapack_int ldt, lapack_complex_float* q, lapack_int ldq,
lapack_int ifst, lapack_int ilst );

lapack_int LAPACKE_ztrexc( int matrix_layout, char compq, lapack_int n,
lapack_complex_double* t, lapack_int ldt, lapack_complex_double* q, lapack_int ldq,
lapack_int ifst, lapack_int ilst );
```

## Include Files

- mkl.h

## Description

The routine reorders the Schur factorization of a general matrix  $A = Q^*T^*Q^H$ , so that the diagonal element or block of  $T$  with row index  $ifst$  is moved to row  $ilst$ .

The reordered Schur form  $S$  is computed by an unitary (or, for real flavors, orthogonal) similarity transformation:  $S = Z^H * T * Z$ . Optionally the updated matrix  $P$  of Schur vectors is computed as  $P = Q * Z$ , giving  $A = P * S * P^H$ .

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>compq</i>	Must be 'V' or 'N'. If <i>compq</i> = 'V', then the Schur vectors ( $Q$ ) are updated. If <i>compq</i> = 'N', then no Schur vectors are updated.
<i>n</i>	The order of the matrix $T$ ( $n \geq 0$ ).
<i>t, q</i>	Arrays: <i>t</i> (size $\max(1, ldt * n)$ ) contains the $n$ -by- $n$ matrix $T$ . <i>q</i> (size $\max(1, ldq * n)$ ) If <i>compq</i> = 'V', then <i>q</i> must contain $Q$ (Schur vectors). If <i>compq</i> = 'N', then <i>q</i> is not referenced.
<i>ldt</i>	The leading dimension of <i>t</i> ; at least $\max(1, n)$ .
<i>ldq</i>	The leading dimension of <i>q</i> ; If <i>compq</i> = 'N', then $ldq \geq 1$ . If <i>compq</i> = 'V', then $ldq \geq \max(1, n)$ .
<i>ifst, ilst</i>	$1 \leq ifst \leq n$ ; $1 \leq ilst \leq n$ .

Must specify the reordering of the diagonal elements (or blocks, which is possible for real flavors) of the matrix  $T$ . The element (or block) with row index  $ifst$  is moved to row  $ilst$  by a sequence of exchanges between adjacent elements (or blocks).

## Output Parameters

$t$	Overwritten by the updated matrix $S$ .
$q$	If $compq = 'V'$ , $q$ contains the updated matrix of Schur vectors.
$ifst, ilst$	Overwritten for real flavors only. If $ifst$ pointed to the second row of a 2 by 2 block on entry, it is changed to point to the first row; $ilst$ always points to the first row of the block in its final position (which may differ from its input value by $\pm 1$ ).

## Return Values

This function returns a value  $info$ .

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

## Application Notes

The computed matrix  $S$  is exactly similar to a matrix  $T+E$ , where  $\|E\|_2 = O(\epsilon) * \|T\|_2$ , and  $\epsilon$  is the machine precision.

Note that if a 2 by 2 diagonal block is involved in the re-ordering, its off-diagonal elements are in general changed; the diagonal elements and the eigenvalues of the block are unchanged unless the block is sufficiently ill-conditioned, in which case they may be noticeably altered. It is possible for a 2 by 2 block to break into two 1 by 1 blocks, that is, for a pair of complex eigenvalues to become purely real.

The approximate number of floating-point operations is

for real flavors:	$6n(ifst-ilst)$ if $compq = 'N'$ ; $12n(ifst-ilst)$ if $compq = 'V'$ ;
for complex flavors:	$20n(ifst-ilst)$ if $compq = 'N'$ ; $40n(ifst-ilst)$ if $compq = 'V'$ .

### ?trsen

*Reorders the Schur factorization of a matrix and (optionally) computes the reciprocal condition numbers for the selected cluster of eigenvalues and respective invariant subspace.*

## Syntax

```
lapack_int LAPACKE_strsen( int matrix_layout, char job, char compq, const
lapack_logical* select, lapack_int n, float* t, lapack_int ldt, float* q, lapack_int
ldq, float* wr, float* wi, lapack_int* m, float* s, float* sep );
```

```
lapack_int LAPACKE_dtrsen( int matrix_layout, char job, char compq, const
lapack_logical* select, lapack_int n, double* t, lapack_int ldt, double* q, lapack_int
ldq, double* wr, double* wi, lapack_int* m, double* s, double* sep );
```

```
lapack_int LAPACKE_ctrssen( int matrix_layout, char job, char compq, const
lapack_logical* select, lapack_int n, lapack_complex_float* t, lapack_int ldt,
lapack_complex_float* q, lapack_int ldq, lapack_complex_float* w, lapack_int* m, float*
s, float* sep );
```

```
lapack_int LAPACKE_ztrssen( int matrix_layout, char job, char compq, const
lapack_logical* select, lapack_int n, lapack_complex_double* t, lapack_int ldt,
lapack_complex_double* q, lapack_int ldq, lapack_complex_double* w, lapack_int* m,
double* s, double* sep );
```

## Include Files

- mkl.h

## Description

The routine reorders the Schur factorization of a general matrix  $A = Q^*T^*Q^T$  (for real flavors) or  $A = Q^*T^*Q^H$  (for complex flavors) so that a selected cluster of eigenvalues appears in the leading diagonal elements (or, for real flavors, diagonal blocks) of the Schur form. The reordered Schur form  $R$  is computed by a unitary (orthogonal) similarity transformation:  $R = Z^H * T * Z$ . Optionally the updated matrix  $P$  of Schur vectors is computed as  $P = Q * Z$ , giving  $A = P * R * P^H$ .

Let

$$R = \begin{bmatrix} T_{11} & T_{12} \\ 0 & T_{13} \end{bmatrix}$$

where the selected eigenvalues are precisely the eigenvalues of the leading  $m$ -by- $m$  submatrix  $T_{11}$ . Let  $P$  be correspondingly partitioned as  $(Q_1 Q_2)$  where  $Q_1$  consists of the first  $m$  columns of  $Q$ . Then  $A^* Q_1 = Q_1^* T_{11}$ , and so the  $m$  columns of  $Q_1$  form an orthonormal basis for the invariant subspace corresponding to the selected cluster of eigenvalues.

Optionally the routine also computes estimates of the reciprocal condition numbers of the average of the cluster of eigenvalues and of the invariant subspace.

## Input Parameters

*matrix\_layout* Specifies whether matrix storage layout is row major (LAPACK\_ROW\_MAJOR) or column major (LAPACK\_COL\_MAJOR).

*job* Must be 'N' or 'E' or 'V' or 'B'.

If *job* = 'N', then no condition numbers are required.

If  $job = 'E'$ , then only the condition number for the cluster of eigenvalues is computed.

If  $job = 'V'$ , then only the condition number for the invariant subspace is computed.

If  $job = 'B'$ , then condition numbers for both the cluster and the invariant subspace are computed.

*compq*

Must be 'V' or 'N'.

If  $compq = 'V'$ , then  $Q$  of the Schur vectors is updated.

If  $compq = 'N'$ , then no Schur vectors are updated.

*select*

Array, size at least  $\max(1, n)$ .

Specifies the eigenvalues in the selected cluster. To select an eigenvalue  $\lambda_j$ ,  $select[j]$  must be 1

*For real flavors:* to select a complex conjugate pair of eigenvalues  $\lambda_j$  and  $\lambda_{j+1}$  (corresponding 2 by 2 diagonal block),  $select[j - 1]$  and/or  $select[j]$  must be 1; the complex conjugate  $\lambda_j$  and  $\lambda_{j+1}$  must be either both included in the cluster or both excluded.

*n*

The order of the matrix  $T$  ( $n \geq 0$ ).

*t, q*

Arrays:

$t$  (size  $\max(1, ldt * n)$ ) The upper quasi-triangular  $n$ -by- $n$  matrix  $T$ , in Schur canonical form.

$q$  (size  $\max(1, ldq * n)$ )

If  $compq = 'V'$ , then  $q$  must contain the matrix  $Q$  of Schur vectors.

If  $compq = 'N'$ , then  $q$  is not referenced.

*ldt*

The leading dimension of  $t$ ; at least  $\max(1, n)$ .

*ldq*

The leading dimension of  $q$ ;

If  $compq = 'N'$ , then  $ldq \geq 1$ .

If  $compq = 'V'$ , then  $ldq \geq \max(1, n)$ .

## Output Parameters

*t*

Overwritten by the reordered matrix  $R$  in Schur canonical form with the selected eigenvalues in the leading diagonal blocks.

*q*

If  $compq = 'V'$ ,  $q$  contains the updated matrix of Schur vectors; the first  $m$  columns of the  $Q$  form an orthogonal basis for the specified invariant subspace.

*w*

Array, size at least  $\max(1, n)$ . The recorded eigenvalues of  $R$ . The eigenvalues are stored in the same order as on the diagonal of  $R$ .

$wr, wi$	Arrays, size at least $\max(1, n)$ . Contain the real and imaginary parts, respectively, of the reordered eigenvalues of $R$ . The eigenvalues are stored in the same order as on the diagonal of $R$ . Note that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.
$m$	<p><i>For complex flavors:</i> the dimension of the specified invariant subspaces, which is the same as the number of selected eigenvalues (see <i>select</i>).</p> <p><i>For real flavors:</i> the dimension of the specified invariant subspace. The value of <math>m</math> is obtained by counting 1 for each selected real eigenvalue and 2 for each selected complex conjugate pair of eigenvalues (see <i>select</i>).</p> <p>Constraint: <math>0 \leq m \leq n</math>.</p>
$s$	<p>If <math>job = 'E'</math> or <math>'B'</math>, <math>s</math> is a lower bound on the reciprocal condition number of the average of the selected cluster of eigenvalues.</p> <p>If <math>m = 0</math> or <math>n</math>, then <math>s = 1</math>.</p> <p><i>For real flavors:</i> if <math>info = 1</math>, then <math>s</math> is set to zero. <math>s</math> is not referenced if <math>job = 'N'</math> or <math>'V'</math>.</p>
$sep$	<p>If <math>job = 'V'</math> or <math>'B'</math>, <math>sep</math> is the estimated reciprocal condition number of the specified invariant subspace.</p> <p>If <math>m = 0</math> or <math>n</math>, then <math>sep =  T </math>.</p> <p><i>For real flavors:</i> if <math>info = 1</math>, then <math>sep</math> is set to zero.</p> <p><math>sep</math> is not referenced if <math>job = 'N'</math> or <math>'E'</math>.</p>

## Return Values

This function returns a value  $info$ .

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = 1$ , the reordering of  $T$  failed because some eigenvalues are too close to separate (the problem is very ill-conditioned);  $T$  may have been partially reordered, and  $wr$  and  $wi$  contain the eigenvalues in the same order as in  $T$ ;  $s$  and  $sep$  (if requested) are set to zero.

## Application Notes

The computed matrix  $R$  is exactly similar to a matrix  $T+E$ , where  $\|E\|_2 = O(\epsilon) * \|T\|_2$ , and  $\epsilon$  is the machine precision. The computed  $s$  cannot underestimate the true reciprocal condition number by more than a factor of  $(\min(m, n-m))_{1/2}$ ;  $sep$  may differ from the true value by  $(m*n-m^2)_{1/2}$ . The angle between the computed invariant subspace and the true subspace is  $O(\epsilon) * \|A\|_2 / sep$ . Note that if a 2-by-2 diagonal block is involved in the re-ordering, its off-diagonal elements are in general changed; the diagonal elements and the eigenvalues of the block are unchanged unless the block is sufficiently ill-conditioned, in which case they may be noticeably altered. It is possible for a 2-by-2 block to break into two 1-by-1 blocks, that is, for a pair of complex eigenvalues to become purely real.

?trsyl

*Solves Sylvester equation for real quasi-triangular or complex triangular matrices.*

## Description

The routine solves the Sylvester matrix equation  $\text{op}(A) * X \pm X * \text{op}(B) = \alpha * C$ , where  $\text{op}(A) = A$  or  $A^H$ , and the matrices  $A$  and  $B$  are upper triangular (or, for real flavors, upper quasi-triangular in canonical Schur form);  $\alpha \leq 1$  is a scale factor determined by the routine to avoid overflow in  $X$ ;  $A$  is  $m$ -by- $m$ ,  $B$  is  $n$ -by- $n$ , and  $C$  and  $X$  are both  $m$ -by- $n$ . The matrix  $X$  is obtained by a straightforward process of back substitution.

The equation has a unique solution if and only if  $\alpha_i \pm \beta_j \neq 0$ , where  $\{\alpha_i\}$  and  $\{\beta_j\}$  are the eigenvalues of  $A$  and  $B$ , respectively, and the sign (+ or -) is the same as that used in the equation to be solved.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>trana</i>	Must be 'N' or 'T' or 'C'. If <i>trana</i> = 'N', then $\text{op}(A) = A$ . If <i>trana</i> = 'T', then $\text{op}(A) = A^T$ (real flavors only). If <i>trana</i> = 'C' then $\text{op}(A) = A^H$ .
<i>tranb</i>	Must be 'N' or 'T' or 'C'. If <i>tranb</i> = 'N', then $\text{op}(B) = B$ . If <i>tranb</i> = 'T', then $\text{op}(B) = B^T$ (real flavors only). If <i>tranb</i> = 'C', then $\text{op}(B) = B^H$ .
<i>isgn</i>	Indicates the form of the Sylvester equation. If <i>isgn</i> = +1, $\text{op}(A) * X + X * \text{op}(B) = \text{alpha} * C$ . If <i>isgn</i> = -1, $\text{op}(A) * X - X * \text{op}(B) = \text{alpha} * C$ .

$m$	The order of $A$ , and the number of rows in $X$ and $C$ ( $m \geq 0$ ).
$n$	The order of $B$ , and the number of columns in $X$ and $C$ ( $n \geq 0$ ).
$a, b, c$	Arrays: $a$ (size $\max(1, lda * m)$ ) contains the matrix $A$ . $b$ (size $\max(1, ldb * n)$ ) contains the matrix $B$ . $c$ (size $\max(1, ldc * n)$ for column major layout and $\max(1, ldc * m)$ for row major layout) contains the matrix $C$ .
$lda$	The leading dimension of $a$ ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.
$ldb$	The leading dimension of $b$ ; at least $\max(1, n)$ .
$ldc$	The leading dimension of $c$ ; at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout .

## Output Parameters

$c$	Overwritten by the solution matrix $X$ .
$scale$	The value of the scale factor $\alpha$ .

## Return Values

This function returns a value *info*.

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = 1$ ,  $A$  and  $B$  have common or close eigenvalues; perturbed values were used to solve the equation.

## Application Notes

Let  $X$  be the exact,  $Y$  the corresponding computed solution, and  $R$  the residual matrix:  $R = C - (AY \pm YB)$ . Then the residual is always small:

$$\|R\|_F = O(\epsilon) * (\|A\|_F + \|B\|_F) * \|Y\|_F.$$

However,  $Y$  is not necessarily the exact solution of a slightly perturbed equation; in other words, the solution is not backwards stable.

For the forward error, the following bound holds:

$$\|Y - X\|_F \leq \|R\|_F / \text{sep}(A, B)$$

but this may be a considerable overestimate. See [Golub96] for a definition of  $\text{sep}(A, B)$ .

The approximate number of floating-point operations for real flavors is  $m * n * (m + n)$ . For complex flavors it is 4 times greater.

## Generalized Nonsymmetric Eigenvalue Problems: LAPACK Computational Routines

This topic describes LAPACK routines for solving generalized nonsymmetric eigenvalue problems, reordering the generalized Schur factorization of a pair of matrices, as well as performing a number of related computational tasks.

A *generalized nonsymmetric eigenvalue problem* is as follows: given a pair of nonsymmetric (or non-Hermitian)  $n$ -by- $n$  matrices  $A$  and  $B$ , find the *generalized eigenvalues*  $\lambda$  and the corresponding *generalized eigenvectors*  $x$  and  $y$  that satisfy the equations

$Ax = \lambda Bx$  (right generalized eigenvectors  $x$ )

and

$y^H A = \lambda y^H B$  (left generalized eigenvectors  $y$ ).

Table "Computational Routines for Solving Generalized Nonsymmetric Eigenvalue Problems" lists LAPACK routines used to solve the generalized nonsymmetric eigenvalue problems and the generalized Sylvester equation.

### Computational Routines for Solving Generalized Nonsymmetric Eigenvalue Problems

Routine name	Operation performed
ggghrd	Reduces a pair of matrices to generalized upper Hessenberg form using orthogonal/unitary transformations.
ggbal	Balances a pair of general real or complex matrices.
ggbak	Forms the right or left eigenvectors of a generalized eigenvalue problem.
ggghd3	Reduces a pair of matrices to generalized upper Hessenberg form.
hgeqz	Implements the QZ method for finding the generalized eigenvalues of the matrix pair (H,T).
tgevc	Computes some or all of the right and/or left generalized eigenvectors of a pair of upper triangular matrices
tgexc	Reorders the generalized Schur decomposition of a pair of matrices (A,B) so that one diagonal block of (A,B) moves to another row index.
tggen	Reorders the <i>generalized</i> Schur decomposition of a pair of matrices (A,B) so that a selected cluster of eigenvalues appears in the leading diagonal blocks of (A,B).
tgsyl	Solves the generalized Sylvester equation.
tgsyl	Estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a pair of matrices in generalized real Schur canonical form.

?ggghrd

*Reduces a pair of matrices to generalized upper Hessenberg form using orthogonal/unitary transformations.*

## Description

The routine reduces a pair of real/complex matrices ( $A, B$ ) to generalized upper Hessenberg form using orthogonal/unitary transformations, where  $A$  is a general matrix and  $B$  is upper triangular. The form of the generalized eigenvalue problem is  $A^*x = \lambda^*B^*x$ , and  $B$  is typically made upper triangular by computing its  $QR$  factorization and moving the orthogonal matrix  $Q$  to the left side of the equation.

This routine simultaneously reduces  $A$  to a Hessenberg matrix  $H$ :

$$Q^H A Z = H$$

and transforms  $B$  to another upper triangular matrix  $T$ :

$$Q^H B Z = T$$

in order to reduce the problem to its standard form  $H^*y = \lambda^*T^*y$ , where  $y = Z^H x$ .

The orthogonal/unitary matrices  $Q$  and  $Z$  are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices  $Q_1$  and  $Z_1$ , so that

$$Q_1^* A Z_1^H = (Q_1^* Q)^* H^* (Z_1^* Z)^H$$

$$Q_1^* B Z_1^H = (Q_1^* Q)^* T^* (Z_1^* Z)^H$$

If  $Q_1$  is the orthogonal/unitary matrix from the  $QR$  factorization of  $B$  in the original equation  $A^*x = \lambda^*B^*x$ , then the routine `?ggghrd` reduces the original problem to generalized Hessenberg form.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>compq</i>	Must be 'N', 'I', or 'V'. If <i>compq</i> = 'N', matrix $Q$ is not computed. If <i>compq</i> = 'I', $Q$ is initialized to the unit matrix, and the orthogonal/unitary matrix $Q$ is returned; If <i>compq</i> = 'V', $Q$ must contain an orthogonal/unitary matrix $Q_1$ on entry, and the product $Q_1^*Q$ is returned.
<i>compz</i>	Must be 'N', 'I', or 'V'. If <i>compz</i> = 'N', matrix $Z$ is not computed. If <i>compz</i> = 'I', $Z$ is initialized to the unit matrix, and the orthogonal/unitary matrix $Z$ is returned; If <i>compz</i> = 'V', $Z$ must contain an orthogonal/unitary matrix $Z_1$ on entry, and the product $Z_1^*Z$ is returned.
<i>n</i>	The order of the matrices $A$ and $B$ ( $n \geq 0$ ).

<i>ilo, ihi</i>	<p><i>ilo</i> and <i>ihi</i> mark the rows and columns of <i>A</i> which are to be reduced. It is assumed that <i>A</i> is already upper triangular in rows and columns 1:<i>ilo</i>-1 and <i>ihi</i>+1:<i>n</i>. Values of <i>ilo</i> and <i>ihi</i> are normally set by a previous call to <a href="#">ggbal</a>; otherwise they should be set to 1 and <i>n</i> respectively.</p> <p>Constraint:</p> <p>If <math>n &gt; 0</math>, then <math>1 \leq ilo \leq ihi \leq n</math>;</p> <p>if <math>n = 0</math>, then <math>ilo = 1</math> and <math>ihi = 0</math>.</p>
<i>a, b, q, z</i>	<p>Arrays:</p> <p><i>a</i> (size <math>\max(1, lda * n)</math>) contains the <i>n</i>-by-<i>n</i> general matrix <i>A</i>.</p> <p><i>b</i> (size <math>\max(1, ldb * n)</math>) contains the <i>n</i>-by-<i>n</i> upper triangular matrix <i>B</i>.</p> <p><i>q</i> (size <math>\max(1, ldq * n)</math>)</p> <p>If <i>compq</i> = 'N', then <i>q</i> is not referenced.</p> <p>If <i>compq</i> = 'V', then <i>q</i> must contain the orthogonal/unitary matrix <math>Q_1</math>, typically from the QR factorization of <i>B</i>.</p> <p><i>z</i> (size <math>\max(1, ldz * n)</math>)</p> <p>If <i>compz</i> = 'N', then <i>z</i> is not referenced.</p> <p>If <i>compz</i> = 'V', then <i>z</i> must contain the orthogonal/unitary matrix <math>Z_1</math>.</p>
<i>lda</i>	The leading dimension of <i>a</i> ; at least $\max(1, n)$ .
<i>ldb</i>	The leading dimension of <i>b</i> ; at least $\max(1, n)$ .
<i>ldq</i>	<p>The leading dimension of <i>q</i>;</p> <p>If <i>compq</i> = 'N', then <math>ldq \geq 1</math>.</p> <p>If <i>compq</i> = 'I' or 'V', then <math>ldq \geq \max(1, n)</math>.</p>
<i>ldz</i>	<p>The leading dimension of <i>z</i>;</p> <p>If <i>compz</i> = 'N', then <math>ldz \geq 1</math>.</p> <p>If <i>compz</i> = 'I' or 'V', then <math>ldz \geq \max(1, n)</math>.</p>

## Output Parameters

<i>a</i>	On exit, the upper triangle and the first subdiagonal of <i>A</i> are overwritten with the upper Hessenberg matrix <i>H</i> , and the rest is set to zero.
<i>b</i>	On exit, overwritten by the upper triangular matrix $T = Q^H * B * Z$ . The elements below the diagonal are set to zero.
<i>q</i>	<p>If <i>compq</i> = 'I', then <i>q</i> contains the orthogonal/unitary matrix <i>Q</i> ;</p> <p>If <i>compq</i> = 'V', then <i>q</i> is overwritten by the product <math>Q_1 * Q</math>.</p>
<i>z</i>	<p>If <i>compz</i> = 'I', then <i>z</i> contains the orthogonal/unitary matrix <i>Z</i>;</p> <p>If <i>compz</i> = 'V', then <i>z</i> is overwritten by the product <math>Z_1 * Z</math>.</p>

## Return Values

This function returns a value *info*.

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

*?ggbal*

Balances a pair of general real or complex matrices.

## Syntax

```
lapack_int LAPACKE_sggbal( int matrix_layout, char job, lapack_int n, float* a,

lapack_int* ilo, lapack_int* ihi, double* lscale, double* rscale );
```

## Include Files

- mkl.h

## Description

The routine balances a pair of general real/complex matrices ( $A, B$ ). This involves, first, permuting  $A$  and  $B$  by similarity transformations to isolate eigenvalues in the first 1 to  $ilo-1$  and last  $ihi+1$  to  $n$  elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns  $ilo$  to  $ihi$  to make the rows and columns as close in norm as possible. Both steps are optional. Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem  $A*x = \lambda*B*x$ .

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>job</i>	Specifies the operations to be performed on $A$ and $B$ . Must be 'N' or 'P' or 'S' or 'B'.  If $job = 'N'$ , then no operations are done; simply set $ilo = 1, ihi = n, lscale[i] = 1.0$ and $rscale[i] = 1.0$ for $i = 0, \dots, n - 1$ .  If $job = 'P'$ , then permute only.  If $job = 'S'$ , then scale only.  If $job = 'B'$ , then both permute and scale.
<i>n</i>	The order of the matrices $A$ and $B$ ( $n \geq 0$ ).

<i>a, b</i>	Arrays: <i>a</i> (size $\max(1, lda*n)$ ) contains the matrix <i>A</i> . <i>b</i> (size $\max(1, ldb*n)$ ) contains the matrix <i>B</i> . If <i>job</i> = 'N', <i>a</i> and <i>b</i> are not referenced.
<i>lda</i>	The leading dimension of <i>a</i> ; at least $\max(1, n)$ .
<i>ldb</i>	The leading dimension of <i>b</i> ; at least $\max(1, n)$ .

## Output Parameters

<i>a, b</i>	Overwritten by the balanced matrices <i>A</i> and <i>B</i> , respectively.
<i>ilo, ihi</i>	<i>ilo</i> and <i>ihi</i> are set to integers such that on exit $A_{i,j} = 0$ and $B_{i,j} = 0$ if $i > j$ and $j = 1, \dots, ilo-1$ or $i = ihi+1, \dots, n$ . If <i>job</i> = 'N' or 'S', then <i>ilo</i> = 1 and <i>ihi</i> = <i>n</i> .
<i>lscale, rscale</i>	Arrays, size at least $\max(1, n)$ . <i>lscale</i> contains details of the permutations and scaling factors applied to the left side of <i>A</i> and <i>B</i> . If $P_j$ is the index of the row interchanged with row <i>j</i> , and $D_j$ is the scaling factor applied to row <i>j</i> , then $lscale[j - 1] = P_j, \text{ for } j = 1, \dots, ilo-1$ $= D_j, \text{ for } j = ilo, \dots, ihi$ $= P_j, \text{ for } j = ihi+1, \dots, n.$ <i>rscale</i> contains details of the permutations and scaling factors applied to the right side of <i>A</i> and <i>B</i> . If $P_j$ is the index of the column interchanged with column <i>j</i> , and $D_j$ is the scaling factor applied to column <i>j</i> , then $rscale[j - 1] = P_j, \text{ for } j = 1, \dots, ilo-1$ $= D_j, \text{ for } j = ilo, \dots, ihi$ $= P_j, \text{ for } j = ihi+1, \dots, n$ The order in which the interchanges are made is <i>n</i> to <i>ihi+1</i> , then 1 to <i>ilo-1</i> .

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

*?ggbak*

*Forms the right or left eigenvectors of a generalized eigenvalue problem.*

## Description

The routine forms the right or left eigenvectors of a real/complex generalized eigenvalue problem

$$A*x = \lambda*B*x$$

by backward transformation on the computed eigenvectors of the balanced pair of matrices output by [ggbal](#).

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>job</i>	Specifies the type of backward transformation required. Must be 'N', 'P', 'S', or 'B'. If <i>job</i> = 'N', then no operations are done; return. If <i>job</i> = 'P', then do backward transformation for permutation only. If <i>job</i> = 'S', then do backward transformation for scaling only. If <i>job</i> = 'B', then do backward transformation for both permutation and scaling. This argument must be the same as the argument <i>job</i> supplied to <a href="#">?ggbal</a> .
<i>side</i>	Must be 'L' or 'R'. If <i>side</i> = 'L', then <i>v</i> contains left eigenvectors. If <i>side</i> = 'R', then <i>v</i> contains right eigenvectors.
<i>n</i>	The number of rows of the matrix <i>V</i> ( $n \geq 0$ ).
<i>ilo, ihi</i>	The integers <i>ilo</i> and <i>ihi</i> determined by <a href="#">?ggbal</a> . Constraint: If $n > 0$ , then $1 \leq ilo \leq ihi \leq n$ ; if $n = 0$ , then $ilo = 1$ and $ihi = 0$ .

<i>lscale, rscale</i>	Arrays, size at least $\max(1, n)$ . The array <i>lscale</i> contains details of the permutations and/or scaling factors applied to the left side of <i>A</i> and <i>B</i> , as returned by <code>?ggbal</code> . The array <i>rscale</i> contains details of the permutations and/or scaling factors applied to the right side of <i>A</i> and <i>B</i> , as returned by <code>?ggbal</code> .
<i>m</i>	The number of columns of the matrix <i>V</i> ( $m \geq 0$ ).
<i>v</i>	Array <i>v</i> (size $\max(1, ldv*m)$ for column major layout and $\max(1, ldv*n)$ for row major layout) . Contains the matrix of right or left eigenvectors to be transformed, as returned by <code>tgevc</code> .
<i>ldv</i>	The leading dimension of <i>v</i> ; at least $\max(1, n)$ for column major layout and at least $\max(1, m)$ for row major layout .

## Output Parameters

<i>v</i>	Overwritten by the transformed eigenvectors
----------	---

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = *-i*, the *i*-th parameter had an illegal value.

### ?gghd3

## Description

?gghd3 reduces a pair of real or complex matrices ( $A$ ,  $B$ ) to generalized upper Hessenberg form using orthogonal/unitary transformations, where  $A$  is a general matrix and  $B$  is upper triangular. The form of the generalized eigenvalue problem is

$$A*x = \lambda*B*x,$$

and  $B$  is typically made upper triangular by computing its QR factorization and moving the orthogonal/unitary matrix  $Q$  to the left side of the equation.

This subroutine simultaneously reduces  $A$  to a Hessenberg matrix  $H$ :

$$Q^T*A*Z = H \text{ for real flavors}$$

or

$$Q^T*A*Z = H \text{ for complex flavors}$$

and transforms  $B$  to another upper triangular matrix  $T$ :

$$Q^T*B*Z = T \text{ for real flavors}$$

or

$$Q^T*B*Z = T \text{ for complex flavors}$$

in order to reduce the problem to its standard form

$$H*y = \lambda*T*y$$

where  $y = Z^T*x$  for real flavors

or

$$y = Z^T*x \text{ for complex flavors.}$$

The orthogonal/unitary matrices  $Q$  and  $Z$  are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices  $Q_1$  and  $Z_1$ , so that

for real flavors:

$$Q_1 * A * Z_1^T = (Q_1 * Q) * H * (Z_1 * Z)^T$$

$$Q_1 * B * Z_1^T = (Q_1 * Q) * T * (Z_1 * Z)^T$$

for complex flavors:

$$Q_1 * A * Z_1^H = (Q_1 * Q) * H * (Z_1 * Z)^T$$

$$Q_1 * B * Z_1^T = (Q_1 * Q) * T * (Z_1 * Z)^T$$

If  $Q_1$  is the orthogonal/unitary matrix from the QR factorization of  $B$  in the original equation  $A*x = \lambda*B*x$ , then ?gghd3 reduces the original problem to generalized Hessenberg form.

This is a blocked variant of ?gghrd, using matrix-matrix multiplications for parts of the computation to enhance performance.

## Input Parameters

*matrix\_layout* Specifies whether matrix storage layout is row major (LAPACK\_ROW\_MAJOR) or column major (LAPACK\_COL\_MAJOR).

*compq* = 'N': do not compute  $q$ ;  
 = 'I':  $q$  is initialized to the unit matrix, and the orthogonal/unitary matrix  $Q$  is returned;

	= 'V': $q$ must contain an orthogonal/unitary matrix $Q_1$ on entry, and the product $Q_1 * q$ is returned.
<i>compz</i>	= 'N': do not compute $z$ ; = 'I': $z$ is initialized to the unit matrix, and the orthogonal/unitary matrix $Z$ is returned; = 'V': $z$ must contain an orthogonal/unitary matrix $Z_1$ on entry, and the product $Z_1 * z$ is returned.
<i>n</i>	The order of the matrices $A$ and $B$ . $n \geq 0$ .
<i>ilo, ihi</i>	$ilo$ and $ihi$ mark the rows and columns of $a$ which are to be reduced. It is assumed that $a$ is already upper triangular in rows and columns $1:ilo - 1$ and $ihi + 1:n$ . $ilo$ and $ihi$ are normally set by a previous call to ?ggbal; otherwise they should be set to 1 and $n$ , respectively. $1 \leq ilo \leq ihi \leq n$ , if $n > 0$ ; $ilo=1$ and $ihi=0$ , if $n=0$ .
<i>a</i>	Array, size ( $lda * n$ ). On entry, the $n$ -by- $n$ general matrix to be reduced.
<i>lda</i>	The leading dimension of the array $a$ . $lda \geq \max(1, n)$ .
<i>b</i>	Array, ( $ldb * n$ ). On entry, the $n$ -by- $n$ upper triangular matrix $B$ .
<i>ldb</i>	The leading dimension of the array $b$ . $ldb \geq \max(1, n)$ .
<i>q</i>	Array, size ( $ldq * n$ ). On entry, if <i>compq</i> = 'V', the orthogonal/unitary matrix $Q_1$ , typically from the QR factorization of $b$ .
<i>ldq</i>	The leading dimension of the array $q$ . $ldq \geq n$ if <i>compq</i> ='V' or 'I'; $ldq \geq 1$ otherwise.
<i>z</i>	Array, size ( $ldz * n$ ). On entry, if <i>compz</i> = 'V', the orthogonal/unitary matrix $Z_1$ . Not referenced if <i>compz</i> ='N'.
<i>ldz</i>	The leading dimension of the array $z$ . $ldz \geq n$ if <i>compz</i> ='V' or 'I'; $ldz \geq 1$ otherwise.

## Output Parameters

<i>a</i>	On exit, the upper triangle and the first subdiagonal of $a$ are overwritten with the upper Hessenberg matrix $H$ , and the rest is set to zero.
----------	--

<i>b</i>	On exit, the upper triangular matrix $T = Q^T B Z$ for real flavors or $T = Q^H B Z$ for complex flavors. The elements below the diagonal are set to zero.
<i>q</i>	On exit, if <i>compq</i> ='I', the orthogonal/unitary matrix <i>Q</i> , and if <i>compq</i> ='V', the product $Q_1 * Q$ . Not referenced if <i>compq</i> ='N'.
<i>z</i>	On exit, if <i>compz</i> ='I', the orthogonal/unitary matrix <i>Z</i> , and if <i>compz</i> ='V', the product $Z_1 * Z$ . Not referenced if <i>compz</i> ='N'.

## Return Values

This function returns a value *info*.

= 0: successful exit.

< 0: if *info* = -*i*, the *i*-th argument had an illegal value.

## Application Notes

This routine reduces *A* to Hessenberg form and maintains *B* in using a blocked variant of Moler and Stewart's original algorithm, as described by Kagstrom, Kressner, Quintana-Orti, and Quintana-Orti (BIT 2008).

### ?hgeqz

*Implements the QZ method for finding the generalized eigenvalues of the matrix pair (H,T).*

## Description

The routine computes the eigenvalues of a real/complex matrix pair  $(H,T)$ , where  $H$  is an upper Hessenberg matrix and  $T$  is upper triangular, using the double-shift version (for real flavors) or single-shift version (for complex flavors) of the  $QZ$  method. Matrix pairs of this type are produced by the reduction to generalized upper Hessenberg form of a real/complex matrix pair  $(A,B)$ :

$$A = Q_1^* H^* Z_1^H, B = Q_1^* T^* Z_1^H,$$

as computed by `?gghrd`.

*For real flavors:*

If `job = 'S'`, then the Hessenberg-triangular pair  $(H,T)$  is reduced to generalized Schur form,

$$H = Q^* S^* Z^T, T = Q^* P^* Z^T,$$

where  $Q$  and  $Z$  are orthogonal matrices,  $P$  is an upper triangular matrix, and  $S$  is a quasi-triangular matrix with 1-by-1 and 2-by-2 diagonal blocks. The 1-by-1 blocks correspond to real eigenvalues of the matrix pair  $(H,T)$  and the 2-by-2 blocks correspond to complex conjugate pairs of eigenvalues.

Additionally, the 2-by-2 upper triangular diagonal blocks of  $P$  corresponding to 2-by-2 blocks of  $S$  are reduced to positive diagonal form, that is, if  $S_{j+1,j}$  is non-zero, then  $P_{j+1,j} = P_{j,j+1} = 0$ ,  $P_{j,j} > 0$ , and  $P_{j+1,j+1} > 0$ .

*For complex flavors:*

If `job = 'S'`, then the Hessenberg-triangular pair  $(H,T)$  is reduced to generalized Schur form,

$$H = Q^* S^* Z^H, T = Q^* P^* Z^H,$$

where  $Q$  and  $Z$  are unitary matrices, and  $S$  and  $P$  are upper triangular.

*For all function flavors:*

Optionally, the orthogonal/unitary matrix  $Q$  from the generalized Schur factorization may be post-multiplied by an input matrix  $Q_1$ , and the orthogonal/unitary matrix  $Z$  may be post-multiplied by an input matrix  $Z_1$ .

If  $Q_1$  and  $Z_1$  are the orthogonal/unitary matrices from `?gghrd` that reduced the matrix pair  $(A,B)$  to generalized upper Hessenberg form, then the output matrices  $Q_1 Q$  and  $Z_1 Z$  are the orthogonal/unitary factors from the generalized Schur factorization of  $(A,B)$ :

$$A = (Q_1 Q)^* S^* (Z_1 Z)^H, B = (Q_1 Q)^* P^* (Z_1 Z)^H.$$

To avoid overflow, eigenvalues of the matrix pair  $(H,T)$  (equivalently, of  $(A,B)$ ) are computed as a pair of values  $(\alpha, \beta)$ . For `chgeqz/zhgeqz`,  $\alpha$  and  $\beta$  are complex, and for `shgeqz/dhgeqz`,  $\alpha$  is complex and  $\beta$  real. If  $\beta$  is nonzero,  $\lambda = \alpha/\beta$  is an eigenvalue of the generalized nonsymmetric eigenvalue problem (GNEP)

$$A^* x = \lambda^* B^* x$$

and if  $\alpha$  is nonzero,  $\mu = \beta/\alpha$  is an eigenvalue of the alternate form of the GNEP

$$\mu^* A^* y = B^* y.$$

Real eigenvalues (for real flavors) or the values of  $\alpha$  and  $\beta$  for the  $i$ -th eigenvalue (for complex flavors) can be read directly from the generalized Schur form:

$$\alpha = S_{i,i}, \beta = P_{i,i}.$$

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>job</code>	Specifies the operations to be performed. Must be 'E' or 'S'.

	<p>If <i>job</i> = 'E', then compute eigenvalues only;</p> <p>If <i>job</i> = 'S', then compute eigenvalues and the Schur form.</p>
<i>compq</i>	<p>Must be 'N', 'I', or 'V'.</p> <p>If <i>compq</i> = 'N', left Schur vectors (<i>q</i>) are not computed;</p> <p>If <i>compq</i> = 'I', <i>q</i> is initialized to the unit matrix and the matrix of left Schur vectors of (<i>H,T</i>) is returned;</p> <p>If <i>compq</i> = 'V', <i>q</i> must contain an orthogonal/unitary matrix <math>Q_1</math> on entry and the product <math>Q_1*Q</math> is returned.</p>
<i>compz</i>	<p>Must be 'N', 'I', or 'V'.</p> <p>If <i>compz</i> = 'N', right Schur vectors (<i>z</i>) are not computed;</p> <p>If <i>compz</i> = 'I', <i>z</i> is initialized to the unit matrix and the matrix of right Schur vectors of (<i>H,T</i>) is returned;</p> <p>If <i>compz</i> = 'V', <i>z</i> must contain an orthogonal/unitary matrix <math>Z_1</math> on entry and the product <math>Z_1*Z</math> is returned.</p>
<i>n</i>	<p>The order of the matrices <i>H</i>, <i>T</i>, <i>Q</i>, and <i>Z</i></p> <p>(<math>n \geq 0</math>).</p>
<i>ilo, ihi</i>	<p><i>ilo</i> and <i>ihi</i> mark the rows and columns of <i>H</i> which are in Hessenberg form. It is assumed that <i>H</i> is already upper triangular in rows and columns 1:<i>ilo</i>-1 and <i>ihi</i>+1:<i>n</i>.</p> <p>Constraint:</p> <p>If <math>n &gt; 0</math>, then <math>1 \leq ilo \leq ihi \leq n</math>;</p> <p>if <math>n = 0</math>, then <math>ilo = 1</math> and <math>ihi = 0</math>.</p>
<i>h, t, q, z</i>	<p>Arrays:</p> <p>On entry, <i>h</i> (size <math>\max(1, ldh*n)</math>) contains the <i>n</i>-by-<i>n</i> upper Hessenberg matrix <i>H</i>.</p> <p>On entry, <i>t</i> (size <math>\max(1, ldt*n)</math>) contains the <i>n</i>-by-<i>n</i> upper triangular matrix <i>T</i>.</p> <p><i>q</i> (size <math>\max(1, ldq*n)</math>) :</p> <p>On entry, if <i>compq</i> = 'V', this array contains the orthogonal/unitary matrix <math>Q_1</math> used in the reduction of (<i>A,B</i>) to generalized Hessenberg form.</p> <p>If <i>compq</i> = 'N', then <i>q</i> is not referenced.</p> <p><i>z</i> (size <math>\max(1, ldz*n)</math>) :</p> <p>On entry, if <i>compz</i> = 'V', this array contains the orthogonal/unitary matrix <math>Z_1</math> used in the reduction of (<i>A,B</i>) to generalized Hessenberg form.</p> <p>If <i>compz</i> = 'N', then <i>z</i> is not referenced.</p>
<i>ldh</i>	The leading dimension of <i>h</i> ; at least $\max(1, n)$ .
<i>ldt</i>	The leading dimension of <i>t</i> ; at least $\max(1, n)$ .
<i>ldq</i>	The leading dimension of <i>q</i> ;

If  $compq = 'N'$ , then  $ldq \geq 1$ .

If  $compq = 'I'$  or  $'V'$ , then  $ldq \geq \max(1, n)$ .

$ldz$  The leading dimension of  $z$ ;

If  $compq = 'N'$ , then  $ldz \geq 1$ .

If  $compq = 'I'$  or  $'V'$ , then  $ldz \geq \max(1, n)$ .

## Output Parameters

$h$  *For real flavors:*

If  $job = 'S'$ , then on exit  $h$  contains the upper quasi-triangular matrix  $S$  from the generalized Schur factorization.

If  $job = 'E'$ , then on exit the diagonal blocks of  $h$  match those of  $S$ , but the rest of  $h$  is unspecified.

*For complex flavors:*

If  $job = 'S'$ , then, on exit,  $h$  contains the upper triangular matrix  $S$  from the generalized Schur factorization.

If  $job = 'E'$ , then on exit the diagonal of  $h$  matches that of  $S$ , but the rest of  $h$  is unspecified.

$t$  If  $job = 'S'$ , then, on exit,  $t$  contains the upper triangular matrix  $P$  from the generalized Schur factorization.

*For real flavors:*

2-by-2 diagonal blocks of  $P$  corresponding to 2-by-2 blocks of  $S$  are reduced to positive diagonal form, that is, if  $h(j+1,j)$  is non-zero, then  $t(j+1,j) = t(j,j+1) = 0$  and  $t(j,j)$  and  $t(j+1,j+1)$  will be positive.

If  $job = 'E'$ , then on exit the diagonal blocks of  $t$  match those of  $P$ , but the rest of  $t$  is unspecified.

*For complex flavors:*

if  $job = 'E'$ , then on exit the diagonal of  $t$  matches that of  $P$ , but the rest of  $t$  is unspecified.

$alphar, alphai$  Arrays, size at least  $\max(1, n)$ . The real and imaginary parts, respectively, of each scalar  $alpha$  defining an eigenvalue of GNEP.

If  $alphai[j - 1]$  is zero, then the  $j$ -th eigenvalue is real; if positive, then the  $j$ -th and  $(j+1)$ -th eigenvalues are a complex conjugate pair, with

$$alphai[j] = -alphai[j - 1].$$

$alpha$  Array, size at least  $\max(1, n)$ .

The complex scalars  $alpha$  that define the eigenvalues of GNEP.  $alphai[i - 1] = S_i$ ,  $i$  in the generalized Schur factorization.

$beta$  Array, size at least  $\max(1, n)$ .

*For real flavors:*

The scalars  $beta$  that define the eigenvalues of GNEP.

Together, the quantities  $\alpha = (\alpha_r[j - 1], \alpha_i[j - 1])$  and  $\beta = \beta[j - 1]$  represent the  $j$ -th eigenvalue of the matrix pair  $(A, B)$ , in one of the forms  $\lambda = \alpha/\beta$  or  $\mu = \beta/\alpha$ . Since either  $\lambda$  or  $\mu$  may overflow, they should not, in general, be computed.

*For complex flavors:*

The real non-negative scalars  $\beta$  that define the eigenvalues of GNEP.

$\beta[i - 1] = P_{i, i}$  in the generalized Schur factorization. Together, the quantities  $\alpha = \alpha[j - 1]$  and  $\beta = \beta[j - 1]$  represent the  $j$ -th eigenvalue of the matrix pair  $(A, B)$ , in one of the forms  $\lambda = \alpha/\beta$  or  $\mu = \beta/\alpha$ . Since either  $\lambda$  or  $\mu$  may overflow, they should not, in general, be computed.

$q$

On exit, if  $compq = 'I'$ ,  $q$  is overwritten by the orthogonal/unitary matrix of left Schur vectors of the pair  $(H, T)$ , and if  $compq = 'V'$ ,  $q$  is overwritten by the orthogonal/unitary matrix of left Schur vectors of  $(A, B)$ .

$z$

On exit, if  $compz = 'I'$ ,  $z$  is overwritten by the orthogonal/unitary matrix of right Schur vectors of the pair  $(H, T)$ , and if  $compz = 'V'$ ,  $z$  is overwritten by the orthogonal/unitary matrix of right Schur vectors of  $(A, B)$ .

## Return Values

This function returns a value  $info$ .

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = 1, \dots, n$ , the QZ iteration did not converge.

$(H, T)$  is not in Schur form, but  $\alpha_r[i - 1]$ ,  $\alpha_i[i - 1]$  (for real flavors),  $\alpha[i - 1]$  (for complex flavors), and  $\beta[i - 1]$ ,  $i=info+1, \dots, n$  should be correct.

If  $info = n+1, \dots, 2n$ , the shift calculation failed.

$(H, T)$  is not in Schur form, but  $\alpha_r[i - 1]$ ,  $\alpha_i[i - 1]$  (for real flavors),  $\alpha[i - 1]$  (for complex flavors), and  $\beta[i - 1]$ ,  $i = info-n+1, \dots, n$  should be correct.

?tgevc

*Computes some or all of the right and/or left generalized eigenvectors of a pair of upper triangular matrices.*

## Description

The routine computes some or all of the right and/or left eigenvectors of a pair of real/complex matrices  $(S,P)$ , where  $S$  is quasi-triangular (for real flavors) or upper triangular (for complex flavors) and  $P$  is upper triangular.

Matrix pairs of this type are produced by the generalized Schur factorization of a real/complex matrix pair  $(A,B)$ :

$$A = Q^* S^* Z^H, B = Q^* P^* Z^H$$

as computed by ?gghrd plus ?hgeqz.

The right eigenvector  $x$  and the left eigenvector  $y$  of  $(S,P)$  corresponding to an eigenvalue  $w$  are defined by:

$$S^* x = w^* P^* x, y^H S = w^* y^H P$$

The eigenvalues are not input to this routine, but are computed directly from the diagonal blocks or diagonal elements of  $S$  and  $P$ .

This routine returns the matrices  $X$  and/or  $Y$  of right and left eigenvectors of  $(S,P)$ , or the products  $Z^* X$  and/or  $Q^* Y$ , where  $Z$  and  $Q$  are input matrices.

If  $Q$  and  $Z$  are the orthogonal/unitary factors from the generalized Schur factorization of a matrix pair  $(A,B)$ , then  $Z^* X$  and  $Q^* Y$  are the matrices of right and left eigenvectors of  $(A,B)$ .

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>side</i>	Must be 'R', 'L', or 'B'. If <i>side</i> = 'R', compute right eigenvectors only. If <i>side</i> = 'L', compute left eigenvectors only. If <i>side</i> = 'B', compute both right and left eigenvectors.
<i>howmny</i>	Must be 'A', 'B', or 'S'. If <i>howmny</i> = 'A', compute all right and/or left eigenvectors. If <i>howmny</i> = 'B', compute all right and/or left eigenvectors, backtransformed by the matrices in <i>vr</i> and/or <i>vl</i> . If <i>howmny</i> = 'S', compute selected right and/or left eigenvectors, specified by the logical array <i>select</i> .

*select*Array, size at least  $\max(1, n)$ .If *howmny* = 'S', *select* specifies the eigenvectors to be computed.If *howmny* = 'A' or 'B', *select* is not referenced.*For real flavors:*If  $w[j]$  is a real eigenvalue, the corresponding real eigenvector is computed if *select*[*j*] is 1.If  $w[j]$  and  $\omega[j + 1]$  are the real and imaginary parts of a complex eigenvalue, the corresponding complex eigenvector is computed if either *select*[*j*] or *select*[*j* + 1] is 1, and on exit *select*[*j*] is set to 1 and *select*[*j* + 1] is set to 0.*For complex flavors:*The eigenvector corresponding to the *j*-th eigenvalue is computed if *select*[*j*] is 1.*n*The order of the matrices *S* and *P* ( $n \geq 0$ ).*s, p, vl, vr*

Arrays:

*s* (size  $\max(1, lds*n)$ ) contains the matrix *S* from a generalized Schur factorization as computed by ?hgeqz. This matrix is upper quasi-triangular for real flavors, and upper triangular for complex flavors.*p* (size  $\max(1, ldp*n)$ ) contains the upper triangular matrix *P* from a generalized Schur factorization as computed by ?hgeqz.For real flavors, 2-by-2 diagonal blocks of *P* corresponding to 2-by-2 blocks of *S* must be in positive diagonal form.For complex flavors, *P* must have real diagonal elements.If *side* = 'L' or 'B' and *howmny* = 'B', *vl* (size  $\max(1, ldvl*mm)$  for column major layout and  $\max(1, ldvl*n)$  for row major layout) must contain an *n*-by-*n* matrix *Q* (usually the orthogonal/unitary matrix *Q* of left Schur vectors returned by ?hgeqz).If *side* = 'R', *vl* is not referenced.If *side* = 'R' or 'B' and *howmny* = 'B', *vr* (size  $\max(1, ldvr*mm)$  for column major layout and  $\max(1, ldvr*n)$  for row major layout) must contain an *n*-by-*n* matrix *Z* (usually the orthogonal/unitary matrix *Z* of right Schur vectors returned by ?hgeqz).If *side* = 'L', *vr* is not referenced.*lds*The leading dimension of *s*; at least  $\max(1, n)$ .*ldp*The leading dimension of *p*; at least  $\max(1, n)$ .*ldvl*The leading dimension of *vl*;If *side* = 'L' or 'B', then  $ldvl \geq n$  for column major layout and  $ldvl \geq \max(1, mm)$  for row major layout.If *side* = 'R', then  $ldvl \geq 1$ .*ldvr*The leading dimension of *vr*;

If  $side = 'R'$  or  $'B'$ , then  $ldvr \geq n$  for column major layout and  $ldvr \geq \max(1, mm)$  for row major layout.

If  $side = 'L'$ , then  $ldvr \geq 1$ .

$mm$

The number of columns in the arrays  $vl$  and/or  $vr$  ( $mm \geq m$ ).

## Output Parameters

$vl$

On exit, if  $side = 'L'$  or  $'B'$ ,  $vl$  contains:

if  $howmny = 'A'$ , the matrix  $Y$  of left eigenvectors of  $(S,P)$ ;

if  $howmny = 'B'$ , the matrix  $Q*Y$ ;

if  $howmny = 'S'$ , the left eigenvectors of  $(S,P)$  specified by  $select$ , stored consecutively in the columns of  $vl$ , in the same order as their eigenvalues.

*For real flavors:*

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.

$vr$

On exit, if  $side = 'R'$  or  $'B'$ ,  $vr$  contains:

if  $howmny = 'A'$ , the matrix  $X$  of right eigenvectors of  $(S,P)$ ;

if  $howmny = 'B'$ , the matrix  $Z*X$ ;

if  $howmny = 'S'$ , the right eigenvectors of  $(S,P)$  specified by  $select$ , stored consecutively in the columns of  $vr$ , in the same order as their eigenvalues.

*For real flavors:*

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.

$m$

The number of columns in the arrays  $vl$  and/or  $vr$  actually used to store the eigenvectors.

If  $howmny = 'A'$  or  $'B'$ ,  $m$  is set to  $n$ .

*For real flavors:*

Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

*For complex flavors:*

Each selected eigenvector occupies one column.

## Return Values

This function returns a value  $info$ .

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

*For real flavors:*

if  $info = i > 0$ , the 2-by-2 block  $(i:i+1)$  does not have a complex eigenvalue.

## ?tgexc

Reorders the generalized Schur decomposition of a pair of matrices  $(A,B)$  so that one diagonal block of  $(A,B)$  moves to another row index.

### Syntax

```
lapack_int LAPACKE_stgexc (int matrix_layout, lapack_logical wantq, lapack_logical wantz, lapack_int n, float* a, lapack_int lda, float* b, lapack_int ldb, float* q, lapack_int ldq, float* z, lapack_int ldz, lapack_int* ifst, lapack_int* ilst);
```

```
lapack_int LAPACKE_dtgexc (int matrix_layout, lapack_logical wantq, lapack_logical wantz, lapack_int n, double* a, lapack_int lda, double* b, lapack_int ldb, double* q, lapack_int ldq, double* z, lapack_int ldz, lapack_int* ifst, lapack_int* ilst);
```

```
lapack_int LAPACKE_ctgexc (int matrix_layout, lapack_logical wantq, lapack_logical wantz, lapack_int n, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb, lapack_complex_float* q, lapack_int ldq, lapack_complex_float* z, lapack_int ldz, lapack_int ifst, lapack_int ilst);
```

```
lapack_int LAPACKE_ztgexc (int matrix_layout, lapack_logical wantq, lapack_logical wantz, lapack_int n, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb, lapack_complex_double* q, lapack_int ldq, lapack_complex_double* z, lapack_int ldz, lapack_int ifst, lapack_int ilst);
```

### Include Files

- mkl.h

### Description

The routine reorders the generalized real-Schur/Schur decomposition of a real/complex matrix pair  $(A,B)$  using an orthogonal/unitary equivalence transformation

$$(A, B) = Q * (A, B) * Z^H,$$

so that the diagonal block of  $(A, B)$  with row index *ifst* is moved to row *ilst*. Matrix pair  $(A, B)$  must be in a generalized real-Schur/Schur canonical form (as returned by [gges](#)), that is,  $A$  is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks and  $B$  is upper triangular. Optionally, the matrices  $Q$  and  $Z$  of generalized Schur vectors are updated.

$$Q_{in} * A_{in} * Z_{in}^T = Q_{out} * A_{out} * Z_{out}^T$$

$$Q_{in} * B_{in} * Z_{in}^T = Q_{out} * B_{out} * Z_{out}^T.$$

### Input Parameters

*matrix\_layout* Specifies whether matrix storage layout is row major (LAPACK\_ROW\_MAJOR) or column major (LAPACK\_COL\_MAJOR).

*wantq, wantz* If *wantq* = 1, update the left transformation matrix  $Q$ ;  
If *wantq* = 0, do not update  $Q$ ;  
If *wantz* = 1, update the right transformation matrix  $Z$ ;  
If *wantz* = 0, do not update  $Z$ .

*n* The order of the matrices  $A$  and  $B$  ( $n \geq 0$ ).

<i>a, b, q, z</i>	<p>Arrays:</p> <p><i>a</i> (size <math>\max(1, lda*n)</math>) contains the matrix <i>A</i>.</p> <p><i>b</i> (size <math>\max(1, ldb*n)</math>) contains the matrix <i>B</i>.</p> <p><i>q</i> (size at least 1 if <i>wantq</i> = 0 and at least <math>\max(1, ldq*n)</math> if <i>wantq</i> = 1)</p> <p>If <i>wantq</i> = 0, then <i>q</i> is not referenced.</p> <p>If <i>wantq</i> = 1, then <i>q</i> must contain the orthogonal/unitary matrix <i>Q</i>.</p> <p><i>z</i> (size at least 1 if <i>wantz</i> = 0 and at least <math>\max(1, ldz*n)</math> if <i>wantz</i> = 1)</p> <p>If <i>wantz</i> = 0, then <i>z</i> is not referenced.</p> <p>If <i>wantz</i> = 1, then <i>z</i> must contain the orthogonal/unitary matrix <i>Z</i>.</p>
<i>lda</i>	The leading dimension of <i>a</i> ; at least $\max(1, n)$ .
<i>ldb</i>	The leading dimension of <i>b</i> ; at least $\max(1, n)$ .
<i>ldq</i>	The leading dimension of <i>q</i> ;
	If <i>wantq</i> = 0, then $ldq \geq 1$ .
	If <i>wantq</i> = 1, then $ldq \geq \max(1, n)$ .
<i>ldz</i>	The leading dimension of <i>z</i> ;
	If <i>wantz</i> = 0, then $ldz \geq 1$ .
	If <i>wantz</i> = 1, then $ldz \geq \max(1, n)$ .
<i>ifst, ilst</i>	Specify the reordering of the diagonal blocks of ( <i>A</i> , <i>B</i> ). The block with row index <i>ifst</i> is moved to row <i>ilst</i> , by a sequence of swapping between adjacent blocks. Constraint: $1 \leq ifst, ilst \leq n$ .

## Output Parameters

<i>a, b, q, z</i>	Overwritten by the updated matrices <i>A</i> , <i>B</i> , <i>Q</i> , and <i>Z</i> respectively.
<i>ifst, ilst</i>	Overwritten for real flavors only.
	If <i>ifst</i> pointed to the second row of a 2 by 2 block on entry, it is changed to point to the first row; <i>ilst</i> always points to the first row of the block in its final position (which may differ from its input value by $\pm 1$ ).

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = 1, the transformed matrix pair (*A*, *B*) would be too far from generalized Schur form; the problem is ill-conditioned. (*A*, *B*) may have been partially reordered, and *ilst* points to the first row of the current position of the block being moved.

### ?tgsen

Reorders the generalized Schur decomposition of a pair of matrices  $(A,B)$  so that a selected cluster of eigenvalues appears in the leading diagonal blocks of  $(A,B)$ .

### Syntax

```

### Description

The routine reorders the generalized real-Schur/Schur decomposition of a real/complex matrix pair  $(A, B)$  (in terms of an orthogonal/unitary equivalence transformation  $Q^T(A, B)Z$  for real flavors or  $Q^H(A, B)Z$  for complex flavors), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair  $(A, B)$ . The leading columns of  $Q$  and  $Z$  form orthonormal/unitary bases of the corresponding left and right eigenspaces (deflating subspaces).

$(A, B)$  must be in generalized real-Schur/Schur canonical form (as returned by [gges](#)), that is,  $A$  and  $B$  are both upper triangular.

?tgsen also computes the generalized eigenvalues

$$\omega_j = (\text{alphar}(j) + \text{alphai}(j)*i)/\text{beta}(j) \text{ (for real flavors)}$$

$$\omega_j = \text{alpha}(j)/\text{beta}(j) \text{ (for complex flavors)}$$

of the reordered matrix pair  $(A, B)$ .

Optionally, the routine computes the estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are  $\text{Difu}[(A_{11}, B_{11}), (A_{22}, B_{22})]$  and  $\text{Difl}[(A_{11}, B_{11}), (A_{22}, B_{22})]$ , that is, the separation(s) between the matrix pairs  $(A_{11}, B_{11})$  and  $(A_{22}, B_{22})$  that correspond to the selected cluster and the eigenvalues outside the cluster, respectively, and norms of "projections" onto left and right eigenspaces with respect to the selected cluster in the (1,1)-block.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<i>ijob</i>	<p>Specifies whether condition numbers are required for the cluster of eigenvalues (<i>pl</i> and <i>pr</i>) or the deflating subspaces <code>Difu</code> and <code>Difl</code>.</p> <p>If <i>ijob</i> = 0, only reorder with respect to <i>select</i>;</p> <p>If <i>ijob</i> = 1, reciprocal of norms of "projections" onto left and right eigenspaces with respect to the selected cluster (<i>pl</i> and <i>pr</i>);</p> <p>If <i>ijob</i> = 2, compute upper bounds on <code>Difu</code> and <code>Difl</code>, using F-norm-based estimate (<i>dif</i> (1:2));</p> <p>If <i>ijob</i> = 3, compute estimate of <code>Difu</code> and <code>Difl</code>, using 1-norm-based estimate (<i>dif</i> (1:2)). This option is about 5 times as expensive as <i>ijob</i> = 2;</p> <p>If <i>ijob</i> = 4, compute <i>pl</i>, <i>pr</i> and <i>dif</i> (i.e., options 0, 1 and 2 above). This is an economic version to get it all;</p> <p>If <i>ijob</i> = 5, compute <i>pl</i>, <i>pr</i> and <i>dif</i> (i.e., options 0, 1 and 3 above).</p>
<i>wantq, wantz</i>	<p>If <i>wantq</i> = 1, update the left transformation matrix <i>Q</i>;</p> <p>If <i>wantq</i> = 0, do not update <i>Q</i>;</p> <p>If <i>wantz</i> = 1, update the right transformation matrix <i>Z</i>;</p> <p>If <i>wantz</i> = 0, do not update <i>Z</i>.</p>
<i>select</i>	<p>Array, size at least <math>\max(1, n)</math>. Specifies the eigenvalues in the selected cluster.</p> <p>To select an eigenvalue <math>\omega_j</math>, <i>select</i>[<i>j</i> - 1] must be 1. For real flavors: to select a complex conjugate pair of eigenvalues <math>\omega_j</math> and <math>\omega_{j+1}</math> (corresponding 2 by 2 diagonal block), <i>select</i>[<i>j</i> - 1] and/or <i>select</i>[<i>j</i>] must be set to 1; the complex conjugate <math>\omega_j</math> and <math>\omega_{j+1}</math> must be either both included in the cluster or both excluded.</p>
<i>n</i>	The order of the matrices <i>A</i> and <i>B</i> ( $n \geq 0$ ).
<i>a, b, q, z</i>	<p>Arrays:</p> <p><i>a</i> (size <math>\max(1, lda * n)</math>) contains the matrix <i>A</i>.</p> <p>For real flavors: <i>A</i> is upper quasi-triangular, with (<i>A</i>, <i>B</i>) in generalized real Schur canonical form.</p> <p>For complex flavors: <i>A</i> is upper triangular, in generalized Schur canonical form.</p> <p><i>b</i> (size <math>\max(1, ldb * n)</math>) contains the matrix <i>B</i>.</p> <p>For real flavors: <i>B</i> is upper triangular, with (<i>A</i>, <i>B</i>) in generalized real Schur canonical form.</p>

For complex flavors:  $B$  is upper triangular, in generalized Schur canonical form.

$q$  (size at least 1 if  $wantq = 0$  and at least  $\max(1, ldq*n)$  if  $wantq = 1$ )

If  $wantq = 1$ , then  $q$  is an  $n$ -by- $n$  matrix;

If  $wantq = 0$ , then  $q$  is not referenced.

$z$  (size at least 1 if  $wantz = 0$  and at least  $\max(1, ldz*n)$  if  $wantz = 1$ )

If  $wantz = 1$ , then  $z$  is an  $n$ -by- $n$  matrix;

If  $wantz = 0$ , then  $z$  is not referenced.

$lda$  The leading dimension of  $a$ ; at least  $\max(1, n)$ .

$ldb$  The leading dimension of  $b$ ; at least  $\max(1, n)$ .

$ldq$  The leading dimension of  $q$ ;  $ldq \geq 1$ .

If  $wantq = 1$ , then  $ldq \geq \max(1, n)$ .

$ldz$  The leading dimension of  $z$ ;  $ldz \geq 1$ .

If  $wantz = 1$ , then  $ldz \geq \max(1, n)$ .

## Output Parameters

$a, b$  Overwritten by the reordered matrices  $A$  and  $B$ , respectively.

$alphar, alphai$  Arrays, size at least  $\max(1, n)$ . Contain values that form generalized eigenvalues in real flavors.

See *beta*.

$alpha$  Array, size at least  $\max(1, n)$ . Contain values that form generalized eigenvalues in complex flavors.

See *beta*.

$beta$  Array, size at least  $\max(1, n)$ .

For real flavors:

On exit,  $(alphar[j] + alphai[j]*i)/beta[j]$ ,  $j=0, \dots, n-1$ , will be the generalized eigenvalues.

$alphar[j] + alphai[j]*i$  and  $beta[j]$ ,  $j=0, \dots, n-1$  are the diagonals of the complex Schur form  $(S, T)$  that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of  $(A, B)$  were further reduced to triangular form using complex unitary transformations.

If  $alphai[j-1]$  is zero, then the  $j$ -th eigenvalue is real; if positive, then the  $j$ -th and  $(j+1)$ -st eigenvalues are a complex conjugate pair, with  $alphai[j]$  negative.

For complex flavors:

The diagonal elements of  $A$  and  $B$ , respectively, when the pair  $(A, B)$  has been reduced to generalized Schur form.  $alpha[i]/beta[i]$ ,  $i=0, \dots, n-1$  are the generalized eigenvalues.

<i>q</i>	If <i>wantq</i> = 1, then, on exit, <i>Q</i> has been postmultiplied by the left orthogonal transformation matrix which reorder ( <i>A</i> , <i>B</i> ). The leading <i>m</i> columns of <i>Q</i> form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces).
<i>z</i>	If <i>wantz</i> = 1, then, on exit, <i>Z</i> has been postmultiplied by the left orthogonal transformation matrix which reorder ( <i>A</i> , <i>B</i> ). The leading <i>m</i> columns of <i>Z</i> form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces).
<i>m</i>	The dimension of the specified pair of left and right eigen-spaces (deflating subspaces); $0 \leq m \leq n$ .
<i>pl, pr</i>	If <i>ijob</i> = 1, 4, or 5, <i>pl</i> and <i>pr</i> are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspaces with respect to the selected cluster.  $0 < pl, pr \leq 1$ . If $m = 0$ or $m = n$ , $pl = pr = 1$ . If <i>ijob</i> = 0, 2 or 3, <i>pl</i> and <i>pr</i> are not referenced
<i>dif</i>	Array, size (2). If $ijob \geq 2$ , <i>dif</i> (1:2) store the estimates of <i>Difu</i> and <i>Difl</i> . If <i>ijob</i> = 2 or 4, <i>dif</i> (1:2) are F-norm-based upper bounds on <i>Difu</i> and <i>Difl</i> . If <i>ijob</i> = 3 or 5, <i>dif</i> (1:2) are 1-norm-based estimates of <i>Difu</i> and <i>Difl</i> . If $m = 0$ or $m = n$ , $dif(1:2) = F\text{-norm}([A, B])$ . If <i>ijob</i> = 0 or 1, <i>dif</i> is not referenced.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = 1, Reordering of (*A*, *B*) failed because the transformed matrix pair (*A*, *B*) would be too far from generalized Schur form; the problem is very ill-conditioned. (*A*, *B*) may have been partially reordered.

If *ijob* > 0, 0 is returned in *dif*, *pl* and *pr*.

## ?tgsyl

Solves the generalized Sylvester equation.

## Include Files

- mkl.h

## Description

The routine solves the generalized Sylvester equation:

$$A^*R - L^*B = scale^*C$$

$$D^*R - L^*E = scale^*F$$

where  $R$  and  $L$  are unknown  $m$ -by- $n$  matrices,  $(A, D)$ ,  $(B, E)$  and  $(C, F)$  are given matrix pairs of size  $m$ -by- $m$ ,  $n$ -by- $n$  and  $m$ -by- $n$ , respectively, with real/complex entries.  $(A, D)$  and  $(B, E)$  must be in generalized real-Schur/Schur canonical form, that is,  $A, B$  are upper quasi-triangular/triangular and  $D, E$  are upper triangular.

The solution  $(R, L)$  overwrites  $(C, F)$ . The factor  $scale$ ,  $0 \leq scale \leq 1$ , is an output scaling factor chosen to avoid overflow.

In matrix notation the above equation is equivalent to the following: solve  $Z^*x = scale^*b$ , where  $Z$  is defined as

$$Z = \begin{pmatrix} kron(I_n, A) & -kron(B^T, I_m) \\ kron(I_n, D) & -kron(E^T, I_m) \end{pmatrix}$$

Here  $I_k$  is the identity matrix of size  $k$  and  $X^T$  is the transpose/conjugate-transpose of  $X$ .  $kron(X, Y)$  is the Kronecker product between the matrices  $X$  and  $Y$ .

If  $trans = 'T'$  (for real flavors), or  $trans = 'C'$  (for complex flavors), the routine `?tgsyl` solves the transposed/conjugate-transposed system  $Z^T*y = scale*b$ , which is equivalent to solve for  $R$  and  $L$  in

$$A^T*R + D^T*L = scale^*C$$

$$R^*B^T + L^*E^T = scale^*(-F)$$

This case ( $trans = 'T'$  for `stgsyl/dtgsyl` or  $trans = 'C'$  for `ctgsyl/ztgsyl`) is used to compute an one-norm-based estimate of  $Dif[(A, D), (B, E)]$ , the separation between the matrix pairs  $(A, D)$  and  $(B, E)$ .

If  $ijob \geq 1$ , `?tgsyl` computes a Frobenius norm-based estimate of  $Dif[(A, D), (B, E)]$ . That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of  $Z$ . This is a level 3 BLAS algorithm.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<i>trans</i>	Must be 'N', 'T', or 'C'. If <i>trans</i> = 'N', solve the generalized Sylvester equation. If <i>trans</i> = 'T', solve the 'transposed' system (for real flavors only). If <i>trans</i> = 'C', solve the 'conjugate transposed' system (for complex flavors only).
<i>ijob</i>	Specifies what kind of functionality to be performed: If <i>ijob</i> = 0, solve the generalized Sylvester equation only; If <i>ijob</i> = 1, perform the functionality of <i>ijob</i> = 0 and <i>ijob</i> = 3; If <i>ijob</i> = 2, perform the functionality of <i>ijob</i> = 0 and <i>ijob</i> = 4; If <i>ijob</i> = 3, only an estimate of $\text{Diff}[(A, D), (B, E)]$ is computed (look ahead strategy is used); If <i>ijob</i> = 4, only an estimate of $\text{Diff}[(A, D), (B, E)]$ is computed (?gecon on sub-systems is used). If <i>trans</i> = 'T' or 'C', <i>ijob</i> is not referenced.
<i>m</i>	The order of the matrices <i>A</i> and <i>D</i> , and the row dimension of the matrices <i>C</i> , <i>F</i> , <i>R</i> and <i>L</i> .
<i>n</i>	The order of the matrices <i>B</i> and <i>E</i> , and the column dimension of the matrices <i>C</i> , <i>F</i> , <i>R</i> and <i>L</i> .
<i>a, b, c, d, e, f</i>	Arrays: <i>a</i> (size $\max(1, lda * m)$ ) contains the upper quasi-triangular (for real flavors) or upper triangular (for complex flavors) matrix <i>A</i> . <i>b</i> (size $\max(1, ldb * n)$ ) contains the upper quasi-triangular (for real flavors) or upper triangular (for complex flavors) matrix <i>B</i> . <i>c</i> (size $\max(1, ldc * n)$ for column major layout and $\max(1, ldc * m)$ for row major layout) contains the right-hand-side of the first matrix equation in the generalized Sylvester equation (as defined by <i>trans</i> ) <i>d</i> (size $\max(1, ldd * m)$ ) contains the upper triangular matrix <i>D</i> . <i>e</i> (size $\max(1, lde * n)$ ) contains the upper triangular matrix <i>E</i> . <i>f</i> (size $\max(1, ldf * n)$ for column major layout and $\max(1, ldf * m)$ for row major layout) contains the right-hand-side of the second matrix equation in the generalized Sylvester equation (as defined by <i>trans</i> )
<i>lda</i>	The leading dimension of <i>a</i> ; at least $\max(1, m)$ .
<i>ldb</i>	The leading dimension of <i>b</i> ; at least $\max(1, n)$ .
<i>ldc</i>	The leading dimension of <i>c</i> ; at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout .
<i>ldd</i>	The leading dimension of <i>d</i> ; at least $\max(1, m)$ .
<i>lde</i>	The leading dimension of <i>e</i> ; at least $\max(1, n)$ .

*ldf* The leading dimension of *f*; at least  $\max(1, m)$  for column major layout and at least  $\max(1, n)$  for row major layout .

## Output Parameters

*c* If *ijob*=0, 1, or 2, overwritten by the solution *R*.  
If *ijob*=3 or 4 and *trans* = 'N', *c* holds *R*, the solution achieved during the computation of the Dif-estimate.

*f* If *ijob*=0, 1, or 2, overwritten by the solution *L*.  
If *ijob*=3 or 4 and *trans* = 'N', *f* holds *L*, the solution achieved during the computation of the Dif-estimate.

*dif* On exit, *dif* is the reciprocal of a lower bound of the reciprocal of the Dif-function, that is, *dif* is an upper bound of  $\text{Dif}[(A, D), (B, E)] = \sigma_{\min}(Z)$ , where *Z* as defined in the description.  
If *ijob* = 0, or *trans* = 'T' (for real flavors), or *trans* = 'C' (for complex flavors), *dif* is not touched.

*scale* On exit, *scale* is the scaling factor in the generalized Sylvester equation.  
If  $0 < \text{scale} < 1$ , *c* and *f* hold the solutions *R* and *L*, respectively, to a slightly perturbed system but the input matrices *A*, *B*, *D* and *E* have not been changed.  
If *scale* = 0, *c* and *f* hold the solutions *R* and *L*, respectively, to the homogeneous system with  $C = F = 0$ . Normally, *scale* = 1.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, (*A*, *D*) and (*B*, *E*) have common or close eigenvalues.

### ?tgsna

*Estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a pair of matrices in generalized real Schur canonical form.*

## Syntax

## Description

The real flavors `stgsna/dtgsna` of this routine estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair  $(A, B)$  in generalized real Schur canonical form (or of any matrix pair  $(Q^*A^*Z^T, Q^*B^*Z^T)$  with orthogonal matrices  $Q$  and  $Z$ ).

$(A, B)$  must be in generalized real Schur form (as returned by `gges/gges`), that is,  $A$  is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks.  $B$  is upper triangular.

The complex flavors `ctgsna/ztgsna` estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair  $(A, B)$ .  $(A, B)$  must be in generalized Schur canonical form, that is,  $A$  and  $B$  are both upper triangular.

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>job</code>	Specifies whether condition numbers are required for eigenvalues or eigenvectors. Must be 'E' or 'V' or 'B'. If <code>job = 'E'</code> , for eigenvalues only (compute <code>s</code> ). If <code>job = 'V'</code> , for eigenvectors only (compute <code>dif</code> ). If <code>job = 'B'</code> , for both eigenvalues and eigenvectors (compute both <code>s</code> and <code>dif</code> ).
<code>howmny</code>	Must be 'A' or 'S'. If <code>howmny = 'A'</code> , compute condition numbers for all eigenpairs. If <code>howmny = 'S'</code> , compute condition numbers for selected eigenpairs specified by the logical array <code>select</code> .
<code>select</code>	Array, size at least $\max(1, n)$ . If <code>howmny = 'S'</code> , <code>select</code> specifies the eigenpairs for which condition numbers are required. If <code>howmny = 'A'</code> , <code>select</code> is not referenced. <i>For real flavors:</i>

To select condition numbers for the eigenpair corresponding to a real eigenvalue  $\omega_j$ , *select*[*j* - 1] must be set to 1; to select condition numbers corresponding to a complex conjugate pair of eigenvalues  $\omega_j$  and  $\omega_{j+1}$ , either *select*[*j* - 1] or *select*[*j*] must be set to 1.

*For complex flavors:*

To select condition numbers for the corresponding *j*-th eigenvalue and/or eigenvector, *select*[*j* - 1] must be set to 1.

<i>n</i>	The order of the square matrix pair ( <i>A</i> , <i>B</i> ) ( $n \geq 0$ ).
<i>a</i> , <i>b</i> , <i>vl</i> , <i>vr</i>	<p>Arrays:</p> <p><i>a</i> (size <math>\max(1, lda * n)</math>) contains the upper quasi-triangular (for real flavors) or upper triangular (for complex flavors) matrix <i>A</i> in the pair (<i>A</i>, <i>B</i>).</p> <p><i>b</i> (size <math>\max(1, ldb * n)</math>) contains the upper triangular matrix <i>B</i> in the pair (<i>A</i>, <i>B</i>).</p> <p>If <i>job</i> = 'E' or 'B', <i>vl</i> (size <math>\max(1, ldvl * m)</math> for column major layout and <math>\max(1, ldvl * n)</math> for row major layout) must contain left eigenvectors of (<i>A</i>, <i>B</i>), corresponding to the eigenpairs specified by <i>howmny</i> and <i>select</i>. The eigenvectors must be stored in consecutive columns of <i>vl</i>, as returned by ?tgevc.</p> <p>If <i>job</i> = 'V', <i>vl</i> is not referenced.</p> <p>If <i>job</i> = 'E' or 'B', <i>vr</i> (size <math>\max(1, ldvr * m)</math> for column major layout and <math>\max(1, ldvr * n)</math> for row major layout) must contain right eigenvectors of (<i>A</i>, <i>B</i>), corresponding to the eigenpairs specified by <i>howmny</i> and <i>select</i>. The eigenvectors must be stored in consecutive columns of <i>vr</i>, as returned by ?tgevc.</p> <p>If <i>job</i> = 'V', <i>vr</i> is not referenced.</p>
<i>lda</i>	The leading dimension of <i>a</i> ; at least $\max(1, n)$ .
<i>ldb</i>	The leading dimension of <i>b</i> ; at least $\max(1, n)$ .
<i>ldvl</i>	<p>The leading dimension of <i>vl</i>; <math>ldvl \geq 1</math>.</p> <p>If <i>job</i> = 'E' or 'B', then <math>ldvl \geq \max(1, n)</math> for column major layout and <math>ldvl \geq \max(1, m)</math> for row major layout .</p>
<i>ldvr</i>	<p>The leading dimension of <i>vr</i>; <math>ldvr \geq 1</math>.</p> <p>If <i>job</i> = 'E' or 'B', then <math>ldvr \geq \max(1, n)</math> for column major layout and <math>ldvr \geq \max(1, m)</math> for row major layout.</p>
<i>mm</i>	The number of elements in the arrays <i>s</i> and <i>dif</i> ( $mm \geq m$ ).

## Output Parameters

<i>s</i>	<p>Array, size <i>mm</i>.</p> <p>If <i>job</i> = 'E' or 'B', contains the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array.</p> <p>If <i>job</i> = 'V', <i>s</i> is not referenced.</p>
----------	--

For real flavors:

For a complex conjugate pair of eigenvalues two consecutive elements of  $s$  are set to the same value. Thus,  $s[j - 1]$ ,  $dif[j - 1]$ , and the  $j$ -th columns of  $vl$  and  $vr$  all correspond to the same eigenpair (but not in general the  $j$ -th eigenpair, unless all eigenpairs are selected).

$dif$

Array, size  $mm$ .

If  $job = 'V'$  or  $'B'$ , contains the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array.

If the eigenvalues cannot be reordered to compute  $dif[j]$ ,  $dif[j]$  is set to 0; this can only occur when the true value would be very small anyway.

If  $job = 'E'$ ,  $dif$  is not referenced.

For real flavors:

For a complex eigenvector, two consecutive elements of  $dif$  are set to the same value.

For complex flavors:

For each eigenvalue/vector specified by  $select$ ,  $dif$  stores a Frobenius norm-based estimate of  $Difl$ .

$m$

The number of elements in the arrays  $s$  and  $dif$  used to store the specified condition numbers; for each selected eigenvalue one element is used.

If  $howmny = 'A'$ ,  $m$  is set to  $n$ .

## Return Values

This function returns a value  $info$ .

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

## Generalized Singular Value Decomposition: LAPACK Computational Routines

This topic describes LAPACK computational routines used for finding the generalized singular value decomposition (GSVD) of two matrices  $A$  and  $B$  as

$$U^H A Q = D_1 * (0 \ R),$$

$$V^H B Q = D_2 * (0 \ R),$$

where  $U$ ,  $V$ , and  $Q$  are orthogonal/unitary matrices,  $R$  is a nonsingular upper triangular matrix, and  $D_1$ ,  $D_2$  are "diagonal" matrices of the structure detailed in the routines description section.

Table "Computational Routines for Generalized Singular Value Decomposition" lists LAPACK routines that perform generalized singular value decomposition of matrices.

### Computational Routines for Generalized Singular Value Decomposition

Routine name	Operation performed
<a href="#">ggsvp</a>	Computes the preprocessing decomposition for the generalized SVD
<a href="#">ggsvp3</a>	Performs preprocessing for a generalized SVD.
<a href="#">ggsvd3</a>	Computes generalized SVD.

Routine name	Operation performed
<a href="#">tgsja</a>	Computes the generalized SVD of two upper triangular or trapezoidal matrices

You can use routines listed in the above table as well as the driver routine [ggsvd](#) to find the GSVD of a pair of general rectangular matrices.

*?ggsvp*

*Computes the preprocessing decomposition for the generalized SVD (deprecated).*

### Description

This routine is deprecated; use [ggsvp3](#).

The routine computes orthogonal matrices  $U$ ,  $V$  and  $Q$  such that

$$U^H A Q = \begin{matrix} & n - k - l & k & l \\ & k & & \\ & l & & \\ m - k - l & & & \end{matrix} \begin{pmatrix} \mathbf{0} & A_{12} & A_{13} \\ \mathbf{0} & \mathbf{0} & A_{23} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} \end{pmatrix}, \quad \text{if } m - k - l \geq 0$$

$$= \begin{matrix} & n-k-l & k & l \\ & k & & \\ m-k & \begin{pmatrix} \mathbf{0} & A_{12} & A_{13} \\ \mathbf{0} & \mathbf{0} & A_{23} \end{pmatrix} & & \end{matrix}, \quad \text{if } m-k-l < 0$$

$$V^H B Q = \begin{matrix} & n-k-l & k & l \\ & l & & \\ p-l & \begin{pmatrix} \mathbf{0} & \mathbf{0} & B_{13} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} \end{pmatrix} & & \end{matrix}$$

where the  $k$ -by- $k$  matrix  $A_{12}$  and  $l$ -by- $l$  matrix  $B_{13}$  are nonsingular upper triangular;  $A_{23}$  is  $l$ -by- $l$  upper triangular if  $m-k-l \geq 0$ , otherwise  $A_{23}$  is  $(m-k)$ -by- $l$  upper trapezoidal. The sum  $k+l$  is equal to the effective numerical rank of the  $(m+p)$ -by- $n$  matrix  $(A^H, B^H)^H$ .

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine [?tgsja](#).

### Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>jobu</code>	Must be 'U' or 'N'. If <code>jobu = 'U'</code> , orthogonal/unitary matrix $U$ is computed. If <code>jobu = 'N'</code> , $U$ is not computed.
<code>jobv</code>	Must be 'V' or 'N'. If <code>jobv = 'V'</code> , orthogonal/unitary matrix $V$ is computed. If <code>jobv = 'N'</code> , $V$ is not computed.
<code>jobq</code>	Must be 'Q' or 'N'. If <code>jobq = 'Q'</code> , orthogonal/unitary matrix $Q$ is computed. If <code>jobq = 'N'</code> , $Q$ is not computed.
<code>m</code>	The number of rows of the matrix $A$ ( $m \geq 0$ ).
<code>p</code>	The number of rows of the matrix $B$ ( $p \geq 0$ ).
<code>n</code>	The number of columns of the matrices $A$ and $B$ ( $n \geq 0$ ).
<code>a, b</code>	Arrays: <code>a</code> (size at least $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout) contains the $m$ -by- $n$ matrix $A$ .

$b$  (size at least  $\max(1, ldb*n)$  for column major layout and  $\max(1, ldb*p)$  for row major layout) contains the  $p$ -by- $n$  matrix  $B$ .

<code>lda</code>	The leading dimension of $a$ ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.
<code>ldb</code>	The leading dimension of $b$ ; at least $\max(1, p)$ for column major layout and $\max(1, n)$ for row major layout.
<code>tola, tolb</code>	<p><math>tola</math> and <math>tolb</math> are the thresholds to determine the effective numerical rank of matrix <math>B</math> and a subblock of <math>A</math>. Generally, they are set to</p> $tola = \max(m, n) *   A   * \text{MACHEPS},$ $tolb = \max(p, n) *   B   * \text{MACHEPS}.$ <p>The size of <math>tola</math> and <math>tolb</math> may affect the size of backward errors of the decomposition.</p>
<code>ldu</code>	The leading dimension of the output array $u$ . $ldu \geq \max(1, m)$ if $jobu = 'U'$ ; $ldu \geq 1$ otherwise.
<code>ldv</code>	The leading dimension of the output array $v$ . $ldv \geq \max(1, p)$ if $jobv = 'V'$ ; $ldv \geq 1$ otherwise.
<code>ldq</code>	The leading dimension of the output array $q$ . $ldq \geq \max(1, n)$ if $jobq = 'Q'$ ; $ldq \geq 1$ otherwise.

## Output Parameters

<code>a</code>	Overwritten by the triangular (or trapezoidal) matrix described in the <i>Description</i> section.
<code>b</code>	Overwritten by the triangular matrix described in the <i>Description</i> section.
<code>k, l</code>	On exit, $k$ and $l$ specify the dimension of subblocks. The sum $k + l$ is equal to effective numerical rank of $(A^H, B^H)^H$ .
<code>u, v, q</code>	<p>Arrays:</p> <p>If <math>jobu = 'U'</math>, <math>u</math> (size <math>\max(1, ldu*m)</math>) contains the orthogonal/unitary matrix <math>U</math>.</p> <p>If <math>jobu = 'N'</math>, <math>u</math> is not referenced.</p> <p>If <math>jobv = 'V'</math>, <math>v</math> (size <math>\max(1, ldv*p)</math>) contains the orthogonal/unitary matrix <math>V</math>.</p> <p>If <math>jobv = 'N'</math>, <math>v</math> is not referenced.</p> <p>If <math>jobq = 'Q'</math>, <math>q</math> (size <math>\max(1, ldq*n)</math>) contains the orthogonal/unitary matrix <math>Q</math>.</p> <p>If <math>jobq = 'N'</math>, <math>q</math> is not referenced.</p>

## Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, the  $i$ -th parameter had an illegal value.

### ?ggsvp3

Performs preprocessing for a generalized SVD.

#### Syntax

#### Description

?ggsvp3 computes orthogonal or unitary matrices  $U$ ,  $V$ , and  $Q$  such that

for real flavors:

$$U^T A Q = \begin{matrix} & & n-k-l & k & l \\ & k & & & \\ & l & & & \\ m-k-l & & \begin{pmatrix} 0 & A12 & A13 \\ 0 & 0 & A23 \\ 0 & 0 & 0 \end{pmatrix} & & \end{matrix} \text{ if } m-k-l \geq 0;$$

$$U^T A Q = \begin{matrix} & & n-k-l & k & l \\ & k & & & \\ m-k & & \begin{pmatrix} 0 & A12 & A13 \\ 0 & 0 & A23 \end{pmatrix} & & \end{matrix} \text{ if } m-k-l < 0;$$

$$V^T B Q = \begin{matrix} & & n-k-l & k & l \\ & l & & & \\ p-l & & \begin{pmatrix} 0 & 0 & B13 \\ 0 & 0 & 0 \end{pmatrix} & & \end{matrix}$$

for complex flavors:

$$U^H A Q = \begin{matrix} & & n-k-l & k & l \\ & k & & & \\ & l & & & \\ m-k-l & & \begin{pmatrix} 0 & A12 & A13 \\ 0 & 0 & A23 \\ 0 & 0 & 0 \end{pmatrix} & & \end{matrix} \text{ if } m-k-l \geq 0;$$

$$U^H A Q = \begin{matrix} & & n-k-l & k & l \\ & k & \begin{pmatrix} 0 & A12 & A13 \\ 0 & 0 & A23 \end{pmatrix} & & \\ m-k & & & & \end{matrix} \text{ if } m-k-l < 0;$$

$$V^H B Q = \begin{matrix} & & n-k-l & k & l \\ & l & \begin{pmatrix} 0 & 0 & B13 \\ 0 & 0 & 0 \end{pmatrix} & & \\ p-l & & & & \end{matrix}$$

where the  $k$ -by- $k$  matrix  $A12$  and  $l$ -by- $l$  matrix  $B13$  are nonsingular upper triangular;  $A23$  is  $l$ -by- $l$  upper triangular if  $m-k-l \geq 0$ , otherwise  $A23$  is  $(m-k)$ -by- $l$  upper trapezoidal.  $k + l =$  the effective numerical rank of the  $(m + p)$ -by- $n$  matrix  $(A^T, B^T)^T$  for real flavors or  $(A^H, B^H)^H$  for complex flavors.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see `?ggsvd3`.

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>jobu</code>	= 'U': Orthogonal/unitary matrix $U$ is computed; = 'N': $U$ is not computed.
<code>jobv</code>	= 'V': Orthogonal/unitary matrix $V$ is computed; = 'N': $V$ is not computed.
<code>jobq</code>	= 'Q': Orthogonal/unitary matrix $Q$ is computed; = 'N': $Q$ is not computed.
<code>m</code>	The number of rows of the matrix $A$ . $m \geq 0$ .
<code>p</code>	The number of rows of the matrix $B$ . $p \geq 0$ .
<code>n</code>	The number of columns of the matrices $A$ and $B$ . $n \geq 0$ .
<code>a</code>	Array, size $(lda * n)$ . On entry, the $m$ -by- $n$ matrix $A$ .
<code>lda</code>	The leading dimension of the array $a$ . $lda \geq \max(1, m)$ .
<code>b</code>	Array, size $(ldb * n)$ . On entry, the $p$ -by- $n$ matrix $B$ .
<code>ldb</code>	The leading dimension of the array $b$ . $ldb \geq \max(1, p)$ .
<code>tol_a, tol_b</code>	$tol_a$ and $tol_b$ are the thresholds to determine the effective numerical rank of matrix $B$ and a subblock of $A$ . Generally, they are set to $tol_a = \max(m, n) * \text{norm}(a) * \text{MACHEPS}$ ,

$tolb = \max(p,n) * \text{norm}(b) * \text{MACHEPS}$ .

The size of  $tola$  and  $tolb$  may affect the size of backward errors of the decomposition.

$ldu$	The leading dimension of the array $u$ . $ldu \geq \max(1,m)$ if $jobu = 'U'$ ; $ldu \geq 1$ otherwise.
$ldv$	The leading dimension of the array $v$ . $ldv \geq \max(1,p)$ if $jobv = 'V'$ ; $ldv \geq 1$ otherwise.
$ldq$	The leading dimension of the array $q$ . $ldq \geq \max(1,n)$ if $jobq = 'Q'$ ; $ldq \geq 1$ otherwise.

## Output Parameters

$a$	On exit, $a$ contains the triangular (or trapezoidal) matrix described in the Description section.
$b$	On exit, $b$ contains the triangular matrix described in the Description section.
$k, l$	On exit, $k$ and $l$ specify the dimension of the subblocks described in Description section. $k + l = \text{effective numerical rank of } (A^T, B^T)^T \text{ for real flavors or } (A^H, B^H)^H \text{ for complex flavors.}$
$u$	Array, size $(ldu * m)$ . If $jobu = 'U'$ , $u$ contains the orthogonal/unitary matrix $U$ . If $jobu = 'N'$ , $u$ is not referenced.
$v$	Array, size $(ldv * p)$ . If $jobv = 'V'$ , $v$ contains the orthogonal/unitary matrix $V$ . If $jobv = 'N'$ , $v$ is not referenced.
$q$	Array, size $(ldq * n)$ . If $jobq = 'Q'$ , $q$ contains the orthogonal/unitary matrix $Q$ . If $jobq = 'N'$ , $q$ is not referenced.

## Return Values

This function returns a value  $info$ .

= 0: successful exit.

< 0: if  $info = -i$ , the  $i$ -th argument had an illegal value.

## Application Notes

The subroutine uses LAPACK subroutine `?geqp3` for the QR factorization with column pivoting to detect the effective numerical rank of the  $A$  matrix. It may be replaced by a better rank determination strategy.

`?ggsvp3` replaces the deprecated subroutine `?ggsvp`.

## ?ggsvd3

Computes generalized SVD.

### Description

?ggsvd3 computes the generalized singular value decomposition (GSVD) of an  $m$ -by- $n$  real or complex matrix  $A$  and  $p$ -by- $n$  real or complex matrix  $B$ :

$$U^T A Q = D_1 (0 R), \quad V^T B Q = D_2 (0 R) \text{ for real flavors}$$

or

$$U^H A Q = D_1 (0 R), \quad V^H B Q = D_2 (0 R) \text{ for complex flavors}$$

where  $U$ ,  $V$  and  $Q$  are orthogonal/unitary matrices.

Let  $k+1$  = the effective numerical rank of the matrix  $(A^T B^T)^T$  for real flavors or the matrix  $(A^H B^H)^H$  for complex flavors, then  $R$  is a  $(k+1)$ -by- $(k+1)$  nonsingular upper triangular matrix,  $D_1$  and  $D_2$  are  $m$ -by- $(k+1)$  and  $p$ -by- $(k+1)$  "diagonal" matrices and of the following structures, respectively:

If  $m-k-l \geq 0$ ,

$$D_1 = \begin{matrix} & & & k & l \\ & & & I & 0 \\ & & & 0 & C \\ m-k-l & & & 0 & 0 \end{matrix}$$

$$D_2 = \begin{matrix} & & k & l \\ l & & (0 & S) \\ & p-l & (0 & 0) \end{matrix}$$

$$\begin{pmatrix} & & & n-k-l & k & l \\ 0 & R & = & k & \begin{pmatrix} 0 & R11 & R12 \\ l & 0 & R22 \end{pmatrix} \end{pmatrix}$$

where

$$C = \text{diag}(\alpha(k+1), \dots, \alpha(k+l)),$$

$$S = \text{diag}(\beta(k+1), \dots, \beta(k+l)),$$

$$C^2 + S^2 = I.$$

If  $m - k - l < 0$ ,

$$D_1 = \begin{matrix} & & k & m-k & k+l-m \\ m-k & \begin{pmatrix} I & 0 & 0 \\ 0 & C & 0 \end{pmatrix} \end{matrix}$$

$$D_2 = \begin{matrix} & & & k & m-k & k+l-m \\ m-k & \begin{pmatrix} 0 & S & 0 \\ k+l-m & 0 & I \\ p-l & 0 & 0 \end{pmatrix} \end{matrix}$$

$$\begin{pmatrix} & & & & n-k-l & k & m-k & k+l-m \\ 0 & R & = & k & \begin{pmatrix} 0 & R11 & R12 & R13 \\ m-k & 0 & R22 & R23 \\ k+l-m & 0 & 0 & R33 \end{pmatrix} \end{pmatrix}$$

where

$$C = \text{diag}(\alpha(k+1), \dots, \alpha(m)),$$

$$S = \text{diag}(\beta(k+1), \dots, \beta(m)),$$

$$C^2 + S^2 = I.$$

The routine computes  $C$ ,  $S$ ,  $R$ , and optionally the orthogonal/unitary transformation matrices  $U$ ,  $V$  and  $Q$ .

In particular, if  $B$  is an  $n$ -by- $n$  nonsingular matrix, then the GSVD of  $A$  and  $B$  implicitly gives the SVD of  $A \cdot \text{inv}(B)$ :

$$A \cdot \text{inv}(B) = U \cdot (D_1 \cdot \text{inv}(D_2)) \cdot V^T \text{ for real flavors}$$

or

$$A \cdot \text{inv}(B) = U \cdot (D_1 \cdot \text{inv}(D_2)) \cdot V^H \text{ for complex flavors.}$$

If  $(A^T, B^T)^T$  for real flavors or  $(A^H, B^H)^H$  for complex flavors has orthonormal columns, then the GSVD of  $A$  and  $B$  is also equal to the CS decomposition of  $A$  and  $B$ . Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

$$A^T \cdot A \cdot X = \lambda \cdot B^T \cdot B \cdot X \text{ for real flavors}$$

or

$$A^H \cdot A \cdot X = \lambda \cdot B^H \cdot B \cdot X \text{ for complex flavors}$$

In some literature, the GSVD of  $A$  and  $B$  is presented in the form

$$U^T \cdot A \cdot X = (0 \ D_1), \quad V^T \cdot B \cdot X = (0 \ D_2) \text{ for real } (A, B)$$

or

$U^H * A * X = ( 0 D_1 ), V^H * B * X = ( 0 D_2 )$  for complex  $(A, B)$

where  $U$  and  $V$  are orthogonal and  $X$  is nonsingular,  $D_1$  and  $D_2$  are "diagonal". The former GSVD form can be converted to the latter form by taking the nonsingular matrix  $X$  as

$$X = Q * \begin{pmatrix} I & 0 \\ 0 & \text{inv}(R) \end{pmatrix}$$

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>jobu</i>	= 'U': Orthogonal/unitary matrix $U$ is computed; = 'N': $U$ is not computed.
<i>jobv</i>	= 'V': Orthogonal/unitary matrix $V$ is computed; = 'N': $V$ is not computed.
<i>jobq</i>	= 'Q': Orthogonal/unitary matrix $Q$ is computed; = 'N': $Q$ is not computed.
<i>m</i>	The number of rows of the matrix $A$ . $m \geq 0$ .
<i>n</i>	The number of columns of the matrices $A$ and $B$ . $n \geq 0$ .
<i>p</i>	The number of rows of the matrix $B$ . $p \geq 0$ .
<i>a</i>	Array, size ( $lda * n$ ). On entry, the $m$ -by- $n$ matrix $A$ .
<i>lda</i>	The leading dimension of the array $a$ . $lda \geq \max(1, m)$ .
<i>b</i>	Array, size ( $ldb * n$ ). On entry, the $p$ -by- $n$ matrix $B$ .
<i>ldb</i>	The leading dimension of the array $b$ . $ldb \geq \max(1, p)$ .
<i>ldu</i>	The leading dimension of the array $u$ . $ldu \geq \max(1, m)$ if $jobu = 'U'$ ; $ldu \geq 1$ otherwise.
<i>ldv</i>	The leading dimension of the array $v$ . $ldv \geq \max(1, p)$ if $jobv = 'V'$ ; $ldv \geq 1$ otherwise.
<i>ldq</i>	The leading dimension of the array $q$ . $ldq \geq \max(1, n)$ if $jobq = 'Q'$ ; $ldq \geq 1$ otherwise.
<i>iwork</i>	Array, size ( $n$ ).

## Output Parameters

<i>k, l</i>	<p>On exit, <i>k</i> and <i>l</i> specify the dimension of the subblocks described in the Description section.</p> <p><math>k + l</math> = effective numerical rank of <math>(A^T, B^T)^T</math> for real flavors or <math>(A^H, B^H)^H</math> for complex flavors.</p>
<i>a</i>	<p>On exit, <i>a</i> contains the triangular matrix <i>R</i>, or part of <i>R</i>.</p> <p>If <math>m - k - l \geq 0</math>, <i>R</i> is stored in the elements of array <i>a</i> corresponding to <math>A_{1:k+l, n-k-l+1:n}</math>.</p> <p>If <math>m - k - l &lt; 0</math>, <math>\begin{pmatrix} R11 &amp; R12 &amp; R13 \\ 0 &amp; R22 &amp; R23 \end{pmatrix}</math> is stored in the elements of array <i>a</i> corresponding to <math>A_{(1:m, n-k-l+1:n)}</math>, and <i>R33</i> is stored in the elements of array <i>a</i> corresponding to <math>A_{m-k+1:l, n+m-k-l+1:n}</math> on exit.</p>
<i>b</i>	<p>On exit, <i>b</i> contains part of the triangular matrix <i>R</i> if <math>m - k - l &lt; 0</math>.</p> <p>See Description for details.</p>
<i>alpha</i>	Array, size ( <i>n</i> )
<i>beta</i>	<p>Array, size (<i>n</i>)</p> <p>On exit, <i>alpha</i> and <i>beta</i> contain the generalized singular value pairs of <i>a</i> and <i>b</i>;</p> <p><math>alpha[0:k-1] = 1</math>,</p> <p><math>beta[0:k-1] = 0</math>,</p> <p>and if <math>m - k - l \geq 0</math>,</p> <p><math>alpha[k:k+l-1] = C</math>,</p> <p><math>beta[k:k+l-1] = S</math>,</p> <p>or if <math>m - k - l &lt; 0</math>,</p> <p><math>alpha[k:m-1] = C</math>, <math>alpha[m:k+l-1] = 0</math></p> <p><math>beta[k:m-1] = S</math>, <math>beta[m:k+l-1] = 1</math></p> <p>and</p> <p><math>alpha[k+l:n-1] = 0</math></p> <p><math>beta[k+l:n-1] = 0</math></p>
<i>u</i>	<p>Array, size (<i>ldu</i>*<i>m</i>).</p> <p>If <i>jobu</i> = 'U', <i>u</i> contains the m-by-m orthogonal/unitary matrix <i>U</i>.</p> <p>If <i>jobu</i> = 'N', <i>u</i> is not referenced.</p>
<i>v</i>	<p>Array, size (<i>ldv</i>*<i>p</i>).</p> <p>If <i>jobv</i> = 'V', <i>v</i> contains the <i>p</i>-by-<i>p</i> orthogonal/unitary matrix <i>V</i>.</p> <p>If <i>jobv</i> = 'N', <i>v</i> is not referenced.</p>
<i>q</i>	Array, size ( <i>ldq</i> * <i>n</i> ).

If *jobq* = 'Q', *q* contains the *n*-by-*n* orthogonal/unitary matrix *Q*.

If *jobq* = 'N', *q* is not referenced.

*iwork*

On exit, *iwork* stores the sorting information. More precisely, the following loop uses *iwork* to sort *alpha*:

```
for (i = k; i < min(m, k + 1); i++) {
    swap (alpha[i], alpha[iwork[i] - 1]);
}
```

such that  $\alpha[0] \geq \alpha[1] \geq \dots \geq \alpha[n - 1]$ .

## Return Values

This function returns a value *info*.

= 0: successful exit.

< 0: if *info* = -*i*, the *i*-th argument had an illegal value.

> 0: if *info* = 1, the Jacobi-type procedure failed to converge.

For further details, see subroutine ?tgsja.

## Application Notes

?ggsvd3 replaces the deprecated subroutine ?ggsvd.

### ?tgsja

*Computes the generalized SVD of two upper triangular or trapezoidal matrices.*

## Description

The routine computes the generalized singular value decomposition (GSVD) of two real/complex upper triangular (or trapezoidal) matrices  $A$  and  $B$ . On entry, it is assumed that matrices  $A$  and  $B$  have the following forms, which may be obtained by the preprocessing subroutine `ggsvp` from a general  $m$ -by- $n$  matrix  $A$  and  $p$ -by- $n$  matrix  $B$ :

$$A = \begin{matrix} & n-k-l & k & l \\ & k & \begin{pmatrix} 0 & A_{12} & A_{13} \\ 0 & 0 & A_{23} \\ 0 & 0 & 0 \end{pmatrix} \\ & l & \\ m-k-l & \end{matrix}, \quad \text{if } m-k-l \geq 0$$

$$= \begin{matrix} & n-k-l & k & l \\ & k & \begin{pmatrix} 0 & A_{12} & A_{13} \\ 0 & 0 & A_{23} \end{pmatrix} \\ & m-k & \\ & \end{matrix}, \quad \text{if } m-k-l < 0$$

$$B = \begin{matrix} & n-k-l & k & l \\ & l & \begin{pmatrix} 0 & 0 & B_{13} \\ 0 & 0 & 0 \end{pmatrix} \\ p-l & \end{matrix}$$

where the  $k$ -by- $k$  matrix  $A_{12}$  and  $l$ -by- $l$  matrix  $B_{13}$  are nonsingular upper triangular;  $A_{23}$  is  $l$ -by- $l$  upper triangular if  $m-k-l \geq 0$ , otherwise  $A_{23}$  is  $(m-k)$ -by- $l$  upper trapezoidal.

On exit,

$$U^H * A * Q = D_1 * (0 \ R), \quad V^H * B * Q = D_2 * (0 \ R),$$

where  $U$ ,  $V$  and  $Q$  are orthogonal/unitary matrices,  $R$  is a nonsingular upper triangular matrix, and  $D_1$  and  $D_2$  are "diagonal" matrices, which are of the following structures:

If  $m-k-l \geq 0$ ,

$R$  is stored in  $a(1:k+l, n-k-l+1:n)$  on exit.

If  $m-k-l < 0$ ,

$$\begin{matrix} & k & m-k & k+1-m \\ k & \left( \begin{array}{ccc} I & 0 & 0 \\ 0 & C & 0 \end{array} \right) \\ m-k & & & \end{matrix}$$

$$D_2 = \begin{matrix} & k & m-k & k+l-m \\ m-k & \left( \begin{array}{ccc} 0 & S & 0 \\ 0 & 0 & I \\ p-l & 0 & 0 \end{array} \right) \\ k+l-m & & & \\ p-l & & & \end{matrix}$$

$$(0 R) = \begin{matrix} & n-k-l & k & m-k & k+l-m \\ & k & \left( \begin{array}{ccc} 0 & R_{11} & R_{12} & R_{13} \\ 0 & 0 & R_{22} & R_{23} \\ 0 & 0 & 0 & R_{33} \end{array} \right) \\ m-k & & & & \\ k+l-m & & & & \end{matrix}$$

where

$C = \text{diag}(\alpha[k], \dots, \alpha[m-1])$ ,

$S = \text{diag}(\beta[k], \dots, \beta[m-1])$ ,

$C^2 + S^2 = I$

On exit,

$$\begin{pmatrix} R_{11} & R_{12} & R_{13} \\ 0 & R_{22} & R_{23} \end{pmatrix}$$

is stored in  $a(1:m, n-k-l+1:n)$  and  $R_{33}$  is stored

in  $b(m-k+1:l, n+m-k-l+1:n)$ .

The computation of the orthogonal/unitary transformation matrices  $U$ ,  $V$  or  $Q$  is optional. These matrices may either be formed explicitly, or they may be postmultiplied into input matrices  $U_1$ ,  $V_1$ , or  $Q_1$ .

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<i>jobu</i>	<p>Must be 'U', 'I', or 'N'.</p> <p>If <i>jobu</i> = 'U', <i>u</i> must contain an orthogonal/unitary matrix <math>U_1</math> on entry.</p> <p>If <i>jobu</i> = 'I', <i>u</i> is initialized to the unit matrix.</p> <p>If <i>jobu</i> = 'N', <i>u</i> is not computed.</p>
<i>jobv</i>	<p>Must be 'V', 'I', or 'N'.</p> <p>If <i>jobv</i> = 'V', <i>v</i> must contain an orthogonal/unitary matrix <math>V_1</math> on entry.</p> <p>If <i>jobv</i> = 'I', <i>v</i> is initialized to the unit matrix.</p> <p>If <i>jobv</i> = 'N', <i>v</i> is not computed.</p>
<i>jobq</i>	<p>Must be 'Q', 'I', or 'N'.</p> <p>If <i>jobq</i> = 'Q', <i>q</i> must contain an orthogonal/unitary matrix <math>Q_1</math> on entry.</p> <p>If <i>jobq</i> = 'I', <i>q</i> is initialized to the unit matrix.</p> <p>If <i>jobq</i> = 'N', <i>q</i> is not computed.</p>
<i>m</i>	The number of rows of the matrix <i>A</i> ( $m \geq 0$ ).
<i>p</i>	The number of rows of the matrix <i>B</i> ( $p \geq 0$ ).
<i>n</i>	The number of columns of the matrices <i>A</i> and <i>B</i> ( $n \geq 0$ ).
<i>k, l</i>	Specify the subblocks in the input matrices <i>A</i> and <i>B</i> , whose GSVD is computed.
<i>a, b, u, v, q</i>	<p>Arrays:</p> <p><i>a</i> (size at least <math>\max(1, lda * n)</math> for column major layout and <math>\max(1, lda * m)</math> for row major layout) contains the <i>m</i>-by-<i>n</i> matrix <i>A</i>.</p> <p><i>b</i> (size at least <math>\max(1, ldb * n)</math> for column major layout and <math>\max(1, ldb * p)</math> for row major layout) contains the <i>p</i>-by-<i>n</i> matrix <i>B</i>.</p> <p>If <i>jobu</i> = 'U', <i>u</i> (size <math>\max(1, ldu * m)</math>) must contain a matrix <math>U_1</math> (usually the orthogonal/unitary matrix returned by <code>?ggsvp</code>).</p> <p>If <i>jobv</i> = 'V', <i>v</i> (size at least <math>\max(1, ldv * p)</math>) must contain a matrix <math>V_1</math> (usually the orthogonal/unitary matrix returned by <code>?ggsvp</code>).</p> <p>If <i>jobq</i> = 'Q', <i>q</i> (size at least <math>\max(1, ldq * n)</math>) must contain a matrix <math>Q_1</math> (usually the orthogonal/unitary matrix returned by <code>?ggsvp</code>).</p>
<i>lda</i>	The leading dimension of <i>a</i> ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.
<i>ldb</i>	The leading dimension of <i>b</i> ; at least $\max(1, p)$ for column major layout and $\max(1, n)$ for row major layout.
<i>ldu</i>	<p>The leading dimension of the array <i>u</i>.</p> <p><math>ldu \geq \max(1, m)</math> if <i>jobu</i> = 'U'; <math>ldu \geq 1</math> otherwise.</p>

<i>ldv</i>	The leading dimension of the array <i>v</i> . $ldv \geq \max(1, p)$ if <i>jobv</i> = 'V'; $ldv \geq 1$ otherwise.
<i>ldq</i>	The leading dimension of the array <i>q</i> . $ldq \geq \max(1, n)$ if <i>jobq</i> = 'Q'; $ldq \geq 1$ otherwise.
<i>tolA, tolB</i>	<i>tolA</i> and <i>tolB</i> are the convergence criteria for the Jacobi-Kogbetliantz iteration procedure. Generally, they are the same as used in ?ggsvp: $tolA = \max(m, n) *  A  * \text{MACHEPS}$ , $tolB = \max(p, n) *  B  * \text{MACHEPS}$ .

## Output Parameters

<i>a</i>	On exit, <i>a</i> ( <i>n-k+1:n</i> , 1:min( <i>k+l</i> , <i>m</i> )) contains the triangular matrix <i>R</i> or part of <i>R</i> .
<i>b</i>	On exit, if necessary, <i>b</i> ( <i>m-k+1:l</i> , <i>n+m-k-l+1:n</i> ) contains a part of <i>R</i> .
<i>alpha, beta</i>	Arrays, size at least max(1, <i>n</i> ). Contain the generalized singular value pairs of <i>A</i> and <i>B</i> : $alpha(1:k) = 1$ , $beta(1:k) = 0$ , and if $m-k-l \geq 0$ , $alpha(k+1:k+l) = \text{diag}(C)$ , $beta(k+1:k+l) = \text{diag}(S)$ , or if $m-k-l < 0$ , $alpha(k+1:m) = \text{diag}(C)$ , $alpha(m+1:k+l) = 0$ $beta(k+1:m) = \text{diag}(S)$ , $beta(m+1:k+l) = 1$ . Furthermore, if $k+l < n$ , $alpha(k+l+1:n) = 0$ and $beta(k+l+1:n) = 0$ .
<i>u</i>	If <i>jobu</i> = 'I', <i>u</i> contains the orthogonal/unitary matrix <i>U</i> . If <i>jobu</i> = 'U', <i>u</i> contains the product $U_1 * U$ . If <i>jobu</i> = 'N', <i>u</i> is not referenced.
<i>v</i>	If <i>jobv</i> = 'I', <i>v</i> contains the orthogonal/unitary matrix <i>U</i> . If <i>jobv</i> = 'V', <i>v</i> contains the product $V_1 * V$ . If <i>jobv</i> = 'N', <i>v</i> is not referenced.
<i>q</i>	If <i>jobq</i> = 'I', <i>q</i> contains the orthogonal/unitary matrix <i>U</i> . If <i>jobq</i> = 'Q', <i>q</i> contains the product $Q_1 * Q$ . If <i>jobq</i> = 'N', <i>q</i> is not referenced.

*ncycle* The number of cycles required for convergence.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = 1, the procedure does not converge after MAXIT cycles.

## Cosine-Sine Decomposition: LAPACK Computational Routines

This topic describes LAPACK computational routines for computing the *cosine-sine decomposition* (CS decomposition) of a partitioned unitary/orthogonal matrix. The algorithm computes a complete 2-by-2 CS decomposition, which requires simultaneous diagonalization of all the four blocks of a unitary/orthogonal matrix partitioned into a 2-by-2 block structure.

The computation has the following phases:

1. The matrix is reduced to a bidiagonal block form.
2. The blocks are simultaneously diagonalized using techniques from the bidiagonal SVD algorithms.

Table "Computational Routines for Cosine-Sine Decomposition (CSD)" lists LAPACK routines that perform CS decomposition of matrices.

### Computational Routines for Cosine-Sine Decomposition (CSD)

Operation	Real matrices	Complex matrices
Compute the CS decomposition of an orthogonal/unitary matrix in bidiagonal-block form	<a href="#">bbcsd/bbcsd</a>	<a href="#">bbcsd/bbcsd</a>
Simultaneously bidiagonalize the blocks of a partitioned orthogonal matrix	<a href="#">orbdb unbdb</a>	
Simultaneously bidiagonalize the blocks of a partitioned unitary matrix		<a href="#">orbdb unbdb</a>

## Description

mkl\_lapack.fi The routine ?bbcsd computes the CS decomposition of an orthogonal or unitary matrix in bidiagonal-block form:

$$X = \begin{pmatrix} b_{11} & | & b_{12} & & 0 & 0 \\ 0 & | & 0 & & -I & 0 \\ b_{21} & | & b_{22} & & 0 & 0 \\ 0 & | & 0 & & 0 & I \end{pmatrix} = \begin{pmatrix} u_1 & | & \\ & | & u_2 \end{pmatrix} \begin{pmatrix} C & | & -S & 0 & 0 \\ 0 & | & 0 & -I & 0 \\ S & | & C & 0 & 0 \\ 0 & | & 0 & 0 & I \end{pmatrix} \begin{pmatrix} v_1 & | & \\ & | & v_2 \end{pmatrix}^T$$

or

$$X = \begin{pmatrix} b_{11} & | & b_{12} & & 0 & 0 \\ 0 & | & 0 & & -I & 0 \\ b_{21} & | & b_{22} & & 0 & 0 \\ 0 & | & 0 & & 0 & I \end{pmatrix} = \begin{pmatrix} u_1 & | & \\ & | & u_2 \end{pmatrix} \begin{pmatrix} C & | & -S & 0 & 0 \\ 0 & | & 0 & -I & 0 \\ S & | & C & 0 & 0 \\ 0 & | & 0 & 0 & I \end{pmatrix} \begin{pmatrix} v_1 & | & \\ & | & v_2 \end{pmatrix}^H$$

respectively.

$x$  is  $m$ -by- $m$  with the top-left block  $p$ -by- $q$ . Note that  $q$  must not be larger than  $p$ ,  $m-p$ , or  $m-q$ . If  $q$  is not the smallest index,  $x$  must be transposed and/or permuted in constant time using the *trans* option.

See ?orcsd/?uncsd for details.

The bidiagonal matrices  $b_{11}$ ,  $b_{12}$ ,  $b_{21}$ , and  $b_{22}$  are represented implicitly by angles  $theta(1:q)$  and  $phi(1:q-1)$ .

The orthogonal/unitary matrices  $u_1$ ,  $u_2$ ,  $v_1^t$ , and  $v_2^t$  are input/output. The input matrices are pre- or post-multiplied by the appropriate singular vector matrices.

## Input Parameters

*matrix\_layout* Specifies whether matrix storage layout is row major (LAPACK\_ROW\_MAJOR) or column major (LAPACK\_COL\_MAJOR).

*jobu1* If equals Y, then  $u_1$  is updated. Otherwise,  $u_1$  is not updated.

<i>jobu2</i>	If equals $Y$ , then $u_2$ is updated. Otherwise, $u_2$ is not updated.
<i>jobv1t</i>	If equals $Y$ , then $v_1^t$ is updated. Otherwise, $v_1^t$ is not updated.
<i>jobv2t</i>	If equals $Y$ , then $v_2^t$ is updated. Otherwise, $v_2^t$ is not updated.
<i>trans</i>	= 'T': $X, u_1, u_2, v_1^t, v_2^t$ are stored in row-major order. otherwise $X, u_1, u_2, v_1^t, v_2^t$ are stored in column-major order.
<i>m</i>	The number of rows and columns of the orthogonal/unitary matrix $X$ in bidiagonal-block form.
<i>p</i>	The number of rows in the top-left block of $x$ . $0 \leq p \leq m$ . $\leq$
<i>q</i>	The number of columns in the top-left block of $x$ . $0 \leq q \leq \min(p, m-p, m-q)$ .
<i>theta</i>	Array, size $q$ . On entry, the angles $theta[0], \dots, theta[q - 1]$ that, along with $phi[0], \dots, phi[q - 2]$ , define the matrix in bidiagonal-block form as returned by <a href="#">orbdb/unbdb</a> .
<i>phi</i>	Array, size $q-1$ . The angles $phi[0], \dots, phi[q - 2]$ that, along with $theta[0], \dots, theta[q - 1]$ , define the matrix in bidiagonal-block form as returned by <a href="#">orbdb/unbdb</a> .
<i>u1</i>	Array, size at least $\max(1, ldu1 * p)$ . On entry, a $p$ -by- $p$ matrix.
<i>ldu1</i>	The leading dimension of the array $u_1$ , $ldu1 \leq \max(1, p)$ .
<i>u2</i>	Array, size $\max(1, ldu2 * (m-p))$ . On entry, an $(m-p)$ -by- $(m-p)$ matrix.
<i>ldu2</i>	The leading dimension of the array $u_2$ , $ldu2 \leq \max(1, m-p)$ .
<i>v1t</i>	Array, size $\max(1, ldv1t * q)$ . On entry, a $q$ -by- $q$ matrix.
<i>ldv1t</i>	The leading dimension of the array $v1t$ , $ldv1t \leq \max(1, q)$ .
<i>v2t</i>	Array, size. On entry, an $(m-q)$ -by- $(m-q)$ matrix.
<i>ldv2t</i>	The leading dimension of the array $v2t$ , $ldv2t \leq \max(1, m-q)$ .

## Output Parameters

<i>theta</i>	On exit, the angles whose cosines and sines define the diagonal blocks in the CS decomposition.
<i>u1</i>	On exit, $u1$ is postmultiplied by the left singular vector matrix common to $\begin{bmatrix} b11 & & & \\ & 0 & & \end{bmatrix}$ and $\begin{bmatrix} b12 & 0 & 0 & \\ & 0 & -I & 0 \end{bmatrix}$ .

<i>u2</i>	On exit, <i>u2</i> is postmultiplied by the left singular vector matrix common to [ <i>b21</i> ; 0 ] and [ <i>b22</i> 0 0 ; 0 0 I ].
<i>v1t</i>	Array, size <i>q</i> . On exit, <i>v1t</i> is premultiplied by the transpose of the right singular vector matrix common to [ <i>b11</i> ; 0 ] and [ <i>b21</i> ; 0 ].
<i>v2t</i>	On exit, <i>v2t</i> is premultiplied by the transpose of the right singular vector matrix common to [ <i>b12</i> 0 0 ; 0 -I 0 ] and [ <i>b22</i> 0 0 ; 0 0 I ].
<i>b11d</i>	Array, size <i>q</i> . When <code>?bbcsd</code> converges, <i>b11d</i> contains the cosines of <i>theta</i> [0], ..., <i>theta</i> [ <i>q</i> - 1]. If <code>?bbcsd</code> fails to converge, <i>b11d</i> contains the diagonal of the partially reduced top left block.
<i>b11e</i>	Array, size <i>q</i> -1. When <code>?bbcsd</code> converges, <i>b11e</i> contains zeros. If <code>?bbcsd</code> fails to converge, <i>b11e</i> contains the superdiagonal of the partially reduced top left block.
<i>b12d</i>	Array, size <i>q</i> . When <code>?bbcsd</code> converges, <i>b12d</i> contains the negative sines of <i>theta</i> [0], ..., <i>theta</i> [ <i>q</i> - 1]. If <code>?bbcsd</code> fails to converge, <i>b12d</i> contains the diagonal of the partially reduced top right block.
<i>b12e</i>	Array, size <i>q</i> -1. When <code>?bbcsd</code> converges, <i>b12e</i> contains zeros. If <code>?bbcsd</code> fails to converge, <i>b11e</i> contains the superdiagonal of the partially reduced top right block.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0 and if `?bbcsd` did not converge, *info* specifies the number of nonzero entries in *phi*, and *b11d*, *b11e*, etc. contain the partially reduced matrix.

## Description

The routines `?orbdb/?unbdb` simultaneously bidiagonalizes the blocks of an  $m$ -by- $m$  partitioned orthogonal matrix  $X$ :

$$X = \begin{pmatrix} x_{11} & | & x_{12} \\ x_{21} & | & x_{22} \end{pmatrix} = \begin{pmatrix} p_1 & | \\ & | & p_2 \end{pmatrix} \begin{pmatrix} b_{11} | b_{12} & 0 & 0 \\ 0 & | & 0 & -I & 0 \\ b_{21} | b_{22} & 0 & 0 \\ 0 & | & 0 & 0 & I \end{pmatrix} \begin{pmatrix} q_1 & | \\ & | & q_2 \end{pmatrix}^T$$

or unitary matrix:

$$X = \begin{pmatrix} x_{11} & | & x_{12} \\ x_{21} & | & x_{22} \end{pmatrix} = \begin{pmatrix} p_1 & | \\ & | & p_2 \end{pmatrix} \begin{pmatrix} b_{11} | b_{12} & 0 & 0 \\ 0 & | & 0 & -I & 0 \\ b_{21} | b_{22} & 0 & 0 \\ 0 & | & 0 & 0 & I \end{pmatrix} \begin{pmatrix} q_1 & | \\ & | & q_2 \end{pmatrix}^H$$

$x_{11}$  is  $p$ -by- $q$ .  $q$  must not be larger than  $p$ ,  $m-p$ , or  $m-q$ . Otherwise,  $x$  must be transposed and/or permuted in constant time using the *trans* and *signs* options.

The orthogonal/unitary matrices  $p_1$ ,  $p_2$ ,  $q_1$ , and  $q_2$  are  $p$ -by- $p$ ,  $(m-p)$ -by- $(m-p)$ ,  $q$ -by- $q$ ,  $(m-q)$ -by- $(m-q)$ , respectively. They are represented implicitly by Housholder vectors.

The bidiagonal matrices  $b_{11}$ ,  $b_{12}$ ,  $b_{21}$ , and  $b_{22}$  are  $q$ -by- $q$  bidiagonal matrices represented implicitly by angles  $theta[0], \dots, theta[q - 1]$  and  $phi[0], \dots, phi[q - 2]$ .  $b_{11}$  and  $b_{12}$  are upper bidiagonal, while  $b_{21}$  and  $b_{22}$  are lower bidiagonal. Every entry in each bidiagonal band is a product of a sine or cosine of  $theta$  with a sine or cosine of  $phi$ . See [Sutton09] for details.

$p_1$ ,  $p_2$ ,  $q_1$ , and  $q_2$  are represented as products of elementary reflectors. .

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<i>trans</i>	<p>= 'T': <math>X, u_1, u_2, v_1^t, v_2^t</math> are stored in row-major order.</p> <p>otherwise <math>X, u_1, u_2, v_1^t, v_2^t</math> are stored in column-major order.</p>
<i>signs</i>	<p>= 'O': The lower-left block is made nonpositive (the "other" convention).</p> <p>otherwise The upper-right block is made nonpositive (the "default" convention).</p>
<i>m</i>	The number of rows and columns of the matrix $X$ .
<i>p</i>	The number of rows in $x_{11}$ and $x_{12}$ . $0 \leq p \leq m$ .
<i>q</i>	The number of columns in $x_{11}$ and $x_{21}$ . $0 \leq q \leq \min(p, m-p, m-q)$ .
<i>x11</i>	<p>Array, size (size <math>\max(1, ldx11*q)</math> for column major layout and <math>\max(1, ldx11*p)</math> for row major layout) .</p> <p>On entry, the top-left block of the orthogonal/unitary matrix to be reduced.</p>
<i>ldx11</i>	The leading dimension of the array $X_{11}$ . If <i>trans</i> = 'T', $ldx11 \geq p$ for column major layout and $ldx11 \geq q$ for row major layout. Otherwise, $ldx11 \geq q$ .
<i>x12</i>	<p>Array, size (size <math>\max(1, ldx12*(m-q))</math> for column major layout and <math>\max(1, ldx12*p)</math> for row major layout).</p> <p>On entry, the top-right block of the orthogonal/unitary matrix to be reduced.</p>
<i>ldx12</i>	The leading dimension of the array $X_{12}$ . If <i>trans</i> = 'N', $ldx12 \geq p$ for column major layout and $ldx12 \geq m - q$ for row major layout. . Otherwise, $ldx12 \geq m - q$ .
<i>x21</i>	<p>Array, size (size <math>\max(1, ldx21*q)</math> for column major layout and <math>\max(1, ldx21*(m-p))</math> for row major layout).</p> <p>On entry, the bottom-left block of the orthogonal/unitary matrix to be reduced.</p>
<i>ldx21</i>	The leading dimension of the array $X_{21}$ . If <i>trans</i> = 'N', $ldx21 \geq m - p$ for column major layout and $ldx21 \geq q$ for row major layout. . Otherwise, $ldx21 \geq q$ .
<i>x22</i>	<p>Array, size ((size <math>\max(1, ldx22*(m-q))</math> for column major layout and <math>\max(1, ldx22*(m - p))</math> for row major layout).</p> <p>On entry, the bottom-right block of the orthogonal/unitary matrix to be reduced.</p>
<i>ldx22</i>	The leading dimension of the array $X_{21}$ . If <i>trans</i> = 'N', $ldx22 \geq m - p$ for column major layout and $ldx22 \geq m - q$ for row major layout. . Otherwise, $ldx22 \geq m - q$ .

## Output Parameters

<i>x11</i>	<p>On exit, the form depends on <i>trans</i>:</p> <p>If <i>trans</i>='N', the columns of the lower triangle of <i>x11</i> specify reflectors for <math>p_1</math>, the rows of the upper triangle of <math>x11(1:q - 1, q:q - 1)</math> specify reflectors for <math>q_1</math></p> <p>otherwise <i>trans</i>='T', the rows of the upper triangle of <i>x11</i> specify reflectors for <math>p_1</math>, the columns of the lower triangle of <math>x11(1:q - 1, q:q - 1)</math> specify reflectors for <math>q_1</math></p>
<i>x12</i>	<p>On exit, the form depends on <i>trans</i>:</p> <p>If <i>trans</i>='N', the columns of the upper triangle of <i>x12</i> specify the first <math>p</math> reflectors for <math>q_2</math></p> <p>otherwise <i>trans</i>='T', the columns of the lower triangle of <i>x12</i> specify the first <math>p</math> reflectors for <math>q_2</math></p>
<i>x21</i>	<p>On exit, the form depends on <i>trans</i>:</p> <p>If <i>trans</i>='N', the columns of the lower triangle of <i>x21</i> specify the reflectors for <math>p_2</math></p> <p>otherwise <i>trans</i>='T', the columns of the upper triangle of <i>x21</i> specify the reflectors for <math>p_2</math></p>
<i>x22</i>	<p>On exit, the form depends on <i>trans</i>:</p> <p>If <i>trans</i>='N', the rows of the upper triangle of <math>x22(q+1:m-p, p+1:m-q)</math> specify the last <math>m-p-q</math> reflectors for <math>q_2</math></p> <p>otherwise <i>trans</i>='T', the columns of the lower triangle of <math>x22(p+1:m-q, q+1:m-p)</math> specify the last <math>m-p-q</math> reflectors for <math>p_2</math></p>
<i>theta</i>	Array, size $q$ . The entries of bidiagonal blocks $b_{11}$ , $b_{12}$ , $b_{21}$ , and $b_{22}$ can be computed from the angles <i>theta</i> and <i>phi</i> . See the Description section for details.
<i>phi</i>	Array, size $q-1$ . The entries of bidiagonal blocks $b_{11}$ , $b_{12}$ , $b_{21}$ , and $b_{22}$ can be computed from the angles <i>theta</i> and <i>phi</i> . See the Description section for details.
<i>taup1</i>	Array, size $p$ . Scalar factors of the elementary reflectors that define $p_1$ .
<i>taup2</i>	Array, size $m-p$ . Scalar factors of the elementary reflectors that define $p_2$ .
<i>tauq1</i>	Array, size $q$ . Scalar factors of the elementary reflectors that define $q_1$ .
<i>tauq2</i>	Array, size $m-q$ . Scalar factors of the elementary reflectors that define $q_2$ .

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

## Include Files

- mkl.h

## Description

The routine solves overdetermined or underdetermined real/ complex linear systems involving an  $m$ -by- $n$  matrix  $A$ , or its transpose/ conjugate-transpose, using a  $QR$  or  $LQ$  factorization of  $A$ . It is assumed that  $A$  has full rank.

The following options are provided:

1. If  $trans = 'N'$  and  $m \geq n$ : find the least squares solution of an overdetermined system, that is, solve the least squares problem

$$\text{minimize } \|b - A \cdot x\|_2$$

2. If  $trans = 'N'$  and  $m < n$ : find the minimum norm solution of an underdetermined system  $A \cdot X = B$ .

3. If  $trans = 'T'$  or  $'C'$  and  $m \geq n$ : find the minimum norm solution of an undetermined system  $A^H \cdot X = B$ .

4. If  $trans = 'T'$  or  $'C'$  and  $m < n$ : find the least squares solution of an overdetermined system, that is, solve the least squares problem

$$\text{minimize } \|b - A^H \cdot x\|_2$$

Several right hand side vectors  $b$  and solution vectors  $x$  can be handled in a single call; they are formed by the columns of the right hand side matrix  $B$  and the solution matrix  $X$  (when coefficient matrix is  $A$ ,  $B$  is  $m$ -by- $nrhs$  and  $X$  is  $n$ -by- $nrhs$ ; if the coefficient matrix is  $A^T$  or  $A^H$ ,  $B$  is  $n$ -by- $nrhs$  and  $X$  is  $m$ -by- $nrhs$ ).

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>trans</i>	Must be 'N', 'T', or 'C'. If $trans = 'N'$ , the linear system involves matrix $A$ ; If $trans = 'T'$ , the linear system involves the transposed matrix $A^T$ (for real flavors only); If $trans = 'C'$ , the linear system involves the conjugate-transposed matrix $A^H$ (for complex flavors only).
<i>m</i>	The number of rows of the matrix $A$ ( $m \geq 0$ ).
<i>n</i>	The number of columns of the matrix $A$ ( $n \geq 0$ ).

<i>nrhs</i>	The number of right-hand sides; the number of columns in $B$ ( $nrhs \geq 0$ ).
<i>a, b</i>	Arrays: $a$ (size $\max(1, lda * n)$ for column major layout and $\max(1, lda * m)$ for row major layout) contains the $m$ -by- $n$ matrix $A$ . $b$ (size $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * \max(m, n))$ for row major layout) contains the matrix $B$ of right hand side vectors.
<i>lda</i>	The leading dimension of $a$ ; at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout.
<i>ldb</i>	The leading dimension of $b$ ; must be at least $\max(1, m, n)$ for column major layout if $trans = 'N'$ and at least $\max(1, n)$ if $trans = 'T'$ and at least $\max(1, nrhs)$ for row major layout regardless of the value of $trans$ .

## Output Parameters

<i>a</i>	On exit, overwritten by the factorization data as follows: if $m \geq n$ , array $a$ contains the details of the $QR$ factorization of the matrix $A$ as returned by <code>?geqrf</code> ; if $m < n$ , array $a$ contains the details of the $LQ$ factorization of the matrix $A$ as returned by <code>?gelqf</code> .
<i>b</i>	If $info = 0$ , $b$ overwritten by the solution vectors, stored columnwise: if $trans = 'N'$ and $m \geq n$ , rows 1 to $n$ of $b$ contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of modulus of elements $n+1$ to $m$ in that column; if $trans = 'N'$ and $m < n$ , rows 1 to $n$ of $b$ contain the minimum norm solution vectors; if $trans = 'T'$ or $'C'$ and $m \geq n$ , rows 1 to $m$ of $b$ contain the minimum norm solution vectors; if $trans = 'T'$ or $'C'$ and $m < n$ , rows 1 to $m$ of $b$ contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of modulus of elements $m+1$ to $n$ in that column.

## Return Values

This function returns a value *info*.

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = i$ , the  $i$ -th diagonal element of the triangular factor of  $A$  is zero, so that  $A$  does not have full rank; the least squares solution could not be computed.

### ?gelsy

Computes the minimum-norm solution to a linear least squares problem using a complete orthogonal factorization of  $A$ .

## Syntax

```
lapack_int LAPACKE_sgelsy( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, float* a, lapack_int lda, float* b, lapack_int ldb, lapack_int* jpvt, float rcond,
lapack_int* rank );
```

```
lapack_int LAPACKE_dgelsy( int matrix_layout, lapack_int m, lapack_int n, lapack_int

ldb, lapack_int* jpvt, double rcond, lapack_int* rank );
```

## Include Files

- mkl.h

## Description

The ?gelsy routine computes the minimum-norm solution to a real/complex linear least squares problem:

minimize  $\|b - A*x\|_2$

using a complete orthogonal factorization of  $A$ .  $A$  is an  $m$ -by- $n$  matrix which may be rank-deficient. Several right hand side vectors  $b$  and solution vectors  $x$  can be handled in a single call; they are stored as the columns of the  $m$ -by- $nrhs$  right hand side matrix  $B$  and the  $n$ -by- $nrhs$  solution matrix  $X$ .

The routine first computes a  $QR$  factorization with column pivoting:

$$AP = Q \begin{pmatrix} R_{11} & R_{12} \\ 0 & R_{22} \end{pmatrix}$$

with  $R_{11}$  defined as the largest leading submatrix whose estimated condition number is less than  $1/rcond$ . The order of  $R_{11}$ ,  $rank$ , is the effective rank of  $A$ . Then,  $R_{22}$  is considered to be negligible, and  $R_{12}$  is annihilated by orthogonal/unitary transformations from the right, arriving at the complete orthogonal factorization:

$$AP = Q \begin{pmatrix} T_{11} & 0 \\ 0 & 0 \end{pmatrix} Z$$

The minimum-norm solution is then

$$X = PZ^T \begin{pmatrix} T_{11}^{-1} Q_1^T B \\ 0 \end{pmatrix}$$

for real flavors and

$$X = PZ^H \begin{pmatrix} T_{11}^{-1} Q_1^H B \\ 0 \end{pmatrix}$$

for complex flavors,

where  $Q_1$  consists of the first *rank* columns of  $Q$ .

The `?gelsy` routine is identical to the original deprecated `?gelsx` routine except for the following differences:

- The call to the subroutine `?geqpf` has been substituted by the call to the subroutine `?geqp3`, which is a BLAS-3 version of the  $QR$  factorization with column pivoting.
- The matrix  $B$  (the right hand side) is updated with BLAS-3.
- The permutation of the matrix  $B$  (the right hand side) is faster and more simple.

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>m</code>	The number of rows of the matrix $A$ ( $m \geq 0$ ).
<code>n</code>	The number of columns of the matrix $A$ ( $n \geq 0$ ).
<code>nrhs</code>	The number of right-hand sides; the number of columns in $B$ ( $nrhs \geq 0$ ).
<code>a, b</code>	Arrays: $a$ (size $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout) contains the $m$ -by- $n$ matrix $A$ . $b$ (size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*\max(m, n))$ for row major layout) contains the $m$ -by- $nrhs$ right hand side matrix $B$ .
<code>lda</code>	The leading dimension of $a$ ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

<i>ldb</i>	The leading dimension of <i>b</i> ; must be at least $\max(1, m, n)$ for column major layout and at least $\max(1, nrhs)$ for row major layout.
<i>jpvt</i>	Array, size at least $\max(1, n)$ . On entry, if <i>jpvt</i> [ <i>i</i> - 1] $\neq 0$ , the <i>i</i> -th column of <i>A</i> is permuted to the front of <i>AP</i> , otherwise the <i>i</i> -th column of <i>A</i> is a free column.
<i>rcond</i>	<i>rcond</i> is used to determine the effective rank of <i>A</i> , which is defined as the order of the largest leading triangular submatrix $R_{11}$ in the <i>QR</i> factorization with pivoting of <i>A</i> , whose estimated condition number $< 1/rcond$ .

## Output Parameters

<i>a</i>	On exit, overwritten by the details of the complete orthogonal factorization of <i>A</i> .
<i>b</i>	Overwritten by the <i>n</i> -by- <i>nrhs</i> solution matrix <i>X</i> .
<i>jpvt</i>	On exit, if <i>jpvt</i> [ <i>i</i> - 1] = <i>k</i> , then the <i>i</i> -th column of <i>AP</i> was the <i>k</i> -th column of <i>A</i> .
<i>rank</i>	The effective rank of <i>A</i> , that is, the order of the submatrix $R_{11}$ . This is the same as the order of the submatrix $T_{11}$ in the complete orthogonal factorization of <i>A</i> .

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

### ?gelss

*Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A.*

## Syntax

```
lapack_int LAPACKE_sgelss( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, float* a, lapack_int lda, float* b, lapack_int ldb, float* s, float rcond,
lapack_int* rank );
```

```
lapack_int LAPACKE_dgelss( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, double* a, lapack_int lda, double* b, lapack_int ldb, double* s, double rcond,
lapack_int* rank );
```

```
lapack_int LAPACKE_cgelss( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb,
float* s, float rcond, lapack_int* rank );
```

```
lapack_int LAPACKE_zgelss( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int
ldb, double* s, double rcond, lapack_int* rank );
```

## Include Files

- mkl.h

## Description

The routine computes the minimum norm solution to a real linear least squares problem:

minimize  $\|b - A*x\|_2$

using the singular value decomposition (SVD) of  $A$ .  $A$  is an  $m$ -by- $n$  matrix which may be rank-deficient. Several right hand side vectors  $b$  and solution vectors  $x$  can be handled in a single call; they are stored as the columns of the  $m$ -by- $nrhs$  right hand side matrix  $B$  and the  $n$ -by- $nrhs$  solution matrix  $X$ . The effective rank of  $A$  is determined by treating as zero those singular values which are less than  $rcond$  times the largest singular value.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>m</i>	The number of rows of the matrix $A$ ( $m \geq 0$ ).
<i>n</i>	The number of columns of the matrix $A$ ( $n \geq 0$ ).
<i>nrhs</i>	The number of right-hand sides; the number of columns in $B$ ( $nrhs \geq 0$ ).
<i>a, b</i>	Arrays: $a$ (size $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout) contains the $m$ -by- $n$ matrix $A$ . $b$ (size $\max(1, ldb*nrhs)$ for column major layout and $\max(1, ldb*\max(m, n))$ for row major layout) contains the $m$ -by- $nrhs$ right hand side matrix $B$ .
<i>lda</i>	The leading dimension of $a$ ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.
<i>ldb</i>	The leading dimension of $b$ ; must be at least $\max(1, m, n)$ for column major layout and at least $\max(1, nrhs)$ for row major layout.
<i>rcond</i>	$rcond$ is used to determine the effective rank of $A$ . Singular values $s(i) \leq rcond * s(1)$ are treated as zero. If $rcond < 0$ , machine precision is used instead.

## Output Parameters

<i>a</i>	On exit, the first $\min(m, n)$ rows of $a$ are overwritten with the matrix of right singular vectors of $A$ , stored row-wise.
<i>b</i>	Overwritten by the $n$ -by- $nrhs$ solution matrix $X$ . If $m \geq n$ and $rank = n$ , the residual sum-of-squares for the solution in the $i$ -th column is given by the sum of squares of modulus of elements $n+1:m$ in that column.

<i>s</i>	Array, size at least $\max(1, \min(m, n))$ . The singular values of <i>A</i> in decreasing order. The condition number of <i>A</i> in the 2-norm is $k_2(A) = s(1) / s(\min(m, n)) .$
<i>rank</i>	The effective rank of <i>A</i> , that is, the number of singular values which are greater than $rcond * s(1)$ .

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, then the algorithm for computing the SVD failed to converge; *i* indicates the number of off-diagonal elements of an intermediate bidiagonal form which did not converge to zero.

## ?gelsd

*Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A and a divide and conquer method.*

## Syntax

```
lapack_int LAPACKE_sgelsd( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, float* a, lapack_int lda, float* b, lapack_int ldb, float* s, float rcond,
lapack_int* rank );
```

```
lapack_int LAPACKE_dgelsd( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, double* a, lapack_int lda, double* b, lapack_int ldb, double* s, double rcond,
lapack_int* rank );
```

```
lapack_int LAPACKE_cgelsd( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb,
float* s, float rcond, lapack_int* rank );
```

```
lapack_int LAPACKE_zgelsd( int matrix_layout, lapack_int m, lapack_int n, lapack_int
nrhs, lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int
ldb, double* s, double rcond, lapack_int* rank );
```

## Include Files

- mkl.h

## Description

The routine computes the minimum-norm solution to a real linear least squares problem:

$$\text{minimize } \|b - A*x\|_2$$

using the singular value decomposition (SVD) of *A*. *A* is an *m*-by-*n* matrix which may be rank-deficient.

Several right hand side vectors *b* and solution vectors *x* can be handled in a single call; they are stored as the columns of the *m*-by-*nrhs* right hand side matrix *B* and the *n*-by-*nrhs* solution matrix *X*.

The problem is solved in three steps:

1. Reduce the coefficient matrix *A* to bidiagonal form with Householder transformations, reducing the original problem into a "bidiagonal least squares problem" (BLS).

2. Solve the BLS using a divide and conquer approach.
3. Apply back all the Householder transformations to solve the original least squares problem.

The effective rank of  $A$  is determined by treating as zero those singular values which are less than  $rcond$  times the largest singular value.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>m</i>	The number of rows of the matrix $A$ ( $m \geq 0$ ).
<i>n</i>	The number of columns of the matrix $A$ ( $n \geq 0$ ).
<i>nrhs</i>	The number of right-hand sides; the number of columns in $B$ ( $nrhs \geq 0$ ).
<i>a, b</i>	Arrays: $a$ (size $\max(1, lda * n)$ for column major layout and $\max(1, lda * m)$ for row major layout) contains the $m$ -by- $n$ matrix $A$ . $b$ (size $\max(1, ldb * nrhs)$ for column major layout and $\max(1, ldb * \max(m, n))$ for row major layout) contains the $m$ -by- $nrhs$ right hand side matrix $B$ .
<i>lda</i>	The leading dimension of $a$ ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.
<i>ldb</i>	The leading dimension of $b$ ; must be at least $\max(1, m, n)$ for column major layout and at least $\max(1, nrhs)$ for row major layout.
<i>rcond</i>	$rcond$ is used to determine the effective rank of $A$ . Singular values $s(i) \leq rcond * s(1)$ are treated as zero. If $rcond \leq 0$ , machine precision is used instead.

## Output Parameters

<i>a</i>	On exit, $A$ has been overwritten.
<i>b</i>	Overwritten by the $n$ -by- $nrhs$ solution matrix $X$ . If $m \geq n$ and $rank = n$ , the residual sum-of-squares for the solution in the $i$ -th column is given by the sum of squares of modulus of elements $n+1:m$ in that column.
<i>s</i>	Array, size at least $\max(1, \min(m, n))$ . The singular values of $A$ in decreasing order. The condition number of $A$ in the 2-norm is $k_2(A) = s(1) / s(\min(m, n))$ .
<i>rank</i>	The effective rank of $A$ , that is, the number of singular values which are greater than $rcond * s(1)$ .

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* =  $-i$ , the  $i$ -th parameter had an illegal value.

If  $info = i$ , then the algorithm for computing the SVD failed to converge;  $i$  indicates the number of off-diagonal elements of an intermediate bidiagonal form that did not converge to zero.

## Generalized Linear Least Squares (LLS) Problems: LAPACK Driver Routines

This topic describes LAPACK driver routines used for solving generalized linear least squares problems. Table "Driver Routines for Solving Generalized LLS Problems" lists all such routines.

### Driver Routines for Solving Generalized LLS Problems

Routine Name	Operation performed
<a href="#">gglse</a>	Solves the linear equality-constrained least squares problem using a generalized RQ factorization.
<a href="#">ggglm</a>	Solves a general Gauss-Markov linear model problem using a generalized QR factorization.

*?gglse*

*Solves the linear equality-constrained least squares problem using a generalized RQ factorization.*

### Syntax

```
lapack_int LAPACKE_sgglse (int matrix_layout, lapack_int m, lapack_int n, lapack_int p,
float* a, lapack_int lda, float* b, lapack_int ldb, float* c, float* d, float* x);
```

```
lapack_int LAPACKE_dgglse (int matrix_layout, lapack_int m, lapack_int n, lapack_int p,
double* a, lapack_int lda, double* b, lapack_int ldb, double* c, double* d, double* x);
```

```
lapack_int LAPACKE_cgglse (int matrix_layout, lapack_int m, lapack_int n, lapack_int p,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb,
lapack_complex_float* c, lapack_complex_float* d, lapack_complex_float* x);
```

```
lapack_int LAPACKE_zgglse (int matrix_layout, lapack_int m, lapack_int n, lapack_int p,
lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb,
lapack_complex_double* c, lapack_complex_double* d, lapack_complex_double* x);
```

### Include Files

- `mkl.h`

### Description

The routine solves the linear equality-constrained least squares (LSE) problem:

minimize  $\|c - A*x\|^2$  subject to  $B*x = d$

where  $A$  is an  $m$ -by- $n$  matrix,  $B$  is a  $p$ -by- $n$  matrix,  $c$  is a given  $m$ -vector, and  $d$  is a given  $p$ -vector. It is assumed that  $p \leq n \leq m+p$ , and

$$\text{rank}(B) = p \quad \text{and} \quad \text{rank} \begin{pmatrix} A \\ B \end{pmatrix} = n .$$

These conditions ensure that the LSE problem has a unique solution, which is obtained using a generalized RQ factorization of the matrices  $(B, A)$  given by

$$B = (0 \ R)^* Q, \quad A = Z^* T^* Q$$

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>m</i>	The number of rows of the matrix $A$ ( $m \geq 0$ ).
<i>n</i>	The number of columns of the matrices $A$ and $B$ ( $n \geq 0$ ).
<i>p</i>	The number of rows of the matrix $B$ ( $0 \leq p \leq n \leq m+p$ ).
<i>a, b, c, d</i>	Arrays:  <i>a</i> (size $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout) contains the $m$ -by- $n$ matrix $A$ . <i>b</i> (size $\max(1, ldb*n)$ for column major layout and $\max(1, ldb*p)$ for row major layout) contains the $p$ -by- $n$ matrix $B$ . <i>c</i> size at least $\max(1, m)$ , contains the right hand side vector for the least squares part of the LSE problem. <i>d</i> , size at least $\max(1, p)$ , contains the right hand side vector for the constrained equation.
<i>lda</i>	The leading dimension of <i>a</i> ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.
<i>ldb</i>	The leading dimension of <i>b</i> ; at least $\max(1, p)$ for column major layout and $\max(1, n)$ for row major layout.

## Output Parameters

<i>a</i>	The elements on and above the diagonal contain the $\min(m, n)$ -by- $n$ upper trapezoidal matrix $T$ as returned by <code>?ggrqf</code> .
<i>x</i>	The solution of the LSE problem.
<i>b</i>	On exit, the upper right triangle contains the $p$ -by- $p$ upper triangular matrix $R$ as returned by <code>?ggrqf</code> .
<i>d</i>	On exit, <i>d</i> is destroyed.
<i>c</i>	On exit, the residual sum-of-squares for the solution is given by the sum of squares of elements $n-p+1$ to $m$ of vector <i>c</i> .

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* =  $-i$ , the  $i$ -th parameter had an illegal value.

If  $info = 1$ , the upper triangular factor  $R$  associated with  $B$  in the generalized RQ factorization of the pair  $(B, A)$  is singular, so that  $rank(B) < p$ ; the least squares solution could not be computed.

If  $info = 2$ , the  $(n-p)$ -by- $(n-p)$  part of the upper trapezoidal factor  $T$  associated with  $A$  in the generalized RQ factorization of the pair  $(B, A)$  is singular, so that

$$rank \begin{pmatrix} A \\ B \end{pmatrix} < n$$

; the least squares solution could not be computed.

## ?sgglm

Solves a general Gauss-Markov linear model problem using a generalized QR factorization.

### Syntax

```
lapack_int LAPACKE_sggglm (int matrix_layout, lapack_int n, lapack_int m, lapack_int p,
float* a, lapack_int lda, float* b, lapack_int ldb, float* d, float* x, float* y);
```

```
lapack_int LAPACKE_dggglm (int matrix_layout, lapack_int n, lapack_int m, lapack_int p,
double* a, lapack_int lda, double* b, lapack_int ldb, double* d, double* x, double* y);
```

```
lapack_int LAPACKE_cggglm (int matrix_layout, lapack_int n, lapack_int m, lapack_int p,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb,
lapack_complex_float* d, lapack_complex_float* x, lapack_complex_float* y);
```

```
lapack_int LAPACKE_zggglm (int matrix_layout, lapack_int n, lapack_int m, lapack_int p,
lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int ldb,
lapack_complex_double* d, lapack_complex_double* x, lapack_complex_double* y);
```

### Include Files

- mkl.h

### Description

The routine solves a general Gauss-Markov linear model (GLM) problem:

$$\text{minimize}_x \|y\|_2 \text{ subject to } d = A*x + B*y$$

where  $A$  is an  $n$ -by- $m$  matrix,  $B$  is an  $n$ -by- $p$  matrix, and  $d$  is a given  $n$ -vector. It is assumed that  $m \leq n \leq m+p$ , and  $rank(A) = m$  and  $rank(AB) = n$ .

Under these assumptions, the constrained equation is always consistent, and there is a unique solution  $x$  and a minimal 2-norm solution  $y$ , which is obtained using a generalized QR factorization of the matrices  $(A, B)$  given by

$$A = Q \begin{pmatrix} R \\ 0 \end{pmatrix}; \quad B = Q * T * Z.$$

In particular, if matrix  $B$  is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

$$\text{minimize}_x \|B^{-1}(d-A*x)\|_2.$$

### Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>n</code>	The number of rows of the matrices $A$ and $B$ ( $n \geq 0$ ).
<code>m</code>	The number of columns in $A$ ( $m \geq 0$ ).
<code>p</code>	The number of columns in $B$ ( $p \geq n - m$ ).
<code>a, b, d</code>	Arrays: $a$ (size $\max(1, lda*m)$ for column major layout and $\max(1, lda*n)$ for row major layout) contains the $n$ -by- $m$ matrix $A$ . $b$ (size $\max(1, ldb*p)$ for column major layout and $\max(1, ldb*n)$ for row major layout) contains the $n$ -by- $p$ matrix $B$ . $d$ , size at least $\max(1, n)$ , contains the left hand side of the GLM equation.
<code>lda</code>	The leading dimension of $a$ ; at least $\max(1, n)$ for column major layout and $\max(1, m)$ for row major layout.
<code>ldb</code>	The leading dimension of $b$ ; at least $\max(1, n)$ for column major layout and $\max(1, p)$ for row major layout.

### Output Parameters

<code>x, y</code>	Arrays $x, y$ . size at least $\max(1, m)$ for $x$ and at least $\max(1, p)$ for $y$ . On exit, $x$ and $y$ are the solutions of the GLM problem.
<code>a</code>	On exit, the upper triangular part of the array $a$ contains the $m$ -by- $m$ upper triangular matrix $R$ .
<code>b</code>	On exit, if $n \leq p$ , the upper right triangle contains the $n$ -by- $n$ upper triangular matrix $T$ as returned by <code>?ggrqf</code> ; if $n > p$ , the elements on and above the $(n-p)$ -th subdiagonal contain the $n$ -by- $p$ upper trapezoidal matrix $T$ .
<code>d</code>	On exit, $d$ is destroyed

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = 1, the upper triangular factor *R* associated with *A* in the generalized QR factorization of the pair (*A*, *B*) is singular, so that  $\text{rank}(A) < m$ ; the least squares solution could not be computed.

If *info* = 2, the bottom (*n-m*)-by-(*n-m*) part of the upper trapezoidal factor *T* associated with *B* in the generalized QR factorization of the pair (*A*, *B*) is singular, so that  $\text{rank}(AB) < n$ ; the least squares solution could not be computed.

## Symmetric Eigenvalue Problems: LAPACK Driver Routines

This topic describes LAPACK driver routines used for solving symmetric eigenvalue problems. See also [computational routines](#) that can be called to solve these problems. [Table "Driver Routines for Solving Symmetric Eigenproblems"](#) lists all such driver routines.

### Driver Routines for Solving Symmetric Eigenproblems

Routine Name	Operation performed
<a href="#">syev/heev</a>	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix.
<a href="#">syevd/heevd</a>	Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric / Hermitian matrix using divide and conquer algorithm.
<a href="#">syevx/heevx</a>	Computes selected eigenvalues and, optionally, eigenvectors of a symmetric / Hermitian matrix.
<a href="#">syevr/heevr</a>	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix using the Relatively Robust Representations.
<a href="#">spev/hpev</a>	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix in packed storage.
<a href="#">spevd/hpevd</a>	Uses divide and conquer algorithm to compute all eigenvalues and (optionally) all eigenvectors of a real symmetric / Hermitian matrix held in packed storage.
<a href="#">spevx/hpevx</a>	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix in packed storage.
<a href="#">sbev /hbev</a>	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian band matrix.
<a href="#">sbevd/hbevd</a>	Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric / Hermitian band matrix using divide and conquer algorithm.
<a href="#">sbevx/hbevx</a>	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian band matrix.
<a href="#">stev</a>	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix.
<a href="#">stevd</a>	Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric tridiagonal matrix using divide and conquer algorithm.
<a href="#">stevx</a>	Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

Routine Name	Operation performed
<a href="#">stevr</a>	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix using the Relatively Robust Representations.

[?syev](#)

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix.

## Syntax

```
lapack_int LAPACKE_ssyev (int matrix_layout, char jobz, char uplo, lapack_int n, float* a, lapack_int lda, float* w);
```

```
lapack_int LAPACKE_dsyev (int matrix_layout, char jobz, char uplo, lapack_int n, double* a, lapack_int lda, double* w);
```

## Include Files

- mkl.h

## Description

The routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix  $A$ .

Note that for most cases of real symmetric eigenvalue problems the default choice should be [syevr](#) function as its underlying algorithm is faster and uses less workspace.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of $A$ . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of $A$ .
<i>n</i>	The order of the matrix $A$ ( $n \geq 0$ ).
<i>a</i>	<i>a</i> (size $\max(1, lda*n)$ ) is an array containing either upper or lower triangular part of the symmetric matrix $A$ , as specified by <i>uplo</i> .
<i>lda</i>	The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$ .

## Output Parameters

<i>a</i>	On exit, if <i>jobz</i> = 'V', then if <i>info</i> = 0, array <i>a</i> contains the orthonormal eigenvectors of the matrix $A$ . If <i>jobz</i> = 'N', then on exit the lower triangle
----------	---

(if `uplo = 'L'`) or the upper triangle (if `uplo = 'U'`) of  $A$ , including the diagonal, is overwritten.

`w`

Array, size at least  $\max(1, n)$ .

If `info = 0`, contains the eigenvalues of the matrix  $A$  in ascending order.

## Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, the  $i$ -th parameter had an illegal value.

If `info = i`, then the algorithm failed to converge;  $i$  indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

*?heev*

*Computes all eigenvalues and, optionally, eigenvectors of a Hermitian matrix.*

## Syntax

```
lapack_int LAPACKE_cheev( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_complex_float* a, lapack_int lda, float* w );
```

```
lapack_int LAPACKE_zheev( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_complex_double* a, lapack_int lda, double* w );
```

## Include Files

- `mk1.h`

## Description

The routine computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix  $A$ .

Note that for most cases of complex Hermitian eigenvalue problems the default choice should be [heevr](#) function as its underlying algorithm is faster and uses less workspace.

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>jobz</code>	Must be <code>'N'</code> or <code>'V'</code> . If <code>jobz = 'N'</code> , then only eigenvalues are computed. If <code>jobz = 'V'</code> , then eigenvalues and eigenvectors are computed.
<code>uplo</code>	Must be <code>'U'</code> or <code>'L'</code> . If <code>uplo = 'U'</code> , $a$ stores the upper triangular part of $A$ . If <code>uplo = 'L'</code> , $a$ stores the lower triangular part of $A$ .
<code>n</code>	The order of the matrix $A$ ( $n \geq 0$ ).

<i>a</i>	<i>a</i> (size $\max(1, lda*n)$ ) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> , as specified by <i>uplo</i> .
<i>lda</i>	The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$ .

## Output Parameters

<i>a</i>	On exit, if <i>jobz</i> = 'V', then if <i>info</i> = 0, array <i>a</i> contains the orthonormal eigenvectors of the matrix <i>A</i> .  If <i>jobz</i> = 'N', then on exit the lower triangle (if <i>uplo</i> = 'L') or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
<i>w</i>	Array, size at least $\max(1, n)$ .  If <i>info</i> = 0, contains the eigenvalues of the matrix <i>A</i> in ascending order.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, then the algorithm failed to converge; *i* indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

### ?syevd

*Computes all eigenvalues and, optionally, all eigenvectors of a real symmetric matrix using divide and conquer algorithm.*

## Syntax

```
lapack_int LAPACKE_ssyevd (int matrix_layout, char jobz, char uplo, lapack_int n, float* a, lapack_int lda, float* w);
```

```
lapack_int LAPACKE_dsyevd (int matrix_layout, char jobz, char uplo, lapack_int n, double* a, lapack_int lda, double* w);
```

## Include Files

- mkl.h

## Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric matrix *A*. In other words, it can compute the spectral factorization of *A* as:  $A = Z*\Lambda*Z^T$ .

Here  $\Lambda$  is a diagonal matrix whose diagonal elements are the eigenvalues  $\lambda_i$ , and *Z* is the orthogonal matrix whose columns are the eigenvectors  $z_i$ . Thus,

$$A*z_i = \lambda_i*z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the *QL* or *QR* algorithm.

Note that for most cases of real symmetric eigenvalue problems the default choice should be [syevr](#) function as its underlying algorithm is faster and uses less workspace. `?syevd` requires more workspace but is faster in some cases, especially for large matrices.

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>jobz</code>	Must be 'N' or 'V'. If <code>jobz = 'N'</code> , then only eigenvalues are computed. If <code>jobz = 'V'</code> , then eigenvalues and eigenvectors are computed.
<code>uplo</code>	Must be 'U' or 'L'. If <code>uplo = 'U'</code> , <code>a</code> stores the upper triangular part of <code>A</code> . If <code>uplo = 'L'</code> , <code>a</code> stores the lower triangular part of <code>A</code> .
<code>n</code>	The order of the matrix <code>A</code> ( $n \geq 0$ ).
<code>a</code>	Array, size ( <code>lda</code> , *). <code>a</code> (size $\max(1, lda * n)$ ) is an array containing either upper or lower triangular part of the symmetric matrix <code>A</code> , as specified by <code>uplo</code> .
<code>lda</code>	The leading dimension of the array <code>a</code> . Must be at least $\max(1, n)$ .

## Output Parameters

<code>w</code>	Array, size at least $\max(1, n)$ . If <code>info = 0</code> , contains the eigenvalues of the matrix <code>A</code> in ascending order. See also <code>info</code> .
<code>a</code>	If <code>jobz = 'V'</code> , then on exit this array is overwritten by the orthogonal matrix <code>Z</code> which contains the eigenvectors of <code>A</code> .

## Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = i`, and `jobz = 'N'`, then the algorithm failed to converge; `i` indicates the number of off-diagonal elements of an intermediate tridiagonal form which did not converge to zero.

If `info = i`, and `jobz = 'V'`, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns `info/(n+1)` through `mod(info, n+1)`.

If `info = -i`, the `i`-th parameter had an illegal value.

## Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix  $A+E$  such that  $\|E\|_2 = O(\varepsilon) * \|A\|_2$ , where  $\varepsilon$  is the machine precision.

The complex analogue of this routine is [heevd](#)

## ?heevd

Computes all eigenvalues and, optionally, all eigenvectors of a complex Hermitian matrix using divide and conquer algorithm.

### Syntax

```
lapack_int LAPACKE_cheevd( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_complex_float* a, lapack_int lda, float* w );
```

```
lapack_int LAPACKE_zheevd( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_complex_double* a, lapack_int lda, double* w );
```

### Include Files

- mkl.h

### Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a complex Hermitian matrix  $A$ . In other words, it can compute the spectral factorization of  $A$  as:  $A = Z \Lambda Z^H$ .

Here  $\Lambda$  is a real diagonal matrix whose diagonal elements are the eigenvalues  $\lambda_i$ , and  $Z$  is the (complex) unitary matrix whose columns are the eigenvectors  $z_i$ . Thus,

$$A z_i = \lambda_i z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the  $QL$  or  $QR$  algorithm.

Note that for most cases of complex Hermitian eigenvalue problems the default choice should be [heevr](#) function as its underlying algorithm is faster and uses less workspace. `?heevd` requires more workspace but is faster in some cases, especially for large matrices.

### Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of $A$ . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of $A$ .
<i>n</i>	The order of the matrix $A$ ( $n \geq 0$ ).
<i>a</i>	<i>a</i> (size $\max(1, lda * n)$ ) is an array containing either upper or lower triangular part of the Hermitian matrix $A$ , as specified by <i>uplo</i> .
<i>lda</i>	The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$ .

## Output Parameters

<i>w</i>	Array, size at least $\max(1, n)$ . If <i>info</i> = 0, contains the eigenvalues of the matrix <i>A</i> in ascending order. See also <i>info</i> .
<i>a</i>	If <i>jobz</i> = 'V', then on exit this array is overwritten by the unitary matrix <i>Z</i> which contains the eigenvectors of <i>A</i> .

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = *i*, and *jobz* = 'N', then the algorithm failed to converge; *i* off-diagonal elements of an intermediate tridiagonal form did not converge to zero;

if *info* = *i*, and *jobz* = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns *info*/(*n*+1) through  $\text{mod}(\text{info}, n+1)$ .

If *info* = -*i*, the *i*-th parameter had an illegal value.

## Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix  $A + E$  such that  $\|E\|_2 = O(\varepsilon) * \|A\|_2$ , where  $\varepsilon$  is the machine precision.

The real analogue of this routine is [syevd](#). See also [hpevd](#) for matrices held in packed storage, and [hbevd](#) for banded matrices.

?syevx

*Computes selected eigenvalues and, optionally, eigenvectors of a symmetric matrix.*

## Syntax

```
lapack_int LAPACKE_ssyevx (int matrix_layout, char jobz, char range, char uplo,
lapack_int n, float* a, lapack_int lda, float vl, float vu, lapack_int il, lapack_int
iu, float abstol, lapack_int* m, float* w, float* z, lapack_int ldz, lapack_int* ifail);

lapack_int LAPACKE_dsyevx (int matrix_layout, char jobz, char range, char uplo,
lapack_int n, double* a, lapack_int lda, double vl, double vu, lapack_int il, lapack_int
iu, double abstol, lapack_int* m, double* w, double* z, lapack_int ldz, lapack_int*
ifail);
```

## Include Files

- mkl.h

## Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix *A*. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Note that for most cases of real symmetric eigenvalue problems the default choice should be [syevr](#) function as its underlying algorithm is faster and uses less workspace. ?syevx is faster for a few selected eigenvalues.

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>jobz</code>	Must be 'N' or 'V'. If <code>jobz = 'N'</code> , then only eigenvalues are computed. If <code>jobz = 'V'</code> , then eigenvalues and eigenvectors are computed.
<code>range</code>	Must be 'A', 'V', or 'I'. If <code>range = 'A'</code> , all eigenvalues will be found. If <code>range = 'V'</code> , all eigenvalues in the half-open interval $(vl, vu]$ will be found. If <code>range = 'I'</code> , the eigenvalues with indices <i>il</i> through <i>iu</i> will be found.
<code>uplo</code>	Must be 'U' or 'L'. If <code>uplo = 'U'</code> , <i>a</i> stores the upper triangular part of <i>A</i> . If <code>uplo = 'L'</code> , <i>a</i> stores the lower triangular part of <i>A</i> .
<code>n</code>	The order of the matrix <i>A</i> ( $n \geq 0$ ).
<code>a</code>	<i>a</i> (size $\max(1, lda * n)$ ) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> , as specified by <code>uplo</code> .
<code>lda</code>	The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$ .
<code>vl, vu</code>	If <code>range = 'V'</code> , the lower and upper bounds of the interval to be searched for eigenvalues; $vl \leq vu$ . Not referenced if <code>range = 'A'</code> or 'I'.
<code>il, iu</code>	If <code>range = 'I'</code> , the indices of the smallest and largest eigenvalues to be returned. Constraints: $1 \leq il \leq iu \leq n$ , if $n > 0$ ; $il = 1$ and $iu = 0$ , if $n = 0$ . Not referenced if <code>range = 'A'</code> or 'V'.
<code>abstol</code>	The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information.
<code>ldz</code>	The leading dimension of the output array <i>z</i> ; $ldz \geq 1$ . If <code>jobz = 'V'</code> , then $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout.

## Output Parameters

<code>a</code>	On exit, the lower triangle (if <code>uplo = 'L'</code> ) or the upper triangle (if <code>uplo = 'U'</code> ) of <i>A</i> , including the diagonal, is overwritten.
<code>m</code>	The total number of eigenvalues found; $0 \leq m \leq n$ .

If  $range = 'A'$ ,  $m = n$ , and if  $range = 'I'$ ,  $m = iu-il+1$ .

$w$

Array, size at least  $\max(1, n)$ . The first  $m$  elements contain the selected eigenvalues of the matrix  $A$  in ascending order.

$z$

Array  $z$  (size  $\max(1, ldz*m)$  for column major layout and  $\max(1, ldz*n)$  for row major layout) contains eigenvectors.

If  $jobz = 'V'$ , then if  $info = 0$ , the first  $m$  columns of  $z$  contain the orthonormal eigenvectors of the matrix  $A$  corresponding to the selected eigenvalues, with the  $i$ -th column of  $z$  holding the eigenvector associated with  $w(i)$ .

If an eigenvector fails to converge, then that column of  $z$  contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If  $jobz = 'N'$ , then  $z$  is not referenced.

Note: you must ensure that at least  $\max(1, m)$  columns are supplied in the array  $z$ ; if  $range = 'V'$ , the exact value of  $m$  is not known in advance and an upper bound must be used.

*ifail*

Array, size at least  $\max(1, n)$ .

If  $jobz = 'V'$ , then if  $info = 0$ , the first  $m$  elements of *ifail* are zero; if  $info > 0$ , then *ifail* contains the indices of the eigenvectors that failed to converge.

If  $jobz = 'V'$ , then *ifail* is not referenced.

## Return Values

This function returns a value *info*.

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = i$ , then  $i$  eigenvectors failed to converge; their indices are stored in the array *ifail*.

## Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval  $[a,b]$  of width less than or equal to  $abstol + \epsilon \cdot \max(|a|, |b|)$ , where  $\epsilon$  is the machine precision.

If *abstol* is less than or equal to zero, then  $\epsilon \cdot ||T||$  is used as tolerance, where  $||T||$  is the 1-norm of the tridiagonal matrix obtained by reducing  $A$  to tridiagonal form. Eigenvalues are computed most accurately when *abstol* is set to twice the underflow threshold  $2 * \text{?lamch}('S')$ , not zero.

If this routine returns with  $info > 0$ , indicating that some eigenvectors did not converge, try setting *abstol* to  $2 * \text{?lamch}('S')$ .

*?heevx*

*Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix.*

## Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix  $A$ . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

The routine first reduces the matrix  $A$  to tridiagonal form  $T$ . Then, whenever possible, `?syevr` calls `stemr` to compute the eigenspectrum using Relatively Robust Representations. `stemr` computes eigenvalues by the `dqds` algorithm, while orthogonal eigenvectors are computed from various "good"  $L * D * L^T$  representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the each unreduced block of  $T$ :

- Compute  $T - \sigma * I = L * D * L^T$ , so that  $L$  and  $D$  define all the wanted eigenvalues to high relative accuracy. This means that small relative changes in the entries of  $D$  and  $L$  cause only small relative changes in the eigenvalues and eigenvectors. The standard (unfactored) representation of the tridiagonal matrix  $T$  does not have this property in general.
- Compute the eigenvalues to suitable accuracy. If the eigenvectors are desired, the algorithm attains full accuracy of the computed eigenvalues only right before the corresponding vectors have to be computed, (see Steps c) and d).
- For each cluster of close eigenvalues, select a new shift close to the cluster, find a new factorization, and refine the shifted eigenvalues to suitable accuracy.
- For each eigenvalue with a large enough relative separation, compute the corresponding eigenvector by forming a rank revealing twisted factorization. Go back to Step c) for any clusters that remain.

The desired accuracy of the output can be specified by the input parameter *abstol*.

The routine `?syevr` calls `stemr` when the full spectrum is requested on machines that conform to the IEEE-754 floating point standard. `?syevr` calls `stebz` and `stein` on non-IEEE machines and when partial spectrum requests are made.

Normal execution of `?dsyevr` may create NaNs and infinities and may abort due to a floating point exception in environments that do not handle NaNs and infinities in the IEEE standard default manner.

Note that `?syevr` is preferable for most cases of real symmetric eigenvalue problems as its underlying algorithm is fast and uses less workspace.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval: $vl < w[i] \leq vu.$ If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> . For <i>range</i> = 'V' or 'I' and $iu-il < n-1$ , <code>sstebz/dstebz</code> and <code>sstein/dstein</code> are called.
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	The order of the matrix <i>A</i> ( $n \geq 0$ ).
<i>a</i>	<i>a</i> (size $\max(1, lda*n)$ ) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> , as specified by <i>uplo</i> .
<i>lda</i>	The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$ .
<i>vl, vu</i>	If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$ . If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$ , if $n > 0$ ; $il=1$ and $iu=0$ , if $n = 0$ .

If *range* = 'A' or 'V', *il* and *iu* are not referenced.

*abstol*

If *jobz* = 'V', the eigenvalues and eigenvectors output have residual norms bounded by *abstol*, and the dot products between different eigenvectors are bounded by *abstol*.

If  $abstol < n * \epsilon * ||T||$ , then  $n * \epsilon * ||T||$  is used instead, where  $\epsilon$  is the machine precision, and  $||T||$  is the 1-norm of the matrix *T*. The eigenvalues are computed to an accuracy of  $\epsilon * ||T||$  irrespective of *abstol*.

If high relative accuracy is important, set *abstol* to `?lamch('S')`.

*ldz*

The leading dimension of the output array *z*.

Constraints:

$ldz \geq 1$  if *jobz* = 'N' and

$ldz \geq \max(1, n)$  for column major layout and  $ldz \geq \max(1, m)$  for row major layout if *jobz* = 'V'.

## Output Parameters

*a*

On exit, the lower triangle (if *uplo* = 'L') or the upper triangle (if *uplo* = 'U') of *A*, including the diagonal, is overwritten.

*m*

The total number of eigenvalues found,  $0 \leq m \leq n$ .

If *range* = 'A',  $m = n$ , if *range* = 'I',  $m = iu - il + 1$ , and if *range* = 'V' the exact value of *m* is not known in advance.

*w, z*

Arrays:

*w*, size at least  $\max(1, n)$ , contains the selected eigenvalues in ascending order, stored in *w*[0] to *w*[*m* - 1];

*z* (size  $\max(1, ldz * m)$  for column major layout and  $\max(1, ldz * n)$  for row major layout) .

If *jobz* = 'V', then if *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *A* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with *w*[*i* - 1].

If *jobz* = 'N', then *z* is not referenced.

*isuppz*

Array, size at least  $2 * \max(1, m)$ .

The support of the eigenvectors in *z*, i.e., the indices indicating the nonzero elements in *z*. The *i*-th eigenvector is nonzero only in elements *isuppz*[2*i* - 2] through *isuppz*[2*i* - 1]. Referenced only if eigenvectors are needed (*jobz* = 'V') and all eigenvalues are needed, that is, *range* = 'A' or *range* = 'I' and *il* = 1 and *iu* = *n*.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = i$ , an internal error has occurred.

## Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix  $A$ . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

The routine first reduces the matrix  $A$  to tridiagonal form  $T$  with a call to [hetrd](#). Then, whenever possible, *?heevr* calls [stegr](#) to compute the eigenspectrum using Relatively Robust Representations. *?stegr* computes eigenvalues by the *dqds* algorithm, while orthogonal eigenvectors are computed from various "good"  $L^*D^*L^T$  representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For each unreduced block (submatrix) of  $T$ :

- Compute  $T - \sigma I = L^*D^*L^T$ , so that  $L$  and  $D$  define all the wanted eigenvalues to high relative accuracy. This means that small relative changes in the entries of  $D$  and  $L$  cause only small relative changes in the eigenvalues and eigenvectors. The standard (unfactored) representation of the tridiagonal matrix  $T$  does not have this property in general.
- Compute the eigenvalues to suitable accuracy. If the eigenvectors are desired, the algorithm attains full accuracy of the computed eigenvalues only right before the corresponding vectors have to be computed, see Steps c) and d).
- For each cluster of close eigenvalues, select a new shift close to the cluster, find a new factorization, and refine the shifted eigenvalues to suitable accuracy.
- For each eigenvalue with a large enough relative separation, compute the corresponding eigenvector by forming a rank revealing twisted factorization. Go back to Step c) for any clusters that remain.

The desired accuracy of the output can be specified by the input parameter *abstol*.

The routine *?heevr* calls [stemr](#) when the full spectrum is requested on machines which conform to the IEEE-754 floating point standard, or [stebz](#) and [stein](#) on non-IEEE machines and when partial spectrum requests are made.

Note that the routine `zheevr` is preferable for most cases of complex Hermitian eigenvalue problems as its underlying algorithm is fast and uses less workspace.

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>jobz</code>	Must be 'N' or 'V'. If <code>jobz = 'N'</code> , then only eigenvalues are computed. If <code>jobz = 'V'</code> , then eigenvalues and eigenvectors are computed.
<code>range</code>	Must be 'A' or 'V' or 'I'. If <code>range = 'A'</code> , the routine computes all eigenvalues. If <code>range = 'V'</code> , the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu$ . If <code>range = 'I'</code> , the routine computes eigenvalues with indices <code>il</code> to <code>iu</code> . For <code>range = 'V'</code> or 'I', <code>sstebz/dstebz</code> and <code>cstein/zstein</code> are called.
<code>uplo</code>	Must be 'U' or 'L'. If <code>uplo = 'U'</code> , <code>a</code> stores the upper triangular part of <code>A</code> . If <code>uplo = 'L'</code> , <code>a</code> stores the lower triangular part of <code>A</code> .
<code>n</code>	The order of the matrix <code>A</code> ( $n \geq 0$ ).
<code>a</code>	<code>a</code> (size $\max(1, lda * n)$ ) is an array containing either upper or lower triangular part of the Hermitian matrix <code>A</code> , as specified by <code>uplo</code> .
<code>lda</code>	The leading dimension of the array <code>a</code> . Must be at least $\max(1, n)$ .
<code>vl, vu</code>	If <code>range = 'V'</code> , the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$ . If <code>range = 'A'</code> or 'I', <code>vl</code> and <code>vu</code> are not referenced.
<code>il, iu</code>	If <code>range = 'I'</code> , the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$ , if $n > 0$ ; <code>il=1</code> and <code>iu=0</code> if $n = 0$ . If <code>range = 'A'</code> or 'V', <code>il</code> and <code>iu</code> are not referenced.
<code>abstol</code>	The absolute error tolerance to which each eigenvalue/eigenvector is required. If <code>jobz = 'V'</code> , the eigenvalues and eigenvectors output have residual norms bounded by <code>abstol</code> , and the dot products between different eigenvectors are bounded by <code>abstol</code> .

If  $abstol < n * eps * ||T||$ , then  $n * eps * ||T||$  is used instead, where  $eps$  is the machine precision, and  $||T||$  is the 1-norm of the matrix  $T$ . The eigenvalues are computed to an accuracy of  $eps * ||T||$  irrespective of  $abstol$ .

If high relative accuracy is important, set  $abstol$  to `?lamch('S')`.

*ldz*

The leading dimension of the output array  $z$ . Constraints:

$ldz \geq 1$  if  $jobz = 'N'$ ;

$ldz \geq \max(1, n)$  for column major layout and  $ldz \geq \max(1, m)$  for row major layout if  $jobz = 'V'$ .

## Output Parameters

*a*

On exit, the lower triangle (if  $uplo = 'L'$ ) or the upper triangle (if  $uplo = 'U'$ ) of  $A$ , including the diagonal, is overwritten.

*m*

The total number of eigenvalues found,

$0 \leq m \leq n$ .

If  $range = 'A'$ ,  $m = n$ , if  $range = 'I'$ ,  $m = iu - il + 1$ , and if  $range = 'V'$  the exact value of  $m$  is not known in advance.

*w*

Array, size at least  $\max(1, n)$ , contains the selected eigenvalues in ascending order, stored in  $w[0]$  to  $w[m - 1]$ .

*z*

Array  $z$  (size  $\max(1, ldz * m)$  for column major layout and  $\max(1, ldz * n)$  for row major layout).

If  $jobz = 'V'$ , then if  $info = 0$ , the first  $m$  columns of  $z$  contain the orthonormal eigenvectors of the matrix  $A$  corresponding to the selected eigenvalues, with the  $i$ -th column of  $z$  holding the eigenvector associated with  $w[i - 1]$ .

If  $jobz = 'N'$ , then  $z$  is not referenced.

*isuppz*

Array, size at least  $2 * \max(1, m)$ .

The support of the eigenvectors in  $z$ , i.e., the indices indicating the nonzero elements in  $z$ . The  $i$ -th eigenvector is nonzero only in elements  $isuppz[2i - 2]$  through  $isuppz[2i - 1]$ . Referenced only if eigenvectors are needed ( $jobz = 'V'$ ) and all eigenvalues are needed, that is,  $range = 'A'$  or  $range = 'I'$  and  $il = 1$  and  $iu = n$ .

## Return Values

This function returns a value *info*.

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = i$ , an internal error has occurred.

## Application Notes

Normal execution of `?stemr` may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the IEEE standard default manner.

## Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric matrix  $A$  (held in packed storage). In other words, it can compute the spectral factorization of  $A$  as:

$$A = Z \Lambda Z^T.$$

Here  $\Lambda$  is a diagonal matrix whose diagonal elements are the eigenvalues  $\lambda_i$ , and  $Z$  is the orthogonal matrix whose columns are the eigenvectors  $z_i$ . Thus,

$$A z_i = \lambda_i z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the  $QL$  or  $QR$  algorithm.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of $A$ . If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of $A$ .
<i>n</i>	The order of the matrix $A$ ( $n \geq 0$ ).
<i>ap</i>	<i>ap</i> contains the packed upper or lower triangle of symmetric matrix $A$ , as specified by <i>uplo</i> . The dimension of <i>ap</i> must be $\max(1, n*(n+1)/2)$
<i>ldz</i>	The leading dimension of the output array $z$ . Constraints: if <i>jobz</i> = 'N', then $ldz \geq 1$ ; if <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$ .

## Output Parameters

<i>w, z</i>	<p>Arrays:</p> <p><i>w</i>, size at least <math>\max(1, n)</math>.</p> <p>If <i>info</i> = 0, contains the eigenvalues of the matrix <i>A</i> in ascending order. See also <i>info</i>.</p> <p><i>z</i> (size <math>\max(1, ldz*n)</math>).</p> <p>If <i>jobz</i> = 'V', then this array is overwritten by the orthogonal matrix <i>Z</i> which contains the eigenvectors of <i>A</i>. If <i>jobz</i> = 'N', then <i>z</i> is not referenced.</p>
<i>ap</i>	<p>On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of <i>A</i>.</p>

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = *i*, then the algorithm failed to converge; *i* indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

If *info* = -*i*, the *i*-th parameter had an illegal value.

## Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix  $A+E$  such that  $\|E\|_2 = O(\varepsilon) * \|A\|_2$ , where  $\varepsilon$  is the machine precision.

The complex analogue of this routine is [hpevd](#).

See also [syevd](#) for matrices held in full storage, and [sbevd](#) for banded matrices.

### ?hpevd

*Uses divide and conquer algorithm to compute all eigenvalues and, optionally, all eigenvectors of a complex Hermitian matrix held in packed storage.*

## Syntax

```
lapack_int LAPACKE_chpevd( int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_complex_float* ap, float* w, lapack_complex_float* z, lapack_int ldz );
lapack_int LAPACKE_zhpevd( int matrix_layout, char jobz, char uplo, lapack_int n,

## Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix  $A$  in packed storage. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>jobz</i>	Must be 'N' or 'V'. If $job = 'N'$ , then only eigenvalues are computed. If $job = 'V'$ , then eigenvalues and eigenvectors are computed.
<i>range</i>	Must be 'A' or 'V' or 'I'. If $range = 'A'$ , the routine computes all eigenvalues. If $range = 'V'$ , the routine computes eigenvalues $w[i]$ in the half-open interval: $vl < w[i] \leq vu$ . If $range = 'I'$ , the routine computes eigenvalues with indices $il$ to $iu$ .

<i>uplo</i>	<p>Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of <i>A</i>.</p> <p>If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of <i>A</i>.</p>
<i>n</i>	The order of the matrix <i>A</i> ( $n \geq 0$ ).
<i>ap</i>	<p>Array <i>ap</i> contains the packed upper or lower triangle of the symmetric matrix <i>A</i>, as specified by <i>uplo</i>.</p> <p>The size of <i>ap</i> must be at least <math>\max(1, n*(n+1)/2)</math>.</p>
<i>vl, vu</i>	<p>If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.</p> <p>Constraint: <math>vl &lt; vu</math>.</p> <p>If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.</p>
<i>il, iu</i>	<p>If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.</p> <p>Constraint: <math>1 \leq il \leq iu \leq n</math>, if <math>n &gt; 0</math>; <math>il=1</math> and <math>iu=0</math> if <math>n = 0</math>.</p> <p>If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.</p>
<i>abstol</i>	The absolute error tolerance to which each eigenvalue is required. See <i>Application notes</i> for details on error tolerance.
<i>ldz</i>	<p>The leading dimension of the output array <i>z</i>.</p> <p>Constraints:</p> <p>if <i>jobz</i> = 'N', then <math>ldz \geq 1</math>;</p> <p>if <i>jobz</i> = 'V', then <math>ldz \geq \max(1, n)</math> for column major layout and <math>ldz \geq \max(1, m)</math> for row major layout.</p>

## Output Parameters

<i>ap</i>	On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of <i>A</i> .
<i>m</i>	<p>The total number of eigenvalues found,</p> <p><math>0 \leq m \leq n</math>. If <i>range</i> = 'A', <math>m = n</math>, if <i>range</i> = 'I', <math>m = iu - il + 1</math>, and if <i>range</i> = 'V' the exact value of <i>m</i> is not known in advance..</p>
<i>w, z</i>	<p>Arrays:</p> <p><i>w</i>, size at least <math>\max(1, n)</math>.</p> <p>If <i>info</i> = 0, contains the selected eigenvalues of the matrix <i>A</i> in ascending order.</p> <p><i>z</i>(size <math>\max(1, ldz*m)</math> for column major layout and <math>\max(1, ldz*n)</math> for row major layout).</p>

If  $jobz = 'V'$ , then if  $info = 0$ , the first  $m$  columns of  $z$  contain the orthonormal eigenvectors of the matrix  $A$  corresponding to the selected eigenvalues, with the  $i$ -th column of  $z$  holding the eigenvector associated with  $w[i - 1]$ .

If an eigenvector fails to converge, then that column of  $z$  contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in  $ifail$ .

If  $jobz = 'N'$ , then  $z$  is not referenced.

*ifail*

Array, size at least  $\max(1, n)$ .

If  $jobz = 'V'$ , then if  $info = 0$ , the first  $m$  elements of  $ifail$  are zero; if  $info > 0$ , the  $ifail$  contains the indices the eigenvectors that failed to converge.

If  $jobz = 'N'$ , then  $ifail$  is not referenced.

## Return Values

This function returns a value  $info$ .

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = i$ , then  $i$  eigenvectors failed to converge; their indices are stored in the array  $ifail$ .

## Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval  $[a,b]$  of width less than or equal to  $abstol + \epsilon \cdot \max(|a|, |b|)$ , where  $\epsilon$  is the machine precision.

If  $abstol$  is less than or equal to zero, then  $\epsilon \cdot \|T\|_1$  will be used in its place, where  $T$  is the tridiagonal matrix obtained by reducing  $A$  to tridiagonal form. Eigenvalues will be computed most accurately when  $abstol$  is set to twice the underflow threshold  $2 * \text{?lamch}('S')$ , not zero.

If this routine returns with  $info > 0$ , indicating that some eigenvectors did not converge, try setting  $abstol$  to  $2 * \text{?lamch}('S')$ .

*?hpevx*

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix in packed storage.

## Syntax

```
lapack_int LAPACKE_chpevx( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_complex_float* ap, float vl, float vu, lapack_int il, lapack_int
iu, float abstol, lapack_int* m, float* w, lapack_complex_float* z, lapack_int ldz,
lapack_int* ifail );
```

```
lapack_int LAPACKE_zhpevx( int matrix_layout, char jobz, char range, char uplo,
lapack_int n, lapack_complex_double* ap, double vl, double vu, lapack_int il,
lapack_int iu, double abstol, lapack_int* m, double* w, lapack_complex_double* z,
lapack_int ldz, lapack_int* ifail );
```

## Include Files

- mkl.h

## Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix  $A$  in packed storage. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval: $vl < w[i] \leq vu$ . If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> .
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of $A$ . If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of $A$ .
<i>n</i>	The order of the matrix $A$ ( $n \geq 0$ ).
<i>ap</i>	Array <i>ap</i> contains the packed upper or lower triangle of the Hermitian matrix $A$ , as specified by <i>uplo</i> . The size of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$ .
<i>vl, vu</i>	If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$ . If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$ , if $n > 0$ ; $il=1$ and $iu=0$ if $n = 0$ . If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>abstol</i>	The absolute error tolerance to which each eigenvalue is required. See <i>Application notes</i> for details on error tolerance.
<i>ldz</i>	The leading dimension of the output array <i>z</i> . Constraints: if <i>jobz</i> = 'N', then $ldz \geq 1$ ;

if  $jobz = 'V'$ , then  $ldz \geq \max(1, n)$  for column major layout and  $ldz \geq \max(1, m)$  for row major layout.

## Output Parameters

<i>ap</i>	On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of <i>A</i> .
<i>m</i>	The total number of eigenvalues found, $0 \leq m \leq n$ .  $0 \leq m \leq n$ . If $range = 'A'$ , $m = n$ , if $range = 'I'$ , $m = iu-il+1$ , and if $range = 'V'$ the exact value of <i>m</i> is not known in advance..
<i>w</i>	Array, size at least $\max(1, n)$ .  If $info = 0$ , contains the selected eigenvalues of the matrix <i>A</i> in ascending order.
<i>z</i>	Array <i>z</i> (size $\max(1, ldz*m)$ for column major layout and $\max(1, ldz*n)$ for row major layout).  If $jobz = 'V'$ , then if $info = 0$ , the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>A</i> corresponding to the selected eigenvalues, with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with <i>w</i> ( <i>i</i> ).  If an eigenvector fails to converge, then that column of <i>z</i> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i> .  If $jobz = 'N'$ , then <i>z</i> is not referenced.
<i>ifail</i>	Array, size at least $\max(1, n)$ .  If $jobz = 'V'$ , then if $info = 0$ , the first <i>m</i> elements of <i>ifail</i> are zero; if $info > 0$ , the <i>ifail</i> contains the indices the eigenvectors that failed to converge.  If $jobz = 'N'$ , then <i>ifail</i> is not referenced.

## Return Values

This function returns a value *info*.

If  $info=0$ , the execution is successful.

If  $info = -i$ , the *i*-th parameter had an illegal value.

If  $info = i$ , then *i* eigenvectors failed to converge; their indices are stored in the array *ifail*.

## Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to  $abstol + \epsilon * \max(|a|, |b|)$ , where  $\epsilon$  is the machine precision.

If *abstol* is less than or equal to zero, then  $\epsilon * ||T||_1$  will be used in its place, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold  $2 * ?lamch('S')$ , not zero.

If this routine returns with  $info > 0$ , indicating that some eigenvectors did not converge, try setting  $abstol$  to  $2 * \epsilon_{lamch}('S')$ .

*?sbev*

*Computes all eigenvalues and, optionally, eigenvectors of a real symmetric band matrix.*

## Syntax

```
lapack_int LAPACKE_sbev (int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_int kd, float* ab, lapack_int ldab, float* w, float* z, lapack_int ldz);

lapack_int LAPACKE_dsbev (int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_int kd, double* ab, lapack_int ldab, double* w, double* z, lapack_int ldz);
```

## Include Files

## Description

The routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric band matrix  $A$ .

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of $A$ . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of $A$ .
<i>n</i>	The order of the matrix $A$ ( $n \geq 0$ ).
<i>kd</i>	The number of super- or sub-diagonals in $A$ ( $kd \geq 0$ ).
<i>ab</i>	<i>ab</i> (size at least $\max(1, ldab * n)$ for column major layout and at least $\max(1, ldab * (kd + 1))$ for row major layout) is an array containing either upper or lower triangular part of the symmetric matrix $A$ (as specified by <i>uplo</i> ) in band storage format.
<i>ldab</i>	The leading dimension of <i>ab</i> ; must be at least $kd + 1$ for column major layout and $n$ for row major layout.
<i>ldz</i>	The leading dimension of the output array $z$ . Constraints: if <i>jobz</i> = 'N', then $ldz \geq 1$ ;

if  $jobz = 'V'$ , then  $ldz \geq \max(1, n)$ .

## Output Parameters

$w, z$

Arrays:

$w$ , size at least  $\max(1, n)$ .

If  $info = 0$ , contains the eigenvalues of the matrix  $A$  in ascending order.

$z$ (size  $\max(1, ldz*n)$ ).

If  $jobz = 'V'$ , then if  $info = 0$ ,  $z$  contains the orthonormal eigenvectors of the matrix  $A$ , with the  $i$ -th column of  $z$  holding the eigenvector associated with  $w[i - 1]$ .

If  $jobz = 'N'$ , then  $z$  is not referenced.

$ab$

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form (see the description of [?sbrtd](#)).

## Return Values

This function returns a value  $info$ .

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

[?hbev](#)

lapack_complex_double* z, lapack_int ldz );
```

## Include Files

- `mkl.h`

## Description

The routine computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix  $A$ .

## Input Parameters

$matrix\_layout$

Specifies whether matrix storage layout is row major (`LAPACK_ROW_MAJOR`) or column major (`LAPACK_COL_MAJOR`).

$jobz$

Must be `'N'` or `'V'`.

If  $jobz = 'N'$ , then only eigenvalues are computed.

	If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	The order of the matrix <i>A</i> ( $n \geq 0$ ).
<i>kd</i>	The number of super- or sub-diagonals in <i>A</i> ( $kd \geq 0$ ).
<i>ab</i>	<i>ab</i> (size at least $\max(1, ldab*n)$ for column major layout and at least $\max(1, ldab*(kd + 1))$ for row major layout) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> (as specified by <i>uplo</i> ) in band storage format.
<i>ldab</i>	The leading dimension of <i>ab</i> ; must be at least $kd + 1$ for column major layout and <i>n</i> for row major layout.
<i>ldz</i>	The leading dimension of the output array <i>z</i> . Constraints: if <i>jobz</i> = 'N', then $ldz \geq 1$ ; if <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$ .

## Output Parameters

<i>w</i>	Array, size at least $\max(1, n)$ . If <i>info</i> = 0, contains the eigenvalues in ascending order.
<i>z</i>	Array <i>z</i> (size $\max(1, ldz*n)$ ). If <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>z</i> contains the orthonormal eigenvectors of the matrix <i>A</i> , with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with $w[i - 1]$ . If <i>jobz</i> = 'N', then <i>z</i> is not referenced.
<i>ab</i>	On exit, this array is overwritten by the values generated during the reduction to tridiagonal form(see the description of <a href="#">hbtrd</a> ).

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, then the algorithm failed to converge;

*i* indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

### ?sbevd

Computes all eigenvalues and, optionally, all eigenvectors of a real symmetric band matrix using divide and conquer algorithm.

### Syntax

```
lapack_int LAPACKE_ssbevd (int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_int kd, float* ab, lapack_int ldab, float* w, float* z, lapack_int ldz);
```

```
lapack_int LAPACKE_dsbevd (int matrix_layout, char jobz, char uplo, lapack_int n,
lapack_int kd, double* ab, lapack_int ldab, double* w, double* z, lapack_int ldz);
```

### Include Files

- mkl.h

### Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric band matrix  $A$ . In other words, it can compute the spectral factorization of  $A$  as:

$$A = Z \Lambda Z^T$$

Here  $\Lambda$  is a diagonal matrix whose diagonal elements are the eigenvalues  $\lambda_i$ , and  $Z$  is the orthogonal matrix whose columns are the eigenvectors  $z_i$ . Thus,

$$A z_i = \lambda_i z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the  $QL$  or  $QR$  algorithm.

### Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of $A$ . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of $A$ .
<i>n</i>	The order of the matrix $A$ ( $n \geq 0$ ).
<i>kd</i>	The number of super- or sub-diagonals in $A$ ( $kd \geq 0$ ).
<i>ab</i>	<i>ab</i> (size at least $\max(1, ldab * n)$ for column major layout and at least $\max(1, ldab * (kd + 1))$ for row major layout) is an array containing either upper or lower triangular part of the symmetric matrix $A$ (as specified by <i>uplo</i> ) in band storage format.

*ldab* The leading dimension of *ab*; must be at least  $kd+1$  for column major layout and  $n$  for row major layout.

*ldz* The leading dimension of the output array *z*.

Constraints:

if *jobz* = 'N', then  $ldz \geq 1$ ;

if *jobz* = 'V', then  $ldz \geq \max(1, n)$ .

## Output Parameters

*w, z*

Arrays:

*w*, size at least  $\max(1, n)$ .

If *info* = 0, contains the eigenvalues of the matrix *A* in ascending order. See also *info*.

*z*(size  $\max(1, ldz*n$  if *job* = 'V' and at least 1 if *job* = 'N').

If *job* = 'V', then this array is overwritten by the orthogonal matrix *Z* which contains the eigenvectors of *A*. The *i*-th column of *Z* contains the eigenvector which corresponds to the eigenvalue  $w[i - 1]$ .

If *job* = 'N', then *z* is not referenced.

*ab*

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = *i*, then the algorithm failed to converge; *i* indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

If *info* = -*i*, the *i*-th parameter had an illegal value.

## Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix  $A+E$  such that  $\|E\|_2 = O(\epsilon) * \|A\|_2$ , where  $\epsilon$  is the machine precision.

The complex analogue of this routine is [hbevd](#).

See also [syevd](#) for matrices held in full storage, and [spevd](#) for matrices held in packed storage.

### ?hbevd

## Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix *A*. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval: $vl < w[i] \leq vu$ . If <i>range</i> = 'I', the routine computes eigenvalues with indices in range <i>il</i> to <i>iu</i> .
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	The order of the matrix <i>A</i> ( $n \geq 0$ ).
<i>kd</i>	The number of super- or sub-diagonals in <i>A</i> ( $kd \geq 0$ ).
<i>ab</i>	Arrays: Array <i>ab</i> (size at least $\max(1, ldab*n)$ for column major layout and at least $\max(1, ldab*(kd + 1))$ for row major layout) contains either upper or lower triangular part of the symmetric matrix <i>A</i> (as specified by <i>uplo</i> ) in band storage format.
<i>ldab</i>	The leading dimension of <i>ab</i> ; must be at least $kd + 1$ for column major layout and <i>n</i> for row major layout.
<i>vl, vu</i>	If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$ . If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$ , if $n > 0$ ; $il=1$ and $iu=0$ if $n = 0$ . If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>abstol</i>	The absolute error tolerance to which each eigenvalue is required. See <i>Application notes</i> for details on error tolerance.
<i>ldq, ldz</i>	The leading dimensions of the output arrays <i>q</i> and <i>z</i> , respectively.

Constraints:

$ldq \geq 1, ldz \geq 1;$

If  $jobz = 'V'$ , then  $ldq \geq \max(1, n)$  and  $ldz \geq \max(1, n)$  for column major layout and  $ldz \geq \max(1, m)$  for row major layout .

## Output Parameters

$q$	<p>Array, size <math>\max(1, ldz*n)</math>.</p> <p>If <math>jobz = 'V'</math>, the <math>n</math>-by-<math>n</math> orthogonal matrix is used in the reduction to tridiagonal form.</p> <p>If <math>jobz = 'N'</math>, the array <math>q</math> is not referenced.</p>

## Return Values

This function returns a value *info*.

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = i$ , then  $i$  eigenvectors failed to converge; their indices are stored in the array *ifail*.

## Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval  $[a,b]$  of width less than or equal to  $abstol + \epsilon \cdot \max(|a|, |b|)$ , where  $\epsilon$  is the machine precision.

If  $abstol$  is less than or equal to zero, then  $\epsilon \cdot \|T\|_1$  is used as tolerance, where  $T$  is the tridiagonal matrix obtained by reducing  $A$  to tridiagonal form. Eigenvalues will be computed most accurately when  $abstol$  is set to twice the underflow threshold  $2 \cdot \text{?lamch}('S')$ , not zero.

If this routine returns with  $info > 0$ , indicating that some eigenvectors did not converge, try setting  $abstol$  to  $2 \cdot \text{?lamch}('S')$ .

### *?hbev*

*Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian band matrix.*

## Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix  $A$ . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval: $vl < w[i] \leq vu$ .

	If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> .
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	The order of the matrix <i>A</i> ( $n \geq 0$ ).
<i>kd</i>	The number of super- or sub-diagonals in <i>A</i> ( $kd \geq 0$ ).
<i>ab</i>	<i>ab</i> (size at least $\max(1, ldab*n)$ for column major layout and at least $\max(1, ldab*(kd + 1))$ for row major layout) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> (as specified by <i>uplo</i> ) in band storage format.
<i>ldab</i>	The leading dimension of <i>ab</i> ; must be at least <i>kd</i> + 1 for column major layout and <i>n</i> for row major layout.
<i>vl, vu</i>	If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$ . If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$ , if $n > 0$ ; $il=1$ and $iu=0$ if $n = 0$ . If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>abstol</i>	The absolute error tolerance to which each eigenvalue is required. See <i>Application notes</i> for details on error tolerance.
<i>ldq, ldz</i>	The leading dimensions of the output arrays <i>q</i> and <i>z</i> , respectively. Constraints: $ldq \geq 1, ldz \geq 1$ ; If <i>jobz</i> = 'V', then $ldq \geq \max(1, n)$ and $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout.

## Output Parameters

<i>q</i>	Array, size $\max(1, ldz*n)$ . If <i>jobz</i> = 'V', the <i>n</i> -by- <i>n</i> unitary matrix is used in the reduction to tridiagonal form. If <i>jobz</i> = 'N', the array <i>q</i> is not referenced.
<i>m</i>	The total number of eigenvalues found, $0 \leq m \leq n$ . If <i>range</i> = 'A', $m = n$ , if <i>range</i> = 'I', $m = iu - il + 1$ , and if <i>range</i> = 'V', the exact value of <i>m</i> is not known in advance..

<i>w</i>	Array, size at least $\max(1, n)$ . The first $m$ elements contain the selected eigenvalues of the matrix $A$ in ascending order.
<i>z</i>	<p>Array <math>z</math> (size at least <math>\max(1, ldz*m)</math> for column major layout and <math>\max(1, ldz*n)</math> for row major layout).</p> <p>If <math>jobz = 'V'</math>, then if <math>info = 0</math>, the first <math>m</math> columns of <math>z</math> contain the orthonormal eigenvectors of the matrix <math>A</math> corresponding to the selected eigenvalues, with the <math>i</math>-th column of <math>z</math> holding the eigenvector associated with <math>w[i - 1]</math>.</p> <p>If an eigenvector fails to converge, then that column of <math>z</math> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i>.</p> <p>If <math>jobz = 'N'</math>, then <math>z</math> is not referenced.</p>
<i>ab</i>	<p>On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.</p> <p>If <math>uplo = 'U'</math>, the first superdiagonal and the diagonal of the tridiagonal matrix <math>T</math> are returned in rows <math>kd</math> and <math>kd+1</math> of <math>ab</math>, and if <math>uplo = 'L'</math>, the diagonal and first subdiagonal of <math>T</math> are returned in the first two rows of <math>ab</math>.</p>
<i>ifail</i>	<p>Array, size at least <math>\max(1, n)</math>.</p> <p>If <math>jobz = 'V'</math>, then if <math>info = 0</math>, the first <math>m</math> elements of <i>ifail</i> are zero; if <math>info &gt; 0</math>, the <i>ifail</i> contains the indices of the eigenvectors that failed to converge.</p> <p>If <math>jobz = 'N'</math>, then <i>ifail</i> is not referenced.</p>

## Return Values

This function returns a value *info*.

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = i$ , then  $i$  eigenvectors failed to converge; their indices are stored in the array *ifail*.

## Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval  $[a,b]$  of width less than or equal to  $abstol + \epsilon * \max(|a|, |b|)$ , where  $\epsilon$  is the machine precision.

If *abstol* is less than or equal to zero, then  $\epsilon * ||T||_1$  will be used in its place, where  $T$  is the tridiagonal matrix obtained by reducing  $A$  to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold  $2 * \text{lamch}('S')$ , not zero.

If this routine returns with  $info > 0$ , indicating that some eigenvectors did not converge, try setting *abstol* to  $2 * \text{lamch}('S')$ .

*?stev*

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix.

## Syntax

<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>n</i>	The order of the matrix $A$ ( $n \geq 0$ ).
<i>d</i> , <i>e</i>	Arrays: Array <i>d</i> contains the $n$ diagonal elements of the tridiagonal matrix $A$ . The size of <i>d</i> must be at least $\max(1, n)$ . Array <i>e</i> contains the $n-1$ subdiagonal elements of the tridiagonal matrix $A$ . The size of <i>e</i> must be at least $\max(1, n)$ . The $n$ -th element of this array is used as workspace.
<i>ldz</i>	The leading dimension of the output array <i>z</i> ; $ldz \geq 1$ . If <i>jobz</i> = 'V' then $ldz \geq \max(1, n)$ .

## Output Parameters

<i>d</i>	On exit, if <i>info</i> = 0, contains the eigenvalues of the matrix $A$ in ascending order.
<i>z</i>	Array, size (size $\max(1, ldz*n)$ ). If <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>z</i> contains the orthonormal eigenvectors of the matrix $A$ , with the $i$ -th column of <i>z</i> holding the eigenvector associated with the eigenvalue returned in $d[i - 1]$ . If <i>jobz</i> = 'N', then <i>z</i> is not referenced.
<i>e</i>	On exit, this array is overwritten with intermediate results.

## Return Values

This function returns a value *info*.

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = i$ , then the algorithm failed to converge;

$i$  elements of  $e$  did not converge to zero.

### ?stevd

Computes all eigenvalues and, optionally, all eigenvectors of a real symmetric tridiagonal matrix using divide and conquer algorithm.

## Syntax

```
lapack_int LAPACKE_sstevd (int matrix_layout, char jobz, lapack_int n, float* d, float* e, float* z, lapack_int ldz);
```

```
lapack_int LAPACKE_dstevd (int matrix_layout, char jobz, lapack_int n, double* d, double* e, double* z, lapack_int ldz);
```

## Include Files

- mkl.h

## Description

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric tridiagonal matrix  $T$ . In other words, the routine can compute the spectral factorization of  $T$  as:  $T = Z\Lambda Z^T$ .

Here  $\Lambda$  is a diagonal matrix whose diagonal elements are the eigenvalues  $\lambda_i$ , and  $Z$  is the orthogonal matrix whose columns are the eigenvectors  $z_i$ . Thus,

$$T^*z_i = \lambda_i^*z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the  $QL$  or  $QR$  algorithm.

There is no complex analogue of this routine.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>n</i>	The order of the matrix $T$ ( $n \geq 0$ ).
<i>d, e</i>	Arrays: <i>d</i> contains the $n$ diagonal elements of the tridiagonal matrix $T$ . The dimension of <i>d</i> must be at least $\max(1, n)$ . <i>e</i> contains the $n-1$ off-diagonal elements of $T$ .

The dimension of  $e$  must be at least  $\max(1, n)$ . The  $n$ -th element of this array is used as workspace.

$ldz$

The leading dimension of the output array  $z$ . Constraints:

$ldz \geq 1$  if  $job = 'N'$ ;

$ldz \geq \max(1, n)$  if  $job = 'V'$ .

## Output Parameters

$d$

On exit, if  $info = 0$ , contains the eigenvalues of the matrix  $T$  in ascending order.

See also *info*.

$z$

Array, size  $\max(1, ldz*n)$  if  $jobz = 'V'$  and 1 if  $jobz = 'N'$  .

If  $jobz = 'V'$ , then this array is overwritten by the orthogonal matrix  $Z$  which contains the eigenvectors of  $T$ .

If  $jobz = 'N'$ , then  $z$  is not referenced.

$e$

On exit, this array is overwritten with intermediate results.

## Return Values

This function returns a value *info*.

If  $info=0$ , the execution is successful.

If  $info = i$ , then the algorithm failed to converge;  $i$  indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

## Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix  $T+E$  such that  $\|E\|_2 = O(\epsilon) * \|T\|_2$ , where  $\epsilon$  is the machine precision.

If  $\lambda_j$  is an exact eigenvalue, and  $\mu_j$  is the corresponding computed value, then

$$|\mu_j - \lambda_j| \leq c(n) * \epsilon * \|T\|_2$$

where  $c(n)$  is a modestly increasing function of  $n$ .

If  $z_j$  is the corresponding exact eigenvector, and  $w_j$  is the corresponding computed vector, then the angle  $\theta(z_j, w_j)$  between them is bounded as follows:

$$\theta(z_j, w_j) \leq c(n) * \epsilon * \|T\|_2 / \min_{i \neq j} |\lambda_i - \lambda_j|.$$

Thus the accuracy of a computed eigenvector depends on the gap between its eigenvalue and all the other eigenvalues.

?stevx

*Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.*

## Syntax

```
lapack_int LAPACKE_sstevx (int matrix_layout, char jobz, char range, lapack_int n,
float* d, float* e, float vl, float vu, lapack_int il, lapack_int iu, float abstol,
lapack_int* m, float* w, float* z, lapack_int ldz, lapack_int* ifail);
```

```
lapack_int LAPACKE_dstevx (int matrix_layout, char jobz, char range, lapack_int n,
double* d, double* e, double vl, double vu, lapack_int il, lapack_int iu, double abstol,
lapack_int* m, double* w, double* z, lapack_int ldz, lapack_int* ifail);
```

## Include Files

The $n$ -th element of this array is used as workspace.
<i>vl, vu</i>	If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$ . If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$ , if $n > 0$ ; $il=1$ and $iu=0$ if $n = 0$ . If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>abstol</i>	

*ldz* The leading dimensions of the output array *z*;  $ldz \geq 1$ . If *jobz* = 'V', then  $ldz \geq \max(1, n)$  for column major layout and  $ldz \geq \max(1, m)$  for row major layout.

## Output Parameters

*m* The total number of eigenvalues found,  
 $0 \leq m \leq n$ .  
 If *range* = 'A',  $m = n$ , if *range* = 'I',  $m = iu - il + 1$ , and if *range* = 'V' the exact value of *m* is unknown.

*w, z* Arrays:  
*w*, size at least  $\max(1, n)$ .  
 The first *m* elements of *w* contain the selected eigenvalues of the matrix *A* in ascending order.  
*z* (size at least  $\max(1, ldz * m)$  for column major layout and  $\max(1, ldz * n)$  for row major layout) .  
 If *jobz* = 'V', then if *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *A* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with  $w[i - 1]$ .  
 If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.  
 If *jobz* = 'N', then *z* is not referenced.

*d, e* On exit, these arrays may be multiplied by a constant factor chosen to avoid overflow or underflow in computing the eigenvalues.

*ifail* Array, size at least  $\max(1, n)$ .  
 If *jobz* = 'V', then if *info* = 0, the first *m* elements of *ifail* are zero; if *info* > 0, the *ifail* contains the indices of the eigenvectors that failed to converge.  
 If *jobz* = 'N', then *ifail* is not referenced.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, then *i* eigenvectors failed to converge; their indices are stored in the array *ifail*.

## Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to  $abstol + \epsilon * \max(|a|, |b|)$ , where  $\epsilon$  is the machine precision.

If *abstol* is less than or equal to zero, then  $\epsilon * |A|_1$  is used instead. Eigenvalues are computed most accurately when *abstol* is set to twice the underflow threshold  $2 * \text{?lamch}('S')$ , not zero.

If this routine returns with  $info > 0$ , indicating that some eigenvectors did not converge, set  $abstol$  to  $2 * \epsilon_{lamch}('S')$ .

### ?stevr

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix using the Relatively Robust Representations.

## Syntax

lapack_int LAPACKE_sstevr (int matrix_layout, char jobz, char range, lapack_int n,
float* d, float* e, float vl, float vu, lapack_int il, lapack_int iu, float abstol,
lapack_int* m, float* w, float* z, lapack_int ldz, lapack_int* isuppz);
```

```
lapack_int LAPACKE_dstevr (int matrix_layout, char jobz, char range, lapack_int n,
double* d, double* e, double vl, double vu, lapack_int il, lapack_int iu, double abstol,
lapack_int* m, double* w, double* z, lapack_int ldz, lapack_int* isuppz);
```

## Include Files

- mkl.h

## Description

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix  $T$ . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, the routine calls [stemr](#) to compute the eigenspectrum using Relatively Robust Representations. [stegr](#) computes eigenvalues by the  $dqds$  algorithm, while orthogonal eigenvectors are computed from various "good"  $L * D * L^T$  representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the  $i$ -th unreduced block of  $T$ :

- Compute  $T - \sigma_i = L_i * D_i * L_i^T$ , such that  $L_i * D_i * L_i^T$  is a relatively robust representation.
- Compute the eigenvalues,  $\lambda_j$ , of  $L_i * D_i * L_i^T$  to high relative accuracy by the  $dqds$  algorithm.
- If there is a cluster of close eigenvalues, "choose"  $\sigma_i$  close to the cluster, and go to Step (a).
- Given the approximate eigenvalue  $\lambda_j$  of  $L_i * D_i * L_i^T$ , compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter  $abstol$ .

The routine `?stevr` calls [stemr](#) when the full spectrum is requested on machines which conform to the IEEE-754 floating point standard. `?stevr` calls [stebz](#) and [stein](#) on non-IEEE machines and when partial spectrum requests are made.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	Must be 'A' or 'V' or 'I'.

If  $range = 'A'$ , the routine computes all eigenvalues.

If  $range = 'V'$ , the routine computes eigenvalues  $w[i]$  in the half-open interval:

$$vl < w[i] \leq vu.$$

If  $range = 'I'$ , the routine computes eigenvalues with indices  $il$  to  $iu$ .

For  $range = 'V'$  or  $'I'$  and  $iu - il < n - 1$ , `sstebz/dstebz` and `sstein/dstein` are called.

$n$  The order of the matrix  $T$  ( $n \geq 0$ ).

$d, e$  Arrays:

$d$  contains the  $n$  diagonal elements of the tridiagonal matrix  $T$ .

The dimension of  $d$  must be at least  $\max(1, n)$ .

$e$  contains the  $n-1$  subdiagonal elements of  $A$ .

The dimension of  $e$  must be at least  $\max(1, n-1)$ . The  $n$ -th element of this array is used as workspace.

$vl, vu$  If  $range = 'V'$ , the lower and upper bounds of the interval to be searched for eigenvalues.

Constraint:  $vl < vu$ .

If  $range = 'A'$  or  $'I'$ ,  $vl$  and  $vu$  are not referenced.

$il, iu$  If  $range = 'I'$ , the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint:  $1 \leq il \leq iu \leq n$ , if  $n > 0$ ;  $il=1$  and  $iu=0$  if  $n = 0$ .

If  $range = 'A'$  or  $'V'$ ,  $il$  and  $iu$  are not referenced.

$abstol$  The absolute error tolerance to which each eigenvalue/eigenvector is required.

If  $jobz = 'V'$ , the eigenvalues and eigenvectors output have residual norms bounded by  $abstol$ , and the dot products between different eigenvectors are bounded by  $abstol$ . If  $abstol < n * eps * ||T||$ , then  $n * eps * ||T||$  will be used in its place, where  $eps$  is the machine precision, and  $||T||$  is the 1-norm of the matrix  $T$ . The eigenvalues are computed to an accuracy of  $eps * ||T||$  irrespective of  $abstol$ .

If high relative accuracy is important, set  $abstol$  to `?lamch('S')`.

$ldz$  The leading dimension of the output array  $z$ .

Constraints:

$ldz \geq 1$  if  $jobz = 'N'$ ;

$ldz \geq \max(1, n)$  for column major layout and  $ldz \geq \max(1, m)$  for row major layout if  $jobz = 'V'$ .

## Output Parameters

$m$  The total number of eigenvalues found,

$0 \leq m \leq n$ . If  $range = 'A'$ ,  $m = n$ , if  $range = 'I'$ ,  $m = iu-il+1$ , and if  $range = 'V'$  the exact value of  $m$  is unknown..

$w, z$

Arrays:

$w$ , size at least  $\max(1, n)$ .

The first  $m$  elements of  $w$  contain the selected eigenvalues of the matrix  $T$  in ascending order.

$z$  (size at least  $\max(1, ldz*m)$  for column major layout and  $\max(1, ldz*n)$  for row major layout).

If  $jobz = 'V'$ , then if  $info = 0$ , the first  $m$  columns of  $z$  contain the orthonormal eigenvectors of the matrix  $T$  corresponding to the selected eigenvalues, with the  $i$ -th column of  $z$  holding the eigenvector associated with  $w[i - 1]$ .

If  $jobz = 'N'$ , then  $z$  is not referenced.

$d, e$

On exit, these arrays may be multiplied by a constant factor chosen to avoid overflow or underflow in computing the eigenvalues.

$isuppz$

Array, size at least  $2 * \max(1, m)$ .

The support of the eigenvectors in  $z$ , i.e., the indices indicating the nonzero elements in  $z$ . The  $i$ -th eigenvector is nonzero only in elements  $isuppz[2i - 2]$  through  $isuppz[2i - 1]$ .

Implemented only for  $range = 'A'$  or  $'I'$  and  $iu-il = n-1$ .

## Return Values

This function returns a value  $info$ .

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = i$ , an internal error has occurred.

## Application Notes

Normal execution of the routine `?stegr` may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the IEEE standard default manner.

## Nonsymmetric Eigenvalue Problems: LAPACK Driver Routines

This topic describes LAPACK driver routines used for solving nonsymmetric eigenproblems. See also [computational routines](#) that can be called to solve these problems.

Table "Driver Routines for Solving Nonsymmetric Eigenproblems" lists all such driver routines.

### Driver Routines for Solving Nonsymmetric Eigenproblems

Routine Name	Operation performed
<a href="#">gees</a>	Computes the eigenvalues and Schur factorization of a general matrix, and orders the factorization so that selected eigenvalues are at the top left of the Schur form.

### Description

The routine computes for an  $n$ -by- $n$  real/complex nonsymmetric matrix  $A$ , the eigenvalues, the real Schur form  $T$ , and, optionally, the matrix of Schur vectors  $Z$ . This gives the Schur factorization  $A = Z^* T^* Z^H$ .

Optionally, it also orders the eigenvalues on the diagonal of the real-Schur/Schur form so that selected eigenvalues are at the top left. The leading columns of  $Z$  then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A real matrix is in real-Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

where  $b*c < 0$ . The eigenvalues of such a block are

$$a \pm i\sqrt{bc}$$

A complex matrix is in Schur form if it is upper triangular.

### Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>jobvs</i>	Must be 'N' or 'V'. If <i>jobvs</i> = 'N', then Schur vectors are not computed. If <i>jobvs</i> = 'V', then Schur vectors are computed.
<i>sort</i>	Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. If <i>sort</i> = 'N', then eigenvalues are not ordered. If <i>sort</i> = 'S', eigenvalues are ordered (see <i>select</i> ).
<i>select</i>	If <i>sort</i> = 'S', <i>select</i> is used to select eigenvalues to sort to the top left of the Schur form.

If `sort = 'N'`, `select` is not referenced.

For real flavors:

An eigenvalue  $wr[j] + \sqrt{-1} * wi[j]$  is selected if `select(wr[j], wi[j])` is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

For complex flavors:

An eigenvalue  $w[j]$  is selected if `select(w[j])` is true.

Note that a selected complex eigenvalue may no longer satisfy `select(wr[j], wi[j]) = 1` after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case `info` may be set to  $n+2$  (see `info` below).

`n`

The order of the matrix  $A$  ( $n \geq 0$ ).

`a`

Arrays:

`a` (size at least  $\max(1, lda * n)$ ) is an array containing the  $n$ -by- $n$  matrix  $A$ .

`lda`

The leading dimension of the array `a`. Must be at least  $\max(1, n)$ .

`ldvs`

The leading dimension of the output array `vs`. Constraints:

`ldvs`  $\geq 1$ ;

`ldvs`  $\geq \max(1, n)$  if `jobvs = 'V'`.

## Output Parameters

`a`

On exit, this array is overwritten by the real-Schur/Schur form  $T$ .

`sdim`

If `sort = 'N'`, `sdim` = 0.

If `sort = 'S'`, `sdim` is equal to the number of eigenvalues (after sorting) for which `select` is true.

Note that for real flavors complex conjugate pairs for which `select` is true for either eigenvalue count as 2.

`wr, wi`

Arrays, size at least  $\max(1, n)$  each. Contain the real and imaginary parts, respectively, of the computed eigenvalues, in the same order that they appear on the diagonal of the output real-Schur form  $T$ . Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

`w`

Array, size at least  $\max(1, n)$ . Contains the computed eigenvalues. The eigenvalues are stored in the same order as they appear on the diagonal of the output Schur form  $T$ .

`vs`

Array `vs` (size at least  $\max(1, ldvs * n)$ ).

If `jobvs = 'V'`, `vs` contains the orthogonal/unitary matrix  $Z$  of Schur vectors.

If `jobvs = 'N'`, `vs` is not referenced.

## Return Values

This function returns a value `info`.

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = i$ , and

$i \leq n$ :

the QR algorithm failed to compute all the eigenvalues; elements  $1:i/o-1$  and  $i+1:n$  of  $wr$  and  $wi$  (for real flavors) or  $w$  (for complex flavors) contain those eigenvalues which have converged; if  $jobvs = 'V'$ ,  $vs$  contains the matrix which reduces  $A$  to its partially converged Schur form;

$i = n+1$ :

the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned);

$i = n+2$ :

after reordering, round-off changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy  $select = 1$ . This could also be caused by underflow due to scaling.

**?geesx**

*Computes the eigenvalues and Schur factorization of a general matrix, orders the factorization and computes reciprocal condition numbers.*

## Syntax

```
lapack_int LAPACKE_sgeesx( int matrix_layout, char jobvs, char sort, LAPACK_S_SELECT2

## Description

The routine computes for an  $n$ -by- $n$  real/complex nonsymmetric matrix  $A$ , the eigenvalues and, optionally, the left and/or right eigenvectors. The right eigenvector  $v$  of  $A$  satisfies

$$A*v = \lambda*v$$

where  $\lambda$  is its eigenvalue.

The left eigenvector  $u$  of  $A$  satisfies

$$u^H*A = \lambda*u^H$$

where  $u^H$  denotes the conjugate transpose of  $u$ . The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>jobvl</i>	Must be 'N' or 'V'. If <i>jobvl</i> = 'N', then left eigenvectors of $A$ are not computed. If <i>jobvl</i> = 'V', then left eigenvectors of $A$ are computed.
<i>jobvr</i>	Must be 'N' or 'V'. If <i>jobvr</i> = 'N', then right eigenvectors of $A$ are not computed. If <i>jobvr</i> = 'V', then right eigenvectors of $A$ are computed.
<i>n</i>	The order of the matrix $A$ ( $n \geq 0$ ).
<i>a</i>	$a$ (size at least $\max(1, lda*n)$ ) is an array containing the $n$ -by- $n$ matrix $A$ .
<i>lda</i>	The leading dimension of the array $a$ . Must be at least $\max(1, n)$ .
<i>ldvl, ldvr</i>	The leading dimensions of the output arrays $vl$ and $vr$ , respectively. Constraints: $ldvl \geq 1$ ; $ldvr \geq 1$ . If <i>jobvl</i> = 'V', $ldvl \geq \max(1, n)$ ;

If  $jobvr = 'V'$ ,  $ldvr \geq \max(1, n)$ .

## Output Parameters

$a$	On exit, this array is overwritten.
$wr, wi$	Arrays, size at least $\max(1, n)$ each.  Contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.
$w$	Array, size at least $\max(1, n)$ .  Contains the computed eigenvalues.
$vl, vr$	Arrays:  $vl$ (size at least $\max(1, ldvl*n)$ ).  If $jobvl = 'N'$ , $vl$ is not referenced.  <i>For real flavors:</i>  If the $j$ -th eigenvalue is real, the $i$ -th component of the $j$ -th eigenvector $u_j$ is stored in $vl[(i - 1) + (j - 1)*ldvl]$ for column major layout and in $vl[(i - 1)*ldvl + (j - 1)]$ for row major layout..  If the $j$ -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then for $i = \text{sqrt}(-1)$ , the $k$ -th component of the $j$ -th eigenvector $u_j$ is $vl[(k - 1) + (j - 1)*ldvl] + i*vl[(k - 1) + j*ldvl]$ for column major layout and as $vl[(k - 1)*ldvl + (j - 1)] + i*vl[(k-1)*ldvl + j]$ for row major layout. Similarly, the $k$ -th component of vector $(j+1)$ $u_{j+1}$ is $vl[(k - 1) + (j - 1)*ldvl] - i*vl[(k - 1) + j*ldvl]$ for column major layout and as $vl[(k - 1)*ldvl + (j - 1)] - i*vl[(k - 1)*ldvl + j]$ for row major layout. .  <i>For complex flavors:</i>  The $i$ -th component of the $j$ -th eigenvector $u_j$ is stored in $vl[(i - 1) + (j - 1)*ldvl]$ for column major layout and in $vl[(i - 1)*ldvl + (j - 1)]$ for row major layout.  $vr$ (size at least $\max(1, ldvr*n)$ ).  If $jobvr = 'N'$ , $vr$ is not referenced.  <i>For real flavors:</i>  If the $j$ -th eigenvalue is real, then the $i$ -th component of $j$ -th eigenvector $v_j$ is stored in $vr[(i - 1) + (j - 1)*ldvr]$ for column major layout and in $vr[(i - 1)*ldvr + (j - 1)]$ for row major layout..  If the $j$ -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then for $i = \text{sqrt}(-1)$ , the $k$ -th component of the $j$ -th eigenvector $v_j$ is $vr[(k - 1) + (j - 1)*ldvr] + i*vr[(k - 1) + j*ldvr]$ for column major layout and as $vr[(k - 1)*ldvr + (j - 1)] + i*vr[(k - 1)*ldvr + j]$ for row major layout. Similarly, the $k$ -th component of vector $j + 1$ $v_{j+1}$ is $vr[(k - 1) + (j - 1)*ldvr] - i*vr[(k - 1) + j*ldvr]$ for column major layout and as $vr[(k - 1)*ldvr + (j - 1)] - i*vr[(k - 1)*ldvr + j]$ for row major layout.  <i>For complex flavors:</i>

The  $i$ -th component of the  $j$ -th eigenvector  $v_j$  is stored in  $vr[(i - 1) + (j - 1)*ldvr]$  for column major layout and in  $vr[(i - 1)*ldvr + (j - 1)]$  for row major layout.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors have been computed; elements  $i+1:n$  of *wr* and *wi* (for real flavors) or *w* (for complex flavors) contain those eigenvalues which have converged.

### ?ggev

*Computes the eigenvalues and left and right eigenvectors of a general matrix, with preliminary matrix balancing, and computes reciprocal condition numbers for the eigenvalues and right eigenvectors.*

## Description

The routine computes for an  $n$ -by- $n$  real/complex nonsymmetric matrix  $A$ , the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (*ilo*, *ihi*, *scale*, and *abnrm*), reciprocal condition numbers for the eigenvalues (*rconde*), and reciprocal condition numbers for the right eigenvectors (*rcondv*).

The right eigenvector  $v$  of  $A$  satisfies

$$A \cdot v = \lambda \cdot v$$

where  $\lambda$  is its eigenvalue.

The left eigenvector  $u$  of  $A$  satisfies

$$u^H A = \lambda u^H$$

where  $u^H$  denotes the conjugate transpose of  $u$ . The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation  $D \cdot A \cdot \text{inv}(D)$ , where  $D$  is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see [LUG], Section 4.10.

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<code>balanc</code>	<p>Must be 'N', 'P', 'S', or 'B'. Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues.</p> <p>If <code>balanc</code> = 'N', do not diagonally scale or permute;</p> <p>If <code>balanc</code> = 'P', perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale;</p> <p>If <code>balanc</code> = 'S', diagonally scale the matrix, i.e. replace <math>A</math> by <math>D \cdot A \cdot \text{inv}(D)</math>, where <math>D</math> is a diagonal matrix chosen to make the rows and columns of <math>A</math> more equal in norm. Do not permute;</p> <p>If <code>balanc</code> = 'B', both diagonally scale and permute <math>A</math>.</p> <p>Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.</p>
<code>jobvl</code>	<p>Must be 'N' or 'V'.</p> <p>If <code>jobvl</code> = 'N', left eigenvectors of <math>A</math> are not computed;</p> <p>If <code>jobvl</code> = 'V', left eigenvectors of <math>A</math> are computed.</p> <p>If <code>sense</code> = 'E' or 'B', then <code>jobvl</code> must be 'V'.</p>
<code>jobvr</code>	<p>Must be 'N' or 'V'.</p> <p>If <code>jobvr</code> = 'N', right eigenvectors of <math>A</math> are not computed;</p> <p>If <code>jobvr</code> = 'V', right eigenvectors of <math>A</math> are computed.</p> <p>If <code>sense</code> = 'E' or 'B', then <code>jobvr</code> must be 'V'.</p>
<code>sense</code>	<p>Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.</p> <p>If <code>sense</code> = 'N', none are computed;</p>

	If <i>sense</i> = 'E', computed for eigenvalues only;
	If <i>sense</i> = 'V', computed for right eigenvectors only;
	If <i>sense</i> = 'B', computed for eigenvalues and right eigenvectors.
	If <i>sense</i> is 'E' or 'B', both left and right eigenvectors must also be computed ( <i>jobvl</i> = 'V' and <i>jobvr</i> = 'V').
<i>n</i>	The order of the matrix <i>A</i> ( $n \geq 0$ ).
<i>a</i>	Arrays: <i>a</i> (size at least $\max(1, lda*n)$ ) is an array containing the <i>n</i> -by- <i>n</i> matrix <i>A</i> .
<i>lda</i>	The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$ .
<i>ldvl, ldvr</i>	The leading dimensions of the output arrays <i>vl</i> and <i>vr</i> , respectively. Constraints: $ldvl \geq 1; ldvr \geq 1$ . If <i>jobvl</i> = 'V', $ldvl \geq \max(1, n)$ ; If <i>jobvr</i> = 'V', $ldvr \geq \max(1, n)$ .

## Output Parameters

<i>a</i>	On exit, this array is overwritten. If <i>jobvl</i> = 'V' or <i>jobvr</i> = 'V', it contains the real-Schur/Schur form of the balanced version of the input matrix <i>A</i> .
<i>wr, wi</i>	Arrays, size at least $\max(1, n)$ each. Contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.
<i>w</i>	Array, size at least $\max(1, n)$ . Contains the computed eigenvalues.
<i>vl, vr</i>	Arrays: <i>vl</i> (size at least $\max(1, ldvl*n)$ ) . If <i>jobvl</i> = 'N', <i>vl</i> is not referenced. <i>For real flavors:</i> If the <i>j</i> -th eigenvalue is real, the <i>i</i> -th component of the <i>j</i> -th eigenvector $u_j$ is stored in $vl[(i - 1) + (j - 1)*ldvl]$ for column major layout and in $vl[(i - 1)*ldvl + (j - 1)]$ for row major layout.. If the <i>j</i> -th and ( <i>j</i> +1)-st eigenvalues form a complex conjugate pair, then for $i = \text{sqrt}(-1)$ , the <i>k</i> -th component of the <i>j</i> -th eigenvector $u_j$ is $vl[(k - 1) + (j - 1)*ldvl] + i*vl[(k - 1) + j*ldvl]$ for column major layout and as $vl[(k - 1)*ldvl + (j - 1)] + i*vl[(k-1)*ldvl + j]$ for row major layout. Similarly, the <i>k</i> -th component of vector ( <i>j</i> +1) $u_{j+1}$ is $vl[(k - 1) + (j - 1)*ldvl] - i*vl[(k - 1) + j*ldvl]$ for column major layout and as $vl[(k - 1)*ldvl + (j - 1)] - i*vl[(k - 1)*ldvl + j]$ for row major layout. . <i>For complex flavors:</i>

The  $i$ -th component of the  $j$ -th eigenvector  $u_j$  is stored in  $vl[(i - 1) + (j - 1)*ldvl]$  for column major layout and in  $vl[(i - 1)*ldvl + (j - 1)]$  for row major layout.

$vr$  (size at least  $\max(1, ldvr*n)$ ).

If  $jobvr = 'N'$ ,  $vr$  is not referenced.

*For real flavors:*

If the  $j$ -th eigenvalue is real, then the  $i$ -th component of  $j$ -th eigenvector  $v_j$  is stored in  $vr[(i - 1) + (j - 1)*ldvr]$  for column major layout and in  $vr[(i - 1)*ldvr + (j - 1)]$  for row major layout..

If the  $j$ -th and  $(j+1)$ -st eigenvalues form a complex conjugate pair, then for  $i = \text{sqrt}(-1)$ , the  $k$ -th component of the  $j$ -th eigenvector  $v_j$  is  $vr[(k - 1) + (j - 1)*ldvr] + i*vr[(k - 1) + j*ldvr]$  for column major layout and as  $vr[(k - 1)*ldvr + (j - 1)] + i*vr[(k - 1)*ldvr + j]$  for row major layout. Similarly, the  $k$ -th component of vector  $j + 1$   $v_{j+1}$  is  $vr[(k - 1) + (j - 1)*ldvr] - i*vr[(k - 1) + j*ldvr]$  for column major layout and as  $vr[(k - 1)*ldvr + (j - 1)] - i*vr[(k - 1)*ldvr + j]$  for row major layout.

*For complex flavors:*

The  $i$ -th component of the  $j$ -th eigenvector  $v_j$  is stored in  $vr[(i - 1) + (j - 1)*ldvr]$  for column major layout and in  $vr[(i - 1)*ldvr + (j - 1)]$  for row major layout.

*ilo, ihi*

*ilo* and *ihi* are integer values determined when  $A$  was balanced.

The balanced  $A(i, j) = 0$  if  $i > j$  and  $j = 1, \dots, ilo-1$  or  $i = ihi + 1, \dots, n$ .

If *balanc* = 'N' or 'S', *ilo* = 1 and *ihi* =  $n$ .

*scale*

Array, size at least  $\max(1, n)$ . Details of the permutations and scaling factors applied when balancing  $A$ .

If  $P[j - 1]$  is the index of the row and column interchanged with row and column  $j$ , and  $D[j - 1]$  is the scaling factor applied to row and column  $j$ , then

$$\begin{aligned} scale[j - 1] &= P[j - 1], \text{ for } j = 1, \dots, ilo-1 \\ &= D[j - 1], \text{ for } j = ilo, \dots, ihi \\ &= P[j - 1] \text{ for } j = ihi+1, \dots, n. \end{aligned}$$

The order in which the interchanges are made is  $n$  to  $ihi+1$ , then 1 to  $ilo-1$ .

*abnrm*

The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

*rconde, rcondv*

Arrays, size at least  $\max(1, n)$  each.

$rconde[j - 1]$  is the reciprocal condition number of the  $j$ -th eigenvalue.

$rcondv[j - 1]$  is the reciprocal condition number of the  $j$ -th right eigenvector.

## Return Values

This function returns a value *info*.

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = i$ , the QR algorithm failed to compute all the eigenvalues, and no eigenvectors or condition numbers have been computed; elements  $1:i/o-1$  and  $i+1:n$  of  $wr$  and  $wi$  (for real flavors) or  $w$  (for complex flavors) contain eigenvalues which have converged.

## Singular Value Decomposition: LAPACK Driver Routines

Table "Driver Routines for Singular Value Decomposition" lists the LAPACK driver routines that perform singular value decomposition .

### Driver Routines for Singular Value Decomposition

Routine Name	Operation performed
?gesvd	Computes the singular value decomposition of a general rectangular matrix.
?gesdd	Computes the singular value decomposition of a general rectangular matrix using a divide and conquer method.
?gejsv	Computes the singular value decomposition of a real matrix using a preconditioned Jacobi SVD method.
?gesvj	Computes the singular value decomposition of a real matrix using Jacobi plane rotations.
?ggsvd	Computes the generalized singular value decomposition of a pair of general rectangular matrices.
?gesvdx	Computes the SVD and left and right singular vectors for a matrix.
?bdsvdx	Computes the SVD of a bidiagonal matrix.

## Singular Value Decomposition - LAPACK Computational Routines

## Description

The routine computes the singular value decomposition (SVD) of a real/complex  $m$ -by- $n$  matrix  $A$ , optionally computing the left and/or right singular vectors. The SVD is written as

$$A = U^* \Sigma^* V^T \text{ for real routines}$$

$$A = U^* \Sigma^* V^H \text{ for complex routines}$$

where  $\Sigma$  is an  $m$ -by- $n$  matrix which is zero except for its  $\min(m, n)$  diagonal elements,  $U$  is an  $m$ -by- $m$  orthogonal/unitary matrix, and  $V$  is an  $n$ -by- $n$  orthogonal/unitary matrix. The diagonal elements of  $\Sigma$  are the singular values of  $A$ ; they are real and non-negative, and are returned in descending order. The first  $\min(m, n)$  columns of  $U$  and  $V$  are the left and right singular vectors of  $A$ .

The routine returns  $V^T$  (for real flavors) or  $V^H$  (for complex flavors), not  $V$ .

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>jobu</code>	<p>Must be 'A', 'S', 'O', or 'N'. Specifies options for computing all or part of the matrix <math>U</math>.</p> <p>If <code>jobu</code> = 'A', all <math>m</math> columns of <math>U</math> are returned in the array <math>u</math>;</p> <p>if <code>jobu</code> = 'S', the first <math>\min(m, n)</math> columns of <math>U</math> (the left singular vectors) are returned in the array <math>u</math>;</p> <p>if <code>jobu</code> = 'O', the first <math>\min(m, n)</math> columns of <math>U</math> (the left singular vectors) are overwritten on the array <math>a</math>;</p> <p>if <code>jobu</code> = 'N', no columns of <math>U</math> (no left singular vectors) are computed.</p>
<code>jobvt</code>	<p>Must be 'A', 'S', 'O', or 'N'. Specifies options for computing all or part of the matrix <math>V^T/V^H</math>.</p> <p>If <code>jobvt</code> = 'A', all <math>n</math> rows of <math>V^T/V^H</math> are returned in the array <math>vt</math>;</p> <p>if <code>jobvt</code> = 'S', the first <math>\min(m, n)</math> rows of <math>V^T/V^H</math> (the right singular vectors) are returned in the array <math>vt</math>;</p> <p>if <code>jobvt</code> = 'O', the first <math>\min(m, n)</math> rows of <math>V^T/V^H</math> (the right singular vectors) are overwritten on the array <math>a</math>;</p> <p>if <code>jobvt</code> = 'N', no rows of <math>V^T/V^H</math> (no right singular vectors) are computed.</p> <p><code>jobvt</code> and <code>jobu</code> cannot both be 'O'.</p>
<code>m</code>	The number of rows of the matrix $A$ ( $m \geq 0$ ).
<code>n</code>	The number of columns in $A$ ( $n \geq 0$ ).
<code>a</code>	<p>Arrays:</p> <p><math>a</math> (size at least <math>\max(1, lda * n)</math> for column major layout and <math>\max(1, lda * m)</math> for row major layout) is an array containing the <math>m</math>-by-<math>n</math> matrix <math>A</math>.</p>
<code>lda</code>	<p>The leading dimension of the array <math>a</math>.</p> <p>Must be at least <math>\max(1, m)</math> for column major layout and at least <math>\max(1, n)</math> for row major layout .</p>

$ldu, ldvt$ 

The leading dimensions of the output arrays  $u$  and  $vt$ , respectively.

Constraints:

$ldu \geq 1; ldvt \geq 1.$

If  $jobu = 'A'$ ,  $ldu \geq m$ ;

If  $jobu = 'S'$ ,  $ldu \geq m$  for column major layout and  $ldu \geq \min(m, n)$  for row major layout;

If  $jobvt = 'A'$ ,  $ldvt \geq n$ ;

If  $jobvt = 'S'$ ,  $ldvt \geq \min(m, n)$  for column major layout and  $ldvt \geq n$  for row major layout .

## Output Parameters

 $a$ 

On exit,

If  $jobu = 'O'$ ,  $a$  is overwritten with the first  $\min(m, n)$  columns of  $U$  (the left singular vectors stored columnwise);

If  $jobvt = 'O'$ ,  $a$  is overwritten with the first  $\min(m, n)$  rows of  $V^T/V^H$  (the right singular vectors stored rowwise);

If  $jobu \neq 'O'$  and  $jobvt \neq 'O'$ , the contents of  $a$  are destroyed.

 $s$ 

Array, size at least  $\max(1, \min(m, n))$ . Contains the singular values of  $A$  sorted so that  $s[i] \geq s[i + 1]$ .

 $u, vt$ 

Arrays:

Array  $u$  minimum size:

	Column major layout	Row major layout
$jobu = 'A'$	$\max(1, ldu * m)$	$\max(1, ldu * m)$
$jobu = 'S'$	$\max(1, ldu * \min(m, n))$	$\max(1, ldu * m)$

If  $jobu = 'A'$ ,  $u$  contains the  $m$ -by- $m$  orthogonal/unitary matrix  $U$ .

If  $jobu = 'S'$ ,  $u$  contains the first  $\min(m, n)$  columns of  $U$  (the left singular vectors stored column-wise).

If  $jobu = 'N'$  or  $'O'$ ,  $u$  is not referenced.

Array  $v$  minimum size:

	Column major layout	Row major layout
$jobvt = 'A'$	$\max(1, ldvt * n)$	$\max(1, ldvt * n)$
$jobvt = 'S'$	$\max(1, ldvt * \min(m, n))$	$\max(1, ldvt * n)$

If  $jobvt = 'A'$ ,  $vt$  contains the  $n$ -by- $n$  orthogonal/unitary matrix  $V^T/V^H$ .

If  $jobvt = 'S'$ ,  $vt$  contains the first  $\min(m, n)$  rows of  $V^T/V^H$  (the right singular vectors stored row-wise).

If `jobvt = 'N'` or `'O'`, `vt` is not referenced.

`superb`

If `?bdsqr` does not converge (indicated by the return value `info > 0`), on exit `superb(0:min(m,n)-2)` contains the unconverged superdiagonal elements of an upper bidiagonal matrix  $B$  whose diagonal is in `s` (not necessarily sorted).  $B$  satisfies  $A = u*B*v^T$  (real flavors) or  $A = u*B*v^H$  (complex flavors), so it has the same singular values as  $A$ , and singular vectors related by  $u$  and  $vt$ .

## Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful.

If `info = -i`, the  $i$ -th parameter had an illegal value.

If `info = i`, then if `?bdsqr` did not converge,  $i$  specifies how many superdiagonals of the intermediate bidiagonal form  $B$  did not converge to zero (see the description of the `superb` parameter for details).

`?gesdd`

*Computes the singular value decomposition of a general rectangular matrix using a divide and conquer method.*

## Syntax

```
lapack_int LAPACKE_sgesdd( int matrix_layout, char jobz, lapack_int m, lapack_int n,
float* a, lapack_int lda, float* s, float* u, lapack_int ldu, float* vt, lapack_int
ldvt );
```

```
lapack_int LAPACKE_dgesdd( int matrix_layout, char jobz, lapack_int m, lapack_int n,
double* a, lapack_int lda, double* s, double* u, lapack_int ldu, double* vt, lapack_int
ldvt );
```

```
lapack_int LAPACKE_cgesdd( int matrix_layout, char jobz, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, float* s, lapack_complex_float* u, lapack_int
ldu, lapack_complex_float* vt, lapack_int ldvt );
```

```
lapack_int LAPACKE_zgesdd( int matrix_layout, char jobz, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, double* s, lapack_complex_double* u,
lapack_int ldu, lapack_complex_double* vt, lapack_int ldvt );
```

## Include Files

## Description

The routine computes the singular value decomposition (SVD) of a real/complex  $m$ -by- $n$  matrix  $A$ , optionally computing the left and/or right singular vectors.

If singular vectors are desired, it uses a divide-and-conquer algorithm. The SVD is written

$A = U*\Sigma*V^T$  for real routines,

$A = U*\Sigma*V^H$  for complex routines,

where  $\Sigma$  is an  $m$ -by- $n$  matrix which is zero except for its  $\min(m,n)$  diagonal elements,  $U$  is an  $m$ -by- $m$  orthogonal/unitary matrix, and  $V$  is an  $n$ -by- $n$  orthogonal/unitary matrix. The diagonal elements of  $\Sigma$  are the singular values of  $A$ ; they are real and non-negative, and are returned in descending order. The first  $\min(m, n)$  columns of  $U$  and  $V$  are the left and right singular vectors of  $A$ .

Note that the routine returns  $vt = V^T$  (for real flavors) or  $vt = V^H$  (for complex flavors), not  $V$ .

**Input Parameters**

*matrix\_layout* Specifies whether matrix storage layout is row major (LAPACK\_ROW\_MAJOR) or column major (LAPACK\_COL\_MAJOR).

*jobz* Must be 'A', 'S', 'O', or 'N'.  
 Specifies options for computing all or part of the matrices  $U$  and  $V$ .  
 If *jobz* = 'A', all  $m$  columns of  $U$  and all  $n$  rows of  $V^T$  or  $V^H$  are returned in the arrays  $u$  and  $vt$ ;  
 if *jobz* = 'S', the first  $\min(m, n)$  columns of  $U$  and the first  $\min(m, n)$  rows of  $V^T$  or  $V^H$  are returned in the arrays  $u$  and  $vt$ ;  
 if *jobz* = 'O', then  
 if  $m \geq n$ , the first  $n$  columns of  $U$  are overwritten in the array  $a$  and all rows of  $V^T$  or  $V^H$  are returned in the array  $vt$ ;  
 if  $m < n$ , all columns of  $U$  are returned in the array  $u$  and the first  $m$  rows of  $V^T$  or  $V^H$  are overwritten in the array  $a$ ;  
 if *jobz* = 'N', no columns of  $U$  or rows of  $V^T$  or  $V^H$  are computed.

*m* The number of rows of the matrix  $A$  ( $m \geq 0$ ).

*n* The number of columns in  $A$  ( $n \geq 0$ ).

*a*  $a(\text{size } \max(1, lda * n)$  for column major layout and  $\max(1, lda * m)$  for row major layout) is an array containing the  $m$ -by- $n$  matrix  $A$ .

*lda* The leading dimension of the array  $a$ . Must be at least  $\max(1, m)$  for column major layout and at least  $\max(1, n)$  for row major layout.

*ldu, ldvt* The leading dimensions of the output arrays  $u$  and  $vt$ , respectively.

The minimum size of *ldu* is

<i>jobz</i>	$m \geq n$	$m < n$
'N'	1	1
'A'	$m$	$m$
'S'	$m$ for column major layout; $n$ for row major layout	$m$
'O'	1	$m$

The minimum size of *ldvt* is

<i>jobz</i>	$m \geq n$	$m < n$
'N'	1	1

<i>jobz</i>	$m \geq n$	$m < n$
'A'	$n$	$n$
'S'	$n$	$m$ for column major layout; $n$ for row major layout
'O'	$n$	1

## Output Parameters

*a*

On exit:

If  $jobz = 'O'$ , then if  $m \geq n$ , *a* is overwritten with the first  $n$  columns of  $U$  (the left singular vectors, stored columnwise). If  $m < n$ , *a* is overwritten with the first  $m$  rows of  $V^T$  (the right singular vectors, stored rowwise);

If  $jobz \neq 'O'$ , the contents of *a* are destroyed.

*s*

Array, size at least  $\max(1, \min(m, n))$ . Contains the singular values of  $A$  sorted so that  $s(i) \geq s(i+1)$ .

*u, vt*

Arrays:

Array *u* is of size:

<i>jobz</i>	$m \geq n$	$m < n$
'N'	1	1
'A'	$\max(1, ldu * m)$	$\max(1, ldu * m)$
'S'	$\max(1, ldu * n)$ for column major layout; $\max(1, ldu * m)$ for row major layout	$\max(1, ldu * m)$
'O'	1	$\max(1, ldu * m)$

If  $jobz = 'A'$  or  $jobz = 'O'$  and  $m < n$ , *u* contains the  $m$ -by- $m$  orthogonal/unitary matrix  $U$ .

If  $jobz = 'S'$ , *u* contains the first  $\min(m, n)$  columns of  $U$  (the left singular vectors, stored columnwise).

If  $jobz = 'O'$  and  $m \geq n$ , or  $jobz = 'N'$ , *u* is not referenced.

Array *vt* is of size:

<i>jobz</i>	$m \geq n$	$m < n$
'N'	1	1
'A'	$\max(1, ldvt * n)$	$\max(1, ldvt * n)$
'S'	$\max(1, ldvt * n)$	$\max(1, ldvt * n)$ for column major layout; $\max(1, ldvt * m)$ for row major layout;

<i>jobz</i>	$m \geq n$	$m < n$
'O'	$\max(1, l_{dvt} * n)$	1

If  $jobz = 'A'$  or  $jobz = 'O'$  and  $m \geq n$ , *vt* contains the  $n$ -by- $n$  orthogonal/unitary matrix  $V^T$ .

If  $jobz = 'S'$ , *vt* contains the first  $\min(m, n)$  rows of  $V^T$  (the right singular vectors, stored rowwise).

If  $jobz = 'O'$  and  $m < n$ , or  $jobz = 'N'$ , *vt* is not referenced.

## Return Values

This function returns a value *info*.

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = -4$ , *A* had a NAN entry.

If  $info = i$ , then ?bdsdc did not converge, updating process failed.

## ?gejsv

Computes the singular value decomposition using a preconditioned Jacobi SVD method.

## Include Files

- mkl.h

## Description

The routine computes the singular value decomposition (SVD) of a real/complex  $m$ -by- $n$  matrix *A*, where  $m \geq n$ .

The SVD is written as

$$A = U * \Sigma * V^T, \text{ for real routines}$$

$A = U \Sigma V^H$ , for complex routines

where  $\Sigma$  is an  $m$ -by- $n$  matrix which is zero except for its  $n$  diagonal elements,  $U$  is an  $m$ -by- $n$  (or  $m$ -by- $m$ ) orthonormal matrix, and  $V$  is an  $n$ -by- $n$  orthogonal matrix. The diagonal elements of  $\Sigma$  are the singular values of  $A$ ; the columns of  $U$  and  $V$  are the left and right singular vectors of  $A$ , respectively. The matrices  $U$  and  $V$  are computed and stored in the arrays  $u$  and  $v$ , respectively. The diagonal of  $\Sigma$  is computed and stored in the array  $sva$ .

The `?gejsv` routine can sometimes compute tiny singular values and their singular vectors much more accurately than other SVD routines.

The routine implements a preconditioned Jacobi SVD algorithm. It uses `?geqp3`, `?geqrf`, and `?gelqf` as preprocessors and preconditioners. Optionally, an additional row pivoting can be used as a preprocessor, which in some cases results in much higher accuracy. An example is matrix  $A$  with the structure  $A = D1 * C * D2$ , where  $D1$ ,  $D2$  are arbitrarily ill-conditioned diagonal matrices and  $C$  is a well-conditioned matrix. In that case, complete pivoting in the first QR factorizations provides accuracy dependent on the condition number of  $C$ , and independent of  $D1$ ,  $D2$ . Such higher accuracy is not completely understood theoretically, but it works well in practice.

If  $A$  can be written as  $A = B * D$ , with well-conditioned  $B$  and some diagonal  $D$ , then the high accuracy is guaranteed, both theoretically and in software, independent of  $D$ . For more details see [Drmac08-1], [Drmac08-2].

The computational range for the singular values can be the full range ( `UNDERFLOW,OVERFLOW` ), provided that the machine arithmetic and the BLAS and LAPACK routines called by `?gejsv` are implemented to work in that range. If that is not the case, the restriction for safe computation with the singular values in the range of normalized IEEE numbers is that the spectral condition number  $\kappa(A) = \sigma_{\max}(A) / \sigma_{\min}(A)$  does not overflow. This code (`?gejsv`) is best used in this restricted range, meaning that singular values of magnitude below  $\|A\|_2 / \text{slamch}('O')$  (for single precision) or  $\|A\|_2 / \text{dlamch}('O')$  (for double precision) are returned as zeros. See `jobr` for details on this.

This implementation is slower than the one described in [Drmac08-1], [Drmac08-2] due to replacement of some non-LAPACK components, and because the choice of some tuning parameters in the iterative part (`?gesvj`) is left to the implementer on a particular machine.

The rank revealing QR factorization (in this code: `?geqp3`) should be implemented as in [Drmac08-3].

If  $m$  is much larger than  $n$ , it is obvious that the initial QRF with column pivoting can be preprocessed by the QRF without pivoting. That well known trick is not used in `?gejsv` because in some cases heavy row weighting can be treated with complete pivoting. The overhead in cases  $m$  much larger than  $n$  is then only due to pivoting, but the benefits in accuracy have prevailed. You can incorporate this extra QRF step easily and also improve data movement (matrix transpose, matrix copy, matrix transposed copy) - this implementation of `?gejsv` uses only the simplest, naive data movement.

## Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>joba</code>	Must be 'C', 'E', 'F', 'G', 'A', or 'R'. Specifies the level of accuracy:

If  $joba = 'C'$ , high relative accuracy is achieved if  $A = B \cdot D$  with well-conditioned  $B$  and arbitrary diagonal matrix  $D$ . The accuracy cannot be spoiled by column scaling. The accuracy of the computed output depends on the condition of  $B$ , and the procedure aims at the best theoretical accuracy. The relative error  $\max_{i=1:N} |\delta \sigma_i| / \sigma_i$  is bounded by  $f(M,N) \cdot \epsilon \cdot \text{cond}(B)$ , independent of  $D$ . The input matrix is preprocessed with the QRF with column pivoting. This initial preprocessing and preconditioning by a rank revealing QR factorization is common for all values of  $joba$ . Additional actions are specified as follows:

If  $joba = 'E'$ , computation as with 'C' with an additional estimate of the condition number of  $B$ . It provides a realistic error bound.

If  $joba = 'F'$ , accuracy higher than in the 'C' option is achieved, if  $A = D1 \cdot C \cdot D2$  with ill-conditioned diagonal scalings  $D1, D2$ , and a well-conditioned matrix  $C$ . This option is advisable, if the structure of the input matrix is not known and relative accuracy is desirable. The input matrix  $A$  is preprocessed with QR factorization with full (row and column) pivoting.

If  $joba = 'G'$ , computation as with 'F' with an additional estimate of the condition number of  $B$ , where  $A = B \cdot D$ . If  $A$  has heavily weighted rows, using this condition number gives too pessimistic error bound.

If  $joba = 'A'$ , small singular values are the noise and the matrix is treated as numerically rank deficient. The error in the computed singular values is bounded by  $f(m,n) \cdot \epsilon \cdot \|A\|$ . The computed SVD  $A = U \cdot S \cdot V^T$  (for real flavors) or  $A = U \cdot S \cdot V^H$  (for complex flavors) restores  $A$  up to  $f(m,n) \cdot \epsilon \cdot \|A\|$ . This enables the procedure to set all singular values below  $n \cdot \epsilon \cdot \|A\|$  to zero.

If  $joba = 'R'$ , the procedure is similar to the 'A' option. Rank revealing property of the initial QR factorization is used to reveal (using triangular factor) a gap  $\sigma_{r+1} < \epsilon \cdot \sigma_r$ , in which case the numerical rank is declared to be  $r$ . The SVD is computed with absolute error bounds, but more accurately than with 'A'.

Must be 'U', 'F', 'W', or 'N'.

Specifies whether to compute the columns of the matrix  $U$ :

If  $jobu = 'U'$ ,  $n$  columns of  $U$  are returned in the array  $u$

If  $jobu = 'F'$ , a full set of  $m$  left singular vectors is returned in the array  $u$ .

If  $jobu = 'W'$ ,  $u$  may be used as workspace of length  $m \cdot n$ . See the description of  $u$ .

If  $jobu = 'N'$ ,  $u$  is not computed.

Must be 'V', 'J', 'W', or 'N'.

Specifies whether to compute the matrix  $V$ :

If  $jobv = 'V'$ ,  $n$  columns of  $V$  are returned in the array  $v$ ; Jacobi rotations are not explicitly accumulated.

If  $jobv = 'J'$ ,  $n$  columns of  $V$  are returned in the array  $v$  but they are computed as the product of Jacobi rotations. This option is allowed only if  $jobu \neq 'N'$

$jobu$

$jobv$

If  $jobv = 'W'$ ,  $v$  may be used as workspace of length  $n*n$ . See the description of  $v$ .

If  $jobv = 'N'$ ,  $v$  is not computed.

$jobr$

Must be 'N' or 'R'.

Specifies the range for the singular values. If small positive singular values are outside the specified range, they may be set to zero. If  $A$  is scaled so that the largest singular value of the scaled matrix is around  $\sqrt{\text{big}}$ ,  $\text{big} = ?\text{lamch}('O')$ , the function can remove columns of  $A$  whose norm in the scaled matrix is less than  $\sqrt{?\text{lamch}('S')}$  (for  $jobr = 'R'$ ), or less than  $\text{small} = ?\text{lamch}('S')/?\text{lamch}('E')$ .

If  $jobr = 'N'$ , the function does not remove small columns of the scaled matrix. This option assumes that BLAS and QR factorizations and triangular solvers are implemented to work in that range. If the condition of  $A$  is greater than  $\text{big}$ , use  $?\text{gesvj}$ .

If  $jobr = 'R'$ , restricted range for singular values of the scaled matrix  $A$  is  $[\sqrt{?\text{lamch}('S')}, \sqrt{\text{big}}]$ , roughly as described above. This option is recommended.

For computing the singular values in the full range  $[?\text{lamch}('S'), \text{big}]$ , use  $?\text{gesvj}$ .

$jobt$

Must be 'T' or 'N'.

If the matrix is square, the procedure may determine to use a transposed  $A$  if  $A^T$  (for real flavors) or  $A^H$  (for complex flavors) seems to be better with respect to convergence. If the matrix is not square,  $jobt$  is ignored.

The decision is based on two values of entropy over the adjoint orbit of  $A^T * A$  (for real flavors) or  $A^H * A$  (for complex flavors). See the descriptions of  $\text{stat}[5]$  and  $\text{stat}[6]$ .

If  $jobt = 'T'$ , the function performs transposition if the entropy test indicates possibly faster convergence of the Jacobi process, if  $A$  is taken as input. If  $A$  is replaced with  $A^T$  or  $A^H$ , the row pivoting is included automatically.

If  $jobt = 'N'$ , the functions attempts no speculations. This option can be used to compute only the singular values, or the full SVD ( $u$ ,  $\text{sigma}$ , and  $v$ ). For only one set of singular vectors ( $u$  or  $v$ ), the caller should provide both  $u$  and  $v$ , as one of the arrays is used as workspace if the matrix  $A$  is transposed. The implementer can easily remove this constraint and make the code more complicated. See the descriptions of  $u$  and  $v$ .

---

### Caution

The  $jobt = 'T'$  option is experimental and its effect might not be the same in subsequent releases. Consider using the  $jobt = 'N'$  instead.

---

$jobp$

Must be 'P' or 'N'.

Enables structured perturbations of denormalized numbers. This option should be active if the denormals are poorly implemented, causing slow computation, especially in cases of fast convergence. For details, see [Drmac08-1], [Drmac08-2]. For simplicity, such perturbations are included only when the full SVD or only the singular values are requested. You can add the perturbation for the cases of computing one set of singular vectors.

If  $jobp = 'P'$ , the function introduces perturbation.

If  $jobp = 'N'$ , the function introduces no perturbation.

$m$	The number of rows of the input matrix $A$ ; $m \geq 0$ .
$n$	The number of columns in the input matrix $A$ ; $m \geq n \geq 0$ .
$a, u, v$	<p>Array <math>a</math> (size <math>lda*n</math> for column major layout and <math>lda*m</math> for row major layout) is an array containing the <math>m</math>-by-<math>n</math> matrix <math>A</math>.</p> <p><math>u</math> is a workspace array, its size for column major layout is <math>ldu*n</math> for <math>jobu='U'</math> or <math>'W'</math> and <math>ldu*m</math> for <math>jobu='F'</math>; for row major layout its size is at least <math>ldu*m</math>. When <math>jobt = 'T'</math> and <math>m = n</math>, <math>u</math> must be provided even though <math>jobu = 'N'</math>.</p> <p><math>v</math> is a workspace array, its size is <math>ldv*n</math>. When <math>jobt = 'T'</math> and <math>m = n</math>, <math>v</math> must be provided even though <math>jobv = 'N'</math>.</p>
$lda$	The leading dimension of the array $a$ . Must be at least $\max(1, m)$ for column major layout and at least $\max(1, n)$ for row major layout.
$sva$	$sva$ is a workspace array, its size is $n$ .
$ldu$	<p>The leading dimension of the array <math>u</math>; <math>ldu \geq 1</math>.</p> <p><math>jobu = 'U'</math> or <math>'F'</math> or <math>'W'</math>, <math>ldu \geq m</math> for column major layout; for row major layout if <math>jobu = 'U'</math> or <math>jobu = 'W'</math> <math>ldu \geq n</math> and if <math>jobu = 'F'</math> <math>ldu \geq m</math>.</p>
$ldv$	<p>The leading dimension of the array <math>v</math>; <math>ldv \geq 1</math>.</p> <p><math>jobv = 'V'</math> or <math>'J'</math> or <math>'W'</math>, <math>ldv \geq n</math>.</p>
$cwork$	$cwork$ is a workspace array of size $\max(2, lwork)$ .
$rwork$	$rwork$ is an array of size at least $\max(7, lrwork)$ for real flavors and at least $\max(7, lwork)$ for complex flavors.

## Output Parameters

$sva$	<p>On exit:</p> <p>For <math>stat[0]/stat[1] = 1</math>: the singular values of <math>A</math>. During the computation <math>sva</math> contains Euclidean column norms of the iterated matrices in the array <math>a</math>.</p> <p>For <math>stat[0] \neq stat[1]</math>: the singular values of <math>A</math> are <math>(stat[0]/stat[1]) * sva[0:n - 1]</math>. This factored form is used if <math>\sigma_{\max}(A)</math> overflows or if small singular values have been saved from underflow by scaling the input matrix <math>A</math>.</p>
-------	---

$jobr = 'R'$ , some of the singular values may be returned as exact zeros obtained by 'setting to zero' because they are below the numerical rank threshold or are denormalized numbers.

$u$

On exit:

If  $jobu = 'U'$ , contains the  $m$ -by- $n$  matrix of the left singular vectors.

If  $jobu = 'F'$ , contains the  $m$ -by- $m$  matrix of the left singular vectors, including an orthonormal basis of the orthogonal complement of the range of  $A$ .

If  $jobu = 'W'$  and  $jobv = 'V'$ ,  $jobt = 'T'$ , and  $m = n$ , then  $u$  is used as workspace if the procedure replaces  $A$  with  $A^T$  (for real flavors) or  $A^H$  (for complex flavors). In that case,  $v$  is computed in  $u$  as left singular vectors of  $A^T$  or  $A^H$  and copied back to the  $v$  array. This 'W' option is just a reminder to the caller that in this case  $u$  is reserved as workspace of length  $n*n$ .

If  $jobu = 'N'$ ,  $u$  is not referenced.

$v$

On exit:

If  $jobv = 'V'$  or  $'J'$ , contains the  $n$ -by- $n$  matrix of the right singular vectors.

If  $jobv = 'W'$  and  $jobu = 'U'$ ,  $jobt = 'T'$ , and  $m = n$ , then  $v$  is used as workspace if the procedure replaces  $A$  with  $A^T$  (for real flavors) or  $A^H$  (for complex flavors). In that case,  $u$  is computed in  $v$  as right singular vectors of  $A^T$  or  $A^H$  and copied back to the  $u$  array. This 'W' option is just a reminder to the caller that in this case  $v$  is reserved as workspace of length  $n*n$ .

If  $jobv = 'N'$ ,  $v$  is not referenced.

$stat$

On exit,

$stat[0] = scale = stat[1]/stat[0]$  is the scaling factor such that  $scale*sva(1:n)$  are the computed singular values of  $A$ . See the description of  $sva$ .

$stat[1] =$  see the description of  $stat[0]$ .

$stat[2] = sconda$  is an estimate for the condition number of column equilibrated  $A$ . If  $joba = 'E'$  or  $'G'$ ,  $sconda$  is an estimate of  $\sqrt{(|R^T * R)^{-1}|_1}$ . It is computed using `?pocon`. It holds  $n^{-1/4} * sconda \leq ||R^{-1}||_2 \leq n^{1/4} * sconda$ , where  $R$  is the triangular factor from the QRF of  $A$ . However, if  $R$  is truncated and the numerical rank is determined to be strictly smaller than  $n$ ,  $sconda$  is returned as -1, indicating that the smallest singular values might be lost.

If full SVD is needed, the following two condition numbers are useful for the analysis of the algorithm. They are provided for a user who is familiar with the details of the method.

$stat[3] =$  an estimate of the scaled condition number of the triangular factor in the first QR factorization.

$stat[4] =$  an estimate of the scaled condition number of the triangular factor in the second QR factorization.

The following two parameters are computed if *jobt* = 'T'. They are provided for a user who is familiar with the details of the method.

*stat[5]* = the entropy of  $A^T * A$  :: this is the Shannon entropy of  $\text{diag}(A^T * A) / \text{Trace}(A^T * A)$  taken as point in the probability simplex.

*stat[6]* = the entropy of  $A * A^T$ .

*istat*

On exit,

*istat[0]* = the numerical rank determined after the initial QR factorization with pivoting. See the descriptions of *joba* and *jobr*.

*istat[1]* = the number of the computed nonzero singular value.

*istat[2]* = if nonzero, a warning message. If *istat[2]*=1, some of the column norms of *A* were denormalized floats. The requested high accuracy is not warranted by the data.

For complex flavors, *istat[3]* = 1 or -1. If *istat[3]* = 1, then the procedure used  $A^H$  to do the job as specified by the *job* parameters.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, the function did not converge in the maximal number of sweeps. The computed values may be inaccurate.

## Description

The routine computes the singular value decomposition (SVD) of a real or complex  $m$ -by- $n$  matrix  $A$ , where  $m \geq n$ .

The SVD of  $A$  is written as

$A = U \cdot \Sigma \cdot V^T$  for real flavors, or

$A = U \cdot \Sigma \cdot V^H$  for complex flavors,

where  $\Sigma$  is an  $m$ -by- $n$  diagonal matrix,  $U$  is an  $m$ -by- $n$  orthonormal matrix, and  $V$  is an  $n$ -by- $n$  orthogonal/unitary matrix. The diagonal elements of  $\Sigma$  are the singular values of  $A$ ; the columns of  $U$  and  $V$  are the left and right singular vectors of  $A$ , respectively. The matrices  $U$  and  $V$  are computed and stored in the arrays  $u$  and  $v$ , respectively. The diagonal of  $\Sigma$  is computed and stored in the array  $sva$ .

The `?gesvj` routine can sometimes compute tiny singular values and their singular vectors much more accurately than other SVD routines.

The  $n$ -by- $n$  orthogonal matrix  $V$  is obtained as a product of Jacobi plane rotations. The rotations are implemented as fast scaled rotations of Anda and Park [AndaPark94]. In the case of underflow of the Jacobi angle, a modified Jacobi transformation of Drmac ([Drmac08-4]) is used. Pivot strategy uses column interchanges of de Rijk ([deRijk98]). The relative accuracy of the computed singular values and the accuracy of the computed singular vectors (in angle metric) is as guaranteed by the theory of Demmel and Veselic [Demmel92]. The condition number that determines the accuracy in the full rank case is essentially

$$\left( \min_i d_{ii} \right) \cdot \kappa(A \cdot D)$$

where  $\kappa(\cdot)$  is the spectral condition number. The best performance of this Jacobi SVD procedure is achieved if used in an accelerated version of Drmac and Veselic [Drmac08-1], [Drmac08-2].

The computational range for the nonzero singular values is the machine number interval ( UNDERFLOW,OVERFLOW ). In extreme cases, even denormalized singular values can be computed with the corresponding gradual loss of accurate digit.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>joba</i>	Must be 'L', 'U' or 'G'. Specifies the structure of $A$ : If <i>joba</i> = 'L', the input matrix $A$ is lower triangular.

	<p>If <math>joba = 'U'</math>, the input matrix <math>A</math> is upper triangular.</p> <p>If <math>joba = 'G'</math>, the input matrix <math>A</math> is a general <math>m</math>-by-<math>n</math>, <math>m \geq n</math>.</p> <p>Must be 'U', 'C' or 'N'.</p> <p>Specifies whether to compute the left singular vectors (columns of <math>U</math>):</p> <p>If <math>jobu = 'U'</math>, the left singular vectors corresponding to the nonzero singular values are computed and returned in the leading columns of <math>A</math>. See more details in the description of <math>a</math>. The default numerical orthogonality threshold is set to approximately <math>TOL=CTOL*EPS</math>, <math>CTOL=\text{sqrt}(m)</math>, <math>EPS = ?\text{lamch}('E')</math></p> <p>If <math>jobu = 'C'</math>, analogous to <math>jobu = 'U'</math>, except that you can control the level of numerical orthogonality of the computed left singular vectors. <math>TOL</math> can be set to <math>TOL=CTOL*EPS</math>, where <math>CTOL</math> is given on input in the array <math>stat</math>. No <math>CTOL</math> smaller than ONE is allowed. <math>CTOL</math> greater than <math>1 / EPS</math> is meaningless. The option 'C' can be used if <math>m*EPS</math> is satisfactory orthogonality of the computed left singular vectors, so <math>CTOL=m</math> could save a few sweeps of Jacobi rotations. See the descriptions of <math>a</math> and <math>stat[0]</math>.</p> <p>If <math>jobu = 'N'</math>, <math>u</math> is not computed. However, see the description of <math>a</math>.</p>
$jobv$	<p>Must be 'V', 'A' or 'N'.</p> <p>Specifies whether to compute the right singular vectors, that is, the matrix <math>V</math>:</p> <p>If <math>jobv = 'V'</math>, the matrix <math>V</math> is computed and returned in the array <math>v</math>.</p> <p>If <math>jobv = 'A'</math>, the Jacobi rotations are applied to the <math>mv</math>-by-<math>n</math> array <math>v</math>. In other words, the right singular vector matrix <math>V</math> is not computed explicitly, instead it is applied to an <math>mv</math>-by-<math>n</math> matrix initially stored in the first <math>mv</math> rows of <math>V</math>.</p> <p>If <math>jobv = 'N'</math>, the matrix <math>V</math> is not computed and the array <math>v</math> is not referenced.</p>
$m$	<p>The number of rows of the input matrix <math>A</math>.</p> <p><math>1/\text{slamch}('E') &gt; m \geq 0</math> for <math>\text{sgesvj}</math>.</p> <p><math>1/\text{dlamch}('E') &gt; m \geq 0</math> for <math>\text{dgesvj}</math>.</p>
$n$	<p>The number of columns in the input matrix <math>A</math>; <math>m \geq n \geq 0</math>.</p>
$a, v$	<p>Array <math>a</math> (size at least <math>lda*n</math> for column major layout and <math>lda*m</math> for row major layout) is an array containing the <math>m</math>-by-<math>n</math> matrix <math>A</math>.</p> <p>Array <math>v</math> (size at least <math>\max(1, ldv*n)</math>) contains, if <math>jobv = 'A'</math> the <math>mv</math>-by-<math>n</math> matrix to be post-multiplied by Jacobi rotations.</p>
$lda$	<p>The leading dimension of the array <math>a</math>. Must be at least <math>\max(1, m)</math> for column major layout and at least <math>\max(1, n)</math> for row major layout .</p>
$mv$	<p>If <math>jobv = 'A'</math>, the product of Jacobi rotations in <math>?gesvj</math> is applied to the first <math>mv</math> rows of <math>v</math>. See the description of <math>jobv</math>. <math>0 \leq mv \leq ldv</math>.</p>
$ldv$	<p>The leading dimension of the array <math>v</math>; <math>ldv \geq 1</math>.</p> <p><math>jobv = 'V', ldv \geq \max(1, n)</math>.</p>

$jobv = 'A'$ ,  $ldv \geq \max(1, mv)$  for column major layout and  $ldv \geq \max(1, n)$  for row major layout.

*stat*

Array size 6. If  $jobu = 'C'$ ,  $stat[0] = CTOL$ , where  $CTOL$  defines the threshold for convergence. The process stops if all columns of  $A$  are mutually orthogonal up to  $CTOL * EPS$ , where  $EPS = ?lamch('E')$ . It is required that  $CTOL \geq 1$  - that is, it is not allowed to force the routine to obtain orthogonality below  $\epsilon$ .

## Output Parameters

*a*

On exit:

If  $jobu = 'U'$  or  $jobu = 'C'$ :

- if  $info = 0$ , the leading columns of  $A$  contain left singular vectors corresponding to the computed singular values of  $a$  that are above the underflow threshold  $?lamch('S')$ , that is, non-zero singular values. The number of the computed non-zero singular values is returned in  $stat[1]$ . Also see the descriptions of *sva* and *stat*. The computed columns of  $u$  are mutually numerically orthogonal up to approximately  $TOL = \sqrt{m} * EPS$  (default); or  $TOL = CTOL * EPS$   $jobu = 'C'$ , see the description of *jobu*.
- if  $info > 0$ , the procedure `?gesvj` did not converge in the given number of iterations (sweeps). In that case, the computed columns of  $u$  may not be orthogonal up to  $TOL$ . The output  $u$  (stored in *a*),  $\sigma$  (given by the computed singular values in  $sva(1:n)$ ) and  $v$  is still a decomposition of the input matrix  $A$  in the sense that the residual  $\| |A - scale * U * \sigma * V^T| \|_2 / \| |A| \|_2$  for real flavors or  $\| |A - scale * U * \sigma * V^H| \|_2 / \| |A| \|_2$  for complex flavors (where  $scale = stat[0]$ ) is small.

If  $jobu = 'N'$ :

- if  $info = 0$ , note that the left singular vectors are 'for free' in the one-sided Jacobi SVD algorithm. However, if only the singular values are needed, the level of numerical orthogonality of  $u$  is not an issue and iterations are stopped when the columns of the iterated matrix are numerically orthogonal up to approximately  $m * EPS$ . Thus, on exit, *a* contains the columns of  $u$  scaled with the corresponding singular values.
- if  $info > 0$ , the procedure `?gesvj` did not converge in the given number of iterations (sweeps).

*sva*

Array size  $n$ .

If  $info = 0$ , depending on the value  $scale = stat[0]$ , where  $scale$  is the scaling factor:

- if  $scale = 1$ ,  $sva[0:n - 1]$  contains the computed singular values of  $a$ .
- if  $scale \neq 1$ , the singular values of  $a$  are  $scale * sva(1:n)$ , and this factored representation is due to the fact that some of the singular values of  $a$  might underflow or overflow.

If  $info > 0$ , the procedure `?gesvj` did not converge in the given number of iterations (sweeps) and  $scale * sva(1:n)$  may not be accurate.

*v* On exit:

If *jobv* = 'V', contains the *n*-by-*n* matrix of the right singular vectors.

If *jobv* = 'A', then *v* contains the product of the computed right singular vector matrix and the initial matrix in the array *v*.

If *jobv* = 'N', *v* is not referenced.

*stat* On exit,

*stat*[0] = *scale* is the scaling factor such that *scale*\**sva*(1:*n*) are the computed singular values of *A*. See the description of *sva*.

*stat*[1] is the number of the computed nonzero singular values.

*stat*[2] is the number of the computed singular values that are larger than the underflow threshold.

*stat*[3] is the number of sweeps of Jacobi rotations needed for numerical convergence.

*stat*[4] =  $\max_{\{i \neq j\}} |\cos(A(:,i), A(:,j))|$  in the last sweep. This is useful information in cases when *?gesvj* did not converge, as it can be used to estimate whether the output is still useful and for post festum analysis.

*stat*[5] is the largest absolute value over all sines of the Jacobi rotation angles in the last sweep. It can be useful in a post festum analysis.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, the function did not converge in the maximal number (30) of sweeps. The output may still be useful. See the description of *stat*.

### *?ggsvd*

*Computes the generalized singular value decomposition of a pair of general rectangular matrices (deprecated).*

## Syntax

```
lapack_int LAPACKE_sggsvd( int matrix_layout, char jobu, char jobv, char jobq,
lapack_int m, lapack_int n, lapack_int p, lapack_int* k, lapack_int* l, float* a,
lapack_int lda, float* b, lapack_int ldb, float* alpha, float* beta, float* u,
lapack_int ldu, float* v, lapack_int ldv, float* q, lapack_int ldq, lapack_int* iwork );
```

```
lapack_int LAPACKE_dggsvd( int matrix_layout, char jobu, char jobv, char jobq,
lapack_int m, lapack_int n, lapack_int p, lapack_int* k, lapack_int* l, double* a,
lapack_int lda, double* b, lapack_int ldb, double* alpha, double* beta, double* u,
lapack_int ldu, double* v, lapack_int ldv, double* q, lapack_int ldq, lapack_int*
iwork );
```

```
lapack_int LAPACKE_cggsvd( int matrix_layout, char jobu, char jobv, char jobq,
lapack_int m, lapack_int n, lapack_int p, lapack_int* k, lapack_int* l,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int ldb,
```

$$D_2 = \begin{matrix} & & & k & l \\ & & & I & S \\ p - l & & & \begin{pmatrix} 0 & \\ 0 & 0 \end{pmatrix} \end{matrix}$$

$$(0 \ R) = \begin{matrix} & & k & l \\ & & \begin{pmatrix} 0 & R_{11} & R_{12} \\ 0 & 0 & R_{22} \end{pmatrix}, \\ n - k - l & & k & l \end{matrix}$$

where

$C = \text{diag}(\alpha[k], \dots, \alpha[k + l - 1])$

$S = \text{diag}(\beta[k], \dots, \beta[k + l - 1])$

$C^2 + S^2 = I$

Nonzero element  $r_{ij}$  ( $1 \leq j \leq k + l$ ) of  $R$  is stored in  $a[(i - 1) + (n - k - l + j - 1) * lda]$  for column major layout and in  $a[(i - 1) * lda + (n - k - l + j - 1)]$  for row major layout.

If  $m - k - l < 0$ ,

$$D_1 = \begin{matrix} & & k & m - k & k + l - m \\ & & \begin{pmatrix} I & 0 & 0 \\ 0 & C & 0 \end{pmatrix} \\ m - k & & k & m - k & k + l - m \end{matrix}$$

$$D_2 = \begin{matrix} & & k & m - k & k + l - m \\ & m - k & \begin{pmatrix} 0 & S & 0 \end{pmatrix} \\ k + l - m & \begin{pmatrix} 0 & 0 & I \end{pmatrix} \\ p - l & \begin{pmatrix} 0 & 0 & 0 \end{pmatrix} \end{matrix}$$

$$(0 \ R) = \begin{matrix} & & n - k - l & k & m - k & k + l - m \\ & k & \begin{pmatrix} 0 & R_{11} & R_{12} & R_{13} \end{pmatrix} \\ m - k & \begin{pmatrix} 0 & 0 & R_{22} & R_{23} \end{pmatrix} \\ k + l - m & \begin{pmatrix} 0 & 0 & 0 & R_{33} \end{pmatrix} \end{matrix}$$

where

$$C = \text{diag}(\alpha[k], \dots, \alpha[m]),$$

$$S = \text{diag}(\beta[k], \dots, \beta[m - 1]),$$

$$C_2 + S_2 = I$$

On exit, the location of nonzero element  $r_{ij}$  ( $1 \leq j \leq k + l$ ) of  $R$  depends on the value of  $i$ . For  $i \leq m$  this element is stored in  $a[(i - 1) + (n - k - l + j - 1) * lda]$  for column major layout and in  $a[(i - 1) * lda + (n - k - l + j - 1)]$  for row major layout. For  $m < i \leq k + l$  it is stored in  $b[(i - k - 1) + (n - k - l + j - 1) * ldb]$  for column major layout and in  $b[(i - k - 1) * ldb + (n - k - l + j - 1)]$  for row major layout.

The routine computes  $C$ ,  $S$ ,  $R$ , and optionally the orthogonal/unitary transformation matrices  $U$ ,  $V$  and  $Q$ .

In particular, if  $B$  is an  $n$ -by- $n$  nonsingular matrix, then the GSVD of  $A$  and  $B$  implicitly gives the SVD of  $A * B^{-1}$ :

$$A * B^{-1} = U * (D_1 * D_2^{-1}) * V'.$$

If  $(A', B)'$  has orthonormal columns, then the GSVD of  $A$  and  $B$  is also equal to the CS decomposition of  $A$  and  $B$ . Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

$$A' * A * x = \lambda * B' * B * x.$$

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>jobu</i>	Must be 'U' or 'N'. If <i>jobu</i> = 'U', orthogonal/unitary matrix $U$ is computed. If <i>jobu</i> = 'N', $U$ is not computed.
<i>jobv</i>	Must be 'V' or 'N'. If <i>jobv</i> = 'V', orthogonal/unitary matrix $V$ is computed.

	If $jobv = 'N'$ , $V$ is not computed.
$jobq$	Must be $'Q'$ or $'N'$ . If $jobq = 'Q'$ , orthogonal/unitary matrix $Q$ is computed. If $jobq = 'N'$ , $Q$ is not computed.
$m$	The number of rows of the matrix $A$ ( $m \geq 0$ ).
$n$	The number of columns of the matrices $A$ and $B$ ( $n \geq 0$ ).
$p$	The number of rows of the matrix $B$ ( $p \geq 0$ ).
$a, b$	Arrays: $a$ (size at least $\max(1, lda * n)$ for column major layout and $\max(1, lda * m)$ for row major layout) contains the $m$ -by- $n$ matrix $A$ . $b$ (size at least $\max(1, ldb * n)$ for column major layout and $\max(1, ldb * p)$ for row major layout) contains the $p$ -by- $n$ matrix $B$ .
$lda$	The leading dimension of $a$ ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.
$ldb$	The leading dimension of $b$ ; at least $\max(1, p)$ for column major layout and $\max(1, n)$ for row major layout.
$ldu$	The leading dimension of the array $u$ . $ldu \geq \max(1, m)$ if $jobu = 'U'$ ; $ldu \geq 1$ otherwise.
$ldv$	The leading dimension of the array $v$ . $ldv \geq \max(1, p)$ if $jobv = 'V'$ ; $ldv \geq 1$ otherwise.
$ldq$	The leading dimension of the array $q$ . $ldq \geq \max(1, n)$ if $jobq = 'Q'$ ; $ldq \geq 1$ otherwise.

## Output Parameters

$k, l$	On exit, $k$ and $l$ specify the dimension of the subblocks. The sum $k+l$ is equal to the effective numerical rank of $(A', B)'$ .
$a$	On exit, $a$ contains the triangular matrix $R$ or part of $R$ .
$b$	On exit, $b$ contains part of the triangular matrix $R$ if $m-k-l < 0$ .
$alpha, beta$	Arrays, size at least $\max(1, n)$ each. Contain the generalized singular value pairs of $A$ and $B$ : $alpha(1:k) = 1,$ $beta(1:k) = 0,$ and if $m-k-l \geq 0,$ $alpha(k+1:k+1) = C,$ $beta(k+1:k+1) = S,$ or if $m-k-l < 0,$

```

alpha(k+1:m) = C, alpha(m+1:k+1) = 0
beta(k+1:m) = S, beta(m+1:k+1) = 1
and
alpha(k+1+1:n) = 0
beta(k+1+1:n) = 0.

```

*u, v, q*

Arrays:

*u*, size at least  $\max(1, ldu * m)$ .

If *jobu* = 'U', *u* contains the *m*-by-*m* orthogonal/unitary matrix *U*.

If *jobu* = 'N', *u* is not referenced.

*v*, size at least  $\max(1, ldv * p)$ .

If *jobv* = 'V', *v* contains the *p*-by-*p* orthogonal/unitary matrix *V*.

If *jobv* = 'N', *v* is not referenced.

*q*, size at least  $\max(1, ldq * n)$ .

If *jobq* = 'Q', *q* contains the *n*-by-*n* orthogonal/unitary matrix *Q*.

If *jobq* = 'N', *q* is not referenced.

*iwork*

On exit, *iwork* stores the sorting information.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = 1, the Jacobi-type procedure failed to converge. For further details, see subroutine [tgsja](#).

## ?gesvdx

Computes the SVD and left and right singular vectors for a matrix.

## Syntax

## Description

`?gesvdx` computes the singular value decomposition (SVD) of a real or complex  $m$ -by- $n$  matrix  $A$ , optionally computing the left and right singular vectors. The SVD is written

$$A = U * \Sigma * \text{transpose}(V)$$

where  $\Sigma$  is an  $m$ -by- $n$  matrix which is zero except for its  $\min(m,n)$  diagonal elements,  $U$  is an  $m$ -by- $m$  matrix, and  $V$  is an  $n$ -by- $n$  matrix. The matrices  $U$  and  $V$  are orthogonal for real  $A$ , and unitary for complex  $A$ . The diagonal elements of  $\Sigma$  are the singular values of  $A$ ; they are real and non-negative, and are returned in descending order. The first  $\min(m,n)$  columns of  $U$  and  $V$  are the left and right singular vectors of  $A$ .

`?gesvdx` uses an eigenvalue problem for obtaining the SVD, which allows for the computation of a subset of singular values and vectors. See `?bdsvdx` for details.

Note that the routine returns  $V^T$ , not  $V$ .

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<i>jobu</i>	Specifies options for computing all or part of the matrix $U$ : = 'V': the first $\min(m,n)$ columns of $U$ (the left singular vectors) or as specified by <i>range</i> are returned in the array <i>u</i> ; = 'N': no columns of $U$ (no left singular vectors) are computed.
<i>jobvt</i>	Specifies options for computing all or part of the matrix $V^T$ : = 'V': the first $\min(m,n)$ rows of $V^T$ (the right singular vectors) or as specified by <i>range</i> are returned in the array <i>vt</i> ; = 'N': no rows of $V^T$ (no right singular vectors) are computed.
<i>range</i>	= 'A': find all singular values. = 'V': all singular values in the half-open interval $(vl, vu]$ are found. = 'I': the <i>il</i> -th through <i>iu</i> -th singular values are found.
<i>m</i>	The number of rows of the input matrix $A$ . $m \geq 0$ .
<i>n</i>	The number of columns of the input matrix $A$ . $n \geq 0$ .
<i>a</i>	Array, size $lda * n$ On entry, the $m$ -by- $n$ matrix $A$ .
<i>lda</i>	The leading dimension of the array <i>a</i> . $lda \geq \max(1, m)$ .

<i>vl</i>	$vl \geq 0$ .
<i>vu</i>	If <i>range</i> ='V', the lower and upper bounds of the interval to be searched for singular values. $vu > vl$ . Not referenced if <i>range</i> = 'A' or 'I'.
<i>il</i>	
<i>iu</i>	If <i>range</i> ='I', the indices (in ascending order) of the smallest and largest singular values to be returned. $1 \leq il \leq iu \leq \min(m, n)$ , if $\min(m, n) > 0$ . Not referenced if <i>range</i> = 'A' or 'V'.
<i>ldu</i>	The leading dimension of the array <i>u</i> . $ldu \geq 1$ ; if <i>jobu</i> = 'V', $ldu \geq m$ .
<i>ldvt</i>	The leading dimension of the array <i>vt</i> . $ldvt \geq 1$ ; if <i>jobvt</i> = 'V', $ldvt \geq ns$ (see above).

## Output Parameters

<i>a</i>	On exit, the contents of <i>a</i> are destroyed.
<i>ns</i>	The total number of singular values found, $0 \leq ns \leq \min(m, n)$ . If <i>range</i> = 'A', $ns = \min(m, n)$ ; if <i>range</i> = 'I', $ns = iu - il + 1$ .
<i>s</i>	Array, size $\min(m, n)$ The singular values of <i>A</i> , sorted so that $s[i] \geq s[i + 1]$ .
<i>u</i>	Array, size $ldu * ucol$ If <i>jobu</i> = 'V', <i>u</i> contains columns of <i>U</i> (the left singular vectors, stored columnwise) as specified by <i>range</i> ; if <i>jobu</i> = 'N', <i>u</i> is not referenced.

---

### NOTE

Make sure that  $ucol \geq ns$ ; if *range* = 'V', the exact value of *ns* is not known in advance and an upper bound must be used.

---

<i>vt</i>	Array, size $ldvt * n$ If <i>jobvt</i> = 'V', <i>vt</i> contains the rows of $V^T$ (the right singular vectors, stored rowwise) as specified by <i>range</i> ; if <i>jobvt</i> = 'N', <i>vt</i> is not referenced.
-----------	---

---

### NOTE

Make sure that  $ldvt \geq ns$ ; if *range* = 'V', the exact value of *ns* is not known in advance and an upper bound must be used.

---

<i>superb</i>	Array, size $(12 * \min(m, n))$ . If <i>info</i> = 0, the first <i>ns</i> elements of <i>superb</i> are zero. If <i>info</i> > 0, then <i>superb</i> contains the indices of the eigenvectors that failed to converge in ?bdsvdX/?stevX.
---------------	---

## Return Values

This function returns a value *info*.

= 0: successful exit.

< 0: if *info* = -*i*, the *i*-th argument had an illegal value.

> 0: if *info* = *i*, then *i* eigenvectors failed to converge in `?bdsvd`/`?stevx`. if *info* =  $n*2 + 1$ , an internal error occurred in `?bdsvd`.

`?bdsvd`

*Computes the SVD of a bidiagonal matrix.*

## Syntax

```
lapack_int LAPACKE_sbdsvd (int matrix_layout, char uplo, char jobz, char range,
lapack_int n, float * d, float * e, float vl, float vu, lapack_int il, lapack_int iu,
lapack_int * ns, float * s, float * z, lapack_int ldz, lapack_int * superb);
```

```
lapack_int LAPACKE_dbdsvd (int matrix_layout, char uplo, char jobz, char range,
lapack_int n, double * d, double * e, double vl, double vu, lapack_int il, lapack_int
iu, lapack_int * ns, double * s, double * z, lapack_int ldz, lapack_int * superb);
```

## Include Files

- `mkl.h`

## Description

`?bdsvd` computes the singular value decomposition (SVD) of a real  $n$ -by- $n$  (upper or lower) bidiagonal matrix  $B$ ,  $B = U * S * VT$ , where  $S$  is a diagonal matrix with non-negative diagonal elements (the singular values of  $B$ ), and  $U$  and  $VT$  are orthogonal matrices of left and right singular vectors, respectively.

Given an upper bidiagonal  $B$  with diagonal  $d = [d_1 d_2 \dots d_n]$  and superdiagonal  $e = [e_1 e_2 \dots e_{n-1}]$ , `?bdsvd` computes the singular value decomposition of  $B$  through the eigenvalues and eigenvectors of the  $n*2$ -by- $n*2$  tridiagonal matrix

$$TGK = \begin{pmatrix} 0 & d_1 & & & \\ d_1 & 0 & e_1 & & \\ & e_1 & 0 & d_2 & \\ & & d_2 & \ddots & \ddots \\ & & & \ddots & \ddots \end{pmatrix}$$

If  $(s, u, v)$  is a singular triplet of  $B$  with  $\|u\| = \|v\| = 1$ , then  $(\pm s, q)$ ,  $\|q\| = 1$ , are eigenpairs of  $TGK$ , with

$$q = P * \frac{(u \pm v)}{\sqrt{2}} = \frac{(v_1 u_1 v_2 u_2 \dots v_n u_n)}{\sqrt{2}}, \text{ and } P = (e_{n+1} \ e_1 \ e_{n+2} \ e_2 \ \dots).$$

Given a  $TGK$  matrix, one can either

1. compute  $-s$ ,  $-v$  and change signs so that the singular values (and corresponding vectors) are already in descending order (as in `?gesvd`/`?gesdd`) or
2. compute  $s$ ,  $v$  and reorder the values (and corresponding vectors).

`?bdsvd` implements (1) by calling `?stevx` (bisection plus inverse iteration, to be replaced with a version of the Multiple Relative Robust Representation algorithm. (See P. Willems and B. Lang, A framework for the MR<sup>3</sup> algorithm: theory and implementation, SIAM J. Sci. Comput., 35:740-766, 2013.)

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<i>uplo</i>	= 'U': <i>B</i> is upper bidiagonal; = 'L': <i>B</i> is lower bidiagonal.
<i>jobz</i>	= 'N': Compute singular values only; = 'V': Compute singular values and singular vectors.
<i>range</i>	= 'A': Find all singular values. = 'V': all singular values in the half-open interval $[v_l, v_u)$ are found. = 'I': the <i>il</i> -th through <i>iu</i> -th singular values are found.
<i>n</i>	The order of the bidiagonal matrix. $n \geq 0$ .
<i>d</i>	Array, size <i>n</i> . The <i>n</i> diagonal elements of the bidiagonal matrix <i>B</i> .
<i>e</i>	Array, size $\max(1, n - 1)$ The $(n - 1)$ superdiagonal elements of the bidiagonal matrix <i>B</i> in elements 1 to <i>n</i> - 1.
<i>v_l</i>	$v_l \geq 0$ .
<i>v_u</i>	If <i>range</i> ='V', the lower and upper bounds of the interval to be searched for singular values. $v_u > v_l$ . Not referenced if <i>range</i> = 'A' or 'I'.
<i>il, iu</i>	If <i>range</i> ='I', the indices (in ascending order) of the smallest and largest singular values to be returned. $1 \leq il \leq iu \leq \min(m, n)$ , if $\min(m, n) > 0$ . Not referenced if <i>range</i> = 'A' or 'V'.
<i>ldz</i>	The leading dimension of the array <i>z</i> . $ldz \geq 1$ , and if <i>jobz</i> = 'V', $ldz \geq \max(2, n*2)$ .

## Output Parameters

<i>ns</i>	The total number of singular values found. $0 \leq ns \leq n$ . If <i>range</i> = 'A', $ns = n$ , and if <i>range</i> = 'I', $ns = iu - il + 1$ .
<i>s</i>	Array, size ( <i>n</i> ) The first <i>ns</i> elements contain the selected singular values in ascending order.
<i>z</i>	Array, size $2*n*k$

If  $jobz = 'V'$ , then if  $info = 0$  the first  $ns$  columns of  $z$  contain the singular vectors of the matrix  $B$  corresponding to the selected singular values, with  $U$  in rows 1 to  $n$  and  $V$  in rows  $n+1$  to  $n*2$ , i.e.

$$z = \begin{pmatrix} U \\ V \end{pmatrix}$$

If  $jobz = 'N'$ , then  $z$  is not referenced.

---

**NOTE**

Make sure that at least  $k = ns+1$  columns are supplied in the array  $z$ ; if  $range = 'V'$ , the exact value of  $ns$  is not known in advance and an upper bound must be used.

---

*superb*

Array, size  $(12*n)$ .

If  $jobz = 'V'$ , then if  $info = 0$ , the first  $ns$  elements of  $iwork$  are zero. If  $info > 0$ , then  $iwork$  contains the indices of the eigenvectors that failed to converge in `?stevx`.

## Return Values

This function returns a value  $info$ .

= 0: successful exit.

< 0: if  $info = -i$ , the  $i$ -th argument had an illegal value.

> 0:

if  $info = i$ , then  $i$  eigenvectors failed to converge in `?stevx`. The indices of the eigenvectors (as returned by `?stevx`) are stored in the array  $iwork$ .

if  $info = n*2 + 1$ , an internal error occurred.

## Cosine-Sine Decomposition: LAPACK Driver Routines

This topic describes LAPACK driver routines for computing the *cosine-sine decomposition* (CS decomposition). You can also call the corresponding computational routines to perform the same task.

The computation has the following phases:

1. The matrix is reduced to a bidiagonal block form.
2. The blocks are simultaneously diagonalized using techniques from the bidiagonal SVD algorithms.

Table "Driver Routines for Cosine-Sine Decomposition (CSD)" lists LAPACK routines that perform CS decomposition of matrices.

### Computational Routines for Cosine-Sine Decomposition (CSD)

Operation	Real matrices	Complex matrices
Compute the CS decomposition of a block-partitioned orthogonal matrix	<a href="#">orcsd</a> <a href="#">uncsd</a>	
Compute the CS decomposition of a block-partitioned unitary matrix		<a href="#">orcsd</a> <a href="#">uncsd</a>

### Description

The routines ?orcsd/?uncsd compute the CS decomposition of an  $m$ -by- $m$  partitioned orthogonal matrix  $X$ :

$$X = \begin{pmatrix} x_{11} & | & x_{12} \\ x_{21} & | & x_{22} \end{pmatrix} = \begin{pmatrix} u_1 & | \\ & | & u_2 \end{pmatrix} \begin{pmatrix} I & 0 & 0 & | & 0 & 0 & 0 \\ 0 & C & 0 & | & 0 & -S & 0 \\ 0 & 0 & 0 & | & 0 & 0 & -I \\ 0 & 0 & 0 & | & I & 0 & 0 \\ 0 & S & 0 & | & 0 & C & 0 \\ 0 & 0 & I & | & 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} v_1 & | \\ & | & v_2 \end{pmatrix}^T$$

or unitary matrix:

$$X = \left( \begin{array}{c|c} x_{11} & x_{12} \\ \hline x_{21} & x_{22} \end{array} \right) = \left( \begin{array}{c|c} u_1 & \\ \hline & u_2 \end{array} \right) \left( \begin{array}{ccc|ccc} I & 0 & 0 & 0 & 0 & 0 \\ 0 & C & 0 & 0 & -S & 0 \\ \hline 0 & 0 & 0 & 0 & 0 & -I \\ 0 & 0 & 0 & I & 0 & 0 \\ 0 & S & 0 & 0 & C & 0 \\ 0 & 0 & I & 0 & 0 & 0 \end{array} \right) \left( \begin{array}{c|c} v_1 & \\ \hline & v_2 \end{array} \right)^H$$

$x_{11}$  is  $p$ -by- $q$ . The orthogonal/unitary matrices  $u_1$ ,  $u_2$ ,  $v_1$ , and  $v_2$  are  $p$ -by- $p$ ,  $(m-p)$ -by- $(m-p)$ ,  $q$ -by- $q$ ,  $(m-q)$ -by- $(m-q)$ , respectively.  $C$  and  $S$  are  $r$ -by- $r$  nonnegative diagonal matrices satisfying  $C^2 + S^2 = I$ , in which  $r = \min(p, m-p, q, m-q)$ .

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<code>jobu1</code>	If equals <code>Y</code> , then $u_1$ is computed. Otherwise, $u_1$ is not computed.
<code>jobu2</code>	If equals <code>Y</code> , then $u_2$ is computed. Otherwise, $u_2$ is not computed.
<code>jobv1t</code>	If equals <code>Y</code> , then $v_1^t$ is computed. Otherwise, $v_1^t$ is not computed.
<code>jobv2t</code>	If equals <code>Y</code> , then $v_2^t$ is computed. Otherwise, $v_2^t$ is not computed.
<code>trans</code>	= 'T': $x$ , $u_1$ , $u_2$ , $v_1^t$ , $v_2^t$ are stored in row-major order. otherwise $x$ , $u_1$ , $u_2$ , $v_1^t$ , $v_2^t$ are stored in column-major order.
<code>signs</code>	= 'O': The lower-left block is made nonpositive (the "other" convention). otherwise The upper-right block is made nonpositive (the "default" convention).
<code>m</code>	The number of rows and columns of the matrix $X$ .
<code>p</code>	The number of rows in $x_{11}$ and $x_{12}$ . $0 \leq p \leq m$ .
<code>q</code>	The number of columns in $x_{11}$ and $x_{21}$ . $0 \leq q \leq m$ .
<code>x11, x12, x21, x22</code>	Arrays of size $x11$ ( $ldx11, q$ ), $x12$ ( $ldx12, m - q$ ), $x21$ ( $ldx21, q$ ), and $x22$ ( $ldx22, m - q$ ). Contain the parts of the orthogonal/unitary matrix whose CSD is desired.
<code>ldx11, ldx12, ldx21, ldx22</code>	The leading dimensions of the parts of array $X$ . $ldx11 \geq \max(1, p)$ , $ldx12 \geq \max(1, p)$ , $ldx21 \geq \max(1, m - p)$ , $ldx22 \geq \max(1, m - p)$ .
<code>ldu1</code>	The leading dimension of the array $u_1$ . If <code>jobu1 = 'Y'</code> , $ldu1 \geq \max(1, p)$ .
<code>ldu2</code>	The leading dimension of the array $u_2$ . If <code>jobu2 = 'Y'</code> , $ldu2 \geq \max(1, m - p)$ .
<code>ldv1t</code>	The leading dimension of the array $v_1^t$ . If <code>jobv1t = 'Y'</code> , $ldv1t \geq \max(1, q)$ .

*ldv2t* The leading dimension of the array *v2t*. If *jobv2t* = 'Y',  $ldv2t \geq \max(1, m - q)$ .

## Output Parameters

*theta* Array, size *r*, in which  $r = \min(p, m - p, q, m - q)$ .  
 $C = \text{diag}(\cos(\theta[0]), \dots, \cos(\theta[r - 1]))$ , and  
 $S = \text{diag}(\sin(\theta[0]), \dots, \sin(\theta[r - 1]))$ .

*u1* Array, size at least  $\max(1, ldu1 * p)$ .  
 If *jobu1* = 'Y', *u1* contains the *p*-by-*p* orthogonal/unitary matrix  $u_1$ .

*u2* Array, size at least  $\max(1, ldu2 * (m - p))$ .  
 If *jobu2* = 'Y', *u2* contains the (*m*-*p*)-by-(*m*-*p*) orthogonal/unitary matrix  $u_2$ .

*v1t* Array, size at least  $\max(1, ldv1t * q)$ .  
 If *jobv1t* = 'Y', *v1t* contains the *q*-by-*q* orthogonal matrix  $v_1^T$  or unitary matrix  $v_1^H$ .

*v2t* Array, size at least  $\max(1, ldv2t * (m - q))$ .  
 If *jobv2t* = 'Y', *v2t* contains the (*m*-*q*)-by-(*m*-*q*) orthogonal matrix  $v_2^T$  or unitary matrix  $v_2^H$ .

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

> 0: ?orcsd/?uncsd did not converge.

## Description

The routines `?orcsd2by1/?uncsd2by1` compute the CS decomposition of an  $m$ -by- $q$  matrix  $X$  with orthonormal columns that has been partitioned into a 2-by-1 block structure:

$$X = \begin{bmatrix} X_{11} \\ X_{21} \end{bmatrix} = \begin{bmatrix} U_1 & | & \\ \hline & & U_2 \end{bmatrix} \begin{bmatrix} I & 0 & 0 \\ 0 & C & 0 \\ 0 & 0 & 0 \\ \hline 0 & 0 & 0 \\ 0 & S & 0 \\ 0 & 0 & I \end{bmatrix} V_1^H$$

$X_{11}$  is  $p$ -by- $q$ . The orthogonal/unitary matrices  $u_1$ ,  $u_2$ ,  $v_1$ , and  $v_2$  are  $p$ -by- $p$ ,  $(m-p)$ -by- $(m-p)$ ,  $q$ -by- $q$ ,  $(m-q)$ -by- $(m-q)$ , respectively.  $C$  and  $S$  are  $r$ -by- $r$  nonnegative diagonal matrices satisfying  $C^2 + S^2 = I$ , in which  $r = \min(p, m-p, q, m-q)$ .

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>jobu1</code>	If equal to 'Y', then $u_1$ is computed. Otherwise, $u_1$ is not computed.
<code>jobu2</code>	If equal to 'Y', then $u_2$ is computed. Otherwise, $u_2$ is not computed.
<code>jobvt</code>	If equal to 'Y', then $v_1^t$ is computed. Otherwise, $v_1^t$ is not computed.
<code>m</code>	The number of rows and columns of the matrix $X$ .

$p$	The number of rows in $x_{11}$ . $0 \leq p \leq m$ .
$q$	The number of columns in $x_{11}$ . $0 \leq q \leq m$ .
$x_{11}$	Array, size $(ldx11*q)$ . On entry, the part of the orthogonal matrix whose CSD is desired.
$ldx11$	The leading dimension of the array $x_{11}$ . $ldx11 \geq \max(1, p)$ .
$x_{21}$	Array, size $(ldx21*q)$ . On entry, the part of the orthogonal matrix whose CSD is desired.
$ldx21$	The leading dimension of the array $X$ . $ldx21 \geq \max(1, m - p)$ .
$ldu1$	The leading dimension of the array $u_1$ . If $jobu1 = 'Y'$ , $ldu1 \geq \max(1, p)$ .
$ldu2$	The leading dimension of the array $u_2$ . If $jobu2 = 'Y'$ , $ldu2 \geq \max(1, m-p)$ .
$ldv1t$	The leading dimension of the array $v_{1t}$ . If $jobv1t = 'Y'$ , $ldv1t \geq \max(1, q)$ .

## Output Parameters

$theta$	Array, size $r$ , in which $r = \min(p, m-p, q, m-q)$ . $C = \text{diag}(\cos(theta(1)), \dots, \cos(theta(r)))$ , and $S = \text{diag}(\sin(theta(1)), \dots, \sin(theta(r)))$ .
$u1$	Array, size $(ldu1*p)$ . If $jobu1 = 'Y'$ , $u1$ contains the $p$ -by- $p$ orthogonal/unitary matrix $u_1$ .
$u2$	Array, size $(ldu2*(m - p))$ . If $jobu2 = 'Y'$ , $u2$ contains the $(m-p)$ -by- $(m-p)$ orthogonal/unitary matrix $u_2$ .
$v_{1t}$	Array, size $(ldv1t*q)$ . If $jobv1t = 'Y'$ , $v_{1t}$ contains the $q$ -by- $q$ orthogonal matrix $v_1^T$ or unitary matrix $v_1^H$ .

## Return Values

This function returns a value *info*.

= 0: successful exit

< 0: if  $info = -i$ , the  $i$ -th argument has an illegal value

## Generalized Symmetric Definite Eigenvalue Problems: LAPACK Driver Routines

This topic describes LAPACK driver routines used for solving generalized symmetric definite eigenproblems. See also [computational routines](#) that can be called to solve these problems. [Table "Driver Routines for Solving Generalized Symmetric Definite Eigenproblems"](#) lists all such driver routines.

## Driver Routines for Solving Generalized Symmetric Definite Eigenproblems

Routine Name	Operation performed
<a href="#">sygv/hegv</a>	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem.
<a href="#">sygvd/hegvd</a>	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem. If eigenvectors are desired, it uses a divide and conquer method.
<a href="#">sygvx/hegvx</a>	Computes selected eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem.
<a href="#">spgv/hpgv</a>	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with matrices in packed storage.
<a href="#">spgvd/hpgvd</a>	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with matrices in packed storage. If eigenvectors are desired, it uses a divide and conquer method.
<a href="#">spgvx/hpgvx</a>	Computes selected eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with matrices in packed storage.
<a href="#">sbgv/hbgv</a>	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with banded matrices.
<a href="#">sbgvd/hbgvd</a>	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with banded matrices. If eigenvectors are desired, it uses a divide and conquer method.
<a href="#">sbgvx/hbgvx</a>	Computes selected eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian positive-definite eigenproblem with banded matrices.

*?sygv*

### Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x.$$

Here  $A$  and  $B$  are assumed to be symmetric and  $B$  is also positive definite.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>itype</i>	Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$ ; if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$ ; if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$ .
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of $A$ and $B$ ; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of $A$ and $B$ .
<i>n</i>	The order of the matrices $A$ and $B$ ( $n \geq 0$ ).
<i>a, b</i>	Arrays: <i>a</i> (size at least $\max(1, lda*n)$ ) contains the upper or lower triangle of the symmetric matrix $A$ , as specified by <i>uplo</i> . <i>b</i> (size at least $\max(1, ldb*n)$ ) contains the upper or lower triangle of the symmetric positive definite matrix $B$ , as specified by <i>uplo</i> .
<i>lda</i>	The leading dimension of <i>a</i> ; at least $\max(1, n)$ .
<i>ldb</i>	The leading dimension of <i>b</i> ; at least $\max(1, n)$ .

## Output Parameters

<i>a</i>	On exit, if <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>a</i> contains the matrix $Z$ of eigenvectors. The eigenvectors are normalized as follows: if <i>itype</i> = 1 or 2, $Z^T*B*Z = I$ ; if <i>itype</i> = 3, $Z^T*inv(B)*Z = I$ ; If <i>jobz</i> = 'N', then on exit the upper triangle (if <i>uplo</i> = 'U') or the lower triangle (if <i>uplo</i> = 'L') of $A$ , including the diagonal, is destroyed.
<i>b</i>	On exit, if $info \leq n$ , the part of <i>b</i> containing the matrix is overwritten by the triangular factor $U$ or $L$ from the Cholesky factorization $B = U^T*U$ or $B = L*L^T$ .
<i>w</i>	Array, size at least $\max(1, n)$ . If <i>info</i> = 0, contains the eigenvalues in ascending order.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, *spotrf/dpotrf* or *ssyev/dsyev* returned an error code:

If *info* = *i* ≤ *n*, *ssyev/dsyev* failed to converge, and *i* off-diagonal elements of an intermediate tridiagonal did not converge to zero;

If *info* = *n* + *i*, for 1 ≤ *i* ≤ *n*, then the leading minor of order *i* of *B* is not positive-definite. The factorization of *B* could not be completed and no eigenvalues or eigenvectors were computed.

*?hegv*

*Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem.*

## Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$A*x = \lambda*B*x, \quad A*B*x = \lambda*x, \quad \text{or} \quad B*A*x = \lambda*x.$$

Here *A* and *B* are assumed to be Hermitian and *B* is also positive definite.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>itype</i>	Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$ ; if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$ ; if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$ .
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only.

	If <code>jobz = 'V'</code> , then compute eigenvalues and eigenvectors.
<code>uplo</code>	Must be 'U' or 'L'. If <code>uplo = 'U'</code> , arrays <code>a</code> and <code>b</code> store the upper triangles of <code>A</code> and <code>B</code> ; If <code>uplo = 'L'</code> , arrays <code>a</code> and <code>b</code> store the lower triangles of <code>A</code> and <code>B</code> .
<code>n</code>	The order of the matrices <code>A</code> and <code>B</code> ( $n \geq 0$ ).
<code>a, b</code>	Arrays: <code>a</code> (size at least $\max(1, lda * n)$ ) contains the upper or lower triangle of the Hermitian matrix <code>A</code> , as specified by <code>uplo</code> . <code>b</code> (size at least $\max(1, ldb * n)$ ) contains the upper or lower triangle of the Hermitian positive definite matrix <code>B</code> , as specified by <code>uplo</code> .
<code>lda</code>	The leading dimension of <code>a</code> ; at least $\max(1, n)$ .
<code>ldb</code>	The leading dimension of <code>b</code> ; at least $\max(1, n)$ .

## Output Parameters

<code>a</code>	On exit, if <code>jobz = 'V'</code> , then if <code>info = 0</code> , <code>a</code> contains the matrix <code>Z</code> of eigenvectors. The eigenvectors are normalized as follows: if <code>itype = 1</code> or <code>2</code> , $Z^H * B * Z = I$ ; if <code>itype = 3</code> , $Z^H * \text{inv}(B) * Z = I$ ; If <code>jobz = 'N'</code> , then on exit the upper triangle (if <code>uplo = 'U'</code> ) or the lower triangle (if <code>uplo = 'L'</code> ) of <code>A</code> , including the diagonal, is destroyed.
<code>b</code>	On exit, if <code>info ≤ n</code> , the part of <code>b</code> containing the matrix is overwritten by the triangular factor <code>U</code> or <code>L</code> from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$ .
<code>w</code>	Array, size at least $\max(1, n)$ . If <code>info = 0</code> , contains the eigenvalues in ascending order.

## Return Values

This function returns a value `info`.

If `info=0`, the execution is successful.

If `info = -i`, the *i*-th parameter had an illegal value.

If `info > 0`, `cpotrf/zpotrf` or `cheev/zheev` return an error code:

If `info = i ≤ n`, `cheev/zheev` fails to converge, and *i* off-diagonal elements of an intermediate tridiagonal do not converge to zero;

If `info = n + i`, for  $1 \leq i \leq n$ , then the leading minor of order *i* of `B` is not positive-definite. The factorization of `B` can not be completed and no eigenvalues or eigenvectors are computed.

### ?sygvd

## Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A*x = \lambda*B*x, \quad A*B*x = \lambda*x, \quad \text{or} \quad B*A*x = \lambda*x.$$

Here  $A$  and  $B$  are assumed to be symmetric and  $B$  is also positive definite.

It uses a divide and conquer algorithm.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>itype</i>	Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$ ; if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$ ; if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$ .
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of $A$ and $B$ ; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of $A$ and $B$ .
<i>n</i>	The order of the matrices $A$ and $B$ ( $n \geq 0$ ).
<i>a, b</i>	Arrays: <i>a</i> (size at least $lda*n$ ) contains the upper or lower triangle of the symmetric matrix $A$ , as specified by <i>uplo</i> . <i>b</i> (size at least $ldb*n$ ) contains the upper or lower triangle of the symmetric positive definite matrix $B$ , as specified by <i>uplo</i> .
<i>lda</i>	The leading dimension of <i>a</i> ; at least $\max(1, n)$ .
<i>ldb</i>	The leading dimension of <i>b</i> ; at least $\max(1, n)$ .

## Output Parameters

<i>a</i>	<p>On exit, if <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>a</i> contains the matrix <i>Z</i> of eigenvectors. The eigenvectors are normalized as follows:</p> <p>if <i>itype</i> = 1 or 2, <math>Z^T * B * Z = I</math>;</p> <p>if <i>itype</i> = 3, <math>Z^T * \text{inv}(B) * Z = I</math>;</p> <p>If <i>jobz</i> = 'N', then on exit the upper triangle (if <i>uplo</i> = 'U') or the lower triangle (if <i>uplo</i> = 'L') of <i>A</i>, including the diagonal, is destroyed.</p>
<i>b</i>	<p>On exit, if <math>\text{info} \leq n</math>, the part of <i>b</i> containing the matrix is overwritten by the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization <math>B = U^T * U</math> or <math>B = L * L^T</math>.</p>
<i>w</i>	<p>Array, size at least <math>\max(1, n)</math>.</p> <p>If <i>info</i> = 0, contains the eigenvalues in ascending order.</p>

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, an error code is returned as specified below.

- For  $\text{info} \leq n$ :
  - If *info* = *i* and *jobz* = 'N', then the algorithm failed to converge; *i* off-diagonal elements of an intermediate tridiagonal form did not converge to zero.
  - If *jobz* = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns  $\text{info}/(n+1)$  through  $\text{mod}(\text{info}, n+1)$ .
- For *info* > *n*:
  - If *info* = *n* + *i*, for  $1 \leq i \leq n$ , then the leading minor of order *i* of *B* is not positive-definite. The factorization of *B* could not be completed and no eigenvalues or eigenvectors were computed.

*?hegvd*

## Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, \quad A^*B^*x = \lambda^*x, \quad \text{or} \quad B^*A^*x = \lambda^*x.$$

Here  $A$  and  $B$  are assumed to be Hermitian and  $B$  is also positive definite.

It uses a divide and conquer algorithm.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>itype</i>	Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A^*x = \lambda^*B^*x$ ; if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda^*x$ ; if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda^*x$ .
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of $A$ and $B$ ; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of $A$ and $B$ .
<i>n</i>	The order of the matrices $A$ and $B$ ( $n \geq 0$ ).
<i>a, b</i>	Arrays: <i>a</i> (size at least $\max(1, lda*n)$ ) contains the upper or lower triangle of the Hermitian matrix $A$ , as specified by <i>uplo</i> . <i>b</i> (size at least $\max(1, ldb*n)$ ) contains the upper or lower triangle of the Hermitian positive definite matrix $B$ , as specified by <i>uplo</i> .
<i>lda</i>	The leading dimension of <i>a</i> ; at least $\max(1, n)$ .
<i>ldb</i>	The leading dimension of <i>b</i> ; at least $\max(1, n)$ .

## Output Parameters

<i>a</i>	On exit, if <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>a</i> contains the matrix $Z$ of eigenvectors. The eigenvectors are normalized as follows: if <i>itype</i> = 1 or 2, $Z^H * B * Z = I$ ; if <i>itype</i> = 3, $Z^H * \text{inv}(B) * Z = I$ ; If <i>jobz</i> = 'N', then on exit the upper triangle (if <i>uplo</i> = 'U') or the lower triangle (if <i>uplo</i> = 'L') of $A$ , including the diagonal, is destroyed.
----------	--

<i>b</i>	On exit, if $info \leq n$ , the part of <i>b</i> containing the matrix is overwritten by the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$ .
<i>w</i>	Array, size at least $\max(1, n)$ . If $info = 0$ , contains the eigenvalues in ascending order.

## Return Values

This function returns a value *info*.

If  $info=0$ , the execution is successful.

If  $info = -i$ , the *i*-th parameter had an illegal value.

If  $info = i$ , and  $jobz = 'N'$ , then the algorithm failed to converge; *i* off-diagonal elements of an intermediate tridiagonal form did not converge to zero;

if  $info = i$ , and  $jobz = 'V'$ , then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns  $info/(n+1)$  through  $\text{mod}(info, n+1)$ .

If  $info = n + i$ , for  $1 \leq i \leq n$ , then the leading minor of order *i* of *B* is not positive-definite. The factorization of *B* could not be completed and no eigenvalues or eigenvectors were computed.

?sygvx

## Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A * x = \lambda * B * x, A * B * x = \lambda * x, \text{ or } B * A * x = \lambda * x.$$

Here *A* and *B* are assumed to be symmetric and *B* is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>itype</i>	Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$ ; if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$ ; if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$ .
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>range</i>	Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval: $vl < w[i] \leq vu$ . If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> .
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of <i>A</i> and <i>B</i> ; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of <i>A</i> and <i>B</i> .
<i>n</i>	The order of the matrices <i>A</i> and <i>B</i> ( $n \geq 0$ ).
<i>a, b</i>	Arrays: <i>a</i> (size at least $\max(1, lda*n)$ ) contains the upper or lower triangle of the symmetric matrix <i>A</i> , as specified by <i>uplo</i> . <i>b</i> (size at least $\max(1, ldb*n)$ ) contains the upper or lower triangle of the symmetric positive definite matrix <i>B</i> , as specified by <i>uplo</i> .
<i>lda</i>	The leading dimension of <i>a</i> ; at least $\max(1, n)$ .
<i>ldb</i>	The leading dimension of <i>b</i> ; at least $\max(1, n)$ .
<i>vl, vu</i>	If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$ . If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$ , if $n > 0$ ; $il=1$ and $iu=0$ if $n = 0$ . If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.

*abstol**ldz*

The leading dimension of the output array *z*. Constraints:

$ldz \geq 1$ ; if *jobz* = 'V',  $ldz \geq \max(1, n)$  for column major layout and  $ldz \geq \max(1, m)$  for row major layout .

## Output Parameters

*a*

On exit, the upper triangle (if *uplo* = 'U') or the lower triangle (if *uplo* = 'L') of *A*, including the diagonal, is overwritten.

*b*

On exit, if  $info \leq n$ , the part of *b* containing the matrix is overwritten by the triangular factor *U* or *L* from the Cholesky factorization  $B = U^T * U$  or  $B = L * L^T$ .

*m*

The total number of eigenvalues found,

$0 \leq m \leq n$ . If *range* = 'A',  $m = n$ , and if *range* = 'I',  
 $m = iu - il + 1$ .

*w, z*

Arrays:

*w*, size at least  $\max(1, n)$ .

The first *m* elements of *w* contain the selected eigenvalues in ascending order.

*z* (size at least  $\max(1, ldz * m)$  for column major layout and  $\max(1, ldz * n)$  for row major layout) .

If *jobz* = 'V', then if *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *A* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with  $w[i - 1]$ . The eigenvectors are normalized as follows:

if *itype* = 1 or 2,  $Z^T * B * Z = I$ ;

if *itype* = 3,  $Z^T * \text{inv}(B) * Z = I$ ;

If *jobz* = 'N', then *z* is not referenced.

If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

Note: you must ensure that at least  $\max(1, m)$  columns are supplied in the array *z*; if *range* = 'V', the exact value of *m* is not known in advance and an upper bound must be used.

*ifail*

Array, size at least  $\max(1, n)$ .

If *jobz* = 'V', then if *info* = 0, the first *m* elements of *ifail* are zero; if *info* > 0, the *ifail* contains the indices of the eigenvectors that failed to converge.

If *jobz* = 'N', then *ifail* is not referenced.

## Return Values

This function returns a value *info*.

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info > 0$ , `spotrf/dpotrf` and `ssyevx/dsyevx` returned an error code:

If  $info = i \leq n$ , `ssyevx/dsyevx` failed to converge, and  $i$  eigenvectors failed to converge. Their indices are stored in the array `ifail`;

If  $info = n + i$ , for  $1 \leq i \leq n$ , then the leading minor of order  $i$  of  $B$  is not positive-definite. The factorization of  $B$  could not be completed and no eigenvalues or eigenvectors were computed.

## Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval  $[a,b]$  of width less than or equal to  $abstol + \epsilon \cdot \max(|a|, |b|)$ , where  $\epsilon$  is the machine precision.

If  $abstol$  is less than or equal to zero, then  $\epsilon \cdot \|T\|_1$  is used as tolerance, where  $T$  is the tridiagonal matrix obtained by reducing  $C$  to tridiagonal form, where  $C$  is the symmetric matrix of the standard symmetric problem to which the generalized problem is transformed. Eigenvalues will be computed most accurately when  $abstol$  is set to twice the underflow threshold  $2 \cdot \text{?lamch}('S')$ , not zero.

If this routine returns with  $info > 0$ , indicating that some eigenvectors did not converge, set  $abstol$  to  $2 \cdot \text{?lamch}('S')$ .

## Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$A^*x = \lambda B^*x, \quad A^*B^*x = \lambda^*x, \quad \text{or} \quad B^*A^*x = \lambda^*x.$$

Here  $A$  and  $B$  are assumed to be Hermitian and  $B$  is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<i>itype</i>	Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$ ; if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$ ; if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$ .
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>range</i>	Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval: $vl < w[i] \leq vu$ . If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> .
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of <i>A</i> and <i>B</i> ; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of <i>A</i> and <i>B</i> .
<i>n</i>	The order of the matrices <i>A</i> and <i>B</i> ( $n \geq 0$ ).
<i>a, b</i>	Arrays: <i>a</i> (size at least $\max(1, lda*n)$ ) contains the upper or lower triangle of the Hermitian matrix <i>A</i> , as specified by <i>uplo</i> . <i>b</i> (size at least $\max(1, ldb*n)$ ) contains the upper or lower triangle of the Hermitian positive definite matrix <i>B</i> , as specified by <i>uplo</i> .
<i>lda</i>	The leading dimension of <i>a</i> ; at least $\max(1, n)$ .
<i>ldb</i>	The leading dimension of <i>b</i> ; at least $\max(1, n)$ .
<i>vl, vu</i>	If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$ . If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$ , if $n > 0$ ; $il=1$ and $iu=0$ if $n = 0$ . If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.

<i>abstol</i>	The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information.
<i>ldz</i>	The leading dimension of the output array <i>z</i> . Constraints: $ldz \geq 1$ ; if <i>jobz</i> = 'V', $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout.

## Output Parameters

<i>a</i>	On exit, the upper triangle (if <i>uplo</i> = 'U') or the lower triangle (if <i>uplo</i> = 'L') of <i>A</i> , including the diagonal, is overwritten.
<i>b</i>	On exit, if $info \leq n$ , the part of <i>b</i> containing the matrix is overwritten by the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$ .
<i>m</i>	The total number of eigenvalues found, $0 \leq m \leq n$ . If <i>range</i> = 'A', $m = n$ , and if <i>range</i> = 'I', $m = iu - il + 1$ .
<i>w</i>	Array, size at least $\max(1, n)$ . The first <i>m</i> elements of <i>w</i> contain the selected eigenvalues in ascending order.
<i>z</i>	Array <i>z</i> (size at least $\max(1, ldz * m)$ for column major layout and $\max(1, ldz * n)$ for row major layout). If <i>jobz</i> = 'V', then if $info = 0$ , the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>A</i> corresponding to the selected eigenvalues, with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with $w[i - 1]$ . The eigenvectors are normalized as follows: if <i>itype</i> = 1 or 2, $Z^H * B * Z = I$ ; if <i>itype</i> = 3, $Z^H * \text{inv}(B) * Z = I$ ; If <i>jobz</i> = 'N', then <i>z</i> is not referenced. If an eigenvector fails to converge, then that column of <i>z</i> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i> . Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array <i>z</i> ; if <i>range</i> = 'V', the exact value of <i>m</i> is not known in advance and an upper bound must be used.
<i>ifail</i>	Array, size at least $\max(1, n)$ . If <i>jobz</i> = 'V', then if $info = 0$ , the first <i>m</i> elements of <i>ifail</i> are zero; if $info > 0$ , the <i>ifail</i> contains the indices of the eigenvectors that failed to converge. If <i>jobz</i> = 'N', then <i>ifail</i> is not referenced.

## Return Values

This function returns a value *info*.

If `info=0`, the execution is successful.

If `info = -i`, the *i*-th parameter had an illegal value.

If `info > 0`, `cpotrf/zpotrf` and `cheevx/zheevx` returned an error code:

If `info = i ≤ n`, `cheevx/zheevx` failed to converge, and *i* eigenvectors failed to converge. Their indices are stored in the array `ifail`;

If `info = n + i`, for  $1 \leq i \leq n$ , then the leading minor of order *i* of *B* is not positive-definite. The factorization of *B* could not be completed and no eigenvalues or eigenvectors were computed.

## Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to  $abstol + \epsilon \max(|a|, |b|)$ , where  $\epsilon$  is the machine precision.

If `abstol` is less than or equal to zero, then  $\epsilon * ||T||_1$  will be used in its place, where *T* is the tridiagonal matrix obtained by reducing *C* to tridiagonal form, where *C* is the symmetric matrix of the standard symmetric problem to which the generalized problem is transformed. Eigenvalues will be computed most accurately when `abstol` is set to twice the underflow threshold  $2 * \text{?lamch}('S')$ , not zero.

If this routine returns with `info > 0`, indicating that some eigenvectors did not converge, try setting `abstol` to  $2 * \text{?lamch}('S')$ .

`?spgv`

## Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$A*x = \lambda*B*x, A*B*x = \lambda*x, \text{ or } B*A*x = \lambda*x.$$

Here  $A$  and  $B$  are assumed to be Hermitian, stored in packed format, and  $B$  is also positive definite.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>itype</i>	Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$ ; if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$ ; if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$ .
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ap</i> and <i>bp</i> store the upper triangles of $A$ and $B$ ; If <i>uplo</i> = 'L', arrays <i>ap</i> and <i>bp</i> store the lower triangles of $A$ and $B$ .
<i>n</i>	The order of the matrices $A$ and $B$ ( $n \geq 0$ ).

<i>ap</i> , <i>bp</i>	<p>Arrays:</p> <p><i>ap</i> contains the packed upper or lower triangle of the Hermitian matrix <i>A</i>, as specified by <i>uplo</i>.</p> <p>The dimension of <i>ap</i> must be at least <math>\max(1, n*(n+1)/2)</math>.</p> <p><i>bp</i> contains the packed upper or lower triangle of the Hermitian matrix <i>B</i>, as specified by <i>uplo</i>.</p> <p>The dimension of <i>bp</i> must be at least <math>\max(1, n*(n+1)/2)</math>.</p>
<i>ldz</i>	The leading dimension of the output array <i>z</i> ; $ldz \geq 1$ . If <i>jobz</i> = 'V', $ldz \geq \max(1, n)$ .

## Output Parameters

<i>ap</i>	On exit, the contents of <i>ap</i> are overwritten.
<i>bp</i>	On exit, contains the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$ , in the same storage format as <i>B</i> .
<i>w</i>	<p>Array, size at least <math>\max(1, n)</math>.</p> <p>If <i>info</i> = 0, contains the eigenvalues in ascending order.</p>
<i>z</i>	<p>Array <i>z</i> (size <math>\max(1, ldz * n)</math>).</p> <p>If <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>z</i> contains the matrix <i>Z</i> of eigenvectors. The eigenvectors are normalized as follows:</p> <p>if <i>itype</i> = 1 or 2, <math>Z^H * B * Z = I</math>;</p> <p>if <i>itype</i> = 3, <math>Z^H * \text{inv}(B) * Z = I</math>;</p> <p>If <i>jobz</i> = 'N', then <i>z</i> is not referenced.</p>

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, *cpptrf/zpptrf* and *chpev/zhpev* returned an error code:

If *info* =  $i \leq n$ , *chpev/zhpev* failed to converge, and *i* off-diagonal elements of an intermediate tridiagonal did not converge to zero;

If *info* =  $n + i$ , for  $1 \leq i \leq n$ , then the leading minor of order *i* of *B* is not positive-definite. The factorization of *B* could not be completed and no eigenvalues or eigenvectors were computed.

### ?spgvd

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with matrices in packed storage using a divide and conquer method.

## Syntax

```
lapack_int LAPACKE_sspgvd (int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, float* ap, float* bp, float* w, float* z, lapack_int ldz);
```

```
lapack_int LAPACKE_dspgvd (int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, double* ap, double* bp, double* w, double* z, lapack_int ldz);
```

## Include Files

- mkl.h

## Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A*x = \lambda*B*x, \quad A*B*x = \lambda*x, \quad \text{or} \quad B*A*x = \lambda*x.$$

Here  $A$  and  $B$  are assumed to be symmetric, stored in packed format, and  $B$  is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>itype</i>	Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$ ; if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$ ; if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$ .
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ap</i> and <i>bp</i> store the upper triangles of $A$ and $B$ ; If <i>uplo</i> = 'L', arrays <i>ap</i> and <i>bp</i> store the lower triangles of $A$ and $B$ .
<i>n</i>	The order of the matrices $A$ and $B$ ( $n \geq 0$ ).
<i>ap, bp</i>	Arrays: <i>ap</i> contains the packed upper or lower triangle of the symmetric matrix $A$ , as specified by <i>uplo</i> . The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$ . <i>bp</i> contains the packed upper or lower triangle of the symmetric matrix $B$ , as specified by <i>uplo</i> . The dimension of <i>bp</i> must be at least $\max(1, n*(n+1)/2)$ .
<i>ldz</i>	The leading dimension of the output array <i>z</i> ; $ldz \geq 1$ . If <i>jobz</i> = 'V', $ldz \geq \max(1, n)$ .

## Output Parameters

*ap* On exit, the contents of *ap* are overwritten.

*bp* On exit, contains the triangular factor  $U$  or  $L$  from the Cholesky factorization  $B = U^T * U$  or  $B = L * L^T$ , in the same storage format as  $B$ .

*w, z* Arrays:  
*w*, size at least  $\max(1, n)$ .  
 If *info* = 0, contains the eigenvalues in ascending order.  
*z* (size at least  $\max(1, ldz * n)$ ).  
 If *jobz* = 'V', then if *info* = 0, *z* contains the matrix  $Z$  of eigenvectors. The eigenvectors are normalized as follows:  
 if *itype* = 1 or 2,  $Z^T * B * Z = I$ ;  
 if *itype* = 3,  $Z^T * \text{inv}(B) * Z = I$ ;  
 If *jobz* = 'N', then *z* is not referenced.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, `spstrf/dppstrf` and `sspevd/dspevd` returned an error code:

If *info* =  $i \leq n$ , `sspevd/dspevd` failed to converge, and *i* off-diagonal elements of an intermediate tridiagonal did not converge to zero;

If *info* =  $n + i$ , for  $1 \leq i \leq n$ , then the leading minor of order *i* of  $B$  is not positive-definite. The factorization of  $B$  could not be completed and no eigenvalues or eigenvectors were computed.

*?hpgvd*

*Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem with matrices in packed storage using a divide and conquer method.*

## Syntax

```
lapack_int LAPACKE_chpgvd( int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, lapack_complex_float* ap, lapack_complex_float* bp, float* w,
lapack_complex_float* z, lapack_int ldz );
```

```
lapack_int LAPACKE_zhpgvd( int matrix_layout, lapack_int itype, char jobz, char uplo,
lapack_int n, lapack_complex_double* ap, lapack_complex_double* bp, double* w,
lapack_complex_double* z, lapack_int ldz );
```

## Include Files

- mkl.h

## Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$A * x = \lambda * B * x, A * B * x = \lambda * x, \text{ or } B * A * x = \lambda * x.$$

Here  $A$  and  $B$  are assumed to be Hermitian, stored in packed format, and  $B$  is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<i>itype</i>	Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$ ; if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$ ; if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$ .
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ap</i> and <i>bp</i> store the upper triangles of $A$ and $B$ ; If <i>uplo</i> = 'L', arrays <i>ap</i> and <i>bp</i> store the lower triangles of $A$ and $B$ .
<i>n</i>	The order of the matrices $A$ and $B$ ( $n \geq 0$ ).
<i>ap, bp</i>	Arrays: <i>ap</i> contains the packed upper or lower triangle of the Hermitian matrix $A$ , as specified by <i>uplo</i> . The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$ . <i>bp</i> contains the packed upper or lower triangle of the Hermitian matrix $B$ , as specified by <i>uplo</i> . The dimension of <i>bp</i> must be at least $\max(1, n*(n+1)/2)$ .
<i>ldz</i>	The leading dimension of the output array $z$ ; $ldz \geq 1$ . If <i>jobz</i> = 'V', $ldz \geq \max(1, n)$ .

## Output Parameters

<i>ap</i>	On exit, the contents of <i>ap</i> are overwritten.
<i>bp</i>	On exit, contains the triangular factor $U$ or $L$ from the Cholesky factorization $B = U^H*U$ or $B = L*L^H$ , in the same storage format as $B$ .
<i>w</i>	Array, size at least $\max(1, n)$ . If <i>info</i> = 0, contains the eigenvalues in ascending order.
<i>z</i>	Array $z$ (size at least $\max(1, ldz*n)$ ). If <i>jobz</i> = 'V', then if <i>info</i> = 0, $z$ contains the matrix $Z$ of eigenvectors. The eigenvectors are normalized as follows: if <i>itype</i> = 1 or 2, $Z^H*B*Z = I$ ; if <i>itype</i> = 3, $Z^H*inv(B)*Z = I$ ;

If  $jobz = 'N'$ , then  $z$  is not referenced.

## Return Values

This function returns a value  $info$ .

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info > 0$ , `cpptrf/zpptrf` and `chpevd/zhpevd` returned an error code:

If  $info = i \leq n$ , `chpevd/zhpevd` failed to converge, and  $i$  off-diagonal elements of an intermediate tridiagonal did not converge to zero;

If  $info = n + i$ , for  $1 \leq i \leq n$ , then the leading minor of order  $i$  of  $B$  is not positive-definite. The factorization of  $B$  could not be completed and no eigenvalues or eigenvectors were computed.

### ?spgvx

lapack_int iu, double abstol, lapack_int* m, double* w, double* z, lapack_int ldz,
lapack_int* ifail);
```

## Include Files

- `mkl.h`

## Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A*x = \lambda*B*x, A*B*x = \lambda*x, \text{ or } B*A*x = \lambda*x.$$

Here  $A$  and  $B$  are assumed to be symmetric, stored in packed format, and  $B$  is also positive definite.

Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<i>itype</i>	Must be 1 or 2 or 3. Specifies the problem type to be solved: if $itype = 1$ , the problem type is $A*x = \lambda*B*x$ ; if $itype = 2$ , the problem type is $A*B*x = \lambda*x$ ;

	if $itype = 3$ , the problem type is $B^*A*x = \lambda*x$ .
<i>jobz</i>	Must be 'N' or 'V'. If $jobz = 'N'$ , then compute eigenvalues only. If $jobz = 'V'$ , then compute eigenvalues and eigenvectors.
<i>range</i>	Must be 'A' or 'V' or 'I'. If $range = 'A'$ , the routine computes all eigenvalues. If $range = 'V'$ , the routine computes eigenvalues $w[i]$ in the half-open interval: $vl < w[i] \leq vu$ . If $range = 'I'$ , the routine computes eigenvalues with indices $il$ to $iu$ .
<i>uplo</i>	Must be 'U' or 'L'. If $uplo = 'U'$ , arrays $ap$ and $bp$ store the upper triangles of $A$ and $B$ ; If $uplo = 'L'$ , arrays $ap$ and $bp$ store the lower triangles of $A$ and $B$ .
<i>n</i>	The order of the matrices $A$ and $B$ ( $n \geq 0$ ).
<i>ap, bp</i>	Arrays: $ap$ contains the packed upper or lower triangle of the symmetric matrix $A$ , as specified by $uplo$ . The size of $ap$ must be at least $\max(1, n*(n+1)/2)$ . $bp$ contains the packed upper or lower triangle of the symmetric matrix $B$ , as specified by $uplo$ . The size of $bp$ must be at least $\max(1, n*(n+1)/2)$ .
<i>vl, vu</i>	If $range = 'V'$ , the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$ . If $range = 'A'$ or 'I', $vl$ and $vu$ are not referenced.
<i>il, iu</i>	If $range = 'I'$ , the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$ , if $n > 0$ ; $il=1$ and $iu=0$ if $n = 0$ . If $range = 'A'$ or 'V', $il$ and $iu$ are not referenced.
<i>abstol</i>	The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information.
<i>ldz</i>	The leading dimension of the output array $z$ . Constraints: $ldz \geq 1$ ; if $jobz = 'V'$ , $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout .

## Output Parameters

<i>ap</i>	On exit, the contents of <i>ap</i> are overwritten.
<i>bp</i>	On exit, contains the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$ , in the same storage format as <i>B</i> .
<i>m</i>	The total number of eigenvalues found, $0 \leq m \leq n$ . If <i>range</i> = 'A', $m = n$ , and if <i>range</i> = 'I', $m = iu - il + 1$ .
<i>w, z</i>	Arrays: <i>w</i> , size at least $\max(1, n)$ . If <i>info</i> = 0, contains the eigenvalues in ascending order. <i>z</i> (size at least $\max(1, ldz * m)$ for column major layout and $\max(1, ldz * n)$ for row major layout) . If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>A</i> corresponding to the selected eigenvalues, with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with <i>w</i> ( <i>i</i> ). The eigenvectors are normalized as follows: if <i>itype</i> = 1 or 2, $Z^T * B * Z = I$ ; if <i>itype</i> = 3, $Z^T * \text{inv}(B) * Z = I$ ; If <i>jobz</i> = 'N', then <i>z</i> is not referenced. If an eigenvector fails to converge, then that column of <i>z</i> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i> . Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array <i>z</i> ; if <i>range</i> = 'V', the exact value of <i>m</i> is not known in advance and an upper bound must be used.
<i>ifail</i>	Array, size at least $\max(1, n)$ . If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> elements of <i>ifail</i> are zero; if <i>info</i> > 0, the <i>ifail</i> contains the indices of the eigenvectors that failed to converge. If <i>jobz</i> = 'N', then <i>ifail</i> is not referenced.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, *sppstrf*/*dpstrf* and *sspevx*/*dspevx* returned an error code:

If *info* = *i* ≤ *n*, *sspevx*/*dspevx* failed to converge, and *i* eigenvectors failed to converge. Their indices are stored in the array *ifail*;

If *info* = *n* + *i*, for  $1 \leq i \leq n$ , then the leading minor of order *i* of *B* is not positive-definite. The factorization of *B* could not be completed and no eigenvalues or eigenvectors were computed.

## Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval  $[a,b]$  of width less than or equal to  $abstol + \epsilon \cdot \max(|a|, |b|)$ , where  $\epsilon$  is the machine precision.

If  $abstol$  is less than or equal to zero, then  $\epsilon \cdot \|T\|_1$  is used instead, where  $T$  is the tridiagonal matrix obtained by reducing  $A$  to tridiagonal form. Eigenvalues are computed most accurately when  $abstol$  is set to twice the underflow threshold  $2 \cdot \text{lamch}('S')$ , not zero.

If this routine returns with  $info > 0$ , indicating that some eigenvectors did not converge, set  $abstol$  to  $2 \cdot \text{lamch}('S')$ .

## Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$A*x = \lambda*B*x, A*B*x = \lambda*x, \text{ or } B*A*x = \lambda*x.$$

Here  $A$  and  $B$  are assumed to be Hermitian, stored in packed format, and  $B$  is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>itype</i>	Must be 1 or 2 or 3. Specifies the problem type to be solved: if $itype = 1$ , the problem type is $A*x = \lambda*B*x$ ; if $itype = 2$ , the problem type is $A*B*x = \lambda*x$ ; if $itype = 3$ , the problem type is $B*A*x = \lambda*x$ .
<i>jobz</i>	Must be 'N' or 'V'.

	<p>If <code>jobz = 'N'</code>, then compute eigenvalues only.</p> <p>If <code>jobz = 'V'</code>, then compute eigenvalues and eigenvectors.</p>
<code>range</code>	<p>Must be 'A' or 'V' or 'I'.</p> <p>If <code>range = 'A'</code>, the routine computes all eigenvalues.</p> <p>If <code>range = 'V'</code>, the routine computes eigenvalues <math>w[i]</math> in the half-open interval:</p> $vl < w[i] \leq vu.$ <p>If <code>range = 'I'</code>, the routine computes eigenvalues with indices <code>il</code> to <code>iu</code>.</p>
<code>uplo</code>	<p>Must be 'U' or 'L'.</p> <p>If <code>uplo = 'U'</code>, arrays <code>ap</code> and <code>bp</code> store the upper triangles of <code>A</code> and <code>B</code>;</p> <p>If <code>uplo = 'L'</code>, arrays <code>ap</code> and <code>bp</code> store the lower triangles of <code>A</code> and <code>B</code>.</p>
<code>n</code>	The order of the matrices <code>A</code> and <code>B</code> ( $n \geq 0$ ).
<code>ap, bp</code>	<p>Arrays:</p> <p><code>ap</code> contains the packed upper or lower triangle of the Hermitian matrix <code>A</code>, as specified by <code>uplo</code>.</p> <p>The dimension of <code>ap</code> must be at least <math>\max(1, n*(n+1)/2)</math>.</p> <p><code>bp</code> contains the packed upper or lower triangle of the Hermitian matrix <code>B</code>, as specified by <code>uplo</code>.</p> <p>The dimension of <code>bp</code> must be at least <math>\max(1, n*(n+1)/2)</math>.</p>
<code>vl, vu</code>	<p>If <code>range = 'V'</code>, the lower and upper bounds of the interval to be searched for eigenvalues.</p> <p>Constraint: <code>vl &lt; vu</code>.</p> <p>If <code>range = 'A'</code> or 'I', <code>vl</code> and <code>vu</code> are not referenced.</p>
<code>il, iu</code>	<p>If <code>range = 'I'</code>, the indices in ascending order of the smallest and largest eigenvalues to be returned.</p> <p>Constraint: <math>1 \leq il \leq iu \leq n</math>, if <math>n &gt; 0</math>; <code>il=1</code> and <code>iu=0</code> if <math>n = 0</math>.</p> <p>If <code>range = 'A'</code> or 'V', <code>il</code> and <code>iu</code> are not referenced.</p>
<code>abstol</code>	<p>The absolute error tolerance for the eigenvalues.</p> <p>See <i>Application Notes</i> for more information.</p>
<code>ldz</code>	The leading dimension of the output array <code>z</code> ; $ldz \geq 1$ . If <code>jobz = 'V'</code> , $ldz \geq \max(1, n)$ for column major layout and $ldz \geq \max(1, m)$ for row major layout.

## Output Parameters

`ap` On exit, the contents of `ap` are overwritten.

<i>bp</i>	On exit, contains the triangular factor $U$ or $L$ from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$ , in the same storage format as $B$ .
<i>m</i>	The total number of eigenvalues found, $0 \leq m \leq n$ . If <i>range</i> = 'A', $m = n$ , and if <i>range</i> = 'I', $m = iu - il + 1$ .
<i>w</i>	Array, size at least $\max(1, n)$ . If <i>info</i> = 0, contains the eigenvalues in ascending order.
<i>z</i>	Array $z$ (size at least $\max(1, ldz * m)$ for column major layout and $\max(1, ldz * n)$ for row major layout). If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first $m$ columns of $z$ contain the orthonormal eigenvectors of the matrix $A$ corresponding to the selected eigenvalues, with the $i$ -th column of $z$ holding the eigenvector associated with $w(i)$ . The eigenvectors are normalized as follows: if <i>itype</i> = 1 or 2, $Z^H * B * Z = I$ ; if <i>itype</i> = 3, $Z^H * \text{inv}(B) * Z = I$ ; If <i>jobz</i> = 'N', then $z$ is not referenced. If an eigenvector fails to converge, then that column of $z$ contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i> . Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array $z$ ; if <i>range</i> = 'V', the exact value of $m$ is not known in advance and an upper bound must be used.
<i>ifail</i>	Array, size at least $\max(1, n)$ . If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first $m$ elements of <i>ifail</i> are zero; if <i>info</i> > 0, the <i>ifail</i> contains the indices of the eigenvectors that failed to converge. If <i>jobz</i> = 'N', then <i>ifail</i> is not referenced.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* =  $-i$ , the  $i$ -th parameter had an illegal value.

If *info* > 0, *cpptrf/zpptrf* and *chpevx/zhpevx* returned an error code:

If *info* =  $i \leq n$ , *chpevx/zhpevx* failed to converge, and  $i$  eigenvectors failed to converge. Their indices are stored in the array *ifail*;

If *info* =  $n + i$ , for  $1 \leq i \leq n$ , then the leading minor of order  $i$  of  $B$  is not positive-definite. The factorization of  $B$  could not be completed and no eigenvalues or eigenvectors were computed.

## Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval  $[a, b]$  of width less than or equal to  $abstol + \epsilon * \max(|a|, |b|)$ , where  $\epsilon$  is the machine precision.

If *abstol* is less than or equal to zero, then  $\epsilon * ||T||_1$  is used as tolerance, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold  $2 * \text{lamch}('S')$ , not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to  $2 * \text{lamch}('S')$ .

## Description

The routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form  $A*x = \lambda*B*x$ . Here *A* and *B* are assumed to be symmetric and banded, and *B* is also positive definite.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>jobz</i>	Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of <i>A</i> and <i>B</i> ; If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of <i>A</i> and <i>B</i> .
<i>n</i>	The order of the matrices <i>A</i> and <i>B</i> ( $n \geq 0$ ).
<i>ka</i>	The number of super- or sub-diagonals in <i>A</i> ( $ka \geq 0$ ).
<i>kb</i>	The number of super- or sub-diagonals in <i>B</i> ( $kb \geq 0$ ).
<i>ab, bb</i>	Arrays:

$ab$  (size at least  $\max(1, ldab*n)$  for column major layout and  $\max(1, ldab*(ka + 1))$  for row major layout) is an array containing either upper or lower triangular part of the symmetric matrix  $A$  (as specified by  $uplo$ ) in band storage format.

$bb$  (size at least  $\max(1, ldbb*n)$  for column major layout and  $\max(1, ldbb*(kb + 1))$  for row major layout) is an array containing either upper or lower triangular part of the symmetric matrix  $B$  (as specified by  $uplo$ ) in band storage format.

$ldab$	The leading dimension of the array $ab$ ; must be at least $ka+1$ for column major layout and at least $\max(1, n)$ for row major layout .
$ldbb$	The leading dimension of the array $bb$ ; must be at least $kb+1$ for column major layout and at least $\max(1, n)$ for row major layout.
$ldz$	The leading dimension of the output array $z$ ; $ldz \geq 1$ . If $jobz = 'V'$ , $ldz \geq \max(1, n)$ .

## Output Parameters

$ab$	On exit, the contents of $ab$ are overwritten.
$bb$	On exit, contains the factor $S$ from the split Cholesky factorization $B = S^T * S$ , as returned by <a href="#">pbstf/pbstf</a> .
$w, z$	Arrays: $w$ , size at least $\max(1, n)$ . If $info = 0$ , contains the eigenvalues in ascending order. $z$ (size at least $\max(1, ldz*n)$ ) . If $jobz = 'V'$ , then if $info = 0$ , $z$ contains the matrix $Z$ of eigenvectors, with the $i$ -th column of $z$ holding the eigenvector associated with $w(i)$ . The eigenvectors are normalized so that $Z^T * B * Z = I$ . If $jobz = 'N'$ , then $z$ is not referenced.

## Return Values

This function returns a value  $info$ .

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info > 0$ , and

if  $i \leq n$ , the algorithm failed to converge, and  $i$  off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if  $info = n + i$ , for  $1 \leq i \leq n$ , then [pbstf/pbstf](#) returned  $info = i$  and  $B$  is not positive-definite. The factorization of  $B$  could not be completed and no eigenvalues or eigenvectors were computed.

## Description

The routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form  $A * x = \lambda * B * x$ . Here  $A$  and  $B$  are assumed to be symmetric and banded, and  $B$  is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>jobz</code>	Must be 'N' or 'V'.

	If <i>jobz</i> = 'N', then compute eigenvalues only.
	If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>range</i>	Must be 'A' or 'V' or 'I'.
	If <i>range</i> = 'A', the routine computes all eigenvalues.
	If <i>range</i> = 'V', the routine computes eigenvalues $w[i]$ in the half-open interval: $vl < w[i] \leq vu$ .
	If <i>range</i> = 'I', the routine computes eigenvalues in range <i>il</i> to <i>iu</i> .
<i>uplo</i>	Must be 'U' or 'L'.
	If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of <i>A</i> and <i>B</i> ;
	If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of <i>A</i> and <i>B</i> .
<i>n</i>	The order of the matrices <i>A</i> and <i>B</i> ( $n \geq 0$ ).
<i>ka</i>	The number of super- or sub-diagonals in <i>A</i> ( $ka \geq 0$ ).
<i>kb</i>	The number of super- or sub-diagonals in <i>B</i> ( $kb \geq 0$ ).
<i>ab, bb</i>	Arrays: <i>ab</i> (size at least $\max(1, ldab * n)$ for column major layout and $\max(1, ldab * (ka + 1))$ for row major layout) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> (as specified by <i>uplo</i> ) in band storage format. <i>bb</i> (size at least $\max(1, ldbb * n)$ for column major layout and $\max(1, ldbb * (kb + 1))$ for row major layout) is an array containing either upper or lower triangular part of the symmetric matrix <i>B</i> (as specified by <i>uplo</i> ) in band storage format.
<i>ldab</i>	The leading dimension of the array <i>ab</i> ; must be at least $ka+1$ for column major layout and at least $\max(1, n)$ for row major layout.
<i>ldbb</i>	The leading dimension of the array <i>bb</i> ; must be at least $kb+1$ for column major layout and at least $\max(1, n)$ for row major layout.
<i>vl, vu</i>	If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$ . If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$ , if $n > 0$ ; $il=1$ and $iu=0$ if $n = 0$ . If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.

<i>abstol</i>	The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information.
<i>ldz</i>	The leading dimension of the output array <i>z</i> ; $ldz \geq 1$ . If <i>jobz</i> = 'V', $ldz \geq \max(1, n)$ .
<i>ldq</i>	The leading dimension of the output array <i>q</i> ; $ldq < 1$ . If <i>jobz</i> = 'V', $ldq < \max(1, n)$ .

## Output Parameters

<i>ab</i>	On exit, the contents of <i>ab</i> are overwritten.
<i>bb</i>	On exit, contains the factor <i>S</i> from the split Cholesky factorization $B = S^T * S$ , as returned by <a href="#">pbstf/pbstf</a> .
<i>m</i>	The total number of eigenvalues found, $0 \leq m \leq n$ . If <i>range</i> = 'A', $m = n$ , and if <i>range</i> = 'I', $m = iu - il + 1$ .
<i>w, z, q</i>	Arrays: <i>w</i> , size at least $\max(1, n)$ . If <i>info</i> = 0, contains the eigenvalues in ascending order. <i>z</i> (size $\max(1, ldz * m)$ for column major layout and $\max(1, ldz * n)$ for row major layout). If <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>z</i> contains the matrix <i>Z</i> of eigenvectors, with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with <i>w</i> ( <i>i</i> ). The eigenvectors are normalized so that $Z^T * B * Z = I$ . If <i>jobz</i> = 'N', then <i>z</i> is not referenced. <i>q</i> (size $\max(1, ldq * n)$ ). If <i>jobz</i> = 'V', then <i>q</i> contains the <i>n</i> -by- <i>n</i> matrix used in the reduction of $A * x = \lambda * B * x$ to standard form, that is, $C * x = \lambda * x$ and consequently <i>C</i> to tridiagonal form. If <i>jobz</i> = 'N', then <i>q</i> is not referenced.
<i>ifail</i>	Array, size <i>m</i> . If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> elements of <i>ifail</i> are zero; if <i>info</i> > 0, the <i>ifail</i> contains the indices of the eigenvectors that failed to converge. If <i>jobz</i> = 'N', then <i>ifail</i> is not referenced.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, and

if  $i \leq n$ , the algorithm failed to converge, and  $i$  off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if  $info = n + i$ , for  $1 \leq i \leq n$ , then `pbstf/pbstf` returned  $info = i$  and  $B$  is not positive-definite. The factorization of  $B$  could not be completed and no eigenvalues or eigenvectors were computed.

## Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval  $[a,b]$  of width less than or equal to  $abstol + \epsilon * \max(|a|, |b|)$ , where  $\epsilon$  is the machine precision.

If  $abstol$  is less than or equal to zero, then  $\epsilon * ||T||_1$  is used as tolerance, where  $T$  is the tridiagonal matrix obtained by reducing  $A$  to tridiagonal form. Eigenvalues will be computed most accurately when  $abstol$  is set to twice the underflow threshold  $2 * ?lamch('S')$ , not zero.

If this routine returns with  $info > 0$ , indicating that some eigenvectors did not converge, try setting  $abstol$  to  $2 * ?lamch('S')$ .

### ?hbgvx

<i>range</i>	<p>Must be 'A' or 'V' or 'I'.</p> <p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes eigenvalues <math>w[i]</math> in the half-open interval:</p> $vl < w[i] \leq vu.$ <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.</p>
<i>uplo</i>	<p>Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of <i>A</i> and <i>B</i>;</p> <p>If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of <i>A</i> and <i>B</i>.</p>
<i>n</i>	The order of the matrices <i>A</i> and <i>B</i> ( $n \geq 0$ ).
<i>ka</i>	The number of super- or sub-diagonals in <i>A</i> ( $ka \geq 0$ ).
<i>kb</i>	The number of super- or sub-diagonals in <i>B</i> ( $kb \geq 0$ ).
<i>ab, bb</i>	<p>Arrays:</p> <p><i>ab</i> (size at least <math>\max(1, ldab * n)</math> for column major layout and <math>\max(1, ldab * (ka + 1))</math> for row major layout) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format.</p> <p><i>bb</i> (size at least <math>\max(1, ldbb * n)</math> for column major layout and <math>\max(1, ldbb * (kb + 1))</math> for row major layout) is an array containing either upper or lower triangular part of the Hermitian matrix <i>B</i> (as specified by <i>uplo</i>) in band storage format.</p>
<i>ldab</i>	The leading dimension of the array <i>ab</i> ; must be at least $ka+1$ for column major layout and at least $\max(1, n)$ for row major layout.
<i>ldbb</i>	The leading dimension of the array <i>bb</i> ; must be at least $kb+1$ for column major layout and at least $\max(1, n)$ for row major layout.
<i>vl, vu</i>	<p>If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.</p> <p>Constraint: <math>vl &lt; vu</math>.</p> <p>If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.</p>
<i>il, iu</i>	<p>If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.</p> <p>Constraint: <math>1 \leq il \leq iu \leq n</math>, if <math>n &gt; 0</math>; <math>il=1</math> and <math>iu=0</math> if <math>n = 0</math>.</p> <p>If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.</p>
<i>abstol</i>	The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information.

<i>ldz</i>	The leading dimension of the output array <i>z</i> ; $ldz \geq 1$ . If <i>jobz</i> = 'V', $ldz \geq \max(1, n)$ for column major layout and at least $\max(1, m)$ for row major layout.
<i>ldq</i>	The leading dimension of the output array <i>q</i> ; $ldq \geq 1$ . If <i>jobz</i> = 'V', $ldq \geq \max(1, n)$ .

## Output Parameters

<i>ab</i>	On exit, the contents of <i>ab</i> are overwritten.
<i>bb</i>	On exit, contains the factor <i>S</i> from the split Cholesky factorization $B = S^H * S$ , as returned by <a href="#">pbstf/pbstf</a> .
<i>m</i>	The total number of eigenvalues found, $0 \leq m \leq n$ . If <i>range</i> = 'A', $m = n$ , and if <i>range</i> = 'I', $m = iu - il + 1$ .
<i>w</i>	Array <i>w</i> , size at least $\max(1, n)$ . If <i>info</i> = 0, contains the eigenvalues in ascending order.
<i>z, q</i>	Arrays: <i>z</i> (size $\max(1, ldz * m)$ for column major layout and $\max(1, ldz * n)$ for row major layout). If <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>z</i> contains the matrix <i>Z</i> of eigenvectors, with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with $w[i - 1]$ . The eigenvectors are normalized so that $Z^H * B * Z = I$ . If <i>jobz</i> = 'N', then <i>z</i> is not referenced. <i>q</i> (size $\max(1, ldq * n)$ ). If <i>jobz</i> = 'V', then <i>q</i> contains the <i>n</i> -by- <i>n</i> matrix used in the reduction of $Ax = \lambda Bx$ to standard form, that is, $Cx = \lambda x$ and consequently <i>C</i> to tridiagonal form. If <i>jobz</i> = 'N', then <i>q</i> is not referenced.
<i>ifail</i>	Array, size at least $\max(1, n)$ . If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> elements of <i>ifail</i> are zero; if <i>info</i> > 0, the <i>ifail</i> contains the indices of the eigenvectors that failed to converge. If <i>jobz</i> = 'N', then <i>ifail</i> is not referenced.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* > 0, and

if  $i \leq n$ , the algorithm failed to converge, and  $i$  off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if  $info = n + i$ , for  $1 \leq i \leq n$ , then `pbstf/pbstf` returned  $info = i$  and  $B$  is not positive-definite. The factorization of  $B$  could not be completed and no eigenvalues or eigenvectors were computed.

## Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval  $[a,b]$  of width less than or equal to  $abstol + \epsilon \cdot \max(|a|, |b|)$ , where  $\epsilon$  is the machine precision.

If  $abstol$  is less than or equal to zero, then  $\epsilon \cdot \|T\|_1$  will be used in its place, where  $T$  is the tridiagonal matrix obtained by reducing  $A$  to tridiagonal form. Eigenvalues will be computed most accurately when  $abstol$  is set to twice the underflow threshold  $2 * \text{?lamch}('S')$ , not zero.

If this routine returns with  $info > 0$ , indicating that some eigenvectors did not converge, try setting  $abstol$  to  $2 * \text{?lamch}('S')$ .

## Generalized Nonsymmetric Eigenvalue Problems: LAPACK Driver Routines

This topic describes LAPACK driver routines used for solving generalized nonsymmetric eigenproblems. See also [computational routines](#) that can be called to solve these problems. [Table "Driver Routines for Solving Generalized Nonsymmetric Eigenproblems"](#) lists all such driver routines.

### Driver Routines for Solving Generalized Nonsymmetric Eigenproblems

---

Routine Name	Operation performed
<a href="#">gges</a>	Computes the generalized eigenvalues, Schur form, and the left and/or right Schur vectors for a pair of nonsymmetric matrices.
<a href="#">ggesx</a>	Computes the generalized eigenvalues, Schur form, and, optionally, the left and/or right matrices of Schur vectors.
<a href="#">gges3</a>	Computes generalized Schur factorization for a pair of matrices.
<a href="#">ggev</a>	Computes the generalized eigenvalues, and the left and/or right generalized eigenvectors for a pair of nonsymmetric matrices.
<a href="#">ggev3</a>	Computes the generalized eigenvalues, and, optionally, the left and/or right generalized eigenvectors.
<a href="#">ggev3</a>	Computes generalized Schur factorization for a pair of matrices.

---

`?gges`

*Computes the generalized eigenvalues, Schur form, and the left and/or right Schur vectors for a pair of nonsymmetric matrices.*

## Description

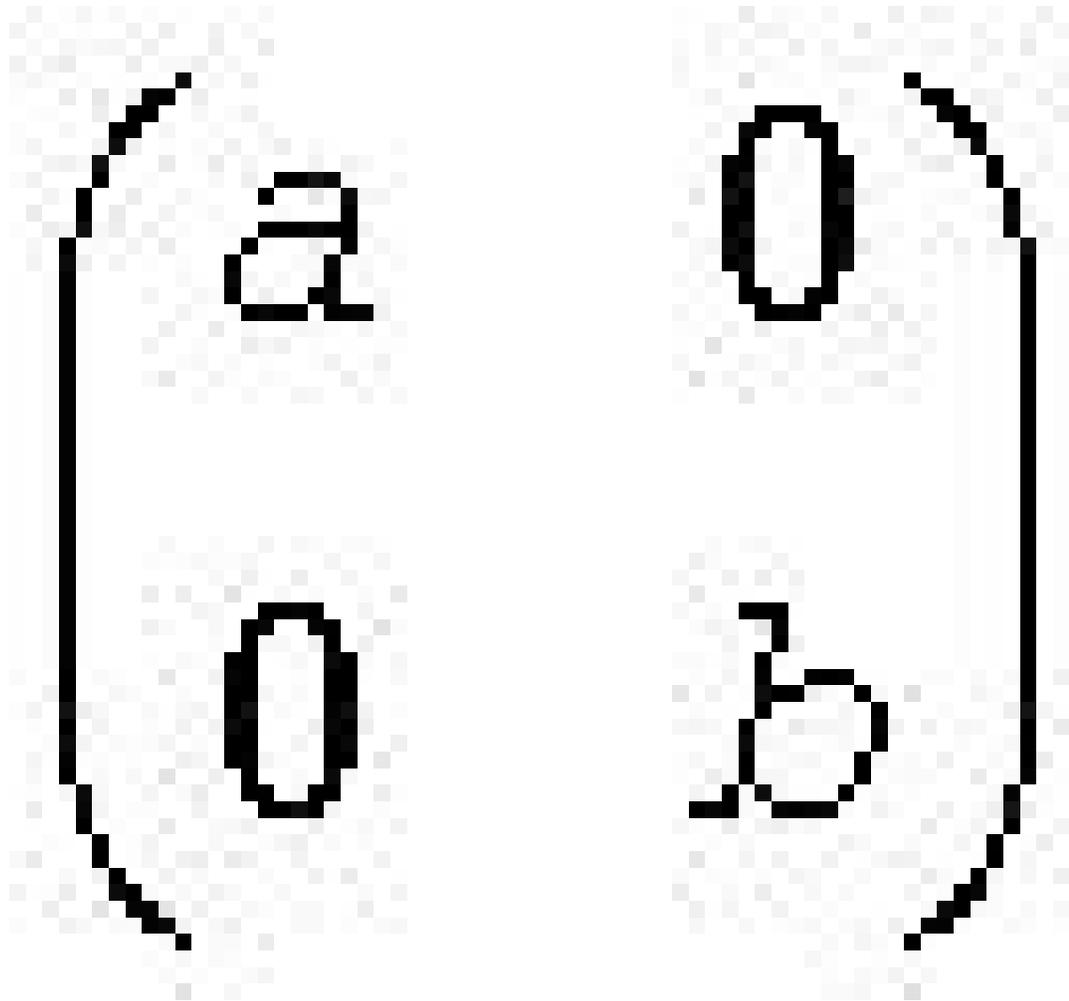

The `?gges` routine computes the generalized eigenvalues, the generalized real/complex Schur form  $(S,T)$ , optionally, the left and/or right matrices of Schur vectors ( $vsl$  and  $vsr$ ) for a pair of  $n$ -by- $n$  real/complex nonsymmetric matrices  $(A,B)$ . This gives the generalized Schur factorization

$$(A,B) = ( vsl * S * vsr^H, vsl * T * vsr^H )$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix  $S$  and the upper triangular matrix  $T$ . The leading columns of  $vsl$  and  $vsr$  then form an orthonormal/unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

If only the generalized eigenvalues are needed, use the driver `ggev` instead, which is faster.

A generalized eigenvalue for a pair of matrices  $(A,B)$  is a scalar  $w$  or a ratio  $alpha / beta = w$ , such that  $A - w * B$  is singular. It is usually represented as the pair  $(alpha, beta)$ , as there is a reasonable interpretation for  $beta=0$  or for both being zero. A pair of matrices  $(S,T)$  is in the generalized real Schur form if  $T$  is upper triangular with non-negative diagonal and  $S$  is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of  $S$  are "standardized" by making the corresponding elements of  $T$  have the form:

and the pair of corresponding 2-by-2 blocks in  $S$  and  $T$  will have a complex conjugate pair of generalized eigenvalues. A pair of matrices  $(S, T)$  is in generalized complex Schur form if  $S$  and  $T$  are upper triangular and, in addition, the diagonal of  $T$  are non-negative real numbers.

The `?gges` routine replaces the deprecated `?gegs` routine.

### Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>jobvs1</code>	Must be 'N' or 'V'. If <code>jobvs1 = 'N'</code> , then the left Schur vectors are not computed. If <code>jobvs1 = 'V'</code> , then the left Schur vectors are computed.
<code>jobvsr</code>	Must be 'N' or 'V'. If <code>jobvsr = 'N'</code> , then the right Schur vectors are not computed. If <code>jobvsr = 'V'</code> , then the right Schur vectors are computed.
<code>sort</code>	Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form.

	<p>If <code>sort = 'N'</code>, then eigenvalues are not ordered.</p> <p>If <code>sort = 'S'</code>, eigenvalues are ordered (see <code>select</code>).</p>
<code>select</code>	<p>The <code>select</code> parameter is a pointer to a function returning a value of <code>lapack_logical</code> type. For different flavors the function has different arguments:</p> <pre>LAPACKE_sgges: lapack_logical (*LAPACK_S_SELECT3) ( const float*, const float*, const float* ); LAPACKE_dgges: lapack_logical (*LAPACK_D_SELECT3) ( const double*, const double*, const double* ); LAPACKE_cgges: lapack_logical (*LAPACK_C_SELECT2) ( const lapack_complex_float*, const lapack_complex_float* ); LAPACKE_zgges: lapack_logical (*LAPACK_Z_SELECT2) ( const lapack_complex_double*, const lapack_complex_double* );</pre> <p>If <code>sort = 'S'</code>, <code>select</code> is used to select eigenvalues to sort to the top left of the Schur form.</p> <p>If <code>sort = 'N'</code>, <code>select</code> is not referenced.</p> <p><i>For real flavors:</i></p> <p>An eigenvalue <math>(\text{alphan}[j] + \text{alphai}[j])/beta[j]</math> is selected if <code>select(alphan[j], alphai[j], beta[j])</code> is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.</p> <p>Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy <code>select(alphan[j], alphai[j], beta[j]) = 1</code> after ordering. In this case <code>info</code> is set to <math>n+2</math>.</p> <p><i>For complex flavors:</i></p> <p>An eigenvalue <math>\text{alpha}[j] / \text{beta}[j]</math> is selected if <code>select(alpha[j], beta[j])</code> is true.</p> <p>Note that a selected complex eigenvalue may no longer satisfy <code>select(alpha[j], beta[j]) = 1</code> after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case <code>info</code> is set to <math>n+2</math> (see <code>info</code> below).</p>
<code>n</code>	The order of the matrices <code>A</code> , <code>B</code> , <code>vsl</code> , and <code>vsr</code> ( $n \geq 0$ ).
<code>a, b</code>	<p>Arrays:</p> <p><code>a</code> (size at least <math>\max(1, lda*n)</math>) is an array containing the <math>n</math>-by-<math>n</math> matrix <code>A</code> (first of the pair of matrices).</p> <p><code>b</code> (size at least <math>\max(1, ldb*n)</math>) is an array containing the <math>n</math>-by-<math>n</math> matrix <code>B</code> (second of the pair of matrices).</p>
<code>lda</code>	The leading dimension of the array <code>a</code> . Must be at least $\max(1, n)$ .
<code>ldb</code>	The leading dimension of the array <code>b</code> . Must be at least $\max(1, n)$ .
<code>ldvsl, ldvsr</code>	<p>The leading dimensions of the output matrices <code>vsl</code> and <code>vsr</code>, respectively.</p> <p>Constraints:</p> <p><math>ldvsl \geq 1</math>. If <code>jobvsl = 'V'</code>, <math>ldvsl \geq \max(1, n)</math>.</p>

$ldvsr \geq 1$ . If  $jobvsr = 'V'$ ,  $ldvsr \geq \max(1, n)$ .

## Output Parameters

<i>a</i>	On exit, this array has been overwritten by its generalized Schur form <i>S</i> .
<i>b</i>	On exit, this array has been overwritten by its generalized Schur form <i>T</i> .
<i>sdim</i>	<p>If <math>sort = 'N'</math>, <math>sdim = 0</math>.</p> <p>If <math>sort = 'S'</math>, <math>sdim</math> is equal to the number of eigenvalues (after sorting) for which <i>select</i> is true.</p> <p>Note that for real flavors complex conjugate pairs for which <i>select</i> is true for either eigenvalue count as 2.</p>
<i>alphar, alphai</i>	<p>Arrays, size at least <math>\max(1, n)</math> each. Contain values that form generalized eigenvalues in real flavors.</p> <p>See <i>beta</i>.</p>
<i>alpha</i>	Array, size at least $\max(1, n)$ . Contain values that form generalized eigenvalues in complex flavors. See <i>beta</i> .
<i>beta</i>	<p>Array, size at least <math>\max(1, n)</math>.</p> <p>For real flavors:</p> <p>On exit, <math>(alphar[j] + alphai[j]*i)/beta[j]</math>, <math>j=0, \dots, n-1</math>, will be the generalized eigenvalues.</p> <p><math>alphar[j] + alphai[j]*i</math> and <math>beta[j]</math>, <math>j=0, \dots, n-1</math> are the diagonals of the complex Schur form (<i>S,T</i>) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (<i>A,B</i>) were further reduced to triangular form using complex unitary transformations. If <math>alphai[j]</math> is zero, then the <i>j</i>-th eigenvalue is real; if positive, then the <i>j</i>-th and (<i>j</i>+1)-st eigenvalues are a complex conjugate pair, with <math>alphai[j+1]</math> negative.</p> <p>For complex flavors:</p> <p>On exit, <math>alpha[j]/beta[j]</math>, <math>j=0, \dots, n-1</math>, will be the generalized eigenvalues. <math>alpha[j]</math> and <math>beta[j]</math>, <math>j=0, \dots, n-1</math> are the diagonals of the complex Schur form (<i>S,T</i>) output by <i>cggges/zggges</i>. The <math>beta[j]</math> will be non-negative real.</p> <p>See also <i>Application Notes</i> below.</p>
<i>vs1, vsr</i>	<p>Arrays:</p> <p><i>vs1</i> (size at least <math>\max(1, ldvs1*n)</math>).</p> <p>If <math>jobvs1 = 'V'</math>, this array will contain the left Schur vectors.</p> <p>If <math>jobvs1 = 'N'</math>, <i>vs1</i> is not referenced.</p> <p><i>vsr</i> (size at least <math>\max(1, ldvsr*n)</math>).</p> <p>If <math>jobvsr = 'V'</math>, this array will contain the right Schur vectors.</p> <p>If <math>jobvsr = 'N'</math>, <i>vsr</i> is not referenced.</p>

## Return Values

This function returns a value *info*.

If  $info=0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = i$ , and

$i \leq n$ :

the QZ iteration failed.  $(A, B)$  is not in Schur form, but  $alpha_r[j]$ ,  $alpha_i[j]$  (for real flavors), or  $alpha[j]$  (for complex flavors), and  $beta[j]$ ,  $j = info, \dots, n - 1$  should be correct.

$i > n$ : errors that usually indicate LAPACK problems:

$i = n+1$ : other than QZ iteration failed in [hgeqz](#);

$i = n+2$ : after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the generalized Schur form no longer satisfy  $select = 1$ . This could also be caused due to scaling;

$i = n+3$ : reordering failed in [tgsen](#).

## Application Notes

The quotients  $alpha_r[j]/beta[j]$  and  $alpha_i[j]/beta[j]$  may easily over- or underflow, and  $beta[j]$  may even be zero. Thus, you should avoid simply computing the ratio. However,  $alpha_r$  and  $alpha_i$  will be always less than and usually comparable with  $norm(A)$  in magnitude, and  $beta$  always less than and usually comparable with  $norm(B)$ .

**?ggesx**

*Computes the generalized eigenvalues, Schur form, and, optionally, the left and/or right matrices of Schur vectors.*

## Description

The routine computes for a pair of  $n$ -by- $n$  real/complex nonsymmetric matrices  $(A,B)$ , the generalized eigenvalues, the generalized real/complex Schur form  $(S,T)$ , optionally, the left and/or right matrices of Schur vectors ( $vs_l$  and  $vs_r$ ). This gives the generalized Schur factorization

$$(A,B) = ( vs_l * S * vs_r^H, vs_l * T * vs_r^H )$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix  $S$  and the upper triangular matrix  $T$ ; computes a reciprocal condition number for the average of the selected eigenvalues ( $rconde$ ); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues ( $rcondv$ ). The leading columns of  $vs_l$  and  $vs_r$  then form an orthonormal/unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices  $(A,B)$  is a scalar  $w$  or a ratio  $alpha / beta = w$ , such that  $A - w*B$  is singular. It is usually represented as the pair  $(alpha, beta)$ , as there is a reasonable interpretation for  $beta=0$  or for both being zero. A pair of matrices  $(S,T)$  is in generalized real Schur form if  $T$  is upper triangular with non-negative diagonal and  $S$  is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of  $S$  will be "standardized" by making the corresponding elements of  $T$  have the form:

and the pair of corresponding 2-by-2 blocks in  $S$  and  $T$  will have a complex conjugate pair of generalized eigenvalues. A pair of matrices  $(S, T)$  is in generalized complex Schur form if  $S$  and  $T$  are upper triangular and, in addition, the diagonal of  $T$  are non-negative real numbers.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>jobvsl</i>	Must be 'N' or 'V'. If <i>jobvsl</i> = 'N', then the left Schur vectors are not computed. If <i>jobvsl</i> = 'V', then the left Schur vectors are computed.
<i>jobvsr</i>	Must be 'N' or 'V'. If <i>jobvsr</i> = 'N', then the right Schur vectors are not computed. If <i>jobvsr</i> = 'V', then the right Schur vectors are computed.
<i>sort</i>	Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. If <i>sort</i> = 'N', then eigenvalues are not ordered. If <i>sort</i> = 'S', eigenvalues are ordered (see <i>select</i> ).
<i>select</i>	The <i>select</i> parameter is a pointer to a function returning a value of <code>lapack_logical</code> type. For different flavors the function has different arguments:  <pre>LAPACKE_sggesx: lapack_logical (*LAPACK_S_SELECT3) ( const float*, const float*, const float* );</pre> <pre>LAPACKE_dggesx: lapack_logical (*LAPACK_D_SELECT3) ( const double*, const double*, const double* );</pre> <pre>LAPACKE_cggesx: lapack_logical (*LAPACK_C_SELECT2) ( const lapack_complex_float*, const lapack_complex_float* );</pre> <pre>LAPACKE_zggesx: lapack_logical (*LAPACK_Z_SELECT2) ( const lapack_complex_double*, const lapack_complex_double* );</pre> If <i>sort</i> = 'S', <i>select</i> is used to select eigenvalues to sort to the top left of the Schur form. If <i>sort</i> = 'N', <i>select</i> is not referenced.  <i>For real flavors:</i>  An eigenvalue $(\alpha_j + \beta_j i) / \beta_j$ is selected if <i>select</i> ( $\alpha_j$ , $\beta_j$ ) is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.  Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy <i>select</i> ( $\alpha_j$ , $\beta_j$ ) = 1 after ordering. In this case <i>info</i> is set to $n+2$ .  <i>For complex flavors:</i>  An eigenvalue $\alpha_j / \beta_j$ is selected if <i>select</i> ( $\alpha_j$ , $\beta_j$ ) is true.

Note that a selected complex eigenvalue may no longer satisfy  $select(alpha[j], beta[j]) = 1$  after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case *info* is set to  $n+2$  (see *info* below).

*sense*

Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.

If *sense* = 'N', none are computed;

If *sense* = 'E', computed for average of selected eigenvalues only;

If *sense* = 'V', computed for selected deflating subspaces only;

If *sense* = 'B', computed for both.

If *sense* is 'E', 'V', or 'B', then *sort* must equal 'S'.

*n*

The order of the matrices *A*, *B*, *vsL*, and *vsR* ( $n \geq 0$ ).

*a*, *b*

Arrays:

*a* (size at least  $\max(1, lda*n)$ ) is an array containing the  $n$ -by- $n$  matrix *A* (first of the pair of matrices).

*b* (size at least  $\max(1, ldb*n)$ ) is an array containing the  $n$ -by- $n$  matrix *B* (second of the pair of matrices).

*lda*

The leading dimension of the array *a*.

Must be at least  $\max(1, n)$ .

*ldb*

The leading dimension of the array *b*.

Must be at least  $\max(1, n)$ .

*ldvsl*, *ldvsr*

The leading dimensions of the output matrices *vsL* and *vsR*, respectively.  
Constraints:

$ldvsl \geq 1$ . If *jobvsl* = 'V',  $ldvsl \geq \max(1, n)$ .

$ldvsr \geq 1$ . If *jobvsr* = 'V',  $ldvsr \geq \max(1, n)$ .

## Output Parameters

*a*

On exit, this array has been overwritten by its generalized Schur form *S*.

*b*

On exit, this array has been overwritten by its generalized Schur form *T*.

*sdim*

If *sort* = 'N', *sdim* = 0.

If *sort* = 'S', *sdim* is equal to the number of eigenvalues (after sorting) for which *select* is true.

Note that for real flavors complex conjugate pairs for which *select* is true for either eigenvalue count as 2.

*alphar*, *alphai*

Arrays, size at least  $\max(1, n)$  each. Contain values that form generalized eigenvalues in real flavors.

See *beta*.

<i>alpha</i>	Array, size at least $\max(1, n)$ . Contain values that form generalized eigenvalues in complex flavors. See <i>beta</i> .
<i>beta</i>	<p>Array, size at least <math>\max(1, n)</math>.</p> <p><i>For real flavors:</i></p> <p>On exit, <math>(\text{alpha}[j] + \text{alpha}[j]*i)/\text{beta}[j]</math>, <math>j=0, \dots, n - 1</math> will be the generalized eigenvalues.</p> <p><math>\text{alpha}[j] + \text{alpha}[j]*i</math> and <math>\text{beta}[j]</math>, <math>j=0, \dots, n - 1</math> are the diagonals of the complex Schur form <math>(S, T)</math> that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of <math>(A, B)</math> were further reduced to triangular form using complex unitary transformations. ## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* =  $-i$ , the  $i$ -th parameter had an illegal value.

If *info* =  $i$ , and

$i \leq n$ :

the QZ iteration failed.  $(A, B)$  is not in Schur form, but  $\text{alpha}[j]$ ,  $\text{alpha}[j]$  (for real flavors), or  $\text{alpha}[j]$  (for complex flavors), and  $\text{beta}[j]$ ,  $j = \text{info}, \dots, n - 1$  should be correct.

$i > n$ : errors that usually indicate LAPACK problems:

$i = n+1$ : other than QZ iteration failed in [hgeqz](#);

$i = n+2$ : after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the generalized Schur form no longer satisfy  $select = 1$ . This could also be caused due to scaling;

$i = n+3$ : reordering failed in [tgsen](#).

## Application Notes

The quotients  $alphan[j]/beta[j]$  and  $alphai[j]/beta[j]$  may easily over- or underflow, and  $beta[j]$  may even be zero. Thus, you should avoid simply computing the ratio. However,  $alphan$  and  $alphai$  will be always less than and usually comparable with  $norm(A)$  in magnitude, and  $beta$  always less than and usually comparable with  $norm(B)$ .

`?gges3`

*Computes generalized Schur factorization for a pair of matrices.*

## Description

For a pair of  $n$ -by- $n$  real or complex nonsymmetric matrices  $(A,B)$ , `?gges3` computes the generalized eigenvalues, the generalized real or complex Schur form  $(S,T)$ , and optionally the left or right matrices of Schur vectors  $(VSL$  and  $VSR)$ . This gives the generalized Schur factorization

$$(A,B) = ( (VSL)*S*(VSR)^T, (VSL)*T*(VSR)^T ) \text{ for real } (A,B)$$

or

$$(A,B) = ( (VSL)*S*(VSR)^H, (VSL)*T*(VSR)^H ) \text{ for complex } (A,B)$$

where  $(VSR)^H$  is the conjugate-transpose of  $VSR$ .

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix  $S$  and the upper triangular matrix  $T$ . The leading columns of  $VSL$  and  $VSR$  then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

---

#### NOTE

If only the generalized eigenvalues are needed, use the driver `?ggeev` instead, which is faster.

---

A generalized eigenvalue for a pair of matrices  $(A,B)$  is a scalar  $w$  or a ratio  $alpha/beta = w$ , such that  $A - w*B$  is singular. It is usually represented as the pair  $(alpha,beta)$ , as there is a reasonable interpretation for  $beta=0$  or both being zero.

For real flavors:

A pair of matrices  $(S,T)$  is in generalized real Schur form if  $T$  is upper triangular with non-negative diagonal and  $S$  is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of  $S$  will be "standardized" by making the corresponding elements of  $T$  have the form:

$$\begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}$$

and the pair of corresponding 2-by-2 blocks in  $S$  and  $T$  have a complex conjugate pair of generalized eigenvalues.

For complex flavors:

A pair of matrices  $(S,T)$  is in generalized complex Schur form if  $S$  and  $T$  are upper triangular and, in addition, the diagonal elements of  $T$  are non-negative real numbers.

### Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>jobvsl</code>	= 'N': do not compute the left Schur vectors;
<code>jobvsr</code>	= 'N': do not compute the right Schur vectors; = 'V': compute the right Schur vectors.
<code>sort</code>	Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered; = 'S': Eigenvalues are ordered (see <code>selctg</code> ).
<code>selctg</code>	<code>selctg</code> is a function of three arguments for real flavors or two arguments for complex flavors. <code>selctg</code> must be declared EXTERNAL in the calling subroutine. If <code>sort = 'N'</code> , <code>selctg</code> is not referenced. If <code>sort = 'S'</code> , <code>selctg</code> is used to select eigenvalues to sort to the top left of the Schur form.  For real flavors: An eigenvalue $(\alpha_{\text{real}}[j - 1] + \alpha_{\text{imag}}[j - 1]i)/\beta[j - 1]$ is selected if <code>selctg(alpha_real[j - 1],alpha_imag[j - 1],beta[j - 1])</code> is true. In other words, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy  $selctg(\alpha_{j-1}, \alpha_{i,j-1}, \beta_{j-1}) \neq 0$  after ordering. *info* is to be set to  $n+2$  in this case.

For complex flavors:

An eigenvalue  $\alpha_{j-1}/\beta_{j-1}$  is selected if  $selctg(\alpha_{j-1}, \beta_{j-1})$  is true.

Note that a selected complex eigenvalue may no longer satisfy  $selctg(\alpha_{j-1}, \beta_{j-1}) \neq 0$  after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case *iges3* returns  $n+2$ .

<i>n</i>	The order of the matrices <i>A</i> , <i>B</i> , <i>VSL</i> , and <i>VSR</i> . $n \geq 0$ .
<i>a</i>	Array, size ( $lda*n$ ). On entry, the first of the pair of matrices.
<i>lda</i>	The leading dimension of <i>a</i> . $lda \geq \max(1, n)$ .
<i>b</i>	Array, size ( $ldb*n$ ). On entry, the second of the pair of matrices.
<i>ldb</i>	The leading dimension of <i>b</i> . $ldb \geq \max(1, n)$ .
<i>ldvsl</i>	The leading dimension of the matrix <i>VSL</i> . $ldvsl \geq 1$ , and if <i>jobvsl</i> = 'V', $ldvsl \geq n$ .
<i>ldvsr</i>	The leading dimension of the matrix <i>VSR</i> . $ldvsr \geq 1$ , and if <i>jobvsr</i> = 'V', $ldvsr \geq n$ .

## Output Parameters

<i>a</i>	On exit, <i>a</i> is overwritten by its generalized Schur form <i>S</i> .
<i>b</i>	On exit, <i>b</i> is overwritten by its generalized Schur form <i>T</i> .
<i>sdim</i>	If <i>sort</i> = 'N', <i>sdim</i> = 0. If <i>sort</i> = 'S', <i>sdim</i> = number of eigenvalues (after sorting) for which <i>selctg</i> is true.
<i>alpha</i>	Array, size ( <i>n</i> ).
<i>alphar</i>	Array, size ( <i>n</i> ).
<i>alpha_i</i>	Array, size ( <i>n</i> ).
<i>beta</i>	Array, size ( <i>n</i> ).

For real flavors:

On exit,  $(\alpha_{j-1} + \alpha_{i,j-1}*i)/\beta_{j-1}$ ,  $j=1, \dots, n$ , are the generalized eigenvalues.  $\alpha_{j-1} + \alpha_{i,j-1}*i$ , and  $\beta_{j-1}$ ,  $j=1, \dots, n$  are the diagonals of the complex Schur form (*S*, *T*) that would result if the 2-by-2 diagonal blocks of the real Schur form of (*a*, *b*) were further reduced to triangular form using 2-by-2 complex unitary transformations. If  $\alpha_{i,j-1}$  is zero, then the *j*-th eigenvalue is real; if positive, then the *j*-th and (*j*+1)-st eigenvalues are a complex conjugate pair, with  $\alpha_{i,j}$  negative.

Note: the quotients  $\alpha_{\text{r}}[j - 1]/\beta_{\text{r}}[j - 1]$  and  $\alpha_{\text{i}}[j - 1]/\beta_{\text{i}}[j - 1]$  can easily over- or underflow, and  $\beta_{\text{r}}[j - 1]$  might even be zero. Thus, you should avoid computing the ratio  $\alpha/\beta$  by simply dividing  $\alpha$  by  $\beta$ . However,  $\alpha_{\text{r}}$  and  $\alpha_{\text{i}}$  is always less than and usually comparable with  $\text{norm}(a)$  in magnitude, and  $\beta_{\text{r}}$  is always less than and usually comparable with  $\text{norm}(b)$ .

For complex flavors:

On exit,  $\alpha_{\text{r}}[j - 1][j - 1]/\beta_{\text{r}}[j - 1]$ ,  $j=1, \dots, n$ , are the generalized eigenvalues.  $\alpha_{\text{r}}[j - 1]$ ,  $j=1, \dots, n$  and  $\beta_{\text{r}}[j - 1]$ ,  $j=1, \dots, n$  are the diagonals of the complex Schur form  $(a, b)$  output by ?gges3. The  $\beta_{\text{r}}[j - 1]$  is non-negative real.

Note: the quotient  $\alpha_{\text{r}}[j - 1]/\beta_{\text{r}}[j - 1]$  can easily over- or underflow, and  $\beta_{\text{r}}[j - 1]$  might even be zero. Thus, you should avoid computing the ratio  $\alpha/\beta$  by simply dividing  $\alpha$  by  $\beta$ . However,  $\alpha_{\text{r}}$  is always less than and usually comparable with  $\text{norm}(a)$  in magnitude, and  $\beta_{\text{r}}$  is always less than and usually comparable with  $\text{norm}(b)$ .

*vs1*

Array, size ( $ldvs1 * n$ ).

If  $jobvs1 = 'V'$ , *vs1* contains the left Schur vectors. Not referenced if  $jobvs1 = 'N'$ .

*vsr*

Array, size ( $ldvsr * n$ ).

If  $jobvsr = 'V'$ , *vsr* contains the right Schur vectors. Not referenced if  $jobvsr = 'N'$ .

## Return Values

This function returns a value *info*.

= 0: successful exit < 0: if  $info = -i$ , the  $i$ -th argument had an illegal value.

= 1, ..., n:

for real flavors:

The QZ iteration failed.  $(a, b)$  are not in Schur form, but  $\alpha_{\text{r}}[j]$ ,  $\alpha_{\text{i}}[j]$  and  $\beta_{\text{r}}[j]$  should be correct for  $j=info, \dots, n - 1$ .

The QZ iteration failed.  $(a, b)$  are not in Schur form, but  $\alpha_{\text{r}}[j]$  and  $\beta_{\text{r}}[j]$  should be correct for  $j=info, \dots, n - 1$ .

for complex flavors:

> n:

= n+1: other than QZ iteration failed in ?hgeqz.

= n+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy  $selctg \neq 0$  This could also be caused due to scaling.

= n+3: reordering failed in ?tgsen.

### Description

The ?ggev routine computes the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors for a pair of  $n$ -by- $n$  real/complex nonsymmetric matrices  $(A,B)$ .

A generalized eigenvalue for a pair of matrices  $(A,B)$  is a scalar  $\lambda$  or a ratio  $alpha / beta = \lambda$ , such that  $A - \lambda*B$  is singular. It is usually represented as the pair  $(alpha, beta)$ , as there is a reasonable interpretation for  $beta = 0$  and even for both being zero.

The right generalized eigenvector  $v(j)$  corresponding to the generalized eigenvalue  $\lambda(j)$  of  $(A,B)$  satisfies  $A*v(j) = \lambda(j)*B*v(j)$ .

The left generalized eigenvector  $u(j)$  corresponding to the generalized eigenvalue  $\lambda(j)$  of  $(A,B)$  satisfies  $u(j)^H*A = \lambda(j)*u(j)^H*B$

where  $u(j)^H$  denotes the conjugate transpose of  $u(j)$ .

The ?ggev routine replaces the deprecated ?gegv routine.

### Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>jobvl</i>	Must be 'N' or 'V'. If <i>jobvl</i> = 'N', the left generalized eigenvectors are not computed; If <i>jobvl</i> = 'V', the left generalized eigenvectors are computed.

<i>jobvr</i>	Must be 'N' or 'V'. If <i>jobvr</i> = 'N', the right generalized eigenvectors are not computed; If <i>jobvr</i> = 'V', the right generalized eigenvectors are computed.
<i>n</i>	The order of the matrices <i>A</i> , <i>B</i> , <i>vl</i> , and <i>vr</i> ( $n \geq 0$ ).
<i>a</i> , <i>b</i>	Arrays: <i>a</i> (size at least $\max(1, lda * n)$ ) is an array containing the <i>n</i> -by- <i>n</i> matrix <i>A</i> (first of the pair of matrices). <i>b</i> (size at least $\max(1, ldb * n)$ ) is an array containing the <i>n</i> -by- <i>n</i> matrix <i>B</i> (second of the pair of matrices).
<i>lda</i>	The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$ .
<i>ldb</i>	The leading dimension of the array <i>b</i> . Must be at least $\max(1, n)$ .
<i>ldvl</i> , <i>ldvr</i>	The leading dimensions of the output matrices <i>vl</i> and <i>vr</i> , respectively. Constraints: <i>ldvl</i> $\geq 1$ . If <i>jobvl</i> = 'V', <i>ldvl</i> $\geq \max(1, n)$ . <i>ldvr</i> $\geq 1$ . If <i>jobvr</i> = 'V', <i>ldvr</i> $\geq \max(1, n)$ .

## Output Parameters

<i>a</i> , <i>b</i>	On exit, these arrays have been overwritten.
<i>alphar</i> , <i>alphai</i>	Arrays, size at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors. See <i>beta</i> .
<i>alpha</i>	Array, size at least $\max(1, n)$ . Contain values that form generalized eigenvalues in complex flavors. See <i>beta</i> .
<i>beta</i>	Array, size at least $\max(1, n)$ . <i>For real flavors:</i> On exit, $(\text{alphar}[j] + \text{alphai}[j]*i)/\text{beta}[j]$ , $j=0, \dots, n - 1$ , are the generalized eigenvalues. If <i>alphai</i> [ <i>j</i> ] is zero, then the <i>j</i> -th eigenvalue is real; if positive, then the <i>j</i> -th and ( <i>j</i> +1)-st eigenvalues are a complex conjugate pair, with <i>alphai</i> [ <i>j</i> +1] negative. <i>For complex flavors:</i> On exit, $\text{alpha}[j]/\text{beta}[j]$ , $j=0, \dots, n - 1$ , are the generalized eigenvalues. See also <i>Application Notes</i> below.
<i>vl</i> , <i>vr</i>	Arrays: <i>vl</i> (size at least $\max(1, ldvl * n)$ ). Contains the matrix of left generalized eigenvectors <i>VL</i> .

If  $jobvl = 'V'$ , the left generalized eigenvectors  $u_j$  are stored one after another in the columns of  $VL$ , in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has  $abs(Re) + abs(Im) = 1$ .

If  $jobvl = 'N'$ ,  $vl$  is not referenced.

*For real flavors:*

If the  $j$ -th eigenvalue is real, then the  $k$ -th component of the  $j$ -th left eigenvector  $u_j$  is stored in  $vl[(k - 1) + (j - 1)*ldvl]$  for column major layout and in  $vl[(k - 1)*ldvl + (j - 1)]$  for row major layout..

If the  $j$ -th and  $(j+1)$ -st eigenvalues form a complex conjugate pair, then for  $i = \sqrt{-1}$ , the  $k$ -th components of the  $j$ -th left eigenvector  $u_j$  are  $vl[(k - 1) + (j - 1)*ldvl] + i*vl[(k - 1) + j*ldvl]$  for column major layout and  $vl[(k - 1)*ldvl + (j - 1)] + i*vl[(k - 1)*ldvl + j]$  for row major layout. Similarly, the  $k$ -th components of left eigenvector  $j+1$   $u_{j+1}$  are  $vl[(k - 1) + (j - 1)*ldvl] - i*vl[(k - 1) + j*ldvl]$  for column major layout and  $vl[(k - 1)*ldvl + (j - 1)] - i*vl[(k - 1)*ldvl + j]$  for row major layout..

*For complex flavors:*

The  $k$ -th component of the  $j$ -th left eigenvector  $u_j$  is stored in  $vl[(k - 1) + (j - 1)*ldvl]$  for column major layout and in  $vl[(k - 1)*ldvl + (j - 1)]$  for row major layout.

$vr$  (size at least  $\max(1, ldvr*n)$ ). Contains the matrix of right generalized eigenvectors  $VR$ .

If  $jobvvr = 'V'$ , the right generalized eigenvectors  $v_j$  are stored one after another in the columns of  $VR$ , in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has  $abs(Re) + abs(Im) = 1$ .

If  $jobvvr = 'N'$ ,  $vr$  is not referenced.

*For real flavors:*

If the  $j$ -th eigenvalue is real, then The  $k$ -th component of the  $j$ -th right eigenvector  $v_j$  is stored in  $vr[(k - 1) + (j - 1)*ldvr]$  for column major layout and in  $vr[(k - 1)*ldvr + (j - 1)]$  for row major layout..

If the  $j$ -th and  $(j+1)$ -st eigenvalues form a complex conjugate pair, then the  $k$ -th components of the  $j$ -th right eigenvector  $v_j$  can be computed as  $vr[(k - 1) + (j - 1)*ldvr] + i*vr[(k - 1) + j*ldvr]$  for column major layout and  $vr[(k - 1)*ldvr + (j - 1)] + i*vr[(k - 1)*ldvr + j]$  for row major layout. Similarly, the  $k$ -th components of the right eigenvector  $j+1$   $v_{j+1}$  can be computed as  $vr[(k - 1) + (j - 1)*ldvr] - i*vr[(k - 1) + j*ldvr]$  for column major layout and  $vr[(k - 1)*ldvr + (j - 1)] - i*vr[(k - 1)*ldvr + j]$  for row major layout..

*For complex flavors:*

The  $k$ -th component of the  $j$ -th right eigenvector  $v_j$  is stored in  $vr[(k - 1) + (j - 1)*ldvr]$  for column major layout and in  $vr[(k - 1)*ldvr + (j - 1)]$  for row major layout.

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, and

$i \leq n$ : the QZ iteration failed. No eigenvectors have been calculated, but *alphar*[*j*], *alphai*[*j*] (for real flavors), or *alpha*[*j*] (for complex flavors), and *beta*[*j*],  $j = info, \dots, n - 1$  should be correct.

$i > n$ : errors that usually indicate LAPACK problems:

$i = n+1$ : other than QZ iteration failed in [hgeqz](#);

$i = n+2$ : error return from [tgevc](#).

## Application Notes

The quotients *alphar*[*j*]/*beta*[*j*] and *alphai*[*j*]/*beta*[*j*] may easily over- or underflow, and *beta*[*j*] may even be zero. Thus, you should avoid simply computing the ratio. However, *alphar* and *alphai* (for real flavors) or *alpha* (for complex flavors) will be always less than and usually comparable with norm(*A*) in magnitude, and *beta* always less than and usually comparable with norm(*B*).

### ?ggev

*Computes the generalized eigenvalues, and, optionally, the left and/or right generalized eigenvectors.*

## Description

The routine computes for a pair of  $n$ -by- $n$  real/complex nonsymmetric matrices  $(A,B)$ , the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (*ilo*, *ihi*, *lscale*, *rscale*, *abnrm*, and *bbnrm*), reciprocal condition numbers for the eigenvalues (*rconde*), and reciprocal condition numbers for the right eigenvectors (*rcondv*).

A generalized eigenvalue for a pair of matrices  $(A,B)$  is a scalar  $\lambda$  or a ratio  $alpha / beta = \lambda$ , such that  $A - \lambda*B$  is singular. It is usually represented as the pair  $(alpha, beta)$ , as there is a reasonable interpretation for  $beta=0$  and even for both being zero. The right generalized eigenvector  $v(j)$  corresponding to the generalized eigenvalue  $\lambda(j)$  of  $(A,B)$  satisfies

$$A*v(j) = \lambda(j)*B*v(j).$$

The left generalized eigenvector  $u(j)$  corresponding to the generalized eigenvalue  $\lambda(j)$  of  $(A,B)$  satisfies

$$u(j)^H*A = \lambda(j)*u(j)^H*B$$

where  $u(j)^H$  denotes the conjugate transpose of  $u(j)$ .

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>balanc</i>	<p>Must be 'N', 'P', 'S', or 'B'. Specifies the balance option to be performed.</p> <p>If <i>balanc</i> = 'N', do not diagonally scale or permute;</p> <p>If <i>balanc</i> = 'P', permute only;</p> <p>If <i>balanc</i> = 'S', scale only;</p> <p>If <i>balanc</i> = 'B', both permute and scale.</p> <p>Computed reciprocal condition numbers will be for the matrices after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.</p>
<i>jobvl</i>	<p>Must be 'N' or 'V'.</p> <p>If <i>jobvl</i> = 'N', the left generalized eigenvectors are not computed;</p> <p>If <i>jobvl</i> = 'V', the left generalized eigenvectors are computed.</p>
<i>jobvr</i>	<p>Must be 'N' or 'V'.</p> <p>If <i>jobvr</i> = 'N', the right generalized eigenvectors are not computed;</p> <p>If <i>jobvr</i> = 'V', the right generalized eigenvectors are computed.</p>
<i>sense</i>	<p>Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.</p> <p>If <i>sense</i> = 'N', none are computed;</p>

	If <i>sense</i> = 'E', computed for eigenvalues only;
	If <i>sense</i> = 'V', computed for eigenvectors only;
	If <i>sense</i> = 'B', computed for eigenvalues and eigenvectors.
<i>n</i>	The order of the matrices <i>A</i> , <i>B</i> , <i>vl</i> , and <i>vr</i> ( $n \geq 0$ ).
<i>a</i> , <i>b</i>	Arrays: <i>a</i> (size at least $\max(1, lda * n)$ ) is an array containing the <i>n</i> -by- <i>n</i> matrix <i>A</i> (first of the pair of matrices). <i>b</i> (size at least $\max(1, ldb * n)$ ) is an array containing the <i>n</i> -by- <i>n</i> matrix <i>B</i> (second of the pair of matrices).
<i>lda</i>	The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$ .
<i>ldb</i>	The leading dimension of the array <i>b</i> . Must be at least $\max(1, n)$ .
<i>ldvl</i> , <i>ldvr</i>	The leading dimensions of the output matrices <i>vl</i> and <i>vr</i> , respectively. Constraints: <i>ldvl</i> $\geq 1$ . If <i>jobvl</i> = 'V', <i>ldvl</i> $\geq \max(1, n)$ . <i>ldvr</i> $\geq 1$ . If <i>jobvr</i> = 'V', <i>ldvr</i> $\geq \max(1, n)$ .

## Output Parameters

<i>a</i> , <i>b</i>	On exit, these arrays have been overwritten. If <i>jobvl</i> = 'V' or <i>jobvr</i> = 'V' or both, then <i>a</i> contains the first part of the real Schur form of the "balanced" versions of the input <i>A</i> and <i>B</i> , and <i>b</i> contains its second part.
<i>alphan</i> , <i>alphai</i>	Arrays, size at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors. See <i>beta</i> .
<i>alpha</i>	Array, size at least $\max(1, n)$ . Contain values that form generalized eigenvalues in complex flavors. See <i>beta</i> .
<i>beta</i>	Array, size at least $\max(1, n)$ . <i>For real flavors:</i> On exit, $(alphan[j] + alphai[j]*i)/beta[j]$ , $j=0, \dots, n - 1$ , will be the generalized eigenvalues. If <i>alphai</i> [ <i>j</i> ] is zero, then the <i>j</i> -th eigenvalue is real; if positive, then the <i>j</i> -th and ( <i>j</i> +1)-st eigenvalues are a complex conjugate pair, with <i>alphai</i> [ <i>j</i> +1] negative. <i>For complex flavors:</i> On exit, <i>alpha</i> [ <i>j</i> ]/ <i>beta</i> [ <i>j</i> ], $j=0, \dots, n - 1$ , will be the generalized eigenvalues. See also <i>Application Notes</i> below.
<i>vl</i> , <i>vr</i>	Arrays:

$vl$  (size at least  $\max(1, ldvl*n)$ ).

If  $jobvl = 'V'$ , the left generalized eigenvectors  $u(j)$  are stored one after another in the columns of  $vl$ , in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component have  $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$ .

If  $jobvl = 'N'$ ,  $vl$  is not referenced.

*For real flavors:*

If the  $j$ -th eigenvalue is real, then  $k$ -th component of  $j$ -th left eigenvector  $u_j$  is stored in  $vl[(k - 1) + (j - 1)*ldvl]$  for column major layout and in  $vl[(k - 1)*ldvl + (j - 1)]$  for row major layout..

If the  $j$ -th and  $(j+1)$ -st eigenvalues form a complex conjugate pair, then for  $i = \text{sqrt}(-1)$ , the  $k$ -th components of the  $j$ -th left eigenvector  $u_j$  can be computed as  $vl[(k - 1) + (j - 1)*ldvl] + i*vl[(k - 1) + j*ldvl]$  for column major layout and  $vl[(k - 1)*ldvl + (j - 1)] + i*vl[(k - 1)*ldvl + j]$  for row major layout. Similarly, the  $k$ -th components of the left eigenvector  $j+1$   $u_{j+1}$  can be computed as  $vl[(k - 1) + (j - 1)*ldvl] - i*vl[(k - 1) + j*ldvl]$  for column major layout and  $vl[(k - 1)*ldvl + (j - 1)] - i*vl[(k - 1)*ldvl + j]$  for row major layout..

*For complex flavors:*

The  $k$ -th component of the  $j$ -th left eigenvector  $u_j$  is stored in  $vl[(k - 1) + (j - 1)*ldvl]$  for column major layout and in  $vl[(k - 1)*ldvl + (j - 1)]$  for row major layout.

$vr$  (size at least  $\max(1, ldvr*n)$ ).

If  $jobvr = 'V'$ , the right generalized eigenvectors  $v(j)$  are stored one after another in the columns of  $vr$ , in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component have  $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$ .

If  $jobvr = 'N'$ ,  $vr$  is not referenced.

*For real flavors:*

If the  $j$ -th eigenvalue is real, then the  $k$ -th component of the  $j$ -th right eigenvector  $v_j$  is stored in  $vr[(k - 1) + (j - 1)*ldvr]$  for column major layout and in  $vr[(k - 1)*ldvr + (j - 1)]$  for row major layout..

If the  $j$ -th and  $(j+1)$ -st eigenvalues form a complex conjugate pair, then The  $k$ -th components of the  $j$ -th right eigenvector  $v_j$  can be computed as  $vr[(k - 1) + (j - 1)*ldvr] + i*vr[(k - 1) + j*ldvr]$  for column major layout and  $vr[(k - 1)*ldvr + (j - 1)] + i*vr[(k - 1)*ldvr + j]$  for row major layout. Respectively, the  $k$ -th components of right eigenvector  $j+1$   $v_{j+1}$  can be computed as  $vr[(k - 1) + (j - 1)*ldvr] - i*vr[(k - 1) + j*ldvr]$  for column major layout and  $vr[(k - 1)*ldvr + (j - 1)] - i*vr[(k - 1)*ldvr + j]$  for row major layout..

*For complex flavors:*

The  $k$ -th component of the  $j$ -th right eigenvector  $v_j$  is stored in  $vr[(k - 1) + (j - 1)*ldvr]$  for column major layout and in  $vr[(k - 1)*ldvr + (j - 1)]$  for row major layout.

<i>ilo, ihi</i>	<p><i>ilo</i> and <i>ihi</i> are integer values such that on exit <math>A_{i\ j} = 0</math> and <math>B_{i\ j} = 0</math> if <math>i &gt; j</math> and <math>j = 1, \dots, ilo-1</math> or <math>i = ihi+1, \dots, n</math>.</p> <p>If <i>balanc</i> = 'N' or 'S', <i>ilo</i> = 1 and <i>ihi</i> = <i>n</i>.</p>
<i>lscale, rscale</i>	<p>Arrays, size at least <math>\max(1, n)</math> each.</p> <p><i>lscale</i> contains details of the permutations and scaling factors applied to the left side of <i>A</i> and <i>B</i>.</p> <p>If <math>PL(j)</math> is the index of the row interchanged with row <i>j</i>, and <math>DL(j)</math> is the scaling factor applied to row <i>j</i>, then</p> <p><math>lscale[j - 1] = PL(j)</math>, for <math>j = 1, \dots, ilo-1</math>  <math>= DL(j)</math>, for <math>j = ilo, \dots, ihi</math>  <math>= PL(j)</math> for <math>j = ihi+1, \dots, n</math>.</p> <p>The order in which the interchanges are made is <i>n</i> to <i>ihi+1</i>, then 1 to <i>ilo-1</i>.</p> <p><i>rscale</i> contains details of the permutations and scaling factors applied to the right side of <i>A</i> and <i>B</i>.</p> <p>If <math>PR(j)</math> is the index of the column interchanged with column <i>j</i>, and <math>DR(j)</math> is the scaling factor applied to column <i>j</i>, then</p> <p><math>rscale[j - 1] = PR(j)</math>, for <math>j = 1, \dots, ilo-1</math>  <math>= DR(j)</math>, for <math>j = ilo, \dots, ihi</math>  <math>= PR(j)</math> for <math>j = ihi+1, \dots, n</math>.</p> <p>The order in which the interchanges are made is <i>n</i> to <i>ihi+1</i>, then 1 to <i>ilo-1</i>.</p>
<i>abnrm, bbnrm</i>	<p>The one-norms of the balanced matrices <i>A</i> and <i>B</i>, respectively.</p>
<i>rconde, rcondv</i>	<p>Arrays, size at least <math>\max(1, n)</math> each.</p> <p>If <i>sense</i> = 'E', or 'B', <i>rconde</i> contains the reciprocal condition numbers of the eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of <i>rconde</i> are set to the same value. Thus <i>rconde</i>[<i>j</i>], <i>rcondv</i>[<i>j</i>], and the <i>j</i>-th columns of <i>vl</i> and <i>vr</i> all correspond to the same eigenpair (but not in general the <i>j</i>-th eigenpair, unless all eigenpairs are selected).</p> <p>If <i>sense</i> = 'N', or 'V', <i>rconde</i> is not referenced.</p> <p>If <i>sense</i> = 'V', or 'B', <i>rcondv</i> contains the estimated reciprocal condition numbers of the eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of <i>rcondv</i> are set to the same value.</p> <p>If the eigenvalues cannot be reordered to compute , <i>rcondv</i>[<i>j</i>] is set to 0; this can only occur when the true value would be very small anyway.</p> <p>If <i>sense</i> = 'N', or 'E', <i>rcondv</i> is not referenced.</p>

## Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = *-i*, the *i*-th parameter had an illegal value.

If  $info = i$ , and

$i \leq n$ : the QZ iteration failed. No eigenvectors have been calculated, but  $alphar[j]$ ,  $alphai[j]$  (for real flavors), or  $alpha[j]$  (for complex flavors), and  $beta[j]$ ,  $j=info, \dots, n - 1$  should be correct.

$i > n$ : errors that usually indicate LAPACK problems:

$i = n+1$ : other than QZ iteration failed in [hgeqz](#);

$i = n+2$ : error return from [tgevc](#).

## Application Notes

The quotients  $alphar[j]/beta[j]$  and  $alphai[j]/beta[j]$  may easily over- or underflow, and  $beta[j]$  may even be zero. Thus, you should avoid simply computing the ratio. However,  $alphar$  and  $alphai$  (for real flavors) or  $alpha$  (for complex flavors) will be always less than and usually comparable with  $\text{norm}(A)$  in magnitude, and  $beta$  always less than and usually comparable with  $\text{norm}(B)$ .

### ?ggev3

*Computes the generalized eigenvalues and the left and right generalized eigenvectors for a pair of matrices.*

## Description

For a pair of  $n$ -by- $n$  real or complex nonsymmetric matrices  $(A, B)$ , `?ggeev3` computes the generalized eigenvalues, and optionally, the left and right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices  $(A, B)$  is a scalar  $\lambda$  or a ratio  $alpha/beta = \lambda$ , such that  $A - \lambda*B$  is singular. It is usually represented as the pair  $(alpha, beta)$ , as there is a reasonable interpretation for  $beta=0$ , and even for both being zero.

For real flavors:

The right eigenvector  $v_j$  corresponding to the eigenvalue  $\lambda_j$  of  $(A, B)$  satisfies

$$A * v_j = \lambda_j * B * v_j.$$

The left eigenvector  $u_j$  corresponding to the eigenvalue  $\lambda_j$  of  $(A, B)$  satisfies

$$u_j^H * A = \lambda_j * u_j^H * B$$

where  $u_j^H$  is the conjugate-transpose of  $u_j$ .

For complex flavors:

The right generalized eigenvector  $v_j$  corresponding to the generalized eigenvalue  $\lambda_j$  of  $(A, B)$  satisfies

$$A * v_j = \lambda_j * B * v_j.$$

The left generalized eigenvector  $u_j$  corresponding to the generalized eigenvalues  $\lambda_j$  of  $(A, B)$  satisfies

$$u_j^H * A = \lambda_j * u_j^H * B$$

where  $u_j^H$  is the conjugate-transpose of  $u_j$ .

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>jobvl</i>	= 'N': do not compute the left generalized eigenvectors; = 'V': compute the left generalized eigenvectors.
<i>jobvr</i>	= 'N': do not compute the right generalized eigenvectors; = 'V': compute the right generalized eigenvectors.
<i>n</i>	The order of the matrices <i>A</i> , <i>B</i> , <i>VL</i> , and <i>VR</i> . $n \geq 0$ .
<i>a</i>	Array, size ( $lda * n$ ). On entry, the matrix <i>A</i> in the pair $(A, B)$ .
<i>lda</i>	The leading dimension of <i>a</i> . $lda \geq \max(1, n)$ .
<i>b</i>	Array, size ( $ldb * n$ ). On entry, the matrix <i>B</i> in the pair $(A, B)$ .
<i>ldb</i>	The leading dimension of <i>b</i> . $ldb \geq \max(1, n)$ .
<i>ldvl</i>	The leading dimension of the matrix <i>VL</i> . $ldvl \geq 1$ , and if <i>jobvl</i> = 'V', $ldvl \geq n$ .
<i>ldvr</i>	The leading dimension of the matrix <i>VR</i> . $ldvr \geq 1$ , and if <i>jobvr</i> = 'V', $ldvr \geq n$ .

## Output Parameters

<i>a</i>	On exit, <i>a</i> is overwritten.
<i>b</i>	On exit, <i>b</i> is overwritten.
<i>alphar</i>	Array, size ( <i>n</i> ).
<i>alphai</i>	Array, size ( <i>n</i> ).

<i>alpha</i>	Array, size ( <i>n</i> ).
<i>beta</i>	<p>Array, size (<i>n</i>).</p> <p>For real flavors:</p> <p>On exit, <math>(\text{alphar}[j] + \text{alphai}[j]*i)/\text{beta}[j]</math>, <math>j=0,\dots,n-1</math>, are the generalized eigenvalues. If <math>\text{alphai}[j-1]</math> is zero, then the <math>j</math>-th eigenvalue is real; if positive, then the <math>j</math>-th and <math>(j+1)</math>-st eigenvalues are a complex conjugate pair, with <math>\text{alphai}[j]</math> negative.</p> <p>Note: the quotients <math>\text{alphar}[j-1]/\text{beta}[j-1]</math> and <math>\text{alphai}[j-1]/\text{beta}[j-1]</math> can easily over- or underflow, and <math>\text{beta}(j)</math> might even be zero. Thus, you should avoid computing the ratio <math>\text{alpha}/\text{beta}</math> by simply dividing <math>\text{alpha}</math> by <math>\text{beta}</math>. However, <math>\text{alphar}</math> and <math>\text{alphai}</math> are always less than and usually comparable with <math>\text{norm}(A)</math> in magnitude, and <math>\text{beta}</math> is always less than and usually comparable with <math>\text{norm}(B)</math>.</p> <p>For complex flavors:</p> <p>On exit, <math>\text{alpha}[j]/\text{beta}[j]</math>, <math>j=0,\dots,n-1</math>, are the generalized eigenvalues.</p> <p>Note: the quotients <math>\text{alpha}[j-1]/\text{beta}[j-1]</math> may easily over- or underflow, and <math>\text{beta}(j)</math> can even be zero. Thus, you should avoid computing the ratio <math>\text{alpha}/\text{beta}</math> by simply dividing <math>\text{alpha}</math> by <math>\text{beta}</math>. However, <math>\text{alpha}</math> is always less than and usually comparable with <math>\text{norm}(A)</math> in magnitude, and <math>\text{beta}</math> is always less than and usually comparable with <math>\text{norm}(B)</math>.</p>
<i>v1</i>	<p>Array, size (<math>\text{ldv1}*n</math>).</p> <p>For real flavors:</p> <p>If <math>\text{jobv1} = 'V'</math>, the left eigenvectors <math>u_j</math> are stored one after another in the columns of <i>v1</i>, in the same order as their eigenvalues. If the <math>j</math>-th eigenvalue is real, then <math>u_j</math> = the <math>j</math>-th column of <i>v1</i>. If the <math>j</math>-th and <math>(j+1)</math>-st eigenvalues form a complex conjugate pair, then the real part of <math>u_j</math> = the <math>j</math>-th column of <i>v1</i> and the imaginary part of <math>v_j</math> = the <math>(j+1)</math>-st column of <i>v1</i>.</p> <p>Each eigenvector is scaled so the largest component has <math>\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1</math>.</p> <p>Not referenced if <math>\text{jobv1} = 'N'</math>.</p> <p>For complex flavors:</p> <p>If <math>\text{jobv1} = 'V'</math>, the left generalized eigenvectors <math>u_j</math> are stored one after another in the columns of <i>v1</i>, in the same order as their eigenvalues.</p> <p>Each eigenvector is scaled so the largest component has <math>\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1</math>.</p> <p>Not referenced if <math>\text{jobv1} = 'N'</math>.</p>
<i>vr</i>	<p>Array, size (<math>\text{ldvr}*n</math>).</p> <p>For real flavors:</p>

If  $jobvr = 'V'$ , the right eigenvectors  $v_j$  are stored one after another in the columns of  $vr$ , in the same order as their eigenvalues. If the  $j$ -th eigenvalue is real, then  $v_j =$  the  $j$ -th column of  $vr$ . If the  $j$ -th and  $(j + 1)$ -st eigenvalues form a complex conjugate pair, then the real part of  $v_j =$  the  $j$ -th column of  $vr$  and the imaginary part of  $v_j =$  the  $(j + 1)$ -st column of  $vr$ .

Each eigenvector is scaled so the largest component has  $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$ .

Not referenced if  $jobvr = 'N'$ .

For complex flavors:

If  $jobvr = 'V'$ , the right generalized eigenvectors  $v_j$  are stored one after another in the columns of  $vr$ , in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has  $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$ .

Not referenced if  $jobvr = 'N'$ .

## Return Values

This function returns a value *info*.

= 0: successful exit

< 0: if  $info = -i$ , the  $i$ -th argument had an illegal value.

= 1, ...,  $n$ :

for real flavors:

The QZ iteration failed. No eigenvectors have been calculated, but  $alpha[j]$ ,  $alpha[j]$  and  $beta[j]$  should be correct for  $j = info, \dots, n - 1$ .

for complex flavors:

The QZ iteration failed. No eigenvectors have been calculated, but  $alpha[j]$  and  $beta[j]$  should be correct for  $j = info, \dots, n - 1$ .

>  $n$ :

=  $n + 1$ : other than QZ iteration failed in `?hgeqz`,

=  $n + 2$ : error return from `?tgevc`.

## LAPACK Auxiliary Routines

Routine naming conventions, mathematical notation, and matrix storage schemes used for LAPACK auxiliary routines are the same as for the driver and computational routines described in previous chapters.

### ?lacgv

Conjugates a complex vector.

### Syntax

```
lapack_int LAPACKE_clacgv (lapack_int n, lapack_complex_float* x, lapack_int incx);
```

```
lapack_int LAPACKE_zlacgv (lapack_int n, lapack_complex_double* x, lapack_int incx);
```

## Include Files

- mkl.h

## Description

The routine conjugates a complex vector  $x$  of length  $n$  and increment  $incx$  (see "Vector Arguments in BLAS" in Appendix B).

## Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

$n$	The length of the vector $x$ ( $n \geq 0$ ).
$x$	Array, dimension $(1+(n-1)* incx )$ . Contains the vector of length $n$ to be conjugated.
$incx$	The spacing between successive elements of $x$ .

## Output Parameters

$x$	On exit, overwritten with <code>conjg(x)</code> .
-----	---

## ?lacrm

Multiplies a complex matrix by a square real matrix.

## Syntax

```
call clacrm( m, n, a, lda, b, ldb, c, ldc, rwork )
call zlacrm( m, n, a, lda, b, ldb, c, ldc, rwork )
```

## Include Files

- mkl.h

## Description

The routine performs a simple matrix-matrix multiplication of the form

$$C = A*B,$$

where  $A$  is  $m$ -by- $n$  and complex,  $B$  is  $n$ -by- $n$  and real,  $C$  is  $m$ -by- $n$  and complex.

## Input Parameters

$m$	INTEGER. The number of rows of the matrix $A$ and of the matrix $C$ ( $m \geq 0$ ).
$n$	INTEGER. The number of columns and rows of the matrix $B$ and the number of columns of the matrix $C$ ( $n \geq 0$ ).
$a$	COMPLEX for <code>clacrm</code> DOUBLE COMPLEX for <code>zlacrm</code>

	Array, DIMENSION( $lda, n$ ). Contains the $m$ -by- $n$ matrix $A$ .
$lda$	INTEGER. The leading dimension of the array $a$ , $lda \geq \max(1, m)$ .
$b$	REAL for <code>clacrm</code> DOUBLE PRECISION for <code>zlacrm</code>
	Array, DIMENSION( $ldb, n$ ). Contains the $n$ -by- $n$ matrix $B$ .
$ldb$	INTEGER. The leading dimension of the array $b$ , $ldb \geq \max(1, n)$ .
$ldc$	INTEGER. The leading dimension of the output array $c$ , $ldc \geq \max(1, n)$ .
$rwork$	REAL for <code>clacrm</code> DOUBLE PRECISION for <code>zlacrm</code> Workspace array, DIMENSION( $2*m*n$ ).

## Output Parameters

$c$	COMPLEX for <code>clacrm</code> DOUBLE COMPLEX for <code>zlacrm</code> Array, DIMENSION ( $ldc, n$ ). Contains the $m$ -by- $n$ matrix $C$ .
-----	--

## ?ssyconv

*Converts a symmetric matrix given by a triangular matrix factorization into two matrices and vice versa.*

### Syntax

```
lapack_int LAPACKE_ssyconv (int matrix_layout, char uplo, char way, lapack_int n, float * a, lapack_int lda, const lapack_int * ipiv, float * e);
```

```
lapack_int LAPACKE_dsyconv (int matrix_layout, char uplo, char way, lapack_int n, double* a, lapack_int lda, const lapack_int * ipiv, double * e);
```

```
lapack_int LAPACKE_csyconv (int matrix_layout, char uplo, char way, lapack_int n, lapack_complex_float * a, lapack_int lda, const lapack_int * ipiv, lapack_complex_float * e);
```

```
lapack_int LAPACKE_zsyconv (int matrix_layout, char uplo, char way, lapack_int n, lapack_complex_double* a, lapack_int lda, const lapack_int * ipiv, lapack_complex_double * e);
```

### Include Files

- `mkl.h`

### Description

The routine converts matrix  $A$ , which results from a triangular matrix factorization, into matrices  $L$  and  $D$  and vice versa. The routine returns non-diagonalized elements of  $D$  and applies or reverses permutation done with the triangular matrix factorization.

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>uplo</code>	Must be 'U' or 'L'.  Indicates whether the details of the factorization are stored as an upper or lower triangular matrix:  If <code>uplo = 'U'</code> : the upper triangular, $A = U*D*U^T$ .  If <code>uplo = 'L'</code> : the lower triangular, $A = L*D*L^T$ .
<code>way</code>	Must be 'C' or 'R'.
<code>n</code>	The order of matrix $A$ ; $n \geq 0$ .
<code>a</code>	Array of size $\max(1, lda * n)$ .  The block diagonal matrix $D$ and the multipliers used to obtain the factor $U$ or $L$ as computed by <code>?sytrf</code> .
<code>lda</code>	The leading dimension of $a$ ; $lda \geq \max(1, n)$ .
<code>ipiv</code>	Array, size at least $\max(1, n)$ .  Details of the interchanges and the block structure of $D$ , as returned by <code>?sytrf</code> .

## Output Parameters

<code>e</code>	Array of size $\max(1, n)$ containing the superdiagonal/subdiagonal of the symmetric 1-by-1 or 2-by-2 block diagonal matrix $D$ in $L*D*L^T$ .
----------------	--

## Return Values

<code>info</code>	If <code>info = 0</code> , the execution is successful.  If <code>info &lt; 0</code> , the $i$ -th parameter had an illegal value.  If <code>info = -1011</code> , memory allocation error occurred.
-------------------	--

## See Also

[?sytrf](#)

## ?syr

*Performs the symmetric rank-1 update of a complex symmetric matrix.*

## Syntax

```
lapack_int LAPACKE_csyr (int matrix_layout, char uplo, lapack_int n,
lapack_complex_float alpha, const lapack_complex_float * x, lapack_int incx,
lapack_complex_float * a, lapack_int lda);
```

```
lapack_int LAPACKE_zsyr (int matrix_layout, char uplo, lapack_int n,
lapack_complex_double alpha, const lapack_complex_double * x, lapack_int incx,
lapack_complex_double * a, lapack_int lda);
```

## Include Files

- `mkl.h`

## Description

The routine performs the symmetric rank 1 operation defined as

$$a := \alpha * x * x^H + a,$$

where:

- $\alpha$  is a complex scalar.
- $x$  is an  $n$ -element complex vector.
- $a$  is an  $n$ -by- $n$  complex symmetric matrix.

These routines have their real equivalents in BLAS (see [?syr](#) in Chapter "BLAS and Sparse BLAS Routines").

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>uplo</code>	Specifies whether the upper or lower triangular part of the array $a$ is used: If <code>uplo = 'U'</code> or <code>'u'</code> , then the upper triangular part of the array $a$ is used. If <code>uplo = 'L'</code> or <code>'l'</code> , then the lower triangular part of the array $a$ is used.
<code>n</code>	Specifies the order of the matrix $a$ . The value of $n$ must be at least zero.
<code>alpha</code>	Specifies the scalar $\alpha$ .
<code>x</code>	Array, size at least $(1 + (n - 1) * \text{abs}(\text{incx}))$ . Before entry, the incremented array $x$ must contain the $n$ -element vector $x$ .
<code>incx</code>	Specifies the increment for the elements of $x$ . The value of <code>incx</code> must not be zero.
<code>a</code>	Array, size $\max(1, \text{lda} * n)$ . Before entry with <code>uplo = 'U'</code> or <code>'u'</code> , the leading $n$ -by- $n$ upper triangular part of the array $a$ must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of $a$ is not referenced. Before entry with <code>uplo = 'L'</code> or <code>'l'</code> , the leading $n$ -by- $n$ lower triangular part of the array $a$ must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of $a$ is not referenced.
<code>lda</code>	Specifies the leading dimension of $a$ as declared in the calling (sub)program. The value of <code>lda</code> must be at least $\max(1, n)$ .

## Output Parameters

<code>a</code>	With <code>uplo = 'U'</code> or <code>'u'</code> , the upper triangular part of the array $a$ is overwritten by the upper triangular part of the updated matrix. With <code>uplo = 'L'</code> or <code>'l'</code> , the lower triangular part of the array $a$ is overwritten by the lower triangular part of the updated matrix.
----------------	--

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

## *i?*max1

*Finds the index of the vector element whose real part has maximum absolute value.*

---

## Syntax

```
MKL_INT icmax1(const MKL_INT*n, const MKL_Complex8*cx, const MKL_INT*incx)
```

```
MKL_INT izmax1(const MKL_INT*n, const MKL_Complex16*cx, const MKL_INT*incx)
```

## Include Files

- mkl.h

## Description

Given a complex vector *cx*, the *i?*max1 functions return the index of the first vector element of maximum absolute value. These functions are based on the BLAS functions *icamax/izamax*, but using the absolute value of components. They are designed for use with *clacon/zlacon*.

## Input Parameters

<i>n</i>	Specifies the number of elements in the vector <i>cx</i> .
<i>cx</i>	Array, size at least $(1 + (n-1) * \text{abs}(incx))$ . Contains the input vector.
<i>incx</i>	Specifies the spacing between successive elements of <i>cx</i> .

## Return Values

Index of the vector element of maximum absolute value.

## ?sum1

*Forms the 1-norm of the complex vector using the true absolute value.*

---

## Syntax

```
float scsum1(const MKL_INT*n, const MKL_Complex8*cx, const MKL_INT*incx)
```

```
double dzsum1(const MKL_INT*n, const MKL_Complex16*cx, const MKL_INT*incx)
```

## Include Files

- mkl.h

## Description

Given a complex vector  $cx$ , `scsum1/dzsum1` functions take the sum of the absolute values of vector elements and return a single/double precision result, respectively. These functions are based on `scasum/dzasum` from Level 1 BLAS, but use the true absolute value and were designed for use with `clacon/zlacon`.

## Input Parameters

$n$	Specifies the number of elements in the vector $cx$ .
$cx$	Array, size at least $(1+(n-1)*abs(incx))$ . Contains the input vector whose elements will be summed.
$incx$	Specifies the spacing between successive elements of $cx$ ( $incx > 0$ ).

## Return Values

Sum of absolute values.

## ?gelq2

*Computes the LQ factorization of a general rectangular matrix using an unblocked algorithm.*

## Syntax

```
lapack_int LAPACKE_sgelq2 (int matrix_layout, lapack_int m, lapack_int n, float* a,
lapack_int lda, float* tau);

lapack_int LAPACKE_dgelq2 (int matrix_layout, lapack_int m, lapack_int n, double* a,
lapack_int lda, double * tau);

lapack_int LAPACKE_cgelq2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* tau);

lapack_int LAPACKE_zgelq2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_complex_double* tau);
```

## Include Files

- mkl.h

## Description

The routine computes an LQ factorization of a real/complex  $m$ -by- $n$  matrix  $A$  as  $A = L*Q$ .

The routine does not form the matrix  $Q$  explicitly. Instead,  $Q$  is represented as a product of  $\min(m, n)$  elementary reflectors :

$Q = H(k) \dots H(2) H(1)$  (or  $Q = H(k)^H \dots H(2)^H H(1)^H$  for complex flavors), where  $k = \min(m, n)$

Each  $H(i)$  has the form

$H(i) = I - \tau*v*v^T$  for real flavors, or

$H(i) = I - \tau*v*v^H$  for complex flavors,

where  $\tau$  is a real/complex scalar stored in  $\tau(i)$ , and  $v$  is a real/complex vector with  $v_{1:i-1} = 0$  and  $v_i = 1$ .

On exit, the  $j$ -th ( $i+1 \leq j \leq n$ ) component of vector  $v$  (for real functions) or its conjugate (for complex functions) is stored in  $a[i - 1 + lda*(j - 1)]$  for column major layout or in  $a[j - 1 + lda*(i - 1)]$  for row major layout.

## Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<code>m</code>	The number of rows in the matrix $A$ ( $m \geq 0$ ).
<code>n</code>	The number of columns in $A$ ( $n \geq 0$ ).
<code>a</code>	Array, size at least $\max(1, lda*n)$ for column major and $\max(1, lda*m)$ for row major layout. Array $a$ contains the $m$ -by- $n$ matrix $A$ .
<code>lda</code>	The leading dimension of $a$ ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

## Output Parameters

<code>a</code>	Overwritten by the factorization data as follows: on exit, the elements on and below the diagonal of the array $a$ contain the $m$ -by- $\min(n, m)$ lower trapezoidal matrix $L$ ( $L$ is lower triangular if $n \geq m$ ); the elements above the diagonal, with the array $tau$ , represent the orthogonal/unitary matrix $Q$ as a product of $\min(n, m)$ elementary reflectors.
<code>tau</code>	Array, size at least $\max(1, \min(m, n))$ . Contains scalar factors of the elementary reflectors.

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* =  $-i$ , the  $i$ -th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

## ?geqr2

Computes the QR factorization of a general rectangular matrix using an unblocked algorithm.

## Syntax

```
lapack_int LAPACKE_sgeqr2 (int matrix_layout, lapack_int m, lapack_int n, float* a,
lapack_int lda, float* tau);
```

```
lapack_int LAPACKE_dgeqr2 (int matrix_layout, lapack_int m, lapack_int n, double* a,
lapack_int lda, double* tau);
```

```
lapack_int LAPACKE_cgeqr2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* tau);
```

```
lapack_int LAPACKE_zgeqr2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_complex_double* tau);
```

## Include Files

- mkl.h

## Description

The routine computes a QR factorization of a real/complex  $m$ -by- $n$  matrix  $A$  as  $A = Q^*R$ .

The routine does not form the matrix  $Q$  explicitly. Instead,  $Q$  is represented as a product of  $\min(m, n)$  elementary reflectors :

$$Q = H(1) * H(2) * \dots * H(k), \text{ where } k = \min(m, n)$$

Each  $H(i)$  has the form

$$H(i) = I - \tau v v^T \text{ for real flavors, or}$$

$$H(i) = I - \tau v v^H \text{ for complex flavors}$$

where  $\tau$  is a real/complex scalar stored in  $\tau[i]$ , and  $v$  is a real/complex vector with  $v_{1:i-1} = 0$  and  $v_i = 1$ .

On exit,  $v_{i+1:m}$  is stored in  $a(i+1:m, i)$ .

## Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

$m$	The number of rows in the matrix $A$ ( $m \geq 0$ ).
$n$	The number of columns in $A$ ( $n \geq 0$ ).
$a$	Array, size at least $\max(1, lda * n)$ for column major and $\max(1, lda * m)$ for row major layout. Array $a$ contains the $m$ -by- $n$ matrix $A$ .
$lda$	The leading dimension of $a$ ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

## Output Parameters

$a$	Overwritten by the factorization data as follows: on exit, the elements on and above the diagonal of the array $a$ contain the $\min(n, m)$ -by- $n$ upper trapezoidal matrix $R$ ( $R$ is upper triangular if $m \geq n$ ); the elements below the diagonal, with the array $\tau$ , represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors.
$\tau$	Array, size at least $\max(1, \min(m, n))$ . Contains scalar factors of the elementary reflectors.

## Return Values

This function returns a value *info*.

If  $info = 0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = -1011$ , memory allocation error occurred.

## ?geqrt2

Computes a QR factorization of a general real or complex matrix using the compact WY representation of  $Q$ .

---

### Syntax

```
lapack_int LAPACKE_sgeqrt2 (int matrix_layout, lapack_int m, lapack_int n, float * a,
lapack_int lda, float * t, lapack_int ldt );

lapack_int LAPACKE_dgeqrt2 (int matrix_layout, lapack_int m, lapack_int n, double * a,
lapack_int lda, double * t, lapack_int ldt );

lapack_int LAPACKE_cgeqrt2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float * a, lapack_int lda, lapack_complex_float * t, lapack_int ldt );

lapack_int LAPACKE_zgeqrt2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double * a, lapack_int lda, lapack_complex_double * t, lapack_int ldt );
```

### Include Files

- mkl.h

### Description

The strictly lower triangular matrix  $V$  contains the elementary reflectors  $H(i)$  in the  $i$ th column below the diagonal. For example, if  $m=5$  and  $n=3$ , the matrix  $V$  is

$$V = \begin{bmatrix} 1 & & & \\ v_1 & 1 & & \\ v_1 & v_2 & 1 & \\ v_1 & v_2 & v_3 & \\ v_1 & v_2 & v_3 & \end{bmatrix}$$

where  $v_i$  represents the vector that defines  $H(i)$ . The vectors are returned in the lower triangular part of array  $a$ .

---

**NOTE**

The 1s along the diagonal of  $V$  are not stored in  $a$ .

---

The block reflector  $H$  is then given by

$$H = I - V^* T^* V^T \text{ for real flavors, and}$$

$$H = I - V^* T^* V^H \text{ for complex flavors,}$$

where  $V^T$  is the transpose and  $V^H$  is the conjugate transpose of  $V$ .

## Input Parameters

<i>m</i>	The number of rows in the matrix <i>A</i> ( $m \geq n$ ).
<i>n</i>	The number of columns in <i>A</i> ( $n \geq 0$ ).
<i>a</i>	Array, size at least $\max(1, lda*n)$ for column major and $\max(1, lda*m)$ for row major layout. Array <i>a</i> contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> .
<i>lda</i>	The leading dimension of <i>a</i> ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.
<i>ldt</i>	The leading dimension of <i>t</i> ; at least $\max(1, n)$ .

## Output Parameters

<i>a</i>	Overwritten by the factorization data as follows: The elements on and above the diagonal of the array contain the <i>n</i> -by- <i>n</i> upper triangular matrix <i>R</i> . The elements below the diagonal are the columns of <i>V</i> .
<i>t</i>	Array, size at least $\max(1, ldt*n)$ . The <i>n</i> -by- <i>n</i> upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector <i>T</i> . The elements below the diagonal are not used.

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0 and *info* = -*i*, the *i*th argument had an illegal value.

If *info* = -1011, memory allocation error occurred.

## ?geqrt3

*Recursively computes a QR factorization of a general real or complex matrix using the compact WY representation of Q.*

## Syntax

```
lapack_int LAPACKE_sgeqrt3 (int matrix_layout , lapack_int m , lapack_int n , float *
a , lapack_int lda , float * t , lapack_int ldt );
```

```
lapack_int LAPACKE_dgeqrt3 (int matrix_layout , lapack_int m , lapack_int n , double *
a , lapack_int lda , double * t , lapack_int ldt );
```

```
lapack_int LAPACKE_cgeqrt3 (int matrix_layout , lapack_int m , lapack_int n ,
lapack_complex_float * a , lapack_int lda , lapack_complex_float * t , lapack_int
ldt );
```

```
lapack_int LAPACKE_zgeqrt3 (int matrix_layout , lapack_int m , lapack_int n ,
lapack_complex_double * a , lapack_int lda , lapack_complex_double * t , lapack_int
ldt );
```

**NOTE**

The 1s along the diagonal of  $V$  are not stored in  $a$ .

The block reflector  $H$  is then given by

$$H = I - V^* T^* V^T \text{ for real flavors, and}$$

$$H = I - V^* T^* V^H \text{ for complex flavors,}$$

where  $V^T$  is the transpose and  $V^H$  is the conjugate transpose of  $V$ .

**Input Parameters**

$m$	The number of rows in the matrix $A$ ( $m \geq n$ ).
$n$	The number of columns in $A$ ( $n \geq 0$ ).
$a$	Array, size at least $\max(1, lda * n)$ for column major and $\max(1, lda * m)$ for row major layout. Array $a$ contains the $m$ -by- $n$ matrix $A$ .
$lda$	The leading dimension of $a$ ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.
$ldt$	The leading dimension of $t$ ; at least $\max(1, n)$ .

**Output Parameters**

$a$	The elements on and above the diagonal of the array contain the $n$ -by- $n$ upper triangular matrix $R$ . The elements below the diagonal are the columns of $V$ .
$t$	Array, size $ldt$ by $n$ .  The $n$ -by- $n$ upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector $T$ . The elements below the diagonal are not used.

**Return Values**

This function returns a value  $info$ .

If  $info = 0$ , the execution is successful.

If  $info < 0$  and  $info = -i$ , the  $i$ th argument had an illegal value.

If  $info = -1011$ , memory allocation error occurred.

**?getf2**

Computes the LU factorization of a general  $m$ -by- $n$  matrix using partial pivoting with row interchanges (unblocked algorithm).

**Syntax**

```
lapack_int LAPACKE_sgetf2 (int matrix_layout, lapack_int m, lapack_int n, float* a,
lapack_int lda, lapack_int * ipiv);

lapack_int LAPACKE_dgetf2 (int matrix_layout, lapack_int m, lapack_int n, double* a,
lapack_int lda, lapack_int * ipiv);
```

```
lapack_int LAPACKE_cgetf2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_int * ipiv);
```

```
lapack_int LAPACKE_zgetf2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_int * ipiv);
```

## Include Files

- mkl.h

## Description

The routine computes the  $LU$  factorization of a general  $m$ -by- $n$  matrix  $A$  using partial pivoting with row interchanges. The factorization has the form

$$A = P * L * U$$

where  $p$  is a permutation matrix,  $L$  is lower triangular with unit diagonal elements (lower trapezoidal if  $m > n$ ) and  $U$  is upper triangular (upper trapezoidal if  $m < n$ ).

## Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

$m$	The number of rows in the matrix $A$ ( $m \geq 0$ ).
$n$	The number of columns in $A$ ( $n \geq 0$ ).
$a$	Array, size at least $\max(1, lda * n)$ for column major and $\max(1, lda * m)$ for row major layout. Array $a$ contains the $m$ -by- $n$ matrix $A$ .
$lda$	The leading dimension of $a$ ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

## Output Parameters

$a$	Overwritten by $L$ and $U$ . The unit diagonal elements of $L$ are not stored.
$ipiv$	Array, size at least $\max(1, \min(m, n))$ . The pivot indices: for $1 \leq i \leq n$ , row $i$ was interchanged with row $ipiv(i)$ .

## Return Values

This function returns a value *info*.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = i > 0$ ,  $u_{ij}$  is 0. The factorization has been completed, but  $U$  is exactly singular. Division by 0 will occur if you use the factor  $U$  for solving a system of linear equations.

If  $info = -1011$ , memory allocation error occurred.

## ?lacn2

*Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.*

---

## Syntax

### C:

```
lapack_int LAPACKE_slacn2 (lapack_int n, float * v, float * x, lapack_int * isgn, float * est, lapack_int * kase, lapack_int * isave);
```

```
lapack_int LAPACKE_clacn2 (lapack_int n, lapack_complex_float * v, lapack_complex_float * x, float * est, lapack_int * kase, lapack_int * isave);
```

```
lapack_int LAPACKE_dlacn2 (lapack_int n, double * v, double * x, lapack_int * isgn, double * est, lapack_int * kase, lapack_int * isave);
```

```
lapack_int LAPACKE_zlacn2 (lapack_int n, lapack_complex_double * v, lapack_complex_double * x, double * est, lapack_int * kase, lapack_int * isave);
```

## Include Files

- mkl.h

## Description

The routine estimates the 1-norm of a square, real or complex matrix  $A$ . Reverse communication is used for evaluating matrix-vector products.

## Input Parameters

$n$	The order of the matrix $A$ ( $n \geq 1$ ).
$v, x$	Arrays, size ( $n$ ) each. $v$ is a workspace array. $x$ is used as input after an intermediate return.
$isgn$	Workspace array, size ( $n$ ), used with real flavors only.
$est$	On entry with $kase$ set to 1 or 2, and $isave(1) = 1$ , $est$ must be unchanged from the previous call to the routine.
$kase$	On the initial call to the routine, $kase$ must be set to 0.
$isave$	Array, size (3). Contains variables from the previous call to the routine.

## Output Parameters

$est$	An estimate (a lower bound) for $\text{norm}(A)$ .
$kase$	On an intermediate return, $kase$ is set to 1 or 2, indicating whether $x$ is overwritten by $A*x$ or $A^T*x$ for real flavors and $A*x$ or $A^H*x$ for complex flavors. On the final return, $kase$ is set to 0.
$v$	On the final return, $v = A*w$ , where $est = \text{norm}(v) / \text{norm}(w)$ ( $w$ is not returned).
$x$	On an intermediate return, $x$ is overwritten by $A*x$ , if $kase = 1$ ,

$A^T * x$ , if *kase* = 2 (for real flavors),

$A^H * x$ , if *kase* = 2 (for complex flavors),

and the routine must be re-called with all the other parameters unchanged.

*isave*

This parameter is used to save variables between calls to the routine.

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

## ?lacpy

*Copies all or part of one two-dimensional array to another.*

### Syntax

```
lapack_int LAPACKE_slacpy (int matrix_layout, char uplo, lapack_int m, lapack_int n,
const float* a, lapack_int lda, float* b, lapack_int ldb);
```

```
lapack_int LAPACKE_dlacpy (int matrix_layout, char uplo, lapack_int m, lapack_int n,
const double* a, lapack_int lda, double* b, lapack_int ldb);
```

```
lapack_int LAPACKE_clacpy (int matrix_layout, char uplo, lapack_int m, lapack_int n,
const lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int
ldb);
```

```
lapack_int LAPACKE_zlacpy (int matrix_layout, char uplo, lapack_int m, lapack_int n,
const lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int
ldb);
```

### Include Files

- mkl.h

### Description

The routine copies all or part of a two-dimensional matrix *A* to another matrix *B*.

### Input Parameters

A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

*uplo*

Specifies the part of the matrix *A* to be copied to *B*.

If *uplo* = 'U', the upper triangular part of *A*;

if *uplo* = 'L', the lower triangular part of *A*.

Otherwise, all of the matrix *A* is copied.

*m*

The number of rows in the matrix *A* ( $m \geq 0$ ).

*n*

The number of columns in *A* ( $n \geq 0$ ).

<i>a</i>	Array, size at least $\max(1, lda*n)$ for column major and $\max(1, lda*m)$ for row major layout. <i>A</i> contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> .  If <i>uplo</i> = 'U', only the upper triangle or trapezoid is accessed; if <i>uplo</i> = 'L', only the lower triangle or trapezoid is accessed.
<i>lda</i>	The leading dimension of <i>a</i> ; $lda \geq \max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.
<i>ldb</i>	The leading dimension of the output array <i>b</i> ; $ldb \geq \max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

## Output Parameters

<i>b</i>	Array, size at least $\max(1, ldb*n)$ for column major and $\max(1, ldb*m)$ for row major layout. Array <i>a</i> contains the <i>m</i> -by- <i>n</i> matrix <i>B</i> .  On exit, $B = A$ in the locations specified by <i>uplo</i> .
----------	--

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

## ?lakf2

*Forms a matrix containing Kronecker products between the given matrices.*

## Syntax

```
void slakf2 (lapack_int *m, lapack_int *n, float *a, lapack_int *lda, float *b, float *d, float *e, float *z, lapack_int *ldz);
```

```
void dlakf2 (lapack_int *m, lapack_int *n, double *a, lapack_int *lda, double *b, double *d, double *e, double *z, lapack_int *ldz);
```

```
void clakf2 (lapack_int *m, lapack_int *n, lapack_complex *a, lapack_int *lda, lapack_complex *b, lapack_complex *d, lapack_complex *e, lapack_complex *z, lapack_int *ldz);
```

```
void zlakf2 (lapack_int *m, lapack_int *n, lapack_complex_double *a, lapack_int *lda, lapack_complex_double *b, lapack_complex_double *d, lapack_complex_double *e, lapack_complex_double *z, lapack_int *ldz);
```

## Include Files

- mkl.h

## Description

The routine ?lakf2 forms the  $2*m*n$  by  $2*m*n$  matrix *Z*.

$$Z = \begin{bmatrix} \text{kron}(In, A) & -\text{kron}(B^T, Im) \\ \text{kron}(In, D) & -\text{kron}(E^T, Im) \end{bmatrix}$$

where  $I_n$  is the identity matrix of size  $n$  and  $X^T$  is the transpose of  $X$ .  $\text{kron}(X, Y)$  is the Kronecker product between the matrices  $X$  and  $Y$ .

### Input Parameters

$m$	Size of matrix, $m \geq 1$
$n$	Size of matrix, $n \geq 1$
$a$	Array, size $lda$ -by- $n$ . The matrix $A$ in the output matrix $Z$ .
$lda$	The leading dimension of $a$ , $b$ , $d$ , and $e$ . $lda \geq m+n$ .
$b$	Array, size $lda$ by $n$ . Matrix used in forming the output matrix $Z$ .
$d$	Array, size $lda$ by $m$ . Matrix used in forming the output matrix $Z$ .
$e$	Array, size $lda$ by $n$ . Matrix used in forming the output matrix $Z$ .
$ldz$	The leading dimension of $Z$ . $ldz \geq 2 * m * n$ .

### Output Parameters

$z$	Array, size $ldz$ -by- $2*m*n$ . The resultant Kronecker $m*n*2$ -by- $m*n*2$ matrix.
-----	---

### ?lange

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general rectangular matrix.

### Syntax

```
float LAPACKE_slange (int matrix_layout, char norm, lapack_int m, lapack_int n, const
float * a, lapack_int lda);

double LAPACKE_dlange (int matrix_layout, char norm, lapack_int m, lapack_int n, const
double * a, lapack_int lda);

float LAPACKE_clange (int matrix_layout, char norm, lapack_int m, lapack_int n, const
lapack_complex_float * a, lapack_int lda);

double LAPACKE_zlange (int matrix_layout, char norm, lapack_int m, lapack_int n, const
lapack_complex_double * a, lapack_int lda);
```

### Include Files

- mkl.h

### Description

The function ?lange returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex matrix  $A$ .

### Input Parameters

A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<i>norm</i>	<p>Specifies the value to be returned by the routine:</p> <ul style="list-style-type: none"> <li>= 'M' or 'm': <math>val = \max(\text{abs}(A_{ij}))</math>, largest absolute value of the matrix <i>A</i>.</li> <li>= '1' or 'O' or 'o': <math>val = \text{norm1}(A)</math>, 1-norm of the matrix <i>A</i> (maximum column sum),</li> <li>= 'I' or 'i': <math>val = \text{normI}(A)</math>, infinity norm of the matrix <i>A</i> (maximum row sum),</li> <li>= 'F', 'f', 'E' or 'e': <math>val = \text{normF}(A)</math>, Frobenius norm of the matrix <i>A</i> (square root of sum of squares).</li> </ul>
<i>m</i>	<p>The number of rows of the matrix <i>A</i>.</p> <p><math>m \geq 0</math>. When <math>m = 0</math>, <i>?lange</i> is set to zero.</p>
<i>n</i>	<p>The number of columns of the matrix <i>A</i>.</p> <p><math>n \geq 0</math>. When <math>n = 0</math>, <i>?lange</i> is set to zero.</p>
<i>a</i>	<p>Array, size at least <math>\max(1, lda * n)</math> for column major and <math>\max(1, lda * m)</math> for row major layout. Array <i>a</i> contains the <i>m</i>-by-<i>n</i> matrix <i>A</i>.</p>
<i>lda</i>	<p>The leading dimension of the array <i>a</i>.</p> <p><math>lda \geq \max(n, 1)</math> for column major layout and <math>\max(1, n)</math> for row major layout.</p>

### **?lansy**

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix.

### **Syntax**

```
float LAPACKE_slansy (int matrix_layout, char norm, char uplo, lapack_int n, const float * a, lapack_int lda);
```

```
double LAPACKE_dlansy (int matrix_layout, char norm, char uplo, lapack_int n, const double * a, lapack_int lda);
```

```
float LAPACKE_clansy (int matrix_layout, char norm, char uplo, lapack_int n, const lapack_complex_float * a, lapack_int lda);
```

```
double LAPACKE_zlansy (int matrix_layout, char norm, char uplo, lapack_int n, const lapack_complex_double * a, lapack_int lda);
```

### **Include Files**

- mkl.h

### **Description**

The function *?lansy* returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix *A*.

## Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<code>norm</code>	<p>Specifies the value to be returned by the routine:</p> <ul style="list-style-type: none"> <li>= 'M' or 'm': <math>val = \max(\text{abs}(A_{ij}))</math>, largest absolute value of the matrix <math>A</math>.</li> <li>= '1' or 'O' or 'o': <math>val = \text{norm1}(A)</math>, 1-norm of the matrix <math>A</math> (maximum column sum),</li> <li>= 'I' or 'i': <math>val = \text{normI}(A)</math>, infinity norm of the matrix <math>A</math> (maximum row sum),</li> <li>= 'F', 'f', 'E' or 'e': <math>val = \text{normF}(A)</math>, Frobenius norm of the matrix <math>A</math> (square root of sum of squares).</li> </ul>
<code>uplo</code>	<p>Specifies whether the upper or lower triangular part of the symmetric matrix <math>A</math> is to be referenced.</p> <ul style="list-style-type: none"> <li>= 'U': Upper triangular part of <math>A</math> is referenced.</li> <li>= 'L': Lower triangular part of <math>A</math> is referenced</li> </ul>
<code>n</code>	The order of the matrix $A$ . $n \geq 0$ . When $n = 0$ , <code>?lanhe</code> is set to zero.
<code>a</code>	<p>Array, size at least <math>\max(1, lda * n)</math>. The symmetric matrix <math>A</math>.</p> <p>If <code>uplo = 'U'</code>, the leading <math>n</math>-by-<math>n</math> upper triangular part of <math>a</math> contains the upper triangular part of the matrix <math>A</math>, and the strictly lower triangular part of <math>a</math> is not referenced.</p> <p>If <code>uplo = 'L'</code>, the leading <math>n</math>-by-<math>n</math> lower triangular part of <math>a</math> contains the lower triangular part of the matrix <math>A</math>, and the strictly upper triangular part of <math>a</math> is not referenced.</p>
<code>lda</code>	<p>The leading dimension of the array <math>a</math>.</p> <p><math>lda \geq \max(n, 1)</math>.</p>

## ?lanhe

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix.

## Syntax

```
float LAPACKE_clanhe (int matrix_layout, char norm, char uplo, lapack_int n, const
lapack_complex_float * a, lapack_int lda);
```

```
double LAPACKE_zlanhe (int matrix_layout, char norm, char uplo, lapack_int n, const
lapack_complex_double * a, lapack_int lda);
```

## Include Files

- mkl.h

## Description

The function `?lanhe` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix  $A$ .

### Input Parameters

$A$  `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<code>norm</code>	<p>Specifies the value to be returned by the routine:</p> <ul style="list-style-type: none"> <li>= 'M' or 'm': <math>val = \max(\text{abs}(A_{ij}))</math>, largest absolute value of the matrix <math>A</math>.</li> <li>= '1' or 'O' or 'o': <math>val = \text{norm1}(A)</math>, 1-norm of the matrix <math>A</math> (maximum column sum),</li> <li>= 'I' or 'i': <math>val = \text{normI}(A)</math>, infinity norm of the matrix <math>A</math> (maximum row sum),</li> <li>= 'F', 'f', 'E' or 'e': <math>val = \text{normF}(A)</math>, Frobenius norm of the matrix <math>A</math> (square root of sum of squares).</li> </ul>
<code>uplo</code>	<p>Specifies whether the upper or lower triangular part of the Hermitian matrix <math>A</math> is to be referenced.</p> <ul style="list-style-type: none"> <li>= 'U': Upper triangular part of <math>A</math> is referenced.</li> <li>= 'L': Lower triangular part of <math>A</math> is referenced</li> </ul>
<code>n</code>	The order of the matrix $A$ . $n \geq 0$ . When $n = 0$ , <code>?lanhe</code> is set to zero.
<code>a</code>	<p>Array, size at least <math>\max(1, lda*n)</math>. The Hermitian matrix <math>A</math>.</p> <p>If <code>uplo = 'U'</code>, the leading <math>n</math>-by-<math>n</math> upper triangular part of <math>a</math> contains the upper triangular part of the matrix <math>A</math>, and the strictly lower triangular part of <math>a</math> is not referenced.</p> <p>If <code>uplo = 'L'</code>, the leading <math>n</math>-by-<math>n</math> lower triangular part of <math>a</math> contains the lower triangular part of the matrix <math>A</math>, and the strictly upper triangular part of <math>a</math> is not referenced.</p>
<code>lda</code>	<p>The leading dimension of the array <math>a</math>.</p> <p><math>lda \geq \max(n, 1)</math>.</p>

### ?lantr

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix.

### Syntax

```
float LAPACKE_slantr (char * norm, char * uplo, char * diag, lapack_int * m, lapack_int * n, const float * a, lapack_int * lda, float * work);
double LAPACKE_dlantr (char * norm, char * uplo, char * diag, lapack_int * m, lapack_int * n, const double * a, lapack_int * lda, double * work);
float LAPACKE_clantr (char * norm, char * uplo, char * diag, lapack_int * m, lapack_int * n, const lapack_complex_float * a, lapack_int * lda, float * work);
double LAPACKE_zlantr (char * norm, char * uplo, char * diag, lapack_int * m, lapack_int * n, const lapack_complex_double * a, lapack_int * lda, double * work);
```

## Include Files

- mkl.h

## Description

The function `?lantr` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix  $A$ .

## Input Parameters

$A$  `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<i>norm</i>	<p>Specifies the value to be returned by the routine:</p> <ul style="list-style-type: none"> <li>= 'M' or 'm': <math>val = \max(\text{abs}(A_{ij}))</math>, largest absolute value of the matrix <math>A</math>.</li> <li>= '1' or 'O' or 'o': <math>val = \text{norm1}(A)</math>, 1-norm of the matrix <math>A</math> (maximum column sum),</li> <li>= 'I' or 'i': <math>val = \text{normI}(A)</math>, infinity norm of the matrix <math>A</math> (maximum row sum),</li> <li>= 'F', 'f', 'E' or 'e': <math>val = \text{normF}(A)</math>, Frobenius norm of the matrix <math>A</math> (square root of sum of squares).</li> </ul>
<i>uplo</i>	<p>Specifies whether the matrix <math>A</math> is upper or lower trapezoidal.</p> <ul style="list-style-type: none"> <li>= 'U': Upper trapezoidal</li> <li>= 'L': Lower trapezoidal.</li> </ul> <p>Note that <math>A</math> is triangular instead of trapezoidal if <math>m = n</math>.</p>
<i>diag</i>	<p>Specifies whether or not the matrix <math>A</math> has unit diagonal.</p> <ul style="list-style-type: none"> <li>= 'N': Non-unit diagonal</li> <li>= 'U': Unit diagonal.</li> </ul>
<i>m</i>	<p>The number of rows of the matrix <math>A</math>. <math>m \geq 0</math>, and if <i>uplo</i> = 'U', <math>m \leq n</math>.</p> <p>When <math>m = 0</math>, <code>?lantr</code> is set to zero.</p>
<i>n</i>	<p>The number of columns of the matrix <math>A</math>. <math>n \geq 0</math>, and if <i>uplo</i> = 'L', <math>n \leq m</math>.</p> <p>When <math>n = 0</math>, <code>?lantr</code> is set to zero.</p>
<i>a</i>	<p>Array, size at least <math>\max(1, lda*n)</math> for column major and <math>\max(1, lda*m)</math> for row major layout.</p> <p>The trapezoidal matrix <math>A</math> (<math>A</math> is triangular if <math>m = n</math>).</p> <p>If <i>uplo</i> = 'U', the leading <math>m</math>-by-<math>n</math> upper trapezoidal part of the array <math>a</math> contains the upper trapezoidal matrix, and the strictly lower triangular part of <math>A</math> is not referenced.</p>

If *uplo* = 'L', the leading *m*-by-*n* lower trapezoidal part of the array *a* contains the lower trapezoidal matrix, and the strictly upper triangular part of *A* is not referenced. Note that when *diag* = 'U', the diagonal elements of *A* are not referenced and are assumed to be one.

*lda*

The leading dimension of the array *a*.

$lda \geq \max(m, 1)$  for column major layout and  $\geq \max(1, n)$  for row major layout.

## LAPACKE\_set\_nancheck

*Turns NaN checking off or on*

---

```
LAPACKE_set_nancheck(int flag);
```

### Description

The routine sets a value for the LAPACKE NaN checking flag, which indicates whether or not LAPACKE routines check input matrices for NaNs.

### Input Parameters

*flag*

If *flag*= 0, NaN checking is turned OFF. Otherwise, it is turned ON.

## LAPACKE\_get\_nancheck

*Gets the current NaN checking flag, which indicates whether NaN checking has been turned off or on.*

---

```
int flag = LAPACKE_get_nancheck ();
```

### Description

The function returns the current value for the LAPACKE NaN checking flag, which indicates whether or not LAPACKE routines check input matrices for NaNs.

### Return Value

An integer value is returned which indicates the current NaN checking status.

The returned flag value is either 0 (OFF) or 1 (ON), even though any integer value can be used as an input parameter for LAPACKE\_set\_nancheck.

For example, the following code turns on NaN checking:

```
LAPACKE_set_nancheck(100);
int flag = LAPACKE_get_nancheck(); // flag==1, not 100.
```

## ?lapmr

*Rearranges rows of a matrix as specified by a permutation vector.*

---

### Syntax

```
lapack_int LAPACKE_slapmr (int matrix_layout, lapack_logical forwr, lapack_int m,
lapack_int n, float* x, lapack_int ldx, lapack_int * k);
```

```
lapack_int LAPACKE_dlapmr (int matrix_layout, lapack_logical forwr, lapack_int m,
lapack_int n, double* x, lapack_int ldx, lapack_int * k);
```

```
lapack_int LAPACKE_clapmr (int matrix_layout, lapack_logical forwr, lapack_int m,
lapack_int n, lapack_complex_float* x, lapack_int ldx, lapack_int * k);
```

```
lapack_int LAPACKE_zlapmr (int matrix_layout, lapack_logical forwr, lapack_int m,
lapack_int n, lapack_complex_double* x, lapack_int ldx, lapack_int * k);
```

## Include Files

- mkl.h

## Description

The `?lapmr` routine rearranges the rows of the  $m$ -by- $n$  matrix  $X$  as specified by the permutation  $k[0]$ ,  $k[1]$ , ...,  $k[m-1]$  of the integers  $1, \dots, m$ .

If *forwr* is true, forward permutation:

$X(k[i-1], :)$  is moved to  $X(i, :)$  for  $i = 1, 2, \dots, m$ .

If *forwr* is false, backward permutation:

$X(i, :)$  is moved to  $X(k[i-1], :)$  for  $i = 1, 2, \dots, m$ .

## Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<i>forwr</i>	If <i>forwr</i> is true, forward permutation. If <i>forwr</i> is false, backward permutation.
<i>m</i>	The number of rows of the matrix $X$ . $m \geq 0$ .
<i>n</i>	The number of columns of the matrix $X$ . $n \geq 0$ .
<i>x</i>	Array, size at least $\max(1, ldx * n)$ for column major and $\max(1, ldx * m)$ for row major layout. On entry, the $m$ -by- $n$ matrix $X$ .
<i>ldx</i>	The leading dimension of the array $X$ , $ldx \geq \max(1, m)$ for column major layout and $ldx \geq \max(1, n)$ for row major layout.
<i>k</i>	Array, size ( $m$ ). On entry, $k$ contains the permutation vector and is used as internal workspace.

## Output Parameters

<i>x</i>	On exit, $x$ contains the permuted matrix $X$ .
<i>k</i>	On exit, $k$ is reset to its original value.

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* =  $-i$ , the  $i$ -th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

## See Also

### ?lapmt

Performs a forward or backward permutation of the columns of a matrix.

### Syntax

```
lapack_int LAPACKE_slapmt (int matrix_layout, lapack_logical forwr, lapack_int m,
lapack_int n, float * x, lapack_int ldx, lapack_int * k);
```

```
lapack_int LAPACKE_dlapmt (int matrix_layout, lapack_logical forwr, lapack_int m,
lapack_int n, double * x, lapack_int ldx, lapack_int * k);
```

```
lapack_int LAPACKE_clapmt (int matrix_layout, lapack_logical forwr, lapack_int m,
lapack_int n, lapack_complex_float * x, lapack_int ldx, lapack_int * k);
```

```
lapack_int LAPACKE_zlapmt (int matrix_layout, lapack_logical forwr, lapack_int m,
lapack_int n, lapack_complex_double * x, lapack_int ldx, lapack_int * k);
```

### Include Files

- mkl.h

### Description

The routine ?lapmt rearranges the columns of the  $m$ -by- $n$  matrix  $X$  as specified by the permutation  $k[i - 1]$  for  $i = 1, \dots, n$ .

If  $forwr \neq 0$ , forward permutation:

$X(*, k(j))$  is moved to  $X(*, j)$  for  $j=1, 2, \dots, n$ .

If  $forwr = 0$ , backward permutation:

$X(*, j)$  is moved to  $X(*, k(j))$  for  $j = 1, 2, \dots, n$ .

### Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>forwr</i>	If $forwr \neq 0$ , forward permutation If $forwr = 0$ , backward permutation
<i>m</i>	The number of rows of the matrix $X$ . $m \geq 0$ .
<i>n</i>	The number of columns of the matrix $X$ . $n \geq 0$ .
<i>x</i>	Array, size $ldx*n$ . On entry, the $m$ -by- $n$ matrix $X$ .
<i>ldx</i>	The leading dimension of the array $x$ , $ldx \geq \max(1, m)$ .
<i>k</i>	Array, size ( $n$ ). On entry, $k$ contains the permutation vector and is used as internal workspace.

### Output Parameters

<i>x</i>	On exit, $x$ contains the permuted matrix $X$ .
<i>k</i>	On exit, $k$ is reset to its original value.

## See Also

[?lapmr](#)

## ?lapy2

Returns  $\sqrt{x^2+y^2}$ .

---

### Syntax

```
float LAPACKE_slapy2 (floatx, floaty);  
double LAPACKE_dlapy2 (doublex, doubley);
```

### Include Files

- mkl.h

### Description

The function `?lapy2` returns  $\sqrt{x^2+y^2}$ , avoiding unnecessary overflow or harmful underflow.

### Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

`x, y` Specify the input values `x` and `y`.

### Return Values

The function returns a value `val`.

If `val=-1D0`, the first argument was NaN.

If `val=-2D0`, the second argument was NaN.

## ?lapy3

Returns  $\sqrt{x^2+y^2+z^2}$ .

---

### Syntax

```
float LAPACKE_slapy3 (floatx, floaty, floatz);  
double LAPACKE_dlapy3 (double x, doubley, doublez);
```

### Include Files

- mkl.h

### Description

The function `?lapy3` returns  $\sqrt{x^2+y^2+z^2}$ , avoiding unnecessary overflow or harmful underflow.

### Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

`x, y, z` Specify the input values `x`, `y` and `z`.

```
lapack_int LAPACKE_zlarfb (int matrix_layout , char side , char trans , char direct ,
char storev , lapack_int m , lapack_int n , lapack_int k , const lapack_complex_double
* v , lapack_int ldv , const lapack_complex_double * t , lapack_int ldt ,
lapack_complex_double * c , lapack_int ldc );
```

## Include Files

- mkl.h

## Description

The real flavors of the routine `?larfb` apply a real block reflector  $H$  or its transpose  $H^T$  to a real  $m$ -by- $n$  matrix  $C$  from either left or right.

The complex flavors of the routine `?larfb` apply a complex block reflector  $H$  or its conjugate transpose  $H^H$  to a complex  $m$ -by- $n$  matrix  $C$  from either left or right.

## Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<i>side</i>	<p>If <i>side</i> = 'L': apply <math>H</math> or <math>H^T</math> for real flavors and <math>H</math> or <math>H^H</math> for complex flavors from the left.</p> <p>If <i>side</i> = 'R': apply <math>H</math> or <math>H^T</math> for real flavors and <math>H</math> or <math>H^H</math> for complex flavors from the right.</p>
<i>trans</i>	<p>If <i>trans</i> = 'N': apply <math>H</math> (No transpose).</p> <p>If <i>trans</i> = 'C': apply <math>H^H</math> (Conjugate transpose).</p> <p>If <i>trans</i> = 'T': apply <math>H^T</math> (Transpose).</p>
<i>direct</i>	<p>Indicates how <math>H</math> is formed from a product of elementary reflectors</p> <p>If <i>direct</i> = 'F': <math>H = H(1) * H(2) * \dots * H(k)</math> (forward)</p> <p>If <i>direct</i> = 'B': <math>H = H(k) * \dots * H(2) * H(1)</math> (backward)</p>
<i>storev</i>	<p>Indicates how the vectors which define the elementary reflectors are stored:</p> <p>If <i>storev</i> = 'C': Column-wise</p> <p>If <i>storev</i> = 'R': Row-wise</p>
<i>m</i>	The number of rows of the matrix $C$ .
<i>n</i>	The number of columns of the matrix $C$ .
<i>k</i>	The order of the matrix $T$ (equal to the number of elementary reflectors whose product defines the block reflector).
<i>v</i>	The size limitations depend on values of parameters <i>storev</i> and <i>side</i> as described in the following table:

<i>storev</i> = C		<i>storev</i> = R	
<i>side</i> = L	<i>side</i> = R	<i>side</i> = L	<i>side</i> = R

Column major	$\max(1, ldv * k)$	$\max(1, ldv * k)$	$\max(1, ldv * m)$	$\max(1, ldv * n)$
Row major	$\max(1, ldv * m)$	$\max(1, ldv * n)$	$\max(1, ldv * k)$	$\max(1, ldv * k)$

The matrix  $v$ . See *Application Notes* below.

$ldv$

The leading dimension of the array  $v$ . It should satisfy the following conditions:

	$storev = C$		$storev = R$	
	$side = L$	$side = R$	$side = L$	$side = R$
Column major	$\max(1, m)$	$\max(1, n)$	$\max(1, k)$	$\max(1, k)$
Row major	$\max(1, k)$	$\max(1, k)$	$\max(1, m)$	$\max(1, n)$

$t$

Array, size at least  $\max(1, ldt * k)$ .

Contains the triangular  $k$ -by- $k$  matrix  $T$  in the representation of the block reflector.

$ldt$

The leading dimension of the array  $t$ .

$ldt \geq k$ .

$c$

Array, size at least  $\max(1, ldc * n)$  for column major layout and  $\max(1, ldc * m)$  for row major layout.

On entry, the  $m$ -by- $n$  matrix  $C$ .

$ldc$

The leading dimension of the array  $c$ .

$ldc \geq \max(1, m)$  for column major layout and  $ldc \geq \max(1, n)$  for row major layout.

## Output Parameters

$c$

On exit,  $c$  is overwritten by the product of the following:

- $H * C$ , or  $H^T * C$ , or  $C * H$ , or  $C * H^T$  for real flavors
- $H * C$ , or  $H^H * C$ , or  $C * H$ , or  $C * H^H$  for complex flavors

## Return Values

This function returns a value  $info$ .

If  $info = 0$ , the execution is successful.

If  $info = -i$ , the  $i$ -th parameter had an illegal value.

If  $info = -1011$ , memory allocation error occurred.

## Application Notes

The shape of the matrix  $V$  and the storage of the vectors which define the  $H(i)$  is best illustrated by the following example with  $n = 5$  and  $k = 3$ . The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

`direct = 'F' and storev = 'C':`      `direct = 'F' and storev = 'R':`

$$\begin{bmatrix} 1 & & & & \\ v_1 & 1 & & & \\ v_1 & v_2 & 1 & & \\ v_1 & v_2 & v_3 & & \\ v_1 & v_2 & v_3 & & \end{bmatrix}$$

$$\begin{bmatrix} 1 & v_1 & v_1 & v_1 & v_1 \\ & 1 & v_2 & v_2 & v_2 \\ & & 1 & v_3 & v_3 \end{bmatrix}$$

`direct = 'B' and storev = 'C':`      `direct = 'B' and storev = 'R':`

$$\begin{bmatrix} v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ 1 & v_2 & v_3 \\ & 1 & v_3 \\ & & 1 \end{bmatrix}$$

$$\begin{bmatrix} v_1 & v_1 & 1 & & \\ v_2 & v_2 & v_2 & 1 & \\ v_3 & v_3 & v_3 & v_3 & 1 \end{bmatrix}$$

## ?larfg

Generates an elementary reflector (Householder matrix).

### Syntax

```
lapack_int LAPACKE_slarfg (lapack_int n , float * alpha , float * x , lapack_int incx , float * tau );
```

```
lapack_int LAPACKE_dlarfg (lapack_int n , double * alpha , double * x , lapack_int incx , double * tau );
```

```
lapack_int LAPACKE_clarfg (lapack_int n , lapack_complex_float * alpha , lapack_complex_float * x , lapack_int incx , lapack_complex_float * tau );
```

```
lapack_int LAPACKE_zlarfg (lapack_int n , lapack_complex_double * alpha , lapack_complex_double * x , lapack_int incx , lapack_complex_double * tau );
```

### Include Files

- mkl.h

### Description

The routine ?larfg generates a real/complex elementary reflector  $H$  of order  $n$ , such that

$$H^* \begin{bmatrix} \alpha \\ x \end{bmatrix} = \begin{bmatrix} \beta \\ 0 \end{bmatrix}, \quad H^T * H = I,$$

for real flavors and

$$H^X * \begin{bmatrix} \text{alpha} \\ x \end{bmatrix} = \begin{bmatrix} \text{beta} \\ 0 \end{bmatrix}, H^X * H = I,$$

for complex flavors,

where *alpha* and *beta* are scalars (with *beta* real for all flavors), and *x* is an  $(n-1)$ -element real/complex vector. *H* is represented in the form

$$H = I - \text{tau} * \begin{bmatrix} 1 \\ v \end{bmatrix} * \begin{bmatrix} 1 & v^T \end{bmatrix}$$

for real flavors and

$$H = I - \text{tau} * \begin{bmatrix} 1 \\ v \end{bmatrix} * \begin{bmatrix} 1 & v^H \end{bmatrix}$$

for complex flavors,

where *tau* is a real/complex scalar and *v* is a real/complex  $(n-1)$ -element vector, respectively. Note that for `clarfg/zlarfg`, *H* is not Hermitian.

If the elements of *x* are all zero (and, for complex flavors, *alpha* is real), then *tau* = 0 and *H* is taken to be the unit matrix.

Otherwise,  $1 \leq \text{tau} \leq 2$  (for real flavors), or

$1 \leq \text{Re}(\text{tau}) \leq 2$  and  $\text{abs}(\text{tau}-1) \leq 1$  (for complex flavors).

## Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<i>n</i>	The order of the elementary reflector.
<i>alpha</i>	
<i>x</i>	Array, size $(1+(n-2)*\text{abs}(\text{incx}))$ . On entry, the vector <i>x</i> .
<i>incx</i>	The increment between elements of <i>x</i> . <i>incx</i> > 0.

## Output Parameters

<i>alpha</i>	On exit, it is overwritten with the value <i>beta</i> .
<i>x</i>	On exit, it is overwritten with the vector <i>v</i> .
<i>tau</i>	

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -2, *alpha* is NaN

If *info* = -3, array *x* contains NaN components.

## ?larft

Forms the triangular factor  $T$  of a block reflector  $H = I - V^*T^*V^{**}H$ .

### Syntax

```
lapack_int LAPACKE_slarft (int matrix_layout , char direct , char storev , lapack_int
n , lapack_int k , const float * v , lapack_int ldv , const float * tau , float * t ,
lapack_int ldt );
```

```
lapack_int LAPACKE_dlarft (int matrix_layout , char direct , char storev , lapack_int
n , lapack_int k , const double * v , lapack_int ldv , const double * tau , double * t ,
lapack_int ldt );
```

```
lapack_int LAPACKE_clarft (int matrix_layout , char direct , char storev , lapack_int
n , lapack_int k , const lapack_complex_float * v , lapack_int ldv , const
lapack_complex_float * tau , lapack_complex_float * t , lapack_int ldt );
```

```
lapack_int LAPACKE_zlarft (int matrix_layout , char direct , char storev , lapack_int
n , lapack_int k , const lapack_complex_double * v , lapack_int ldv , const
lapack_complex_double * tau , lapack_complex_double * t , lapack_int ldt );
```

### Include Files

- mkl.h

### Description

The routine ?larft forms the triangular factor  $T$  of a real/complex block reflector  $H$  of order  $n$ , which is defined as a product of  $k$  elementary reflectors.

If  $direct = 'F'$ ,  $H = H(1)^*H(2)^* \dots *H(k)$  and  $T$  is upper triangular;

If  $direct = 'B'$ ,  $H = H(k)^* \dots *H(2)^*H(1)$  and  $T$  is lower triangular.

If  $storev = 'C'$ , the vector which defines the elementary reflector  $H(i)$  is stored in the  $i$ -th column of the array  $v$ , and  $H = I - V^*T^*V^T$  (for real flavors) or  $H = I - V^*T^*V^H$  (for complex flavors) .

If  $storev = 'R'$ , the vector which defines the elementary reflector  $H(i)$  is stored in the  $i$ -th row of the array  $v$ , and  $H = I - V^T^*T^*V$  (for real flavors) or  $H = I - V^H^*T^*V$  (for complex flavors).

### Input Parameters

A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<i>direct</i>	Specifies the order in which the elementary reflectors are multiplied to form the block reflector: = 'F': $H = H(1)^*H(2)^* \dots *H(k)$ (forward) = 'B': $H = H(k)^* \dots *H(2)^*H(1)$ (backward)
<i>storev</i>	Specifies how the vectors which define the elementary reflectors are stored (see also <i>Application Notes</i> below): = 'C': column-wise = 'R': row-wise.
<i>n</i>	The order of the block reflector $H$ . $n \geq 0$ .

$k$  The order of the triangular factor  $T$  (equal to the number of elementary reflectors).  $k \geq 1$ .

$v$  The size limitations depend on values of parameters *storev* and *side* as described in the following table:

	<i>storev</i> = C	<i>storev</i> = R
Column major	$\max(1, ldv * k)$	$\max(1, ldv * n)$
Row major	$\max(1, ldv * n)$	$\max(1, ldv * k)$

The matrix  $v$ . See *Application Notes* below.

$ldv$  The leading dimension of the array  $v$ .

If *storev* = 'C',  $ldv \geq \max(1, n)$  for column major and  $ldv \geq \max(1, k)$  for row major;

if *storev* = 'R',  $ldv \geq k$  for column major and  $ldv \geq \max(1, n)$  for row major.

$\tau$  Array, size ( $k$ ).  $\tau[i-1]$  must contain the scalar factor of the elementary reflector  $H(i)$ .

$ldt$  The leading dimension of the output array  $t$ .  $ldt \geq k$ .

## Output Parameters

$t$  Array, size  $ldt * k$ . The  $k$ -by- $k$  triangular factor  $T$  of the block reflector. If *direct* = 'F',  $T$  is upper triangular; if *direct* = 'B',  $T$  is lower triangular. The rest of the array is not used.

$v$  The matrix  $V$ .

## Application Notes

The shape of the matrix  $V$  and the storage of the vectors which define the  $H(i)$  is best illustrated by the following example with  $n = 5$  and  $k = 3$ . The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

*direct* = 'F' and *storev* = 'C':      *direct* = 'F' and *storev* = 'R':

$$\begin{bmatrix} 1 & & & & \\ v_1 & 1 & & & \\ v_1 & v_2 & 1 & & \\ v_1 & v_2 & v_3 & & \\ v_1 & v_2 & v_3 & & \end{bmatrix}$$

$$\begin{bmatrix} 1 & v_1 & v_1 & v_1 & v_1 \\ & 1 & v_2 & v_2 & v_2 \\ & & 1 & v_3 & v_3 \end{bmatrix}$$

`direct = 'B' and storev = 'C':`      `direct = 'B' and storev = 'R':`

$$\begin{bmatrix} v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ 1 & v_2 & v_3 \\ & 1 & v_3 \\ & & 1 \end{bmatrix}$$

$$\begin{bmatrix} v_1 & v_1 & 1 & & \\ v_2 & v_2 & v_2 & 1 & \\ v_3 & v_3 & v_3 & v_3 & 1 \end{bmatrix}$$

## ?larfx

Applies an elementary reflector to a general rectangular matrix, with loop unrolling when the reflector has order less than or equal to 10.

### Syntax

```
lapack_int LAPACKE_slarfx (int matrix_layout , char side , lapack_int m , lapack_int n , const float * v , float tau , float * c , lapack_int ldc , float * work );
```

```
lapack_int LAPACKE_dlarfx (int matrix_layout , char side , lapack_int m , lapack_int n , const double * v , double tau , double * c , lapack_int ldc , double * work );
```

```
lapack_int LAPACKE_clarfx (int matrix_layout , char side , lapack_int m , lapack_int n , const lapack_complex_float * v , lapack_complex_float tau , lapack_complex_float * c , lapack_int ldc , lapack_complex_float * work );
```

```
lapack_int LAPACKE_zlarfx (int matrix_layout , char side , lapack_int m , lapack_int n , const lapack_complex_double * v , lapack_complex_double tau , lapack_complex_double * c , lapack_int ldc , lapack_complex_double * work );
```

### Include Files

- mkl.h

### Description

The routine ?larfx applies a real/complex elementary reflector  $H$  to a real/complex  $m$ -by- $n$  matrix  $C$ , from either the left or the right.

$H$  is represented in the following forms:

- $H = I - \tau * v * v^T$ , where  $\tau$  is a real scalar and  $v$  is a real vector.
- $H = I - \tau * v * v^H$ , where  $\tau$  is a complex scalar and  $v$  is a complex vector.

If  $\tau = 0$ , then  $H$  is taken to be the unit matrix.

### Input Parameters

A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

`side`                                      If `side = 'L'`: form  $H * C$   
     If `side = 'R'`: form  $C * H$ .

<i>m</i>	The number of rows of the matrix <i>C</i> .
<i>n</i>	The number of columns of the matrix <i>C</i> .
<i>v</i>	Array, size ( <i>m</i> ) if <i>side</i> = 'L' or ( <i>n</i> ) if <i>side</i> = 'R'. The vector <i>v</i> in the representation of <i>H</i> .
<i>tau</i>	The value <i>tau</i> in the representation of <i>H</i> .
<i>c</i>	Array, size at least $\max(1, ldc*n)$ for column major layout and $\max(1, ldc*m)$ for row major layout. On entry, the <i>m</i> -by- <i>n</i> matrix <i>c</i> .
<i>ldc</i>	The leading dimension of the array <i>c</i> . $lda \geq (1,m)$ .
<i>work</i>	Workspace array, size ( <i>n</i> ) if <i>side</i> = 'L' or ( <i>m</i> ) if <i>side</i> = 'R'. <i>work</i> is not referenced if <i>H</i> has order < 11.

## Output Parameters

<i>c</i>	On exit, <i>c</i> is overwritten by the matrix $H*C$ if <i>side</i> = 'L', or $C*H$ if <i>side</i> = 'R'.
----------	---

## ?large

*Pre- and post-multiplies a real general matrix with a random orthogonal matrix.*

## Syntax

```
void slarge (lapack_int *n, float *a, lapack_int *lda, lapack_int *iseed, float * work, lapack_int *info);
```

```
void dlarge (lapack_int *n, double *a, lapack_int *lda, lapack_int *iseed, double * work, lapack_int *info);
```

```
void clarge (lapack_int *n, lapack_complex *a, lapack_int *lda, lapack_int *iseed, lapack_complex * work, lapack_int *info);
```

```
void zlarge (lapack_int *n, lapack_complex_double *a, lapack_int *lda, lapack_int *iseed, lapack_complex_double * work, lapack_int *info);
```

## Include Files

- mkl.h

## Description

The routine ?large pre- and post-multiplies a general *n*-by-*n* matrix *A* with a random orthogonal or unitary matrix:  $A = U*D*U^T$ .

## Input Parameters

<i>n</i>	The order of the matrix <i>A</i> . $n \geq 0$
<i>a</i>	Array, size <i>lda</i> by <i>n</i> . On entry, the original <i>n</i> -by- <i>n</i> matrix <i>A</i> .
<i>lda</i>	The leading dimension of the array <i>a</i> . $lda \geq n$ .
<i>iseed</i>	Array, size 4. On entry, the seed of the random number generator. The array elements must be between 0 and 4095, and <i>iseed</i> [3] must be odd.
<i>work</i>	Workspace array, size $2*n$ .

## Output Parameters

<i>a</i>	On exit, <i>A</i> is overwritten by $U*A*U'$ for some random orthogonal matrix <i>U</i> .
<i>iseed</i>	On exit, the seed is updated.
<i>info</i>	If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, the <i>i</i> -th parameter had an illegal value.

## ?larnd

Returns a random real number from a uniform or normal distribution.

## Syntax

```
float slarnd (lapack_int *idist, lapack_int *iseed);
double dlarnd (lapack_int *idist, lapack_int *iseed);
```

The data types for complex variations depend on whether or not the application links with Gnu Fortran (gfortran) libraries.

For non-gfortran (libmkl\_intel\_\*) interface libraries:

```
void clarnd (lapack_complex_float *res, lapack_int *idist, lapack_int *iseed);
void zlarnd (lapack_complex_double *res, lapack_int *idist, lapack_int *iseed);
```

For gfortran (libmkl\_gf\_\*) interface libraries:

```
lapack_complex_float clarnd (lapack_int *idist, lapack_int *iseed);
lapack_complex_double zlarnd (lapack_int *idist, lapack_int *iseed);
```

To understand the difference between the non-gfortran and gfortran interfaces and when to use each of them, see Dynamic Libraries in the lib/intel64 Directory in the *oneAPI Math Kernel Library Developer Guide*.

## Include Files

- mkl.h

## Description

The routine ?larnd returns a random number from a uniform or normal distribution.

## Input Parameters

<i>idist</i>	<p>Specifies the distribution of the random numbers. For <code>slarnv</code> and <code>dlarnv</code>:</p> <ul style="list-style-type: none"> <li>= 1: uniform (0,1)</li> <li>= 2: uniform (-1,1)</li> <li>= 3: normal (0,1).</li> </ul> <p>For <code>clarnd</code> and <code>zlanrd</code>:</p> <ul style="list-style-type: none"> <li>= 1: real and imaginary parts each uniform (0,1)</li> <li>= 2: real and imaginary parts each uniform (-1,1)</li> <li>= 3: real and imaginary parts each normal (0,1)</li> <li>= 4: uniformly distributed on the disc <math>\text{abs}(z) \leq 1</math></li> <li>= 5: uniformly distributed on the circle <math>\text{abs}(z) = 1</math></li> </ul>
<i>iseed</i>	<p>Array, size 4.</p> <p>On entry, the seed of the random number generator. The array elements must be between 0 and 4095, and <code>iseed[3]</code> must be odd.</p>

## Output Parameters

<i>iseed</i>	On exit, the seed is updated.
--------------	-------------------------------

## Return Values

The function returns a random number (for complex variations `libmkl_gf_*` interface layer/libraries return the result as the parameter `res`).

## ?larnv

Returns a vector of random numbers from a uniform or normal distribution.

## Syntax

```
lapack_int LAPACKE_slarnv (lapack_int idist , lapack_int * iseed , lapack_int n , float * x );
```

```
lapack_int LAPACKE_dlarnv (lapack_int idist , lapack_int * iseed , lapack_int n , double * x );
```

```
lapack_int LAPACKE_clarnv (lapack_int idist , lapack_int * iseed , lapack_int n , lapack_complex_float * x );
```

```
lapack_int LAPACKE_zlarnv (lapack_int idist , lapack_int * iseed , lapack_int n , lapack_complex_double * x );
```

## Include Files

- `mkl.h`

## Description

The routine `?larnv` returns a vector of  $n$  random real/complex numbers from a uniform or normal distribution.

This routine calls the auxiliary routine `?laruv` to generate random real numbers from a uniform (0,1) distribution, in batches of up to 128 using vectorisable code. The Box-Muller method is used to transform numbers from a uniform to a normal distribution.

### Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<code>idist</code>	Specifies the distribution of the random numbers: for <code>slarnv</code> and <code>dlarnv</code> : = 1: uniform (0,1) = 2: uniform (-1,1) = 3: normal (0,1). for <code>clarv</code> and <code>zlarv</code> : = 1: real and imaginary parts each uniform (0,1) = 2: real and imaginary parts each uniform (-1,1) = 3: real and imaginary parts each normal (0,1) = 4: uniformly distributed on the disc $\text{abs}(z) < 1$ = 5: uniformly distributed on the circle $\text{abs}(z) = 1$
<code>iseed</code>	Array, size (4). On entry, the seed of the random number generator; the array elements must be between 0 and 4095, and <code>iseed(4)</code> must be odd.
<code>n</code>	The number of random numbers to be generated.

### Output Parameters

<code>x</code>	Array, size ( <code>n</code> ). The generated random numbers.
<code>iseed</code>	On exit, the seed is updated.

### Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful.

### ?laror

*Pre- or post-multiplies an m-by-n matrix by a random orthogonal/unitary matrix.*

### Syntax

```
void slaror (char *side, char *init, lapack_int *m, lapack_int *n, float *a, lapack_int
*lda, lapack_int *iseed, float *x, lapack_int *info);
void dlaror (char *side, char *init, lapack_int *m, lapack_int *n, double *a, lapack_int
*lda, lapack_int *iseed, double *x, lapack_int *info);
void claror (char *side, char *init, lapack_int *m, lapack_int *n, lapack_complex *a,
lapack_int *lda, lapack_int *iseed, lapack_complex *x, lapack_int *info);
```

```
void zlaror (char *side, char *init, lapack_int *m, lapack_int *n,
lapack_complex_double *a, lapack_int *lda, lapack_int *iseed, lapack_complex_double *x,
lapack_int *info);
```

## Include Files

- mkl.h

## Description

The routine `?laror` pre- or post-multiplies an  $m$ -by- $n$  matrix  $A$  by a random orthogonal or unitary matrix  $U$ , overwriting  $A$ .  $A$  may optionally be initialized to the identity matrix before multiplying by  $U$ .  $U$  is generated using the method of G.W. Stewart (SIAM J. Numer. Anal. 17, 1980, 403-409).

## Input Parameters

<i>side</i>	<p>Specifies whether <math>A</math> is multiplied by <math>U</math> on the left or right.</p> <p>for <code>slaror</code> and <code>dlaror</code>:</p> <p>If <i>side</i> = 'L', multiply <math>A</math> on the left (premultiply) by <math>U</math>.</p> <p>If <i>side</i> = 'R', multiply <math>A</math> on the right (postmultiply) by <math>U^T</math>.</p> <p>If <i>side</i> = 'C' or 'T', multiply <math>A</math> on the left by <math>U</math> and the right by <math>U^T</math>.</p> <p>for <code>claror</code> and <code>zlaror</code>:</p> <p>If <i>side</i> = 'L', multiply <math>A</math> on the left (premultiply) by <math>U</math>.</p> <p>If <i>side</i> = 'R', multiply <math>A</math> on the right (postmultiply) by <math>UC^&gt;</math>.</p> <p>If <i>side</i> = 'C', multiply <math>A</math> on the left by <math>U</math> and the right by <math>UC^&gt;</math>.</p> <p>If <i>side</i> = 'T', multiply <math>A</math> on the left by <math>U</math> and the right by <math>U^T</math>.</p>
<i>init</i>	<p>Specifies whether or not <math>a</math> should be initialized to the identity matrix.</p> <p>If <i>init</i> = 'I', initialize <math>a</math> to (a section of) the identity matrix before applying <math>U</math>.</p> <p>If <i>init</i> = 'N', no initialization. Apply <math>U</math> to the input matrix <math>A</math>.</p> <p><i>init</i> = 'I' generates square or rectangular orthogonal matrices:</p> <p>For <math>m = n</math> and <i>side</i> = 'L' or 'R', the rows and the columns are orthogonal to each other.</p> <p>For rectangular matrices where <math>m &lt; n</math>:</p> <ul style="list-style-type: none"> <li>• If <i>side</i> = 'R', <code>?laror</code> produces a dense matrix in which rows are orthogonal and columns are not.</li> <li>• If <i>side</i> = 'L', <code>?laror</code> produces a matrix in which rows are orthogonal, first <math>m</math> columns are orthogonal, and remaining columns are zero.</li> </ul> <p>For rectangular matrices where <math>m &gt; n</math>:</p> <ul style="list-style-type: none"> <li>• If <i>side</i> = 'L', <code>?laror</code> produces a dense matrix in which columns are orthogonal and rows are not.</li> <li>• If <i>side</i> = 'R', <code>?laror</code> produces a matrix in which columns are orthogonal, first <math>m</math> rows are orthogonal, and remaining rows are zero.</li> </ul>
<i>m</i>	The number of rows of $A$ .

$n$	The number of columns of $A$ .
$a$	Array, size $lda$ by $n$ .
$lda$	The leading dimension of the array $a$ . $lda \geq \max(1, m)$ .
$iseed$	Array, size (4). On entry, specifies the seed of the random number generator. The array elements must be between 0 and 4095; if not they are reduced mod 4096. Also, $iseed[3]$ must be odd.
$x$	Workspace array, size $(3 * \max(m, n))$ .

Value of $side$	Length of workspace
'L'	$2 * m + n$
'R'	$2 * n + m$
'C' or 'T'	$3 * n$

## Output Parameters

$a$	On exit, overwritten by $UA$ ( if $side = 'L'$ ), by $AU$ ( if $side = 'R'$ ), by $UAU^T$ ( if $side = 'C'$ or $'T'$ ).
$iseed$	The values of $iseed$ are changed on exit, and can be used in the next call to continue the same random number sequence.
$info$	Array, size (4). For <code>slaror</code> and <code>dlaror</code> : If $info = 0$ , the execution is successful. If $info < 0$ , the $i$ -th parameter had an illegal value. If $info = 1$ , the random numbers generated by <code>?laror</code> are bad. For <code>claror</code> and <code>zlaror</code> : If $info = 0$ , the execution is successful. If $info = -1$ , $side$ is not 'L', 'R', 'C', or 'T'. If $info = -3$ , if $m$ is negative. If $info = -4$ , if $m$ is negative or if $side$ is 'C' or 'T' and $n$ is not equal to $m$ . If $info = -6$ , if $lda$ is less than $m$ .

## ?larot

Applies a Givens rotation to two adjacent rows or columns.

---

## Syntax

```
void slarot (lapack_logical *lrows, lapack_logical *ileft, lapack_logical *iright,
lapack_int *nl, float *c, float *s, float *a, lapack_int *lda, float *xleft, float
*xright);
```

```
void dlarot (lapack_logical *lrows, lapack_logical *ileft, lapack_logical *iright,
lapack_int *nl, double *c, double *s, double *a, lapack_int *lda, double *xleft, double
*xright);
```

```
void clarot (lapack_logical *lrows, lapack_logical *ileft, lapack_logical *iright,
lapack_int *nl, lapack_complex *c, lapack_complex *s, lapack_complex *a, lapack_int
*lda, lapack_complex *xleft, lapack_complex *xright);
```

```
void zlarot (lapack_logical *lrows, lapack_logical *ileft, lapack_logical *iright,
lapack_int *nl, lapack_complex_double *c, lapack_complex_double *s,
lapack_complex_double *a, lapack_int *lda, lapack_complex_double *xleft,
lapack_complex_double *xright);
```

## Include Files

- mkl.h

## Description

The routine ?larot applies a Givens rotation to two adjacent rows or columns, where one element of the first or last column or row is stored in some format other than GE so that elements of the matrix may be used or modified for which no array element is provided.

One example is a symmetric matrix in SB format (bandwidth = 4), for which *uplo* = 'L'. Two adjacent rows will have the format:

```
row j :      C > C > C > C > C > . . . .
row j + 1 :  C > C > C > C > C > . . . .
```

'\*' indicates elements for which storage is provided.

'.' indicates elements for which no storage is provided, but are not necessarily zero; their values are determined by symmetry.

' ' indicates elements which are required to be zero, and have no storage provided.

Those columns which have two '\*' entries can be handled by *srot* (for *slarot* and *clarot*), or by *drot* (for *dlarot* and *zlarot*).

Those columns which have no '\*' entries can be ignored, since as long as the Givens rotations are carefully applied to preserve symmetry, their values are determined.

Those columns which have one '\*' have to be handled separately, by using separate variables *p* and *q* :

```
row j :      C > C > C > C > C > p . . . .
row j + 1 :  q C > C > C > C > C > . . . .
```

If element *p* is set correctly, ?larot rotates the column and sets *p* to its new value. The next call to ?larot rotates columns *j* and *j + 1*, and restore symmetry. The element *q* is zero at the beginning, and non-zero after the rotation. Later, rotations would presumably be chosen to zero *q* out.

Typical Calling Sequences: rotating the *i*-th and (*i + 1*)-st rows.

## Input Parameters

<i>lrows</i>	<p>If <i>lrows</i> = 1, <i>?larot</i> rotates two rows.</p> <p>If <i>lrows</i> = 0, <i>?larot</i> rotates two columns.</p>
<i>lleft</i>	<p>If <i>lleft</i> = 1, <i>xleft</i> is used instead of the corresponding element of <i>a</i> for the first element in the second row (if <i>lrows</i> = 0) or column (if <i>lrows</i>=1).</p> <p>If <i>lleft</i> = 0, the corresponding element of <i>a</i> is used.</p>
<i>lright</i>	<p>If <i>lleft</i> = 1, <i>xright</i> is used instead of the corresponding element of <i>a</i> for the first element in the second row (if <i>lrows</i> = 0) or column (if <i>lrows</i>=1).</p> <p>If <i>lright</i> = 0, the corresponding element of <i>a</i> is used.</p>
<i>nl</i>	<p>The length of the rows (if <i>lrows</i>=1) or columns (if <i>lrows</i>=1) to be rotated.</p> <p>If <i>xleft</i> or <i>xright</i> are used, the columns or rows they are in should be included in <i>nl</i>, e.g., if <i>lleft</i> = <i>lright</i> = 1, then <i>nl</i> must be at least 2.</p> <p>The number of rows or columns to be rotated exclusive of those involving <i>xleft</i> and/or <i>xright</i> may not be negative, i.e., <i>nl</i> minus how many of <i>lleft</i> and <i>lright</i> are 1 must be at least zero; if not, <i>xerbla</i> is called.</p>
<i>c, s</i>	<p>Specify the Givens rotation to be applied.</p> <p>If <i>lrows</i> = 1, then the matrix</p> $\begin{bmatrix} c & s \\ -s & c \end{bmatrix}$ <p>is applied from the left.</p> <p>If <i>lrows</i> = 0, then the transpose thereof is applied from the right.</p>
<i>a</i>	<p>The array containing the rows or columns to be rotated. The first element of <i>a</i> should be the upper left element to be rotated.</p>
<i>lda</i>	<p>The "effective" leading dimension of <i>a</i>.</p> <p>If <i>a</i> contains a matrix stored in GE or SY format, then this is just the leading dimension of <i>A</i>.</p> <p>If <i>a</i> contains a matrix stored in band (GB or SB) format, then this should be one less than the leading dimension used in the calling routine. Thus, if <i>a</i> in <i>?larot</i> is of size <i>lda</i>*<i>n</i>, then <i>a</i>[(<i>j</i> - 1)*<i>lda</i>] would be the <i>j</i>-th element in the first of the two rows to be rotated, and <i>a</i>[(<i>j</i> - 1)*<i>lda</i> + 1] would be the <i>j</i>-th in the second, regardless of how the array may be stored in the calling routine. <i>a</i> cannot be dimensioned, because for band format the row number may exceed <i>lda</i>, which is not legal FORTRAN.</p> <p>If <i>lrows</i> = 1, then <i>lda</i> must be at least 1, otherwise it must be at least <i>nl</i> minus the number of 1 values in <i>xleft</i> and <i>xright</i>.</p>
<i>xleft</i>	<p>If <i>lrows</i> = 1, <i>xleft</i> is used and modified instead of <i>a</i>[1] (if <i>lrows</i> = 1) or <i>a</i>[<i>lda</i> + 1] (if <i>lrows</i> = 0).</p>

*xright* If *lright* = 1, *xright* is used and modified instead of  $a[(nl - 1)*lda]$  (if *lrows* = 1) or  $a[nl - 1]$  (if *lrows* = 0).

## Output Parameters

*a* On exit, modified array A.

## ?lartgp

*Generates a plane rotation.*

---

## Syntax

```
lapack_int LAPACKE_slartgp (float f, float g, float* cs, float* sn, float* r);
lapack_int LAPACKE_dlartgp (double f, double g, double* cs, double* sn, double* r);
```

## Include Files

- mkl.h

## Description

The routine generates a plane rotation so that

$$\begin{bmatrix} cs & sn \\ -sn & cs \end{bmatrix} \cdot \begin{bmatrix} f \\ g \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix}$$

where  $cs^2 + sn^2 = 1$

This is a slower, more accurate version of the BLAS Level 1 routine `?rotg`, except for the following differences:

- *f* and *g* are unchanged on return.
- If *g*=0, then  $cs=(+/-)1$  and  $sn=0$ .
- If *f*=0 and *g*≠ 0, then  $cs=0$  and  $sn=(+/-)1$ .

The sign is chosen so that  $r \geq 0$ .

## Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

*f, g* The first and second component of the vector to be rotated.

## Output Parameters

*cs* The cosine of the rotation.

*sn* The sine of the rotation.

$r$  The nonzero component of the rotated vector.

## Return Values

If  $info = 0$ , the execution is successful.

If  $info = -1$ ,  $f$  is NaN.

If  $info = -2$ ,  $g$  is NaN.

## ?lartgs

*Generates a plane rotation designed to introduce a bulge in implicit QR iteration for the bidiagonal SVD problem.*

## Syntax

```
lapack_int LAPACKE_slartgs (floatx, floaty, floatsigma, float* cs, float* sn);
```

```
lapack_int LAPACKE_dlartgs (doublex, doubley, doublesigma, double* cs, double* sn);
```

## Include Files

- `mkl.h`

## Description

The routine generates a plane rotation designed to introduce a bulge in Golub-Reinsch-style implicit QR iteration for the bidiagonal SVD problem.  $x$  and  $y$  are the top-row entries, and  $sigma$  is the shift. The computed  $cs$  and  $sn$  define a plane rotation that satisfies the following:

$$\begin{bmatrix} cs & sn \\ -sn & cs \end{bmatrix} \cdot \begin{bmatrix} x^2 - sigma \\ x * y \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix}$$

with  $r$  nonnegative.

If  $x^2 - sigma$  and  $x * y$  are 0, the rotation is by  $\pi/2$

## Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

$x, y$  The (1,1) and (1,2) entries of an upper bidiagonal matrix, respectively.

$sigma$  Shift

## Output Parameters

$cs$  The cosine of the rotation.

*sn* The sine of the rotation.

## Return Values

If *info* = 0, the execution is successful.

If *info* = - 1, *x* is NaN.

If *info* = - 2, *y* is NaN.

If *info* = - 3, *sigma* is NaN.

```

```
lapack_int LAPACKE_clascl (int matrix_layout, char type, lapack_int kl, lapack_int ku,
float cfrom, float cto, lapack_int m, lapack_int n, lapack_complex_float * a,
lapack_int lda);
```

```
lapack_int LAPACKE_zlascl (int matrix_layout, char type, lapack_int kl, lapack_int ku,
double cfrom, double cto, lapack_int m, lapack_int n, lapack_complex_double * a,
lapack_int lda);
```

## Include Files

- mkl.h

## Description

The routine `?lascl` multiplies the *m*-by-*n* real/complex matrix *A* by the real scalar  $c_{to}/c_{from}$ . The operation is performed without over/underflow as long as the final result  $c_{to} * A(i, j) / c_{from}$  does not over/underflow.

*type* specifies that *A* may be full, upper triangular, lower triangular, upper Hessenberg, or banded.

## Input Parameters

*matrix\_layout* Specifies whether matrix storage layout is row major (LAPACK\_ROW\_MAJOR) or column major (LAPACK\_COL\_MAJOR).

*type* This parameter specifies the storage type of the input matrix.

= 'G': *A* is a full matrix.

= 'L': *A* is a lower triangular matrix.

= 'U': *A* is an upper triangular matrix.

= 'H': *A* is an upper Hessenberg matrix.

= 'B':  $A$  is a symmetric band matrix with lower bandwidth  $kl$  and upper bandwidth  $ku$  and with the only the lower half stored

= 'Q':  $A$  is a symmetric band matrix with lower bandwidth  $kl$  and upper bandwidth  $ku$  and with the only the upper half stored.

= 'Z':  $A$  is a band matrix with lower bandwidth  $kl$  and upper bandwidth  $ku$ . See description of the `?gbtrf` function for storage details.

<code>kl</code>	The lower bandwidth of $A$ . Referenced only if <code>type = 'B', 'Q' or 'Z'</code> .
<code>ku</code>	The upper bandwidth of $A$ . Referenced only if <code>type = 'B', 'Q' or 'Z'</code> .
<code>cfrom, cto</code>	The matrix $A$ is multiplied by <code>cto/cfrom</code> . $A(i, j)$ is computed without over/underflow if the final result $cto * A(i, j) / cfrom$ can be represented without over/underflow. <code>cfrom</code> must be nonzero.
<code>m</code>	The number of rows of the matrix $A$ . $m \geq 0$ .
<code>n</code>	The number of columns of the matrix $A$ . $n \geq 0$ .
<code>a</code>	Array, size $(lda * n)$ . The matrix to be multiplied by <code>cto/cfrom</code> . See <code>type</code> for the storage type.
<code>lda</code>	The leading dimension of the array $a$ . $lda \geq \max(1, m)$ .

## Output Parameters

<code>a</code>	The multiplied matrix $A$ .
<code>info</code>	If <code>info = 0</code> - successful exit If <code>info = -i &lt; 0</code> , the $i$ -th argument had an illegal value.

## ?lasd0

*Computes the singular values of a real upper bidiagonal  $n$ -by- $m$  matrix  $B$  with diagonal  $d$  and off-diagonal  $e$ . Used by `?bdsdc`.*

## Syntax

```
void slasd0( lapack_int *n, lapack_int *sqre, float *d, float *e, float *u, lapack_int *ldu, float *vt, lapack_int *ldvt, lapack_int *smlsiz, lapack_int *iwork, float *work, lapack_int *info );
```

```
void dlasd0( lapack_int *n, lapack_int *sqre, double *d, double *e, double *u, lapack_int *ldu, double *vt, lapack_int *ldvt, lapack_int *smlsiz, lapack_int *iwork, double *work, lapack_int *info );
```

## Include Files

- `mk1.h`

## Description

Using a divide and conquer approach, the routine `?lasd0` computes the singular value decomposition (SVD) of a real upper bidiagonal  $n$ -by- $m$  matrix  $B$  with diagonal  $d$  and offdiagonal  $e$ , where  $m = n + sqre$ .

The algorithm computes orthogonal matrices  $U$  and  $VT$  such that  $B = U^* S^* VT$ . The singular values  $S$  are overwritten on  $d$ .

The related subroutine `?lasda` computes only the singular values, and optionally, the singular vectors in compact form.

### Input Parameters

<code>n</code>	On entry, the row dimension of the upper bidiagonal matrix. This is also the dimension of the main diagonal array $d$ .
<code>sqre</code>	Specifies the column dimension of the bidiagonal matrix. If <code>sqre = 0</code> : the bidiagonal matrix has column dimension $m = n$ . If <code>sqre = 1</code> : the bidiagonal matrix has column dimension $m = n+1$ .
<code>d</code>	Array, DIMENSION ( $n$ ). On entry, $d$ contains the main diagonal of the bidiagonal matrix.
<code>e</code>	Array, DIMENSION ( $m-1$ ). Contains the subdiagonal entries of the bidiagonal matrix. On exit, $e$ is destroyed.
<code>ldu</code>	On entry, leading dimension of the output array $u$ .
<code>ldvt</code>	On entry, leading dimension of the output array $vt$ .
<code>smlsiz</code>	On entry, maximum size of the subproblems at the bottom of the computation tree.
<code>iwork</code>	Workspace array, dimension must be at least $(8n)$ .
<code>work</code>	Workspace array, dimension must be at least $(3m^2+2m)$ .

### Output Parameters

<code>d</code>	On exit $d$ , If <code>info = 0</code> , contains singular values of the bidiagonal matrix.
<code>u</code>	Array, DIMENSION at least $(ldu, n)$ . On exit, $u$ contains the left singular vectors.
<code>vt</code>	Array, DIMENSION at least $(ldvt, m)$ . On exit, $vt^T$ contains the right singular vectors.
<code>info</code>	If <code>info = 0</code> : successful exit. If <code>info = -i &lt; 0</code> , the $i$ -th argument had an illegal value. If <code>info = 1</code> , a singular value did not converge.

### ?lasd1

Computes the SVD of an upper bidiagonal matrix  $B$  of the specified size. Used by `?bdsdc`.

## Syntax

```
void slasd1( lapack_int *nl, lapack_int *nr, lapack_int *sqre, float *d, float *alpha,
float *beta, float *u, lapack_int *ldu, float *vt, lapack_int *ldvt, lapack_int *idxq,
lapack_int *iwork, float *work, lapack_int *info );
```

```
void dlasd1( lapack_int *nl, lapack_int *nr, lapack_int *sqre, double *d, double *alpha,
double *beta, double *u, lapack_int *ldu, double *vt, lapack_int *ldvt, lapack_int
*idxq, lapack_int *iwork, double *work, lapack_int *info );
```

## Include Files

- mkl.h

## Description

The routine computes the SVD of an upper bidiagonal  $n$ -by- $m$  matrix  $B$ , where  $n = nl + nr + 1$  and  $m = n + sqre$ .

The routine `?lasd1` is called from `?lasd0`.

A related subroutine `?lasd7` handles the case in which the singular values (and the singular vectors in factored form) are desired.

`?lasd1` computes the SVD as follows:

$$VT = U(in) * \begin{bmatrix} D1(in) & 0 & 0 & 0 \\ Z1^T & a & Z2^T & b \\ 0 & 0 & D2(in) & 0 \end{bmatrix} * VT(in)$$

$= U(out) * (D(out) \ 0) * VT(out)$

where  $Z^T = (Z1^T a Z2^T b) = u^T * VT^T$ , and  $u$  is a vector of dimension  $m$  with  $alpha$  and  $beta$  in the  $nl+1$  and  $nl+2$ -th entries and zeros elsewhere; and the entry  $b$  is empty if  $sqre = 0$ .

The left singular vectors of the original matrix are stored in  $u$ , and the transpose of the right singular vectors are stored in  $vt$ , and the singular values are in  $d$ . The algorithm consists of three stages:

1. The first stage consists of deflating the size of the problem when there are multiple singular values or when there are zeros in the  $Z$  vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine `?lasd2`.
2. The second stage consists of calculating the updated singular values. This is done by finding the square roots of the roots of the secular equation via the routine `?lasd4` (as called by `?lasd3`). This routine also calculates the singular vectors of the current problem.
3. The final stage consists of computing the updated singular vectors directly using the updated singular values. The singular vectors for the current problem are multiplied with the singular vectors from the overall problem.

## Input Parameters

$nl$  The row dimension of the upper block.

$nl \geq 1$ .

<i>nr</i>	The row dimension of the lower block. $nr \geq 1$ .
<i>sqre</i>	If $sqre = 0$ : the lower block is an $nr$ -by- $nr$ square matrix. If $sqre = 1$ : the lower block is an $nr$ -by- $(nr+1)$ rectangular matrix. The bidiagonal matrix has row dimension $n = nl + nr + 1$ , and column dimension $m = n + sqre$ .
<i>d</i>	Array, DIMENSION $(nl+nr+1)$ . $n = nl+nr+1$ . On entry $d(1:nl, 1:nl)$ contains the singular values of the upper block; and $d(nl+2:n)$ contains the singular values of the lower block.
<i>alpha</i>	Contains the diagonal element associated with the added row.
<i>beta</i>	Contains the off-diagonal element associated with the added row.
<i>u</i>	Array, DIMENSION $(ldu, n)$ . On entry $u(1:nl, 1:nl)$ contains the left singular vectors of the upper block; $u(nl+2:n, nl+2:n)$ contains the left singular vectors of the lower block.
<i>ldu</i>	The leading dimension of the array $U$ . $ldu \geq \max(1, n)$ .
<i>vt</i>	Array, DIMENSION $(ldvt, m)$ , where $m = n + sqre$ . On entry $vt(1:nl+1, 1:nl+1)^T$ contains the right singular vectors of the upper block; $vt(nl+2:m, nl+2:m)^T$ contains the right singular vectors of the lower block.
<i>ldvt</i>	The leading dimension of the array $vt$ . $ldvt \geq \max(1, M)$ .
<i>iwork</i>	Workspace array, DIMENSION $(4n)$ .
<i>work</i>	Workspace array, DIMENSION $(3m_2 + 2m)$ .

## Output Parameters

<i>d</i>	On exit $d(1:n)$ contains the singular values of the modified matrix.
<i>alpha</i>	On exit, the diagonal element associated with the added row deflated by $\max(\text{abs}(\text{alpha}), \text{abs}(\text{beta}), \text{abs}(\text{D(I)}))$ , $I = 1, n$ .
<i>beta</i>	On exit, the off-diagonal element associated with the added row deflated by $\max(\text{abs}(\text{alpha}), \text{abs}(\text{beta}), \text{abs}(\text{D(I)}))$ , $I = 1, n$ .
<i>u</i>	On exit $u$ contains the left singular vectors of the bidiagonal matrix.
<i>vt</i>	On exit $vt^T$ contains the right singular vectors of the bidiagonal matrix.
<i>idxq</i>	Array, DIMENSION $(n)$ . Contains the permutation which will reintegrate the subproblem just solved back into sorted order, that is, $d(\text{idxq}(i = 1, n))$ will be in ascending order.
<i>info</i>	If $info = 0$ : successful exit. If $info = -i < 0$ , the $i$ -th argument had an illegal value.

If *info* = 1, a singular value did not converge.

## ?lasd2

Merges the two sets of singular values together into a single sorted set. Used by ?bdsdc.

### Syntax

```
void slasd2( lapack_int *nl, lapack_int *nr, lapack_int *sqre, lapack_int *k, float *d,
float *z, float *alpha, float *beta, float *u, lapack_int *ldu, float *vt, lapack_int
*ldvt, float *dsigma, float *u2, lapack_int *ldu2, float *vt2, lapack_int *ldvt2,
lapack_int *idxp, lapack_int *idx, lapack_int *idxq, lapack_int *coltyp, lapack_int
*info );
```

```
void dlasd2( lapack_int *nl, lapack_int *nr, lapack_int *sqre, lapack_int *k, double *d,
double *z, double *alpha, double *beta, double *u, lapack_int *ldu, double *vt,
lapack_int *ldvt, double *dsigma, double *u2, lapack_int *ldu2, double *vt2, lapack_int
*ldvt2, lapack_int *idxp, lapack_int *idx, lapack_int *idxq, lapack_int *coltyp,
lapack_int *info );
```

### Include Files

- mkl.h

### Description

The routine ?lasd2 merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more singular values are close together or if there is a tiny entry in the Z vector. For each such occurrence the order of the related secular equation problem is reduced by one.

The routine ?lasd2 is called from ?lasd1.

### Input Parameters

<i>nl</i>	The row dimension of the upper block. $nl \geq 1$ .
<i>nr</i>	The row dimension of the lower block. $nr \geq 1$ .
<i>sqre</i>	If <i>sqre</i> = 0): the lower block is an <i>nr</i> -by- <i>nr</i> square matrix If <i>sqre</i> = 1): the lower block is an <i>nr</i> -by- $(nr+1)$ rectangular matrix. The bidiagonal matrix has $n = nl + nr + 1$ rows and $m = n + sqre \geq n$ columns.
<i>d</i>	Array, DIMENSION ( <i>n</i> ). On entry <i>d</i> contains the singular values of the two submatrices to be combined.
<i>alpha</i>	Contains the diagonal element associated with the added row.
<i>beta</i>	Contains the off-diagonal element associated with the added row.

<i>u</i>	Array, DIMENSION ( <i>ldu</i> , <i>n</i> ). On entry <i>u</i> contains the left singular vectors of two submatrices in the two square blocks with corners at (1,1), ( <i>nl</i> , <i>nl</i> ), and ( <i>nl</i> +2, <i>nl</i> +2), ( <i>n</i> , <i>n</i> ).
<i>ldu</i>	The leading dimension of the array <i>u</i> . <i>ldu</i> ≥ <i>n</i> .
<i>ldu2</i>	The leading dimension of the output array <i>u2</i> . <i>ldu2</i> ≥ <i>n</i> .
<i>vt</i>	Array, DIMENSION ( <i>ldvt</i> , <i>m</i> ). On entry, <i>vt</i> <sup>T</sup> contains the right singular vectors of two submatrices in the two square blocks with corners at (1,1), ( <i>nl</i> +1, <i>nl</i> +1), and ( <i>nl</i> +2, <i>nl</i> +2), ( <i>m</i> , <i>m</i> ).
<i>ldvt</i>	The leading dimension of the array <i>vt</i> . <i>ldvt</i> ≥ <i>m</i> .
<i>ldvt2</i>	The leading dimension of the output array <i>vt2</i> . <i>ldvt2</i> ≥ <i>m</i> .
<i>idxp</i>	Workspace array, DIMENSION ( <i>n</i> ). This will contain the permutation used to place deflated values of <i>D</i> at the end of the array. On output <i>idxp</i> (2: <i>k</i> ) points to the nondeflated <i>d</i> -values and <i>idxp</i> ( <i>k</i> +1: <i>n</i> ) points to the deflated singular values.
<i>idx</i>	Workspace array, DIMENSION ( <i>n</i> ). This will contain the permutation used to sort the contents of <i>d</i> into ascending order.
<i>coltyp</i>	Workspace array, DIMENSION ( <i>n</i> ). As workspace, this array contains a label that indicates which of the following types a column in the <i>u2</i> matrix or a row in the <i>vt2</i> matrix is: 1 : non-zero in the upper half only 2 : non-zero in the lower half only 3 : dense 4 : deflated.
<i>idxq</i>	Array, DIMENSION ( <i>n</i> ). This parameter contains the permutation that separately sorts the two sub-problems in <i>D</i> in the ascending order. Note that entries in the first half of this permutation must first be moved one position backwards and entries in the second half must have <i>nl</i> +1 added to their values.

## Output Parameters

<i>k</i>	Contains the dimension of the non-deflated matrix, This is the order of the related secular equation. $1 \leq k \leq n$ .
<i>d</i>	On exit <i>D</i> contains the trailing ( <i>n</i> - <i>k</i> ) updated singular values (those which were deflated) sorted into increasing order.
<i>u</i>	On exit <i>u</i> contains the trailing ( <i>n</i> - <i>k</i> ) updated left singular vectors (those which were deflated) in its last <i>n</i> - <i>k</i> columns.
<i>z</i>	Array, DIMENSION ( <i>n</i> ). On exit, <i>z</i> contains the updating row vector in the secular equation.
<i>dsigma</i>	Array, DIMENSION ( <i>n</i> ). Contains a copy of the diagonal elements ( <i>k</i> -1 singular values and one zero) in the secular equation.

<i>u2</i>	Array, DIMENSION ( <i>ldu2</i> , <i>n</i> ). Contains a copy of the first $k-1$ left singular vectors which will be used by <code>?lasd3</code> in a matrix multiply ( <code>?gemm</code> ) to solve for the new left singular vectors. <i>u2</i> is arranged into four blocks. The first block contains a column with 1 at $n1+1$ and zero everywhere else; the second block contains non-zero entries only at and above $n1$ ; the third contains non-zero entries only below $n1+1$ ; and the fourth is dense.
<i>vt</i>	On exit, $vt^T$ contains the trailing $(n-k)$ updated right singular vectors (those which were deflated) in its last $n-k$ columns. In case $sqre = 1$ , the last row of <i>vt</i> spans the right null space.
<i>vt2</i>	Array, DIMENSION ( <i>ldvt2</i> , <i>n</i> ). $vt2^T$ contains a copy of the first $k$ right singular vectors which will be used by <code>?lasd3</code> in a matrix multiply ( <code>?gemm</code> ) to solve for the new right singular vectors. <i>vt2</i> is arranged into three blocks. The first block contains a row that corresponds to the special 0 diagonal element in <i>sigma</i> ; the second block contains non-zeros only at and before $n1 + 1$ ; the third block contains non-zeros only at and after $n1 + 2$ .
<i>idxc</i>	Array, DIMENSION ( <i>n</i> ). This will contain the permutation used to arrange the columns of the deflated <i>u</i> matrix into three groups: the first group contains non-zero entries only at and above $n1$ , the second contains non-zero entries only below $n1+2$ , and the third is dense.
<i>coltyp</i>	On exit, it is an array of dimension 4, with <i>coltyp</i> ( <i>i</i> ) being the dimension of the <i>i</i> -th type columns.
<i>info</i>	If <i>info</i> = 0): successful exit If <i>info</i> = - <i>i</i> < 0, the <i>i</i> -th argument had an illegal value.

### ?lasd3

*Finds all square roots of the roots of the secular equation, as defined by the values in D and Z, and then updates the singular vectors by matrix multiplication. Used by ?bdsdc.*

### Syntax

```
void slasd3( lapack_int *nl, lapack_int *nr, lapack_int *sqre, lapack_int *k, float *d,
float *q, lapack_int *ldq, float *dsigma, float *u, lapack_int *ldu, float *u2,
lapack_int *ldu2, float *vt, lapack_int *ldvt, float *vt2, lapack_int *ldvt2,
lapack_int *idxc, lapack_int *ctot, float *z, lapack_int *info );

void dlasd3( lapack_int *nl, lapack_int *nr, lapack_int *sqre, lapack_int *k, double *d,
double *q, lapack_int *ldq, double *dsigma, double *u, lapack_int *ldu, double *u2,
lapack_int *ldu2, double *vt, lapack_int *ldvt, double *vt2, lapack_int *ldvt2,
lapack_int *idxc, lapack_int *ctot, double *z, lapack_int *info );
```

### Include Files

- mkl.h

### Description

The routine `?lasd3` finds all the square roots of the roots of the secular equation, as defined by the values in *D* and *Z*.

It makes the appropriate calls to `?lasd4` and then updates the singular vectors by matrix multiplication.

The routine `?lasd3` is called from `?lasd1`.

## Input Parameters

<code>n1</code>	The row dimension of the upper block. $n1 \geq 1$ .
<code>nr</code>	The row dimension of the lower block. $nr \geq 1$ .
<code>sqre</code>	If <code>sqre = 0</code> ): the lower block is an $nr$ -by- $nr$ square matrix. If <code>sqre = 1</code> ): the lower block is an $nr$ -by- $(nr+1)$ rectangular matrix. The bidiagonal matrix has $n = n1 + nr + 1$ rows and $m = n + sqre \geq n$ columns.
<code>k</code>	The size of the secular equation, $1 \leq k \leq n$ .
<code>q</code>	Workspace array, DIMENSION at least $(ldq, k)$ .
<code>ldq</code>	The leading dimension of the array <code>Q</code> . $ldq \geq k$ .
<code>dsigma</code>	Array, DIMENSION $(k)$ . The first $k$ elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.
<code>ldu</code>	The leading dimension of the array <code>u</code> . $ldu \geq n$ .
<code>u2</code>	Array, DIMENSION $(ldu2, n)$ . The first $k$ columns of this matrix contain the non-deflated left singular vectors for the split problem.
<code>ldu2</code>	The leading dimension of the array <code>u2</code> . $ldu2 \geq n$ .
<code>ldvt</code>	The leading dimension of the array <code>vt</code> . $ldvt \geq n$ .
<code>vt2</code>	Array, DIMENSION $(ldvt2, n)$ . The first $k$ columns of <code>vt2'</code> contain the non-deflated right singular vectors for the split problem.
<code>ldvt2</code>	The leading dimension of the array <code>vt2</code> . $ldvt2 \geq n$ .
<code>idxc</code>	Array, DIMENSION $(n)$ . The permutation used to arrange the columns of <code>u</code> (and rows of <code>vt</code> ) into three groups: the first group contains non-zero entries only at and above (or before) $n1 + 1$ ; the second contains non-zero entries only at and below (or after) $n1 + 2$ ; and the third is dense. The first column of <code>u</code> and the row of

$vt$  are treated separately, however. The rows of the singular vectors found by `?lasd4` must be likewise permuted before the matrix multiplies can take place.

`ctot` Array, DIMENSION (4). A count of the total number of the various types of columns in  $u$  (or rows in  $vt$ ), as described in `idxc`.

The fourth column type is any column which has been deflated.

`z` Array, DIMENSION ( $k$ ). The first  $k$  elements of this array contain the components of the deflation-adjusted updating row vector.

## Output Parameters

`d` Array, DIMENSION ( $k$ ). On exit the square roots of the roots of the secular equation, in ascending order.

`u` Array, DIMENSION ( $ldu, n$ ).

The last  $n - k$  columns of this matrix contain the deflated left singular vectors.

`vt` Array, DIMENSION ( $ldvt, m$ ).

The last  $m - k$  columns of  $vt'$  contain the deflated right singular vectors.

`vt2` Destroyed on exit.

`z` Destroyed on exit.

`info` If `info = 0`): successful exit.

If `info = -i < 0`, the  $i$ -th argument had an illegal value.

If `info = 1`, an singular value did not converge.

## Application Notes

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray XMP, Cray YMP, Cray C 90, or Cray 2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

## ?lasd4

*Computes the square root of the  $i$ -th updated eigenvalue of a positive symmetric rank-one modification to a positive diagonal matrix. Used by ?bdsdc.*

## Syntax

```
void slasd4( lapack_int *n, lapack_int *i, float *d, float *z, float *delta, float *rho,
float *sigma, float *work, lapack_int *info);
```

```
void dlasd4( lapack_int *n, lapack_int *i, double *d, double *z, double *delta, double
*rho, double *sigma, double *work, lapack_int *info);
```

## Include Files

- `mkl.h`

## Description

The routine computes the square root of the  $i$ -th updated eigenvalue of a positive symmetric rank-one modification to a positive diagonal matrix whose entries are given as the squares of the corresponding entries in the array  $d$ , and that  $0 \leq d(i) < d(j)$  for  $i < j$  and that  $\rho > 0$ . This is arranged by the calling routine, and is no loss in generality. The rank-one modified system is thus

$$\text{diag}(d) * \text{diag}(d) + \rho * Z * Z^T,$$

where the Euclidean norm of  $Z$  is equal to 1. The method consists of approximating the rational functions in the secular equation by simpler interpolating rational functions.

## Input Parameters

$n$	The length of all arrays.
$i$	The index of the eigenvalue to be computed. $1 \leq i \leq n$ .
$d$	Array, DIMENSION ( $n$ ). The original eigenvalues. They must be in order, $0 \leq d(i) < d(j)$ for $i < j$ .
$z$	Array, DIMENSION ( $n$ ). The components of the updating vector.
$\rho$	The scalar in the symmetric updating formula.
$work$	Workspace array, DIMENSION ( $n$ ). If $n \neq 1$ , $work$ contains $(d(j) + \sigma_i)$ in its $j$ -th component. If $n = 1$ , then $work(1) = 1$ .

## Output Parameters

$\delta$	Array, DIMENSION ( $n$ ). If $n \neq 1$ , $\delta$ contains $(d(j) - \sigma_i)$ in its $j$ -th component. If $n = 1$ , then $\delta(1) = 1$ . The vector $\delta$ contains the information necessary to construct the (singular) eigenvectors.
$\sigma$	The computed $\sigma_i$ , the $i$ -th updated eigenvalue.
$info$	= 0: successful exit > 0: If $info = 1$ , the updating process failed.

## ?lasd5

Computes the square root of the  $i$ -th eigenvalue of a positive symmetric rank-one modification of a 2-by-2 diagonal matrix. Used by ?bdsdc.

## Syntax

```
void slasd5( lapack_int *i, float *d, float *z, float *delta, float *rho, float *dsigma, float *work );
```

```
void dlasd5( lapack_int *i, double *d, double *z, double *delta, double *rho, double
*dsigma, double *work );
```

## Include Files

- mkl.h

## Description

The routine computes the square root of the  $i$ -th eigenvalue of a positive symmetric rank-one modification of a 2-by-2 diagonal matrix  $\text{diag}(d) * \text{diag}(d) + \rho * Z * Z^T$

The diagonal entries in the array  $d$  must satisfy  $0 \leq d(i) < d(j)$  for  $i < j$ ,  $\rho$  must be greater than 0, and that the Euclidean norm of the vector  $Z$  is equal to 1.

## Input Parameters

$i$	The index of the eigenvalue to be computed. $i = 1$ or $i = 2$ .
$d$	Array, dimension ( 2 ). The original eigenvalues, $0 \leq d(1) < d(2)$ .
$z$	Array, dimension ( 2 ). The components of the updating vector.
$\rho$	The scalar in the symmetric updating formula.
$work$	Workspace array, dimension ( 2 ). Contains $(d(j) + \sigma_i)$ in its $j$ -th component.

## Output Parameters

$\delta$	Array, dimension ( 2 ). Contains $(d(j) - \sigma_i)$ in its $j$ -th component. The vector $\delta$ contains the information necessary to construct the eigenvectors.
$\sigma_i$	The computed $\sigma_i$ , the $i$ -th updated eigenvalue.

## ?lasd6

*Computes the SVD of an updated upper bidiagonal matrix obtained by merging two smaller ones by appending a row. Used by ?bdsdc.*

## Syntax

```

## Description

The routine `?lasd6` computes the *SVD* of an updated upper bidiagonal matrix  $B$  obtained by merging two smaller ones by appending a row. This routine is used only for the problem which requires all singular values and optionally singular vector matrices in factored form.  $B$  is an  $n$ -by- $m$  matrix with  $n = n1 + nr + 1$  and  $m = n + sqre$ . A related subroutine, `?lasd1`, handles the case in which all singular values and singular vectors of the bidiagonal matrix are desired. `?lasd6` computes the *SVD* as follows:

$$B = U(in)^* \begin{bmatrix} D1(in) & 0 & 0 & 0 \\ Z1' & a & Z2' & b \\ 0 & 0 & D2(in) & 0 \end{bmatrix} * VT(in)$$

=  $U(out) * (D(out) * VT(out))$

where  $Z' = (Z1' \ aZ2' \ b) = u' * VT'$ , and  $u$  is a vector of dimension  $m$  with *alpha* and *beta* in the  $n/1+1$  and  $n/1+2$ -th entries and zeros elsewhere; and the entry  $b$  is empty if  $sqre = 0$ .

The singular values of  $B$  can be computed using  $D1$ ,  $D2$ , the first components of all the right singular vectors of the lower block, and the last components of all the right singular vectors of the upper block. These components are stored and updated in  $vf$  and  $vl$ , respectively, in `?lasd6`. Hence  $U$  and  $VT$  are not explicitly referenced.

The singular values are stored in  $D$ . The algorithm consists of two stages:

1. The first stage consists of deflating the size of the problem when there are multiple singular values or if there is a zero in the  $Z$  vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine `?lasd7`.
2. The second stage consists of calculating the updated singular values. This is done by finding the roots of the secular equation via the routine `?lasd4` (as called by `?lasd8`). This routine also updates  $vf$  and  $vl$  and computes the distances between the updated singular values and the old singular values. `?lasd6` is called from `?lasda`.

## Input Parameters

<i>icompg</i>	Specifies whether singular vectors are to be computed in factored form: = 0: Compute singular values only = 1: Compute singular vectors in factored form as well.
<i>n1</i>	The row dimension of the upper block. $n1 \geq 1$ .
<i>nr</i>	The row dimension of the lower block.

	$nr \geq 1$ .
<i>sqre</i>	<p>= 0: the lower block is an <math>nr</math>-by-<math>nr</math> square matrix.</p> <p>= 1: the lower block is an <math>nr</math>-by-<math>(nr+1)</math> rectangular matrix.</p> <p>The bidiagonal matrix has row dimension <math>n=nl+nr+1</math>, and column dimension <math>m = n + sqre</math>.</p>
<i>d</i>	Array, dimension ( $nl+nr+1$ ). On entry $d(1:nl,1:nl)$ contains the singular values of the upper block, and $d(nl+2:n)$ contains the singular values of the lower block.
<i>vf</i>	<p>Array, dimension ( <math>m</math> ).</p> <p>On entry, <math>vf(1:nl+1)</math> contains the first components of all right singular vectors of the upper block; and <math>vf(nl+2:m)</math> contains the first components of all right singular vectors of the lower block.</p>
<i>v1</i>	<p>Array, dimension ( <math>m</math> ).</p> <p>On entry, <math>v1(1:nl+1)</math> contains the last components of all right singular vectors of the upper block; and <math>v1(nl+2:m)</math> contains the last components of all right singular vectors of the lower block.</p>
<i>alpha</i>	Contains the diagonal element associated with the added row.
<i>beta</i>	Contains the off-diagonal element associated with the added row.
<i>ldgcol</i>	The leading dimension of the output array <i>givcol</i> , must be at least $n$ .
<i>ldgnum</i>	The leading dimension of the output arrays <i>givnum</i> and <i>poles</i> , must be at least $n$ .
<i>work</i>	Workspace array, dimension ( $4m$ ).
<i>iwork</i>	Workspace array, dimension ( $3n$ ).

## Output Parameters

<i>d</i>	On exit $d(1:n)$ contains the singular values of the modified matrix.
<i>vf</i>	On exit, <i>vf</i> contains the first components of all right singular vectors of the bidiagonal matrix.
<i>v1</i>	On exit, <i>v1</i> contains the last components of all right singular vectors of the bidiagonal matrix.
<i>alpha</i>	On exit, the diagonal element associated with the added row deflated by $\max(\text{abs}(\text{alpha}), \text{abs}(\text{beta}), \text{abs}(\text{D}(\text{I}))), I = 1, n$ .
<i>beta</i>	On exit, the off-diagonal element associated with the added row deflated by $\max(\text{abs}(\text{alpha}), \text{abs}(\text{beta}), \text{abs}(\text{D}(\text{I}))), I = 1, n$ .
<i>idxq</i>	Array, dimension ( $n$ ). This contains the permutation which will reintegrate the subproblem just solved back into sorted order, that is, $d(\text{idxq}(i = 1, n))$ will be in ascending order.
<i>perm</i>	Array, dimension ( $n$ ). The permutations (from deflation and sorting) to be applied to each block. Not referenced if <i>icompg</i> = 0.

<i>givptr</i>	The number of Givens rotations which took place in this subproblem. Not referenced if <i>icompg</i> = 0.
<i>givcol</i>	Array, dimension ( <i>ldgcol</i> , 2 ). Each pair of numbers indicates a pair of columns to take place in a Givens rotation. Not referenced if <i>icompg</i> = 0.
<i>givnum</i>	Array, dimension ( <i>ldgnum</i> , 2 ). Each number indicates the C or S value to be used in the corresponding Givens rotation. Not referenced if <i>icompg</i> = 0.
<i>poles</i>	Array, dimension ( <i>ldgnum</i> , 2 ). On exit, <i>poles</i> (1,*) is an array containing the new singular values obtained from solving the secular equation, and <i>poles</i> (2,*) is an array containing the poles in the secular equation. Not referenced if <i>icompg</i> = 0.
<i>difl</i>	Array, dimension ( <i>n</i> ). On exit, <i>difl</i> ( <i>i</i> ) is the distance between <i>i</i> -th updated (undeflated) singular value and the <i>i</i> -th (undeflated) old singular value.
<i>difr</i>	Array, dimension ( <i>ldgnum</i> , 2 ) if <i>icompg</i> = 1 and dimension ( <i>n</i> ) if <i>icompg</i> = 0.  On exit, <i>difr</i> ( <i>i</i> , 1) is the distance between <i>i</i> -th updated (undeflated) singular value and the <i>i</i> +1-th (undeflated) old singular value. If <i>icompg</i> = 1, <i>difr</i> (1: <i>k</i> , 2) is an array containing the normalizing factors for the right singular vector matrix.  See ?lasd8 for details on <i>difl</i> and <i>difr</i> .
<i>z</i>	Array, dimension ( <i>m</i> ).  The first elements of this array contain the components of the deflation-adjusted updating row vector.
<i>k</i>	Contains the dimension of the non-deflated matrix. This is the order of the related secular equation. $1 \leq k \leq n$ .
<i>c</i>	<i>c</i> contains garbage if <i>sqre</i> = 0 and the C-value of a Givens rotation related to the right null space if <i>sqre</i> = 1.
<i>s</i>	<i>s</i> contains garbage if <i>sqre</i> = 0 and the S-value of a Givens rotation related to the right null space if <i>sqre</i> = 1.
<i>info</i>	= 0: successful exit. < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value. > 0: if <i>info</i> = 1, an singular value did not converge

**?lasd7**

Merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. Used by ?bdsdc.

## Description

The routine `?lasd7` merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more singular values are close together or if there is a tiny entry in the Z vector. For each such occurrence the order of the related secular equation problem is reduced by one. `?lasd7` is called from `?lasd6`.

## Input Parameters

<i>icompq</i>	Specifies whether singular vectors are to be computed in compact form, as follows: = 0: Compute singular values only. = 1: Compute singular vectors of upper bidiagonal matrix in compact form.
<i>nl</i>	The row dimension of the upper block. $nl \geq 1$ .
<i>nr</i>	The row dimension of the lower block. $nr \geq 1$ .
<i>sqre</i>	= 0: the lower block is an $nr$ -by- $nr$ square matrix. = 1: the lower block is an $nr$ -by- $(nr+1)$ rectangular matrix. The bidiagonal matrix has $n = nl + nr + 1$ rows and $m = n + sqre \geq n$ columns.
<i>d</i>	Array, DIMENSION ( $n$ ). On entry <i>d</i> contains the singular values of the two submatrices to be combined.
<i>zw</i>	Array, DIMENSION ( $m$ ). Workspace for <i>z</i> .
<i>vf</i>	Array, DIMENSION ( $m$ ). On entry, <i>vf</i> (1: $nl+1$ ) contains the first components of all right singular vectors of the upper block; and <i>vf</i> ( $nl+2$ : $m$ ) contains the first components of all right singular vectors of the lower block.

<i>vfw</i>	Array, DIMENSION ( <i>m</i> ). Workspace for <i>vf</i> .
<i>vl</i>	Array, DIMENSION ( <i>m</i> ). On entry, <i>vl</i> (1: <i>n</i> l+1) contains the last components of all right singular vectors of the upper block; and <i>vl</i> ( <i>n</i> l+2: <i>m</i> ) contains the last components of all right singular vectors of the lower block.
<i>VLW</i>	Array, DIMENSION ( <i>m</i> ). Workspace for <i>VL</i> .
<i>alpha</i>	REAL for <i>slasd7</i> DOUBLE PRECISION for <i>dlsd7</i> . Contains the diagonal element associated with the added row.
<i>beta</i>	Contains the off-diagonal element associated with the added row.
<i>idx</i>	Workspace array, DIMENSION ( <i>n</i> ). This will contain the permutation used to sort the contents of <i>d</i> into ascending order.
<i>idxp</i>	Workspace array, DIMENSION ( <i>n</i> ). This will contain the permutation used to place deflated values of <i>d</i> at the end of the array.
<i>idxq</i>	Array, DIMENSION ( <i>n</i> ). This contains the permutation which separately sorts the two sub-problems in <i>d</i> into ascending order. Note that entries in the first half of this permutation must first be moved one position backward; and entries in the second half must first have <i>n</i> l+1 added to their values.
<i>ldgcol</i>	The leading dimension of the output array <i>givcol</i> , must be at least <i>n</i> .
<i>ldgnum</i>	The leading dimension of the output array <i>givnum</i> , must be at least <i>n</i> .

## Output Parameters

<i>k</i>	Contains the dimension of the non-deflated matrix, this is the order of the related secular equation. $1 \leq k \leq n$ .
<i>d</i>	On exit, <i>d</i> contains the trailing ( <i>n</i> - <i>k</i> ) updated singular values (those which were deflated) sorted into increasing order.
<i>z</i>	Array, DIMENSION ( <i>m</i> ). On exit, <i>Z</i> contains the updating row vector in the secular equation.
<i>vf</i>	On exit, <i>vf</i> contains the first components of all right singular vectors of the bidiagonal matrix.
<i>vl</i>	On exit, <i>vl</i> contains the last components of all right singular vectors of the bidiagonal matrix.
<i>dsigma</i>	Array, DIMENSION ( <i>n</i> ). Contains a copy of the diagonal elements ( <i>k</i> -1 singular values and one zero) in the secular equation.

<i>idxp</i>	On output, <i>idxp</i> (2: <i>k</i> ) points to the nondeflated <i>d</i> -values and <i>idxp</i> ( <i>k</i> +1: <i>n</i> ) points to the deflated singular values.
<i>perm</i>	Array, DIMENSION ( <i>n</i> ). The permutations (from deflation and sorting) to be applied to each singular block. Not referenced if <i>icompg</i> = 0.
<i>givptr</i>	The number of Givens rotations which took place in this subproblem. Not referenced if <i>icompg</i> = 0.
<i>givcol</i>	Array, DIMENSION ( <i>ldgcol</i> , 2 ). Each pair of numbers indicates a pair of columns to take place in a Givens rotation. Not referenced if <i>icompg</i> = 0.
<i>givnum</i>	Array, DIMENSION ( <i>ldgnum</i> , 2 ). Each number indicates the C or S value to be used in the corresponding Givens rotation. Not referenced if <i>icompg</i> = 0.
<i>c</i>	If <i>sqre</i> = 0, then <i>c</i> contains garbage, and if <i>sqre</i> = 1, then <i>c</i> contains C-value of a Givens rotation related to the right null space.
<i>s</i>	If <i>sqre</i> = 0, then <i>s</i> contains garbage, and if <i>sqre</i> = 1, then <i>s</i> contains S-value of a Givens rotation related to the right null space.
<i>info</i>	= 0: successful exit. < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value.

## ?lasd8

*Finds the square roots of the roots of the secular equation, and stores, for each element in D, the distance to its two nearest poles. Used by ?bdsdc.*

### Syntax

```
void slasd8( lapack_int *icompg, lapack_int *k, float *d, float *z, float *vf, float
*vl, float *difl, float *difr, lapack_int *lddifr, float *dsigma, float *work,
lapack_int *info );
```

```
void dlasd8( lapack_int *icompg, lapack_int *k, double *d, double *z, double *vf, double
*vl, double *difl, double *difr, lapack_int *lddifr, double *dsigma, double *work,
lapack_int *info );
```

### Include Files

- mkl.h

### Description

The routine ?lasd8 finds the square roots of the roots of the secular equation, as defined by the values in *dsigma* and *z*. It makes the appropriate calls to ?lasd4, and stores, for each element in *d*, the distance to its two nearest poles (elements in *dsigma*). It also updates the arrays *vf* and *vl*, the first and last components of all the right singular vectors of the original bidiagonal matrix. ?lasd8 is called from ?lasd6.

## Input Parameters

<i>icompq</i>	Specifies whether singular vectors are to be computed in factored form in the calling routine: = 0: Compute singular values only. = 1: Compute singular vectors in factored form as well.
<i>k</i>	The number of terms in the rational function to be solved by ?lasd4. $k \geq 1$ .
<i>z</i>	Array, DIMENSION ( <i>k</i> ). The first <i>k</i> elements of this array contain the components of the deflation-adjusted updating row vector.
<i>vf</i>	Array, DIMENSION ( <i>k</i> ). On entry, <i>vf</i> contains information passed through <i>dbede8</i> .
<i>vl</i>	Array, DIMENSION ( <i>k</i> ). On entry, <i>vl</i> contains information passed through <i>dbede8</i> .
<i>lddifr</i>	The leading dimension of the output array <i>difr</i> , must be at least <i>k</i> .
<i>dsigma</i>	Array, DIMENSION ( <i>k</i> ). The first <i>k</i> elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.
<i>work</i>	Workspace array, DIMENSION at least (3 <i>k</i> ).

## Output Parameters

<i>d</i>	Array, DIMENSION ( <i>k</i> ). On output, <i>D</i> contains the updated singular values.
<i>z</i>	Updated on exit.
<i>vf</i>	On exit, <i>vf</i> contains the first <i>k</i> components of the first components of all right singular vectors of the bidiagonal matrix.
<i>vl</i>	On exit, <i>vl</i> contains the first <i>k</i> components of the last components of all right singular vectors of the bidiagonal matrix.
<i>difl</i>	Array, DIMENSION ( <i>k</i> ). On exit, $difl(i) = d(i) - dsigma(i)$ .
<i>difr</i>	Array, DIMENSION ( <i>lddifr</i> , 2 ) if <i>icompq</i> = 1 and DIMENSION ( <i>k</i> ) if <i>icompq</i> = 0. On exit, $difr(i,1) = d(i) - dsigma(i+1)$ , $difr(k,1)$ is not defined and will not be referenced. If <i>icompq</i> = 1, $difr(1:k,2)$ is an array containing the normalizing factors for the right singular vector matrix.
<i>dsigma</i>	The elements of this array may be very slightly altered in value.
<i>info</i>	= 0: successful exit. < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value.

> 0: If *info* = 1, an singular value did not converge.

## ?lasd9

*Finds the square roots of the roots of the secular equation, and stores, for each element in D, the distance to its two nearest poles. Used by ?bdsdc.*

### Syntax

```
void slasd9( lapack_int *icompq, lapack_int *k, float *d, float *z, float *vf, float
*vl, float *difl, float *difr, float *dsigma, float *work, lapack_int *info );
```

```
void dlasd9( lapack_int *icompq, lapack_int *k, double *d, double *z, double *vf, double
*vl, double *difl, double *difr, double *dsigma, double *work, lapack_int *info );
```

### Include Files

double *d, double *e, double *u, lapack_int *ldu, double *vt, lapack_int *k, double
*difl, double *difr, double *z, double *poles, lapack_int *givptr, lapack_int *givcol,
lapack_int *ldgcol, lapack_int *perm, double *givnum, double *c, double *s, double
*work, lapack_int *iwork, lapack_int *info );
```

### Include Files

- mkl.h

### Description

Using a divide and conquer approach, ?lasda computes the singular value decomposition (SVD) of a real upper bidiagonal *n*-by-*m* matrix *B* with diagonal *d* and off-diagonal *e*, where  $m = n + sqre$ .

The algorithm computes the singular values in the  $SVDB = U*S*VT$ . The orthogonal matrices *U* and *VT* are optionally computed in compact form. A related subroutine ?lasd0 computes the singular values and the singular vectors in explicit form.

## Input Parameters

<i>icompg</i>	Specifies whether singular vectors are to be computed in compact form, as follows: = 0: Compute singular values only. = 1: Compute singular vectors of upper bidiagonal matrix in compact form.
<i>smlsiz</i>	The maximum size of the subproblems at the bottom of the computation tree.
<i>n</i>	The row dimension of the upper bidiagonal matrix. This is also the dimension of the main diagonal array <i>d</i> .
<i>sqre</i>	Specifies the column dimension of the bidiagonal matrix. If <i>sqre</i> = 0: the bidiagonal matrix has column dimension $m = n$ If <i>sqre</i> = 1: the bidiagonal matrix has column dimension $m = n + 1$ .
<i>d</i>	Array, DIMENSION ( <i>n</i> ). On entry, <i>d</i> contains the main diagonal of the bidiagonal matrix.
<i>e</i>	Array, DIMENSION ( $m - 1$ ). Contains the subdiagonal entries of the bidiagonal matrix. On exit, <i>e</i> is destroyed.
<i>ldu</i>	The leading dimension of arrays <i>u</i> , <i>vt</i> , <i>difl</i> , <i>difr</i> , <i>poles</i> , <i>givnum</i> , and <i>z</i> . $ldu \geq n$ .
<i>ldgcol</i>	The leading dimension of arrays <i>givcol</i> and <i>perm</i> . $ldgcol \geq n$ .
<i>work</i>	Workspace array, DIMENSION ( $6n + (smlsiz + 1)^2$ ).
<i>iwork</i>	Workspace array, Dimension must be at least ( $7n$ ).

## Output Parameters

<i>d</i>	On exit <i>d</i> , if <i>info</i> = 0, contains the singular values of the bidiagonal matrix.
<i>u</i>	Array, DIMENSION ( <i>ldu</i> , <i>smlsiz</i> ) if <i>icompg</i> = 1. Not referenced if <i>icompg</i> = 0. If <i>icompg</i> = 1, on exit, <i>u</i> contains the left singular vector matrices of all subproblems at the bottom level.
<i>vt</i>	Array, DIMENSION ( <i>ldu</i> , <i>smlsiz</i> + 1) if <i>icompg</i> = 1, and not referenced if <i>icompg</i> = 0. If <i>icompg</i> = 1, on exit, <i>vt'</i> contains the right singular vector matrices of all subproblems at the bottom level.
<i>k</i>	Array, DIMENSION ( <i>n</i> ) if <i>icompg</i> = 1 and DIMENSION (1) if <i>icompg</i> = 0. If <i>icompg</i> = 1, on exit, <i>k</i> ( <i>i</i> ) is the dimension of the <i>i</i> -th secular equation on the computation tree.
<i>difl</i>	REAL for slasda DOUBLE PRECISION for dlasda.

	<p>Array, DIMENSION ( <i>ldu</i>, <i>nlvl</i> ),</p> <p>where <math>nlvl = \text{floor}(\log_2(n/smlsiz))</math>.</p>
<i>difr</i>	<p>Array,</p> <p>DIMENSION ( <i>ldu</i>, <math>2 \cdot nlvl</math> ) if <i>icompq</i> = 1 and</p> <p>DIMENSION ( <i>n</i> ) if <i>icompq</i> = 0.</p> <p>If <i>icompq</i> = 1, on exit, <i>difl</i>(1:<i>n</i>, <i>i</i>) and <i>difr</i>(1:<i>n</i>, <math>2i - 1</math>) record distances between singular values on the <i>i</i>-th level and singular values on the (<i>i</i> - 1)-th level, and <i>difr</i>(1:<i>n</i>, <math>2i</math>) contains the normalizing factors for the right singular vector matrix. See ?lasd8 for details.</p>
<i>z</i>	<p>Array,</p> <p>DIMENSION ( <i>ldu</i>, <i>nlvl</i> ) if <i>icompq</i> = 1 and</p> <p>DIMENSION ( <i>n</i> ) if <i>icompq</i> = 0. The first <i>k</i> elements of <i>z</i>(1, <i>i</i>) contain the components of the deflation-adjusted updating row vector for subproblems on the <i>i</i>-th level.</p>
<i>poles</i>	<p>Array, DIMENSION(<i>ldu</i>, <math>2 \cdot nlvl</math>)</p> <p>if <i>icompq</i> = 1, and not referenced if <i>icompq</i> = 0. If <i>icompq</i> = 1, on exit, <i>poles</i>(1, <math>2i - 1</math>) and <i>poles</i>(1, <math>2i</math>) contain the new and old singular values involved in the secular equations on the <i>i</i>-th level.</p>
<i>givptr</i>	<p>Array, DIMENSION ( <i>n</i> ) if <i>icompq</i> = 1, and not referenced if <i>icompq</i> = 0. If <i>icompq</i> = 1, on exit, <i>givptr</i>( <i>i</i> ) records the number of Givens rotations performed on the <i>i</i>-th problem on the computation tree.</p>
<i>givcol</i>	<p>Array, DIMENSION(<i>ldgcol</i>, <math>2 \cdot nlvl</math>) if <i>icompq</i> = 1, and not referenced if <i>icompq</i> = 0. If <i>icompq</i> = 1, on exit, for each <i>i</i>, <i>givcol</i>(1, <math>2i - 1</math>) and <i>givcol</i>(1, <math>2i</math>) record the locations of Givens rotations performed on the <i>i</i>-th level on the computation tree.</p>
<i>perm</i>	<p>Array, DIMENSION ( <i>ldgcol</i>, <i>nlvl</i> ) if <i>icompq</i> = 1, and not referenced if <i>icompq</i> = 0. If <i>icompq</i> = 1, on exit, <i>perm</i> (1, <i>i</i>) records permutations done on the <i>i</i>-th level of the computation tree.</p>
<i>givnum</i>	<p>Array DIMENSION ( <i>ldu</i>, <math>2 \cdot nlvl</math> ) if <i>icompq</i> = 1, and not referenced if <i>icompq</i> = 0. If <i>icompq</i> = 1, on exit, for each <i>i</i>, <i>givnum</i>(1, <math>2i - 1</math>) and <i>givnum</i>(1, <math>2i</math>) record the C- and S-values of Givens rotations performed on the <i>i</i>-th level on the computation tree.</p>
<i>c</i>	<p>Array,</p> <p>DIMENSION ( <i>n</i> ) if <i>icompq</i> = 1, and</p> <p>DIMENSION ( 1 ) if <i>icompq</i> = 0.</p> <p>If <i>icompq</i> = 1 and the <i>i</i>-th subproblem is not square, on exit, <i>c</i>(<i>i</i>) contains the C-value of a Givens rotation related to the right null space of the <i>i</i>-th subproblem.</p>
<i>s</i>	<p>Array,</p> <p>DIMENSION ( <i>n</i> ) if <i>icompq</i> = 1, and</p> <p>DIMENSION ( 1 ) if <i>icompq</i> = 0.</p>

If  $icompg = 1$  and the  $i$ -th subproblem is not square, on exit,  $s(i)$  contains the  $S$ -value of a Givens rotation related to the right null space of the  $i$ -th subproblem.

$info$

= 0: successful exit.

< 0: if  $info = -i$ , the  $i$ -th argument had an illegal value

> 0: If  $info = 1$ , an singular value did not converge

## ?lasdq

Computes the SVD of a real bidiagonal matrix with diagonal  $d$  and off-diagonal  $e$ . Used by ?bdsdc.

### Syntax

```
void slasdq( char *uplo, lapack_int *sqre, lapack_int *n, lapack_int *ncvt, lapack_int
*nru, lapack_int *ncc, float *d, float *e, float *vt, lapack_int *ldvt, float *u,
lapack_int *ldu, float *c, lapack_int *ldc, float *work, lapack_int *info );
```

```
void dlasdq( char *uplo, lapack_int *sqre, lapack_int *n, lapack_int *ncvt, lapack_int
*nru, lapack_int *ncc, double *d, double *e, double *vt, lapack_int *ldvt, double *u,
lapack_int *ldu, double *c, lapack_int *ldc, double *work, lapack_int *info );
```

### Include Files

- mkl.h

### Description

The routine ?lasdq computes the singular value decomposition (SVD) of a real (upper or lower) bidiagonal matrix with diagonal  $d$  and off-diagonal  $e$ , accumulating the transformations if desired. If  $B$  is the input bidiagonal matrix, the algorithm computes orthogonal matrices  $Q$  and  $P$  such that  $B = Q^T S P^T$ . The singular values  $S$  are overwritten on  $d$ .

The input matrix  $U$  is changed to  $U^*Q$  if desired.

The input matrix  $VT$  is changed to  $P^T*VT$  if desired.

The input matrix  $C$  is changed to  $Q^T*C$  if desired.

### Input Parameters

$uplo$

On entry,  $uplo$  specifies whether the input bidiagonal matrix is upper or lower bidiagonal.

If  $uplo = 'U'$  or  $'u'$ ,  $B$  is upper bidiagonal;

If  $uplo = 'L'$  or  $'l'$ ,  $B$  is lower bidiagonal.

$sqre$

= 0: then the input matrix is  $n$ -by- $n$ .

= 1: then the input matrix is  $n$ -by- $(n+1)$  if  $uplu = 'U'$  and  $(n+1)$ -by- $n$  if  $uplu$

=  $'L'$ . The bidiagonal matrix has  $n = nl + nr + 1$  rows and  $m = n + sqre \geq n$  columns.

<i>n</i>	On entry, <i>n</i> specifies the number of rows and columns in the matrix. <i>n</i> must be at least 0.
<i>ncvt</i>	On entry, <i>ncvt</i> specifies the number of columns of the matrix <i>VT</i> . <i>ncvt</i> must be at least 0.
<i>nru</i>	On entry, <i>nru</i> specifies the number of rows of the matrix <i>U</i> . <i>nru</i> must be at least 0.
<i>ncc</i>	On entry, <i>ncc</i> specifies the number of columns of the matrix <i>C</i> . <i>ncc</i> must be at least 0.
<i>d</i>	Array, DIMENSION ( <i>n</i> ). On entry, <i>d</i> contains the diagonal entries of the bidiagonal matrix.
<i>e</i>	Array, DIMENSION is ( <i>n</i> -1) if <i>sGRE</i> = 0 and <i>n</i> if <i>sGRE</i> = 1. On entry, the entries of <i>e</i> contain the off-diagonal entries of the bidiagonal matrix.
<i>vt</i>	Array, DIMENSION ( <i>ldvt</i> , <i>ncvt</i> ). On entry, contains a matrix which on exit has been premultiplied by $P^T$ , dimension <i>n</i> -by- <i>ncvt</i> if <i>sGRE</i> = 0 and ( <i>n</i> +1)-by- <i>ncvt</i> if <i>sGRE</i> = 1 (not referenced if <i>ncvt</i> =0).
<i>ldvt</i>	On entry, <i>ldvt</i> specifies the leading dimension of <i>vt</i> as declared in the calling (sub) program. <i>ldvt</i> must be at least 1. If <i>ncvt</i> is nonzero, <i>ldvt</i> must also be at least <i>n</i> .
<i>u</i>	Array, DIMENSION ( <i>ldu</i> , <i>n</i> ). On entry, contains a matrix which on exit has been postmultiplied by <i>Q</i> , dimension <i>nru</i> -by- <i>n</i> if <i>sGRE</i> = 0 and <i>nru</i> -by-( <i>n</i> +1) if <i>sGRE</i> = 1 (not referenced if <i>nru</i> =0).
<i>ldu</i>	On entry, <i>ldu</i> specifies the leading dimension of <i>u</i> as declared in the calling (sub) program. <i>ldu</i> must be at least $\max(1, nru)$ .
<i>c</i>	Array, DIMENSION ( <i>ldc</i> , <i>ncc</i> ). On entry, contains an <i>n</i> -by- <i>ncc</i> matrix which on exit has been premultiplied by $Q'$ , dimension <i>n</i> -by- <i>ncc</i> if <i>sGRE</i> = 0 and ( <i>n</i> +1)-by- <i>ncc</i> if <i>sGRE</i> = 1 (not referenced if <i>ncc</i> =0).
<i>ldc</i>	On entry, <i>ldc</i> specifies the leading dimension of <i>C</i> as declared in the calling (sub) program. <i>ldc</i> must be at least 1. If <i>ncc</i> is non-zero, <i>ldc</i> must also be at least <i>n</i> .
<i>work</i>	Array, DIMENSION (4 <i>n</i> ). This is a workspace array. Only referenced if one of <i>ncvt</i> , <i>nru</i> , or <i>ncc</i> is nonzero, and if <i>n</i> is at least 2.

## Output Parameters

<i>d</i>	On normal exit, <i>d</i> contains the singular values in ascending order.
<i>e</i>	On normal exit, <i>e</i> will contain 0. If the algorithm does not converge, <i>d</i> and <i>e</i> will contain the diagonal and superdiagonal entries of a bidiagonal matrix orthogonally equivalent to the one given as input.
<i>vt</i>	On exit, the matrix has been premultiplied by $P'$ .
<i>u</i>	On exit, the matrix has been postmultiplied by <i>Q</i> .
<i>c</i>	On exit, the matrix has been premultiplied by $Q'$ .

*info* On exit, a value of 0 indicates a successful exit. If *info* < 0, argument number *-info* is illegal. If *info* > 0, the algorithm did not converge, and *info* specifies how many superdiagonals did not converge.

## ?lasdt

*Creates a tree of subproblems for bidiagonal divide and conquer. Used by ?bdsdc.*

### Syntax

```
void slasdt( lapack_int *n, lapack_int *lvl, lapack_int *nd, lapack_int *inode,
lapack_int *ndiml, lapack_int *ndimr, lapack_int *msub );
```

```
void dlasdt( lapack_int *n, lapack_int *lvl, lapack_int *nd, lapack_int *inode,
lapack_int *ndiml, lapack_int *ndimr, lapack_int *msub );
```

### Include Files

- mkl.h

### Description

The routine creates a tree of subproblems for bidiagonal divide and conquer.

### Input Parameters

*n* On entry, the number of diagonal elements of the bidiagonal matrix.

*msub* On entry, the maximum row dimension each subproblem at the bottom of the tree can be of.

### Output Parameters

*lvl* On exit, the number of levels on the computation tree.

*nd* On exit, the number of nodes on the tree.

*inode* Array, DIMENSION (*n*). On exit, centers of subproblems.

*ndiml* Array, DIMENSION (*n*). On exit, row dimensions of left children.

*ndimr* Array, DIMENSION (*n*). On exit, row dimensions of right children.

## ?laset

*Initializes the off-diagonal elements and the diagonal elements of a matrix to given values.*

### Syntax

```
lapack_int LAPACKE_slaset (int matrix_layout , char uplo , lapack_int m , lapack_int
n , float alpha , float beta , float * a , lapack_int lda );
```

```
lapack_int LAPACKE_dlaset (int matrix_layout , char uplo , lapack_int m , lapack_int
n , double alpha , double beta , double * a , lapack_int lda );
```

```

lapack_int LAPACKE_claset (int matrix_layout , char uplo , lapack_int m , lapack_int
n , lapack_complex_float alpha , lapack_complex_float beta , lapack_complex_float * a ,
lapack_int lda );

lapack_int LAPACKE_zlaset (int matrix_layout , char uplo , lapack_int m , lapack_int
n , lapack_complex_double alpha , lapack_complex_double beta , lapack_complex_double *
a , lapack_int lda );

```

## Include Files

- mkl.h

## Description

The routine initializes an  $m$ -by- $n$  matrix  $A$  to  $\beta$  on the diagonal and  $\alpha$  on the off-diagonals.

## Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>uplo</i>	Specifies the part of the matrix $A$ to be set. If <i>uplo</i> = 'U', upper triangular part is set; the strictly lower triangular part of $A$ is not changed. If <i>uplo</i> = 'L': lower triangular part is set; the strictly upper triangular part of $A$ is not changed. Otherwise: All of the matrix $A$ is set.
<i>m</i>	The number of rows of the matrix $A$ . $m \geq 0$ .
<i>n</i>	The number of columns of the matrix $A$ . $n \geq 0$ .
<i>alpha, beta</i>	The constants to which the off-diagonal and diagonal elements are to be set, respectively.
<i>a</i>	Array, size at least $\max(1, lda * n)$ for column major and $\max(1, lda * m)$ for row major layout. The array <i>a</i> contains the $m$ -by- $n$ matrix $A$ .
<i>lda</i>	The leading dimension of the array <i>a</i> . $lda \geq \max(1, m)$ for column major layout and $lda \geq \max(1, n)$ for row major layout.

## Output Parameters

<i>a</i>	On exit, the leading $m$ -by- $n$ submatrix of $A$ is set as follows: if <i>uplo</i> = 'U', $A_{ij} = \alpha, 1 \leq i \leq j-1, 1 \leq j \leq n$ , if <i>uplo</i> = 'L', $A_{ij} = \alpha, j+1 \leq i \leq m, 1 \leq j \leq n$ , otherwise, $A_{ij} = \alpha, 1 \leq i \leq m, 1 \leq j \leq n, i \neq j$ ,
----------	---

and, for all  $uplo$ ,  $A_{ii} = beta$ ,  $1 \leq i \leq \min(m, n)$ .

## Return Values

This function returns a value *info*.

If  $info = 0$ , the execution is successful.

If  $info = i < 0$ , the  $i$ -th parameter had an illegal value.

If  $info = -1011$ , memory allocation error occurred.

## ?lasrt

Sorts numbers in increasing or decreasing order.

## Syntax

```
lapack_int LAPACKE_slasrt (char id , lapack_int n , float * d );
lapack_int LAPACKE_dlasrt (char id , lapack_int n , double * d );
```

## Include Files

- mkl.h

## Description

The routine ?lasrt sorts the numbers in  $d$  in increasing order (if  $id = 'I'$ ) or in decreasing order (if  $id = 'D'$ ). It uses Quick Sort, reverting to Insertion Sort on arrays of size  $\leq 20$ . Dimension of `stack` limits  $n$  to about  $2^{32}$ .

## Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

$id$  = 'I': sort  $d$  in increasing order;  
= 'D': sort  $d$  in decreasing order.

$n$  The length of the array  $d$ .

$d$  On entry, the array to be sorted.

## Output Parameters

$d$  On exit,  $d$  has been sorted into increasing order  
( $d[0] \leq d[1] \leq \dots \leq d[n-1]$ ) or into decreasing order  
( $d[0] \geq d[1] \geq \dots \geq d[n-1]$ ), depending on  $id$ .

## Return Values

This function returns a value *info*.

If  $info = 0$ , the execution is successful.

If  $info < 0$ , the  $i$ -th parameter had an illegal value.

## ?laswp

Performs a series of row interchanges on a general rectangular matrix.

### Syntax

```
lapack_int LAPACKE_slaswp (int matrix_layout , lapack_int n , float * a , lapack_int
lda , lapack_int k1 , lapack_int k2 , const lapack_int * ipiv , lapack_int incx );
lapack_int LAPACKE_dlaswp (int matrix_layout , lapack_int n , double * a , lapack_int
lda , lapack_int k1 , lapack_int k2 , const lapack_int * ipiv , lapack_int incx );
lapack_int LAPACKE_claswp (int matrix_layout , lapack_int n , lapack_complex_float *
a , lapack_int lda , lapack_int k1 , lapack_int k2 , const lapack_int * ipiv ,
lapack_int incx );
lapack_int LAPACKE_zlaswp (int matrix_layout , lapack_int n , lapack_complex_double *
a , lapack_int lda , lapack_int k1 , lapack_int k2 , const lapack_int * ipiv ,
lapack_int incx );
```

### Include Files

- mkl.h

### Description

The routine performs a series of row interchanges on the matrix *A*. One row interchange is initiated for each of rows *k1* through *k2* of *A*.

### Input Parameters

A <datatype> placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>n</i>	The number of columns of the matrix <i>A</i> .
<i>a</i>	Array, size $\max(1, lda*n)$ for column major and $\max(1, lda*mm)$ for row major layout. Here <i>mm</i> is not less than maximum of values $ipiv[k1-1+j* incx ]$ , $0 \leq j < k2-k1$ . Array <i>a</i> contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> .
<i>lda</i>	The leading dimension of the array <i>a</i> .
<i>k1</i>	The first element of <i>ipiv</i> for which a row interchange will be done.
<i>k2</i>	The last element of <i>ipiv</i> for which a row interchange will be done.
<i>ipiv</i>	Array, size $k1+(k2-k1)* incx $ . The vector of pivot indices. Only the elements in positions <i>k1</i> through <i>k2</i> of <i>ipiv</i> are accessed. $ipiv(k) = l$ implies rows <i>k</i> and <i>l</i> are to be interchanged.

*incx* The increment between successive values of *ipiv*. If *ipiv* is negative, the pivots are applied in reverse order.

## Output Parameters

*a* On exit, the permuted matrix.

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

## ?latm1

Computes the entries of a matrix as specified.

## Syntax

```
void slatm1 (lapack_int *mode, *cond, lapack_int *irsign, lapack_int *idist, lapack_int *iseed, float *d, lapack_int *n, lapack_int *info);
```

```
void dlatm1 (lapack_int *mode, *cond, lapack_int *irsign, lapack_int *idist, lapack_int *iseed, double *d, lapack_int *n, lapack_int *info);
```

```
void clatm1 (lapack_int *mode, *cond, lapack_int *irsign, lapack_int *idist, lapack_int *iseed, lapack_complex *d, lapack_int *n, lapack_int *info);
```

```
void zlatm1 (lapack_int *mode, *cond, lapack_int *irsign, lapack_int *idist, lapack_int *iseed, lapack_complex_double *d, lapack_int *n, lapack_int *info);
```

## Include Files

- mkl.h

## Description

The ?latm1 routine computes the entries of  $D(1..n)$  as specified by *mode*, *cond* and *irsign*. *idist* and *iseed* determine the generation of random numbers.

?latm1 is called by slatmr (for slatm1 and dlatm1), and by clatmr (for clatm1 and zlatm1) to generate random test matrices for LAPACK programs.

## Input Parameters

*mode* On entry describes how *d* is to be computed:

*mode* = 0 means do not change *d*.

*mode* = 1 sets  $d[0] = 1$  and  $d[1:n - 1] = 1.0/cond$

*mode* = 2 sets  $d[0:n - 2] = 1$  and  $d[n - 1] = 1.0/cond$

*mode* = 3 sets  $d[i - 1] = cond^{-(i-1)/(n-1)}$

*mode* = 4 sets  $d[i - 1] = 1 - (i-1)/(n-1) * (1 - 1/cond)$

$mode = 5$  sets  $d$  to random numbers in the range  $( 1/cond , 1 )$  such that their logarithms are uniformly distributed.

$mode = 6$  sets  $d$  to random numbers from same distribution as the rest of the matrix.

$mode < 0$  has the same meaning as  $abs(mode)$ , except that the order of the elements of  $d$  is reversed.

Thus if  $mode$  is positive,  $d$  has entries ranging from 1 to  $1/cond$ , if negative, from  $1/cond$  to 1.

*cond* On entry, used as described under *mode* above. If used, it must be  $\geq 1$ .

*irsign* On entry, if *mode* is not -6, 0, or 6, determines sign of entries of  $d$ .

If *irsign* = 0, entries of  $d$  are unchanged.

If *irsign* = 1, each entry of  $d$  is multiplied by a random complex number uniformly distributed with absolute value 1.

*idist* Specifies the distribution of the random numbers.

For *slatm1* and *dlatm1*:

= 1: uniform (0,1)

= 2: uniform (-1,1)

= 3: normal (0,1)

For *clatm1* and *zlatm1*:

= 1: real and imaginary parts each uniform (0,1)

= 2: real and imaginary parts each uniform (-1,1)

= 3: real and imaginary parts each normal (0,1)

= 4: complex number uniform in disk(0, 1)

*iseed* Array, size (4).

Specifies the seed of the random number generator. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers. The values of *iseed*[3] are changed on exit, and can be used in the next call to *?latm1* to continue the same random number sequence.

$d$  Array, size  $n$ .

$n$  Number of entries of  $d$ .

## Output Parameters

*iseed* On exit, the seed is updated.

$d$  On exit,  $d$  is updated, unless  $mode = 0$ .

*info* If *info* = 0, the execution is successful.

If *info* = -1, *mode* is not in range -6 to 6.

If *info* = -2, *mode* is neither -6, 0 nor 6, and *irsign* is neither 0 nor 1.

- If *info* = -3, *mode* is neither -6, 0 nor 6 and *cond* is less than 1.
- If *info* = -4, *mode* equals 6 or -6 and *idist* is not in range 1 to 4.
- If *info* = -7, *n* is negative.

## ?latm2

Returns an entry of a random matrix.

### Syntax

```
float slatm2 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int
*kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed, float *d, lapack_int *igrade,
float *dl, float *dr, lapack_int *ipvtng, lapack_int *iwork, float *sparse);
```

```
double dlatm2 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int
*kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed, double *d, lapack_int
*igrade, double *dl, double *dr, lapack_int *ipvtng, lapack_int *iwork, double *sparse);
```

The data types for complex variations depend on whether or not the application links with Gnu Fortran (gfortran) libraries.

For non-gfortran (libmkl\_intel\_\*) interface libraries:

```
void clatm2 (lapack_complex_float *res, lapack_int *m, lapack_int *n, lapack_int *i,
lapack_int *j, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed,
lapack_complex_float *d, lapack_int *igrade, lapack_complex_float *dl,
lapack_complex_float *dr, lapack_int *ipvtng, lapack_int *iwork, float *sparse);
```

```
void zlatm2 (lapack_complex_double *res, lapack_int *m, lapack_int *n, lapack_int *i,
lapack_int *j, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed,
lapack_complex_double *d, lapack_int *igrade, lapack_complex_double *dl,
lapack_complex_double *dr, lapack_int *ipvtng, lapack_int *iwork, double *sparse);
```

For gfortran (libmkl\_gf\_\*) interface libraries:

```
lapack_complex_float clatm2 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int
*j, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed,
lapack_complex_float *d, lapack_int *igrade, lapack_complex_float *dl,
lapack_complex_float *dr, lapack_int *ipvtng, lapack_int *iwork, float *sparse);
```

```
lapack_complex_double zlatm2 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int
*j, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed,
lapack_complex_double *d, lapack_int *igrade, lapack_complex_double *dl,
lapack_complex_double *dr, lapack_int *ipvtng, lapack_int *iwork, double *sparse);
```

To understand the difference between the non-gfortran and gfortran interfaces and when to use each of them, see Dynamic Libraries in the lib/intel64 Directory in the *oneAPI Math Kernel Library Developer Guide*.

### Include Files

- mkl.h

### Description

The ?latm2 routine returns entry (*i*, *j*) of a random matrix of dimension (*m*, *n*). It is called by the ?latmr routine in order to build random test matrices. No error checking on parameters is done, because this routine is called in a tight loop by ?latmr which has already checked the parameters.

Use of `?latm2` differs from `?latm3` in the order in which the random number generator is called to fill in random matrix entries. With `?latm2`, the generator is called to fill in the pivoted matrix columnwise. With `?latm3`, the generator is called to fill in the matrix columnwise, after which it is pivoted. Thus, `?latm3` can be used to construct random matrices which differ only in their order of rows and/or columns. `?latm2` is used to construct band matrices while avoiding calling the random number generator for entries outside the band (and therefore generating random numbers).

The matrix whose  $(i, j)$  entry is returned is constructed as follows (this routine only computes one entry):

- If  $i$  is outside  $(1..m)$  or  $j$  is outside  $(1..n)$ , returns zero (this is convenient for generating matrices in band format).
- Generate a matrix  $A$  with random entries of distribution  $idist$ .
- Set the diagonal to  $D$ .
- Grade the matrix, if desired, from the left (by  $dl$ ) and/or from the right (by  $dr$  or  $dl$ ) as specified by  $igrade$ .
- Permute, if desired, the rows and/or columns as specified by  $ipvtng$  and  $iwork$ .
- Band the matrix to have lower bandwidth  $kl$  and upper bandwidth  $ku$ .
- Set random entries to zero as specified by  $sparse$ .

## Input Parameters

$m$	Number of rows of the matrix.
$n$	Number of columns of the matrix.
$i$	Row of the entry to be returned.
$j$	Column of the entry to be returned.
$kl$	Lower bandwidth.
$ku$	Upper bandwidth.
$idist$	On entry, $idist$ specifies the type of distribution to be used to generate a random matrix . for <code>slatm2</code> and <code>dlatm2</code> : = 1: uniform (0,1) = 2: uniform (-1,1) = 3: normal (0,1) for <code>clatm2</code> and <code>zlatm2</code> : = 1: real and imaginary parts each uniform (0,1) = 2: real and imaginary parts each uniform (-1,1) = 3: real and imaginary parts each normal (0,1) = 4: complex number uniform in disk (0, 1)
$iseed$	Array, size 4. Seed for the random number generator.
$d$	Array, size $(\min(i, j))$ . Diagonal entries of matrix.
$igrade$	Specifies grading of matrix as follows: = 0: no grading = 1: matrix premultiplied by $\text{diag}(dl)$

= 2: matrix postmultiplied by `diag( dr )`  
 = 3: matrix premultiplied by `diag( dl )` and postmultiplied by `diag( dr )`  
 = 4: matrix premultiplied by `diag( dl )` and postmultiplied by `inv( diag( dl ) )`  
 For `slatm2` and `slatm2`:  
 = 5: matrix premultiplied by `diag( dl )` and postmultiplied by `diag( dl )`  
 For `clatm2` and `zlatm2`:  
 = 5: matrix premultiplied by `diag( dl )` and postmultiplied by `diag( conjg( dl ) )`  
 = 6: matrix premultiplied by `diag( dl )` and postmultiplied by `diag( dl )`

*dl* Array, size (*i* or *j*), as appropriate.  
 Left scale factors for grading matrix.

*dr* Array, size (*i* or *j*), as appropriate.  
 Right scale factors for grading matrix.

*ipvtng* On entry specifies pivoting permutations as follows:  
 = 0: none  
 = 1: row pivoting  
 = 2: column pivoting  
 = 3: full pivoting, i.e., on both sides

*iwork* Array, size (*i* or *j*), as appropriate. This array specifies the permutation used. The row (or column) in position *k* was originally in position `iwork[k - 1]`. This differs from *iwork* for `?latm3`.

*sparse* Specifies the sparsity of the matrix. If sparse matrix is to be generated, *sparse* should lie between 0 and 1. A uniform ( 0, 1 ) random number *x* is generated and compared to *sparse*. If *x* is larger the matrix entry is unchanged and if *x* is smaller the entry is set to zero. Thus on the average a fraction *sparse* of the entries will be set to zero.

## Output Parameters

*iseed* On exit, the seed is updated.

## Return Values

The function returns an entry of a random matrix (for complex variations `libmkl_gf_*` interface layer/ libraries return the result as the parameter *res*).

## ?latm3

*Returns set entry of a random matrix.*

---

## Syntax

```
float slatm3 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int
*isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int
*iseed, float *d, lapack_int *igrade, float *dl, float *dr, lapack_int *ipvtng,
lapack_int *iwork, float *sparse);
```

```
double dlatm3 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int
*isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int
*iseed, double *d, lapack_int *igrade, double *dl, double *dr, lapack_int *ipvtng,
lapack_int *iwork, double *sparse);
```

The data types for complex variations depend on whether or not the application links with Gnu Fortran (gfortran) libraries.

For non-gfortran (libmkl\_intel\_\*) interface libraries:

```
void clatm3 (lapack_complex_float *res, lapack_int *m, lapack_int *n, lapack_int *i,
lapack_int *j, lapack_int *isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku,
lapack_int *idist, lapack_int *iseed, lapack_complex_float *d, lapack_int *igrade,
lapack_complex_float *dl, lapack_complex_float *dr, lapack_int *ipvtng, lapack_int
*iwork, float *sparse);
```

```
void zlatm3 (lapack_complex_double *res, lapack_int *m, lapack_int *n, lapack_int *i,
lapack_int *j, lapack_int *isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku,
lapack_int *idist, lapack_int *iseed, lapack_complex_double *d, lapack_int *igrade,
lapack_complex_double *dl, lapack_complex_double *dr, lapack_int *ipvtng, lapack_int
*iwork, double *sparse);
```

For gfortran (libmkl\_gf\_\*) interface libraries:

```
lapack_complex_float clatm3 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int
*j, lapack_int *isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku, lapack_int
*idist, lapack_int *iseed, lapack_complex_float *d, lapack_int *igrade,
lapack_complex_float *dl, lapack_complex_float *dr, lapack_int *ipvtng, lapack_int
*iwork, float *sparse);
```

```
lapack_complex_double zlatm3 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int
*j, lapack_int *isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku, lapack_int
*idist, lapack_int *iseed, lapack_complex_double *d, lapack_int *igrade,
lapack_complex_double *dl, lapack_complex_double *dr, lapack_int *ipvtng, lapack_int
*iwork, double *sparse);
```

To understand the difference between the non-gfortran and gfortran interfaces and when to use each of them, see Dynamic Libraries in the lib/intel64 Directory in the *oneAPI Math Kernel Library Developer Guide*.

## Include Files

- mkl.h

## Description

The ?latm3 routine returns the (*isub*, *jsub*) entry of a random matrix of dimension (*m*, *n*) described by the other parameters. (*isub*, *jsub*) is the final position of the (*i*, *j*) entry after pivoting according to *ipvtng* and *iwork*. ?latm3 is called by the ?latmr routine in order to build random test matrices. No error checking on parameters is done, because this routine is called in a tight loop by ?latmr which has already checked the parameters.

Use of `?latm3` differs from `?latm2` in the order in which the random number generator is called to fill in random matrix entries. With `?latm2`, the generator is called to fill in the pivoted matrix columnwise. With `?latm3`, the generator is called to fill in the matrix columnwise, after which it is pivoted. Thus, `?latm3` can be used to construct random matrices which differ only in their order of rows and/or columns. `?latm2` is used to construct band matrices while avoiding calling the random number generator for entries outside the band (and therefore generating random numbers in different orders for different pivot orders).

The matrix whose  $(i_{sub}, j_{sub})$  entry is returned is constructed as follows (this routine only computes one entry):

- If  $i_{sub}$  is outside  $(1..m)$  or  $j_{sub}$  is outside  $(1..n)$ , returns zero (this is convenient for generating matrices in band format).
- Generate a matrix  $A$  with random entries of distribution  $idist$ .
- Set the diagonal to  $D$ .
- Grade the matrix, if desired, from the left (by  $dl$ ) and/or from the right (by  $dr$  or  $dl$ ) as specified by  $igrade$ .
- Permute, if desired, the rows and/or columns as specified by  $ipvtng$  and  $iwork$ .
- Band the matrix to have lower bandwidth  $kl$  and upper bandwidth  $ku$ .
- Set random entries to zero as specified by  $sparse$ .

## Input Parameters

$m$	Number of rows of matrix.
$n$	Number of columns of matrix.
$i$	Row of unpivoted entry to be returned.
$j$	Column of unpivoted entry to be returned.
$i_{sub}$	Row of pivoted entry to be returned.
$j_{sub}$	Column of pivoted entry to be returned.
$kl$	Lower bandwidth.
$ku$	Upper bandwidth.
$idist$	On entry, $idist$ specifies the type of distribution to be used to generate a random matrix. for <code>slatm2</code> and <code>dlatm2</code> : = 1: uniform (0,1) = 2: uniform (-1,1) = 3: normal (0,1) for <code>clatm2</code> and <code>zlatm2</code> : = 1: real and imaginary parts each uniform (0,1) = 2: real and imaginary parts each uniform (-1,1) = 3: real and imaginary parts each normal (0,1) = 4: complex number uniform in disk(0, 1)
$iseed$	Array, size 4. Seed for random number generator.
$d$	Array, size $(\min(i, j))$ . Diagonal entries of matrix.

<i>igrade</i>	<p>Specifies grading of matrix as follows:</p> <ul style="list-style-type: none"> <li>= 0: no grading</li> <li>= 1: matrix premultiplied by <code>diag( dl )</code></li> <li>= 2: matrix postmultiplied by <code>diag( dr )</code></li> <li>= 3: matrix premultiplied by <code>diag( dl )</code> and postmultiplied by <code>diag( dr )</code></li> <li>= 4: matrix premultiplied by <code>diag( dl )</code> and postmultiplied by <code>inv( diag( dl ) )</code></li> </ul> <p>For <code>slatm2</code> and <code>slatm2</code>:</p> <ul style="list-style-type: none"> <li>= 5: matrix premultiplied by <code>diag( dl )</code> and postmultiplied by <code>diag( dl )</code></li> </ul> <p>For <code>clatm2</code> and <code>zlatm2</code>:</p> <ul style="list-style-type: none"> <li>= 5: matrix premultiplied by <code>diag( dl )</code> and postmultiplied by <code>diag( conjg( dl ) )</code></li> <li>= 6: matrix premultiplied by <code>diag( dl )</code> and postmultiplied by <code>diag( dl )</code></li> </ul>
<i>dl</i>	<p>Array, size (<i>i</i> or <i>j</i>, as appropriate).</p> <p>Left scale factors for grading matrix.</p>
<i>dr</i>	<p>Array, size (<i>i</i> or <i>j</i>, as appropriate).</p> <p>Right scale factors for grading matrix.</p>
<i>ipvtng</i>	<p>On entry specifies pivoting permutations as follows:</p> <ul style="list-style-type: none"> <li>If <code>ipvtng = 0</code>: none.</li> <li>If <code>ipvtng = 1</code>: row pivoting.</li> <li>If <code>ipvtng = 2</code>: column pivoting.</li> <li>If <code>ipvtng = 3</code>: full pivoting, i.e., on both sides.</li> </ul>
<i>sparse</i>	<p>On entry, specifies the sparsity of the matrix if sparse matrix is to be generated. <i>sparse</i> should lie between 0 and 1. A uniform( 0, 1 ) random number <i>x</i> is generated and compared to <i>sparse</i>; if <i>x</i> is larger the matrix entry is unchanged and if <i>x</i> is smaller the entry is set to zero. Thus on the average a fraction <i>sparse</i> of the entries will be set to zero.</p>
<i>iwork</i>	<p>Array, size (<i>i</i> or <i>j</i>, as appropriate). This array specifies the permutation used. The row (or column) originally in position <i>k</i> is in position <code>iwork[k - 1]</code> after pivoting. This differs from <i>iwork</i> for <code>?latm2</code>.</p>

## Output Parameters

<i>isub</i>	On exit, row of pivoted entry is updated.
<i>jsub</i>	On exit, column of pivoted entry is updated.
<i>iseed</i>	On exit, the seed is updated.

## Return Values

The function returns an entry of a random matrix (for complex variations `libmkl_gf_*` interface layer/libraries return the result as the parameter *res*).

## ?latm5

Generates matrices involved in the Generalized Sylvester equation.

### Syntax

```
void slatm5 (*prtype, lapack_int *m, lapack_int *n, float *a, lapack_int *lda, float *b,
lapack_int *ldb, float *c, lapack_int *ldc, float *d, lapack_int *ldd, float *e,
lapack_int *lde, float *f, lapack_int *ldf, float *r, lapack_int *ldr, float *l,
lapack_int *ldl, float *alpha, lapack_int *qblcka, lapack_int *qblckb);
```

```
void dlatm5 (*prtype, lapack_int *m, lapack_int *n, double *a, lapack_int *lda, double
*b, lapack_int *ldb, double *c, lapack_int *ldc, double *d, lapack_int *ldd, double *e,
lapack_int *lde, double *f, lapack_int *ldf, double *r, lapack_int *ldr, double *l,
lapack_int *ldl, double *alpha, lapack_int *qblcka, lapack_int *qblckb);

### Description

The ?latm5 routine generates matrices involved in the Generalized Sylvester equation:

$$A * R - L * B = C$$

$$D * R - L * E = F$$

They also satisfy the diagonalization condition:

$$\begin{bmatrix} I & -L \\ & I \end{bmatrix} \begin{bmatrix} A & -C \\ & B \end{bmatrix} \begin{bmatrix} I & R \\ & I \end{bmatrix} = \begin{bmatrix} A & \\ & B \end{bmatrix}$$

$$\begin{bmatrix} I & -L \\ & I \end{bmatrix} \begin{bmatrix} D & -F \\ & E \end{bmatrix} \begin{bmatrix} I & R \\ & I \end{bmatrix} = \begin{bmatrix} D & \\ & E \end{bmatrix}$$

### Input Parameters

*prtype*

Specifies the type of matrices to generate.

- If *prtype* = 1, *A* and *B* are Jordan blocks, *D* and *E* are identity matrices.

**A:**

If  $(i == j)$  then  $A_{i,j} = 1.0$ .

If  $(j == i + 1)$  then  $A_{i,j} = -1.0$ .

Otherwise  $A_{i,j} = 0.0, i, j = 1 \dots m$

**B:**

If  $(i == j)$  then  $B_{i,j} = 1.0 - \alpha$ .

If  $(j == i + 1)$  then  $B_{i,j} = 1.0$ .

Otherwise  $B_{i,j} = 0.0, i, j = 1 \dots n$ .

**D:**

If  $(i == j)$  then  $D_{i,j} = 1.0$ .

Otherwise  $D_{i,j} = 0.0, i, j = 1 \dots m$ .

**E:**

If  $(i == j)$  then  $E_{i,j} = 1.0$

Otherwise  $E_{i,j} = 0.0, i, j = 1 \dots n$ .

$L = R$  are chosen from  $[-10 \dots 10]$ , which specifies the right hand sides  $(C, F)$ .

- If  $prtype = 2$  or  $3$ : Triangular and/or quasi- triangular.

**A:**

If  $(i \leq j)$  then  $A_{i,j} = [-1 \dots 1]$ .

Otherwise  $A_{i,j} = 0.0, i, j = 1 \dots M$ .

If  $(prtype = 3)$  then  $A_{k+1,k+1} = A_{k,k}$ ;

$A_{k+1,k} = [-1 \dots 1]$ ;

$\text{sign}(A_{k,k+1}) = -(\text{sign}(A_{k+1,k}))$ .

$k = 1, m-1, qblkca$

**B :**

If  $(i \leq j)$  then  $B_{i,j} = [-1 \dots 1]$ .

Otherwise  $B_{i,j} = 0.0, i, j = 1 \dots n$ .

If  $(prtype = 3)$  then  $B_{k+1,k+1} = B_{k,k}$

$B_{k+1,k} = [-1 \dots 1]$

$\text{sign}(B_{k,k+1}) = -(\text{sign}(B_{k+1,k}))$

$k = 1, n-1, qblkcb$ .

**D:**

If  $(i \leq j)$  then  $D_{i,j} = [-1 \dots 1]$ .

Otherwise  $D_{i,j} = 0.0, i, j = 1 \dots m$ .

**E:**

If  $(i \leq j)$  then  $E_{i,j} = [-1 \dots 1]$ .

Otherwise  $E_{i,j} = 0.0$ ,  $i, j = 1 \dots N$ .

$L, R$  are chosen from  $[-10 \dots 10]$ , which specifies the right hand sides ( $C, F$ ).

- If  $prtype = 4$  Full

$$A_{i,j} = [-10 \dots 10]$$

$$D_{i,j} = [-1 \dots 1] \quad i, j = 1 \dots m$$

$$B_{i,j} = [-10 \dots 10]$$

$$E_{i,j} = [-1 \dots 1] \quad i, j = 1 \dots n$$

$$R_{i,j} = [-10 \dots 10]$$

$$L_{i,j} = [-1 \dots 1] \quad i = 1 \dots m, j = 1 \dots n$$

$L$  and  $R$  specifies the right hand sides ( $C, F$ ).

- If  $prtype = 5$  special case common and/or close eigs.

<i>m</i>	Specifies the order of $A$ and $D$ and the number of rows in $C, F, R$ and $L$ .
<i>n</i>	Specifies the order of $B$ and $E$ and the number of columns in $C, F, R$ and $L$ .
<i>lda</i>	The leading dimension of $a$ .
<i>ldb</i>	The leading dimension of $b$ .
<i>ldc</i>	The leading dimension of $c$ .
<i>ldd</i>	The leading dimension of $d$ .
<i>lde</i>	The leading dimension of $e$ .
<i>ldf</i>	The leading dimension of $f$ .
<i>ldr</i>	The leading dimension of $r$ .
<i>ldl</i>	The leading dimension of $l$ .
<i>alpha</i>	Parameter used in generating $prtype = 1$ and $5$ matrices.
<i>qblcka</i>	When $prtype = 3$ , specifies the distance between 2-by-2 blocks on the diagonal in $A$ . Otherwise, <i>qblcka</i> is not referenced. $qblcka > 1$ .
<i>qblckb</i>	When $prtype = 3$ , specifies the distance between 2-by-2 blocks on the diagonal in $B$ . Otherwise, <i>qblckb</i> is not referenced. $qblckb > 1$ .

## Output Parameters

<i>a</i>	Array, size $lda * m$ . On exit $a$ contains them-by- $m$ array $A$ initialized according to $prtype$ .
<i>b</i>	Array, size $ldb * n$ . On exit $b$ contains the $n$ -by- $n$ array $B$ initialized according to $prtype$ .
<i>c</i>	Array, size $ldc * n$ . On exit $c$ contains the $m$ -by- $n$ array $C$ initialized according to $prtype$ .

<i>d</i>	Array, size <i>ldd</i> * <i>m</i> . On exit <i>d</i> contains the <i>m</i> -by- <i>m</i> array <i>D</i> initialized according to <i>prtype</i> .
<i>e</i>	Array, size <i>lde</i> * <i>n</i> . On exit <i>e</i> contains the <i>n</i> -by- <i>n</i> array <i>E</i> initialized according to <i>prtype</i> .
<i>f</i>	Array, size <i>ldf</i> * <i>n</i> . On exit <i>f</i> contains the <i>m</i> -by- <i>n</i> array <i>F</i> initialized according to <i>prtype</i> .
<i>r</i>	Array, size <i>ldr</i> * <i>n</i> . On exit <i>R</i> contains the <i>m</i> -by- <i>n</i> array <i>R</i> initialized according to <i>prtype</i> .
<i>l</i>	Array, size <i>ldl</i> * <i>n</i> . On exit <i>l</i> contains the <i>m</i> -by- <i>n</i> array <i>L</i> initialized according to <i>prtype</i> .

## ?latm6

*Generates test matrices for the generalized eigenvalue problem, their corresponding right and left eigenvector matrices, and also reciprocal condition numbers for all eigenvalues and the reciprocal condition numbers of eigenvectors corresponding to the 1th and 5th eigenvalues.*

### Syntax

```
void slatm6 (lapack_int *type, lapack_int *n, float *a, lapack_int *lda, float *b, float *x, lapack_int *ldx, float *y, lapack_int *ldy, float *alpha, float *beta, float *wx, float *wy, float *s, float *dif);
```

```
void dlatm6 (lapack_int *type, lapack_int *n, double *a, lapack_int *lda, double *b, double *x, lapack_int *ldx, double *y, lapack_int *ldy, double *alpha, double *beta, double *wx, double *wy, double *s, double *dif);
```

```
void clatm6 (lapack_int *type, lapack_int *n, lapack_complex_float *a, lapack_int *lda, lapack_complex_float *b, lapack_complex_float *x, lapack_int *ldx, lapack_complex_float *y, lapack_int *ldy, lapack_complex_float *alpha, lapack_complex_float *beta, lapack_complex_float *wx, lapack_complex_float *wy, float *s, float *dif);
```

```
void zlatm6 (lapack_int *type, lapack_int *n, lapack_complex_double *a, lapack_int *lda, lapack_complex_double *b, lapack_complex_double *x, lapack_int *ldx, lapack_complex_double *y, lapack_int *ldy, lapack_complex_double *alpha, lapack_complex_double *beta, lapack_complex_double *wx, lapack_complex_double *wy, double *s, double *dif);
```

### Include Files

- mkl.h

### Description

The ?latm6 routine generates test matrices for the generalized eigenvalue problem, their corresponding right and left eigenvector matrices, and also reciprocal condition numbers for all eigenvalues and the reciprocal condition numbers of eigenvectors corresponding to the 1th and 5th eigenvalues.

There two kinds of test matrix pairs:

$$(A, B) = \text{inverse}(YH) * (Da, Db) * \text{inverse}(X)$$

Type 1:

$$Da = \begin{bmatrix} 1+a & 0 & 0 & 0 & 0 \\ 0 & 2+a & 0 & 0 & 0 \\ 0 & 0 & 3+a & 0 & 0 \\ 0 & 0 & 0 & 4+a & 0 \\ 0 & 0 & 0 & 0 & 5+2 \end{bmatrix} \quad Db = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

Type 2:

$$Da = \begin{bmatrix} 1+i & 0 & 0 & 0 & 0 \\ 0 & 1-i & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & (1+a)+(1+b)i & 0 \\ 0 & 0 & 0 & 0 & (1+a)-(1+b)i \end{bmatrix} \quad Db = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

In both cases the same  $\text{inverse}(YH)$  and  $\text{inverse}(X)$  are used to compute  $(A, B)$ , giving the exact eigenvectors to  $(A, B)$  as  $(YH, X)$ :

$$YH = \begin{bmatrix} 1 & 0 & -y & y & -y \\ 0 & 1 & -y & y & -y \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad X = \begin{bmatrix} 1 & 0 & -x & -x & x \\ 0 & 1 & x & -x & -x \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

,

where  $a, b, x$  and  $y$  will have all values independently of each other.

## Input Parameters

<i>type</i>	Specifies the problem type.
<i>n</i>	Size of the matrices $A$ and $B$ .
<i>lda</i>	The leading dimension of $a$ and of $b$ .
<i>ldx</i>	The leading dimension of $x$ .
<i>ldy</i>	The leading dimension of $y$ .
<i>alpha, beta</i>	Weighting constants for matrix $A$ .
<i>wx</i>	Constant for right eigenvector matrix.
<i>wy</i>	Constant for left eigenvector matrix.

## Output Parameters

<i>a</i>	Array, size $lda*n$ . On exit, $a$ contains the $n$ -by- $n$ matrix initialized according to <i>type</i> .
----------	--

<i>b</i>	Array, size <i>lda</i> * <i>n</i> . On exit, <i>b</i> contains the <i>n</i> -by- <i>n</i> matrix initialized according to <i>type</i> .
<i>x</i>	Array, size <i>ldx</i> * <i>n</i> . On exit, <i>x</i> contains the <i>n</i> -by- <i>n</i> matrix of right eigenvectors.
<i>y</i>	Array, size <i>ldy</i> * <i>n</i> . On exit, <i>y</i> is the <i>n</i> -by- <i>n</i> matrix of left eigenvectors.
<i>s</i>	Array, size ( <i>n</i> ). <i>s</i> [ <i>i</i> - 1] is the reciprocal condition number for eigenvalue <i>i</i> .
<i>dif</i>	Array, size( <i>n</i> ). <i>dif</i> [ <i>i</i> - 1] is the reciprocal condition number for eigenvector <i>i</i> .

## ?latme

Generates random non-symmetric square matrices with specified eigenvalues.

### Syntax

```

### Include Files

- mkl.h

### Description

The ?latme routine generates random non-symmetric square matrices with specified eigenvalues. ?latme operates by applying the following sequence of operations:

1. Set the diagonal to *d*, where *d* may be input or computed according to *mode*, *cond*, *dmax*, and *rsign* as described below.
2. If *upper* = 'T', the upper triangle of *a* is set to random values out of distribution *dist*.
3. If *sim*='T', *a* is multiplied on the left by a random matrix *X*, whose singular values are specified by *ds*, *modes*, and *conds*, and on the right by *X* inverse.
4. If *kl* < *n*-1, the lower bandwidth is reduced to *kl* using Householder transformations. If *ku* < *n*-1, the upper bandwidth is reduced to *ku*.

5. If  $anorm$  is not negative, the matrix is scaled to have maximum-element-norm  $anorm$ .

**NOTE**

Since the matrix cannot be reduced beyond Hessenberg form, no packing options are available.

**Input Parameters**

$n$	The number of columns (or rows) of $A$ .
$dist$	On entry, $dist$ specifies the type of distribution to be used to generate the random eigen-/singular values, and on the upper triangle (see <i>upper</i> ). If $dist = 'U'$ : uniform( 0, 1 ) If $dist = 'S'$ : uniform( -1, 1 ) If $dist = 'N'$ : normal( 0, 1 ) If $dist = 'D'$ : uniform on the complex disc $ z  < 1$ .
$iseed$	Array, size 4. On entry $iseed$ specifies the seed of the random number generator. The elements should lie between 0 and 4095 inclusive, and $iseed[3]$ should be odd. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers.
$d$	Array, size ( $n$ ). This array is used to specify the eigenvalues of $A$ . If $mode = 0$ , then $d$ is assumed to contain the eigenvalues. Otherwise they are computed according to $mode$ , $cond$ , $dmax$ , and $rsign$ and placed in $d$ .
$mode$	On entry $mode$ describes how the eigenvalues are to be specified: $mode = 0$ means use $d$ (with $ei$ for <i>slatme</i> and <i>dlatme</i> ) as input. $mode = 1$ sets $d[0] = 1$ and $d(2:n)=1.0/cond$ . $mode = 2$ sets $d[0:n - 2] = 1$ and $d[n - 1]=1.0/cond$ . $mode = 3$ sets $d[i - 1] = cond^{-(i-1)/(n-1)}$ . $mode = 4$ sets $d[i - 1] = 1 - (i-1)/(n-1)*(1 - 1/cond)$ . $mode = 5$ sets $d$ to random numbers in the range ( $1/cond$ , 1 ) such that their logarithms are uniformly distributed. $mode = 6$ sets $d$ to random numbers from same distribution as the rest of the matrix. $mode < 0$ has the same meaning as $abs(mode)$ , except that the order of the elements of $d$ is reversed. Thus if $mode$ is between 1 and 4, $d$ has entries ranging from 1 to $1/cond$ , if between -1 and -4, $d$ has entries ranging from $1/cond$ to 1.
$cond$	On entry, this is used as described under $mode$ above. If used, it must be $\geq 1$ .

<i>dmax</i>	<p>If <i>mode</i> is not -6, 0 or 6, the contents of <i>d</i> as computed according to <i>mode</i> and <i>cond</i> are scaled by <math>dmax / \max(\text{abs}(d[i - 1]))</math>. Note that <i>dmax</i> needs not be positive or real: if <i>dmax</i> is negative or complex (or zero), <i>d</i> will be scaled by a negative or complex number (or zero). If <i>rsign</i>='F' then the largest (absolute) eigenvalue will be equal to <i>dmax</i>.</p>
<i>ei</i>	<p>Used by <i>slatme</i> and <i>dlatme</i> only.</p> <p>Array, size (<i>n</i>).</p> <p>If <i>mode</i> = 0, and <i>ei</i>[0] is not ' ' (space character), this array specifies which elements of <i>d</i> (on input) are real eigenvalues and which are the real and imaginary parts of a complex conjugate pair of eigenvalues. The elements of <i>ei</i> may then only have the values 'R' and 'I'.</p> <p>If <i>ei</i>[<i>j</i> - 1] = 'R' and <i>ei</i>[<i>j</i>] = 'I', then the <i>j</i>-th eigenvalue is <math>\text{cmplx}(d[j - 1], d[j])</math>, and the (<i>j</i> + 1)-th is the complex conjugate thereof.</p> <p>If <i>ei</i>[<i>j</i> - 1] = <i>ei</i>[<i>j</i>] = 'R', then the <i>j</i>-th eigenvalue is <i>d</i>[<i>j</i> - 1] (i.e., real). <i>ei</i>[0] may not be 'I', nor may two adjacent elements of <i>ei</i> both have the value 'I'.</p> <p>If <i>mode</i> is not 0, then <i>ei</i> is ignored. If <i>mode</i> is 0 and <i>ei</i>[0] = ' ', then the eigenvalues will all be real.</p>
<i>rsign</i>	<p>If <i>mode</i> is not 0, 6, or -6, and <i>rsign</i> = 'T', then the elements of <i>d</i>, as computed according to <i>mode</i> and <i>cond</i>, are multiplied by a random sign (+1 or -1) for <i>slatme</i> and <i>dlatme</i> or by a complex number from the unit circle <math> z  = 1</math> for <i>clatme</i> and <i>zlatme</i>.</p> <p>If <i>rsign</i> = 'F', the elements of <i>d</i> are not multiplied. <i>rsign</i> may only have the values 'T' or 'F'.</p>
<i>upper</i>	<p>If <i>upper</i> = 'T', then the elements of <i>a</i> above the diagonal will be set to random numbers out of <i>dist</i>.</p> <p>If <i>upper</i> = 'F', they will not. <i>upper</i> may only have the values 'T' or 'F'.</p>
<i>sim</i>	<p>If <i>sim</i> = 'T', then <i>a</i> will be operated on by a "similarity transform", i.e., multiplied on the left by a matrix <i>X</i> and on the right by <i>X</i> inverse. <math>X = USV</math>, where <i>U</i> and <i>V</i> are random unitary matrices and <i>S</i> is a (diagonal) matrix of singular values specified by <i>ds</i>, <i>modes</i>, and <i>conds</i>.</p> <p>If <i>sim</i> = 'F', then <i>a</i> will not be transformed.</p>
<i>ds</i>	<p>This array is used to specify the singular values of <i>X</i>, in the same way that <i>d</i> specifies the eigenvalues of <i>a</i>. If <i>mode</i> = 0, the <i>ds</i> contains the singular values, which may not be zero.</p>
<i>modes</i>	<p>Similar to <i>mode</i>, but for specifying the diagonal of <i>S</i>. <i>modes</i> = -6 and +6 are not allowed (since they would result in randomly ill-conditioned eigenvalues.)</p>
<i>conds</i>	<p>Similar to <i>cond</i>, but for specifying the diagonal of <i>S</i>.</p>

<i>kl</i>	This specifies the lower bandwidth of the matrix. <i>kl</i> = 1 specifies upper Hessenberg form. If <i>kl</i> is at least $n-1$ , then <i>A</i> will have full lower bandwidth.
<i>ku</i>	This specifies the upper bandwidth of the matrix. <i>ku</i> = 1 specifies lower Hessenberg form. If <i>ku</i> is at least $n-1$ , then <i>a</i> will have full upper bandwidth. If <i>ku</i> and <i>kl</i> are both at least $n-1$ , then <i>a</i> will be dense. Only one of <i>ku</i> and <i>kl</i> may be less than $n-1$ .
<i>anorm</i>	If <i>anorm</i> is not negative, then <i>a</i> is scaled by a non-negative real number to make the maximum-element-norm of <i>a</i> to be <i>anorm</i> .
<i>lda</i>	Number of rows of matrix <i>A</i> .
<i>work</i>	Array, size $(3*n)$ . Workspace.

## Output Parameters

<i>iseed</i>	On exit, the seed is updated.
<i>d</i>	Modified if <i>mode</i> is nonzero.
<i>ds</i>	Modified if <i>mode</i> is nonzero.
<i>a</i>	Array, size $lda*n$ . On exit, <i>a</i> is the desired test matrix.
<i>info</i>	If <i>info</i> = 0, execution is successful. If <i>info</i> = -1, <i>n</i> is negative . If <i>info</i> = -2, <i>dist</i> is an illegal string. If <i>info</i> = -5, <i>mode</i> is not in range -6 to 6. If <i>info</i> = -6, <i>cond</i> is less than 1.0, and <i>mode</i> is not -6, 0, or 6 . If <i>info</i> = -9, <i>rsign</i> is not 'T' or 'F' . If <i>info</i> = -10, <i>upper</i> is not 'T' or 'F'. If <i>info</i> = -11, <i>sim</i> is not 'T' or 'F'. If <i>info</i> = -12, <i>modes</i> = 0 and <i>ds</i> has a zero singular value. If <i>info</i> = -13, <i>modes</i> is not in the range -5 to 5. If <i>info</i> = -14, <i>modes</i> is nonzero and <i>conds</i> is less than 1. . If <i>info</i> = -15, <i>kl</i> is less than 1. If <i>info</i> = -16, <i>ku</i> is less than 1, or <i>kl</i> and <i>ku</i> are both less than $n-1$ . If <i>info</i> = -19, <i>lda</i> is less than <i>m</i> . If <i>info</i> = 1, error return from ?latm1 (computing <i>d</i> ) . If <i>info</i> = 2, cannot scale to <i>dmax</i> (max. eigenvalue is 0) . If <i>info</i> = 3, error return from slatm1(for slatme and clatme), dlatm1 (for dlatme and zlatme) . If <i>info</i> = 4, error return from ?large.

If *info* = 5, zero singular value from slatml(for slatme and clatme), dlatml(for dlatme and zlatme).

## ?latmr

*Generates random matrices of various types.*

### Syntax

```

```

### Description

The ?latmr routine operates by applying the following sequence of operations:

1. Generate a matrix *A* with random entries of distribution *dist*:
  - If *sym* = 'S', the matrix is symmetric,
  - If *sym* = 'H', the matrix is Hermitian,
  - If *sym* = 'N', the matrix is nonsymmetric.
2. Set the diagonal to *D*, where *D* may be input or computed according to *mode*, *cond*, *dmax* and *rsign* as described below.
3. Grade the matrix, if desired, from the left or right as specified by *grade*. The inputs *d1*, *model*, *concl*, *dr*, *moder* and *concl* also determine the grading as described below.
4. Permute, if desired, the rows and/or columns as specified by *pivtng* and *ipivot*.
5. Set random entries to zero, if desired, to get a random sparse matrix as specified by *sparse*.
6. Make *A* a band matrix, if desired, by zeroing out the matrix outside a band of lower bandwidth *kl* and upper bandwidth *ku*.
7. Scale *A*, if desired, to have maximum entry *anorm*.

8. Pack the matrix if desired. See options specified by the *pack* parameter.

---

**NOTE**

If two calls to `?latmr` differ only in the *pack* parameter, they generate mathematically equivalent matrices. If two calls to `?latmr` both have full bandwidth ( $kl = m-1$  and  $ku = n-1$ ), and differ only in the *pivtn*g and *pack* parameters, then the matrices generated differ only in the order of the rows and columns, and otherwise contain the same data. This consistency cannot be and is not maintained with less than full bandwidth.

---

## Input Parameters

<i>m</i>	Number of rows of <i>A</i> .
<i>n</i>	Number of columns of <i>A</i> .
<i>dist</i>	On entry, <i>dist</i> specifies the type of distribution to be used to generate a random matrix . If <i>dist</i> = 'U', real and imaginary parts are independent uniform( 0, 1 ). If <i>dist</i> = 'S', real and imaginary parts are independent uniform( -1, 1 ). If <i>dist</i> = 'N', real and imaginary parts are independent normal( 0, 1 ). If <i>dist</i> = 'D', distribution is uniform on interior of unit disk.
<i>iseed</i>	Array, size 4. On entry, <i>iseed</i> specifies the seed of the random number generator. They should lie between 0 and 4095 inclusive, and <i>iseed</i> [3] should be odd. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers.
<i>sym</i>	If <i>sym</i> = 'S', generated matrix is symmetric. If <i>sym</i> = 'H', generated matrix is Hermitian. If <i>sym</i> = 'N', generated matrix is nonsymmetric.
<i>d</i>	On entry this array specifies the diagonal entries of the diagonal of <i>A</i> . <i>d</i> may either be specified on entry, or set according to <i>mode</i> and <i>cond</i> as described below. If the matrix is Hermitian, the real part of <i>d</i> is taken. May be changed on exit if <i>mode</i> is nonzero.
<i>mode</i>	On entry describes how <i>d</i> is to be used: <i>mode</i> = 0 means use <i>d</i> as input. <i>mode</i> = 1 sets $d[0]=1$ and $d[1:n - 1]=1.0/cond$ . <i>mode</i> = 2 sets $d[0:n - 2]=1$ and $d[n - 1]=1.0/cond$ . <i>mode</i> = 3 sets $d[i - 1]=cond^{-(i-1)/(n-1)}$ . <i>mode</i> = 4 sets $d[i - 1]=1 - (i-1)/(n-1)*(1 - 1/cond)$ . <i>mode</i> = 5 sets <i>d</i> to random numbers in the range ( $1/cond$ , 1 ) such that their logarithms are uniformly distributed.

$mode = 6$  sets  $d$  to random numbers from same distribution as the rest of the matrix.

$mode < 0$  has the same meaning as  $abs(mode)$ , except that the order of the elements of  $d$  is reversed.

Thus if  $mode$  is between 1 and 4,  $d$  has entries ranging from 1 to  $1/cond$ , if between -1 and -4,  $D$  has entries ranging from  $1/cond$  to 1.

*cond*

On entry, used as described under *mode* above. If used, *cond* must be  $\geq 1$ .

*dmax*

If *mode* is not -6, 0, or 6, the diagonal is scaled by  $dmax / \max(abs(d[i]))$ , so that maximum absolute entry of diagonal is  $abs(dmax)$ . If *dmax* is complex (or zero), the diagonal is scaled by a complex number (or zero).

*rsign*

If *mode* is not -6, 0, or 6, specifies the sign of the diagonal as follows:

For *slatmr* and *dlatmr*, if *rsign* = 'T', diagonal entries are multiplied 1 or -1 with a probability of 0.5.

For *clatmr* and *zlatmr*, if *rsign* = 'T', diagonal entries are multiplied by a random complex number uniformly distributed with absolute value 1.

If *rsign* = 'F', diagonal entries are unchanged.

*grade*

Specifies grading of matrix as follows:

If *grade* = 'N', there is no grading

If *grade* = 'L', matrix is premultiplied by  $diag(dl)$  (only if matrix is nonsymmetric)

If *grade* = 'R', matrix is postmultiplied by  $diag(dr)$  (only if matrix is nonsymmetric)

If *grade* = 'B', matrix is premultiplied by  $diag(dl)$  and postmultiplied by  $diag(dr)$  (only if matrix is nonsymmetric)

If *grade* = 'H', matrix is premultiplied by  $diag(dl)$  and postmultiplied by  $diag(conjg(dl))$  (only if matrix is Hermitian or nonsymmetric)

If *grade* = 'S', matrix is premultiplied by  $diag(dl)$  and postmultiplied by  $diag(dl)$  (only if matrix is symmetric or nonsymmetric)

If *grade* = 'E', matrix is premultiplied by  $diag(dl)$  and postmultiplied by  $inv(diag(dl))$  (only if matrix is nonsymmetric)

---

#### NOTE

if *grade* = 'E', then  $m$  must equal  $n$ .

---

*dl*

Array, size ( $m$ ).

If *model* = 0, then on entry this array specifies the diagonal entries of a diagonal matrix used as described under *grade* above.

If *model* is not zero, then *dl* is set according to *model* and *condl*, analogous to the way  $D$  is set according to *mode* and *cond* (except there is no *dmax* parameter for *dl*).

If *grade* = 'E', then *dl* cannot have zero entries.

	Not referenced if $grade = 'N'$ or $'R'$ . Changed on exit.
<i>model</i>	This specifies how the diagonal array <i>dl</i> is computed, just as <i>mode</i> specifies how <i>D</i> is computed.
<i>condl</i>	When <i>model</i> is not zero, this specifies the condition number of the computed <i>dl</i> .
<i>dr</i>	<p>If <i>moder</i> = 0, then on entry this array specifies the diagonal entries of a diagonal matrix used as described under <i>grade</i> above.</p> <p>If <i>moder</i> is not zero, then <i>dr</i> is set according to <i>moder</i> and <i>condr</i>, analogous to the way <i>d</i> is set according to <i>mode</i> and <i>cond</i> (except there is no <i>dmax</i> parameter for <i>dr</i>).</p> <p>Not referenced if <math>grade = 'N', 'L', 'H', 'S'</math> or <math>'E'</math>.</p>
<i>moder</i>	This specifies how the diagonal array <i>dr</i> is to be computed, just as <i>mode</i> specifies how <i>d</i> is to be computed.
<i>condr</i>	When <i>moder</i> is not zero, this specifies the condition number of the computed <i>dr</i> .
<i>pivtnng</i>	<p>On entry specifies pivoting permutations as follows:</p> <p>If <i>pivtnng</i> = <math>'N'</math> or <math>' '</math>: no pivoting permutation.</p> <p>If <i>pivtnng</i> = <math>'L'</math>: left or row pivoting (matrix must be nonsymmetric).</p> <p>If <i>pivtnng</i> = <math>'R'</math>: right or column pivoting (matrix must be nonsymmetric).</p> <p>If <i>pivtnng</i> = <math>'B'</math> or <math>'F'</math>: both or full pivoting, i.e., on both sides. In this case, <i>m</i> must equal <i>n</i>.</p> <p>If two calls to ?latmr both have full bandwidth (<math>kl = m - 1</math> and <math>ku = n - 1</math>), and differ only in the <i>pivtnng</i> and <i>pack</i> parameters, then the matrices generated differs only in the order of the rows and columns, and otherwise contain the same data. This consistency cannot be maintained with less than full bandwidth.</p>
<i>ipivot</i>	<p>Array, size (<i>n</i> or <i>m</i>) This array specifies the permutation used. After the basic matrix is generated, the rows, columns, or both are permuted.</p> <p>If row pivoting is selected, ?latmr starts with the last row and interchanges row <i>m</i> and row <i>ipivot</i>[<i>m</i> - 1], then moves to the next-to-last row, interchanging rows [<i>m</i> - 2] and row <i>ipivot</i>[<i>m</i> - 2], and so on. In terms of "2-cycles", the permutation is (1 <i>ipivot</i>[0]) (2 <i>ipivot</i>[1]) ... (<i>mipivot</i>[<i>m</i> - 1]) where the rightmost cycle is applied first. This is the inverse of the effect of pivoting in LINPACK. The idea is that factoring (with pivoting) an identity matrix which has been inverse-pivoted in this way should result in a pivot vector identical to <i>ipivot</i>. Not referenced if <i>pivtnng</i> = <math>'N'</math>.</p>
<i>sparse</i>	On entry, specifies the sparsity of the matrix if a sparse matrix is to be generated. <i>sparse</i> should lie between 0 and 1. To generate a sparse matrix, for each matrix entry a uniform ( 0, 1 ) random number <i>x</i> is generated and compared to <i>sparse</i> ; if <i>x</i> is larger the matrix entry is unchanged and if <i>x</i> is smaller the entry is set to zero. Thus on the average a fraction <i>sparse</i> of the entries is set to zero.

- kl* On entry, specifies the lower bandwidth of the matrix. For example,  $kl = 0$  implies upper triangular,  $kl = 1$  implies upper Hessenberg, and  $kl$  at least  $m-1$  implies the matrix is not banded. Must equal  $ku$  if matrix is symmetric or Hermitian.
- ku* On entry, specifies the upper bandwidth of the matrix. For example,  $ku = 0$  implies lower triangular,  $ku = 1$  implies lower Hessenberg, and  $ku$  at least  $n-1$  implies the matrix is not banded. Must equal  $kl$  if matrix is symmetric or Hermitian.
- anorm* On entry, specifies maximum entry of output matrix (output matrix is multiplied by a constant so that its largest absolute entry equal *anorm*) if *anorm* is nonnegative. If *anorm* is negative no scaling is done.
- pack* On entry, specifies packing of matrix as follows:
- If *pack* = 'N': no packing
  - If *pack* = 'U': zero out all subdiagonal entries (if symmetric or Hermitian)
  - If *pack* = 'L': zero out all superdiagonal entries (if symmetric or Hermitian)
  - If *pack* = 'C': store the upper triangle columnwise (only if matrix symmetric or Hermitian or square upper triangular)
  - If *pack* = 'R': store the lower triangle columnwise (only if matrix symmetric or Hermitian or square lower triangular) (same as upper half rowwise if symmetric) (same as conjugate upper half rowwise if Hermitian)
  - If *pack* = 'B': store the lower triangle in band storage scheme (only if matrix symmetric or Hermitian)
  - If *pack* = 'Q': store the upper triangle in band storage scheme (only if matrix symmetric or Hermitian)
  - If *pack* = 'Z': store the entire matrix in band storage scheme (pivoting can be provided for by using this option to store *A* in the trailing rows of the allocated storage)
- Using these options, the various LAPACK packed and banded storage schemes can be obtained:

LAPACK storage scheme	Value of <i>pack</i>
GB	'Z'
PB, HB or TB	'B' or 'Q'
PP, HP or TP	'C' or 'R'

If two calls to ?latmr differ only in the *pack* parameter, they generate mathematically equivalent matrices.

- lda* On entry, *lda* specifies the first dimension of *a* as declared in the calling program.
- If *pack* = 'N', 'U' or 'L', *lda* must be at least  $\max(1, m)$ .
  - If *pack* = 'C' or 'R', *lda* must be at least 1.
  - If *pack* = 'B', or 'Q', *lda* must be  $\min(ku + 1, n)$ .

If  $pack = 'Z'$ ,  $lda$  must be at least  $kuu + kll + 1$ , where  $kuu = \min(ku, n-1)$  and  $kll = \min(kl, n-1)$ .

*iwork* Array, size ( $n$  or  $m$ ). Workspace. Not referenced if  $pivtnng = 'N'$ . Changed on exit.

## Output Parameters

*iseed* On exit, the seed is changed.

*d* May be changed on exit if  $mode$  is nonzero.

*dl* On exit, array is changed.

*dr* On exit, array is changed.

*a* On exit,  $a$  is the desired test matrix. Only those entries of  $a$  which are significant on output is referenced (even if  $a$  is in packed or band storage format). The unoccupied corners of  $a$  in band format are zeroed out.

*info*

If  $info = 0$ , the execution is successful.

If  $info = -1$ ,  $m$  is negative or unequal to  $n$  and  $sym = 'S'$  or  $'H'$ .

If  $info = -2$ ,  $n$  is negative .

If  $info = -3$ ,  $dist$  is an illegal string.

If  $info = -5$ ,  $sym$  is an illegal string..

If  $info = -7$ ,  $mode$  is not in range -6 to 6.

If  $info = -8$ ,  $cond$  is less than 1.0, and  $mode$  is neither -6, 0 nor 6.

If  $info = -10$ ,  $mode$  is neither -6, 0 nor 6 and  $rsign$  is an illegal string.

If  $info = -11$ ,  $grade$  is an illegal string, or  $grade = 'E'$  and  $m$  is not equal to  $n$ , or  $grade = 'L', 'R', 'B', 'S'$  or  $'E'$  and  $sym = 'H'$ , or  $grade = 'L', 'R', 'B', 'H'$  or  $'E'$  and  $sym = 'S'$

If  $info = -12$ ,  $grade = 'E'$  and  $dl$  contains zero .

If  $info = -13$ ,  $model$  is not in range -6 to 6 and  $grade = 'L', 'B', 'H', 'S'$  or  $'E'$  .

If  $info = -14$ ,  $concl$  is less than 1.0,  $grade = 'L', 'B', 'H', 'S'$  or  $'E'$ , and  $model$  is neither -6, 0 nor 6.

If  $info = -16$ ,  $moder$  is not in range -6 to 6 and  $grade = 'R'$  or  $'B'$  .

If  $info = -17$ ,  $condr$  is less than 1.0,  $grade = 'R'$  or  $'B'$ , and  $moder$  is neither -6, 0 nor 6 .

If  $info = -18$ ,  $pivtnng$  is an illegal string, or  $pivtnng = 'B'$  or  $'F'$  and  $m$  is not equal to  $n$ , or  $pivtnng = 'L'$  or  $'R'$  and  $sym = 'S'$  or  $'H'$ .

If  $info = -19$ ,  $ipivot$  contains out of range number and  $pivtnng$  is not equal to  $'N'$  .

If  $info = -20$ ,  $kl$  is negative.

If  $info = -21$ ,  $ku$  is negative, or  $sym = 'S'$  or  $'H'$  and  $ku$  not equal to  $kl$ .

If  $info = -22$ ,  $sparse$  is not in range 0 to 1.

If  $info = -24$ ,  $pack$  is an illegal string, or  $pack = 'U'$ ,  $'L'$ ,  $'B'$  or  $'Q'$  and  $sym = 'N'$ , or  $pack = 'C'$  and  $sym = 'N'$  and either  $kl$  is not equal to 0 or  $n$  is not equal to  $m$ , or  $pack = 'R'$  and  $sym = 'N'$ , and either  $ku$  is not equal to 0 or  $n$  is not equal to  $m$ .

If  $info = -26$ ,  $lda$  is too small.

If  $info = 1$ , error return from `?latm1` (computing  $D$ ).

If  $info = 2$ , cannot scale to  $dmax$  (max. entry is 0).

If  $info = 3$ , error return from `?latm1`(computing  $d1$ ).

If  $info = 4$ , error return from `?latm1`(computing  $dr$ ).

If  $info = 5$ ,  $anorm$  is positive, but matrix constructed prior to attempting to scale it to have norm  $anorm$ , is zero.

## ?lauum

Computes the product  $U*U^T(U*U^H)$  or  $L^T*L(L^H*L)$ , where  $U$  and  $L$  are upper or lower triangular matrices (blocked algorithm).

## Syntax

```
lapack_int LAPACKE_slauum (int matrix_layout , char uplo , lapack_int n , float * a ,
lapack_int lda );
```

```
lapack_int LAPACKE_dlauum (int matrix_layout , char uplo , lapack_int n , double * a ,
lapack_int lda );
```

```
lapack_int LAPACKE_clauum (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_float * a , lapack_int lda );
```

```
lapack_int LAPACKE_zlauum (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_double * a , lapack_int lda );
```

## Include Files

- mkl.h

## Description

The routine `?lauum` computes the product  $U*U^T$  or  $L^T*L$  for real flavors, and  $U*U^H$  or  $L^H*L$  for complex flavors. Here the triangular factor  $U$  or  $L$  is stored in the upper or lower triangular part of the array  $a$ .

If  $uplo = 'U'$  or  $'u'$ , then the upper triangle of the result is stored, overwriting the factor  $U$  in  $A$ .

If  $uplo = 'L'$  or  $'l'$ , then the lower triangle of the result is stored, overwriting the factor  $L$  in  $A$ .

This is the blocked form of the algorithm, calling [BLAS Level 3 Routines](#).

## Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<i>uplo</i>	Specifies whether the triangular factor stored in the array <i>a</i> is upper or lower triangular: = 'U': Upper triangular = 'L': Lower triangular
<i>n</i>	The order of the triangular factor <i>U</i> or <i>L</i> . $n \geq 0$ .
<i>a</i>	Array of size $\max(1, lda * n)$ . On entry, the triangular factor <i>U</i> or <i>L</i> .
<i>lda</i>	The leading dimension of the array <i>a</i> . $lda \geq \max(1, n)$ .

## Output Parameters

<i>a</i>	On exit, if <i>uplo</i> = 'U', then the upper triangle of <i>a</i> is overwritten with the upper triangle of the product $U * U^T (U * U^H)$ ; if <i>uplo</i> = 'L', then the lower triangle of <i>a</i> is overwritten with the lower triangle of the product $L^T * L (L^H * L)$ .
----------	--

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*k*, the *k*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

## ?syswapr

*Applies an elementary permutation on the rows and columns of a symmetric matrix.*

## Syntax

```
lapack_int LAPACKE_ssyswapr (int matrix_layout , char uplo , lapack_int n , float * a ,
lapack_int i1 , lapack_int i2 );
```

```
lapack_int LAPACKE_dsyswapr (int matrix_layout , char uplo , lapack_int n , double *
a , lapack_int i1 , lapack_int i2 );
```

```
lapack_int LAPACKE_csyswapr (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_float * a , lapack_int i1 , lapack_int i2 );
```

```
lapack_int LAPACKE_zsyswapr (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_double * a , lapack_int i1 , lapack_int i2 );
```

## Include Files

- mkl.h

## Description

The routine applies an elementary permutation on the rows and columns of a symmetric matrix.

## Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>uplo</code>	Must be 'U' or 'L'.  Indicates how the input matrix $A$ has been factored:  If <code>uplo = 'U'</code> , the array $a$ stores the upper triangular factor $U$ of the factorization $A = U*D*U^T$ .  If <code>uplo = 'L'</code> , the array $a$ stores the lower triangular factor $L$ of the factorization $A = L*D*L^T$ .
<code>n</code>	The order of matrix $A$ ; $n \geq 0$ .
<code>nrhs</code>	The number of right-hand sides; $nrhs \geq 0$ .
<code>a</code>	Array of size at least $\max(1, lda*n)$ .  The array $a$ contains the block diagonal matrix $D$ and the multipliers used to obtain the factor $U$ or $L$ as computed by <code>?sytrf</code> .
<code>i1</code>	Index of the first row to swap.
<code>i2</code>	Index of the second row to swap.

## Output Parameters

<code>a</code>	If <code>info = 0</code> , the symmetric inverse of the original matrix.  If <code>info = 'U'</code> , the upper triangular part of the inverse is formed and the part of $A$ below the diagonal is not referenced.  If <code>info = 'L'</code> , the lower triangular part of the inverse is formed and the part of $A$ above the diagonal is not referenced.
----------------	--

## Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful.

If `info = -i`, the  $i$ -th parameter had an illegal value.

If `info = -1011`, memory allocation error occurred.

[?hetrf](#)

## ?sfrk

Performs a symmetric rank- $k$  operation for matrix in RFP format.

## Syntax

```
lapack_int LAPACKE_ssfrk (int matrix_layout , char transr , char uplo , char trans ,
lapack_int n , lapack_int k , float alpha , const float * a , lapack_int lda , float
beta , float * c );
```

```
lapack_int LAPACKE_dsfrk (int matrix_layout , char transr , char uplo , char trans ,
lapack_int n , lapack_int k , double alpha , const double * a , lapack_int lda , double
beta , double * c );
```

## Include Files

- mkl.h

## Description

The `?sfrk` routines perform a matrix-matrix operation using symmetric matrices. The operation is defined as

$$C := \alpha * A * A^T + \beta * C,$$

or

$$C := \alpha * A^T * A + \beta * C,$$

where:

$\alpha$  and  $\beta$  are scalars,

$C$  is an  $n$ -by- $n$  symmetric matrix in [rectangular full packed \(RFP\) format](#),

$A$  is an  $n$ -by- $k$  matrix in the first case and a  $k$ -by- $n$  matrix in the second case.

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>transr</code>	if <code>transr = 'N'</code> or <code>'n'</code> , the normal form of RFP $C$ is stored; if <code>transr = 'T'</code> or <code>'t'</code> , the transpose form of RFP $C$ is stored.
<code>uplo</code>	Specifies whether the upper or lower triangular part of the array $c$ is used. If <code>uplo = 'U'</code> or <code>'u'</code> , then the upper triangular part of the array $c$ is used. If <code>uplo = 'L'</code> or <code>'l'</code> , then the low triangular part of the array $c$ is used.
<code>trans</code>	Specifies the operation: if <code>trans = 'N'</code> or <code>'n'</code> , then $C := \alpha * A * A^T + \beta * C$ ; if <code>trans = 'T'</code> or <code>'t'</code> , then $C := \alpha * A^T * A + \beta * C$ ;
<code>n</code>	Specifies the order of the matrix $C$ . The value of $n$ must be at least zero.

*k* On entry with *trans* = 'N' or 'n', *k* specifies the number of columns of the matrix *A*, and on entry with *trans* = 'T' or 't', *k* specifies the number of rows of the matrix *A*.

The value of *k* must be at least zero.

*alpha* Specifies the scalar *alpha*.

*a* Array, size  $\max(1, lda * ka)$ , where *ka* is in the following table:

	Col_major	Row_major
<i>trans</i> = 'N'	<i>k</i>	<i>n</i>
<i>trans</i> = 'T'	<i>n</i>	<i>k</i>

Before entry with *trans* = 'N' or 'n', the leading *n*-by-*k* part of the array *a* must contain the matrix *A*, otherwise the leading *k*-by-*n* part of the array *a* must contain the matrix *A*.

*lda* Specifies the leading dimension of *a* as declared in the calling (sub)program. *lda* is defined by the following table:

	Col_major	Row_major
<i>trans</i> = 'N'	$\max(1, n)$	$\max(1, k)$
<i>trans</i> = 'T'	$\max(1, k)$	$\max(1, n)$

*beta* Specifies the scalar *beta*.

*c* Array, size  $(n * (n + 1) / 2)$ . Before entry contains the symmetric matrix *C* in RFP format.

## Output Parameters

*c* If *trans* = 'N' or 'n', then *c* contains  $C := \alpha * A * A' + \beta * C$ ;  
if *trans* = 'T' or 't', then *c* contains  $C := \alpha * A' * A + \beta * C$ ;

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

## ?hfrk

Performs a Hermitian rank-*k* operation for matrix in RFP format.

## Syntax

```
lapack_int LAPACKE_chfrk( int matrix_layout, char transr, char uplo, char trans,
lapack_int n, lapack_int k, float alpha, const lapack_complex_float* a, lapack_int lda,
float beta, lapack_complex_float* c );
```

```
lapack_int LAPACKE_zhfrk( int matrix_layout, char transr, char uplo, char trans,
lapack_int n, lapack_int k, double alpha, const lapack_complex_double* a, lapack_int
lda, double beta, lapack_complex_double* c );
```

## Include Files

- mkl.h

## Description

The `?hfrk` routines perform a matrix-matrix operation using Hermitian matrices. The operation is defined as

$$C := \alpha * A * A^H + \beta * C,$$

or

$$C := \alpha * A^H * A + \beta * C,$$

where:

*alpha* and *beta* are real scalars,

*C* is an *n*-by-*n* Hermitian matrix in [RFP format](#),

*A* is an *n*-by-*k* matrix in the first case and a *k*-by-*n* matrix in the second case.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<i>transr</i>	if <i>transr</i> = 'N' or 'n', the normal form of RFP <i>C</i> is stored; if <i>transr</i> = 'C' or 'c', the conjugate-transpose form of RFP <i>C</i> is stored.
<i>uplo</i>	Specifies whether the upper or lower triangular part of the array <i>c</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>c</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array <i>c</i> is used.
<i>trans</i>	Specifies the operation: if <i>trans</i> = 'N' or 'n', then $C := \alpha * A * A^H + \beta * C$ ; if <i>trans</i> = 'C' or 'c', then $C := \alpha * A^H * A + \beta * C$ .
<i>n</i>	Specifies the order of the matrix <i>C</i> . The value of <i>n</i> must be at least zero.
<i>k</i>	On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the matrix <i>a</i> , and on entry with <i>trans</i> = 'T' or 't' or 'C' or 'c', <i>k</i> specifies the number of rows of the matrix <i>a</i> . The value of <i>k</i> must be at least zero.
<i>alpha</i>	Specifies the scalar <i>alpha</i> .
<i>a</i>	Array, size $\max(1, lda * ka)$ , where <i>ka</i> is in the following table:

	Col_major	Row_major
<i>trans</i> = 'N'	<i>k</i>	<i>n</i>

$trans = 'T'$	$n$	$k$
---------------	-----	-----

Before entry with  $trans = 'N'$  or  $'n'$ , the leading  $n$ -by- $k$  part of the array  $a$  must contain the matrix  $A$ , otherwise the leading  $k$ -by- $n$  part of the array  $a$  must contain the matrix  $A$ .

$lda$

Specifies the leading dimension of  $a$  as declared in the calling (sub)program.  $lda$  is defined by the following table:

	Col_major	Row_major
$trans = 'N'$	$\max(1, n)$	$\max(1, k)$
$trans = 'T'$	$\max(1, k)$	$\max(1, n)$

$beta$

Specifies the scalar  $beta$ .

$c$

Array, size  $(n * (n + 1) / 2)$ . Before entry contains the Hermitian matrix  $C$  in [RFP format](#).

## Output Parameters

$c$

If  $trans = 'N'$  or  $'n'$ , then  $c$  contains  $C := \alpha * A * A^H + \beta * C$ ;  
if  $trans = 'C'$  or  $'c'$ , then  $c$  contains  $C := \alpha * A^H * A + \beta * C$ ;

## Return Values

This function returns a value  $info$ .

If  $info = 0$ , the execution is successful.

If  $info < 0$ , the  $i$ -th parameter had an illegal value.

If  $info = -1011$ , memory allocation error occurred.

## ?tfsm

Solves a matrix equation (one operand is a triangular matrix in RFP format).

## Syntax

```
lapack_int LAPACKE_stfsm (int matrix_layout , char transr , char side , char uplo ,
char trans , char diag , lapack_int m , lapack_int n , float alpha , const float * a ,
float * b , lapack_int ldb );
```

```
lapack_int LAPACKE_dtfsm (int matrix_layout , char transr , char side , char uplo ,
char trans , char diag , lapack_int m , lapack_int n , double alpha , const double * a ,
double * b , lapack_int ldb );
```

```
lapack_int LAPACKE_ctfsm (int matrix_layout , char transr , char side , char uplo ,
char trans , char diag , lapack_int m , lapack_int n , lapack_complex_float alpha ,
const lapack_complex_float * a , lapack_complex_float * b , lapack_int ldb );
```

```
lapack_int LAPACKE_ztfsm (int matrix_layout , char transr , char side , char uplo ,
char trans , char diag , lapack_int m , lapack_int n , lapack_complex_double alpha ,
const lapack_complex_double * a , lapack_complex_double * b , lapack_int ldb );
```

## Include Files

- `mkl.h`

## Description

The `?tfsm` routines solve one of the following matrix equations:

$$\text{op}(A) * X = \text{alpha} * B,$$

or

$$X * \text{op}(A) = \text{alpha} * B,$$

where:

*alpha* is a scalar,

*X* and *B* are *m*-by-*n* matrices,

*A* is a unit, or non-unit, upper or lower triangular matrix in [rectangular full packed \(RFP\) format](#).

`op(A)` can be one of the following:

- $\text{op}(A) = A$  or  $\text{op}(A) = A^T$  for real flavors
- $\text{op}(A) = A$  or  $\text{op}(A) = A^H$  for complex flavors

The matrix *B* is overwritten by the solution matrix *X*.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<i>transr</i>	if <i>transr</i> = 'N' or 'n', the normal form of RFP <i>A</i> is stored; if <i>transr</i> = 'T' or 't', the transpose form of RFP <i>A</i> is stored; if <i>transr</i> = 'C' or 'c', the conjugate-transpose form of RFP <i>A</i> is stored.
<i>side</i>	Specifies whether <code>op(A)</code> appears on the left or right of <i>X</i> in the equation: if <i>side</i> = 'L' or 'l', then $\text{op}(A) * X = \text{alpha} * B$ ; if <i>side</i> = 'R' or 'r', then $X * \text{op}(A) = \text{alpha} * B$ .
<i>uplo</i>	Specifies whether the RFP matrix <i>A</i> is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	Specifies the form of <code>op(A)</code> used in the matrix multiplication: if <i>trans</i> = 'N' or 'n', then $\text{op}(A) = A$ ; if <i>trans</i> = 'T' or 't', then $\text{op}(A) = A'$ ; if <i>trans</i> = 'C' or 'c', then $\text{op}(A) = \text{conjg}(A')$ .
<i>diag</i>	Specifies whether the RFP matrix <i>A</i> is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.

<i>m</i>	Specifies the number of rows of <i>B</i> . The value of <i>m</i> must be at least zero.
<i>n</i>	Specifies the number of columns of <i>B</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	Specifies the scalar <i>alpha</i> . When <i>alpha</i> is zero, then <i>a</i> is not referenced and <i>b</i> need not be set before entry.
<i>a</i>	Array, size $(n*(n+1)/2)$ . Contains the matrix <i>A</i> in RFP format.
<i>b</i>	Array, size $\max(1, ldb*n)$ for column major and $\max(1, ldb*m)$ for row major. Before entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>b</i> must contain the right-hand side matrix <i>B</i> .
<i>ldb</i>	Specifies the leading dimension of <i>b</i> as declared in the calling (sub)program. The value of <i>ldb</i> must be at least $\max(1, m)$ for column major and $\max(1, n)$ for row major.

## Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>X</i> .
----------	---

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

## ?tfttp

*Copies a triangular matrix from the rectangular full packed format (TF) to the standard packed format (TP).*

## Syntax

```
lapack_int LAPACKE_stfttp (int matrix_layout , char transr , char uplo , lapack_int n ,
const float * arf , float * ap );
```

```
lapack_int LAPACKE_dtfttp (int matrix_layout , char transr , char uplo , lapack_int n ,
const double * arf , double * ap );
```

```
lapack_int LAPACKE_ctfttp (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_float * arf , lapack_complex_float * ap );
```

```
lapack_int LAPACKE_ztfttp (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_double * arf , lapack_complex_double * ap );
```

## Include Files

- mkl.h

## Description

The routine copies a triangular matrix *A* from the Rectangular Full Packed (RFP) format to the standard packed format. For the description of the RFP format, see [Matrix Storage Schemes](#).

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>transr</i>	= 'N': <i>arf</i> is in the Normal format, = 'T': <i>arf</i> is in the Transpose format (for <i>stfttp</i> and <i>dtfttp</i> ), = 'C': <i>arf</i> is in the Conjugate-transpose format (for <i>ctfttp</i> and <i>ztfttp</i> ).
<i>uplo</i>	Specifies whether <i>A</i> is upper or lower triangular: = 'U': <i>A</i> is upper triangular, = 'L': <i>A</i> is lower triangular.
<i>n</i>	The order of the matrix <i>A</i> . $n \geq 0$ .
<i>arf</i>	Array, size at least $\max(1, n*(n+1)/2)$ . On entry, the upper or lower triangular matrix <i>A</i> stored in the RFP format.

## Output Parameters

<i>ap</i>	Array, size at least $\max(1, n*(n+1)/2)$ . On exit, the upper or lower triangular matrix <i>A</i> , packed columnwise in a linear array.
-----------	--

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

## ?tfttr

Copies a triangular matrix from the rectangular full packed format (TF) to the standard full format (TR) .

## Syntax

```
lapack_int LAPACKE_stfttr (int matrix_layout , char transr , char uplo , lapack_int n ,
const float * arf , float * a , lapack_int lda );
```

```
lapack_int LAPACKE_dtfttr (int matrix_layout , char transr , char uplo , lapack_int n ,
const double * arf , double * a , lapack_int lda );
```

```
lapack_int LAPACKE_ctfttr (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_float * arf , lapack_complex_float * a , lapack_int lda );
```

```
lapack_int LAPACKE_ztfttr (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_double * arf , lapack_complex_double * a , lapack_int lda );
```

## Include Files

- `mkl.h`

## Description

The routine copies a triangular matrix  $A$  from the Rectangular Full Packed (RFP) format to the standard full format. For the description of the RFP format, see [Matrix Storage Schemes](#).

## Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>transr</code>	<ul style="list-style-type: none"> <li>= 'N': <code>arf</code> is in the Normal format,</li> <li>= 'T': <code>arf</code> is in the Transpose format (for <code>stfttr</code> and <code>dtfttr</code>),</li> <li>= 'C': <code>arf</code> is in the Conjugate-transpose format (for <code>ctfttr</code> and <code>zftttr</code>).</li> </ul>
<code>uplo</code>	Specifies whether $A$ is upper or lower triangular: <ul style="list-style-type: none"> <li>= 'U': <math>A</math> is upper triangular,</li> <li>= 'L': <math>A</math> is lower triangular.</li> </ul>
<code>n</code>	The order of the matrices <code>arf</code> and $a$ . $n \geq 0$ .
<code>arf</code>	Array, size at least $\max(1, n*(n+1)/2)$ . On entry, the upper or lower triangular matrix $A$ stored in the RFP format.
<code>lda</code>	The leading dimension of the array $a$ . $lda \geq \max(1, n)$ .

## Output Parameters

<code>a</code>	Array, size $\max(1, lda * n)$ . On exit, the triangular matrix $A$ . If <code>uplo = 'U'</code> , the leading $n$ -by- $n$ upper triangular part of the array $a$ contains the upper triangular matrix, and the strictly lower triangular part of $a$ is not referenced. If <code>uplo = 'L'</code> , the leading $n$ -by- $n$ lower triangular part of the array $a$ contains the lower triangular matrix, and the strictly upper triangular part of $a$ is not referenced.
----------------	--

## Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful.

If `info < 0`, the  $i$ -th parameter had an illegal value.

If `info = -1011`, memory allocation error occurred.

## ?tpqrt2

Computes a QR factorization of a real or complex "triangular-pentagonal" matrix, which is composed of a triangular block and a pentagonal block, using the compact WY representation for Q.

### Syntax

```
lapack_int LAPACKE_stpqrt2 (int matrix_layout, lapack_int m, lapack_int n, lapack_int l, float * a, lapack_int lda, float * b, lapack_int ldb, float * t, lapack_int ldt);
lapack_int LAPACKE_dtpqrt2 (int matrix_layout, lapack_int m, lapack_int n, lapack_int l, double * a, lapack_int lda, double * b, lapack_int ldb, double * t, lapack_int ldt);
lapack_int LAPACKE_ctpqrt2 (int matrix_layout, lapack_int m, lapack_int n, lapack_int l, lapack_complex_float * a, lapack_int lda, lapack_complex_float * b, lapack_int ldb, lapack_complex_float * t, lapack_int ldt );
lapack_int LAPACKE_ztpqrt2 (int matrix_layout, lapack_int m, lapack_int n, lapack_int l, lapack_complex_double * a, lapack_int lda, lapack_complex_double * b, lapack_int ldb, lapack_complex_double * t, lapack_int ldt );
```

### Include Files

- mkl.h

### Description

The input matrix  $C$  is an  $(n+m)$ -by- $n$  matrix

$$C = \begin{bmatrix} A \\ B \end{bmatrix} \leftarrow \begin{matrix} n \times n \text{ upper triangular} \\ m \times n \text{ pentagonal} \end{matrix}$$

where  $A$  is an  $n$ -by- $n$  upper triangular matrix, and  $B$  is an  $m$ -by- $n$  pentagonal matrix consisting of an  $(m-1)$ -by- $n$  rectangular matrix  $B1$  on top of an  $1$ -by- $n$  upper trapezoidal matrix  $B2$ :

$$B = \begin{bmatrix} B1 \\ B2 \end{bmatrix} \leftarrow \begin{matrix} (m-1) \times n \text{ rectangular} \\ 1 \times n \text{ upper trapezoidal} \end{matrix}$$

The upper trapezoidal matrix  $B2$  consists of the first  $l$  rows of an  $n$ -by- $n$  upper triangular matrix, where  $0 \leq l \leq \min(m,n)$ . If  $l=0$ ,  $B$  is an  $m$ -by- $n$  rectangular matrix. If  $m=l=n$ ,  $B$  is upper triangular. The matrix  $W$  contains the elementary reflectors  $H(i)$  in the  $i$ th column below the diagonal (of  $A$ ) in the  $(n+m)$ -by- $n$  input matrix  $C$  so that  $W$  can be represented as

$$W = \begin{bmatrix} I \\ V \end{bmatrix} \leftarrow \begin{matrix} n \times n \text{ identity} \\ m \times n \text{ pentagonal} \end{matrix}$$

Thus,  $V$  contains all of the information needed for  $W$ , and is returned in array  $b$ .

---

**NOTE**

$V$  has the same form as  $B$ :

$$V = \begin{bmatrix} V1 \\ V2 \end{bmatrix} \leftarrow \begin{matrix} (m-l) \times n \text{ rectangular} \\ l \times n \text{ upper trapezoidal} \end{matrix}$$

---

The columns of  $V$  represent the vectors which define the  $H(i)$ s.

The  $(m+n)$ -by- $(m+n)$  block reflector  $H$  is then given by

$$H = I - W^* T^* W^T \text{ for real flavors, and}$$

$$H = I - W^* T^* W^H \text{ for complex flavors}$$

where  $W^T$  is the transpose of  $W$ ,  $W^H$  is the conjugate transpose of  $W$ , and  $T$  is the upper triangular factor of the block reflector.

### Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>m</code>	The total number of rows in the matrix $B$ ( $m \geq 0$ ).
<code>n</code>	The number of columns in $B$ and the order of the triangular matrix $A$ ( $n \geq 0$ ).
<code>l</code>	The number of rows of the upper trapezoidal part of $B$ ( $\min(m, n) \geq l \geq 0$ ).
<code>a, b</code>	Arrays: $a$ , size $\max(1, lda * n)$ contains the $n$ -by- $n$ upper triangular matrix $A$ . $b$ , size $\max(1, ldb * n)$ for column major and $\max(1, ldb * m)$ for row major, the pentagonal $m$ -by- $n$ matrix $B$ . The first $(m-l)$ rows contain the rectangular $B1$ matrix, and the next $l$ rows contain the upper trapezoidal $B2$ matrix.
<code>lda</code>	The leading dimension of $a$ ; at least $\max(1, n)$ .
<code>ldb</code>	The leading dimension of $b$ ; at least $\max(1, m)$ for column major and $\max(1, n)$ for row major.

*ldt* The leading dimension of *t*; at least  $\max(1, n)$ .

## Output Parameters

*a* The elements on and above the diagonal of the array contain the upper triangular matrix *R*.

*b* The pentagonal matrix *V*.

*t* Array, size  $\max(1, ldt * n)$ .

The upper *n*-by-*n* upper triangular factor *T* of the block reflector.

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0 and *info* = -*i*, the *i*th argument had an illegal value.

If *info* = -1011, memory allocation error occurred.

## ?tprfb

*Applies a real or complex "triangular-pentagonal" blocked reflector to a real or complex matrix, which is composed of two blocks.*

## Syntax

```
lapack_int LAPACKE_stprfb (int matrix_layout, char side, char trans, char direct, char storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const float * v, lapack_int ldv, const float * t, lapack_int ldt, float * a, lapack_int lda, float * b, lapack_int ldb);
```

```
lapack_int LAPACKE_dtprfb (int matrix_layout, char side, char trans, char direct, char storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const double * v, lapack_int ldv, const double * t, lapack_int ldt, double * a, lapack_int lda, double * b, lapack_int ldb);
```

```
lapack_int LAPACKE_ctprfb (int matrix_layout, char side, char trans, char direct, char storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const lapack_complex_float * v, lapack_int ldv, const lapack_complex_float * t, lapack_int ldt, lapack_complex_float * a, lapack_int lda, lapack_complex_float * b, lapack_int ldb);
```

```
lapack_int LAPACKE_ztprfb (int matrix_layout, char side, char trans, char direct, char storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const lapack_complex_double * v, lapack_int ldv, const lapack_complex_double * t, lapack_int ldt, lapack_complex_double * a, lapack_int lda, lapack_complex_double * b, lapack_int ldb);
```

## Include Files

- mkl.h

## Description

The `?tprfb` routine applies a real or complex "triangular-pentagonal" block reflector  $H$ ,  $H^T$ , or  $H^H$  from either the left or the right to a real or complex matrix  $C$ , which is composed of two blocks  $A$  and  $B$ .

The block  $B$  is  $m$ -by- $n$ . If  $side = 'R'$ ,  $A$  is  $m$ -by- $k$ , and if  $side = 'L'$ ,  $A$  is of size  $k$ -by- $n$ .

$$\begin{array}{l}
 \text{direct} = 'F' \quad \text{direct} = 'B' \\
 \text{side} = 'R' \quad C = \begin{bmatrix} A & B \end{bmatrix} \quad C = \begin{bmatrix} B & A \end{bmatrix} \\
 \text{side} = 'L' \quad C = \begin{bmatrix} A \\ B \end{bmatrix} \quad C = \begin{bmatrix} B \\ A \end{bmatrix}
 \end{array}$$

The pentagonal matrix  $V$  is composed of a rectangular block  $V1$  and a trapezoidal block  $V2$ . The size of the trapezoidal block is determined by the parameter  $l$ , where  $0 \leq l \leq k$ . If  $l = k$ , the  $V2$  block of  $V$  is triangular; if  $l = 0$ , there is no trapezoidal block, thus  $V = V1$  is rectangular.

	$direct='F'$	$direct='B'$
$storev='C'$	$V = \begin{bmatrix} V1 \\ V2 \end{bmatrix}$ <p><math>V2</math> is upper trapezoidal (first <math>l</math> rows of <math>k</math>-by-<math>k</math> upper triangular)</p>	$V = \begin{bmatrix} V2 \\ V1 \end{bmatrix}$ <p><math>V2</math> is lower trapezoidal (last <math>l</math> rows of <math>k</math>-by-<math>k</math> lower triangular matrix)</p>
$storev='R'$	$V = \begin{bmatrix} V1 & V2 \end{bmatrix}$ <p><math>V2</math> is lower trapezoidal (first <math>l</math> columns of <math>k</math>-by-<math>k</math> lower triangular matrix)</p>	$V = \begin{bmatrix} V2 & V1 \end{bmatrix}$ <p><math>V2</math> is upper trapezoidal (last <math>l</math> columns of <math>k</math>-by-<math>k</math> upper triangular matrix)</p>

	$side='L'$	$side='R'$
$storev='C'$	$V$ is $m$ -by- $k$ $V2$ is $l$ -by- $k$	$V$ is $n$ -by- $k$ $V2$ is $l$ -by- $k$
$storev='R'$	$V$ is $k$ -by- $m$ $V2$ is $k$ -by- $l$	$V$ is $k$ -by- $n$ $V2$ is $k$ -by- $l$

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>side</i>	= 'L': apply $H$ , $H^T$ , or $H^H$ from the left, = 'R': apply $H$ , $H^T$ , or $H^H$ from the right.
<i>trans</i>	= 'N': apply $H$ (no transpose), = 'T': apply $H^T$ (transpose), = 'C': apply $H^H$ (conjugate transpose).
<i>direct</i>	Indicates how $H$ is formed from a product of elementary reflectors: = 'F': $H = H(1) H(2) \dots H(k)$ (Forward), = 'B': $H = H(k) \dots H(2) H(1)$ (Backward).
<i>storev</i>	Indicates how the vectors that define the elementary reflectors are stored: = 'C': Columns, = 'R': Rows.
<i>m</i>	The total number of rows in the matrix $B$ ( $m \geq 0$ ).
<i>n</i>	The number of columns in $B$ ( $n \geq 0$ ).
<i>k</i>	The order of the matrix $T$ , which is the number of elementary reflectors whose product defines the block reflector. ( $k \geq 0$ )
<i>l</i>	The order of the trapezoidal part of $V$ . ( $k \geq l \geq 0$ ).
<i>v</i>	An array containing the pentagonal matrix $V$ (the elementary reflectors $H(1), H(2), \dots, H(k)$ ). The size limitations depend on values of parameters <i>storev</i> and <i>side</i> as described in the following table

	<i>storev</i> = C		<i>storev</i> = R	
	<i>side</i> = L	<i>side</i> = R	<i>side</i> = L	<i>side</i> = R
Column major	$\max(1, ldv * k)$	$\max(1, ldv * k)$	$\max(1, ldv * m)$	$\max(1, ldv * n)$
Row major	$\max(1, ldv * m)$	$\max(1, ldv * n)$	$\max(1, ldv * k)$	$\max(1, ldv * k)$

*ldv* The leading dimension of the array *v*. It should satisfy the following conditions:

	<i>storev</i> = C		<i>storev</i> = R	
	<i>side</i> = L	<i>side</i> = R	<i>side</i> = L	<i>side</i> = R
Column major	$\max(1, m)$	$\max(1, n)$	$\max(1, k)$	$\max(1, k)$
Row major	$\max(1, k)$	$\max(1, k)$	$\max(1, m)$	$\max(1, n)$

*t* Array size  $\max(1, ldt * k)$ . The triangular  $k$ -by- $k$  matrix  $T$  in the representation of the block reflector.

*ldt* The leading dimension of the array  $t$  ( $ldt \geq k$ ).

*a* size should satisfy the following conditions:

$k$  if *side* = 'R'.

	<i>side</i> = L	<i>side</i> = R
Column major	$\max(1, lda * n)$	$\max(1, lda * k)$
Row major	$\max(1, lda * k)$	$\max(1, lda * m)$

The  $k$ -by- $n$  or  $m$ -by- $k$  matrix  $A$ .

*lda* The leading dimension of the array  $a$  should satisfy the following conditions:

	<i>side</i> = L	<i>side</i> = R
Column major	$\max(1, k)$	$\max(1, m)$
Row major	$\max(1, n)$	$\max(1, k)$

*b* Array size at least  $\max(1, ldb * n)$  for column major layout and  $\max(1, ldb * m)$  for row major layout, the  $m$ -by- $n$  matrix  $B$ .

*ldb* The leading dimension of the array  $b$  ( $ldb \geq \max(1, m)$  for column major layout and  $ldb \geq \max(1, n)$  for row major layout).

## Output Parameters

*a* Contains the corresponding block of  $H^*C$ ,  $H^T*C$ ,  $H^H*C$ ,  $C^*H$ ,  $C^*H^T$ , or  $C^*H^H$ .

*b* Contains the corresponding block of  $H^*C$ ,  $H^T*C$ ,  $H^H*C$ ,  $C^*H$ ,  $C^*H^T$ , or  $C^*H^H$ .

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

## ?tpdff

Copies a triangular matrix from the standard packed format (TP) to the rectangular full packed format (TF).

## Syntax

```
lapack_int LAPACKE_stpdff (int matrix_layout , char transr , char uplo , lapack_int n ,
const float * ap , float * arf );
```

```
lapack_int LAPACKE_dtpdff (int matrix_layout , char transr , char uplo , lapack_int n ,
const double * ap , double * arf );
```

```
lapack_int LAPACKE_ctpdff (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_float * ap , lapack_complex_float * arf );
```

```
lapack_int LAPACKE_ztpdff (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_double * ap , lapack_complex_double * arf );
```

## Include Files

- mkl.h

## Description

The routine copies a triangular matrix  $A$  from the standard packed format to the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>transr</i>	<ul style="list-style-type: none"> <li>= 'N': <i>arf</i> must be in the Normal format,</li> <li>= 'T': <i>arf</i> must be in the Transpose format (for <i>stpdff</i> and <i>dtpdff</i>),</li> <li>= 'C': <i>arf</i> must be in the Conjugate-transpose format (for <i>ctpdff</i> and <i>ztpdff</i>).</li> </ul>
<i>uplo</i>	<p>Specifies whether <math>A</math> is upper or lower triangular:</p> <ul style="list-style-type: none"> <li>= 'U': <math>A</math> is upper triangular,</li> <li>= 'L': <math>A</math> is lower triangular.</li> </ul>
<i>n</i>	The order of the matrix $A$ . $n \geq 0$ .
<i>ap</i>	<p>Array, size at least <math>\max(1, n*(n+1)/2)</math>.</p> <p>On entry, the upper or lower triangular matrix <math>A</math>, packed in a linear array. See <a href="#">Matrix Storage Schemes</a> for more information.</p>

## Output Parameters

<i>arf</i>	<p>Array, size at least <math>\max(1, n*(n+1)/2)</math>.</p> <p>On exit, the upper or lower triangular matrix <math>A</math> stored in the RFP format.</p>
------------	--

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

< 0: if *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

## ?tpdff

*Copies a triangular matrix from the standard packed format (TP) to the standard full format (TR) .*

---

## Syntax

```
lapack_int LAPACKE_stpttr (int matrix_layout , char uplo , lapack_int n , const float *
ap , float * a , lapack_int lda );
```

```
lapack_int LAPACKE_dtptr (int matrix_layout , char uplo , lapack_int n , const double
* ap , double * a , lapack_int lda );

## Description

The routine copies a triangular matrix *A* from the standard packed format to the standard full format.

## Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>uplo</i>	Specifies whether <i>A</i> is upper or lower triangular: = 'U': <i>A</i> is upper triangular, = 'L': <i>A</i> is lower triangular.
<i>n</i>	The order of the matrices <i>ap</i> and <i>a</i> . $n \geq 0$ .
<i>ap</i>	Array, size at least $\max(1, n*(n+1)/2)$ . (see <a href="#">Matrix Storage Schemes</a> ).
<i>lda</i>	The leading dimension of the array <i>a</i> . $lda \geq \max(1, n)$ .

## Output Parameters

<i>a</i>	Array, size $\max(1, lda*n)$ . On exit, the triangular matrix <i>A</i> . If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> contains the upper triangular part of the matrix <i>A</i> , and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> contains the lower triangular part of the matrix <i>A</i> , and the strictly upper triangular part of <i>a</i> is not referenced.
----------	---

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

## ?trttf

*Copies a triangular matrix from the standard full format (TR) to the rectangular full packed format (TF).*

### Syntax

```
lapack_int LAPACKE_strttf (int matrix_layout , char transr , char uplo , lapack_int n ,
const float * a , lapack_int lda , float * arf );
```

```
lapack_int LAPACKE_dtrttf (int matrix_layout , char transr , char uplo , lapack_int n ,
const double * a , lapack_int lda , double * arf );
```

```
lapack_int LAPACKE_ctrttf (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_float * a , lapack_int lda , lapack_complex_float * arf );
```

```
lapack_int LAPACKE_ztrttf (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_double * a , lapack_int lda , lapack_complex_double * arf );
```

### Include Files

- mkl.h

### Description

The routine copies a triangular matrix *A* from the standard full format to the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

### Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major ( LAPACK_COL_MAJOR ).
<i>transr</i>	= 'N': <i>arf</i> must be in the Normal format, = 'T': <i>arf</i> must be in the Transpose format (for <i>strttf</i> and <i>dtrttf</i> ), = 'C': <i>arf</i> must be in the Conjugate-transpose format (for <i>ctrttf</i> and <i>ztrttf</i> ).
<i>uplo</i>	Specifies whether <i>A</i> is upper or lower triangular: = 'U': <i>A</i> is upper triangular, = 'L': <i>A</i> is lower triangular.
<i>n</i>	The order of the matrix <i>A</i> . $n \geq 0$ .
<i>a</i>	Array, size $\max(1, (lda * n))$ . On entry, the triangular matrix <i>A</i> . If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> contains the upper triangular matrix, and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> contains the lower triangular matrix, and the strictly upper triangular part of <i>a</i> is not referenced.
<i>lda</i>	The leading dimension of the array <i>a</i> . $lda \geq \max(1, n)$ .

## Output Parameters

*arf* Array, size at least  $\max(1, n*(n+1)/2)$ .  
On exit, the upper or lower triangular matrix *A* stored in the RFP format.

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

## ?trttp

Copies a triangular matrix from the standard full format (TR) to the standard packed format (TP) .

## Syntax

```
lapack_int LAPACKE_strttp (int matrix_layout , char uplo , lapack_int n , const float * a , lapack_int lda , float * ap );
```

```
lapack_int LAPACKE_dtrttp (int matrix_layout , char uplo , lapack_int n , const double * a , lapack_int lda , double * ap );
```

```
lapack_int LAPACKE_ctrttp (int matrix_layout , char uplo , lapack_int n , const lapack_complex_float * a , lapack_int lda , lapack_complex_float * ap );
```

```
lapack_int LAPACKE_ztrttp (int matrix_layout , char uplo , lapack_int n , const lapack_complex_double * a , lapack_int lda , lapack_complex_double * ap );
```

## Include Files

- mkl.h

## Description

The routine copies a triangular matrix *A* from the standard full format to the standard packed format.

## Input Parameters

*uplo* Specifies whether *A* is upper or lower triangular:  
= 'U': *A* is upper triangular,  
= 'L': *A* is lower triangular.

*n* The order of the matrix *A*,  $n \geq 0$ .

*a* Array, size  $\max(1, lda * n)$ .  
On entry, the triangular matrix *A*. If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of the array *a* contains the upper triangular matrix, and the strictly lower triangular part of *a* is not referenced. If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of the array *a* contains the lower triangular matrix, and the strictly upper triangular part of *a* is not referenced.

*lda* The leading dimension of the array *a*.  $lda \geq \max(1, n)$ .

## Output Parameters

*ap* Array, size at least  $\max(1, n*(n+1)/2)$ .  
On exit, the upper or lower triangular matrix *A*, packed columnwise in a linear array. (see [Matrix Storage Schemes](#))

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

## ?lapc2

Copies all or part of a real two-dimensional array to a complex array.

## Syntax

```
lapack_int LAPACKE_clapc2 (int matrix_layout , char uplo , lapack_int m , lapack_int
n , const float * a , lapack_int lda , lapack_complex_float * b , lapack_int ldb );
lapack_int LAPACKE_zlapc2 (int matrix_layout , char uplo , lapack_int m , lapack_int
n , const double * a , lapack_int lda , lapack_complex_double * b , lapack_int ldb );
```

## Include Files

- mkl.h

## Description

The routine copies all or part of a real matrix *A* to another matrix *B*.

## Input Parameters

*matrix\_layout* Specifies whether matrix storage layout is row major (LAPACK\_ROW\_MAJOR) or column major (LAPACK\_COL\_MAJOR).

*uplo* Specifies the part of the matrix *A* to be copied to *B*.

If *uplo* = 'U', the upper triangular part of *A*;

if *uplo* = 'L', the lower triangular part of *A*.

Otherwise, all of the matrix *A* is copied.

*m* The number of rows in the matrix *A* ( $m \geq 0$ ).

*n* The number of columns in *A* ( $n \geq 0$ ).

*a* Array, size at least  $\max(1, lda*n)$  for column major and  $\max(1, lda*m)$  for row major, contains the *m*-by-*n* matrix *A*.

If `uplo = 'U'`, only the upper triangle or trapezoid is accessed; if `uplo = 'L'`, only the lower triangle or trapezoid is accessed.

`lda` The leading dimension of `a`;  $lda \geq \max(1, m)$  for column major and  $lda \geq \max(1, n)$  for row major.

`ldb` The leading dimension of the output array `b`;  $ldb \geq \max(1, m)$  for column major and  $ldb \geq \max(1, n)$  for row major.

## Output Parameters

`b` Array, size at least  $\max(1, ldb * n)$  for column major layout and  $\max(1, ldb * m)$  for row major layout, contains the  $m$ -by- $n$  matrix  $B$ .  
On exit,  $B = A$  in the locations specified by `uplo`.

## Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful.

If `info < 0`, the  $i$ -th parameter had an illegal value.

If `info = -1011`, memory allocation error occurred.

## ?larcm

Multiplies a square real matrix by a complex matrix.

## Syntax

```
lapack_int LAPACKE_clarcm(int matrix_layout, lapack_int m, lapack_int n, const float
*a, lapack_int lda, const lapack_complex_float * b, lapack_int ldb, lapack_complex_float *
c, lapack_int ldc);
```

```
lapack_int LAPACKE_zlarcm(int matrix_layout, lapack_int m, lapack_int n, const double *
a, lapack_int lda, const lapack_complex_double *b, lapack_int ldb, lapack_complex_double
*c , lapack_int ldc);
```

## Description

The routine performs a simple matrix-matrix multiplication of the form

$$C = A * B,$$

where  $A$  is  $m$ -by- $m$  and real,  $B$  is  $m$ -by- $n$  and complex, and  $C$  is  $m$ -by- $n$  and complex.

## Input Parameters

`m` The number of rows and columns of matrix  $A$  and the number of rows of matrix  $C$  ( $m \geq 0$ ).

`n` The number of columns of matrix  $B$  and the number of columns of matrix  $C$  ( $n \geq 0$ ).

`a` Array, size  $[lda * m]$ . Contains the  $m$ -by- $m$  matrix  $A$ .

<i>lda</i>	The leading dimension of the array <i>a</i> , $lda \geq \max(1, m)$ .
<i>b</i>	Array, size ( <i>ldb</i> , <i>n</i> ). Contains the <i>m</i> -by- <i>n</i> matrix <i>B</i> .
<i>ldb</i>	The leading dimension of the array <i>b</i> , $ldb \geq \max(1, m)$ for column-major layout; $ldb \geq \max(1, n)$ for row-major layout.
<i>ldc</i>	The leading dimension of the array <i>c</i> , $ldc \geq \max(1, m)$ for column-major layout; $ldc \geq \max(1, n)$ for row-major layout.

## Output Parameters

<i>c</i>	Array, size ( <i>ldc</i> , <i>n</i> ). Contains the <i>m</i> -by- <i>n</i> matrix <i>C</i> .
----------	--

## Return Values

This function returns a value *info*. If *info* = 0, the execution is successful. If *info* = -*i*, parameter *i* had an illegal value.

## mkl\_?tppack

Copies a triangular/symmetric matrix or submatrix from standard full format to standard packed format.

## Syntax

```
lapack_int LAPACKE_mkl_stppack (int matrix_layout, char uplo, char trans, lapack_int n,
float* ap, lapack_int i, lapack_int j, lapack_int rows, lapack_int cols, const float* a,
lapack_int lda);
```

```
lapack_int LAPACKE_mkl_dtpack (int matrix_layout, char uplo, char trans, lapack_int n,
double* ap, lapack_int i, lapack_int j, lapack_int rows, lapack_int cols, const double*
a, lapack_int lda);
```

```
lapack_int LAPACKE_mkl_ctppack (int matrix_layout, char uplo, char trans, lapack_int n,
MKL_Complex8* ap, lapack_int i, lapack_int j, lapack_int rows, lapack_int cols, const
MKL_Complex8* a, lapack_int lda);
```

```
lapack_int LAPACKE_mkl_ztpack (int matrix_layout, char uplo, char trans, lapack_int n,
MKL_Complex16* ap, lapack_int i, lapack_int j, lapack_int rows, lapack_int cols, const
MKL_Complex16* a, lapack_int lda);
```

## Include Files

- mkl.h

## Description

The routine copies a triangular or symmetric matrix or its submatrix from standard full format to packed format

```
 $AP_{i:i+rows-1, j:j+cols-1} := op(A)$ 
```

Standard packed formats include:

- TP: triangular packed storage
- SP: symmetric indefinite packed storage
- HP: Hermitian indefinite packed storage
- PP: symmetric or Hermitian positive definite packed storage

Full formats include:

- GE: general
- TR: triangular
- SY: symmetric indefinite
- HE: Hermitian indefinite
- PO: symmetric or Hermitian positive definite

**NOTE**

Any elements of the copied submatrix rectangular outside of the triangular part of the matrix  $AP$  are skipped.

**Input Parameters**

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<i>uplo</i>	Specifies whether the matrix $AP$ is upper or lower triangular. If <i>uplo</i> = 'U', $AP$ is upper triangular. If <i>uplo</i> = 'L': $AP$ is lower triangular.
<i>trans</i>	Specifies whether or not the copied block of $A$ is transposed or not. If <i>trans</i> = 'N', no transpose: $\text{op}(A) = A$ . If <i>trans</i> = 'T', transpose: $\text{op}(A) = A^T$ . If <i>trans</i> = 'C', conjugate transpose: $\text{op}(A) = A^H$ . For real data this is the same as <i>trans</i> = 'T'.
<i>n</i>	The order of the matrix $AP$ ; $n \geq 0$
<i>i, j</i>	Coordinates of the left upper corner of the destination submatrix in $AP$ . If <i>uplo</i> ='U', $1 \leq i \leq j \leq n$ . If <i>uplo</i> ='L', $1 \leq j \leq i \leq n$ .
<i>rows</i>	Number of rows in the destination submatrix. $0 \leq \text{rows} \leq n - i + 1$ .
<i>cols</i>	Number of columns in the destination submatrix. $0 \leq \text{cols} \leq n - j + 1$ .
<i>a</i>	Pointer to the source submatrix. Array <i>a</i> contains the <i>rows</i> -by- <i>cols</i> submatrix stored as unpacked rows-by-columns if <i>trans</i> = 'N', or unpacked columns-by-rows if <i>trans</i> = 'T' or <i>trans</i> = 'C'. The size of <i>a</i> is

	<i>trans</i> = 'N'	<i>trans</i> ='T' or <i>trans</i> ='C'
<i>matrix_layout</i> = LAPACK_COL_MAJOR	<i>lda*cols</i>	<i>lda*rows</i>
<i>matrix_layout</i> = LAPACK_ROW_MAJOR	<i>lda*rows</i>	<i>lda*cols</i>

**NOTE**

If there are elements outside of the triangular part of  $AP$ , they are skipped and are not copied from  $a$ .

$lda$

The leading dimension of the array  $a$ .

	$trans = 'N'$	$trans='T' \text{ or } trans='C'$
$matrix\_layout =$ LAPACK_COL_MAJOR	$lda \geq \max(1,$ $rows)$	$lda \geq \max(1, cols)$
$matrix\_layout =$ LAPACK_ROW_MAJOR	$lda \geq \max(1,$ $cols)$	$lda \geq \max(1, rows)$

**Output Parameters**

$ap$

Array of size at least  $\max(1, n(n+1)/2)$ . The array  $ap$  contains either the upper or the lower triangular part of the matrix  $AP$  (as specified by  $uplo$ ) in packed storage (see [Matrix Storage Schemes](#)). The submatrix of  $ap$  from row  $i$  to row  $i + rows - 1$  and column  $j$  to column  $j + cols - 1$  is overwritten with a copy of the source matrix.

**Return Values**

This function returns a value  $info$ . If  $info=0$ , the execution is successful. If  $info = -i$ , the  $i$ -th parameter had an illegal value.

**mkl\_?tpunpack**

*Copies a triangular/symmetric matrix or submatrix from standard packed format to full format.*

**Syntax**

```
lapack_int LAPACKE_mkl_stpunpack ( int matrix_layout, char uplo, char trans,
    lapack_int n, const float* ap, lapack_int i, lapack_int j, lapack_int rows,
    lapack_int cols, float* a, lapack_int lda );
```

```
lapack_int LAPACKE_mkl_dtpunpack ( int matrix_layout, char uplo, char trans,
    lapack_int n, const double* ap, lapack_int i, lapack_int j, lapack_int rows,
    lapack_int cols, double* a, lapack_int lda );
```

```
lapack_int LAPACKE_mkl_ctpunpack ( int matrix_layout, char uplo, char trans,
    lapack_int n, const MKL_Complex8* ap, lapack_int i, lapack_int j, lapack_int rows,
    lapack_int cols, MKL_Complex8* a, lapack_int lda );
```

```
lapack_int LAPACKE_mkl_ztpunpack ( int matrix_layout, char uplo, char trans,
    lapack_int n, const MKL_Complex16* ap, lapack_int i, lapack_int j, lapack_int rows,
    lapack_int cols, MKL_Complex16* a, lapack_int lda );
```

**Include Files**

### NOTE

Any elements of the copied submatrix rectangular outside of the triangular part of  $AP$  are skipped.

---

## Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<code>uplo</code>	Specifies whether matrix $AP$ is upper or lower triangular. If <code>uplo = 'U'</code> , $AP$ is upper triangular. If <code>uplo = 'L'</code> , $AP$ is lower triangular.
<code>trans</code>	Specifies whether or not the copied block of $AP$ is transposed. If <code>trans = 'N'</code> , no transpose: $\text{op}(AP) = AP$ . If <code>trans = 'T'</code> , transpose: $\text{op}(AP) = AP^T$ . If <code>trans = 'C'</code> , conjugate transpose: $\text{op}(AP) = AP^H$ . For real data this is the same as <code>trans = 'T'</code> .
<code>n</code>	The order of the matrix $AP$ ; $n \geq 0$ .
<code>ap</code>	Array, size at least $\max(1, n(n+1)/2)$ . The array <code>ap</code> contains either the upper or the lower triangular part of the matrix $AP$ (as specified by <code>uplo</code> ) in packed storage (see <a href="#">Matrix Storage Schemes</a> ). It is the source for the submatrix of $AP$ from row $i$ to row $i + rows - 1$ and column $j$ to column $j + cols - 1$ to be copied.
<code>i, j</code>	Coordinates of left upper corner of the submatrix in $AP$ to copy. If <code>uplo='U'</code> , $1 \leq i \leq j \leq n$ .

If  $uplo='L', 1 \leq j \leq i \leq n$ .

*rows*

Number of rows to copy.  $0 \leq rows \leq n - i + 1$ .

*cols*

Number of columns to copy.  $0 \leq cols \leq n - j + 1$ .

*lda*

The leading dimension of array *a*.

	<i>trans</i> = 'N'	<i>trans</i> ='T' or <i>trans</i> ='C'
<i>matrix_layout</i> = LAPACK_COL_MAJOR	$lda \geq \max(1, rows)$	$lda \geq \max(1, cols)$
<i>matrix_layout</i> = LAPACK_ROW_MAJOR	$lda \geq \max(1, cols)$	$lda \geq \max(1, rows)$

## Output Parameters

*a*

Pointer to the destination matrix. On exit, array *a* is overwritten with a copy of the unpacked *rows*-by-*cols* submatrix of *ap* unpacked rows-by-columns if *trans* = 'N', or unpacked columns-by-rows if *trans* = 'T' or *trans* = 'C'.

The size of *a* is

	<i>trans</i> = 'N'	<i>trans</i> ='T' or <i>trans</i> ='C'
<i>matrix_layout</i> = LAPACK_COL_MAJOR	$lda * cols$	$lda * rows$
<i>matrix_layout</i> = LAPACK_ROW_MAJOR	$lda * rows$	$lda * cols$

### NOTE

If there are elements outside of the triangular part of *ap* indicated by *uplo*, they are skipped and are not copied to *a*.

## Return Values

This function returns a value *info*. If *info*=0, the execution is successful. If *info* = -*i*, the *i*-th parameter had an illegal value.

## LAPACK Utility Functions and Routines

This section describes LAPACK utility functions and routines.

Summary information about these routines is given in the following table:

## LAPACK Utility Routines

Routine Name	Data Types	Description
<code>ilaver</code>		Returns the version of the Lapack library.
<code>ilaenv</code>		Environmental enquiry function which returns values for tuning algorithmic performance.
<code>?lamch</code>	s, d	Determines machine parameters for floating-point arithmetic.

### See Also

`lsame` Tests two characters for equality regardless of the case.

`lsamen` Tests two character strings for equality regardless of the case.

`second/dsecnd` Returns elapsed time in seconds. Use to estimate real time between two calls to this function.

`xerbla` Error handling function called by BLAS, LAPACK, Vector Math, and Vector Statistics functions.

### ilaver

*Returns the version of the LAPACK library.*

### Syntax

```
void LAPACKE_ilaver (lapack_int * vers_major, lapack_int * vers_minor, lapack_int *
vers_patch);
```

### Include Files

- `mkl.h`

### Description

This routine returns the version of the LAPACK library.

### Output Parameters

<code>vers_major</code>	Returns the major version of the LAPACK library.
<code>vers_minor</code>	Returns the minor version from the major version of the LAPACK library.
<code>vers_patch</code>	Returns the patch version from the minor version of the LAPACK library.

### ilaenv

*Environmental enquiry function that returns values for tuning algorithmic performance.*

### Syntax

```
MKL_INT ilaenv (const MKL_INT *ispec, const char *name, const char *opts, const MKL_INT
*n1, const MKL_INT *n2, const MKL_INT *n3, const MKL_INT *n4);
```

### Include Files

- `mkl.h`

## Description

The enquiry function `ilaenv` is called from the LAPACK routines to choose problem-dependent parameters for the local environment. See *ispec* below for a description of the parameters.

This version provides a set of parameters that should give good, but not optimal, performance on many of the currently available computers.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

<i>ispec</i>	<p>Specifies the parameter to be returned as the value of <code>ilaenv</code>:</p> <ul style="list-style-type: none"> <li>= 1: the optimal blocksize; if this value is 1, an unblocked algorithm will give the best performance.</li> <li>= 2: the minimum block size for which the block routine should be used; if the usable block size is less than this value, an unblocked routine should be used.</li> <li>= 3: the crossover point (in a block routine, for <math>n</math> less than this value, an unblocked routine should be used)</li> <li>= 4: the number of shifts, used in the nonsymmetric eigenvalue routines (deprecated)</li> <li>= 5: the minimum column dimension for blocking to be used; rectangular blocks must have dimension at least <math>k</math>-by-<math>m</math>, where <math>k</math> is given by <code>ilaenv(2, ...)</code> and <math>m</math> by <code>ilaenv(5, ...)</code></li> <li>= 6: the crossover point for the SVD (when reducing an <math>m</math>-by-<math>n</math> matrix to bidiagonal form, if <math>\max(m, n) / \min(m, n)</math> exceeds this value, a <math>QR</math> factorization is used first to reduce the matrix to a triangular form.)</li> <li>= 7: the number of processors</li> <li>= 8: the crossover point for the multishift <math>QR</math> and <math>QZ</math> methods for nonsymmetric eigenvalue problems (deprecated).</li> <li>= 9: maximum size of the subproblems at the bottom of the computation tree in the divide-and-conquer algorithm (used by <code>?gelsd</code> and <code>?gesdd</code>)</li> <li>=10: ieee NaN arithmetic can be trusted not to trap</li> <li>=11: infinity arithmetic can be trusted not to trap</li> <li><math>12 \leq ispec \leq 16</math>: <code>?hseqr</code> or one of its subroutines, see <code>iparmq</code> for detailed explanation.</li> </ul>
<i>name</i>	The name of the calling subroutine, in either upper case or lower case.
<i>opts</i>	The character options to the subroutine <i>name</i> , concatenated into a single character string. For example, <code>uplo = 'U'</code> , <code>trans = 'T'</code> , and <code>diag = 'N'</code> for a triangular routine would be specified as <code>opts = 'UTN'</code> .

**NOTE**

Use only uppercase characters for the *opts* string.

*n1, n2, n3, n4*

Problem dimensions for the subroutine *name*; these may not all be required.

**Output Parameters**

*value*

If  $value \geq 0$ : the value of the parameter specified by *ispec*;

If  $value = -k < 0$ : the *k*-th argument had an illegal value.

**Return Values**

*ilaenv* returns *value*.

If  $value \geq 0$ : the value of the parameter specified by *ispec*;

If  $value = -k < 0$ : the *k*-th argument had an illegal value.

**Application Notes**

The following conventions have been used when calling *ilaenv* from the LAPACK routines:

1. *opts* is a concatenation of all of the character options to subroutine *name*, in the same order that they appear in the argument list for *name*, even if they are not used in determining the value of the parameter specified by *ispec*.
2. The problem dimensions *n1, n2, n3, n4* are specified in the order that they appear in the argument list for *name*. *n1* is used first, *n2* second, and so on, and unused problem dimensions are passed a value of -1.
3. The parameter value returned by *ilaenv* is checked for validity in the calling subroutine. For example, *ilaenv* is used to retrieve the optimal blocksize for *strtri* as follows:

```
nb := ilaenv( 1, 'strtri', strcat (uplo, diag), n, -1, -1, -1> );
if( nb <= 1 ) {
    nb := max( 1, n );
}
```

Below is an example of *ilaenv* usage in C language:

```
#include <stdio.h>
#include "mkl.h"

int main(void)
{
    int size = 1000;
    int ispec = 1;
    int dummy = -1;
    int blockSize1 = ilaenv(&ispec, "dsytrd", "U", &size, &dummy, &dummy, &dummy);
    int blockSize2 = ilaenv(&ispec, "dormtr", "LUN", &size, &size, &dummy, &dummy);
    printf("DSYTRD blocksize = %d\n", blockSize1);
    printf("DORMTR blocksize = %d\n", blockSize2);
    return 0;
}
```

**See Also**

## ?lamch

Determines machine parameters for floating-point arithmetic.

### Syntax

```
float LAPACKE_slamch (char cmach );
double LAPACKE_dlamch (char cmach );
```

### Include Files

- mkl.h

### Description

The function ?lamch determines single precision and double precision machine parameters.

### Input Parameters

*cmach* Specifies the value to be returned by ?lamch:

- = 'E' or 'e', *val* = *eps*
- = 'S' or 's', *val* = *sfmin*
- = 'B' or 'b', *val* = *base*
- = 'P' or 'p', *val* = *eps\*base*
- = 'n' or 'n', *val* = *t*
- = 'R' or 'r', *val* = *rnd*
- = 'M' or 'm', *val* = *emin*
- = 'U' or 'u', *val* = *rmin*
- = 'L' or 'l', *val* = *emax*
- = 'O' or 'o', *val* = *rmax*

where

*eps* = relative machine precision;

*sfmin* = safe minimum, such that  $1/sfmin$  does not overflow;

*base* = base of the machine;

*prec* =  $eps*base$ ;

*t* = number of (base) digits in the mantissa;

*rnd* = 1.0 when rounding occurs in addition, 0.0 otherwise;

*emin* = minimum exponent before (gradual) underflow;

*rmin* =  $underflow\_threshold - base**(emin-1)$ ;

*emax* = largest exponent before overflow;

*rmax* =  $overflow\_threshold - (base**emax)*(1-eps)$ .

**NOTE**

You can use a character string for *cmach* instead of a single character in order to make your code more readable. The first character of the string determines the value to be returned. For example, 'Precision' is interpreted as 'p'.

**Output Parameters**

*val* Value returned by the function.

**LAPACK Test Functions and Routines**

This section describes LAPACK test functions and routines.

**?lagge**

*Generates a general m-by-n matrix .*

**Syntax**

```
lapack_int LAPACKE_slagge (int matrix_layout , lapack_int m , lapack_int n , lapack_int
kl , lapack_int ku , const float * d , float * a , lapack_int lda , lapack_int *
iseed );
```

```
lapack_int LAPACKE_dlagge (int matrix_layout , lapack_int m , lapack_int n , lapack_int
kl , lapack_int ku , const double * d , double * a , lapack_int lda , lapack_int *
iseed );
```

```
lapack_int LAPACKE_clagge (int matrix_layout , lapack_int m , lapack_int n , lapack_int
kl , lapack_int ku , const float * d , lapack_complex_float * a , lapack_int lda ,
lapack_int * iseed );
```

```
lapack_int LAPACKE_zlagge (int matrix_layout , lapack_int m , lapack_int n , lapack_int
kl , lapack_int ku , const double * d , lapack_complex_double * a , lapack_int lda ,
lapack_int * iseed );
```

**Include Files**

- mkl.h

**Description**

The routine generates a general *m*-by-*n* matrix *A*, by pre- and post- multiplying a real diagonal matrix *D* with random matrices *U* and *V*:

$$A := U * D * V,$$

where *U* and *V* are orthogonal for real flavors and unitary for complex flavors. The lower and upper bandwidths may then be reduced to *kl* and *ku* by additional orthogonal transformations.

**Input Parameters**

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<i>m</i>	The number of rows of the matrix <i>A</i> ( $m \geq 0$ ).
<i>n</i>	The number of columns of the matrix <i>A</i> ( $n \geq 0$ ).
<i>kl</i>	The number of nonzero subdiagonals within the band of <i>A</i> ( $0 \leq kl \leq m-1$ ).
<i>ku</i>	The number of nonzero superdiagonals within the band of <i>A</i> ( $0 \leq ku \leq n-1$ ).
<i>d</i>	The array <i>d</i> with the dimension of $(\min(m, n))$ contains the diagonal elements of the diagonal matrix <i>D</i> .
<i>lda</i>	The leading dimension of the array <i>a</i> ( $lda \geq m$ ) for column major layout and ( $lda \geq n$ ) for row major layout.
<i>iseed</i>	The array <i>iseed</i> with the dimension of 4 contains the seed of the random number generator. The elements must be between 0 and 4095 and <i>iseed</i> must be odd.

## Output Parameters

<i>a</i>	The array <i>a</i> with size at least $\max(1, lda*n)$ for column major layout and $\max(1, lda*m)$ for row major layout contains the generated <i>m</i> -by- <i>n</i> matrix <i>A</i> .
<i>iseed</i>	The array <i>iseed</i> contains the updated seed on exit.

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

## ?laghe

Generates a complex Hermitian matrix .

## Syntax

```
lapack_int LAPACKE_claghe (int matrix_layout , lapack_int n , lapack_int k , const
float * d , lapack_complex_float * a , lapack_int lda , lapack_int * iseed );
lapack_int LAPACKE_zlaghe (int matrix_layout , lapack_int n , lapack_int k , const
double * d , lapack_complex_double * a , lapack_int lda , lapack_int * iseed );
```

## Include Files

- mkl.h

## Description

The routine generates a complex Hermitian matrix *A*, by pre- and post- multiplying a real diagonal matrix *D* with random unitary matrix:

$$A := U * D * U^H$$

The semi-bandwidth may then be reduced to *k* by additional unitary transformations.

## Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>n</code>	The order of the matrix $A$ ( $n \geq 0$ ).
<code>k</code>	The number of nonzero subdiagonals within the band of $A$ ( $0 \leq k \leq n-1$ ).
<code>d</code>	The array $d$ with the dimension of ( $n$ ) contains the diagonal elements of the diagonal matrix $D$ .
<code>lda</code>	The leading dimension of the array $a$ ( $lda \geq n$ ).
<code>iseed</code>	The array <code>iseed</code> with the dimension of 4 contains the seed of the random number generator. The elements must be between 0 and 4095 and <code>iseed[3]</code> must be odd.

## Output Parameters

<code>a</code>	The array $a$ of size at least $\max(1, lda * n)$ contains the generated $n$ -by- $n$ Hermitian matrix $D$ .
<code>iseed</code>	The array <code>iseed</code> contains the updated seed on exit.

## Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful.

If `info < 0`, the  $i$ -th parameter had an illegal value.

If `info = -1011`, memory allocation error occurred.

## ?lagsy

*Generates a symmetric matrix by pre- and post-multiplying a real diagonal matrix with a random unitary matrix.*

## Syntax

```
lapack_int LAPACKE_slagsy (int matrix_layout , lapack_int n , lapack_int k , const float * d , float * a , lapack_int lda , lapack_int * iseed );
```

```
lapack_int LAPACKE_dlagsy (int matrix_layout , lapack_int n , lapack_int k , const double * d , double * a , lapack_int lda , lapack_int * iseed );
```

```
lapack_int LAPACKE_clagsy (int matrix_layout , lapack_int n , lapack_int k , const float * d , lapack_complex_float * a , lapack_int lda , lapack_int * iseed );
```

```
lapack_int LAPACKE_zlagsy (int matrix_layout , lapack_int n , lapack_int k , const double * d , lapack_complex_double * a , lapack_int lda , lapack_int * iseed );
```

## Include Files

- `mkl.h`

## Description

The `?lagsy` routine generates a symmetric matrix  $A$  by pre- and post- multiplying a real diagonal matrix  $D$  with a random matrix  $U$ :

$$A := U * D * U^T,$$

where  $U$  is orthogonal for real flavors and unitary for complex flavors. The semi-bandwidth may then be reduced to  $k$  by additional unitary transformations.

## Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<code>n</code>	The order of the matrix $A$ ( $n \geq 0$ ).
<code>k</code>	The number of nonzero subdiagonals within the band of $A$ ( $0 \leq k \leq n-1$ ).
<code>d</code>	The array $d$ with the dimension of ( $n$ ) contains the diagonal elements of the diagonal matrix $D$ .
<code>lda</code>	The leading dimension of the array $a$ ( $lda \geq n$ ).
<code>iseed</code>	The array <code>iseed</code> with the dimension of 4 contains the seed of the random number generator. The elements must be between 0 and 4095 and <code>iseed[3]</code> must be odd.

## Output Parameters

<code>a</code>	The array <code>a</code> of size <code>max(1,lda*n)</code> contains the generated symmetric $n$ -by- $n$ matrix $D$ .
<code>iseed</code>	The array <code>iseed</code> contains the updated seed on exit.

## Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful.

If `info < 0`, the  $i$ -th parameter had an illegal value.

If `info = -1011`, memory allocation error occurred.

## ?latms

*Generates a general  $m$ -by- $n$  matrix with specific singular values.*

---

## Syntax

```
lapack_int LAPACKE_slatms (int matrix_layout, lapack_int m, lapack_int n, char dist,
lapack_int * iseed, char sym, float * d, lapack_int mode, float cond, float dmax,
lapack_int kl, lapack_int ku, char pack, float * a, lapack_int lda);
```

```
lapack_int LAPACKE_dlatms (int matrix_layout, lapack_int m, lapack_int n, char dist,
lapack_int * iseed, char sym, double * d, lapack_int mode, double cond, double dmax,
lapack_int kl, lapack_int ku, char pack, double * a, lapack_int lda);
```

```

lapack_int LAPACKE_clatms (int matrix_layout, lapack_int m, lapack_int n, char dist,
lapack_int * iseed, char sym, float * d, lapack_int mode, float cond, float dmax,
lapack_int kl, lapack_int ku, char pack, lapack_complex_float * a, lapack_int lda);

lapack_int LAPACKE_zlatms (int matrix_layout, lapack_int m, lapack_int n, char dist,
lapack_int * iseed, char sym, double * d, lapack_int mode, double cond, double dmax,
lapack_int kl, lapack_int ku, char pack, lapack_complex_double * a, lapack_int lda);

```

## Include Files

- mkl.h

## Description

The `?latms` routine generates random matrices with specified singular values, or symmetric/Hermitian matrices with specified eigenvalues for testing LAPACK programs.

It applies this sequence of operations:

1. Set the diagonal to  $d$ , where  $d$  is input or computed according to  $mode$ ,  $cond$ ,  $dmax$ , and  $sym$  as described in Input Parameters.
2. Generate a matrix with the appropriate band structure, by one of two methods:

Method A

1. Generate a dense  $m$ -by- $n$  matrix by multiplying  $d$  on the left and the right by random unitary matrices, then:
2. Reduce the bandwidth according to  $kl$  and  $ku$ , using Householder transformations.

Method B:

Convert the bandwidth-0 (i.e., diagonal) matrix to a bandwidth-1 matrix using Givens rotations, "chasing" out-of-band elements back, much as in QR; then convert the bandwidth-1 to a bandwidth-2 matrix, etc.

Note that for reasonably small bandwidths (relative to  $m$  and  $n$ ) this requires less storage, as a dense matrix is not generated. Also, for symmetric or Hermitian matrices, only one triangle is generated.

Method A is chosen if the bandwidth is a large fraction of the order of the matrix, and  $lda$  is at least  $m$  (so a dense matrix can be stored.) Method B is chosen if the bandwidth is small (less than  $(1/2)*n$  for symmetric or Hermitian or less than  $.3*n+m$  for nonsymmetric), or  $lda$  is less than  $m$  and not less than the bandwidth.

Pack the matrix if desired, using one of the methods specified by the `pack` parameter.

If Method B is chosen and band format is specified, then the matrix is generated in the band format and no repacking is necessary.

## Input Parameters

A `<datatype>` placeholder, if present, is used for the C interface data types in the C interface section above. See [C Interface Conventions](#) for the C interface principal conventions and type definitions.

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major ( <code>LAPACK_ROW_MAJOR</code> ) or column major ( <code>LAPACK_COL_MAJOR</code> ).
<code>m</code>	The number of rows of the matrix $A$ ( $m \geq 0$ ).
<code>n</code>	The number of columns of the matrix $A$ ( $n \geq 0$ ).

<i>dist</i>	<p>Specifies the type of distribution to be used to generate the random singular values or eigenvalues:</p> <ul style="list-style-type: none"> <li>• 'U': uniform distribution (0, 1)</li> <li>• 'S': symmetric uniform distribution (-1, 1)</li> <li>• 'N': normal distribution (0, 1)</li> </ul>
<i>iseed</i>	<p>Array with size 4.</p> <p>Specifies the seed of the random number generator. Values should lie between 0 and 4095 inclusive, and <i>iseed</i>[3] should be odd. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers. The values of the array are modified, and can be used in the next call to <code>?latms</code> to continue the same random number sequence.</p>
<i>sym</i>	<p>If <i>sym</i>='S' or 'H', the generated matrix is symmetric or Hermitian, with eigenvalues specified by <i>d</i>, <i>cond</i>, <i>mode</i>, and <i>dmax</i>; they can be positive, negative, or zero.</p> <p>If <i>sym</i>='P', the generated matrix is symmetric or Hermitian, with eigenvalues (which are singular, non-negative values) specified by <i>d</i>, <i>cond</i>, <i>mode</i>, and <i>dmax</i>.</p> <p>If <i>sym</i>='N', the generated matrix is nonsymmetric, with singular, non-negative values specified by <i>d</i>, <i>cond</i>, <i>mode</i>, and <i>dmax</i>.</p>
<i>d</i>	<p>Array, size (MIN(<i>m</i>, <i>n</i>))</p> <p>This array is used to specify the singular values or eigenvalues of <i>A</i> (see the description of <i>sym</i>). If <i>mode</i>=0, then <i>d</i> is assumed to contain the eigenvalues or singular values, otherwise elements of <i>d</i> are computed according to <i>mode</i>, <i>cond</i>, and <i>dmax</i>.</p>
<i>mode</i>	<p>Describes how the singular/eigenvalues are specified.</p> <ul style="list-style-type: none"> <li>• <i>mode</i> = 0: use <i>d</i> as input</li> <li>• <i>mode</i> = 1: set <math>d[0] = 1</math> and <math>d[1:n - 1] = 1.0/cond</math></li> <li>• <i>mode</i> = 2: set <math>d[0:n - 2] = 1</math> and <math>d[n - 1] = 1.0/cond</math></li> <li>• <i>mode</i> = 3: set <math>d[i] = cond^{-i/(n - 1)}</math></li> <li>• <i>mode</i> = 4: set <math>d[i] = 1 - i/(n - 1) * (1 - 1/cond)</math></li> <li>• <i>mode</i> = 5: set elements of <i>d</i> to random numbers in the range (1/<i>cond</i>, 1) such that their logarithms are uniformly distributed.</li> <li>• <i>mode</i> = 6: set elements of <i>d</i> to random numbers from same distribution as the rest of the matrix.</li> </ul> <p><i>mode</i> &lt; 0 has the same meaning as ABS(<i>mode</i>), except that the order of the elements of <i>d</i> is reversed. Thus, if <i>mode</i> is positive, <i>d</i> has entries ranging from 1 to 1/<i>cond</i>, if negative, from 1/<i>cond</i> to 1.</p> <p>If <i>sym</i>='S' or 'H', and <i>mode</i> is not 0, 6, nor -6, then the elements of <i>d</i> are also given a random sign (multiplied by +1 or -1).</p>
<i>cond</i>	Used in setting <i>d</i> as described for the <i>mode</i> parameter. If used, $cond \geq 1$ .
<i>dmax</i>	If <i>mode</i> is not -6, 0 nor 6, the contents of <i>d</i> , as computed according to <i>mode</i> and <i>cond</i> , are scaled by $dmax / \max(\text{abs}(d[i-1]))$ ; thus, the maximum absolute eigenvalue or singular value (the norm) is $\text{abs}(dmax)$ .

**NOTE**

$d_{max}$  need not be positive: if  $d_{max}$  is negative (or zero),  $d$  will be scaled by a negative number (or zero).

*kl* Specifies the lower bandwidth of the matrix. For example,  $kl=0$  implies upper triangular,  $kl=1$  implies upper Hessenberg, and  $kl$  being at least  $m - 1$  means that the matrix has full lower bandwidth.  $kl$  must equal  $ku$  if the matrix is symmetric or Hermitian.

*ku* Specifies the upper bandwidth of the matrix. For example,  $ku=0$  implies lower triangular,  $ku=1$  implies lower Hessenberg, and  $ku$  being at least  $n - 1$  means that the matrix has full upper bandwidth.  $kl$  must equal  $ku$  if the matrix is symmetric or Hermitian.

*pack* Specifies packing of matrix:

- 'N': no packing
- 'U': zero out all subdiagonal entries (if symmetric or Hermitian)
- 'L': zero out all superdiagonal entries (if symmetric or Hermitian)
- 'B': store the lower triangle in band storage scheme (only if matrix symmetric, Hermitian, or lower triangular)
- 'Q': store the upper triangle in band storage scheme (only if matrix symmetric, Hermitian, or upper triangular)
- 'Z': store the entire matrix in band storage scheme (pivoting can be provided for by using this option to store  $A$  in the trailing rows of the allocated storage)

Using these options, the various LAPACK packed and banded storage schemes can be obtained:

	'Z'	'B'	'Q'	'C'	'R'
GB: general band	x				
PB: symmetric positive definite band		x	x		
SB: symmetric band		x	x		
HB: Hermitian band		x	x		
TB: triangular band		x	x		
PP: symmetric positive definite packed				x	x
SP: symmetric packed				x	x
HP: Hermitian packed				x	x
TP: triangular packed				x	x

If two calls to `?latms` differ only in the *pack* parameter, they generate mathematically equivalent matrices.

*lda*

*lda* specifies the first dimension of  $a$  as declared in the calling program.

If *pack*='N', 'U', 'L', 'C', or 'R', then *lda* must be at least *m* for column major or at least *n* for row major.

If *pack*='B' or 'Q', then *lda* must be at least  $\text{MIN}(kl, m - 1)$  (which is equal to  $\text{MIN}(ku, n - 1)$ ).

If *pack*='Z', *lda* must be large enough to hold the packed array:  $\text{MIN}(ku, n - 1) + \text{MIN}(kl, m - 1) + 1$ .

## Output Parameters

*iseed* The array *iseed* contains the updated seed.

*d* The array *d* contains the updated seed.

---

### NOTE

The array *d* is not modified if *mode* = 0.

---

*a* Array of size *lda* by *n*.

The array *a* contains the generated *m*-by-*n* matrix *A*.

*a* is first generated in full (unpacked) form, and then packed, if so specified by *pack*. Thus, the first *m* elements of the first *n* columns are always modified. If *pack* specifies a packed or banded storage scheme, all *lda* elements of the first *n* columns are modified; the elements of the array which do not correspond to elements of the generated matrix are set to zero.

## Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

If *info* = 2, cannot scale to *dmax* (maximum singular value is 0).

If *info* = 3, error return from [lagge](#), [?laghe](#), or [lagsy](#).

## Additional LAPACK Routines (Included for Compatibility with Netlib LAPACK)

```

## ScaLAPACK Routines

Intel® oneAPI Math Kernel Library implements routines from the ScaLAPACK package for distributed-memory architectures. Routines are supported for both real and complex dense and band matrices to perform the tasks of solving systems of linear equations, solving linear least-squares problems, eigenvalue and singular value problems, as well as performing a number of related computational tasks.

Intel® oneAPI Math Kernel Library (oneMKL) ScaLAPACK routines are written in FORTRAN 77 with exception of a few utility routines written in C to exploit the IEEE arithmetic. All routines are available in all precision types: single precision, double precision, complexm, and double complex precision. See `themkl_scalapack.h` header file for C declarations of ScaLAPACK routines.

### NOTE

ScaLAPACK routines are provided only for Intel® 64 or Intel® Many Integrated Core architectures.

See descriptions of ScaLAPACK [computational routines](#) that perform distinct computational tasks, as well as [driver routines](#) for solving standard types of problems in one call. Additionally, Intel® oneAPI Math Kernel Library implements ScaLAPACK [Auxiliary Routines](#), [Utility Functions and Routines](#), and [Matrix Redistribution/Copy Routines](#). The library includes routines for both real and complex data.

The `<install_directory>/examples/scalapackf` directory contains sample code demonstrating the use of ScaLAPACK routines.

Generally, ScaLAPACK runs on a network of computers using MPI as a message-passing layer and a set of prebuilt communication subprograms (BLACS), as well as a set of BLAS optimized for the target architecture. Intel® oneAPI Math Kernel Library (oneMKL) version of ScaLAPACK is optimized for Intel® processors. For the detailed system and environment requirements, see *Intel® oneAPI Math Kernel Library (oneMKL) Release Notes* and *Intel® oneAPI Math Kernel Library (oneMKL) Developer Guide*.

For full reference on ScaLAPACK routines and related information, see [\[SLUG\]](#).

### Product and Performance Information

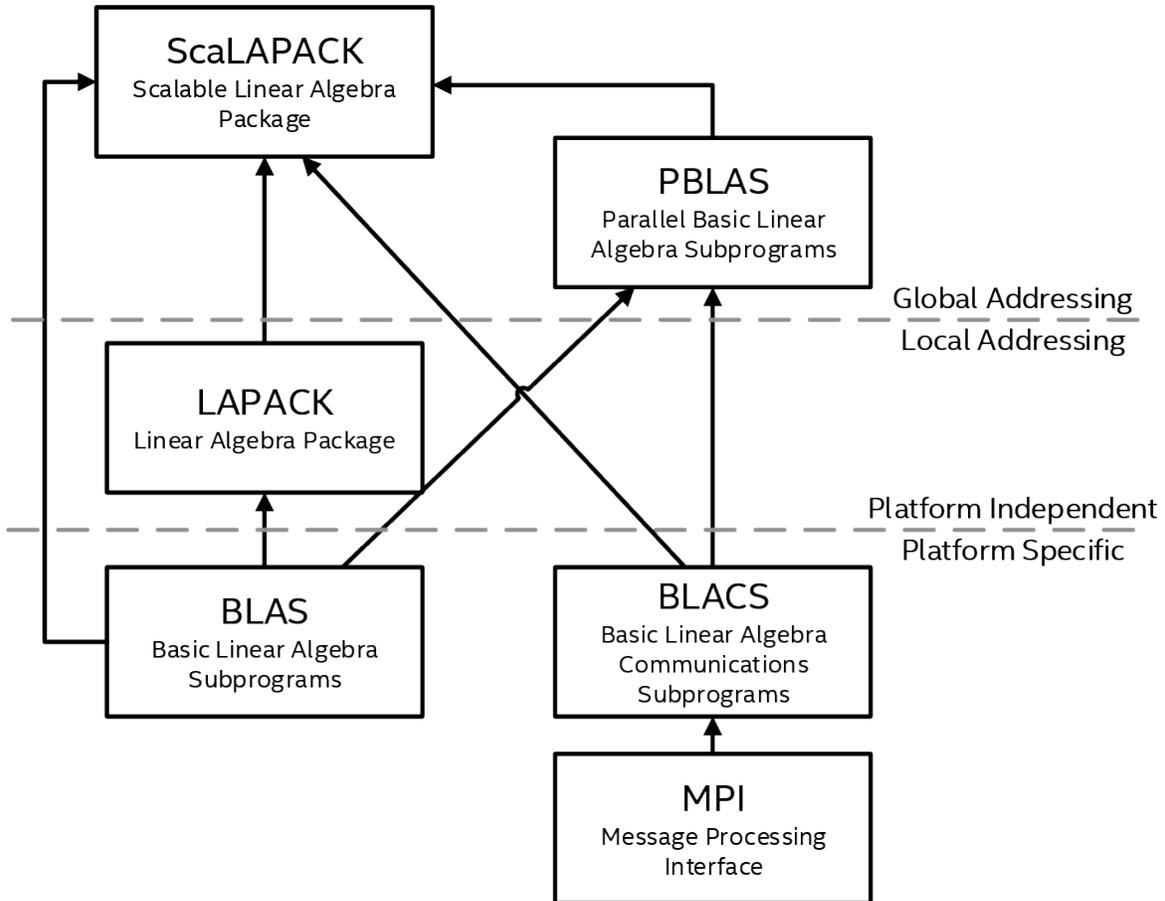

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Overview of ScaLAPACK Routines

The model of the computing environment for ScaLAPACK is represented as a one-dimensional array of processes (for operations on band or tridiagonal matrices) or also a two-dimensional process grid (for operations on dense matrices). To use ScaLAPACK, all global matrices or vectors should be distributed on this array or grid prior to calling the ScaLAPACK routines.

ScaLAPACK is closely tied to other components, including BLAS, BLACS, LAPACK, and PBLAS.

## ScaLAPACK Array Descriptors

ScaLAPACK uses two-dimensional block-cyclic data distribution as a layout for dense matrix computations. This distribution provides good work balance between available processors, and also allows use of BLAS Level 3 routines for optimal local computations. Information about the data distribution that is required to establish the mapping between each global matrix and its corresponding process and memory location is contained in the array called the *array descriptor* associated with each global matrix. The size of the array descriptor is denoted as *dlen\_*.

Let  $A$  be a two-dimensional block cyclicly distributed matrix with the array descriptor array *desca*. The meaning of each array descriptor element depends on the type of the matrix  $A$ . The tables "Array descriptor for dense matrices" and "Array descriptor for narrow-band and tridiagonal matrices" describe the meaning of each element for the different types of matrices.

### Array descriptor for dense matrices (*dlen\_=9*)

Element Name	Stored in	Description	Element Index Number
<i>dtype_a</i>	<i>desca[dtype_]</i>	Descriptor type ( =1 for dense matrices).	0
<i>ctxt_a</i>	<i>desca[ctxt_]</i>	BLACS context handle for the process grid.	1
<i>m_a</i>	<i>desca[m_]</i>	Number of rows in the global matrix $A$ .	2
<i>n_a</i>	<i>desca[n_]</i>	Number of columns in the global matrix $A$ .	3
<i>mb_a</i>	<i>desca[mb_]</i>	Row blocking factor.	4

Element Name	Stored in	Description	Element Index Number
<i>nb_a</i>	<i>desca[nb_]</i>	Column blocking factor.	5
<i>rsrc_a</i>	<i>desca[rsrc_]</i>	Process row over which the first row of the global matrix <i>A</i> is distributed.	6
<i>csrc_a</i>	<i>desca[csrc_]</i>	Process column over which the first column of the global matrix <i>A</i> is distributed.	7
<i>lld_a</i>	<i>desca[lld_]</i>	Leading dimension of the local matrix <i>A</i> .	8

### Array descriptor for narrow-band and tridiagonal matrices (*dlen\_ = 7*)

Element Name	Stored in	Description	Element Index Number
<i>dtype_a</i>	<i>desca[dtype_]</i>	Descriptor type <ul style="list-style-type: none"> <li><i>dtype_a</i>=501: 1-by-<i>P</i> grid,</li> <li><i>dtype_a</i>=502: <i>P</i>-by-1 grid.</li> </ul>	0
<i>ctxt_a</i>	<i>desca[ctxt_]</i>	BLACS context handle indicating the BLACS process grid over which the global matrix <i>A</i> is distributed. The context itself is global, but the handle (the integer value) can vary.	1
<i>n_a</i>	<i>desca[n_]</i>	The size of the matrix dimension being distributed.	2
<i>nb_a</i>	<i>desca[nb_]</i>	The blocking factor used to distribute the distributed dimension of the matrix <i>A</i> .	3
<i>src_a</i>	<i>desca[src_]</i>	The process row or column over which the first row or column of the matrix <i>A</i> is distributed.	4
<i>lld_a</i>	<i>desca[lld_]</i>	The leading dimension of the local matrix storing the local blocks of the distributed matrix <i>A</i> . The minimum value of <i>lld_a</i> depends on <i>dtype_a</i> . <ul style="list-style-type: none"> <li><i>dtype_a</i>=501: <math>lld_a \geq \max(\text{size of undistributed dimension}, 1)</math>,</li> <li><i>dtype_a</i>=502: <math>lld_a \geq \max(nb_a, 1)</math>.</li> </ul>	5
Not applicable		Reserved for future use.	6

Similar notations are used for different matrices. For example: *lld\_b* is the leading dimension of the local matrix storing the local blocks of the distributed matrix *B* and *dtype\_z* is the type of the global matrix *Z*.

The number of rows and columns of a global dense matrix that a particular process in a grid receives after data distributing is denoted by  $LOC_r()$  and  $LOC_c()$ , respectively. To compute these numbers, you can use the ScaLAPACK tool routine `numroc`.

After the block-cyclic distribution of global data is done, you may choose to perform an operation on a submatrix  $\text{sub}(A)$  of the global matrix *A* defined by the following 6 values (for dense matrices):

<i>m</i>	The number of rows of $\text{sub}(A)$
<i>n</i>	The number of columns of $\text{sub}(A)$
<i>a</i>	A pointer to the local matrix containing the entire global matrix <i>A</i>
<i>ia</i>	The row index of $\text{sub}(A)$ in the global matrix <i>A</i>
<i>ja</i>	The column index of $\text{sub}(A)$ in the global matrix <i>A</i>

*desca*The array descriptor for the global matrix *A***Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Naming Conventions for ScaLAPACK Routines

For each routine introduced in this chapter, you can use the ScaLAPACK name. The naming convention for ScaLAPACK routines is similar to that used for LAPACK routines. A general rule is that each routine name in ScaLAPACK, which has an LAPACK equivalent, is simply the LAPACK name prefixed by initial letter *p*.

**ScaLAPACK names** have the structure *p?yyzzz* or *p?yyzz*, which is described below.

The initial letter *p* is a distinctive prefix of ScaLAPACK routines and is present in each such routine.

The second symbol *?* indicates the data type:

<i>s</i>	real, single precision
<i>d</i>	real, double precision
<i>c</i>	complex, single precision
<i>z</i>	complex, double precision

The second and third letters *yy* indicate the matrix type as:

<i>ge</i>	general
<i>gb</i>	general band
<i>gg</i>	a pair of general matrices (for a generalized problem)
<i>dt</i>	general tridiagonal (diagonally dominant-like)
<i>db</i>	general band (diagonally dominant-like)
<i>po</i>	symmetric or Hermitian positive-definite
<i>pb</i>	symmetric or Hermitian positive-definite band
<i>pt</i>	symmetric or Hermitian positive-definite tridiagonal
<i>sy</i>	symmetric
<i>st</i>	symmetric tridiagonal (real)
<i>he</i>	Hermitian
<i>or</i>	orthogonal
<i>tr</i>	triangular (or quasi-triangular)
<i>tz</i>	trapezoidal
<i>un</i>	unitary

For computational routines, the last three letters **zzz** indicate the computation performed and have the same meaning as for LAPACK routines.

For driver routines, the last two letters **zz** or three letters **zzz** have the following meaning:

<code>sv</code>	a <i>simple</i> driver for solving a linear system
<code>svx</code>	an <i>expert</i> driver for solving a linear system
<code>ls</code>	a driver for solving a linear least squares problem
<code>ev</code>	a simple driver for solving a symmetric eigenvalue problem
<code>evd</code>	a simple driver for solving an eigenvalue problem using a divide and conquer algorithm
<code>evx</code>	an expert driver for solving a symmetric eigenvalue problem
<code>svd</code>	a driver for computing a singular value decomposition
<code>gvx</code>	an expert driver for solving a generalized symmetric definite eigenvalue problem

*Simple* driver here means that the driver just solves the general problem, whereas an *expert* driver is more versatile and can also optionally perform some related computations (such, for example, as refining the solution and computing error bounds after the linear system is solved).

## ScaLAPACK Computational Routines

In the sections that follow, the descriptions of ScaLAPACK computational routines are given. These routines perform distinct computational tasks that can be used for:

- [Solving Systems of Linear Equations](#)
- [Orthogonal Factorizations and LLS Problems](#)
- [Symmetric Eigenproblems](#)
- [Nonsymmetric Eigenproblems](#)
- [Singular Value Decomposition](#)
- [Generalized Symmetric-Definite Eigenproblems](#)

See also the respective [driver routines](#).

## Systems of Linear Equations: ScaLAPACK Computational Routines

ScaLAPACK supports routines for the systems of equations with the following types of matrices:

- general
- general banded
- general diagonally dominant-like banded (including general tridiagonal)
- symmetric or Hermitian positive-definite
- symmetric or Hermitian positive-definite banded
- symmetric or Hermitian positive-definite tridiagonal

A *diagonally dominant-like* matrix is defined as a matrix for which it is known in advance that pivoting is not required in the *LU* factorization of this matrix.

For the above matrix types, the library includes routines for performing the following computations: *factoring* the matrix; *equilibrating* the matrix; *solving* a system of linear equations; *estimating the condition number* of a matrix; *refining* the solution of linear equations and computing its error bounds; *inverting* the matrix. Note that for some of the listed matrix types only part of the computational routines are provided (for example, routines that refine the solution are not provided for band or tridiagonal matrices). See [Table "Computational Routines for Systems of Linear Equations"](#) for full list of available routines.

To solve a particular problem, you can either call two or more computational routines or call a corresponding [driver routine](#) that combines several tasks in one call. Thus, to solve a system of linear equations with a general matrix, you can first call `p?getrf` (*LU* factorization) and then `p?getrs` (computing the solution). Then, you might wish to call `p?gerfs` to refine the solution and get the error bounds. Alternatively, you can just use the driver routine `p?gesvx` which performs all these tasks in one call.

Table “Computational Routines for Systems of Linear Equations” lists the ScaLAPACK computational routines for factorizing, equilibrating, and inverting matrices, estimating their condition numbers, solving systems of equations with real matrices, refining the solution, and estimating its error.

### Computational Routines for Systems of Linear Equations

Matrix type, storage scheme	Factorize matrix	Equilibrate matrix	Solve system	Condition number	Estimate error	Invert matrix
general (partial pivoting)	<a href="#">p?getrf</a>	<a href="#">p?geequ</a>	<a href="#">p?getrs</a>	<a href="#">p?gecon</a>	<a href="#">p?gerfs</a>	<a href="#">p?getri</a>
general band (partial pivoting)	<a href="#">p?gbtrf</a>		<a href="#">p?gbtrs</a>			
general band (no pivoting)	<a href="#">p?dbtrf</a>		<a href="#">p?dbtrs</a>			
general tridiagonal (no pivoting)	<a href="#">p?dttrf</a>		<a href="#">p?dttrs</a>			
symmetric/Hermitian positive-definite	<a href="#">p?potrf</a>	<a href="#">p?poequ</a>	<a href="#">p?potrs</a>	<a href="#">p?pocon</a>	<a href="#">p?porfs</a>	<a href="#">p?potri</a>
symmetric/Hermitian positive-definite, band	<a href="#">p?pbtrf</a>		<a href="#">p?pbtrs</a>			
symmetric/Hermitian positive-definite, tridiagonal	<a href="#">p?pttrf</a>		<a href="#">p?pttrs</a>			
triangular			<a href="#">p?trtrs</a>	<a href="#">p?trcon</a>	<a href="#">p?trrfs</a>	<a href="#">p?trtri</a>

In this table ? stands for s (single precision real), d (double precision real), c (single precision complex), or z (double precision complex).

### Matrix Factorization: ScaLAPACK Computational Routines

This section describes the ScaLAPACK routines for matrix factorization. The following factorizations are supported:

- LU factorization of general matrices
- LU factorization of diagonally dominant-like matrices
- Cholesky factorization of real symmetric or complex Hermitian positive-definite matrices

You can compute the factorizations using full and band storage of matrices.

#### [p?getrf](#)

*Computes the LU factorization of a general m-by-n distributed matrix.*

#### Syntax

```
void psgetrf (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
void pdgetrf (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
void pcgetrf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
void pzgetrf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
```

#### Include Files

- `mkl_scalapack.h`

#### Description

The `p?getrf` function forms the  $LU$  factorization of a general  $m$ -by- $n$  distributed matrix  $\text{sub}(A) = A(\text{ia}:\text{ia} + m - 1, \text{ja}:\text{ja} + n - 1)$  as

$$A = P * L * U$$

where  $P$  is a permutation matrix,  $L$  is lower triangular with unit diagonal elements (lower trapezoidal if  $m > n$ ) and  $U$  is upper triangular (upper trapezoidal if  $m < n$ ).  $L$  and  $U$  are stored in  $\text{sub}(A)$ .

The function uses partial pivoting, with row interchanges.

---

#### NOTE

This function supports the Progress Routine feature. See [mkl\\_progress](#) for details.

---

### Input Parameters

<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(A)$ ; $m \geq 0$ .
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(A)$ ; $n \geq 0$ .
<i>a</i>	(local) Pointer into the local memory to an array of local size $\text{lld}_a * \text{LOCc}(\text{ja} + n - 1)$ . Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .

### Output Parameters

<i>a</i>	Overwritten by local pieces of the factors $L$ and $U$ from the factorization $A = P * L * U$ . The unit diagonal elements of $L$ are not stored.
<i>ipiv</i>	(local) Array of size $\text{LOCr}(m\_a) + mb\_a$ . Contains the pivoting information: local row $i$ was interchanged with global row $\text{ipiv}[i - 1]$ . This array is tied to the distributed matrix $A$ .
<i>info</i>	(global) If $\text{info} = 0$ , the execution is successful.  $\text{info} < 0$ : if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then $\text{info} = -(i * 100 + j)$ ; if the $i$ -th argument is a scalar and had an illegal value, then $\text{info} = -i$ .  If $\text{info} = i > 0$ , $u_{\text{ia}+i, \text{ja}+j-1}$ is 0. The factorization has been completed, but the factor $U$ is exactly singular. Division by zero will occur if you use the factor $U$ for solving a system of linear equations.

#### **p?gbtrf**

Computes the  $LU$  factorization of a general  $n$ -by- $n$  banded distributed matrix.

---

## Syntax

```
void psgbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , float *a , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , float *af , MKL_INT *laf , float *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pdgbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , double *a , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , double *af , MKL_INT *laf , double *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pcgbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , MKL_Complex8 *a , MKL_INT
*ja , MKL_INT *desca , MKL_INT *ipiv , MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8
*work , MKL_INT *lwork , MKL_INT *info );
```

```
void pzgbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , MKL_Complex16 *a , MKL_INT
*ja , MKL_INT *desca , MKL_INT *ipiv , MKL_Complex16 *af , MKL_INT *laf , MKL_Complex16
*work , MKL_INT *lwork , MKL_INT *info );
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?gbtrf` function computes the  $LU$  factorization of a general  $n$ -by- $n$  real/complex banded distributed matrix  $A(1:n, ja:ja+n-1)$  using partial pivoting with row interchanges.

The resulting factorization is not the same factorization as returned from the LAPACK function `?gbtrf`. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form

$$A(1:n, ja:ja+n-1) = P*L*U*Q$$

where  $P$  and  $Q$  are permutation matrices, and  $L$  and  $U$  are banded lower and upper triangular matrices, respectively. The matrix  $Q$  represents reordering of columns for the sake of parallelism, while  $P$  represents reordering of rows for numerical stability using classic partial pivoting.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

$n$	(global) The number of rows and columns in the distributed submatrix $A(1:n, ja:ja+n-1)$ ; $n \geq 0$ .
$bwl$	(global) The number of sub-diagonals within the band of $A$ ( $0 \leq bwl \leq n-1$ ).
$bwu$	(global) The number of super-diagonals within the band of $A$ ( $0 \leq bwu \leq n-1$ ).
$a$	(local) Pointer into the local memory to an array of local size $lld_a*LOCc(ja+n-1)$ where

$lld\_a \geq 2*bw1 + 2*bwu + 1$ .

Contains the local pieces of the  $n$ -by- $n$  distributed banded matrix  $A(1:n, ja:ja+n-1)$  to be factored.

<i>ja</i>	(global) The index in the global matrix $A$ indicating the start of the matrix to be operated on (which may be either all of $A$ or a submatrix of $A$ ).
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ . If <i>dtype_a</i> = 501, then <i>dlen_</i> $\geq$ 7; else if <i>dtype_a</i> = 1, then <i>dlen_</i> $\geq$ 9.
<i>laf</i>	(local) The size of the array <i>af</i> . Must be $laf \geq (nb\_a + bwu) * (bw1 + bwu) + 6 * (bw1 + bwu) * (bw1 + 2 * bwu)$ . If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> [0].
<i>work</i>	(local) Same type as <i>a</i> . Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the <i>work</i> array ( $lwork \geq 1$ ). If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i> [0] and an error code is returned.

## Output Parameters

<i>a</i>	On exit, this array contains details of the factorization. Note that additional permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.
<i>ipiv</i>	(local) array. The size of <i>ipiv</i> must be $\geq nb\_a$ . Contains pivot indices for local factorizations. Note that you <i>should not alter</i> the contents of this array between factorization and solve.
<i>af</i>	(local) Array of size <i>laf</i> . Auxiliary fill-in space. The fill-in space is created in a call to the factorization function <code>p?gbtrf</code> and is stored in <i>af</i> . Note that if a linear system is to be solved using <code>p?gbtrs</code> after the factorization function, <i>af</i> must not be altered after the factorization.
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required.
<i>info</i>	(global) If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = $-(i*100+j)$ ; if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$ .

*info* > 0:

If  $info = k \leq \text{NPROCS}$ , the submatrix stored on processor *info* and factored locally was not nonsingular, and the factorization was not completed.

If  $info = k > \text{NPROCS}$ , the submatrix stored on processor  $info - \text{NPROCS}$  representing interactions with other processors was not nonsingular, and the factorization was not completed.

## Description

The `p?dbtrf` function computes the LU factorization of a  $n$ -by- $n$  real/complex diagonally dominant-like banded distributed matrix  $A(1:n, ja:ja+n-1)$  without pivoting.

### NOTE

A matrix is called *diagonally dominant-like* if pivoting is not required for LU to be numerically stable.

Note that the resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

## Description

The `p?dttrf` function computes the *LU* factorization of an *n*-by-*n* real/complex diagonally dominant-like tridiagonal distributed matrix  $A(1:n, ja:ja+n-1)$  without pivoting for stability.

The resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form:

$$A(1:n, ja:ja+n-1) = P*L*U*P^T,$$

where *P* is a permutation matrix, and *L* and *U* are banded lower and upper triangular matrices, respectively.

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

**Input Parameters**

<i>n</i>	(global) The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$ ( $n \geq 0$ ).
<i>dl, d, du</i>	(local) Pointers to the local arrays of size <i>nb_a</i> each.  On entry, the array <i>dl</i> contains the local part of the global vector storing the subdiagonal elements of the matrix. Globally, <i>dl</i> [0] is not referenced, and <i>dl</i> must be aligned with <i>d</i> .  On entry, the array <i>d</i> contains the local part of the global vector storing the diagonal elements of the matrix.  On entry, the array <i>du</i> contains the local part of the global vector storing the super-diagonal elements of the matrix. <i>du</i> [ <i>n</i> -1] is not referenced, and <i>du</i> must be aligned with <i>d</i> .
<i>ja</i>	(global) The index in the global matrix <i>A</i> indicating the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i> ).
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .  If <i>dtype_a</i> = 501, then $dlen_ \geq 7$ ; else if <i>dtype_a</i> = 1, then $dlen_ \geq 9$ .
<i>laf</i>	(local) The size of the array <i>af</i> .  Must be $laf \geq 2*(NB+2)$ .  If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> [0].
<i>work</i>	(local) Same type as <i>d</i> . Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the <i>work</i> array, must be at least $lwork \geq 8*NPCOL$ .

**Output Parameters**

<i>dl, d, du</i>	On exit, overwritten by the information containing the factors of the matrix.
<i>af</i>	(local) Array of size <i>laf</i> .  Auxiliary fill-in space. The fill-in space is created in a call to the factorization function <code>p?dttrf</code> and is stored in <i>af</i> .

Note that if a linear system is to be solved using `p?dttrs` after the factorization function, `af` must not be altered.

`work[0]`

On exit, `work[0]` contains the minimum value of `lwork` required for optimum performance.

`info`

(global)

If `info=0`, the execution is successful.

`info < 0`:

If the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j - 1$ , had an illegal value, then `info = -( $j * 100 + i$ )`; if the  $i$ -th argument is a scalar and had an illegal value, then `info = - $i$` .

`info > 0`:

If `info =  $k \leq$  NPROCS`, the submatrix stored on processor `info` and factored locally was not diagonally dominant-like, and the factorization was not completed.

If `info =  $k >$  NPROCS`, the submatrix stored on processor `info-NPROCS` representing interactions with other processors was not nonsingular, and the factorization was not completed.

## See Also

## p?potrf

*Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite distributed matrix.*

## Syntax

```
void pspotrf (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pdpotrf (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pcpotrf (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pzpotrf (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?potrf` function computes the Cholesky factorization of a real symmetric or complex Hermitian positive-definite distributed  $n$ -by- $n$  matrix  $A(ia:ia+n-1, ja:ja+n-1)$ , denoted below as  $\text{sub}(A)$ .

The factorization has the form

$\text{sub}(A) = U^H * U$  if `uplo='U'`, or

$\text{sub}(A) = L * L^H$  if `uplo='L'`

where  $L$  is a lower triangular matrix and  $U$  is upper triangular.

## Input Parameters

<i>uplo</i>	(global) Indicates whether the upper or lower triangular part of sub( <i>A</i> ) is stored. Must be 'U' or 'L'.  If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular part of the matrix sub( <i>A</i> ) that is factored as $U^H*U$ .  If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular part of the matrix sub( <i>A</i> ) that is factored as $L*L^H$ .
<i>n</i>	(global) The order of the distributed matrix sub( <i>A</i> ) ( $n \geq 0$ ).
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a*LOCc(ja+n-1)$ .  On entry, this array contains the local pieces of the <i>n</i> -by- <i>n</i> symmetric/Hermitian distributed matrix sub( <i>A</i> ) to be factored.  Depending on <i>uplo</i> , the array <i>a</i> contains either the upper or the lower triangular part of the matrix sub( <i>A</i> ) (see <i>uplo</i> ).
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix sub( <i>A</i> ), respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .

## Output Parameters

<i>a</i>	The upper or lower triangular part of <i>a</i> is overwritten by the Cholesky factor <i>U</i> or <i>L</i> , as specified by <i>uplo</i> .
<i>info</i>	(global) .  If <i>info</i> =0, the execution is successful;  <i>info</i> < 0: if the <i>i</i> -th argument is an array, and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -( <i>i</i> *100+ <i>j</i> ); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .  If <i>info</i> = <i>k</i> > 0, the leading minor of order <i>k</i> , $A(ia:ia+k-1, ja:ja+k-1)$ , is not positive-definite, and the factorization could not be completed.

## Description

The `p?pbtrf` function computes the Cholesky factorization of an  $n$ -by- $n$  real symmetric or complex Hermitian positive-definite banded distributed matrix  $A(1:n, ja:ja+n-1)$ .

The resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form:

$A(1:n, ja:ja+n-1) = P*U^H*U*P^T$ , if `uplo='U'`, or

$A(1:n, ja:ja+n-1) = P*L*L^H*P^T$ , if `uplo='L'`,

where  $P$  is a permutation matrix and  $U$  and  $L$  are banded upper and lower triangular matrices, respectively.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

<code>uplo</code>	(global) Must be 'U' or 'L'. If <code>uplo = 'U'</code> , upper triangle of $A(1:n, ja:ja+n-1)$ is stored; If <code>uplo = 'L'</code> , lower triangle of $A(1:n, ja:ja+n-1)$ is stored.
<code>n</code>	(global) The order of the distributed submatrix $A(1:n, ja:ja+n-1)$ . ( $n \geq 0$ ).
<code>bw</code>	(global) The number of superdiagonals of the distributed matrix if <code>uplo = 'U'</code> , or the number of subdiagonals if <code>uplo = 'L'</code> ( $bw \geq 0$ ).
<code>a</code>	(local) Pointer into the local memory to an array of size $lld\_a*LOCc(ja+n-1)$ . On entry, this array contains the local pieces of the upper or lower triangle of the symmetric/Hermitian band distributed matrix $A(1:n, ja:ja+n-1)$ to be factored.
<code>ja</code>	(global) The index in the global matrix $A$ indicating the start of the matrix to be operated on (which may be either all of $A$ or a submatrix of $A$ ).

<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>dtype_a</i> = 501, then $dlen_ \geq 7$ ; else if <i>dtype_a</i> = 1, then $dlen_ \geq 9$ .
<i>laf</i>	(local) The size of the array <i>af</i> . Must be $laf \geq (NB+2*bw) * bw$ . If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> [0].
<i>work</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the <i>work</i> array, must be $lwork \geq bw^2$ .

## Output Parameters

<i>a</i>	On exit, if <i>info</i> =0, contains the permuted triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization of the band matrix $A(1:n, ja:ja+n-1)$ , as specified by <i>uplo</i> .
<i>af</i>	(local) Array of size <i>laf</i> . Auxiliary fill-in space. The fill-in space is created in a call to the factorization function <i>p?pbtrf</i> and stored in <i>af</i> . Note that if a linear system is to be solved using <i>p?pbtrs</i> after the factorization function, <i>af</i> must not be altered.
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then $info = -(i*100+j)$ ; if the <i>i</i> -th argument is a scalar and had an illegal value, then $info = -i$ . <i>info</i> >0: If $info = k \leq NPROCS$ , the submatrix stored on processor <i>info</i> and factored locally was not positive definite, and the factorization was not completed. If $info = k > NPROCS$ , the submatrix stored on processor <i>info</i> -NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

## p?pttrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite tridiagonal distributed matrix.

### Syntax

```
void psptrf (MKL_INT *n , float *d , float *e , MKL_INT *ja , MKL_INT *desca , float
*af , MKL_INT *laf , float *work , MKL_INT *lwork , MKL_INT *info );

void pdptrf (MKL_INT *n , double *d , double *e , MKL_INT *ja , MKL_INT *desca , double
*af , MKL_INT *laf , double *work , MKL_INT *lwork , MKL_INT *info );

void pcptrf (MKL_INT *n , float *d , MKL_Complex8 *e , MKL_INT *ja , MKL_INT *desca ,
MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT
*info );

void pzptrf (MKL_INT *n , double *d , MKL_Complex16 *e , MKL_INT *ja , MKL_INT
*desca , MKL_Complex16 *af , MKL_INT *laf , MKL_Complex16 *work , MKL_INT *lwork ,
MKL_INT *info );
```

### Include Files

- mkl\_scalapack.h

### Description

The p?pttrf function computes the Cholesky factorization of an  $n$ -by- $n$  real symmetric or complex hermitian positive-definite tridiagonal distributed matrix  $A(1:n, ja:ja+n-1)$ .

The resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form:

$$A(1:n, ja:ja+n-1) = P * L * D * L^H * P^T, \text{ or}$$

$$A(1:n, ja:ja+n-1) = P * U^H * D * U * P^T,$$

where  $P$  is a permutation matrix, and  $U$  and  $L$  are tridiagonal upper and lower triangular matrices, respectively.

Notice revision #20201201

### Input Parameters

$n$	(global) The order of the distributed submatrix $A(1:n, ja:ja+n-1)$ ( $n \geq 0$ ).
$d, e$	(local) Pointers into the local memory to arrays of size $nb_a$ each. On entry, the array $d$ contains the local part of the global vector storing the main diagonal of the distributed matrix $A$ .

	On entry, the array <i>e</i> contains the local part of the global vector storing the upper diagonal of the distributed matrix <i>A</i> .
<i>ja</i>	(global) The index in the global matrix <i>A</i> indicating the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i> ).
<i>desca</i>	(global and local ) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>dtype_a</i> = 501, then <i>dlen_</i> ≥ 7; else if <i>dtype_a</i> = 1, then <i>dlen_</i> ≥ 9.
<i>laf</i>	(local) The size of the array <i>af</i> . Must be <i>laf</i> ≥ <i>nb_a</i> + 2. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> [0].
<i>work</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the <i>work</i> array, must be at least <i>lwork</i> ≥ 8 * NPCOL.

## Output Parameters

<i>d, e</i>	On exit, overwritten by the details of the factorization.
<i>af</i>	(local) Array of size <i>laf</i> . Auxiliary fill-in space. The fill-in space is created in a call to the factorization function <i>p?pttrf</i> and stored in <i>af</i> . Note that if a linear system is to be solved using <i>p?pttrs</i> after the factorization function, <i>af</i> must not be altered.
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -( <i>j</i> *100+ <i>j</i> ); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . <i>info</i> > 0: If <i>info</i> = <i>k</i> ≤ NPROCS, the submatrix stored on processor <i>info</i> and factored locally was not positive definite, and the factorization was not completed. If <i>info</i> = <i>k</i> > NPROCS, the submatrix stored on processor <i>info</i> -NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

## Solving Systems of Linear Equations: ScaLAPACK Computational Routines

This section describes the ScaLAPACK routines for solving systems of linear equations. Before calling most of these routines, you need to factorize the matrix of your system of equations (see [Routines for Matrix Factorization](#) in this chapter). However, the factorization is not necessary if your system of equations has a triangular matrix.

### p?getrs

*Solves a system of distributed linear equations with a general square matrix, using the LU factorization computed by p?getrf.*

### Syntax

```
void psgetrs (char *trans , MKL_INT *n , MKL_INT *nrhs , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , float *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , MKL_INT *info );
```

```
void pdgetrs (char *trans , MKL_INT *n , MKL_INT *nrhs , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , double *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , MKL_INT *info );
```

```
void pcgetrs (char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex8 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_Complex8 *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , MKL_INT *info );
```

```
void pzgetrs (char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex16 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_Complex16 *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , MKL_INT *info );
```

### Include Files

- mkl\_scalapack.h

### Description

The p?getrs function solves a system of distributed linear equations with a general  $n$ -by- $n$  distributed matrix  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$  using the  $LU$  factorization computed by p?getrf.

The system has one of the following forms specified by *trans*:

$\text{sub}(A)*X = \text{sub}(B)$  (no transpose),

$\text{sub}(A)^T*X = \text{sub}(B)$  (transpose),

$\text{sub}(A)^H*X = \text{sub}(B)$  (conjugate transpose),

where  $\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+\text{nrhs}-1)$ .

Before calling this function, you must call p?getrf to compute the  $LU$  factorization of  $\text{sub}(A)$ .

### Input Parameters

<i>trans</i>	(global) Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $\text{sub}(A)*X = \text{sub}(B)$ is solved for $X$ . If <i>trans</i> = 'T', then $\text{sub}(A)^T*X = \text{sub}(B)$ is solved for $X$ .
--------------	---

If  $trans = 'C'$ , then  $sub(A)^H * X = sub(B)$  is solved for  $X$ .

<i>n</i>	(global) The number of linear equations; the order of the matrix $sub(A)$ ( $n \geq 0$ ).
<i>nrhs</i>	(global) The number of right hand sides; the number of columns of the distributed matrix $sub(B)$ ( $nrhs \geq 0$ ).
<i>a, b</i>	(local) Pointers into the local memory to arrays of local sizes $lld\_a * LOCC(ja+n-1)$ and $lld\_b * LOCC(jb+nrhs-1)$ , respectively. On entry, the array <i>a</i> contains the local pieces of the factors <i>L</i> and <i>U</i> from the factorization $sub(A) = P * L * U$ ; the unit diagonal elements of <i>L</i> are not stored. On entry, the array <i>b</i> contains the right hand sides $sub(B)$ .
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix $sub(A)$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>ipiv</i>	(local) Array of size of $LOCr(m\_a) + mb\_a$ . Contains the pivoting information: local row <i>i</i> of the matrix was interchanged with the global row <i>ipiv</i> [ <i>i</i> -1]. This array is tied to the distributed matrix <i>A</i> .
<i>ib, jb</i>	(global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the matrix $sub(B)$ , respectively.
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .

## Output Parameters

<i>b</i>	On exit, overwritten by the solution distributed matrix <i>X</i> .
<i>info</i>	If $info=0$ , the execution is successful. $info < 0$ : If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then $info = -(i*100+j)$ ; if the <i>i</i> -th argument is a scalar and had an illegal value, then $info = -i$ .

MKL_INT *ib , MKL_INT *descb , MKL_Complex16 *af , MKL_INT *laf , MKL_Complex16 *work ,
MKL_INT *lwork , MKL_INT *info );
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?gbtrs` function solves a system of distributed linear equations with a general band distributed matrix  $\text{sub}(A) = A(1:n, ja:ja+n-1)$  using the  $LU$  factorization computed by `p?gbtrf`.

The system has one of the following forms specified by `trans`:

$\text{sub}(A)*X = \text{sub}(B)$  (no transpose),

$\text{sub}(A)^T*X = \text{sub}(B)$  (transpose),

$\text{sub}(A)^H*X = \text{sub}(B)$  (conjugate transpose),

where  $\text{sub}(B) = B(ib:ib+n-1, 1:nrhs)$ .

Before calling this function, you must call `p?gbtrf` to compute the  $LU$  factorization of  $\text{sub}(A)$ .

## Input Parameters

<code>trans</code>	(global) Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <code>trans</code> = 'N', then $\text{sub}(A)*X = \text{sub}(B)$ is solved for $X$ . If <code>trans</code> = 'T', then $\text{sub}(A)^T*X = \text{sub}(B)$ is solved for $X$ . If <code>trans</code> = 'C', then $\text{sub}(A)^H *X = \text{sub}(B)$ is solved for $X$ .
<code>n</code>	(global) The number of linear equations; the order of the distributed matrix $\text{sub}(A)$ ( $n \geq 0$ ).
<code>bwl</code>	(global) The number of sub-diagonals within the band of $A$ ( $0 \leq bwl \leq n-1$ ).
<code>bwu</code>	(global) The number of super-diagonals within the band of $A$ ( $0 \leq bwu \leq n-1$ ).
<code>nrhs</code>	(global) The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ( $nrhs \geq 0$ ).
<code>a, b</code>	(local)

Pointers into the local memory to arrays of local sizes  $lld\_a * LOCC(ja+n-1)$  and  $lld\_b * LOCC(nrhs)$ , respectively.

The array  $a$  contains details of the  $LU$  factorization of the distributed band matrix  $A$ .

On entry, the array  $b$  contains the local pieces of the right hand sides  $B(ib:ib+n-1, 1:nrhs)$ .

<i>ja</i>	(global) The index in the global matrix $A$ indicating the start of the matrix to be operated on ( which may be either all of $A$ or a submatrix of $A$ ).
<i>desca</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .  If $dtype\_a = 501$ , then $dlen\_ \geq 7$ ; else if $dtype\_a = 1$ , then $dlen\_ \geq 9$ .
<i>ib</i>	(global) The index in the global matrix $A$ indicating the start of the matrix to be operated on (which may be either all of $A$ or a submatrix of $A$ ).
<i>descb</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .  If $dtype\_b = 502$ , then $dlen\_ \geq 7$ ; else if $dtype\_b = 1$ , then $dlen\_ \geq 9$ .
<i>laf</i>	(local) The size of the array $af$ .  Must be $laf \geq nb\_a * (bwl + bwu) + 6 * (bwl + bwu) * (bwl + 2 * bwu)$ .  If $laf$ is not large enough, an error code will be returned and the minimum acceptable size will be returned in $af[0]$ .
<i>work</i>	(local) Same type as $a$ . Workspace array of size $lwork$ .
<i>lwork</i>	(local or global) The size of the $work$ array, must be at least $lwork \geq nrhs * (nb\_a + 2 * bwl + 4 * bwu)$ .

## Output Parameters

<i>ipiv</i>	(local) array.  The size of $ipiv$ must be $\geq nb\_a$ .  Contains pivot indices for local factorizations. Note that you should not alter the contents of this array between factorization and solve.
<i>b</i>	On exit, overwritten by the local pieces of the solution distributed matrix $X$ .
<i>af</i>	(local)  Array of size $laf$ .  Auxiliary Fill-in space. The fill-in space is created in a call to the factorization function $p?gbtrf$ and is stored in $af$ .  Note that if a linear system is to be solved using $p?gbtrs$ after the factorization function, $af$ must not be altered after the factorization.

`work[0]` On exit, `work[0]` contains the minimum value of `lwork` required for optimum performance.

`info` If `info=0`, the execution is successful.  
`info < 0`:  
 If the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then `info = -(i*100+j)`; if the *i*-th argument is a scalar and had an illegal value, then `info = -i`.

*lwork , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?dbtrs` function solves for *X* one of the systems of equations:

$$\text{sub}(A) * X = \text{sub}(B),$$

$$(\text{sub}(A))^T * X = \text{sub}(B), \text{ or}$$

$$(\text{sub}(A))^H * X = \text{sub}(B),$$

where `sub(A) = A(1:n, ja:ja+n-1)` is a diagonally dominant-like banded distributed matrix, and `sub(B)` denotes the distributed matrix `B(ib:ib+n-1, 1:nrhs)`.

This function uses the *LU* factorization computed by `p?dbtrf`.

## Input Parameters

`trans` (global) Must be 'N' or 'T' or 'C'.

	Indicates the form of the equations: If $trans = 'N'$ , then $sub(A)*X = sub(B)$ is solved for $X$ . If $trans = 'T'$ , then $(sub(A))^T*X = sub(B)$ is solved for $X$ . If $trans = 'C'$ , then $(sub(A))^H*X = sub(B)$ is solved for $X$ .
$n$	(global) The order of the distributed matrix $sub(A)$ ( $n \geq 0$ ).
$bwl$	(global) The number of subdiagonals within the band of $A$ ( $0 \leq bwl \leq n-1$ ).
$bwu$	(global) The number of superdiagonals within the band of $A$ ( $0 \leq bwu \leq n-1$ ).
$nrhs$	(global) The number of right hand sides; the number of columns of the distributed matrix $sub(B)$ ( $nrhs \geq 0$ ).
$a, b$	(local) Pointers into the local memory to arrays of local sizes $lld\_a*LOCc(ja+n-1)$ and $lld\_b*LOCc(nrhs)$ , respectively. On entry, the array $a$ contains details of the $LU$ factorization of the band matrix $A$ , as computed by <code>p?dbtrf</code> . On entry, the array $b$ contains the local pieces of the right hand side distributed matrix $sub(B)$ .
$ja$	(global) The index in the global matrix $A$ indicating the start of the matrix to be operated on (which may be either all of $A$ or a submatrix of $A$ ).
$desca$	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ . If $dtype\_a = 501$ , then $dlen\_ \geq 7$ ; else if $dtype\_a = 1$ , then $dlen\_ \geq 9$ .
$ib$	(global) The row index in the global matrix $B$ indicating the first row of the matrix to be operated on (which may be either all of $B$ or a submatrix of $B$ ).
$descb$	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $B$ . If $dtype\_b = 502$ , then $dlen\_ \geq 7$ ; else if $dtype\_b = 1$ , then $dlen\_ \geq 9$ .
$af, work$	(local) Arrays of size $laf$ and $lwork$ , respectively The array $af$ contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function <code>p?dbtrf</code> and is stored in $af$ . The array $work$ is a workspace array.
$laf$	(local) The size of the array $af$ . Must be $laf \geq NB * (bwl + bwu) + 6 * (\max(bwl, bwu))^2$ .

If *laf* is not large enough, an error code will be returned and the minimum acceptable size will be returned in *af*[0].

*lwork*

(local or global) The size of the array *work*, must be at least

$$lwork \geq (\max(bwl, bwu))^2.$$

## Output Parameters

*b*

On exit, this array contains the local pieces of the solution distributed matrix *X*.

*work*[0]

On exit, *work*[0] contains the minimum value of *lwork* required for optimum performance.

*info*

If *info*=0, the execution is successful. *info* < 0:

If the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then *info* = -(*i*\*100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

## Description

The p?dttrs function solves for *X* one of the systems of equations:

$$\text{sub}(A) * X = \text{sub}(B),$$

$$(\text{sub}(A))^T * X = \text{sub}(B), \text{ or}$$

$$(\text{sub}(A))^{H*X} = \text{sub}(B),$$

where  $\text{sub}(A) = A(1:n, ja:ja+n-1)$  is a diagonally dominant-like tridiagonal distributed matrix, and  $\text{sub}(B)$  denotes the distributed matrix  $B(ib:ib+n-1, 1:nrhs)$ .

This function uses the *LU* factorization computed by `p?dttrf`.

## Input Parameters

<i>trans</i>	(global) Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $\text{sub}(A)*X = \text{sub}(B)$ is solved for <i>X</i> . If <i>trans</i> = 'T', then $(\text{sub}(A))^T*X = \text{sub}(B)$ is solved for <i>X</i> . If <i>trans</i> = 'C', then $(\text{sub}(A))^{H*X} = \text{sub}(B)$ is solved for <i>X</i> .
<i>n</i>	(global) The order of the distributed matrix $\text{sub}(A)$ ( $n \geq 0$ ).
<i>nrhs</i>	(global) The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ( $nrhs \geq 0$ ).
<i>d1, d, du</i>	(local) Pointers to the local arrays of size <i>nb_a</i> each. On entry, these arrays contain details of the factorization. Globally, <i>d1</i> [0] and <i>du</i> [ <i>n</i> -1] are not referenced; <i>d1</i> and <i>du</i> must be aligned with <i>d</i> .
<i>ja</i>	(global) The index in the global matrix <i>A</i> indicating the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i> ).
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>dtype_a</i> = 501 or <i>dtype_a</i> = 502, then <i>dlen_</i> ≥ 7; else if <i>dtype_a</i> = 1, then <i>dlen_</i> ≥ 9.
<i>b</i>	(local) Same type as <i>d</i> . Pointer into the local memory to an array of local size <i>lld_b</i> * <i>LOCc</i> ( <i>nrhs</i> ) On entry, the array <i>b</i> contains the local pieces of the <i>n</i> -by- <i>nrhs</i> right hand side distributed matrix $\text{sub}(B)$ .
<i>ib</i>	(global) The row index in the global matrix <i>B</i> indicating the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i> ).
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> . If <i>dtype_b</i> = 502, then <i>dlen_</i> ≥ 7; else if <i>dtype_b</i> = 1, then <i>dlen_</i> ≥ 9.
<i>af, work</i>	(local) Arrays of size <i>laf</i> and ( <i>lwork</i> ), respectively.

The array *af* contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function `p?dttrf` and is stored in *af*. If a linear system is to be solved using `p?dttrs` after the factorization function, *af* must not be altered.

The array *work* is a workspace array.

<i>laf</i>	(local) The size of the array <i>af</i> . Must be $laf \geq NB * (bwl + bwu) + 6 * (bwl + bwu) * (bwl + 2 * bwu)$ . If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> [0].
<i>lwork</i>	(local or global) The size of the array <i>work</i> , must be at least $lwork \geq 10 * NPCOL + 4 * nrhs$ .

## Output Parameters

<i>b</i>	On exit, this array contains the local pieces of the solution distributed matrix <i>X</i> .
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -( <i>j</i> *100+ <i>j</i> ); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?potrs` function solves for  $X$  a system of distributed linear equations in the form:

$$\text{sub}(A)*X = \text{sub}(B),$$

where  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$  is an  $n$ -by- $n$  real symmetric or complex Hermitian positive definite distributed matrix, and  $\text{sub}(B)$  denotes the distributed matrix  $B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1)$ .

This function uses Cholesky factorization

$$\text{sub}(A) = U^H*U, \text{ or } \text{sub}(A) = L*L^H$$

computed by `p?potrf`.

## Input Parameters

<code>uplo</code>	(global) Must be 'U' or 'L'. If <code>uplo = 'U'</code> , upper triangle of $\text{sub}(A)$ is stored; If <code>uplo = 'L'</code> , lower triangle of $\text{sub}(A)$ is stored.
<code>n</code>	(global) The order of the distributed matrix $\text{sub}(A)$ ( $n \geq 0$ ).
<code>nrhs</code>	(global) The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ( $nrhs \geq 0$ ).
<code>a, b</code>	(local) Pointers into the local memory to arrays of local sizes <code>lld_a*LOCc(ja+n-1)</code> and <code>lld_b*LOCc(jb+nrhs-1)</code> , respectively. The array <code>a</code> contains the factors $L$ or $U$ from the Cholesky factorization $\text{sub}(A) = L*L^H$ or $\text{sub}(A) = U^H*U$ , as computed by <code>p?potrf</code> . On entry, the array <code>b</code> contains the local pieces of the right hand sides $\text{sub}(B)$ .
<code>ia, ja</code>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix $\text{sub}(A)$ , respectively.
<code>desca</code>	(global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix $A$ .
<code>ib, jb</code>	(global) The row and column indices in the global matrix $B$ indicating the first row and the first column of the matrix $\text{sub}(B)$ , respectively.
<code>descb</code>	(local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix $B$ .

## Output Parameters

<code>b</code>	Overwritten by the local pieces of the solution matrix $X$ .
<code>info</code>	If <code>info=0</code> , the execution is successful.  <code>info &lt; 0</code> : if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then <code>info = -(i*100+j)</code> ; if the $i$ -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

## Description

The p?pttrs function solves for  $X$  a system of distributed linear equations in the form:

$$\text{sub}(A)*X = \text{sub}(B) ,$$

where  $\text{sub}(A) = A(1:n, ja:ja+n-1)$  is an  $n$ -by- $n$  real symmetric or complex Hermitian positive definite tridiagonal distributed matrix, and  $\text{sub}(B)$  denotes the distributed matrix  $B(ib:ib+n-1, 1:nrhs)$ .

This function uses the factorization

$$\text{sub}(A) = P*L*D*L^H*P^T, \text{ or } \text{sub}(A) = P*U^H*D*U*P^T$$

computed by p?pttrf.

## Input Parameters

*uplo* (global, used in complex flavors only)  
 Must be 'U' or 'L'.  
 If *uplo* = 'U', upper triangle of sub(A) is stored;  
 If *uplo* = 'L', lower triangle of sub(A) is stored.

<i>n</i>	(global) The order of the distributed matrix sub( <i>A</i> ) ( $n \geq 0$ ).
<i>nrhs</i>	(global) The number of right hand sides; the number of columns of the distributed matrix sub( <i>B</i> ) ( $nrhs \geq 0$ ).
<i>d, e</i>	(local) Pointers into the local memory to arrays of size <i>nb_a</i> each. These arrays contain details of the factorization as returned by <code>p?pttrf</code>
<i>ja</i>	(global) The index in the global matrix <i>A</i> indicating the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i> ).
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .  If <i>dtype_a</i> = 501 or <i>dtype_a</i> = 502, then $dlen_{\geq} 7$ ; else if <i>dtype_a</i> = 1, then $dlen_{\geq} 9$ .
<i>b</i>	(local) Same type as <i>d, e</i> . Pointer into the local memory to an array of local size $lld\_b * LOCC(nrhs)$ .  On entry, the array <i>b</i> contains the local pieces of the <i>n</i> -by- <i>nrhs</i> right hand side distributed matrix sub( <i>B</i> ).
<i>ib</i>	(global) The row index in the global matrix <i>B</i> indicating the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i> ).
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .  If <i>dtype_b</i> = 502, then $dlen_{\geq} 7$ ; else if <i>dtype_b</i> = 1, then $dlen_{\geq} 9$ .
<i>af, work</i>	(local) Arrays of size <i>laf</i> and ( <i>lwork</i> ), respectively. The array <i>af</i> contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function <code>p?pttrf</code> and is stored in <i>af</i> .  The array <i>work</i> is a workspace array.
<i>laf</i>	(local) The size of the array <i>af</i> .  Must be $laf \geq nb\_a + 2$ .  If <i>laf</i> is not large enough, an error code is returned and the minimum acceptable size will be returned in <i>af</i> [0].
<i>lwork</i>	(local or global) The size of the array <i>work</i> , must be at least $lwork \geq (10 + 2 * \min(100, nrhs)) * NPCOL + 4 * nrhs$ .

## Output Parameters

<i>b</i>	On exit, this array contains the local pieces of the solution distributed matrix <i>X</i> .
----------	---

`work[0]`) On exit, `work[0]` contains the minimum value of `lwork` required for optimum performance.

`info` If `info=0`, the execution is successful.

`info < 0`:  
if the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then `info = -(i*100+j)`; if the *i*-th argument is a scalar and had an illegal value, then `info = -i`.

## Description

The `p?trtrs` function solves for  $X$  one of the following systems of linear equations:

$$\text{sub}(A) * X = \text{sub}(B),$$

$$(\text{sub}(A))^T * X = \text{sub}(B), \text{ or}$$

$$(\text{sub}(A))^H * X = \text{sub}(B),$$

where  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$  is a triangular distributed matrix of order  $n$ , and  $\text{sub}(B)$  denotes the distributed matrix  $B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1)$ .

A check is made to verify that  $\text{sub}(A)$  is nonsingular.

## Input Parameters

`uplo` (global) Must be 'U' or 'L'.  
Indicates whether  $\text{sub}(A)$  is upper or lower triangular:  
If `uplo = 'U'`, then  $\text{sub}(A)$  is upper triangular.

	If <i>uplo</i> = 'L', then sub( <i>A</i> ) is lower triangular.
<i>trans</i>	(global) Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then sub( <i>A</i> )* <i>X</i> = sub( <i>B</i> ) is solved for <i>X</i> . If <i>trans</i> = 'T', then sub( <i>A</i> ) <sup>T</sup> * <i>X</i> = sub( <i>B</i> ) is solved for <i>X</i> . If <i>trans</i> = 'C', then sub( <i>A</i> ) <sup>H</sup> * <i>X</i> = sub( <i>B</i> ) is solved for <i>X</i> .
<i>diag</i>	(global) Must be 'N' or 'U'. If <i>diag</i> = 'N', then sub( <i>A</i> ) is not a unit triangular matrix. If <i>diag</i> = 'U', then sub( <i>A</i> ) is unit triangular.
<i>n</i>	(global) The order of the distributed matrix sub( <i>A</i> ) ( <i>n</i> ≥0).
<i>nrhs</i>	(global) The number of right-hand sides; i.e., the number of columns of the distributed matrix sub( <i>B</i> ) ( <i>nrhs</i> ≥0).
<i>a, b</i>	(local) Pointers into the local memory to arrays of local sizes <i>lld_a</i> * <i>LOCc</i> ( <i>ja</i> + <i>n</i> -1) and <i>lld_b</i> * <i>LOCc</i> ( <i>jb</i> + <i>nrhs</i> -1), respectively. The array <i>a</i> contains the local pieces of the distributed triangular matrix sub( <i>A</i> ). If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of sub( <i>A</i> ) contains the upper triangular matrix, and the strictly lower triangular part of sub( <i>A</i> ) is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of sub( <i>A</i> ) contains the lower triangular matrix, and the strictly upper triangular part of sub( <i>A</i> ) is not referenced. If <i>diag</i> = 'U', the diagonal elements of sub( <i>A</i> ) are also not referenced and are assumed to be 1. On entry, the array <i>b</i> contains the local pieces of the right hand side distributed matrix sub( <i>B</i> ).
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix sub( <i>A</i> ), respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>ib, jb</i>	(global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the matrix sub( <i>B</i> ), respectively.
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .

## Output Parameters

<i>b</i>	On exit, if <i>info</i> =0, sub( <i>B</i> ) is overwritten by the solution matrix <i>X</i> .
<i>info</i>	If <i>info</i> =0, the execution is successful.

*info* < 0:

if the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then *info* = -(*i*\*100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

*info* > 0:

if *info* = *i*, the *i*-th diagonal element of sub(*A*) is zero, indicating that the submatrix is singular and the solutions *X* have not been computed.

## Estimating the Condition Number: ScaLAPACK Computational Routines

This section describes the ScaLAPACK routines for estimating the condition number of a matrix. The condition number is used for analyzing the errors in the solution of a system of linear equations. Since the condition number may be arbitrarily large when the matrix is nearly singular, the routines actually compute the *reciprocal* condition number.

### p?gecon

*Estimates the reciprocal of the condition number of a general distributed matrix in either the 1-norm or the infinity-norm.*

### Syntax

```
void psgecon (char *norm , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *anorm , float *rcond , float *work , MKL_INT *lwork , MKL_INT *iwork ,
MKL_INT *liwork , MKL_INT *info );
```

```
void pdgecon (char *norm , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , double *anorm , double *rcond , double *work , MKL_INT *lwork , MKL_INT
*iwork , MKL_INT *liwork , MKL_INT *info );
```

```
void pcgecon (char *norm , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *anorm , float *rcond , MKL_Complex8 *work , MKL_INT *lwork ,
float *rwork , MKL_INT *lrwork , MKL_INT *info );
```

```
void pzgecon (char *norm , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *anorm , double *rcond , MKL_Complex16 *work , MKL_INT *lwork ,
double *rwork , MKL_INT *lrwork , MKL_INT *info );
```

### Include Files

- mkl\_scalapack.h

### Description

The p?gecon function estimates the reciprocal of the condition number of a general distributed real/complex matrix sub(*A*) = *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) in either the 1-norm or infinity-norm, using the *LU* factorization computed by p?getrf.

An estimate is obtained for  $||(\text{sub}(A))^{-1}||$ , and the reciprocal of the condition number is computed as

$$rcond = \frac{1}{\|sub(A)\| \times \|(sub(A))^{-1}\|}$$

## Input Parameters

<i>norm</i>	(global) Must be '1' or 'O' or 'I'. Specifies whether the 1-norm condition number or the infinity-norm condition number is required. If <i>norm</i> = '1' or 'O', then the 1-norm is used; If <i>norm</i> = 'I', then the infinity-norm is used.
<i>n</i>	(global) The order of the distributed matrix sub(A) ( $n \geq 0$ ).
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ . The array <i>a</i> contains the local pieces of the factors <i>L</i> and <i>U</i> from the factorization $sub(A) = P * L * U$ ; the unit diagonal elements of <i>L</i> are not stored.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix sub(A), respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>anorm</i>	(global) If <i>norm</i> = '1' or 'O', the 1-norm of the original distributed matrix sub(A); If <i>norm</i> = 'I', the infinity-norm of the original distributed matrix sub(A).
<i>work</i>	(local) The array <i>work</i> of size <i>lwork</i> is a workspace array.
<i>lwork</i>	(local or global) The size of the array <i>work</i> . <b>For real flavors:</b> <i>lwork</i> must be at least $lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb\_a)) + 2 * LOCC(n + \text{mod}(ja-1, nb\_a)) + \max(2, \max(nb\_a * \max(1, \text{ceil}(NPROW-1, NPCOL)), LOCC(n + \text{mod}(ja-1, nb\_a)) + nb\_a * \max(1, \text{ceil}(NPCOL-1, NPROW))))$ . <b>For complex flavors:</b> <i>lwork</i> must be at least $lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb\_a)) + \max(2, \max(nb\_a * \text{ceil}(NPROW-1, NPCOL), LOCC(n + \text{mod}(ja-1, nb\_a)) + nb\_a * \text{ceil}(NPCOL-1, NPROW)))$ .

$LOCr$  and  $LOCc$  values can be computed using the ScaLAPACK tool function `numroc`;  $NPROW$  and  $NPCOL$  can be determined by calling the function `blacs_gridinfo`.

**NOTE**

$\text{iceil}(x, y)$  is the ceiling of  $x/y$ , and  $\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

<i>iwork</i>	(local) Workspace array of size <i>liwork</i> . Used in real flavors only.
<i>liwork</i>	(local or global) The size of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ia-1, mb\_a)).$
<i>rwork</i>	(local) Workspace array of size <i>lrwork</i> . Used in complex flavors only.
<i>lrwork</i>	(local or global) The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq \max(1, 2 * LOCc(n + \text{mod}(ja-1, nb\_a))).$

**Output Parameters**

<i>rcond</i>	(global) The reciprocal of the condition number of the distributed matrix sub(A). See Description.
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lrwork</i> required for optimum performance.
<i>iwork</i> [0]	On exit, <i>iwork</i> [0] contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).
<i>rwork</i> [0]	On exit, <i>rwork</i> [0] contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors).
<i>info</i>	(global) If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -( <i>j</i> *100+ <i>j</i> ); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

double *rwork , MKL_INT *lrwork , MKL_INT *info );
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?pococon` function estimates the reciprocal of the condition number (in the 1 - norm) of a real symmetric or complex Hermitian positive definite distributed matrix  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ , using the Cholesky factorization  $\text{sub}(A) = U^H * U$  or  $\text{sub}(A) = L * L^H$  computed by `p?potrff`.

An estimate is obtained for  $\|(\text{sub}(A))^{-1}\|$ , and the reciprocal of the condition number is computed as

$$rcond = \frac{1}{\|\text{sub}(A)\| \times \|(\text{sub}(A))^{-1}\|}$$

## Input Parameters

<code>uplo</code>	(global) Must be 'U' or 'L'. Specifies whether the factor stored in $\text{sub}(A)$ is upper or lower triangular. If <code>uplo = 'U'</code> , $\text{sub}(A)$ stores the upper triangular factor $U$ of the Cholesky factorization $\text{sub}(A) = U^H * U$ . If <code>uplo = 'L'</code> , $\text{sub}(A)$ stores the lower triangular factor $L$ of the Cholesky factorization $\text{sub}(A) = L * L^H$ .
<code>n</code>	(global) The order of the distributed matrix $\text{sub}(A)$ ( $n \geq 0$ ).
<code>a</code>	(local) Pointer into the local memory to an array of size <code>lld_a * LOCC(ja+n-1)</code> . The array <code>a</code> contains the local pieces of the factors $L$ or $U$ from the Cholesky factorization $\text{sub}(A) = U^H * U$ , or $\text{sub}(A) = L * L^H$ , as computed by <code>p?potrff</code> .
<code>ia, ja</code>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix $\text{sub}(A)$ , respectively.

<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>anorm</i>	(global) The 1-norm of the symmetric/Hermitian distributed matrix sub( <i>A</i> ).
<i>work</i>	(local) The array <i>work</i> of size <i>lwork</i> is a workspace array.
<i>lwork</i>	(local or global) The size of the array <i>work</i> . <i>For real flavors:</i> <i>lwork</i> must be at least $lwork \geq 2*LOCr(n+\text{mod}(ia-1, mb\_a)) + 2*LOCc(n+\text{mod}(ja-1, nb\_a)) + \max(2, \max(nb\_a*\text{ceil}(NPROW-1, NPCOL), LOCc(n+\text{mod}(ja-1, nb\_a)) + nb\_a*\text{ceil}(NPCOL-1, NPROW)))$ <i>For complex flavors:</i> <i>lwork</i> must be at least $lwork \geq 2*LOCr(n+\text{mod}(ia-1, mb\_a)) + \max(2, \max(nb\_a*\max(1, \text{ceil}(NPROW-1, NPCOL)), LOCc(n+\text{mod}(ja-1, nb\_a)) + nb\_a*\max(1, \text{ceil}(NPCOL-1, NPROW))))$ If <i>lwork</i> = -1, then <i>lwork</i> is a global input and a workspace query is assumed. The routine only calculates the minimum and optimal size for all work arrays. Each value is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i> .

**NOTE**

*ceil*(*x*, *y*) is the ceiling of *x*/*y*, and *mod*(*x*, *y*) is the integer remainder of *x*/*y*.

<i>iwork</i>	(local) Workspace array of size <i>liwork</i> . Used in real flavors only.
<i>liwork</i>	(local or global) The size of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n+\text{mod}(ia-1, mb\_a))$ . If <i>liwork</i> = -1, then <i>liwork</i> is a global input and a workspace query is assumed. The routine only calculates the minimum and optimal size for all work arrays. Each value is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i> .
<i>rwork</i>	(local) Workspace array of size <i>lrwork</i> . Used in complex flavors only.
<i>lrwork</i>	(local or global) The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq 2*LOCc(n+\text{mod}(ja-1, nb\_a))$ . If <i>lrwork</i> = -1, then <i>lrwork</i> is a global input and a workspace query is assumed. The routine only calculates the minimum and optimal size for all work arrays. Each value is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i> .

## Output Parameters

<code>rcond</code>	(global) The reciprocal of the condition number of the distributed matrix sub(A).
<code>work[0]</code>	On exit, <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>iwork[0]</code>	On exit, <code>iwork[0]</code> contains the minimum value of <code>liwork</code> required for optimum performance (for real flavors).
<code>rwork[0]</code>	On exit, <code>rwork[0]</code> contains the minimum value of <code>lrwork</code> required for optimum performance (for complex flavors).
<code>info</code>	(global) If <code>info=0</code> , the execution is successful.  <code>info &lt; 0</code> :  If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <code>info = -(j*100+j)</code> ; if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

MKL_INT *lwork , double *rwork , MKL_INT *lrwork , MKL_INT *info );
```

### Include Files

- `mkl_scalapack.h`

### Description

The `p?trcon` function estimates the reciprocal of the condition number of a triangular distributed matrix  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ , in either the 1-norm or the infinity-norm.

The norm of  $\text{sub}(A)$  is computed and an estimate is obtained for  $\|(\text{sub}(A))^{-1}\|$ , then the reciprocal of the condition number is computed as

$$rcond = \frac{1}{\|sub(A)\| \times \|(sub(A))^{-1}\|}$$

## Input Parameters

<i>norm</i>	(global) Must be '1' or 'O' or 'I'. Specifies whether the 1-norm condition number or the infinity-norm condition number is required. If <i>norm</i> = '1' or 'O', then the 1-norm is used; If <i>norm</i> = 'I', then the infinity-norm is used.
<i>uplo</i>	(global) Must be 'U' or 'L'. If <i>uplo</i> = 'U', sub(A) is upper triangular. If <i>uplo</i> = 'L', sub(A) is lower triangular.
<i>diag</i>	(global) Must be 'N' or 'U'. If <i>diag</i> = 'N', sub(A) is non-unit triangular. If <i>diag</i> = 'U', sub(A) is unit triangular.
<i>n</i>	(global) The order of the distributed matrix sub(A), ( $n \geq 0$ ).
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ . The array <i>a</i> contains the local pieces of the triangular distributed matrix sub(A). If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of this distributed matrix contains the upper triangular matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of this distributed matrix contains the lower triangular matrix, and its strictly upper triangular part is not referenced. If <i>diag</i> = 'U', the diagonal elements of sub(A) are also not referenced and are assumed to be 1.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix sub(A), respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) The array <i>work</i> of size <i>lwork</i> is a workspace array.
<i>lwork</i>	(local or global) The size of the array <i>work</i> . <i>For real flavors:</i>

*lwork* must be at least

$$lwork \geq 2 * LOCr(n + \text{mod}(ia - 1, mb\_a)) + LOcc(n + \text{mod}(ja - 1, nb\_a)) + \max(2, \max(nb\_a * \max(1, \text{iceil}(\text{NPROW} - 1, \text{NPCOL})), LOcc(n + \text{mod}(ja - 1, nb\_a)) + nb\_a * \max(1, \text{iceil}(\text{NPCOL} - 1, \text{NPROW}))))).$$

**For complex flavors:**

*lwork* must be at least

$$lwork \geq 2 * LOCr(n + \text{mod}(ia - 1, mb\_a)) + \max(2, \max(nb\_a * \text{iceil}(\text{NPROW} - 1, \text{NPCOL}), LOcc(n + \text{mod}(ja - 1, nb\_a)) + nb\_a * \text{iceil}(\text{NPCOL} - 1, \text{NPROW}))).$$

---

#### NOTE

$\text{iceil}(x, y)$  is the ceiling of  $x/y$ , and  $\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

---

<i>iwork</i>	(local) Workspace array of size <i>liwork</i> . Used in real flavors only.
<i>liwork</i>	(local or global) The size of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ia - 1, mb\_a))$ .
<i>rwork</i>	(local) Workspace array of size <i>lrwork</i> . Used in complex flavors only.
<i>lrwork</i>	(local or global) The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq LOcc(n + \text{mod}(ja - 1, nb\_a))$ .

## Output Parameters

<i>rcond</i>	(global) The reciprocal of the condition number of the distributed matrix sub(A).
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> [0]	On exit, <i>iwork</i> [0] contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).
<i>rwork</i> [0]	On exit, <i>rwork</i> [0] contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors).
<i>info</i>	(global) If <i>info</i> =0, the execution is successful. $info < 0$ : If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then $info = -(i * 100 + j)$ ; if the <i>i</i> -th argument is a scalar and had an illegal value, then $info = -i$ .

### Description

The p?gerfs function improves the computed solution to one of the systems of linear equations

$$\text{sub}(A) * \text{sub}(X) = \text{sub}(B),$$

$$\text{sub}(A)^T * \text{sub}(X) = \text{sub}(B), \text{ or}$$

$\text{sub}(A)^H * \text{sub}(X) = \text{sub}(B)$  and provides error bounds and backward error estimates for the solution.

Here  $\text{sub}(A) = A(\text{ia}:\text{ia}+\text{n}-1, \text{ja}:\text{ja}+\text{n}-1)$ ,  $\text{sub}(B) = B(\text{ib}:\text{ib}+\text{n}-1, \text{jb}:\text{jb}+\text{nrhs}-1)$ , and  $\text{sub}(X) = X(\text{ix}:\text{ix}+\text{n}-1, \text{jx}:\text{jx}+\text{nrhs}-1)$ .

## Input Parameters

<i>trans</i>	(global) Must be 'N' or 'T' or 'C'. Specifies the form of the system of equations: If <i>trans</i> = 'N', the system has the form $\text{sub}(A) * \text{sub}(X) = \text{sub}(B)$ (No transpose); If <i>trans</i> = 'T', the system has the form $\text{sub}(A)^T * \text{sub}(X) = \text{sub}(B)$ (Transpose); If <i>trans</i> = 'C', the system has the form $\text{sub}(A)^H * \text{sub}(X) = \text{sub}(B)$ (Conjugate transpose).
<i>n</i>	(global) The order of the distributed matrix $\text{sub}(A)$ ( $n \geq 0$ ).
<i>nrhs</i>	(global) The number of right-hand sides, i.e., the number of columns of the matrices $\text{sub}(B)$ and $\text{sub}(X)$ ( $nrhs \geq 0$ ).
<i>a, af, b, x</i>	(local) Pointers into the local memory to arrays of local sizes <i>a</i> : $lld\_a * LOCC(ja+n-1)$ , <i>af</i> : $lld\_af * LOCC(jaf+n-1)$ , <i>b</i> : $lld\_b * LOCC(jb+nrhs-1)$ , <i>x</i> : $lld\_x * LOCC(jx+nrhs-1)$ . The array <i>a</i> contains the local pieces of the distributed matrix $\text{sub}(A)$ . The array <i>af</i> contains the local pieces of the distributed factors of the matrix $\text{sub}(A) = P * L * U$ as computed by <a href="#">p?getrf</a> . The array <i>b</i> contains the local pieces of the distributed matrix of right hand sides $\text{sub}(B)$ . On entry, the array <i>x</i> contains the local pieces of the distributed solution matrix $\text{sub}(X)$ .
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>iaf, jaf</i>	(global) The row and column indices in the global matrix <i>AF</i> indicating the first row and the first column of the matrix $\text{sub}(AF)$ , respectively.
<i>descaf</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>AF</i> .
<i>ib, jb</i>	(global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the matrix $\text{sub}(B)$ , respectively.
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .
<i>ix, jx</i>	(global) The row and column indices in the global matrix <i>X</i> indicating the first row and the first column of the matrix $\text{sub}(X)$ , respectively.

<i>descx</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>X</i> .
<i>ipiv</i>	(local) Array of size $LOCr(m\_af) + mb\_af$ . This array contains pivoting information as computed by <code>p?getrf</code> . If $ipiv[i]=j$ , then the local row $i+1$ was swapped with the global row $j$ where $i=0, \dots, LOCr(m\_af) + mb\_af - 1$ . This array is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) The array <i>work</i> of size <i>lwork</i> is a workspace array.
<i>lwork</i>	(local or global) The size of the array <i>work</i> . <i>For real flavors:</i> <i>lwork</i> must be at least $lwork \geq 3 * LOCr(n + \text{mod}(ia-1, mb\_a))$ <i>For complex flavors:</i> <i>lwork</i> must be at least $lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb\_a))$

**NOTE**

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

<i>iwork</i>	(local) Workspace array, size <i>liwork</i> . Used in real flavors only.
<i>liwork</i>	(local or global) The size of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ib-1, mb\_b))$ .
<i>rwork</i>	(local) Workspace array, size <i>lrwork</i> . Used in complex flavors only.
<i>lrwork</i>	(local or global) The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq LOCr(n + \text{mod}(ib-1, mb\_b))$ .

**Output Parameters**

<i>x</i>	On exit, contains the improved solution vectors.
<i>ferr, berr</i>	Arrays of size $LOCc(jb+nrhs-1)$ each. The array <i>ferr</i> contains the estimated forward error bound for each solution vector of $\text{sub}(X)$ . If <i>XTRUE</i> is the true solution corresponding to $\text{sub}(X)$ , <i>ferr</i> is an estimated upper bound for the magnitude of the largest element in $(\text{sub}(X) - XTRUE)$ divided by the magnitude of the largest element in $\text{sub}(X)$ . The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error.

This array is tied to the distributed matrix  $X$ .

The array *berr* contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of  $\text{sub}(A)$  or  $\text{sub}(B)$  that makes  $\text{sub}(X)$  an exact solution). This array is tied to the distributed matrix  $X$ .

<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> [0]	On exit, <i>iwork</i> [0] contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).
<i>rwork</i> [0]	On exit, <i>rwork</i> [0] contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors).
<i>info</i>	(global) If <i>info</i> =0, the execution is successful.  <i>info</i> < 0:  If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -( <i>i</i> *100+ <i>j</i> ); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

## Description

The `p?porfs` function improves the computed solution to the system of linear equations

$$\text{sub}(A) * \text{sub}(X) = \text{sub}(B),$$

where  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$  is a real symmetric or complex Hermitian positive definite distributed matrix and

$$\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1),$$

$$\text{sub}(X) = X(\text{ix}:\text{ix}+n-1, \text{jx}:\text{jx}+nrhs-1)$$

are right-hand side and solution submatrices, respectively. This function also provides error bounds and backward error estimates for the solution.

## Input Parameters

<code>uplo</code>	(global) Must be 'U' or 'L'.  Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored.  If <code>uplo</code> = 'U', $\text{sub}(A)$ is upper triangular. If <code>uplo</code> = 'L', $\text{sub}(A)$ is lower triangular.
<code>n</code>	(global) The order of the distributed matrix $\text{sub}(A)$ ( $n \geq 0$ ).
<code>nrhs</code>	(global) The number of right-hand sides, i.e., the number of columns of the matrices $\text{sub}(B)$ and $\text{sub}(X)$ ( $nrhs \geq 0$ ).
<code>a, af, b, x</code>	(local)  Pointers into the local memory to arrays of local sizes  <code>a</code> : $lld\_a * LOCC(\text{ja}+n-1)$ , <code>af</code> : $lld\_af * LOCC(\text{jaf}+n-1)$ , <code>b</code> : $lld\_b * LOCC(\text{jb}+nrhs-1)$ , <code>x</code> : $lld\_x * LOCC(\text{jx}+nrhs-1)$ .  The array <code>a</code> contains the local pieces of the $n$ -by- $n$ symmetric/Hermitian distributed matrix $\text{sub}(A)$ .  If <code>uplo</code> = 'U', the leading $n$ -by- $n$ upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.  If <code>uplo</code> = 'L', the leading $n$ -by- $n$ lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced.  The array <code>af</code> contains the factors $L$ or $U$ from the Cholesky factorization $\text{sub}(A) = L * L^H$ or $\text{sub}(A) = U^H * U$ , as computed by <code>p?potrf</code> .  On entry, the array <code>b</code> contains the local pieces of the distributed matrix of right hand sides $\text{sub}(B)$ .

---

	On entry, the array $x$ contains the local pieces of the solution vectors $\text{sub}(X)$ .
$ia, ja$	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix $\text{sub}(A)$ , respectively.
$desca$	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
$iaf, jaf$	(global) The row and column indices in the global matrix $AF$ indicating the first row and the first column of the matrix $\text{sub}(AF)$ , respectively.
$descaf$	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $AF$ .
$ib, jb$	(global) The row and column indices in the global matrix $B$ indicating the first row and the first column of the matrix $\text{sub}(B)$ , respectively.
$descb$	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $B$ .
$ix, jx$	(global) The row and column indices in the global matrix $X$ indicating the first row and the first column of the matrix $\text{sub}(X)$ , respectively.
$descx$	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $X$ .
$work$	(local) The array $work$ of size $lwork$ is a workspace array.
$lwork$	(local) The size of the array $work$ . <i>For real flavors:</i> $lwork$ must be at least $lwork \geq 3 * LOCr(n + \text{mod}(ia-1, mb\_a))$ <i>For complex flavors:</i> $lwork$ must be at least $lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb\_a))$
<hr/> <b>NOTE</b> $\text{mod}(x, y)$ is the integer remainder of $x/y$ . <hr/>	
$iwork$	(local) Workspace array of size $liwork$ . Used in real flavors only.
$liwork$	(local or global) The size of the array $iwork$ ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ib-1, mb\_b))$ .
$rwork$	(local) Workspace array of size $lrwork$ . Used in complex flavors only.
$lrwork$	(local or global) The size of the array $rwork$ ; used in complex flavors only. Must be at least $lrwork \geq LOCr(n + \text{mod}(ib-1, mb\_b))$ .

## Output Parameters

<i>x</i>	On exit, contains the improved solution vectors.
<i>ferr, berr</i>	Arrays of size $LOCc(jb+nrhs-1)$ each.  The array <i>ferr</i> contains the estimated forward error bound for each solution vector of sub(X).  If XTRUE is the true solution corresponding to sub(X), <i>ferr</i> is an estimated upper bound for the magnitude of the largest element in (sub(X) - XTRUE) divided by the magnitude of the largest element in sub(X). The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error.  This array is tied to the distributed matrix X.  The array <i>berr</i> contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of sub(A) or sub(B) that makes sub(X) an exact solution). This array is tied to the distributed matrix X.
<i>work[0]</i>	On exit, <i>work[0]</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork[0]</i>	On exit, <i>iwork[0]</i> contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).
<i>rwork[0]</i>	On exit, <i>rwork[0]</i> contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors).
<i>info</i>	(global) If <i>info</i> =0, the execution is successful.  <i>info</i> < 0:  If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -( <i>j</i> *100+ <i>j</i> ); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

## Description

The `p?trdfs` function provides error bounds and backward error estimates for the solution to one of the systems of linear equations

$$\text{sub}(A) * \text{sub}(X) = \text{sub}(B),$$

$$\text{sub}(A)^T * \text{sub}(X) = \text{sub}(B), \text{ or}$$

$$\text{sub}(A)^H * \text{sub}(X) = \text{sub}(B),$$

where  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$  is a triangular matrix,

$\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1)$ , and

$\text{sub}(X) = X(\text{ix}:\text{ix}+n-1, \text{jx}:\text{jx}+nrhs-1)$ .

The solution matrix  $X$  must be computed by `p?trtrs` or some other means before entering this function. The function `p?trdfs` does not do iterative refinement because doing so cannot improve the backward error.

## Input Parameters

<i>uplo</i>	(global) Must be 'U' or 'L'. If <i>uplo</i> = 'U', $\text{sub}(A)$ is upper triangular. If <i>uplo</i> = 'L', $\text{sub}(A)$ is lower triangular.
<i>trans</i>	(global) Must be 'N' or 'T' or 'C'. Specifies the form of the system of equations: If <i>trans</i> = 'N', the system has the form $\text{sub}(A) * \text{sub}(X) = \text{sub}(B)$ (No transpose); If <i>trans</i> = 'T', the system has the form $\text{sub}(A)^T * \text{sub}(X) = \text{sub}(B)$ (Transpose); If <i>trans</i> = 'C', the system has the form $\text{sub}(A)^H * \text{sub}(X) = \text{sub}(B)$ (Conjugate transpose).
<i>diag</i>	Must be 'N' or 'U'. If <i>diag</i> = 'N', then $\text{sub}(A)$ is non-unit triangular. If <i>diag</i> = 'U', then $\text{sub}(A)$ is unit triangular.
<i>n</i>	(global) The order of the distributed matrix $\text{sub}(A)$ ( $n \geq 0$ ).

<i>nrhs</i>	(global) The number of right-hand sides, that is, the number of columns of the matrices $\text{sub}(B)$ and $\text{sub}(X)$ ( $nrhs \geq 0$ ).
<i>a, b, x</i>	<p>(local)</p> <p>Pointers into the local memory to arrays of local sizes</p> <p><i>a</i>: <math>lld\_a * LOCc(ja+n-1)</math>,</p> <p><i>b</i>: <math>lld\_b * LOCc(jb+nrhs-1)</math>,</p> <p><i>x</i>: <math>lld\_x * LOCc(jx+nrhs-1)</math>.</p> <p>The array <i>a</i> contains the local pieces of the original triangular distributed matrix <math>\text{sub}(A)</math>.</p> <p>If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of <math>\text{sub}(A)</math> contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.</p> <p>If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of <math>\text{sub}(A)</math> contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced.</p> <p>If <i>diag</i> = 'U', the diagonal elements of <math>\text{sub}(A)</math> are also not referenced and are assumed to be 1.</p> <p>On entry, the array <i>b</i> contains the local pieces of the distributed matrix of right hand sides <math>\text{sub}(B)</math>.</p> <p>On entry, the array <i>x</i> contains the local pieces of the solution vectors <math>\text{sub}(X)</math>.</p>
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>ib, jb</i>	(global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the matrix $\text{sub}(B)$ , respectively.
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .
<i>ix, jx</i>	(global) The row and column indices in the global matrix <i>X</i> indicating the first row and the first column of the matrix $\text{sub}(X)$ , respectively.
<i>descx</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>X</i> .
<i>work</i>	<p>(local)</p> <p>The array <i>work</i> of size <i>lwork</i> is a workspace array.</p>
<i>lwork</i>	<p>(local) The size of the array <i>work</i>.</p> <p><i>For real flavors:</i></p> <p><i>lwork</i> must be at least <math>lwork \geq 3 * LOCr(n + \text{mod}(ia-1, mb\_a))</math></p> <p><i>For complex flavors:</i></p> <p><i>lwork</i> must be at least</p>

$$lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb\_a))$$

**NOTE**

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

<i>iwork</i>	(local) Workspace array of size <i>iwork</i> . Used in real flavors only.
<i>liwork</i>	(local or global) The size of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ib-1, mb\_b))$ .
<i>rwork</i>	(local) Workspace array of size <i>lrwork</i> . Used in complex flavors only.
<i>lrwork</i>	(local or global) The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq LOCr(n + \text{mod}(ib-1, mb\_b))$ .

**Output Parameters**

<i>ferr, berr</i>	Arrays of size $LOCc(jb + nrhs - 1)$ each.  The array <i>ferr</i> contains the estimated forward error bound for each solution vector of sub(X).  If XTRUE is the true solution corresponding to sub(X), <i>ferr</i> is an estimated upper bound for the magnitude of the largest element in (sub(X) - XTRUE) divided by the magnitude of the largest element in sub(X). The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error.  This array is tied to the distributed matrix X.  The array <i>berr</i> contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of sub(A) or sub(B) that makes sub(X) an exact solution). This array is tied to the distributed matrix X.
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> [0]	On exit, <i>iwork</i> [0] contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).
<i>rwork</i> [0]	On exit, <i>rwork</i> [0] contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors).
<i>info</i>	(global) If <i>info</i> =0, the execution is successful.  <i>info</i> < 0:  If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -( <i>i</i> *100+ <i>j</i> ); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

## Matrix Inversion: ScaLAPACK Computational Routines

This sections describes ScaLAPACK routines that compute the inverse of a matrix based on the previously obtained factorization. Note that it is not recommended to solve a system of equations  $Ax = b$  by first computing  $A^{-1}$  and then forming the matrix-vector product  $x = A^{-1}b$ . Call a solver routine instead (see [Solving Systems of Linear Equations](#)); this is more efficient and more accurate.

### p?getri

Computes the inverse of a LU-factored distributed matrix.

### Syntax

```
void psgetri (MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
MKL_INT *ipiv , float *work , MKL_INT *lwork , MKL_INT *iwork , MKL_INT *liwork ,
MKL_INT *info );

void pdgetri (MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
MKL_INT *ipiv , double *work , MKL_INT *lwork , MKL_INT *iwork , MKL_INT *liwork ,
MKL_INT *info );

void pcgetri (MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *ipiv , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *iwork , MKL_INT
*liwork , MKL_INT *info );

void pzgetri (MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *ipiv , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *iwork ,
MKL_INT *liwork , MKL_INT *info );
```

### Include Files

- mkl\_scalapack.h

### Description

The p?getri function computes the inverse of a general distributed matrix  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$  using the LU factorization computed by p?getrf. This method inverts  $U$  and then computes the inverse of  $\text{sub}(A)$  by solving the system

$$\text{inv}(\text{sub}(A)) * L = \text{inv}(U)$$

for  $\text{inv}(\text{sub}(A))$ .

### Input Parameters

<i>n</i>	(global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$ ( $n \geq 0$ ).
<i>a</i>	(local) Pointer into the local memory to an array of local size $lld\_a * LOCC(\text{ja}+n-1)$ . On entry, the array <i>a</i> contains the local pieces of the $L$ and $U$ obtained by the factorization $\text{sub}(A) = P * L * U$ computed by p?getrf.
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .

*work* (local)  
The array *work* of size *lwork* is a workspace array.

*lwork* (local) The size of the array *work*. *lwork* must be at least  
 $lwork \geq LOCr(n + \text{mod}(ia-1, mb\_a)) * nb\_a$ .

**NOTE**

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

The array *work* is used to keep at most an entire column block of sub(A).

*iwork* (local) Workspace array used for physically transposing the pivots, size *liwork*.

*liwork* (local or global) The size of the array *iwork*.

The minimal value *liwork* of is determined by the following code:

```
if NPROW == NPCOL then
    liwork = LOCc(n_a + mod(ja-1, nb_a)) + nb_a
else
    liwork = LOCc(n_a + mod(ja-1, nb_a)) +
    max(ceil(ceil(LOCr(m_a)/mb_a)/(lcm/NPROW)), nb_a)
end if
```

where *lcm* is the least common multiple of process rows and columns (NPROW and NPCOL).

**Output Parameters**

*ipiv* (local)  
Array of size  $LOCr(m\_a) + mb\_a$ .  
This array contains the pivoting information.  
If  $ipiv[i]=j$ , then the local row  $i+1$  was swapped with the global row  $j$  where  $i=0, \dots, LOCr(m\_a) + mb\_a - 1$ .  
This array is tied to the distributed matrix *A*.

*work*[0] On exit, *work*[0] contains the minimum value of *lwork* required for optimum performance.

*iwork*[0] On exit, *iwork*[0] contains the minimum value of *liwork* required for optimum performance.

*info* (global) If *info*=0, the execution is successful.  
*info* < 0:  
If the *i*-th argument is an array and the *j*-th entry, indexed  $j - 1$ , had an illegal value, then  $info = -(j*100+j)$ ; if the *i*-th argument is a scalar and had an illegal value, then  $info = -i$ .  
*info* > 0:

If  $info = i$ , the matrix element  $U(i,i)$  is exactly zero. The factorization has been completed, but the factor  $U$  is exactly singular, and division by zero will occur if it is used to solve a system of equations.

## p?potri

*Computes the inverse of a symmetric/Hermitian positive definite distributed matrix.*

## Syntax

```
void pspotri (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
void pdpotri (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
void pcpotri (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
void pzpotri (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

## Include Files

- mkl\_scalapack.h

## Description

The p?potri function computes the inverse of a real symmetric or complex Hermitian positive definite distributed matrix  $sub(A) = A(ia:ia+n-1, ja:ja+n-1)$  using the Cholesky factorization  $sub(A) = U^H * U$  or  $sub(A) = L * L^H$  computed by p?potrf.

## Input Parameters

<i>uplo</i>	(global) Must be 'U' or 'L'.  Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $sub(A)$ is stored.  If <i>uplo</i> = 'U', upper triangle of $sub(A)$ is stored. If <i>uplo</i> = 'L', lower triangle of $sub(A)$ is stored.
<i>n</i>	(global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $sub(A)$ ( $n \geq 0$ ).
<i>a</i>	(local)  Pointer into the local memory to an array of local size $lld\_a * LOCC(ja+n-1)$ .  On entry, the array <i>a</i> contains the local pieces of the triangular factor $U$ or $L$ from the Cholesky factorization $sub(A) = U^H * U$ , or $sub(A) = L * L^H$ , as computed by p?potrf.
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix $sub(A)$ , respectively.

*desca* (global and local) array of size *dlen\_*. The array descriptor for the distributed matrix *A*.

## Output Parameters

*a* On exit, overwritten by the local pieces of the upper or lower triangle of the (symmetric/Hermitian) inverse of sub(*A*).

*info* (global) If *info*=0, the execution is successful.

*info* < 0:

If the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then *info* = -(*j*\*100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

*info* > 0:

If *info* = *i*, the element (*i*, *i*) of the factor *U* or *L* is zero, and the inverse could not be computed.

## p?trtri

*Computes the inverse of a triangular distributed matrix.*

## Syntax

```
void pstrtri (char *uplo , char *diag , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pdtrtri (char *uplo , char *diag , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pctrtri (char *uplo , char *diag , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pztrtri (char *uplo , char *diag , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

## Include Files

- mkl\_scalapack.h

## Description

The p?trtrifunction computes the inverse of a real or complex upper or lower triangular distributed matrix sub(*A*) = *A*(*ia:ia+n-1*, *ja:ja+n-1*).

## Input Parameters

*uplo* (global) Must be 'U' or 'L'.

Specifies whether the distributed matrix sub(*A*) is upper or lower triangular.

If *uplo* = 'U', sub(*A*) is upper triangular.

If *uplo* = 'L', sub(*A*) is lower triangular.

<i>diag</i>	<p>Must be 'N' or 'U'.</p> <p>Specifies whether or not the distributed matrix sub(A) is unit triangular.</p> <p>If <i>diag</i> = 'N', then sub(A) is non-unit triangular.</p> <p>If <i>diag</i> = 'U', then sub(A) is unit triangular.</p>
<i>n</i>	(global) The number of rows and columns to be operated on, that is, the order of the distributed matrix sub(A) ( $n \geq 0$ ).
<i>a</i>	<p>(local)</p> <p>Pointer into the local memory to an array of local size <math>lld\_a * LOCC(j\_a + n - 1)</math>.</p> <p>The array <i>a</i> contains the local pieces of the triangular distributed matrix sub(A).</p> <p>If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of sub(A) contains the upper triangular matrix to be inverted, and the strictly lower triangular part of sub(A) is not referenced.</p> <p>If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of sub(A) contains the lower triangular matrix, and the strictly upper triangular part of sub(A) is not referenced.</p>
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix sub(A), respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .

## Output Parameters

<i>a</i>	On exit, overwritten by the (triangular) inverse of the original matrix.
<i>info</i>	<p>(global) If <i>info</i>=0, the execution is successful.</p> <p><i>info</i> &lt; 0:</p> <p>If the <i>i</i>-th argument is an array and the <i>j</i>-th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i>*100+<i>j</i>); if the <i>i</i>-th argument is a scalar and had an illegal value, then <i>info</i> = -<i>i</i>.</p> <p><i>info</i> &gt; 0:</p> <p>If <i>info</i> = <i>k</i>, the matrix element <math>A(ia+k-1, ja+k-1)</math> is exactly zero. The triangular matrix sub(A) is singular and its inverse cannot be computed.</p>

## Matrix Equilibration: ScaLAPACK Computational Routines

ScaLAPACK routines described in this section are used to compute scaling factors needed to equilibrate a matrix. Note that these routines do not actually scale the matrices.

### **p?geequ**

*Computes row and column scaling factors intended to equilibrate a general rectangular distributed matrix and reduce its condition number.*

## Syntax

```
void psgeequ (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *r , float *c , float *rowcnd , float *colcnd , float *amax , MKL_INT
*info );
```

```
void pdgeequ (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , double *r , double *c , double *rowcnd , double *colcnd , double *amax ,
MKL_INT *info );
```

```
void pcgeequ (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *r , float *c , float *rowcnd , float *colcnd , float *amax ,
MKL_INT *info );
```

```
void pzgeequ (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *r , double *c , double *rowcnd , double *colcnd , double
*amax , MKL_INT *info );
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?geequ` function computes row and column scalings intended to equilibrate an  $m$ -by- $n$  distributed matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$  and reduce its condition number. The output array  $r$  returns the row scale factors  $r_i$ , and the array  $c$  returns the column scale factors  $c_j$ . These factors are chosen to try to make the largest element in each row and column of the matrix  $B$  with elements  $b_{ij}=r_i*a_{ij}*c_j$  have absolute value 1.

$r_i$  and  $c_j$  are restricted to be between  $SMLNUM$  = smallest safe number and  $BIGNUM$  = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of  $\text{sub}(A)$  but works well in practice.

$SMLNUM$  and  $BIGNUM$  are parameters representing machine precision. You can use the `?lamch` routines to compute them. For example, compute single precision values of  $SMLNUM$  and  $BIGNUM$  as follows:

```
SMLNUM = slamch ('s')
BIGNUM = 1 / SMLNUM
```

The auxiliary function `p?laqge` uses scaling factors computed by `p?geequ` to scale a general rectangular matrix.

## Input Parameters

$m$	(global) The number of rows to be operated on, that is, the number of rows of the distributed matrix $\text{sub}(A)$ ( $m \geq 0$ ).
$n$	(global) The number of columns to be operated on, that is, the number of columns of the distributed matrix $\text{sub}(A)$ ( $n \geq 0$ ).
$a$	(local) Pointer into the local memory to an array of local size $lld_a*LOCc(ja+n-1)$ . The array $a$ contains the local pieces of the $m$ -by- $n$ distributed matrix whose equilibration factors are to be computed.
$ia, ja$	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix $\text{sub}(A)$ , respectively.

*desca* (global and local) array of size *dlen\_*. The array descriptor for the distributed matrix *A*.

## Output Parameters

*r, c* (local)  
 Arrays of sizes  $LOCr(m_a)$  and  $LOCc(n_a)$ , respectively.  
 If *info* = 0, or *info* > *ia*+*m*-1, *r*[*i*] contain the row scale factors for sub(*A*) for  $ia-1 \leq i < ia+m-1$ . *r* is aligned with the distributed matrix *A*, and replicated across every process column. *r* is tied to the distributed matrix *A*.  
 If *info* = 0, *c*[*i*] contain the column scale factors for sub(*A*) for  $ja-1 \leq i < ja+n-1$ . *c* is aligned with the distributed matrix *A*, and replicated down every process row. *c* is tied to the distributed matrix *A*.

*rowcnd, colcnd* (global)  
 If *info* = 0 or *info* > *ia*+*m*-1, *rowcnd* contains the ratio of the smallest *r<sub>i</sub>* to the largest *r<sub>i</sub>* ( $ia \leq i \leq ia+m-1$ ). If *rowcnd* ≥ 0.1 and *amax* is neither too large nor too small, it is not worth scaling by *r<sub>i</sub>*.  
 If *info* = 0, *colcnd* contains the ratio of the smallest *c<sub>j</sub>* to the largest *c<sub>j</sub>* ( $ja \leq j \leq ja+n-1$ ).  
 If *colcnd* ≥ 0.1, it is not worth scaling by *c<sub>j</sub>*.

*amax* (global)  
 Absolute value of the largest matrix element. If *amax* is very close to overflow or very close to underflow, the matrix should be scaled.

*info* (global) If *info*=0, the execution is successful.  
*info* < 0:  
 If the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then *info* = -(*i*\*100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.  
*info* > 0:  
 If *info* = *i* and  
 $i \leq m$ , the *i*-th row of the distributed matrix sub(*A*) is exactly zero;  
 $i > m$ , the (*i* - *m*)-th column of the distributed matrix sub(*A*) is exactly zero.

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## [p?poequ](#)

*Computes row and column scaling factors intended to equilibrate a symmetric (Hermitian) positive definite distributed matrix and reduce its condition number.*

## Syntax

```
void pspoequ (MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *sr , float *sc , float *scond , float *amax , MKL_INT *info );
```

```
void pdpoequ (MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *sr , double *sc , double *scond , double *amax , MKL_INT *info );
```

```
void pcpcpoequ (MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *sr , float *sc , float *scond , float *amax , MKL_INT *info );
```

```
void pzpoequ (MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *sr , double *sc , double *scond , double *amax , MKL_INT *info );
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?poequ` function computes row and column scalings intended to equilibrate a real symmetric or complex Hermitian positive definite distributed matrix  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$  and reduce its condition number (with respect to the two-norm). The output arrays `sr` and `sc` return the row and column scale factors

$$s(i) = \frac{1}{\sqrt{a_{i,i}}}$$

These factors are chosen so that the scaled distributed matrix  $B$  with elements  $b_{ij}=s(i)*a_{ij}*s(j)$  has ones on the diagonal.

This choice of `sr` and `sc` puts the condition number of  $B$  within a factor  $n$  of the smallest possible condition number over all possible diagonal scalings.

The auxiliary function `p?laqsy` uses scaling factors computed by `p?geequ` to scale a general rectangular matrix.

## Input Parameters

<code>n</code>	(global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$ ( $n \geq 0$ ).
<code>a</code>	(local) Pointer into the local memory to an array of local size <code>ld_a*LOCc(ja+n-1)</code> . The array <code>a</code> contains the $n$ -by- $n$ symmetric/Hermitian positive definite distributed matrix $\text{sub}(A)$ whose scaling factors are to be computed. Only the diagonal elements of $\text{sub}(A)$ are referenced.
<code>ia, ja</code>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix $\text{sub}(A)$ , respectively.
<code>desca</code>	(global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix $A$ .

## Output Parameters

<code>sr, sc</code>	(local)
---------------------	---------

Arrays of sizes  $LOCr(m\_a)$  and  $LOCc(n\_a)$ , respectively.

If  $info = 0$ , the array  $sr(ia:ia+n-1)$  contains the row scale factors for  $sub(A)$ .  $sr$  is aligned with the distributed matrix  $A$ , and replicated across every process column.  $sr$  is tied to the distributed matrix  $A$ .

If  $info = 0$ , the array  $sc(ja:ja+n-1)$  contains the column scale factors for  $sub(A)$ .  $sc$  is aligned with the distributed matrix  $A$ , and replicated down every process row.  $sc$  is tied to the distributed matrix  $A$ .

*scond*

(global)

If  $info = 0$ , *scond* contains the ratio of the smallest  $sr[i]$  ( or  $sc[j]$ ) to the largest  $sr[i]$  ( or  $sc[j]$ ), with

$ia-1 \leq i < ia+n-1$  and  $ja-1 \leq j < ja+n-1$ .

If  $scond \geq 0.1$  and *amax* is neither too large nor too small, it is not worth scaling by  $sr$  ( or  $sc$ ).

*amax*

(global)

Absolute value of the largest matrix element. If *amax* is very close to overflow or very close to underflow, the matrix should be scaled.

*info*

(global)

If  $info=0$ , the execution is successful.

$info < 0$ :

If the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j - 1$ , had an illegal value, then  $info = -(i*100+j)$ ; if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

$info > 0$ :

If  $info = k$ , the  $k$ -th diagonal entry of  $sub(A)$  is nonpositive.

## Orthogonal Factorizations: ScaLAPACK Computational Routines

This section describes the ScaLAPACK routines for the  $QR(RQ)$  and  $LQ(QL)$  factorization of matrices. Routines for the  $RZ$  factorization as well as for generalized  $QR$  and  $RQ$  factorizations are also included. For the mathematical definition of the factorizations, see the respective LAPACK sections or refer to [SLUG].

Table "Computational Routines for Orthogonal Factorizations" lists ScaLAPACK routines that perform orthogonal factorization of matrices.

### Computational Routines for Orthogonal Factorizations

Matrix type, factorization	Factorize without pivoting	Factorize with pivoting	Generate matrix Q	Apply matrix Q

### [p?geqrf](#)

Computes the QR factorization of a general  $m$ -by- $n$  matrix.

#### Syntax

```
void psgeqrf (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdgeqrf (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
void pcgeqrf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *info );
void pzgeqrf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

#### Include Files

- `mkl_scalapack.h`

#### Description

The `p?geqrf` function forms the QR factorization of a general  $m$ -by- $n$  distributed matrix  $\text{sub}(A) = A(\text{ia}:\text{ia} + m - 1, \text{ja}:\text{ja} + n - 1)$  as

$A = Q * R$ .

#### Input Parameters

$m$  (global) The number of rows in the distributed matrix  $\text{sub}(A)$ ; ( $m \geq 0$ ).

<i>n</i>	(global) The number of columns in the distributed matrix sub( <i>A</i> ); ( $n \geq 0$ ).
<i>a</i>	(local) Pointer into the local memory to an array of local size $lld\_a * LOCC(ja+n-1)$ . Contains the local pieces of the distributed matrix sub( <i>A</i> ) to be factored.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i>
<i>work</i>	(local). Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least $lwork \geq nb\_a * (mp0+nq0+nb\_a)$ , where $iroff = \text{mod}(ia-1, mb\_a), \quad icoff = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$ $mp0 = \text{numroc}(m+iroff, mb\_a, MYROW, iarow, NPROW),$ $nq0 = \text{numroc}(n+icoff, nb\_a, MYCOL, iacol, NPCOL),$ <b>and</b> <i>numroc</i> , <i>indxg2p</i> are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function <code>blacs_gridinfo</code> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> .

## Output Parameters

<i>a</i>	The elements on and above the diagonal of sub( <i>A</i> ) contain the $\min(m,n)$ -by- <i>n</i> upper trapezoidal matrix <i>R</i> ( <i>R</i> is upper triangular if $m \geq n$ ); the elements below the diagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors (see <i>Application Notes</i> below).
<i>tau</i>	(local) Array of size $LOCC(ja+\min(m, n)-1)$ . Contains the scalar factor of elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) = 0, the execution is successful.

$< 0$ , if the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j - 1$ , had an illegal value, then  $info = -(i*100+j)$ ; if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

## Application Notes

The matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(ja)*H(ja+1)*...*H(ja+k-1),$$

where  $k = \min(m,n)$ .

Each  $H(i)$  has the form

$$H(i) = I - \tau*v*v'$$

where  $\tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(1:i-1) = 0$  and  $v(i) = 1$ ;  $v(i+1:m)$  is stored on exit in  $A(ia+i:ia+m-1, ja+i-1)$ , and  $\tau$  in  $\tau[ja+i-2]$ .

MKL_INT *desca , MKL_INT *ipiv , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT
*lwork , double *rwork , MKL_INT *lrwork , MKL_INT *info );
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?geqpf` function forms the QR factorization with column pivoting of a general  $m$ -by- $n$  distributed matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$  as

$$\text{sub}(A)*P=Q*R.$$

## Input Parameters

$m$	(global) The number of rows in the matrix $\text{sub}(A)$ ( $m \geq 0$ ).
$n$	(global) The number of columns in the matrix $\text{sub}(A)$ ( $n \geq 0$ ).
$a$	(local) Pointer into the local memory to an array of local size $lld\_a*LOCc(ja+n-1)$ .

	Contains the local pieces of the distributed matrix sub( <i>A</i> ) to be factored.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> ( <i>ia:ia+m-1, ja:ja+n-1</i> ), respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local). Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least <b>For real flavors:</b> $lwork \geq \max(3, mp0+nq0) + LOCc (ja+n-1) + nq0$ . <b>For complex flavors:</b> $lwork \geq \max(3, mp0+nq0)$ . Here $iroff = \text{mod}(ia-1, mb\_a)$ , $icoff = \text{mod}(ja-1, nb\_a)$ , $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW)$ , $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL)$ , $mp0 = \text{numroc}(m+iroff, mb\_a, MYROW, iarow, NPROW)$ , $nq0 = \text{numroc}(n+icoff, nb\_a, MYCOL, iacol, NPCOL)$ , $LOCc (ja+n-1) = \text{numroc}(ja+n-1, nb\_a, MYCOL, csrc\_a, NPCOL)$ , and $\text{numroc}$ , $\text{indxg2p}$ are ScaLAPACK tool functions. You can determine MYROW, MYCOL, NPROW and NPCOL by calling the <code>blacs_gridinfo</code> function. If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> .
<i>rwork</i>	(local). Workspace array of size <i>lrwork</i> (complex flavors only).
<i>lrwork</i>	(local or global) size of <i>rwork</i> (complex flavors only). The value of <i>lrwork</i> must be at least $lwork \geq LOCc (ja+n-1) + nq0$ . Here $iroff = \text{mod}(ia-1, mb\_a)$ , $icoff = \text{mod}(ja-1, nb\_a)$ , $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW)$ , $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL)$ , $mp0 = \text{numroc}(m+iroff, mb\_a, MYROW, iarow, NPROW)$ , $nq0 = \text{numroc}(n+icoff, nb\_a, MYCOL, iacol, NPCOL)$ ,

$LOCc(ja+n-1) = \text{numroc}(ja+n-1, nb\_a, MYCOL, csrc\_a, NPCOL)$ , and  $\text{numroc}$ ,  $\text{indxg2p}$  are ScaLAPACK tool functions.

You can determine  $MYROW$ ,  $MYCOL$ ,  $NPROW$  and  $NPCOL$  by calling the `blacs_gridinfo` function.

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

$a$	The elements on and above the diagonal of $\text{sub}(A)$ contain the $\min(m,n)$ -by- $n$ upper trapezoidal matrix $R$ ( $R$ is upper triangular if $m \geq n$ ); the elements below the diagonal, with the array $\tau$ , represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors (see <i>Application Notes</i> below).
$ipiv$	(local) Array of size $LOCc(ja+n-1)$ . $ipiv[i] = k$ , the local $(i+1)$ -th column of $\text{sub}(A)*P$ was the global $k$ -th column of $\text{sub}(A)$ ( $0 \leq i < LOCc(ja+n-1)$ ). $ipiv$ is tied to the distributed matrix $A$ .
$\tau$	(local) Array of size $LOCc(ja+\min(m, n)-1)$ . Contains the scalar factor $\tau$ of elementary reflectors. $\tau$ is tied to the distributed matrix $A$ .
$work[0]$	On exit, $work[0]$ contains the minimum value of $lwork$ required for optimum performance.
$rwork[0]$	On exit, $rwork[0]$ contains the minimum value of $lrwork$ required for optimum performance.
$info$	(global) = 0, the execution is successful. < 0, if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then $info = -(i*100+j)$ ; if the $i$ -th argument is a scalar and had an illegal value, then $info = -i$ .

## Application Notes

The matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(1)*H(2)*...*H(k)$$

where  $k = \min(m,n)$ .

Each  $H(i)$  has the form

$$H = I - \tau*v*v'$$

where  $\tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(1:i-1) = 0$  and  $v(i) = 1$ ;  $v(i+1:m)$  is stored on exit in  $A(ia+i:ia+m-1, ja+i-1)$ .

The matrix  $P$  is represented in  $ipiv$  as follows: if  $ipiv[j] = i$  then the  $(j+1)$ -th column of  $P$  is the  $i$ -th canonical unit vector ( $0 \leq j < LOCC(ja+n-1)$ ).

## p?orgqr

Generates the orthogonal matrix  $Q$  of the QR factorization formed by [p?geqrf](#).

## Syntax

```
void psorgqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdorgqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?orgqr` function generates the whole or part of  $m$ -by- $n$  real distributed matrix  $Q$  denoting  $A(ia:ia+m-1, ja:ja+n-1)$  with orthonormal columns, which is defined as the first  $n$  columns of a product of  $k$  elementary reflectors of order  $m$

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by [p?geqrf](#).

## Input Parameters

$m$	(global) The number of rows in the matrix $sub(Q)$ ( $m \geq 0$ ).
$n$	(global) The number of columns in the matrix $sub(Q)$ ( $m \geq n \geq 0$ ).
$k$	(global) The number of elementary reflectors whose product defines the matrix $Q$ ( $n \geq k \geq 0$ ).
$a$	(local) Pointer into the local memory to an array of local size $lld\_a * LOCC(ja+n-1)$ . The $j$ -th column of the matrix stored in $a$ must contain the vector that defines the elementary reflector $H(j)$ , $ja \leq j \leq ja + k - 1$ , as returned by <a href="#">p?geqrf</a> in the $k$ columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$ .
$ia, ja$	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$ , respectively.
$desca$	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
$tau$	(local) Array of size $LOCC(ja+k-1)$ .

Contains the scalar factor  $\tau[j]$  of elementary reflectors  $H(j+1)$  as returned by `p?geqrf` ( $0 \leq j < LOCC(ja+k-1)$ ).  $\tau$  is tied to the distributed matrix  $A$ .

*work*

(local)

Workspace array of size of *lwork*.

*lwork*

(local or global) size of *work*.

Must be at least  $lwork \geq nb\_a * (nqa0 + mpa0 + nb\_a)$ , where  
 $iroffa = \text{mod}(ia-1, mb\_a)$ ,  $icoffa = \text{mod}(ja-1, nb\_a)$ ,  
 $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW)$ ,  
 $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL)$ ,  
 $mpa0 = \text{numroc}(m+iroffa, mb\_a, MYROW, iarow, NPROW)$ ,  
 $nqa0 = \text{numroc}(n+icoffa, nb\_a, MYCOL, iacol, NPCOL)$ ;

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If  $lwork = -1$ , then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

*a*

Contains the local pieces of the  $m$ -by- $n$  distributed matrix  $Q$ .

*work*[0]

On exit, [0] contains the minimum value of *lwork* required for optimum performance.

*info*

(global)

= 0: the execution is successful.

< 0: if the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j - 1$ , had an illegal value, then  $info = -(i*100+j)$ ; if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

## See Also

## p?ungqr

*Generates the complex unitary matrix  $Q$  of the QR factorization formed by `p?geqrf`.*

## Syntax

```
void pcungqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pzungqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT
*lwork , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

This function generates the whole or part of  $m$ -by- $n$  complex distributed matrix  $Q$  denoting  $A(ia:ia+m-1, ja:ja+n-1)$  with orthonormal columns, which is defined as the first  $n$  columns of a product of  $k$  elementary reflectors of order  $m$

$$Q = H(1)*H(2)*...*H(k)$$

as returned by `p?geqrf`.

## Input Parameters

<i>m</i>	(global) The number of rows in the matrix sub( $Q$ ); ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the matrix sub( $Q$ ) ( $m \geq n \geq 0$ ).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix $Q$ ( $n \geq k \geq 0$ ).
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ . The $j$ -th column of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(j)$ , $ja \leq j \leq ja+k-1$ , as returned by <code>p?geqrf</code> in the $k$ columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$ .
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .
<i>tau</i>	(local) Array of size $LOCC(ja+k-1)$ . Contains the scalar factor $tau[j]$ of elementary reflectors $H(j+1)$ as returned by <code>p?geqrf</code> ( $0 \leq j < LOCC(ja+k-1)$ ). <i>tau</i> is tied to the distributed matrix $A$ .
<i>work</i>	(local) Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least $lwork \geq nb\_a * (nqa0 + mpa0 + nb\_a)$ , where $iroffa = \text{mod}(ia-1, mb\_a)$ , $icoffa = \text{mod}(ja-1, nb\_a)$ , $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW)$ , $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL)$ , $mpa0 = \text{numroc}(m+iroffa, mb\_a, MYROW, iarow, NPROW)$ , $nqa0 = \text{numroc}(n+icoffa, nb\_a, MYCOL, iacol, NPCOL)$

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?erbla`.

## Output Parameters

<code>a</code>	Contains the local pieces of the $m$ -by- $n$ distributed matrix $Q$ .
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then <code>info = -(i*100+j)</code> ; if the $i$ -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

### p?ormqr

*Multiplies a general matrix by the orthogonal matrix  $Q$  of the QR factorization formed by p?geqrf.*

### Syntax

```
void psormqr (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *c , MKL_INT *ic ,
MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork , MKL_INT *info );

void pdormqr (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , double
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT *lwork , MKL_INT *info );
```

### Include Files

- `mkl_scalapack.h`

### Description

The `p?ormqr` function overwrites the general real  $m$ -by- $n$  distributed matrix sub ( $C$ ) =  $C(ic:ic+m-1,jc:jc+n-1)$  with

	<code>side = 'L'</code>	<code>side = 'R'</code>
<code>trans = 'N':</code>	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
<code>trans = 'T':</code>	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where  $Q$  is a real orthogonal distributed matrix defined as the product of  $k$  elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by `p?geqrf`.  $Q$  is of order  $m$  if `side = 'L'` and of order  $n$  if `side = 'R'`.

## Input Parameters

<i>side</i>	(global) ='L': $Q$ or $Q^T$ is applied from the left. ='R': $Q$ or $Q^T$ is applied from the right.
<i>trans</i>	(global) ='N', no transpose, $Q$ is applied. ='T', transpose, $Q^T$ is applied.
<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(C)$ ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(C)$ ( $n \geq 0$ ).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix $Q$ . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$ .
<i>a</i>	(local) Pointer into the local memory to an array of size $\text{lld}_a * \text{LOCc}(j_a + n - 1)$ . The $j$ -th column of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(j)$ , $j_a \leq j \leq j_a + k - 1$ , as returned by <code>p?geqrf</code> in the $k$ columns of its distributed matrix argument $A(i_a:*, j_a:j_a + k - 1)$ . $A(i_a:*, j_a:j_a + k - 1)$ is modified by the function but restored on exit. If <i>side</i> = 'L', $\text{lld}_a \geq \max(1, \text{LOCr}(i_a + m - 1))$ If <i>side</i> = 'R', $\text{lld}_a \geq \max(1, \text{LOCr}(i_a + n - 1))$
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .
<i>tau</i>	(local) Array of size $\text{LOCc}(j_a + k - 1)$ . Contains the scalar factor $\text{tau}[j]$ of elementary reflectors $H(j+1)$ as returned by <code>p?geqrf</code> ( $0 \leq j < \text{LOCc}(j_a + k - 1)$ ). <i>tau</i> is tied to the distributed matrix $A$ .
<i>c</i>	(local) Pointer into the local memory to an array of local size $\text{lld}_c * \text{LOCc}(j_c + n - 1)$ . Contains the local pieces of the distributed matrix $\text{sub}(C)$ to be factored.
<i>ic, jc</i>	(global) The row and column indices in the global matrix $C$ indicating the first row and the first column of the matrix $\text{sub}(C)$ , respectively.
<i>descc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $C$ .
<i>work</i>	(local)

Workspace array of size of *lwork*.

*lwork*

(local or global) size of *work*, must be at least:

if *side* = 'L',

$lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + mpc0) * nb\_a) + nb\_a * nb\_a$

else if *side* = 'R',

$lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + \max(npa0 + \text{numroc}(\text{numroc}(n + icoffc, nb\_a, 0, 0, NPCOL), nb\_a, 0, 0, lcmq), mpc0)) * nb\_a) + nb\_a * nb\_a$

end if

where

$lcmq = lcm / NPCOL$  with  $lcm = ilcm(NPROW, NPCOL)$ ,

$iroffa = \text{mod}(ia - 1, mb\_a)$ ,

$icoffa = \text{mod}(ja - 1, nb\_a)$ ,

$iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW)$ ,

$npa0 = \text{numroc}(n + iroffa, mb\_a, MYROW, iarow, NPROW)$ ,

$iroffc = \text{mod}(ic - 1, mb\_c)$ ,

$icoffc = \text{mod}(jc - 1, nb\_c)$ ,

$icrow = \text{indxg2p}(ic, mb\_c, MYROW, rsrc\_c, NPROW)$ ,

$iccol = \text{indxg2p}(jc, nb\_c, MYCOL, csrc\_c, NPCOL)$ ,

$mpc0 = \text{numroc}(m + iroffc, mb\_c, MYROW, icrow, NPROW)$ ,

$nqc0 = \text{numroc}(n + icoffc, nb\_c, MYCOL, iccol, NPCOL)$ ,

*ilcm*, *indxg2p* and *numroc* are **ScaLAPACK** tool functions; *MYROW*, *MYCOL*, *NPROW* and *NPCOL* can be determined by calling the function

*blacs\_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *p\_xerbla*.

## Output Parameters

*c*

Overwritten by the product  $Q * \text{sub}(C)$ , or  $Q^T * \text{sub}(C)$ , or  $\text{sub}(C) * Q^T$ , or  $\text{sub}(C) * Q$ .

*work*[0]

On exit *work*[0] contains the minimum value of *lwork* required for optimum performance.

*info*

(global)

= 0: the execution is successful.

< 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then *info* =  $-(i * 100 + j)$ ; if the *i*-th argument is a scalar and had an illegal value, then *info* =  $-i$ .

## Description

This function overwrites the general complex  $m$ -by- $n$  distributed matrix sub ( $C$ ) =  $C(ic:ic+m-1,jc:jc+n-1)$  with

	<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$Q*\text{sub}(C)$	$\text{sub}(C)*Q$
<i>trans</i> = 'T':	$Q^H*\text{sub}(C)$	$\text{sub}(C)*Q^H$

where  $Q$  is a complex unitary distributed matrix defined as the product of  $k$  elementary reflectors

$Q = H(1)H(2)\dots H(k)$  as returned by p?geqrf.  $Q$  is of order  $m$  if *side* = 'L' and of order  $n$  if *side* = 'R'.

## Input Parameters

<i>side</i>	(global) ='L': $Q$ or $Q^H$ is applied from the left. ='R': $Q$ or $Q^H$ is applied from the right.
<i>trans</i>	(global) ='N', no transpose, $Q$ is applied. ='C', conjugate transpose, $Q^H$ is applied.
<i>m</i>	(global) The number of rows in the distributed matrix sub( $C$ ) ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the distributed matrix sub( $C$ ) ( $n \geq 0$ ).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix $Q$ . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$ .

<i>a</i>	<p>(local)</p> <p>Pointer into the local memory to an array of size <math>lld\_a * LOCC(ja+k-1)</math>. iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),
ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL,
NPROW and NPCOL can be determined by calling the function
blacs_gridinfo.

```

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by p $\times$ erbla.

## Output Parameters

$c$	Overwritten by the product $Q \cdot \text{sub}(C)$ , or $Q^H \cdot \text{sub}(C)$ , or $\text{sub}(C) \cdot Q^H$ , or $\text{sub}(C) \cdot Q$ .
$work[0]$	On exit $work[0]$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) = 0: the execution is successful. < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then $info = -(i \cdot 100 + j)$ ; if the $i$ -th argument is a scalar and had an illegal value, then $info = -i$ .

## p?gelqf

*Computes the LQ factorization of a general rectangular matrix.*

## Syntax

```

void psgelqf (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );

void pdgelqf (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );

void pcgelqf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT
*info );

void pzgelqf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT
*info );

```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?gelqf` function computes the  $LQ$  factorization of a real/complex distributed  $m$ -by- $n$  matrix  $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1) = L*Q$ .

## Input Parameters

<code>m</code>	(global) The number of rows in the distributed submatrix $\text{sub}(A)$ ( $m \geq 0$ ).
<code>n</code>	(global) The number of columns in the distributed submatrix $\text{sub}(A)$ ( $n \geq 0$ ).
<code>a</code>	(local) Pointer into the local memory to an array of local size $\text{lld}_a * \text{LOCc}(\text{ja}+n-1)$ . Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
<code>ia, ja</code>	(global) The row and column indices in the global array $A$ indicating the first row and the first column of the submatrix $A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$ , respectively.
<code>desca</code>	(global and local) array of size $\text{dlen}_$ . The array descriptor for the distributed matrix $A$ .
<code>work</code>	(local) Workspace array of size of $\text{lwork}$ .
<code>lwork</code>	(local or global) size of $\text{work}$ , must be at least $\text{lwork} \geq \text{mb}_a * (\text{mp0} + \text{nq0} + \text{mb}_a)$ , where $\text{iroff} = \text{mod}(\text{ia}-1, \text{mb}_a),$ $\text{icoff} = \text{mod}(\text{ja}-1, \text{nb}_a),$ $\text{iarow} = \text{indxg2p}(\text{ia}, \text{mb}_a, \text{MYROW}, \text{rsrc}_a, \text{NPROW}),$ $\text{iacol} = \text{indxg2p}(\text{ja}, \text{nb}_a, \text{MYCOL}, \text{csrc}_a, \text{NPCOL}),$ $\text{mp0} = \text{numroc}(\text{m}+\text{iroff}, \text{mb}_a, \text{MYROW}, \text{iarow}, \text{NPROW}),$ $\text{nq0} = \text{numroc}(\text{n}+\text{icoff}, \text{nb}_a, \text{MYCOL}, \text{iacol}, \text{NPCOL})$ $\text{indxg2p}$ and $\text{numroc}$ are ScaLAPACK tool functions; $\text{MYROW}$ , $\text{MYCOL}$ , $\text{NPROW}$ and $\text{NPCOL}$ can be determined by calling the function <code>blacs_gridinfo</code> .

---

### NOTE

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

---

If  $\text{lwork} = -1$ , then  $\text{lwork}$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

<code>a</code>	The elements on and below the diagonal of $\text{sub}(A)$ contain the $m$ -by- $\min(m,n)$ lower trapezoidal matrix $L$ ( $L$ is lower trapezoidal if $m \leq n$ ); the elements above the diagonal, with the array <code>tau</code> , represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors (see <i>Application Notes</i> below).
<code>tau</code>	(local) Array of size $\text{LOCr}(ia+\min(m, n)-1)$ . Contains the scalar factors of elementary reflectors. <code>tau</code> is tied to the distributed matrix $A$ .
<code>work[0]</code>	On exit, <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then <code>info = -(i*100+j)</code> ; if the $i$ -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

## Application Notes

The matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(ia+k-1)*H(ia+k-2)*...*H(ia),$$

where  $k = \min(m, n)$

Each  $H(i)$  has the form

$$H(i) = I - \tau * v * v'$$

where  $\tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(1:i-1) = 0$  and  $v(i) = 1$ ;  $v(i+1:n)$  is stored on exit in  $A(ia+i-1, ja+i:ja+n-1)$ , and  $\tau$  in  $\tau[ia+i-2]$ .

### p?orglq

Generates the real orthogonal matrix  $Q$  of the LQ factorization formed by `p?gelqf`.

## Syntax

```
void psorglq (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdorglq (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?orglq` function generates the whole or part of  $m$ -by- $n$  real distributed matrix  $Q$  denoting  $A(ia:ia+m-1, ja:ja+n-1)$  with orthonormal rows, which is defined as the first  $m$  rows of a product of  $k$  elementary reflectors of order  $n$

$$Q = H(k) * \dots * H(2) * H(1)$$

as returned by `p?gelqf`.

## Input Parameters

<i>m</i>	(global) The number of rows in the matrix sub( $Q$ ); ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the matrix sub( $Q$ ) ( $n \geq m \geq 0$ ).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix $Q$ ( $m \geq k \geq 0$ ).
<i>a</i>	(local) Pointer into the local memory to an array of local size $lld\_a * LOCC(ja+n-1)$ . On entry, the $i$ -th row of the matrix stored in $a$ must contain the vector that defines the elementary reflector $H(i)$ , $ia \leq i \leq ia+k-1$ , as returned by <code>p?gelqf</code> in the $k$ rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$ .
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$ , respectively.
<i>desca</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
<i>work</i>	(local) Workspace array of size of $lwork$ .
<i>lwork</i>	(local or global) size of $work$ , must be at least $lwork \geq mb\_a * (mpa0 + nqa0 + mb\_a)$ , where $iroffa = \text{mod}(ia-1, mb\_a),$ $icoffa = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$ $mpa0 = \text{numroc}(m + iroffa, mb\_a, MYROW, iarow, NPROW),$ $nqa0 = \text{numroc}(n + icoffa, nb\_a, MYCOL, iacol, NPCOL)$

---

### NOTE

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

---

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

$a$	Contains the local pieces of the $m$ -by- $n$ distributed matrix $Q$ to be factored.
$tau$	(local) Array of size $LOCr(ia+k-1)$ . Contains the scalar factors $tau[j]$ of elementary reflectors $H(j+1)$ , $0 \leq j < LOCr(ia+k-1)$ . $tau$ is tied to the distributed matrix $A$ .
$work[0]$	On exit, $work[0]$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) = 0: the execution is successful. < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then $info = -(i*100+j)$ ; if the $i$ -th argument is a scalar and had an illegal value, then $info = -i$ .

## p?unglq

*Generates the unitary matrix  $Q$  of the LQ factorization formed by `p?gelqf`.*

## Syntax

```
void pcunglq (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pzunglq (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT
*lwork , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

This function generates the whole or part of  $m$ -by- $n$  complex distributed matrix  $Q$  denoting  $A(ia:ia+m-1,ja:ja+n-1)$  with orthonormal rows, which is defined as the first  $m$  rows of a product of  $k$  elementary reflectors of order  $n$

$Q = (H(k))^H \dots (H(2))^H (H(1))^H$  as returned by `p?gelqf`.

## Input Parameters

$m$  (global) The number of rows in the matrix sub( $Q$ ) ( $m \geq 0$ ).

<i>n</i>	(global) The number of columns in the matrix $\text{sub}(Q)$ ( $n \geq m \geq 0$ ).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix $Q$ ( $m \geq k \geq 0$ ).
<i>a</i>	(local) Pointer into the local memory to an array of local size $ld\_a * LOCC(ja+n-1)$ . On entry, the $i$ -th row of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(i)$ , $ia \leq i \leq ia+k-1$ , as returned by <code>p?gelqf</code> in the $k$ rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$ .
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .
<i>tau</i>	(local) Array of size $LOCr(ia+k-1)$ . Contains the scalar factors $\tau[j]$ of elementary reflectors $H(j+1)$ , $0 \leq j < LOCr(ia+k-1)$ . <i>tau</i> is tied to the distributed matrix $A$ .
<i>work</i>	(local) Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least $lwork \geq mb\_a * (mpa0 + nqa0 + mb\_a)$ , where $iroffa = \text{mod}(ia-1, mb\_a),$ $icoffa = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$ $mpa0 = \text{numroc}(m + iroffa, mb\_a, MYROW, iarow, NPROW),$ $nqa0 = \text{numroc}(n + icoffa, nb\_a, MYCOL, iacol, NPCOL)$ <code>indxg2p</code> and <code>numroc</code> are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function <code>blacs_gridinfo</code> .

**NOTE**

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

If  $lwork = -1$ , then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

<i>a</i>	Contains the local pieces of the $m$ -by- $n$ distributed matrix $Q$ to be factored.
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) = 0: the execution is successful. < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then $info = -(i*100+j)$ ; if the $i$ -th argument is a scalar and had an illegal value, then $info = -i$ .

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

### p?ormlq

*Multiplies a general matrix by the orthogonal matrix  $Q$  of the LQ factorization formed by p?gelqf.*

## Syntax

```
void psormlq (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *c , MKL_INT *ic ,
MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdormlq (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , double
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT *lwork , MKL_INT *info );
```

## Include Files

- mkl\_scalapack.h

## Description

The p?ormlq function overwrites the general real  $m$ -by- $n$  distributed matrix  $sub(C) = C(ic:ic+m-1,jc:jc+n-1)$  with

	<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$Q*sub(C)$	$sub(C)*Q$
<i>trans</i> = 'T':	$Q^T*sub(C)$	$sub(C)*Q^T$

where  $Q$  is a real orthogonal distributed matrix defined as the product of  $k$  elementary reflectors

$$Q = H(k)...H(2) H(1)$$

as returned by p?gelqf.  $Q$  is of order  $m$  if *side* = 'L' and of order  $n$  if *side* = 'R'.

## Input Parameters

<i>side</i>	(global) = 'L': $Q$ or $Q^T$ is applied from the left. = 'R': $Q$ or $Q^T$ is applied from the right.
<i>trans</i>	(global)

	= 'N', no transpose, $Q$ is applied.
	= 'T', transpose, $Q^T$ is applied.
<i>m</i>	(global) The number of rows in the distributed matrix sub( $C$ ) ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the distributed matrix sub( $C$ ) ( $n \geq 0$ ).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix $Q$ . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$ .
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+m-1)$ , if <i>side</i> = 'L' and $lld\_a * LOCC(ja+n-1)$ , if <i>side</i> = 'R'. The $i$ -th row of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(i)$ , $ia \leq i \leq ia+k-1$ , as returned by <code>p?gelqf</code> in the $k$ rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$ . $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit.
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .
<i>tau</i>	(local) Array of size $LOCC(ja+k-1)$ . Contains the scalar factor $tau[j]$ of elementary reflectors $H(j+1)$ as returned by <code>p?gelqf</code> ( $0 \leq j < LOCC(ja+k-1)$ ). <i>tau</i> is tied to the distributed matrix $A$ .
<i>c</i>	(local) Pointer into the local memory to an array of local size $lld\_c * LOCC(jc+n-1)$ . Contains the local pieces of the distributed matrix sub( $C$ ) to be factored.
<i>ic, jc</i>	(global) The row and column indices in the global matrix $C$ indicating the first row and the first column of the submatrix $C$ , respectively.
<i>descc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $C$ .
<i>work</i>	(local) Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) size of the array <i>work</i> ; must be at least: If <i>side</i> = 'L', $lwork \geq \max((mb\_a * (mb\_a - 1)) / 2, (mpc0 + \max(mqa0) + \text{numroc}(\text{numroc}(m + iroffc, mb\_a, 0, 0, NPROW), mb\_a, 0, 0, lcmp), nqc0)) * mb\_a) + mb\_a * mb\_a$ else if <i>side</i> = 'R',

```

lwork ≥ max((mb_a * (mb_a - 1)) / 2, (mpc0 + nqc0) * mb_a + mb_a * mb_a)
end if

```

where

```

lcmp = lcm/NPROW with lcm = ilcm (NPROW, NPCOL),
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mqa0 = numroc(m+icoffa, nb_a, MYCOL, iacol, NPCOL),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

---

#### NOTE

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

---

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

<code>c</code>	Overwritten by the product $Q \cdot \text{sub}(C)$ , or $Q' \cdot \text{sub}(C)$ , or $\text{sub}(C) \cdot Q'$ , or $\text{sub}(C) \cdot Q$
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then <code>info = -(i*100+j)</code> ; if the $i$ -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

## p?unmlq

Multiplies a general matrix by the unitary matrix  $Q$  of the LQ factorization formed by p?gelqf.

### Syntax

```
void pcunmlq (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau ,
MKL_Complex8 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex8 *work ,
MKL_INT *lwork , MKL_INT *info );
```

```
void pzunmlq (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k ,
MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau ,
MKL_Complex16 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex16 *work ,
MKL_INT *lwork , MKL_INT *info );
```

### Include Files

- mkl\_scalapack.h

### Description

This function overwrites the general complex  $m$ -by- $n$  distributed matrix  $\text{sub}(C) = C(ic:ic+m-1,jc:jc+n-1)$  with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^H * \text{sub}(C)$	$\text{sub}(C) * Q^H$

where  $Q$  is a complex unitary distributed matrix defined as the product of  $k$  elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by p?gelqf.  $Q$  is of order  $m$  if  $side = 'L'$  and of order  $n$  if  $side = 'R'$ .

### Input Parameters

$side$	(global) = $'L'$ : $Q$ or $Q^H$ is applied from the left. = $'R'$ : $Q$ or $Q^H$ is applied from the right.
$trans$	(global) = $'N'$ , no transpose, $Q$ is applied. = $'C'$ , conjugate transpose, $Q^H$ is applied.
$m$	(global) The number of rows in the distributed matrix $\text{sub}(C)$ ( $m \geq 0$ ).
$n$	(global) The number of columns in the distributed matrix $\text{sub}(C)$ ( $n \geq 0$ ).
$k$	(global) The number of elementary reflectors whose product defines the matrix $Q$ . Constraints: If $side = 'L'$ , $m \geq k \geq 0$ If $side = 'R'$ , $n \geq k \geq 0$ .
$a$	(local)

Pointer into the local memory to an array of size  $lld\_a * LOCc(ja+m-1)$ , if  $side = 'L'$  and  $lld\_a * LOCc(ja+n-1)$ , if  $side = 'R'$ , where  $lld\_a \geq \max(1, LOCr(ia+k-1))$ . The  $i$ -th column of the matrix stored in  $a$  must contain the vector that defines the elementary reflector  $H(i)$ ,  $ia \leq i \leq ia+k-1$ , as returned by `p?gelqf` in the  $k$  rows of its distributed matrix argument  $A(ia:ia+k-1, ja:*)$ .  $A(ia:ia+k-1, ja:*)$  is modified by the function but restored on exit.

*ia, ja*

(global) The row and column indices in the global matrix  $A$  indicating the first row and the first column of the submatrix  $A$ , respectively.

*desca*

(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $A$ .

*tau*

(local)

Array of size  $LOCc(ia+k-1)$ .

Contains the scalar factor  $tau[j]$  of elementary reflectors  $H(j+1)$  as returned by `p?gelqf` ( $0 \leq j < LOCc(ia+k-1)$ ).  $tau$  is tied to the distributed matrix  $A$ .

*c*

(local)

Pointer into the local memory to an array of local size  $lld\_c * LOCc(jc+n-1)$ .

Contains the local pieces of the distributed matrix sub( $C$ ) to be factored.

*ic, jc*

(global) The row and column indices in the global matrix  $C$  indicating the first row and the first column of the submatrix  $C$ , respectively.

*descc*

(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $C$ .

*work*

(local)

Workspace array of size of  $lwork$ .

*lwork*

(local or global) size of the array  $work$ ; must be at least:

If  $side = 'L'$ ,

$$lwork \geq \max((mb\_a * (mb\_a - 1)) / 2, (mpc0 + maxmqa0) + \text{numroc}(\text{numroc}(m + iroffc, mb\_a, 0, 0, NPROW), mb\_a, 0, 0, lcm), nqc0) * mb\_a) + mb\_a * mb\_a$$

else if  $side = 'R'$ ,

$$lwork \geq \max((mb\_a * (mb\_a - 1)) / 2, (mpc0 + nqc0) * mb\_a + mb\_a * mb\_a)$$

end if

where

$$lcmp = lcm / NPROW \text{ with } lcm = ilcm(NPROW, NPCOL),$$

$$iroffa = \text{mod}(ia - 1, mb\_a),$$

$$icoffa = \text{mod}(ja - 1, nb\_a),$$

$$iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$$

$$mqa0 = \text{numroc}(m + icoffa, nb\_a, MYCOL, iacol, NPCOL),$$

$$iroffc = \text{mod}(ic - 1, mb\_c),$$

```

icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+icoffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

**NOTE**

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

**Output Parameters**

<code>c</code>	Overwritten by the product $Q \cdot \text{sub}(C)$ , or $Q' \cdot \text{sub}(C)$ , or $\text{sub}(C) \cdot Q'$ , or $\text{sub}(C) \cdot Q$
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then <code>info</code> = $-(i \cdot 100 + j)$ ; if the $i$ -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$ .

## Description

The `p?geqlf` function forms the  $QL$  factorization of a real/complex distributed  $m$ -by- $n$  matrix  $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1) = Q * L$ .

## Input Parameters

<code>m</code>	(global) The number of rows in the matrix $\text{sub}(Q)$ ; ( $m \geq 0$ ).
<code>n</code>	(global) The number of columns in the matrix $\text{sub}(Q)$ ( $n \geq 0$ ).
<code>a</code>	(local) Pointer into the local memory to an array of local size $lld\_a * LOCC(\text{ja}+n-1)$ . Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
<code>ia, ja</code>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$ , respectively.
<code>desca</code>	(global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix $A$ .
<code>work</code>	(local) Workspace array of size of <code>lwork</code> .
<code>lwork</code>	(local or global) size of <code>work</code> , must be at least $lwork \geq nb\_a * (mp0 + nq0 + nb\_a)$ , where $iroff = \text{mod}(\text{ia}-1, mb\_a),$ $icoff = \text{mod}(\text{ja}-1, nb\_a),$ $iarow = \text{indxg2p}(\text{ia}, mb\_a, \text{MYROW}, rsrc\_a, \text{NPROW}),$ $iacol = \text{indxg2p}(\text{ja}, nb\_a, \text{MYCOL}, csrc\_a, \text{NPCOL}),$ $mp0 = \text{numroc}(m+iroff, mb\_a, \text{MYROW}, iarow, \text{NPROW}),$ $nq0 = \text{numroc}(n+icoff, nb\_a, \text{MYCOL}, iacol, \text{NPCOL})$

---

### NOTE

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

---

`numroc` and `indxg2p` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

<code>a</code>	On exit, if $m \geq n$ , the lower triangle of the distributed submatrix $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the $n$ -by- $n$ lower triangular matrix $L$ ; if $m \leq n$ , the elements on and below the $(n - m)$ -th superdiagonal contain the $m$ -by- $n$ lower trapezoidal matrix $L$ ; the remaining elements, with the array $\tau$ , represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors (see <i>Application Notes</i> below).
<code>tau</code>	(local) Array of size $LOCc(ja+n-1)$ . Contains the scalar factors of elementary reflectors. $\tau$ is tied to the distributed matrix $A$ .
<code>work[0]</code>	On exit, <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then $info = -(i*100+j)$ ; if the $i$ -th argument is a scalar and had an illegal value, then $info = -i$ .

## Application Notes

The matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(ja+k-1) \dots H(ja+1) H(ja)$$

where  $k = \min(m, n)$

Each  $H(i)$  has the form

$$H(i) = I - \tau v v'$$

where  $\tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(m-k+i+1:m) = 0$  and  $v(m-k+i) = 1$ ;  $v(1:m-k+i-1)$  is stored on exit in  $A(ia:ia+m-k+i-2, ja+n-k+i-1)$ , and  $\tau$  in  $\tau[ja+n-k+i-2]$ .

### p?orgql

Generates the orthogonal matrix  $Q$  of the  $QL$  factorization formed by `p?geqlf`.

## Syntax

```
void psorgql (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdorgql (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?orgql` function generates the whole or part of  $m$ -by- $n$  real distributed matrix  $Q$  denoting  $A(ia:ia+m-1, ja:ja+n-1)$  with orthonormal rows, which is defined as the first  $m$  rows of a product of  $k$  elementary reflectors of order  $n$

$$Q = H(k) * \dots * H(2) * H(1)$$

as returned by `p?geqlf`.

## Input Parameters

<code>m</code>	(global) The number of rows in the matrix $\text{sub}(Q)$ , ( $m \geq 0$ ).
<code>n</code>	(global) The number of columns in the matrix $\text{sub}(Q)$ , ( $m \geq n \geq 0$ ).
<code>k</code>	(global) The number of elementary reflectors whose product defines the matrix $Q$ ( $n \geq k \geq 0$ ).
<code>a</code>	(local) Pointer into the local memory to an array of local size $ld\_a * LOCC(ja+n-1)$ . On entry, the $j$ -th column of the matrix stored in <code>a</code> must contain the vector that defines the elementary reflector $H(j), ja+n-k \leq j \leq ja+n-1$ , as returned by <code>p?geqlf</code> in the $k$ columns of its distributed matrix argument $A(ia:*, ja+n-k:ja+n-1)$ .
<code>ia, ja</code>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$ , respectively.
<code>desca</code>	(global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix $A$ .
<code>tau</code>	(local) Array of size $LOCC(ja+n-1)$ . Contains the scalar factors $\tau[j]$ of elementary reflectors $H(j+1)$ , $0 \leq j < LOCr(ia+n-1)$ . $\tau$ is tied to the distributed matrix $A$ .
<code>work</code>	(local) Workspace array of size of <code>lwork</code> .
<code>lwork</code>	(local or global) size of <code>work</code> , must be at least $lwork \geq nb\_a * (nqa0 + mpa0 + nb\_a)$ , where $iroffa = \text{mod}(ia-1, mb\_a),$ $icoffa = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$ $mpa0 = \text{numroc}(m + iroffa, mb\_a, MYROW, iarow, NPROW),$ $nqa0 = \text{numroc}(n + icoffa, nb\_a, MYCOL, iacol, NPCOL)$

**NOTE**

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

**Output Parameters**

<code>a</code>	Contains the local pieces of the $m$ -by- $n$ distributed matrix $Q$ to be factored.
<code>work[0]</code>	On exit, <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then <code>info = -(i*100+j)</code> ; if the $i$ -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

**See Also**

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

**p?ungql**

Generates the unitary matrix  $Q$  of the  $QL$  factorization formed by `p?geqlf`.

**Syntax**

```
void pcungql (const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , MKL_Complex8
*a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const MKL_Complex8
*tau , MKL_Complex8 *work , const MKL_INT *lwork , MKL_INT *info );

void pzungql (const MKL_INT *m , const MKL_INT *n , const MKL_INT *k , MKL_Complex16
*a , const MKL_INT *ia , const MKL_INT *ja , const MKL_INT *desca , const MKL_Complex16
*tau , MKL_Complex16 *work , const MKL_INT *lwork , MKL_INT *info );
```

**Include Files**

- `mkl_scalapack.h`

**Description**

This function generates the whole or part of  $m$ -by- $n$  complex distributed matrix  $Q$  denoting  $A(ia:ia+m-1, ja:ja+n-1)$  with orthonormal rows, which is defined as the first  $n$  columns of a product of  $k$  elementary reflectors of order  $m$

$Q = (H(k))^H \dots (H(2))^H (H(1))^H$  as returned by `p?geqlf`.

## Input Parameters

<i>m</i>	(global) The number of rows in the matrix $\text{sub}(Q)$ ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the matrix $\text{sub}(Q)$ ( $m \geq n \geq 0$ ).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix $Q$ ( $n \geq k \geq 0$ ).
<i>a</i>	(local) Pointer into the local memory to an array of local size $ld\_a * LOCC(ja + n - 1)$ . On entry, the $j$ -th column of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(j)$ , $ja + n - k \leq j \leq ja + n - 1$ , as returned by <code>p?geqlf</code> in the $k$ columns of its distributed matrix argument $A(ia:*, ja+n-k: ja+n-1)$ .
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .
<i>tau</i>	(local) Array of size $LOCr(ia+n-1)$ . Contains the scalar factors $\tau[j]$ of elementary reflectors $H(j+1)$ , $0 \leq j < LOCr(ia+n-1)$ . <i>tau</i> is tied to the distributed matrix $A$ .
<i>work</i>	(local) Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least $lwork \geq nb\_a * (nqa0 + mpa0 + nb\_a)$ , where $iroffa = \text{mod}(ia-1, mb\_a),$ $icoffa = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$ $mpa0 = \text{numroc}(m+iroffa, mb\_a, MYROW, iarow, NPROW),$ $nqa0 = \text{numroc}(n+icoffa, nb\_a, MYCOL, iacol, NPCOL)$ <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function <code>blacs_gridinfo</code> . If $lwork = -1$ , then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> .

## Output Parameters

<i>a</i>	Contains the local pieces of the $m$ -by- $n$ distributed matrix $Q$ to be factored.
----------	--

`work[0]` On exit, `work[0]` contains the minimum value of `lwork` required for optimum performance.

`info` (global)  
 = 0: the execution is successful.  
 < 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then `info = -(i*100+j)`; if the *i*-th argument is a scalar and had an illegal value, then `info = -i`.

## p?ormql

*Multiplies a general matrix by the orthogonal matrix  $Q$  of the QL factorization formed by p?geqlf.*

## Syntax

```
void psormql (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *c , MKL_INT *ic ,
MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdormql (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , double
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT *lwork , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?ormql` function overwrites the general real *m*-by-*n* distributed matrix  $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$  with

	<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
<i>trans</i> = 'T':	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where  $Q$  is a real orthogonal distributed matrix defined as the product of *k* elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by `p?geqlf`.  $Q$  is of order *m* if *side* = 'L' and of order *n* if *side* = 'R'.

## Input Parameters

`side` (global)  
 = 'L':  $Q$  or  $Q^T$  is applied from the left.  
 = 'R':  $Q$  or  $Q^T$  is applied from the right.

`trans` (global)  
 = 'N', no transpose,  $Q$  is applied.  
 = 'T', transpose,  $Q^T$  is applied.

<i>m</i>	(global) The number of rows in the distributed matrix sub( <i>C</i> ), ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the distributed matrix sub( <i>C</i> ), ( $n \geq 0$ ).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix <i>Q</i> . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$ .
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+k-1)$ . The <i>j</i> -th column of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(j)$ , $ja \leq j \leq ja+k-1$ , as returned by <code>p?geqlf</code> in the <i>k</i> columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$ . $A(ia:*, ja:ja+k-1)$ is modified by the function but restored on exit. If <i>side</i> = 'L', $lld\_a \geq \max(1, LOCr(ia+m-1))$ , If <i>side</i> = 'R', $lld\_a \geq \max(1, LOCr(ia+n-1))$ .
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) Array of size $LOCC(ja+n-1)$ . Contains the scalar factor $tau[j]$ of elementary reflectors $H(j+1)$ as returned by <code>p?geqlf</code> ( $0 \leq j < LOCC(ja+k-1)$ ). <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) Pointer into the local memory to an array of local size $lld\_c * LOCC(jc+n-1)$ . Contains the local pieces of the distributed matrix sub( <i>C</i> ) to be factored.
<i>ic, jc</i>	(global) The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>desc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) dimension of <i>work</i> , must be at least: If <i>side</i> = 'L', $lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + mpc0) * nb\_a + nb\_a * nb\_a)$ else if <i>side</i> = 'R', $lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + \max(npa0 + \text{numroc}(\text{numroc}(n + icoffc, nb\_a, 0, 0, NPCOL), nb\_a, 0, 0, lcmq), mpc0)) * nb\_a) + nb\_a * nb\_a)$

```

end if
where
lcmq = lcm/NPCOL with lcm = ilcm (NPROW, NPCOL),
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
npa0= numroc(n + iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

**NOTE**

`mod(x,y)` is the integer remainder of  $x/y$ .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?erbla`.

**Output Parameters**

<code>c</code>	Overwritten by the product $Q^* \text{sub}(C)$ , or $Q^* \text{sub}(C)$ , or $\text{sub}(C)^* Q'$ , or $\text{sub}(C)^* Q$
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then <code>info = -(i*100+j)</code> ; if the $i$ -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

```

## Include Files

- mkl\_scalapack.h

## Description

This function overwrites the general complex  $m$ -by- $n$  distributed matrix  $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$  with

	<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$Q \cdot \text{sub}(C)$	$\text{sub}(C) \cdot Q$
<i>trans</i> = 'C':	$Q^H \cdot \text{sub}(C)$	$\text{sub}(C) \cdot Q^H$

where  $Q$  is a complex unitary distributed matrix defined as the product of  $k$  elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by `p?geqlf`.  $Q$  is of order  $m$  if *side* = 'L' and of order  $n$  if *side* = 'R'.

## Input Parameters

<i>side</i>	(global) = 'L': $Q$ or $Q^H$ is applied from the left. = 'R': $Q$ or $Q^H$ is applied from the right.
<i>trans</i>	(global) = 'N', no transpose, $Q$ is applied. = 'C', conjugate transpose, $Q^H$ is applied.
<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(C)$ ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(C)$ ( $n \geq 0$ ).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix $Q$ . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$ .
<i>a</i>	(local)

Pointer into the local memory to an array of size  $lld\_a * LOCC(ja+k-1)$ . The  $j$ -th column of the matrix stored in  $a$  must contain the vector that defines the elementary reflector  $H(j)$ ,  $ja \leq j \leq ja+k-1$ , as returned by `p?geqlf` in the  $k$  columns of its distributed matrix argument  $A(ia:*, ja:ja+k-1)$ .  $A(ia:*, ja:ja+k-1)$  is modified by the function but restored on exit.

If  $side = 'L'$ ,  $lld\_a \geq \max(1, LOCr(ia+m-1))$ ,

If  $side = 'R'$ ,  $lld\_a \geq \max(1, LOCr(ia+n-1))$ .

*ia, ja*

(global) The row and column indices in the global matrix  $A$  indicating the first row and the first column of the submatrix  $A$ , respectively.

*desca*

(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $A$ .

*tau*

(local)

Array of size  $LOCC(ia+n-1)$ .

Contains the scalar factor  $tau[j]$  of elementary reflectors  $H(j+1)$  as returned by `p?geqlf` ( $0 \leq j < LOCC(ia+n-1)$ ).  $tau$  is tied to the distributed matrix  $A$ .

*c*

(local)

Pointer into the local memory to an array of local size  $lld\_c * LOCC(jc+n-1)$ .

Contains the local pieces of the distributed matrix  $sub(C)$  to be factored.

*ic, jc*

(global) The row and column indices in the global matrix  $C$  indicating the first row and the first column of the submatrix  $C$ , respectively.

*descc*

(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $C$ .

*work*

(local)

Workspace array of size of  $lwork$ .

*lwork*

(local or global) size of  $work$ , must be at least:

If  $side = 'L'$ ,

$lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + mpc0) * nb\_a + nb\_a * nb\_a)$

else if  $side = 'R'$ ,

$lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + maxnpa0) + \text{numroc}(\text{numroc}(n + icoffc, nb\_a, 0, 0, NPCOL), nb\_a, 0, 0, lcmq), mpc0)) * nb\_a + nb\_a * nb\_a$

end if

where

$lcmp = lcm / NPCOL$  with  $lcm = ilcm(NPROW, NPCOL)$ ,

$iroffa = \text{mod}(ia - 1, mb\_a)$ ,

$icoffa = \text{mod}(ja - 1, nb\_a)$ ,

$iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW)$ ,

$npa0 = \text{numroc}(n + iroffa, mb\_a, MYROW, iarow, NPROW)$ ,

```

iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

**NOTE**

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

**NOTE**

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

**Output Parameters**

<code>c</code>	Overwritten by the product $Q^* \text{sub}(C)$ , or $Q' \text{sub}(C)$ , or $\text{sub}(C)^* Q'$ , or $\text{sub}(C)^* Q$
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then <code>info = -(i*100+j)</code> ; if the $i$ -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

**p?gerqf**

Computes the RQ factorization of a general rectangular matrix.

**Syntax**

```
void psggerqf (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdgerqf (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pcgerqf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT
*info );
```

```
void pzgerqf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT
*info );
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?gerqf` function forms the QR factorization of a general  $m$ -by- $n$  distributed matrix  $\text{sub}(A) = A(\text{ia}:\text{ia} + m - 1, \text{ja}:\text{ja} + n - 1)$  as

$$A = R * Q$$

## Input Parameters

<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(A)$ ; ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(A)$ ; ( $n \geq 0$ ).
<i>a</i>	(local) Pointer into the local memory to an array of local size $lld\_a * LOCC(ja + n - 1)$ . Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A(\text{ia}:\text{ia} + m - 1, \text{ja}:\text{ja} + n - 1)$ , respectively.
<i>desca</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$
<i>work</i>	(local). Workspace array of size $lwork$ .
<i>lwork</i>	(local or global) size of $work$ , must be at least $lwork \geq mb\_a * (mp0 + nq0 + mb\_a)$ , where $iroff = \text{mod}(ia - 1, mb\_a)$ , $icoff = \text{mod}(ja - 1, nb\_a)$ , $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW)$ , $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL)$ , $mp0 = \text{numroc}(m + iroff, mb\_a, MYROW, iarow, NPROW)$ ,

---

### NOTE

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

---

$nq0 = \text{numroc}(n + icoff, nb\_a, MYCOL, iacol, NPCOL)$  and  $\text{numroc}$ ,  $\text{indxg2p}$  are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function `blacs_gridinfo`.

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

$a$	On exit, if $m \leq n$ , the upper triangle of $A(ia:ia+m-1, ja:ja+n-1)$ contains the $m$ -by- $m$ upper triangular matrix $R$ ; if $m \geq n$ , the elements on and above the $(m - n)$ -th subdiagonal contain the $m$ -by- $n$ upper trapezoidal matrix $R$ ; the remaining elements, with the array $\tau$ , represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors (see <i>Application Notes</i> below).
$\tau$	(local) Array of size $LOCr(ia+m-1)$ . Contains the scalar factor of elementary reflectors. $\tau$ is tied to the distributed matrix $A$ .
$work[0]$	On exit, $work[0]$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) = 0, the execution is successful. < 0, if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then $info = -(i*100+j)$ ; if the $i$ -th argument is a scalar and had an illegal value, then $info = -i$ .

## Application Notes

The matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(ia) * H(ia+1) * \dots * H(ia+k-1),$$

where  $k = \min(m, n)$ .

Each  $H(i)$  has the form

$$H(i) = I - \tau * v * v'$$

where  $\tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(n-k+i+1:n) = 0$  and  $v(n-k+i) = 1$ ;  $v(1:n-k+i-1)$  is stored on exit in  $A(ia+m-k+i-1, ja:ja+n-k+i-2)$ , and  $\tau$  in  $\tau[ia+m-k+i-2]$ .

### p?orgqr

Generates the orthogonal matrix  $Q$  of the  $RQ$  factorization formed by `p?gerqf`.

## Syntax

```
void psorgqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdorgqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?orgrqf` function generates the whole or part of  $m$ -by- $n$  real distributed matrix  $Q$  denoting  $A(ia:ia+m-1, ja:ja+n-1)$  with orthonormal rows that is defined as the last  $m$  rows of a product of  $k$  elementary reflectors of order  $n$

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by `p?gerqf`.

## Input Parameters

<i>m</i>	(global) The number of rows in the matrix $\text{sub}(Q)$ , ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the matrix $\text{sub}(Q)$ , ( $n \geq m \geq 0$ ).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix $Q$ ( $m \geq k \geq 0$ ).
<i>a</i>	(local) Pointer into the local memory to an array of local size $ld_a * LOCC(ja+n-1)$ . The $i$ -th row of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(i)$ , $ia \leq i \leq ia+m-1$ , as returned by <code>p?gerqf</code> in the $k$ rows of its distributed matrix argument $A(ia+m-k:ia+m-1, ja:*)$ .
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .
<i>tau</i>	(local) Array of size $LOCc(ja+k-1)$ . Contains the scalar factor $\tau[i]$ of elementary reflectors $H(i+1)$ as returned by <code>p?gerqf</code> , $0 \leq i < LOCr(ja+k-1)$ . <i>tau</i> is tied to the distributed matrix $A$ .
<i>work</i>	(local) Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least $lwork \geq mb\_a * (mpa0 + nqa0 + mb\_a)$ , where $iroffa = \text{mod}(ia-1, mb\_a),$ $icoffa = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$ $mpa0 = \text{numroc}(m+iroffa, mb\_a, MYROW, iarow, NPROW),$ $nqa0 = \text{numroc}(n+icoffa, nb\_a, MYCOL, iacol, NPCOL)$

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

---

#### NOTE

`mod(x, y)` is the integer remainder of  $x/y$ .

---

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

<code>a</code>	Contains the local pieces of the $m$ -by- $n$ distributed matrix $Q$ .
<code>work[0]</code>	On exit, <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then <code>info = -(i*100+j)</code> ; if the $i$ -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## p?ungrq

*Generates the unitary matrix  $Q$  of the RQ factorization formed by `p?gerqf`.*

---

## Syntax

```
void pcungrq (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pzungrq (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT
*lwork , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

This function generates the  $m$ -by- $n$  complex distributed matrix  $Q$  denoting  $A(ia:ia+m-1,ja:ja+n-1)$  with orthonormal rows, which is defined as the last  $m$  rows of a product of  $k$  elementary reflectors of order  $n$

$Q = (H(1))^H * (H(2))^H * \dots * (H(k))^H$  as returned by `p?gerqf`.

## Input Parameters

<code>m</code>	(global) The number of rows in the matrix <code>sub(Q)</code> ; ( $m \geq 0$ ).
----------------	---

<i>n</i>	(global) The number of columns in the matrix $\text{sub}(Q)$ ( $n \geq m \geq 0$ ).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix $Q$ ( $m \geq k \geq 0$ ).
<i>a</i>	(local) Pointer into the local memory to an array of size $\text{lld\_a} * \text{LOCc}(j_{a+n-1})$ . The $i$ -th row of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(i)$ , $ia+m-k \leq i \leq ia+m-1$ , as returned by <code>p?gerqf</code> in the $k$ rows of its distributed matrix argument $A(ia+m-k:ia+m-1, ja:*)$ .
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .
<i>tau</i>	(local) Array of size $\text{LOCr}(ia+m-1)$ . Contains the scalar factor $\text{tau}[i]$ of elementary reflectors $H(i+1)$ as returned by <code>p?gerqf</code> , $0 \leq i < \text{LOCr}(ia+m-1)$ . <i>tau</i> is tied to the distributed matrix $A$ .
<i>work</i>	(local) Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least $\text{lwork} \geq \text{mb\_a} * (\text{mpa0} + \text{nqa0} + \text{mb\_a})$ , where $\text{irowfa} = \text{mod}(ia-1, \text{mb\_a})$ , $\text{icoffa} = \text{mod}(ja-1, \text{nb\_a})$ , $\text{iarow} = \text{indxg2p}(ia, \text{mb\_a}, \text{MYROW}, \text{rsrc\_a}, \text{NPROW})$ , $\text{iacol} = \text{indxg2p}(ja, \text{nb\_a}, \text{MYCOL}, \text{csrc\_a}, \text{NPCOL})$ , $\text{mpa0} = \text{numroc}(m + \text{irowfa}, \text{mb\_a}, \text{MYROW}, \text{iarow}, \text{NPROW})$ , $\text{nqa0} = \text{numroc}(n + \text{icoffa}, \text{nb\_a}, \text{MYCOL}, \text{iacol}, \text{NPCOL})$

**NOTE**

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If  $\text{lwork} = -1$ , then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

**Output Parameters**

*a* Contains the local pieces of the  $m$ -by- $n$  distributed matrix  $Q$ .

`work[0]` On exit `work[0]` contains the minimum value of `lwork` required for optimum performance.

`info` (global)  
 = 0: the execution is successful.  
 < 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then `info = -(i*100+j)`; if the *i*-th argument is a scalar and had an illegal value, then `info = -i`.

## See Also

### p?ormr3

Applies an orthogonal distributed matrix to a general *m*-by-*n* distributed matrix.

### Syntax

```
void psormr3 (const char* side, const char* trans, const MKL_INT* m, const MKL_INT* n,
const MKL_INT* k, const MKL_INT* l, const float* a, const MKL_INT* ia, const MKL_INT*
ja, const MKL_INT* desca, const float* tau, float* c, const MKL_INT* ic, const MKL_INT*
jc, const MKL_INT* descc, float* work, const MKL_INT* lwork, MKL_INT* info);
```

```
void pdormr3 (const char* side, const char* trans, const MKL_INT* m, const MKL_INT* n,
const MKL_INT* k, const MKL_INT* l, const double* a, const MKL_INT* ia, const MKL_INT*
ja, const MKL_INT* desca, const double* tau, double* c, const MKL_INT* ic, const
MKL_INT* jc, const MKL_INT* descc, double* work, const MKL_INT* lwork, MKL_INT* info);
```

### Include Files

- `mkl_scalapack.h`

### Description

`p?ormr3` overwrites the general real *m*-by-*n* distributed matrix  $sub(C) = C(ic:ic+m-1, jc:jc+n-1)$  with

	<code>side = 'L'</code>	<code>side = 'R'</code>
<code>trans = 'N'</code>	$Q * sub(C)$	$sub(C) * Q$
<code>trans = 'T'</code>	$Q^T * sub(C)$ $Q * sub(C)$	$sub(C) * Q^T$

where *Q* is a real orthogonal distributed matrix defined as the product of *k* elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by `p?tzzrf`. *Q* is of order *m* if `side = 'L'` and of order *n* if `side = 'R'`.

### Input Parameters

`side` (global)  
 = 'L': apply *Q* or *Q*<sup>T</sup> from the Left;  
 = 'R': apply *Q* or *Q*<sup>T</sup> from the Right.

<i>trans</i>	(global) = 'N': No transpose, apply $Q$ ; = 'T': Transpose, apply $Q^T$ .
<i>m</i>	(global) The number of rows to be operated on i.e the number of rows of the distributed submatrix sub( $C$ ). $m \geq 0$ .
<i>n</i>	(global) The number of columns to be operated on i.e the number of columns of the distributed submatrix sub( $C$ ). $n \geq 0$ .
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix $Q$ . If <i>side</i> = 'L', $m \geq k \geq 0$ , if <i>side</i> = 'R', $n \geq k \geq 0$ .
<i>l</i>	(global) The columns of the distributed submatrix sub( $A$ ) containing the meaningful part of the Householder reflectors. If <i>side</i> = 'L', $m \geq l \geq 0$ , if <i>side</i> = 'R', $n \geq l \geq 0$ .
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+m-1)$ if <i>side</i> ='L', and $lld\_a * LOCC(ja+n-1)$ if <i>side</i> ='R', where $lld\_a \geq \text{MAX}(1, LOCCr(ia+k-1))$ ; On entry, the $i$ -th row must contain the vector which defines the elementary reflector $H(i)$ , $ia \leq i \leq ia+k-1$ , as returned by <code>p?tzrzf</code> in the $k$ rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$ . $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.
<i>ia</i>	(global) The row index in the global array <i>a</i> indicating the first row of sub( $A$ ).
<i>ja</i>	(global) The column index in the global array <i>a</i> indicating the first column of sub( $A$ ).
<i>desca</i>	(global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .
<i>tau</i>	(local) Array, size $LOCC(ia+k-1)$ . This array contains the scalar factors $tau(i)$ of the elementary reflectors $H(i)$ as returned by <code>p?tzrzf</code> . <i>tau</i> is tied to the distributed matrix $A$ .

<i>c</i>	(local) Pointer into the local memory to an array of size $lld\_c * LOCC(jc+n-1)$ . On entry, the local pieces of the distributed matrix sub( <i>C</i> ).
<i>ic</i>	(global) The row index in the global array <i>c</i> indicating the first row of sub( <i>C</i> ).
<i>jc</i>	(global) The column index in the global array <i>c</i> indicating the first column of sub( <i>C</i> ).
<i>desc</i>	(global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) Array, size ( <i>lwork</i> )
<i>lwork</i>	(local) The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least If <i>side</i> = 'L', $lwork \geq MpCO + \text{MAX}( \text{MAX}( 1, NqCO ), \text{numroc}( \text{numroc}( m + IROFFC, mb\_a, 0, 0, NPROW ), mb\_a, 0, 0, NqCO ) )$ ; if <i>side</i> = 'R', $lwork \geq NqCO + \text{MAX}( 1, MpCO )$ ; where $LCMP = LCM / NPROW$ $LCM = iclm( NPROW, NPCOL )$ , $IROFFC = \text{MOD}( ic-1, mb\_c )$ , $ICOFFC = \text{MOD}( jc-1, nb\_c )$ , $ICROW = \text{indxg2p}( ic, mb\_c, MYROW, rsrc\_c, NPROW )$ , $ICCOL = \text{indxg2p}( jc, nb\_c, MYCOL, csrc\_c, NPCOL )$ , $MpCO = \text{numroc}( m + IROFFC, mb\_c, MYROW, ICROW, NPROW )$ , $NqCO = \text{numroc}( n + ICOFFC, nb\_c, MYCOL, ICCOL, NPCOL )$ , <i>iclm</i> , <i>indxg2p</i> , and <i>numroc</i> are ScaLAPACK tool functions; <i>MYROW</i> , <i>MYCOL</i> , <i>NPROW</i> and <i>NPCOL</i> can be determined by calling the subroutine <i>blacs_gridinfo</i> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i> .

## Output Parameters

<i>c</i>	On exit, sub( <i>C</i> ) is overwritten by $Q * \text{sub}( C )$ or $Q' * \text{sub}( C )$ or $\text{sub}( C ) * Q'$ or $\text{sub}( C ) * Q$ .
----------	---

*work* On exit, *work*[0] returns the minimal and optimal *lwork*.

*info* (local)  
 = 0: successful exit  
 < 0: If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* =  $-(i*100+j)$ , if the *i*-th argument is a scalar and had an illegal value, then *info* =  $-i$ .

## Application Notes

### Alignment requirements

The distributed submatrices  $A(ia:*, ja:*)$  and  $C(ic:ic+m-1, jc:jc+n-1)$  must verify some alignment properties, namely the following expressions should be true:

If *side* = 'L',

( *nb\_a* = *mb\_c* .AND. ICOFFA = IROFFC )

If *side* = 'R',

( *nb\_a* = *nb\_c* .AND. ICOFFA = ICOFFC .AND. IACOL = ICCOL )

### Include Files

- mkl\_scalapack.h

### Description

p?unmr3 overwrites the general complex *m*-by-*n* distributed matrix sub( *C* ) =  $C(ic:ic+m-1, jc:jc+n-1)$  with

*side* = 'L'                      *side* = 'R'

*trans* = 'N':  $Q * \text{sub}(C)$                        $\text{sub}(C) * Q$

*trans* = 'C':  $Q^H * \text{sub}(C)$                        $\text{sub}(C) * Q^H$

where *Q* is a complex unitary distributed matrix defined as the product of *k* elementary reflectors

$Q = H(1)' H(2)' \dots H(k)'$

as returned by p?tzzrf. *Q* is of order *m* if *side* = 'L' and of order *n* if *side* = 'R'.

## Input Parameters

<i>side</i>	(global) = 'L': apply $Q$ or $Q^H$ from the Left; = 'R': apply $Q$ or $Q^H$ from the Right.
<i>trans</i>	(global) = 'N': No transpose, apply $Q$ ; = 'C': Conjugate transpose, apply $Q^H$ .
<i>m</i>	(global) The number of rows to be operated on i.e the number of rows of the distributed submatrix $sub( C )$ . $m \geq 0$ .
<i>n</i>	(global) The number of columns to be operated on i.e the number of columns of the distributed submatrix $sub( C )$ . $n \geq 0$ .
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix $Q$ . If $side = 'L', m \geq k \geq 0$ , if $side = 'R', n \geq k \geq 0$ .
<i>l</i>	(global) The columns of the distributed submatrix $sub( A )$ containing the meaningful part of the Householder reflectors. If $side = 'L', m \geq l \geq 0$ , if $side = 'R', n \geq l \geq 0$ .
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+m-1)$ if $side='L'$ , and $lld\_a * LOCC(ja+n-1)$ if $side='R'$ , where $lld\_a \geq \text{MAX}(1, LOCr(ia+k-1))$ ; On entry, the $i$ -th row must contain the vector which defines the elementary reflector $H(i)$ , $ia \leq i \leq ia+k-1$ , as returned by <code>p?tzrzf</code> in the $k$ rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$ . $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.
<i>ia</i>	(global) The row index in the global array $a$ indicating the first row of $sub( A )$ .
<i>ja</i>	(global) The column index in the global array $a$ indicating the first column of $sub( A )$ .
<i>desca</i>	(global and local) Array of size $dlen_$ . The array descriptor for the distributed matrix $A$ .
<i>tau</i>	(local) Array, size $LOCC(ia+k-1)$ .

This array contains the scalar factors  $\tau(i)$  of the elementary reflectors  $H(i)$  as returned by `p?tzrzf`.  $\tau$  is tied to the distributed matrix  $A$ .

<code>c</code>	(local) Pointer into the local memory to an array of size $lld\_c * LOCC(jc+n-1)$ . On entry, the local pieces of the distributed matrix sub( $C$ ).
<code>ic</code>	(global) The row index in the global array <code>c</code> indicating the first row of sub( $C$ ).
<code>jc</code>	(global) The column index in the global array <code>c</code> indicating the first column of sub( $C$ ).
<code>desc</code>	(global and local) Array of size <code>dlen_</code> . The array descriptor for the distributed matrix $C$ .
<code>work</code>	(local) Array, size ( <code>lwork</code> ) On exit, <code>work(1)</code> returns the minimal and optimal <code>lwork</code> .
<code>lwork</code>	(local or global) The size of the array <code>work</code> .  <code>lwork</code> is local input and must be at least If <code>side = 'L'</code> , <code>lwork</code> $\geq$ <code>MpC0 + MAX( MAX( 1, NqC0 ), numroc( numroc( m +IROFFC,mb_a,0,0,NPROW ),mb_a,0,0,LCMP ) )</code> ; if <code>side = 'R'</code> , <code>lwork</code> $\geq$ <code>NqC0 + MAX( 1, MpC0 )</code> ; where <code>LCMP = LCM / NPROW</code> with <code>LCM = ICLM( NPROW, NPCOL )</code> , <code>IROFFC = MOD( ic-1, MB_C )</code> , <code>ICOFFC = MOD( jc-1, nb_c )</code> , <code>ICROW = indxg2p( ic, MB_C, MYROW, rsrc_c, NPROW )</code> , <code>ICCOL = indxg2p( jc, nb_c, MYCOL, csrc_c, NPCOL )</code> , <code>MpC0 = numroc( m+IROFFC, MB_C, MYROW, ICROW, NPROW )</code> , <code>NqC0 = numroc( n+ICOFFC, nb_c, MYCOL, ICCOL, NPCOL )</code> , <code>ilcm, indxg2p, and numroc</code> are ScaLAPACK tool functions; <code>MYROW, MYCOL, NPROW</code> and <code>NPCOL</code> can be determined by calling the subroutine <code>blacs_gridinfo</code> . If <code>lwork = -1</code> , then <code>lwork</code> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>p_xerbla</code> .

## Output Parameters

<code>c</code>	On exit, <code>sub( C )</code> is overwritten by $Q*\text{sub}( C )$ or $Q'*\text{sub}( C )$ or $\text{sub}( C )*Q'$ or $\text{sub}( C )*Q$ .
<code>work</code>	(local) Array, size ( <code>lwork</code> ) On exit, <code>work[0]</code> returns the minimal and optimal <code>lwork</code> .
<code>info</code>	(local) = 0: successful exit < 0: If the $i$ -th argument is an array and the $j$ -th entry had an illegal value, then <code>info</code> = $-(i*100+j)$ , if the $i$ -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$ .

## Application Notes

### Alignment requirements

The distributed submatrices  $A(ia:*, ja:*)$  and  $C(ic:ic+m-1, jc:jc+n-1)$  must verify some alignment properties, namely the following expressions should be true:

If `side = 'L'`, (`nb_a = MB_C` and `ICOFFA = IROFFC` )

If `side = 'R'`, (`nb_a = nb_c` and `ICOFFA = ICOFFC` and `IACOL = ICCOL` )

### p?ormrq

### Description

The `p?ormrq` function overwrites the general real  $m$ -by- $n$  distributed matrix  $\text{sub}( C ) = C(ic:ic+m-1, jc:jc+n-1)$  with

	<code>side = 'L'</code>	<code>side = 'R'</code>
<code>trans = 'N':</code>	$Q*\text{sub}(C)$	$\text{sub}(C)*Q$
<code>trans = 'T':</code>	$Q^T*\text{sub}(C)$	$\text{sub}(C)*Q^T$

where  $Q$  is a real orthogonal distributed matrix defined as the product of  $k$  elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by `p?gerqf`.  $Q$  is of order  $m$  if `side = 'L'` and of order  $n$  if `side = 'R'`.

## Input Parameters

<i>side</i>	(global) ='L': $Q$ or $Q^T$ is applied from the left. ='R': $Q$ or $Q^T$ is applied from the right.
<i>trans</i>	(global) ='N', no transpose, $Q$ is applied. ='T', transpose, $Q^T$ is applied.
<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(C)$ ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(C)$ ( $n \geq 0$ ).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix $Q$ . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$ .
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+m-1)$ if <i>side</i> = 'L', and $lld\_a * LOCC(ja+n-1)$ if <i>side</i> = 'R'. The <i>i</i> -th row of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(i)$ , $ia \leq i \leq ia+k-1$ , as returned by <code>p?gerqf</code> in the <i>k</i> rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$ . $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit.
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .
<i>tau</i>	(local) Array of size $LOCC(ja+k-1)$ . Contains the scalar factor $\tau[i]$ of elementary reflectors $H(i+1)$ as returned by <code>p?gerqf</code> ( $0 \leq i < LOCC(ja+k-1)$ ). <i>tau</i> is tied to the distributed matrix $A$ .
<i>c</i>	(local) Pointer into the local memory to an array of local size $lld\_c * LOCC(jc+n-1)$ . Contains the local pieces of the distributed matrix $\text{sub}(C)$ to be factored.
<i>ic, jc</i>	(global) The row and column indices in the global matrix $C$ indicating the first row and the first column of the matrix $\text{sub}(C)$ , respectively.
<i>desc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $C$ .
<i>work</i>	(local) Workspace array of size of <i>lwork</i> .

*lwork*(local or global) size of *work*, must be at least:If *side* = 'L',

*info );

```

## Include Files

- mkl\_scalapack.h

## Description

The `pztzrzf` function reduces the  $m$ -by- $n$  ( $m \leq n$ ) real/complex upper trapezoidal matrix  $\text{sub}(A) = A(\text{ia}:\text{ia} + m - 1, \text{ja}:\text{ja} + n - 1)$  to upper triangular form by means of orthogonal/unitary transformations. The upper trapezoidal matrix  $A$  is factored as

$$A = (R \ 0) * Z,$$

where  $Z$  is an  $n$ -by- $n$  orthogonal/unitary matrix and  $R$  is an  $m$ -by- $m$  upper triangular matrix.

## Input Parameters

<i>m</i>	(global) The number of rows in the matrix $\text{sub}(A)$ ; ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the matrix $\text{sub}(A)$ ( $n \geq 0$ ).
<i>a</i>	(local) Pointer into the local memory to an array of size $\text{lld}_a * \text{LOCc}(\text{ja} + n - 1)$ . Contains the local pieces of the $m$ -by- $n$ distributed matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
<i>desca</i>	(global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $A$ .
<i>work</i>	(local) Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least $lwork \geq mb\_a * (mp0 + nq0 + mb\_a)$ , where $iroff = \text{mod}(ia - 1, mb\_a),$ $icoff = \text{mod}(ja - 1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, \text{MYROW}, rsrc\_a, \text{NPROW}),$ $iacol = \text{indxg2p}(ja, nb\_a, \text{MYCOL}, csrc\_a, \text{NPCOL}),$ $mp0 = \text{numroc}(m + iroff, mb\_a, \text{MYROW}, iarow, \text{NPROW}),$ $nq0 = \text{numroc}(n + icoff, nb\_a, \text{MYCOL}, iacol, \text{NPCOL})$

---

### NOTE

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

---

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

<code>a</code>	On exit, the leading $m$ -by- $m$ upper triangular part of <code>sub(A)</code> contains the upper triangular matrix $R$ , and elements $m+1$ to $n$ of the first $m$ rows of <code>sub(A)</code> , with the array <code>tau</code> , represent the orthogonal/unitary matrix $Z$ as a product of $m$ elementary reflectors.
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>tau</code>	(local) Array of size <code>LOCr(ia+m-1)</code> .  Contains the scalar factor of elementary reflectors. <code>tau</code> is tied to the distributed matrix $A$ .
<code>info</code>	(global) = 0: the execution is successful.  < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then <code>info = -(i*100+j)</code> ; if the $i$ -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

## Application Notes

The factorization is obtained by the Householder's method. The  $k$ -th transformation matrix,  $Z(k)$ , which is or whose conjugate transpose is used to introduce zeros into the  $(m - k + 1)$ -th row of `sub(A)`, is given in the form

$$Z(k) = \begin{bmatrix} i & 0 \\ 0 & \mathbf{T}(k) \end{bmatrix}$$

where

$$T(k) = i - \tau u(k) u(k)',$$

$$u(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}$$

`tau` is a scalar and  $Z(k)$  is an  $(n - m)$  element vector. `tau` and  $Z(k)$  are chosen to annihilate the elements of the  $k$ -th row of `sub(A)`. The scalar `tau` is returned in the  $k$ -th element of `tau`, indexed  $k-1$ , and the vector  $u(k)$  in the  $k$ -th row of `sub(A)`, such that the elements of  $Z(k)$  are in  $a(k, m + 1), \dots, a(k, n)$ . The elements of  $R$  are returned in the upper triangular part of `sub(A)`.  $Z$  is given by

$Z = Z(1) * Z(2) * \dots * Z(m)$ .

## Description

This function overwrites the general real  $m$ -by- $n$  distributed matrix  $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$  with

	<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
<i>trans</i> = 'T':	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where  $Q$  is a real orthogonal distributed matrix defined as the product of  $k$  elementary reflectors

$Q = H(1) H(2) \dots H(k)$

as returned by p?tzrzf.  $Q$  is of order  $m$  if *side* = 'L' and of order  $n$  if *side* = 'R'.

## Input Parameters

<i>side</i>	(global) = 'L': $Q$ or $Q^T$ is applied from the left. = 'R': $Q$ or $Q^T$ is applied from the right.
<i>trans</i>	(global) = 'N', no transpose, $Q$ is applied. = 'T', transpose, $Q^T$ is applied.
<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(C)$ ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(C)$ ( $n \geq 0$ ).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix $Q$ . Constraints:

	<p>If <math>side = 'L', m \geq k \geq 0</math></p> <p>If <math>side = 'R', n \geq k \geq 0</math>.</p>
<i>l</i>	<p>(global)</p> <p>The columns of the distributed matrix <math>sub(A)</math> containing the meaningful part of the Householder reflectors.</p> <p>If <math>side = 'L', m \geq l \geq 0</math></p> <p>If <math>side = 'R', n \geq l \geq 0</math>.</p>
<i>a</i>	<p>(local)</p> <p>Pointer into the local memory to an array of size <math>lld\_a * LOCC(ja+m-1)</math> if <math>side = 'L'</math>, and <math>lld\_a * LOCC(ja+n-1)</math> if <math>side = 'R'</math>, where <math>lld\_a \geq \max(1, LOCr(ia+k-1))</math>.</p> <p>The <math>i</math>-th row of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector <math>H(i)</math>, <math>ia \leq i \leq ia+k-1</math>, as returned by <code>p?tzrzf</code> in the <math>k</math> rows of its distributed matrix argument <math>A(ia:ia+k-1, ja:*)</math>. <math>A(ia:ia+k-1, ja:*)</math> is modified by the function but restored on exit.</p>
<i>ia, ja</i>	<p>(global) The row and column indices in the global matrix <math>A</math> indicating the first row and the first column of the submatrix <math>A</math>, respectively.</p>
<i>desca</i>	<p>(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix <math>A</math>.</p>
<i>tau</i>	<p>(local)</p> <p>Array of size <math>LOCC(ia+k-1)</math>.</p> <p>Contains the scalar factor <math>tau[i]</math> of elementary reflectors <math>H(i+1)</math> as returned by <code>p?tzrzf</code> (<math>0 \leq i &lt; LOCC(ia+k-1)</math>). <i>tau</i> is tied to the distributed matrix <math>A</math>.</p>
<i>c</i>	<p>(local)</p> <p>Pointer into the local memory to an array of local size <math>lld\_c * LOCC(jc+n-1)</math>.</p> <p>Contains the local pieces of the distributed matrix <math>sub(C)</math> to be factored.</p>
<i>ic, jc</i>	<p>(global) The row and column indices in the global matrix <math>C</math> indicating the first row and the first column of the submatrix <math>C</math>, respectively.</p>
<i>descc</i>	<p>(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix <math>C</math>.</p>
<i>work</i>	<p>(local)</p> <p>Workspace array of size of <i>lwork</i>.</p>
<i>lwork</i>	<p>(local or global) size of <i>work</i>, must be at least:</p> <p>If <math>side = 'L'</math>,</p> $lwork \geq \max((mb\_a * (mb\_a - 1)) / 2, (mpc0 + \max(mqa0 + \text{numroc}(\text{numroc}(n + iroffc, mb\_a, 0, 0, NPROW), mb\_a, 0, 0, lcmpr), nqc0)) * mb\_a) + mb\_a * mb\_a)$ <p>else if <math>side = 'R'</math>,</p>

```

lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0 + nqc0)*mb_a) + mb_a*mb_a
end if

```

where

```

lcmp = lcm/NPROW with lcm = ilcm (NPROW, NPCOL),
iroffa = mod(ia-1, mb_a), icoffa = mod(ja-1, nb_a),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol, NPCOL),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

---

#### NOTE

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

---

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

<code>c</code>	Overwritten by the product $Q \cdot \text{sub}(C)$ , or $Q' \cdot \text{sub}(C)$ , or $\text{sub}(C) \cdot Q'$ , or $\text{sub}(C) \cdot Q$
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then <code>info = -(i*100+j)</code> ; if the $i$ -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

## Description

The `p?ggqrf` function forms the generalized *QR* factorization of an *n*-by-*m* matrix

$$\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+m-1)$$

and an *n*-by-*p* matrix

$$\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+p-1):$$

as

$$\text{sub}(A) = Q * R, \text{sub}(B) = Q * T * Z,$$

where *Q* is an *n*-by-*n* orthogonal/unitary matrix, *Z* is a *p*-by-*p* orthogonal/unitary matrix, and *R* and *T* assume one of the forms:

If  $n \geq m$

$$R = \begin{pmatrix} R_{11} & & \\ & & \\ & 0 & \end{pmatrix} \begin{matrix} m \\ n - m \\ m \end{matrix}$$

or if  $n < m$

$$R = \begin{pmatrix} R_{11} & R_{12} \\ & \end{pmatrix} \begin{matrix} n \\ n \\ m - n \end{matrix}$$

where  $R_{11}$  is upper triangular, and

$$T = \begin{pmatrix} 0 & T_{12} \\ & \end{pmatrix} \begin{matrix} n, \text{ if } n \leq p, \\ p - n & n \end{matrix}$$

$$\text{or } T = \begin{pmatrix} T_{11} \\ T_{21} \end{pmatrix} \begin{pmatrix} n - p \\ p \end{pmatrix}, \text{ if } n > p,$$

$p$

where  $T_{12}$  or  $T_{21}$  is an upper triangular matrix.

In particular, if  $\text{sub}(B)$  is square and nonsingular, the  $GQR$  factorization of  $\text{sub}(A)$  and  $\text{sub}(B)$  implicitly gives the  $QR$  factorization of  $\text{inv}(\text{sub}(B)) * \text{sub}(A)$ :

$$\text{inv}(\text{sub}(B)) * \text{sub}(A) = Z^H * (\text{inv}(T) * R)$$

## Input Parameters

<i>n</i>	(global) The number of rows in the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$ ( $n \geq 0$ ).
<i>m</i>	(global) The number of columns in the distributed matrix $\text{sub}(A)$ ( $m \geq 0$ ).
<i>p</i>	The number of columns in the distributed matrix $\text{sub}(B)$ ( $p \geq 0$ ).
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+m-1)$ . Contains the local pieces of the $n$ -by- $m$ matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
<i>desca</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
<i>b</i>	(local) Pointer into the local memory to an array of size $lld\_b * LOCC(jb+p-1)$ . Contains the local pieces of the $n$ -by- $p$ matrix $\text{sub}(B)$ to be factored.
<i>ib, jb</i>	(global) The row and column indices in the global matrix $B$ indicating the first row and the first column of the submatrix $B$ , respectively.
<i>descb</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $B$ .
<i>work</i>	(local) Workspace array of size of $lwork$ .
<i>lwork</i>	(local or global) Size of $work$ , must be at least $lwork \geq \max(nb\_a * (npa0 + mqa0 + nb\_a), \max((nb\_a * (nb\_a - 1)) / 2, (pqb0 + npb0) * nb\_a) + nb\_a * nb\_a, mb\_b * (npb0 + pqb0 + mb\_b)),$ where $iroffa = \text{mod}(ia - 1, mb\_A),$ $icoffa = \text{mod}(ja - 1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$

```

npa0 = numroc (n+iroffa, mb_a, MYROW, iarow, NPROW),
mqa0 = numroc (m+icoffa, nb_a, MYCOL, iacol, NPCOL)
iroffb = mod(ib-1, mb_b),
icoffb = mod(jb-1, nb_b),
ibrow = indxg2p(ib, mb_b, MYROW, rsrc_b, NPROW),
ibcol = indxg2p(jb, nb_b, MYCOL, csrc_b, NPCOL),
npb0 = numroc (n+iroffa, mb_b, MYROW, Ibrow, NPROW),
pqb0 = numroc (m+icoffb, nb_b, MYCOL, ibcol, NPCOL)

```

**NOTE**

`mod(x, y)` is the integer remainder of  $x/y$ .

and `numroc`, `indxg2p` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

**Output Parameters**

<code>a</code>	On exit, the elements on and above the diagonal of sub (A) contain the $\min(n, m)$ -by- $m$ upper trapezoidal matrix $R$ ( $R$ is upper triangular if $n \geq m$ ); the elements below the diagonal, with the array <code>taua</code> , represent the orthogonal/unitary matrix $Q$ as a product of $\min(n, m)$ elementary reflectors. (See Application Notes below).
<code>taua, taub</code>	(local) Arrays of size <code>LOCc(ja+min(n,m)-1)</code> for <code>taua</code> and <code>LOCr(ib+n-1)</code> for <code>taub</code> .  The array <code>taua</code> contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix $Q$ . <code>taua</code> is tied to the distributed matrix $A$ . (See Application Notes below).  The array <code>taub</code> contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix $Z$ . <code>taub</code> is tied to the distributed matrix $B$ . (See Application Notes below).
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful.  < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then <code>info = -(i*100+j)</code> ; if the $i$ -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

## Application Notes

The matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(j_a) * H(j_a + 1) * \dots * H(j_a + k - 1),$$

where  $k = \min(n, m)$ .

Each  $H(i)$  has the form

$$H(i) = I - \tau_{a_i} * v * v'$$

where  $\tau_{a_i}$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(1:i-1) = 0$  and  $v(i) = 1$ ;  $v(i+1:n)$  is stored on exit in  $A(i_a+i:i_a+n-1, j_a+i-1)$ , and  $\tau_{a_i}$  in  $\tau_{a_i}[j_a+i-2]$ . To form  $Q$  explicitly, use ScaLAPACK function `p?orgqr/p?ungqr`. To use  $Q$  to update another matrix, use ScaLAPACK function `p?ormqr/p?unmqr`.

The matrix  $Z$  is represented as a product of elementary reflectors

$$Z = H(i_b) * H(i_b + 1) * \dots * H(i_b + k - 1), \text{ where } k = \min(n, p).$$

Each  $H(i)$  has the form

$$H(i) = I - \tau_{b_i} * v * v'$$

where  $\tau_{b_i}$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(p-k+i+1:p) = 0$  and  $v(p-k+i) = 1$ ;  $v(1:p-k+i-1)$  is stored on exit in  $B(i_b+n-k+i-1, j_b:j_b+p-k+i-2)$ , and  $\tau_{b_i}$  in  $\tau_{b_i}[i_b+n-k+i-2]$ . To form  $Z$  explicitly, use ScaLAPACK function `p?orgqr/p?ungrq`. To use  $Z$  to update another matrix, use ScaLAPACK function `p?ormrqr/p?unmrq`.

### Description

The `p?ggrqf` function forms the generalized RQ factorization of an  $m$ -by- $n$  matrix  $\text{sub}(A) = A(i_a:i_a+m-1, j_a:j_a+n-1)$  and a  $p$ -by- $n$  matrix  $\text{sub}(B) = B(i_b:i_b+p-1, j_b:j_b+n-1)$ :

$$\text{sub}(A) = R*Q, \text{ sub}(B) = Z*T*Q,$$

where  $Q$  is an  $n$ -by- $n$  orthogonal/unitary matrix,  $Z$  is a  $p$ -by- $p$  orthogonal/unitary matrix, and  $R$  and  $T$  assume one of the forms:

$$R = \begin{pmatrix} 0 & R_{12} \\ n - m & m \end{pmatrix}, \text{ if } m \leq n,$$

or

$$R = \begin{pmatrix} R_{11} & m - n \\ R_{12} & n \end{pmatrix}, \text{ if } m > n$$

where  $R_{11}$  or  $R_{21}$  is upper triangular, and

$$T = \begin{pmatrix} T_{11} & n \\ 0 & p - n \end{pmatrix}, \text{ if } p \geq n$$

or

$$T = \begin{pmatrix} T_{11} & T_{12} \\ p & n - p \end{pmatrix}, \text{ if } p < n,$$

where  $T_{11}$  is upper triangular.

In particular, if  $\text{sub}(B)$  is square and nonsingular, the  $GRQ$  factorization of  $\text{sub}(A)$  and  $\text{sub}(B)$  implicitly gives the  $RQ$  factorization of  $\text{sub}(A)*\text{inv}(\text{sub}(B))$ :

$$\text{sub}(A)*\text{inv}(\text{sub}(B)) = (R*\text{inv}(T))*Z'$$

where  $\text{inv}(\text{sub}(B))$  denotes the inverse of the matrix  $\text{sub}(B)$ , and  $Z'$  denotes the transpose (conjugate transpose) of matrix  $Z$ .

## Input Parameters

$m$	(global) The number of rows in the distributed matrices $\text{sub}(A)$ ( $m \geq 0$ ).
$p$	The number of rows in the distributed matrix $\text{sub}(B)$ ( $p \geq 0$ ).
$n$	(global) The number of columns in the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$ ( $n \geq 0$ ).
$a$	(local) Pointer into the local memory to an array of size $ld_a*LOCc(j_a+n-1)$ . Contains the local pieces of the $m$ -by- $n$ distributed matrix $\text{sub}(A)$ to be factored.
$ia, ja$	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.

<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local) Pointer into the local memory to an array of size $lld\_b * LOCC(jb+n-1)$ . Contains the local pieces of the <i>p</i> -by- <i>n</i> matrix sub( <i>B</i> ) to be factored.
<i>ib, jb</i>	(global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .
<i>work</i>	(local) Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) Size of <i>work</i> , must be at least $lwork \geq \max(mb\_a * (mpa0 + nqa0 + mb\_a), \max((mb\_a * (mb\_a - 1)) / 2, (ppb0 + nqb0) * mb\_a) + mb\_a * mb\_a, nb\_b * (ppb0 + nqb0 + nb\_b))$ , where $iroffa = \text{mod}(ia-1, mb\_A),$ $icoffa = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$ $mpa0 = \text{numroc}(m + iroffa, mb\_a, MYROW, iarow, NPROW),$ $nqa0 = \text{numroc}(m + icoffa, nb\_a, MYCOL, iacol, NPCOL)$ $iroffb = \text{mod}(ib-1, mb\_b),$ $icoffb = \text{mod}(jb-1, nb\_b),$ $ibrow = \text{indxg2p}(ib, mb\_b, MYROW, rsrc\_b, NPROW),$ $ibcol = \text{indxg2p}(jb, nb\_b, MYCOL, csrc\_b, NPCOL),$ $ppb0 = \text{numroc}(p + iroffb, mb\_b, MYROW, ibrow, NPROW),$ $nqb0 = \text{numroc}(n + icoffb, nb\_b, MYCOL, ibcol, NPCOL)$

**NOTE**

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

and `numroc`, `indxg2p` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

<code>a</code>	On exit, if $m \leq n$ , the upper triangle of $A(ia:ia+m-1, ja+n-m:ja+n-1)$ contains the $m$ -by- $m$ upper triangular matrix $R$ ; if $m \geq n$ , the elements on and above the $(m-n)$ -th subdiagonal contain the $m$ -by- $n$ upper trapezoidal matrix $R$ ; the remaining elements, with the array <code>taua</code> , represent the orthogonal/unitary matrix $Q$ as a product of $\min(n,m)$ elementary reflectors (see <i>Application Notes</i> below).
<code>taua, taub</code>	(local) Arrays of size $LOCr(ia+m-1)$ for <code>taua</code> and $LOCc(jb+\min(p,n)-1)$ for <code>taub</code> .  The array <code>taua</code> contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix $Q$ . <code>taua</code> is tied to the distributed matrix $A$ . (See <i>Application Notes</i> below).  The array <code>taub</code> contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix $Z$ . <code>taub</code> is tied to the distributed matrix $B$ . (See <i>Application Notes</i> below).
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful.  < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then <code>info</code> = $-(i*100+j)$ ; if the $i$ -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$ .

## Application Notes

The matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(ia)*H(ia+1)*...*H(ia+k-1),$$

where  $k = \min(m, n)$ .

Each  $H(i)$  has the form

$$H(i) = I - \tau_a * v * v'$$

where  $\tau_a$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(n-k+i+1:n) = 0$  and  $v(n-k+i) = 1$ ;  $v(1:n-k+i-1)$  is stored on exit in  $A(ia+m-k+i-1, ja:ja+n-k+i-2)$ , and  $\tau_a$  in `taua[ia+m-k+i-2]`. To form  $Q$  explicitly, use ScaLAPACK function `p?orgqr/p?ungrq`. To use  $Q$  to update another matrix, use ScaLAPACK function `p?ormqr/p?unmrq`.

The matrix  $Z$  is represented as a product of elementary reflectors

$$Z = H(jb)*H(jb+1)*...*H(jb+k-1), \text{ where } k = \min(p, n).$$

Each  $H(i)$  has the form

$$H(i) = I - \tau_b * v * v'$$

where  $\tau_b$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(1:i-1) = 0$  and  $v(i) = 1$ ;  $v(i+1:p)$  is stored on exit in  $B(ib+i:ib+p-1, jb+i-1)$ , and  $\tau_b$  in `taub[jb+i-2]`. To form  $Z$  explicitly, use ScaLAPACK function `p?orgqr/p?ungqr`. To use  $Z$  to update another matrix, use ScaLAPACK function `p?ormqr/p?unmqr`.

## Symmetric Eigenvalue Problems: ScaLAPACK Computational Routines

To solve a symmetric eigenproblem with ScaLAPACK, you usually need to reduce the matrix to real tridiagonal form  $T$  and then find the eigenvalues and eigenvectors of the tridiagonal matrix  $T$ . ScaLAPACK includes routines for reducing the matrix to a tridiagonal form by an orthogonal (or unitary) similarity transformation  $A = QTQ^H$  as well as for solving tridiagonal symmetric eigenvalue problems. These routines are listed in [Table "Computational Routines for Solving Symmetric Eigenproblems"](#).

There are different routines for symmetric eigenproblems, depending on whether you need eigenvalues only or eigenvectors as well, and on the algorithm used (either the  $QTQ$  algorithm, or bisection followed by inverse iteration).

### Computational Routines for Solving Symmetric Eigenproblems

Operation	Dense symmetric/ Hermitian matrix	Orthogonal/unitary matrix	Symmetric tridiagonal matrix
Reduce to tridiagonal form $A = QTQ^H$	<a href="#">p?sytrd/p?hetrd</a>		
Multiply matrix after reduction		<a href="#">p?ormtr/p?unmtr</a>	
Find all eigenvalues and eigenvectors of a tridiagonal matrix $T$ by a $QTQ$ method			<a href="#">steqr2*</a>
Find selected eigenvalues of a tridiagonal matrix $T$ via bisection			<a href="#">p?stebz</a>
Find selected eigenvectors of a tridiagonal matrix $T$ by inverse iteration			<a href="#">p?stein</a>

\* This routine is described as part of auxiliary ScaLAPACK routines.

### [p?syngst](#)

*Reduces a complex Hermitian-definite generalized eigenproblem to standard form.*

### Syntax

### Description

`p?syngst` reduces a complex Hermitian-definite generalized eigenproblem to standard form.

`p?syngst` performs the same function as `p?hegst`, but is based on rank 2K updates, which are faster and more scalable than triangular solves (the basis of `p?syngst`).

`p?syngst` calls `p?hegst` when `uplo='U'`, hence `p?hengst` provides improved performance only when `uplo='L'`, `ibtype=1`.

`p?syngst` also calls `p?hegst` when insufficient workspace is provided, hence `p?syngst` provides improved performance only when  $lwork \geq 2 * NP0 * NB + NQ0 * NB + NB * NB$

In the following `sub( A )` denotes  $A( ia:ia+n-1, ja:ja+n-1 )$  and `sub( B )` denotes  $B( ib:ib+n-1, jb:jb+n-1 )$ .

If `ibtype = 1`, the problem is  $sub( A ) * x = lambda * sub( B ) * x$ , and `sub( A )` is overwritten by  $inv(U^H) * sub( A ) * inv(U)$  or  $inv(L) * sub( A ) * inv(L^H)$

If `ibtype = 2` or `3`, the problem is  $sub( A ) * sub( B ) * x = lambda * x$  or  $sub( B ) * sub( A ) * x = lambda * x$ , and `sub( A )` is overwritten by  $U * sub( A ) * U^H$  or  $L^H * sub( A ) * L$ .

`sub( B )` must have been previously factorized as  $U^H * U$  or  $L * L^H$  by `p?potrf`.

## Input Parameters

<code>ibtype</code>	(global) = 1: compute $inv(U^H) * sub( A ) * inv(U)$ or $inv(L) * sub( A ) * inv(L^H)$ ; = 2 or 3: compute $U * sub( A ) * U^H$ or $L^H * sub( A ) * L$ .
<code>uplo</code>	(global) = 'U': Upper triangle of <code>sub( A )</code> is stored and <code>sub( B )</code> is factored as $U^H * U$ ; = 'L': Lower triangle of <code>sub( A )</code> is stored and <code>sub( B )</code> is factored as $L * L^H$ .
<code>n</code>	(global) The order of the matrices <code>sub( A )</code> and <code>sub( B )</code> . $n \geq 0$ .
<code>a</code>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ . On entry, this array contains the local pieces of the $n$ -by- $n$ Hermitian distributed matrix <code>sub( A )</code> . If <code>uplo = 'U'</code> , the leading $n$ -by- $n$ upper triangular part of <code>sub( A )</code> contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <code>uplo = 'L'</code> , the leading $n$ -by- $n$ lower triangular part of <code>sub( A )</code> contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.
<code>ia</code>	(global) A's global row index, which points to the beginning of the submatrix which is to be operated on.
<code>ja</code>	(global) A's global column index, which points to the beginning of the submatrix which is to be operated on.
<code>desca</code>	(global and local) Array of size $dlen\_$ . The array descriptor for the distributed matrix A.
<code>b</code>	(local) Pointer into the local memory to an array of size $lld\_b * LOCC(jb+n-1)$ .

On entry, this array contains the local pieces of the triangular factor from the Cholesky factorization of  $\text{sub}(B)$ , as returned by `p?potrf`.

<i>ib</i>	(global) <i>B</i> 's global row index, which points to the beginning of the submatrix which is to be operated on.
<i>jb</i>	(global) <i>B</i> 's global column index, which points to the beginning of the submatrix which is to be operated on.
<i>descb</i>	(global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .
<i>work</i>	(local) Array, size ( <i>lwork</i> )
<i>lwork</i>	(local or global) The size of the array <i>work</i> .  <i>lwork</i> is local input and must be at least $lwork \geq \text{MAX}(NB * (NPO + 1), 3 * NB)$  When <i>ibtype</i> = 1 and <i>uplo</i> = 'L', <code>p?syngst</code> provides improved performance when $lwork \geq 2 * NPO * NB + NQ0 * NB + NB * NB$ , where $NB = mb\_a = nb\_a$ , $NPO = \text{numroc}(n, NB, 0, 0, NPROW)$ , $NQ0 = \text{numroc}(n, NB, 0, 0, NPROW)$ , <code>numroc</code> is a ScalAPACK tool functions  MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine <code>blacs_gridinfo</code> .  If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>p?xerbla</code> .

## Output Parameters

<i>a</i>	On exit, if <i>info</i> = 0, the transformed matrix, stored in the same format as $\text{sub}(A)$ .
<i>scale</i>	(global) Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this routine. At present, <i>scale</i> is always returned as 1.0, it is returned here to allow for future enhancement.
<i>work</i>	(local) Array, size ( <i>lwork</i> )

On exit, `work[0]` returns the minimal and optimal `lwork`.

`info`

(global)

= 0: successful exit

< 0: If the  $i$ -th argument is an array and the  $j$ -th entry had an illegal value, then  $info = -(j*100+i)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

## p?sytrd

Reduces a real symmetric matrix to symmetric tridiagonal form.

### Syntax

```
void pssytrd (const char* uplo, const MKL_INT* n, float* a, const MKL_INT* ia, const
MKL_INT* ja, const MKL_INT* desca, float* d, float* e, float* tau, float* work, const
MKL_INT* lwork, MKL_INT* info);
```

```
void pdsytrd (const char* uplo, const MKL_INT* n, double* a, const MKL_INT* ia, const
MKL_INT* ja, const MKL_INT* desca, double* d, double* e, double* tau, double* work,
const MKL_INT* lwork, MKL_INT* info);
```

### Include Files

- `mkl_scalapack.h`

### Description

`p?sytrd` is a prototype version of `p?sytrd` which uses tailored codes (either the serial, `?sytrd`, or the parallel code, `p?sytrd`) when the workspace provided by the user is adequate.

`p?sytrd` reduces a real symmetric matrix  $\text{sub}(A)$  to symmetric tridiagonal form  $T$  by an orthogonal similarity transformation:

$$Q' * \text{sub}(A) * Q = T, \text{ where } \text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1).$$

### Features

`p?sytrd` is faster than `p?sytrd` on almost all matrices, particularly small ones (i.e.  $n < 500 * \text{sqrt}(P)$ ), provided that enough workspace is available to use the tailored codes.

The tailored codes provide performance that is essentially independent of the input data layout.

The tailored codes place no restrictions on `ia`, `ja`, `MB` or `NB`. At present, `ia`, `ja`, `MB` and `NB` are restricted to those values allowed by `p?hetrd` to keep the interface simple (see the Application Notes section for more information about the restrictions).

### Input Parameters

`uplo`

(global)

Specifies whether the upper or lower triangular part of the symmetric matrix  $\text{sub}(A)$  is stored:

= 'U': Upper triangular

= 'L': Lower triangular

`n`

(global)

The number of rows and columns to be operated on, i.e. the order of the distributed submatrix  $\text{sub}(A)$ .  $n \geq 0$ .

<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ . On entry, this array contains the local pieces of the symmetric distributed matrix $\text{sub}(A)$ . If <i>uplo</i> = 'U', the leading $n$ -by- $n$ upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = 'L', the leading $n$ -by- $n$ lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.
<i>ia</i>	(global) The row index in the global array <i>a</i> indicating the first row of $\text{sub}(A)$ .
<i>ja</i>	(global) The column index in the global array <i>a</i> indicating the first column of $\text{sub}(A)$ .
<i>desca</i>	(global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) Array, size ( <i>lwork</i> )
<i>lwork</i>	(local or global) The size of the array <i>work</i> .  <i>lwork</i> is local input and must be at least $lwork \geq \text{MAX}(NB * (NP + 1), 3 * NB)$  For optimal performance, greater workspace is needed, i.e. $lwork \geq 2 * (ANB + 1) * (4 * NPS + 2) + (NPS + 4) * NPS$ $ANB = \text{pjlaenv}(ICTXT, 3, 'p?sytttrd', 'L', 0, 0, 0, 0)$ $ICTXT = \text{desca}(ctxt\_)$ $SQNPC = \text{INT}(\text{sqrt}(\text{REAL}(NPROW * NPCOL)))$ <i>numroc</i> is a ScaLAPACK tool function. <i>pjlaenv</i> is a ScaLAPACK environmental inquiry function. <i>NPROW</i> and <i>NPCOL</i> can be determined by calling the subroutine <i>blacs_gridinfo</i> .

## Output Parameters

<i>a</i>	On exit, if <i>uplo</i> = 'U', the diagonal and first superdiagonal of $\text{sub}(A)$ are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements above the first superdiagonal, with the array <i>tau</i> , represent the orthogonal matrix <i>Q</i> as a product of elementary reflectors; if <i>uplo</i> = 'L', the diagonal and first subdiagonal
----------	--

of  $\text{sub}(A)$  are overwritten by the corresponding elements of the tridiagonal matrix  $T$ , and the elements below the first subdiagonal, with the array  $\tau$ , represent the orthogonal matrix  $Q$  as a product of elementary reflectors. See **Further Details**.

$d$	(local) Array, size $\text{LOCc}(ja+n-1)$  The diagonal elements of the tridiagonal matrix $T$ : $d(i) = A(i,i)$ . $d$ is tied to the distributed matrix $A$ .
$e$	(local) Array, size $\text{LOCc}(ja+n-1)$ if $\text{uplo} = 'U'$ , $\text{LOCc}(ja+n-2)$ otherwise.  The off-diagonal elements of the tridiagonal matrix $T$ : $e(i) = A(i,i+1)$ if $\text{uplo} = 'U'$ , $e(i) = A(i+1,i)$ if $\text{uplo} = 'L'$ . $e$ is tied to the distributed matrix $A$ .
$\tau$	(local) Array, size $\text{LOCc}(ja+n-1)$ .  This array contains the scalar factors $\tau$ of the elementary reflectors. $\tau$ is tied to the distributed matrix $A$ .
$\text{work}$	(local) Array, size ( $\text{lwork}$ )  On exit, $\text{work}[0]$ returns the optimal $\text{lwork}$ .
$\text{info}$	(global) = 0: successful exit  < 0: If the $i$ -th argument is an array and the $j$ -th entry had an illegal value, then $\text{info} = -(j*100+i)$ , if the $i$ -th argument is a scalar and had an illegal value, then $\text{info} = -i$ .

## Application Notes

If  $\text{uplo} = 'U'$ , the matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each  $H(i)$  has the form

$H(i) = I - \tau * v * v'$ , where  $\tau$  is a complex scalar, and  $v$  is a complex vector with  $v(i+1:n) = 0$  and  $v(i) = 1$ ;  $v(1:i-1)$  is stored on exit in  $A(ia:ia+i-2, ja+i)$ , and  $\tau$  in  $\tau(ja+i-1)$ .

If  $\text{uplo} = 'L'$ , the matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n-1).$$

Each  $H(i)$  has the form

$H(i) = I - \tau * v * v'$ , where  $\tau$  is a complex scalar, and  $v$  is a complex vector with  $v(1:i) = 0$  and  $v(i+1) = 1$ ;  $v(i+2:n)$  is stored on exit in  $A(ia+i+1:ia+n-1, ja+i-1)$ , and  $\tau$  in  $\tau(ja+i-1)$ .

The contents of  $\text{sub}(A)$  on exit are illustrated by the following examples with  $n = 5$ :

if  $\text{uplo} = 'U'$ :

$$\begin{pmatrix} d & e & v2 & v3 & v4 \\ & d & e & v3 & v4 \\ & & d & e & v3 \\ & & & d & e \\ & & & & d \end{pmatrix}$$

if *uplo* = 'L':

$$\begin{pmatrix} d & & & & \\ e & d & & & \\ v1 & e & d & & \\ v1 & v2 & e & d & \\ v1 & v2 & v3 & e & d \end{pmatrix}$$

where *d* and *e* denote diagonal and off-diagonal elements of *T*, and *vi* denotes an element of the vector defining *H(i)*.

### Alignment requirements

The distributed submatrix sub( *A* ) must verify some alignment properties, namely the following expression should be true:

( *mb\_a* = *nb\_a* and *IROFFA* = *ICOFFA* and *IROFFA* = 0 ) with *IROFFA* = mod( *ia*-1, *mb\_a*), and *ICOFFA* = mod( *ja*-1, *nb\_a* ).

### p?sytrd

*Reduces a symmetric matrix to real symmetric tridiagonal form by an orthogonal similarity transformation.*

---

### Syntax

```
void pssytrd (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *d , float *e , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdsytrd (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *d , double *e , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

### Include Files

- mkl\_scalapack.h

### Description

The p?sytrd function reduces a real symmetric matrix sub(*A*) to symmetric tridiagonal form *T* by an orthogonal similarity transformation:

$$Q^* \text{sub}(A) Q = T,$$

where sub(*A*) = *A*(*ia:ia+n-1,ja:ja+n-1*).

### Input Parameters

*uplo* (global)  
 Specifies whether the upper or lower triangular part of the symmetric matrix sub(*A*) is stored:  
 If *uplo* = 'U', upper triangular

	If <code>uplo = 'L'</code> , lower triangular
<code>n</code>	(global) The order of the distributed matrix <code>sub(A)</code> ( $n \geq 0$ ).
<code>a</code>	(local) Pointer into the local memory to an array of size <code>lld_a*LOCc(ja+n-1)</code> . On entry, this array contains the local pieces of the symmetric distributed matrix <code>sub(A)</code> . If <code>uplo = 'U'</code> , the leading $n$ -by- $n$ upper triangular part of <code>sub(A)</code> contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <code>uplo = 'L'</code> , the leading $n$ -by- $n$ lower triangular part of <code>sub(A)</code> contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. See <i>Application Notes</i> below.
<code>ia, ja</code>	(global) The row and column indices in the global matrix <code>A</code> indicating the first row and the first column of the submatrix <code>A</code> , respectively.
<code>desca</code>	(global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix <code>A</code> .
<code>work</code>	(local) Workspace array of size <code>lwork</code> .
<code>lwork</code>	(local or global) size of <code>work</code> , must be at least: $lwork \geq \max(NB*(np + 1), 3*NB)$ , where $NB = mb\_a = nb\_a$ , $np = \text{numroc}(n, NB, MYROW, iarow, NPROW)$ , $iarow = \text{indxg2p}(ia, NB, MYROW, rsrc\_a, NPROW)$ . <code>indxg2p</code> and <code>numroc</code> are ScaLAPACK tool functions; <code>MYROW</code> , <code>MYCOL</code> , <code>NPROW</code> and <code>NPCOL</code> can be determined by calling the function <code>blacs_gridinfo</code> . If <code>lwork = -1</code> , then <code>lwork</code> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> .

## Output Parameters

<code>a</code>	On exit, if <code>uplo = 'U'</code> , the diagonal and first superdiagonal of <code>sub(A)</code> are overwritten by the corresponding elements of the tridiagonal matrix <code>T</code> , and the elements above the first superdiagonal, with the array <code>tau</code> , represent the orthogonal matrix <code>Q</code> as a product of elementary reflectors; if <code>uplo = 'L'</code> , the diagonal and first subdiagonal of <code>sub(A)</code> are overwritten by the corresponding elements of the tridiagonal matrix <code>T</code> , and the elements below the first subdiagonal, with the array <code>tau</code> , represent the orthogonal matrix <code>Q</code> as a product of elementary reflectors. See <i>Application Notes</i> below.
<code>d</code>	(local) Arrays of size <code>LOCc(ja+n-1)</code> . The diagonal elements of the tridiagonal matrix <code>T</code> :

$d[i] = A(i+1, i+1), 0 \leq i < LOCC(ja+n-1).$

$d$  is tied to the distributed matrix  $A$ .

$e$

(local)

Arrays of size  $LOCC(ja+n-1)$  if  $uplo = 'U'$ ,  $LOCC(ja+n-2)$  otherwise.

The off-diagonal elements of the tridiagonal matrix  $T$ :

$e[i] = A(i+1, i+2), 0 \leq i < LOCC(ja+n-1)$  if  $uplo = 'U'$ ,

$e[i] = A(i+2, i+1)$  if  $uplo = 'L'$ .

$e$  is tied to the distributed matrix  $A$ .

$tau$

(local)

Arrays of size  $LOCC(ja+n-1)$ . This array contains the scalar factors of the elementary reflectors.  $tau$  is tied to the distributed matrix  $A$ .

$work[0]$

On exit  $work[0]$  contains the minimum value of  $lwork$  required for optimum performance.

$info$

(global)

$= 0$ : the execution is successful.

$< 0$ : if the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j - 1$ , had an illegal value, then  $info = -(i*100+j)$ ; if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

## Application Notes

If  $uplo = 'U'$ , the matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each  $H(i)$  has the form

$$H(i) = I - \tau * v * v',$$

where  $\tau$  is a real scalar, and  $v$  is a real vector with  $v(i+1:n) = 0$  and  $v(i) = 1$ ;  $v(1:i-1)$  is stored on exit in  $A(ia:ia+i-2, ja+i)$ , and  $\tau$  in  $tau[ja+i-2]$ .

If  $uplo = 'L'$ , the matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n-1).$$

Each  $H(i)$  has the form

$$H(i) = I - \tau * v * v',$$

where  $\tau$  is a real scalar, and  $v$  is a real vector with  $v(1:i) = 0$  and  $v(i+1) = 1$ ;  $v(i+2:n)$  is stored on exit in  $A(ia+i+1:ia+n-1, ja+i-1)$ , and  $\tau$  in  $tau[ja+i-2]$ .

The contents of sub( $A$ ) on exit are illustrated by the following examples with  $n = 5$ :

If  $uplo = 'U'$ :

$$\begin{bmatrix} d & e & v2 & v3 & v4 \\ & d & e & v3 & v4 \\ & & d & e & v4 \\ & & & d & e \\ & & & & d \end{bmatrix}$$

If `uplo = 'L'`:

$$\begin{bmatrix} d & & & & \\ e & d & & & \\ v1 & e & d & & \\ v1 & v2 & e & d & \\ v1 & v2 & v3 & e & d \end{bmatrix}$$

where  $d$  and  $e$  denote diagonal and off-diagonal elements of  $T$ , and  $v_i$  denotes an element of the vector defining  $H(i)$ .

## p?ormtr

*Multiplies a general matrix by the orthogonal transformation matrix from a reduction to tridiagonal form determined by p?sytrd.*

## Syntax

```
void psormtr (char *side , char *uplo , char *trans , MKL_INT *m , MKL_INT *n , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *c , MKL_INT *ic ,
MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdormtr (char *side , char *uplo , char *trans , MKL_INT *m , MKL_INT *n , double
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT *lwork , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

This function overwrites the general real distributed  $m$ -by- $n$  matrix  $\text{sub}(C) = C(ic:ic+m-1, jc: jc+n-1)$  with

	<code>side = 'L'</code>	<code>side = 'R'</code>
<code>trans = 'N':</code>	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
<code>trans = 'T':</code>	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where  $Q$  is a real orthogonal distributed matrix of order  $nq$ , with  $nq = m$  if `side = 'L'` and  $nq = n$  if `side = 'R'`.

$Q$  is defined as the product of  $nq$  elementary reflectors, as returned by `p?sytrd`.

If `uplo = 'U'`,  $Q = H(nq-1) \dots H(2) H(1)$ ;

If `uplo = 'L'`,  $Q = H(1) H(2) \dots H(nq-1)$ .

## Input Parameters

<code>side</code>	(global) = 'L': $Q$ or $Q^T$ is applied from the left. = 'R': $Q$ or $Q^T$ is applied from the right.
<code>trans</code>	(global) = 'N', no transpose, $Q$ is applied. = 'T', transpose, $Q^T$ is applied.
<code>uplo</code>	(global) = 'U': Upper triangle of $A(ia:*, ja:*)$ contains elementary reflectors from <code>p?sytrd</code> ; = 'L': Lower triangle of $A(ia:*, ja:*)$ contains elementary reflectors from <code>p?sytrd</code>
<code>m</code>	(global) The number of rows in the distributed matrix sub( $C$ ) ( $m \geq 0$ ).
<code>n</code>	(global) The number of columns in the distributed matrix sub( $C$ ) ( $n \geq 0$ ).
<code>a</code>	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(ja+m-1)$ if <code>side = 'L'</code> , and $lld\_a * LOCc(ja+n-1)$ if <code>side = 'R'</code> . Contains the vectors that define the elementary reflectors, as returned by <code>p?sytrd</code> . If <code>side='L'</code> , $lld\_a \geq \max(1, LOCr(ia+m-1))$ ; If <code>side='R'</code> , $lld\_a \geq \max(1, LOCr(ia+n-1))$ .
<code>ia, ja</code>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
<code>desca</code>	(global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix $A$ .
<code>tau</code>	(local) Array of size of <code>ltau</code> where if <code>side = 'L'</code> and <code>uplo = 'U'</code> , $ltau = LOCc(m\_a)$ , if <code>side = 'L'</code> and <code>uplo = 'L'</code> , $ltau = LOCc(ja+m-2)$ , if <code>side = 'R'</code> and <code>uplo = 'U'</code> , $ltau = LOCc(n\_a)$ , if <code>side = 'R'</code> and <code>uplo = 'L'</code> , $ltau = LOCc(ja+n-2)$ . $tau[i]$ must contain the scalar factor of the elementary reflector $H(i+1)$ , as returned by <code>p?sytrd</code> ( $0 \leq i < ltau$ ). $tau$ is tied to the distributed matrix $A$ .
<code>c</code>	(local)

	Pointer into the local memory to an array of size $lld\_c * LOCC(jc+n-1)$ . Contains the local pieces of the distributed matrix sub ( $C$ ).
<i>ic, jc</i>	(global) The row and column indices in the global matrix $C$ indicating the first row and the first column of the submatrix $C$ , respectively.
<i>desc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $C$ .
<i>work</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least: <pre> if uplo = 'U',   iaa= ia; jaa= ja+1, icc= ic; jcc= jc; else uplo = 'L',   iaa= ia+1, jaa= ja; If side = 'L',   icc= ic+1; jcc= jc; else icc= ic; jcc= jc+1; end if end if If side = 'L', mi= m-1; ni= n lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 + mpc0)*nb_a) + nb_a*nb_a else If side = 'R', mi= m; ni = n-1; lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 + max(npa0+numroc(numroc(ni+icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0))*nb_a) + nb_a*nb_a end if where lcmq = lcm/NPCOL with lcm = ilcm(NPROW, NPCOL), iroffa = mod(iaa-1, mb_a), icoffa = mod(jaa-1, nb_a), iarow = indxg2p(iaa, mb_a, MYROW, rsrc_a, NPROW), npa0 = numroc(ni+iroffa, mb_a, MYROW, iarow, NPROW), iroffc = mod(icc-1, mb_c), icoffc = mod(jcc-1, nb_c), icrow = indxg2p(icc, mb_c, MYROW, rsrc_c, NPROW), </pre>

```

iccol = indxg2p(jcc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

**NOTE**

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`. If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?xerbla`.

**Output Parameters**

<code>c</code>	Overwritten by the product $Q \cdot \text{sub}(C)$ , or $Q' \cdot \text{sub}(C)$ , or $\text{sub}(C) \cdot Q'$ , or $\text{sub}(C) \cdot Q$ .
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then <code>info = -(i*100+j)</code> ; if the $i$ -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

## Description

`p?hengst` reduces a complex Hermitian-definite generalized eigenproblem to standard form.

`p?hengst` performs the same function as `p?hegst`, but is based on rank 2K updates, which are faster and more scalable than triangular solves (the basis of `p?hengst`).

`p?hengst` calls `p?hegst` when `uplo='U'`, hence `p?hengst` provides improved performance only when `uplo='L'` and `ibtype=1`.

`p?hengst` also calls `p?hegst` when insufficient workspace is provided, hence `p?hengst` provides improved performance only when `lwork` is sufficient (as described in the parameter descriptions).

In the following `sub( A )` denotes the submatrix  $A( ia:ia+n-1, ja:ja+n-1 )$  and `sub( B )` denotes the submatrix  $B( ib:ib+n-1, jb:jb+n-1 )$ .

If `ibtype = 1`, the problem is  $sub( A ) * x = lambda * sub( B ) * x$ , and `sub( A )` is overwritten by  $inv(U^H) * sub( A ) * inv(U)$  or  $inv(L) * sub( A ) * inv(L^H)$

If `ibtype = 2` or `3`, the problem is  $sub( A ) * sub( B ) * x = lambda * x$  or  $sub( B ) * sub( A ) * x = lambda * x$ , and `sub( A )` is overwritten by  $U * sub( A ) * U^H$  or  $L^H * sub( A ) * L$ .

`sub( B )` must have been previously factorized as  $U^H * U$  or  $L * L^H$  by `p?potrf`.

## Input Parameters

<code>ibtype</code>	(global) = 1: compute $inv(U^H) * sub( A ) * inv(U)$ or $inv(L) * sub( A ) * inv(L^H)$ ; = 2 or 3: compute $U * sub( A ) * U^H$ or $L^H * sub( A ) * L$ .
<code>uplo</code>	(global) = 'U': Upper triangle of <code>sub( A )</code> is stored and <code>sub( B )</code> is factored as $U^H * U$ ; = 'L': Lower triangle of <code>sub( A )</code> is stored and <code>sub( B )</code> is factored as $L * L^H$ .
<code>n</code>	(global) The order of the matrices <code>sub( A )</code> and <code>sub( B )</code> . $n \geq 0$ .
<code>a</code>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ . On entry, this array contains the local pieces of the $n$ -by- $n$ Hermitian distributed matrix <code>sub( A )</code> . If <code>uplo = 'U'</code> , the leading $n$ -by- $n$ upper triangular part of <code>sub( A )</code> contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <code>uplo = 'L'</code> , the leading $n$ -by- $n$ lower triangular part of <code>sub( A )</code> contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.
<code>ia</code>	(global) Global row index of matrix $A$ , which points to the beginning of the submatrix on which to operate.
<code>ja</code>	(global) Global column index of matrix $A$ , which points to the beginning of the submatrix on which to operate.

<i>desca</i>	(global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local) Pointer into the local memory to an array of size $lld\_b * LOCC(jb+n-1)$ .
<i>ib</i>	(global) Global row index of matrix <i>B</i> , which points to the beginning of the submatrix on which to operate.
<i>jb</i>	(global) Global column index of matrix <i>B</i> , which points to the beginning of the submatrix on which to operate.
<i>descb</i>	(global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .
<i>work</i>	(local) Array, size ( <i>lwork</i> ) On exit, <i>work</i> ( 1 ) returns the minimal and optimal <i>lwork</i> .
<i>lwork</i>	(local) The size of the array <i>work</i> .  <i>lwork</i> is local input and must be at least $lwork \geq \text{MAX}( NB * ( NPO + 1 ), 3 * NB )$ .  When <i>ibtype</i> = 1 and <i>uplo</i> = 'L', p?hengst provides improved performance when $lwork \geq 2 * NPO * NB + NQ0 * NB + NB * NB$ , where $NB = mb\_a = nb\_a$ , $NPO = \text{numroc}( n, NB, 0, 0, NPROW )$ , $NQ0 = \text{numroc}( n, NB, 0, 0, NPROW )$ , and <i>numroc</i> is a ScaLAPACK tool function.  MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine <i>blacs_gridinfo</i> .  If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>p?erbla</i> .

## Output Parameters

<i>a</i>	On exit, if <i>info</i> = 0, the transformed matrix, stored in the same format as sub( <i>A</i> ).
<i>scale</i>	(global) Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this routine.  <i>scale</i> is always returned as 1.0.

*work* On exit, *work*[0] returns the minimal and optimal *lwork*.

*info* (global)

= 0: successful exit

< 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* =  $-(i*100+j)$ , if the *i*-th argument is a scalar and had an illegal value, then *info* =  $-i$ .

## p?hentrnd

*Reduces a complex Hermitian matrix to Hermitian tridiagonal form.*

### Syntax

```
void pchentrnd (const char* uplo, const MKL_INT* n, MKL_Complex8* a, const MKL_INT* ia,
const MKL_INT* ja, const MKL_INT* desca, float* d, float* e, MKL_Complex8* tau,
MKL_Complex8* work, const MKL_INT* lwork, float* rwork, const MKL_INT* lrwork, MKL_INT*
info);
```

```
void pzhentrnd (const char* uplo, const MKL_INT* n, MKL_Complex16* a, const MKL_INT* ia,
const MKL_INT* ja, const MKL_INT* desca, double* d, double* e, MKL_Complex16* tau,
MKL_Complex16* work, const MKL_INT* lwork, double* rwork, const MKL_INT* lrwork,
MKL_INT* info);
```

### Include Files

- mkl\_scalapack.h

### Description

p?hentrnd is a prototype version of p?hetrd which uses tailored codes (either the serial, ?hetrd, or the parallel code, p?hettrd) when adequate workspace is provided.

p?hentrnd reduces a complex Hermitian matrix  $\text{sub}(A)$  to Hermitian tridiagonal form  $T$  by an unitary similarity transformation:

$$Q' * \text{sub}(A) * Q = T, \text{ where } \text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1).$$

p?hentrnd is faster than p?hetrd on almost all matrices, particularly small ones (i.e.  $n < 500 * \text{sqrt}(P)$ ), provided that enough workspace is available to use the tailored codes.

The tailored codes provide performance that is essentially independent of the input data layout.

The tailored codes place no restrictions on *ia*, *ja*, MB or NB. At present, *ia*, *ja*, MB and NB are restricted to those values allowed by p?hetrd to keep the interface simple (see the Application Notes section for more information about the restrictions).

### Input Parameters

*uplo* (global)

Specifies whether the upper or lower triangular part of the Hermitian matrix  $\text{sub}(A)$  is stored:

= 'U': Upper triangular

= 'L': Lower triangular

*n* (global)

The number of rows and columns to be operated on, i.e. the order of the distributed submatrix  $\text{sub}(A)$ .  $n \geq 0$ .

<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ . On entry, this array contains the local pieces of the Hermitian distributed matrix $\text{sub}(A)$ . If <i>uplo</i> = 'U', the leading $n$ -by- $n$ upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = 'L', the leading $n$ -by- $n$ lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.
<i>ia</i>	(global) The row index in the global array <i>a</i> indicating the first row of $\text{sub}(A)$ .
<i>ja</i>	(global) The column index in the global array <i>a</i> indicating the first column of $\text{sub}(A)$ .
<i>desca</i>	(global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) Array, size ( <i>lwork</i> )
<i>lwork</i>	(local or global) The size of the array <i>work</i> .  <i>lwork</i> is local input and must be at least $lwork \geq \text{MAX}(NB * (NP + 1), 3 * NB)$ .  For optimal performance, greater workspace is needed: $lwork \geq 2 * (ANB + 1) * (4 * NPS + 2) + (NPS + 4) * NPS$ $ANB = \text{pjlaenv}(ICTXT, 3, 'p?hettrd', 'L', 0, 0, 0, 0)$ $ICTXT = \text{desca}(ctxt_)$ $SQNPC = \text{INT}(\text{sqrt}(\text{REAL}(NPROW * NPCOL)))$ $NPS = \text{MAX}(\text{numroc}(n, 1, 0, 0, SQNPC), 2 * ANB)$ <i>numroc</i> is a ScaLAPACK tool function. <i>pjlaenv</i> is a ScaLAPACK environmental inquiry function. <i>NPROW</i> and <i>NPCOL</i> can be determined by calling the subroutine <i>blacs_gridinfo</i> .
<i>rwork</i>	(local) Array, size ( <i>lrwork</i> )
<i>lrwork</i>	(local or global) The size of the array <i>rwork</i> .

*lwork* is local input and must be at least  $lwork \geq 1$ .

For optimal performance, greater workspace is needed, i.e.  $lwork \geq \text{MAX}(2 * n)$

## Output Parameters

<i>a</i>	On exit, if <i>uplo</i> = 'U', the diagonal and first superdiagonal of sub( <i>A</i> ) are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements above the first superdiagonal, with the array <i>tau</i> , represent the unitary matrix <i>Q</i> as a product of elementary reflectors; if <i>uplo</i> = 'L', the diagonal and first subdiagonal of sub( <i>A</i> ) are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements below the first subdiagonal, with the array <i>tau</i> , represent the unitary matrix <i>Q</i> as a product of elementary reflectors. See Application Notes.
<i>d</i>	(local) Array, size $\text{LOCc}(ja+n-1)$ The diagonal elements of the tridiagonal matrix <i>T</i> : $d[i - 1] = A(i,i)$ . <i>d</i> is tied to the distributed matrix <i>A</i> .
<i>e</i>	(local) Array, size $\text{LOCc}(ja+n-1)$ if <i>uplo</i> = 'U', $\text{LOCc}(ja+n-2)$ otherwise. The off-diagonal elements of the tridiagonal matrix <i>T</i> : $e[i - 1] = A(i,i+1)$ if <i>uplo</i> = 'U', $e[i - 1] = A(i+1,i)$ if <i>uplo</i> = 'L'. <i>e</i> is tied to the distributed matrix <i>A</i> .
<i>tau</i>	(local) Array, size $\text{LOCc}(ja+n-1)$ . This array contains the scalar factors <i>tau</i> of the elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	On exit, <i>work</i> [0] returns the optimal <i>lwork</i> .
<i>rwork</i>	On exit, <i>rwork</i> [0] returns the optimal <i>lrwork</i> .
<i>info</i>	(global) = 0: successful exit < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then $info = -(j*100+i)$ , if the <i>i</i> -th argument is a scalar and had an illegal value, then $info = -i$ .

## Application Notes

If *uplo* = 'U', the matrix *Q* is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each *H*(*i*) has the form

$H(i) = I - \tau * v * v'$ , where *tau* is a complex scalar, and *v* is a complex vector with  $v(i+1:n) = 0$  and  $v(i) = 1$ ;  $v(1:i-1)$  is stored on exit in  $A(ia:ia+i-2,ja+i)$ , and *tau* in  $\tau(ja+i-1)$ .

If `uplo = 'L'`, the matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n-1).$$

Each  $H(i)$  has the form

$H(i) = I - \tau * v * v'$ , where  $\tau$  is a complex scalar, and  $v$  is a complex vector with  $v(1:i) = 0$  and  $v(i+1) = 1$ ;  $v(i+2:n)$  is stored on exit in  $A(ia+i+1:ia+n-1, ja+i-1)$ , and  $\tau$  in  $\tau(ja+i-1)$ .

The contents of `sub( A )` on exit are illustrated by the following examples with  $n = 5$ :

if `uplo = 'U'`:

$$\begin{pmatrix} d & e & v2 & v3 & v4 \\ & d & e & v3 & v4 \\ & & d & e & v3 \\ & & & d & e \\ & & & & d \end{pmatrix}$$

if `uplo = 'L'`:

$$\begin{pmatrix} d & & & & \\ e & d & & & \\ v1 & e & d & & \\ v1 & v2 & e & d & \\ v1 & v2 & v3 & e & d \end{pmatrix}$$

where  $d$  and  $e$  denote diagonal and off-diagonal elements of  $T$ , and  $v_i$  denotes an element of the vector defining  $H(i)$ .

### Alignment requirements

The distributed submatrix `sub( A )` must verify some alignment properties, namely the following expression should be true:

$(mb\_a = nb\_a \text{ and } IROFFA = ICOFFA \text{ and } IROFFA = 0)$  with  $IROFFA = \text{mod}( ia-1, mb\_a)$ , and  $ICOFFA = \text{mod}( ja-1, nb\_a)$ .

### p?hetrd

*Reduces a Hermitian matrix to Hermitian tridiagonal form by a unitary similarity transformation.*

---

### Syntax

```
void pchetrd (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *d , float *e , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pzhetrd (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *d , double *e , MKL_Complex16 *tau , MKL_Complex16 *work ,
MKL_INT *lwork , MKL_INT *info );
```

### Include Files

- `mkl_scalapack.h`

### Description

The `p?hetrd` function reduces a complex Hermitian matrix `sub(A)` to Hermitian tridiagonal form  $T$  by a unitary similarity transformation:

$$Q' * \text{sub}(A) * Q = T$$

where  $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ .

## Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the Hermitian matrix $\text{sub}(A)$ is stored: If <i>uplo</i> = 'U', upper triangular If <i>uplo</i> = 'L', lower triangular
<i>n</i>	(global) The order of the distributed matrix $\text{sub}(A)$ ( $n \geq 0$ ).
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ . On entry, this array contains the local pieces of the Hermitian distributed matrix $\text{sub}(A)$ . If <i>uplo</i> = 'U', the leading $n$ -by- $n$ upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = 'L', the leading $n$ -by- $n$ lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. (see <i>Application Notes</i> below).
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .
<i>work</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least: $lwork \geq \max(NB * (np + 1), 3 * NB)$ where $NB = mb\_a = nb\_a$ , $np = \text{numroc}(n, NB, MYROW, iarow, NPROW)$ , $iarow = \text{indxg2p}(ia, NB, MYROW, rsrc\_a, NPROW)$ . <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function <code>blacs_gridinfo</code> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> .

## Output Parameters

<i>a</i>	On exit,
----------	----------

If  $uplo = 'U'$ , the diagonal and first superdiagonal of  $sub(A)$  are overwritten by the corresponding elements of the tridiagonal matrix  $T$ , and the elements above the first superdiagonal, with the array  $tau$ , represent the unitary matrix  $Q$  as a product of elementary reflectors; if  $uplo = 'L'$ , the diagonal and first subdiagonal of  $sub(A)$  are overwritten by the corresponding elements of the tridiagonal matrix  $T$ , and the elements below the first subdiagonal, with the array  $tau$ , represent the unitary matrix  $Q$  as a product of elementary reflectors (see *Application Notes* below).

$d$	(local) Arrays of size $LOCc(ja+n-1)$ . The diagonal elements of the tridiagonal matrix $T$ : $d[i] = A(i+1, i+1)$ , $0 \leq i < LOCc(ja+n-1)$ . $d$ is tied to the distributed matrix $A$ .
$e$	(local) Arrays of size $LOCc(ja+n-1)$ if $uplo = 'U'$ ; $LOCc(ja+n-2)$ - otherwise. The off-diagonal elements of the tridiagonal matrix $T$ : $e[i] = A(i+1, i+2)$ , $0 \leq i < LOCc(ja+n-1)$ if $uplo = 'U'$ , $e[i] = A(i+2, i+1)$ if $uplo = 'L'$ . $e$ is tied to the distributed matrix $A$ .
$tau$	(local) Array of size $LOCc(ja+n-1)$ . This array contains the scalar factors of the elementary reflectors. $tau$ is tied to the distributed matrix $A$ .
$work[0]$	On exit $work[0]$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) = 0: the execution is successful. < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then $info = -(i*100+j)$ ; if the $i$ -th argument is a scalar and had an illegal value, then $info = -i$ .

## Application Notes

If  $uplo = 'U'$ , the matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(n-1) * \dots * H(2) * H(1).$$

Each  $H(i)$  has the form

$$H(i) = I - \tau * v * v',$$

where  $\tau$  is a complex scalar, and  $v$  is a complex vector with  $v(i+1:n) = 0$  and  $v(i) = 1$ ;  $v(1:i-1)$  is stored on exit in  $A(ia:ia+i-2, ja+i)$ , and  $\tau$  in  $tau[ja+i-2]$ .

If  $uplo = 'L'$ , the matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(n-1).$$

Each  $H(i)$  has the form

$$H(i) = i - \tau v v',$$

where  $\tau$  is a complex scalar, and  $v$  is a complex vector with  $v(1:i) = 0$  and  $v(i+1) = 1$ ;  $v(i+2:n)$  is stored on exit in  $A(ia+i+1:ia+n-1, ja+i-1)$ , and  $\tau$  in  $\tau[ja+i-2]$ .

The contents of  $\text{sub}(A)$  on exit are illustrated by the following examples with  $n = 5$ :

If  $\text{uplo} = 'U'$ :

$$\begin{bmatrix} d & e & v2 & v3 & v4 \\ & d & e & v3 & v4 \\ & & d & e & v4 \\ & & & d & e \\ & & & & d \end{bmatrix}$$

If  $\text{uplo} = 'L'$ :

$$\begin{bmatrix} d & & & & \\ e & d & & & \\ v1 & e & d & & \\ v1 & v2 & e & d & \\ v1 & v2 & v3 & e & d \end{bmatrix}$$

where  $d$  and  $e$  denote diagonal and off-diagonal elements of  $T$ , and  $v_i$  denotes an element of the vector defining  $H(i)$ .

## Description

This function overwrites the general complex distributed  $m$ -by- $n$  matrix  $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$  with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'C':$	$Q^H * \text{sub}(C)$	$\text{sub}(C) * Q^H$

where  $Q$  is a complex unitary distributed matrix of order  $nq$ , with  $nq = m$  if  $side = 'L'$  and  $nq = n$  if  $side = 'R'$ .

$Q$  is defined as the product of  $nq-1$  elementary reflectors, as returned by `p?hetrd`.

If  $uplo = 'U'$ ,  $Q = H(nq-1) \dots H(2) H(1)$ ;

If  $uplo = 'L'$ ,  $Q = H(1) H(2) \dots H(nq-1)$ .

## Input Parameters

$side$	(global) $= 'L'$ : $Q$ or $Q^H$ is applied from the left. $= 'R'$ : $Q$ or $Q^H$ is applied from the right.
$trans$	(global) $= 'N'$ , no transpose, $Q$ is applied. $= 'C'$ , conjugate transpose, $Q^H$ is applied.
$uplo$	(global) $= 'U'$ : Upper triangle of $A(ia:*, ja:*)$ contains elementary reflectors from <code>p?hetrd</code> ; $= 'L'$ : Lower triangle of $A(ia:*, ja:*)$ contains elementary reflectors from <code>p?hetrd</code>
$m$	(global) The number of rows in the distributed matrix $\text{sub}(C)$ ( $m \geq 0$ ).
$n$	(global) The number of columns in the distributed matrix $\text{sub}(C)$ ( $n \geq 0$ ).
$a$	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+m-1)$ if $side = 'L'$ , and $lld\_a * LOCC(ja+n-1)$ if $side = 'R'$ . Contains the vectors which define the elementary reflectors, as returned by <code>p?hetrd</code> . If $side = 'L'$ , $lld\_a \geq \max(1, LOCr(ia+m-1))$ ; If $side = 'R'$ , $lld\_a \geq \max(1, LOCr(ia+n-1))$ .
$ia, ja$	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
$desca$	(global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $A$ .
$tau$	(local)

Array of size of *ltau* where

```
If side = 'L' and uplo = 'U', ltau = LOCC(m_a),
if side = 'L' and uplo = 'L', ltau = LOCC(ja+m-2),
if side = 'R' and uplo = 'U', ltau = LOCC(n_a),
if side = 'R' and uplo = 'L', ltau = LOCC(ja+n-2).
```

*tau*[*i*] must contain the scalar factor of the elementary reflector  $H(i+1)$ , as returned by `p?hetrd` ( $0 \leq i < ltau$ ). *tau* is tied to the distributed matrix *A*.

*c* (local)  
 Pointer into the local memory to an array of size `lld_c*LOCC(jc+n-1)`.  
 Contains the local pieces of the distributed matrix sub (*C*).

*ic, jc* (global) The row and column indices in the global matrix *C* indicating the first row and the first column of the submatrix *C*, respectively.

*desc* (global and local) array of size *dlen\_*. The array descriptor for the distributed matrix *C*.

*work* (local)  
 Workspace array of size *lwork*.

*lwork* (local or global) size of *work*, must be at least:

```
If uplo = 'U',
  iaa= ia; jaa= ja+1, icc= ic; jcc= jc;
else uplo = 'L',
  iaa= ia+1, jaa= ja;
If side = 'L',
  icc= ic+1; jcc= jc;
else icc= ic; jcc= jc+1;
end if
end if
If side = 'L',
  mi= m-1; ni= n
  lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 + mpc0)*nb_a) +
  nb_a*nb_a
else
  If side = 'R',
    mi= m; ni = n-1;
    lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 +
    max(npa0+numroc(numroc(ni+icoffc, nb_a, 0, 0, NPCOL), nb_a,
    0, 0, lcmq), mpc0))*nb_a) + nb_a*nb_a
  end if
where lcmq = lcm/NPCOL with lcm = ilcm(NPROW, NPCOL),
```

```

iroffa = mod(iaa-1, mb_a),
icoffa = mod(jaa-1, nb_a),
iarow = indxg2p(iaa, mb_a, MYROW, rsrc_a, NPROW),
npa0 = numroc(ni+iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(icc-1, mb_c),
icoffc = mod(jcc-1, nb_c),
icrow = indxg2p(icc, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jcc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

**NOTE**

`mod(x, y)` is the integer remainder of  $x/y$ .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`. If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

**Output Parameters**

<code>c</code>	Overwritten by the product $Q*\text{sub}(C)$ , or $Q'*\text{sub}(C)$ , or $\text{sub}(C)*Q'$ , or $\text{sub}(C)*Q$ .
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then <code>info = -(i*100+j)</code> ; if the $i$ -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

MKL_INT *m , MKL_INT *nsplit , double *w , MKL_INT *iblock , MKL_INT *isplit , double
*work , MKL_INT *lwork , MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );
```

## Include Files

- mkl\_scalapack.h

## Description

The `pdstebz` function computes the eigenvalues of a symmetric tridiagonal matrix in parallel. These may be all eigenvalues, all eigenvalues in the interval  $[vl, vu]$ , or the eigenvalues  $il$  through  $iu$ . A static partitioning of work is done at the beginning of `pdstebz` which results in all processes finding an (almost) equal number of eigenvalues.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

<code>ictxt</code>	(global) The <code>BLACS</code> context handle.
<code>range</code>	(global) Must be 'A' or 'V' or 'I'. If <code>range = 'A'</code> , the function computes all eigenvalues. If <code>range = 'V'</code> , the function computes eigenvalues in the interval $[vl, vu]$ . If <code>range = 'I'</code> , the function computes eigenvalues $il$ through $iu$ .
<code>order</code>	(global) Must be 'B' or 'E'. If <code>order = 'B'</code> , the eigenvalues are to be ordered from smallest to largest within each split-off block. If <code>order = 'E'</code> , the eigenvalues for the entire matrix are to be ordered from smallest to largest.
<code>n</code>	(global) The order of the tridiagonal matrix $T (n \geq 0)$ .
<code>vl, vu</code>	(global) If <code>range = 'V'</code> , the function computes the lower and the upper bounds for the eigenvalues on the interval $[1, vu]$ . If <code>range = 'A' or 'I'</code> , <code>vl</code> and <code>vu</code> are not referenced.
<code>il, iu</code>	(global) Constraint: $1 \leq il \leq iu \leq n$ . If <code>range = 'I'</code> , the index of the smallest eigenvalue is returned for $il$ and of the largest eigenvalue for $iu$ (assuming that the eigenvalues are in ascending order) must be returned. If <code>range = 'A' or 'V'</code> , $il$ and $iu$ are not referenced.

<i>abstol</i>	(global) The absolute tolerance to which each eigenvalue is required. An eigenvalue (or cluster) is considered to have converged if it lies in an interval of width <i>abstol</i> . If <i>abstol</i> ≤ 0, then the tolerance is taken as <i>ulp</i>    <i>T</i>   , where <i>ulp</i> is the machine precision, and    <i>T</i>    means the 1-norm of <i>T</i> Eigenvalues will be computed most accurately when <i>abstol</i> is set to the underflow threshold <code>slamch('U')</code> , not 0. Note that if eigenvectors are desired later by inverse iteration ( <code>p?stein</code> ), <i>abstol</i> should be set to <code>2*p?lamch('S')</code> .
<i>d</i>	(global) Array of size <i>n</i> . Contains <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i> . To avoid overflow, the matrix must be scaled so that its largest entry is no greater than the $\text{overflow}^{(1/2)} * \text{underflow}^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.
<i>e</i>	(global) Array of size <i>n</i> - 1. Contains ( <i>n</i> -1) off-diagonal elements of the tridiagonal matrix <i>T</i> . To avoid overflow, the matrix must be scaled so that its largest entry is no greater than $\text{overflow}^{(1/2)} * \text{underflow}^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.
<i>work</i>	(local) Array of size $\max(5n, 7)$ . This is a workspace array.
<i>lwork</i>	(local) The size of the <i>work</i> array must be $\geq \max(5n, 7)$ . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> .
<i>iwork</i>	(local) Array of size $\max(4n, 14)$ . This is a workspace array.
<i>liwork</i>	(local) The size of the <i>iwork</i> array must $\geq \max(4n, 14, \text{NPROCS})$ . If <i>liwork</i> = -1, then <i>liwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> .

## Output Parameters

<i>m</i>	(global) The actual number of eigenvalues found. $0 \leq m \leq n$
<i>nsplit</i>	(global) The number of diagonal blocks detected in <i>T</i> . $1 \leq \text{nsplit} \leq n$
<i>w</i>	(global) Array of size <i>n</i> . On exit, the first <i>m</i> elements of <i>w</i> contain the eigenvalues on all processes.

*iblock* (global)  
 Array of size  $n$ . At each row/column  $j$  where  $e[j-1]$  is zero or small, the matrix  $T$  is considered to split into a block diagonal matrix. On exit *iblock*[ $j$ ] specifies which block (from 1 to the number of blocks) the eigenvalue  $w[j]$  belongs to.

**NOTE**

In the (theoretically impossible) event that bisection does not converge for some or all eigenvalues, *info* is set to 1 and the ones for which it did not are identified by a negative block number.

*isplit* (global)  
 Array of size  $n$ .  
 Contains the splitting points, at which  $T$  breaks up into submatrices. The first submatrix consists of rows/columns 1 to *isplit*[0], the second of rows/columns *isplit*[0]+1 through *isplit*[1], and so on, and the *nsplit*-th submatrix consists of rows/columns *isplit*[*nsplit*-2]+1 through *isplit*[*nsplit*-1]= $n$ . (Only the first *nsplit* elements are used, but since the *nsplit* values are not known,  $n$  words must be reserved for *isplit*.)

*info* (global)  
 If *info* = 0, the execution is successful.  
 If *info* < 0, if *info* = - $i$ , the  $i$ -th argument has an illegal value.  
 If *info* > 0, some or all of the eigenvalues fail to converge or are not computed.  
 If *info* = 1, bisection fails to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances.  
 If *info* = 2, mismatch between the number of eigenvalues output and the number desired.  
 If *info* = 3: *range*='I', and the Gershgorin interval initially used is incorrect. No eigenvalues are computed. Probable cause: the machine has a sloppy floating-point arithmetic. Increase the *fudge* parameter, recompile, and try again.

## Description

p?stedc computes all eigenvalues and eigenvectors of a symmetric tridiagonal matrix in parallel, using the divide and conquer algorithm.

## Input Parameters

<i>compz</i>	= 'N': Compute eigenvalues only. (NOT IMPLEMENTED YET) = 'I': Compute eigenvectors of tridiagonal matrix also. = 'V': Compute eigenvectors of original dense symmetric matrix also. On entry, Z contains the orthogonal matrix used to reduce the original matrix to tridiagonal form. (NOT IMPLEMENTED YET)
<i>n</i>	(global) The order of the tridiagonal matrix $T$ . $n \geq 0$ .
<i>d</i>	(global) Array, size ( $n$ ) On entry, the diagonal elements of the tridiagonal matrix.
<i>e</i>	(global) Array, size ( $n-1$ ). On entry, the subdiagonal elements of the tridiagonal matrix.
<i>iq</i>	(global) Q's global row index, which points to the beginning of the submatrix which is to be operated on.
<i>jq</i>	(global) Q's global column index, which points to the beginning of the submatrix which is to be operated on.
<i>descq</i>	(global and local) Array of size $dlen\_$ . The array descriptor for the distributed matrix $Q$ .
<i>work</i>	(local) Array, size ( $lwork$ )
<i>lwork</i>	(local) The size of the array <i>work</i> . $lwork = 6*n + 2*NP*NQ$ $NP = \text{numroc}(n, NB, MYROW, DESCQ(rsrc\_), NPROW)$

$NQ = \text{numroc}(n, NB, MYCOL, \text{DESCQ}(csrc\_), NPCOL)$

`numroc` is a ScaLAPACK tool function.

If `lwork = -1`, the `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum size for the `work` array. The required workspace is returned as the first element of `work` and no error message is issued by `p?xerbla`.

`iwork` (local)  
Array, size (`liwork`)

`liwork` The size of the array `iwork`.  
 $liwork = 2 + 7*n + 8*NPCOL$

## Output Parameters

`d` On exit, if `info = 0`, the eigenvalues in descending order.

`q` (local)  
Array, local size (`lld_q, LOCC(jq+n-1)`)  
`q` contains the orthonormal eigenvectors of the symmetric tridiagonal matrix.  
On output, `q` is distributed across the P processes in block cyclic format.

`work` On output, `work[0]` returns the workspace needed.

`iwork` On exit, if `liwork > 0`, `iwork[0]` returns the optimal `liwork`.

`info` (global)  
= 0: successful exit.  
< 0: If the *i*-th argument is an array and the *j*-th entry had an illegal value, then `info = -(i*100+j)`, if the *i*-th argument is a scalar and had an illegal value, then `info = -i`.  
> 0: The algorithm failed to compute the `info/(n+1)`-th eigenvalue while working on the submatrix lying in global rows and columns `mod(info,n+1)`.

### p?stein

Computes the eigenvectors of a tridiagonal matrix using inverse iteration.

### Syntax

```

## Include Files

- mkl\_scalapack.h

## Description

The `p?stein` function computes the eigenvectors of a symmetric tridiagonal matrix  $T$  corresponding to specified eigenvalues, by inverse iteration. `p?stein` does not orthogonalize vectors that are on different processes. The extent of orthogonalization is controlled by the input parameter `lwork`. Eigenvectors that are to be orthogonalized are computed by the same process. `p?stein` decides on the allocation of work among the processes and then calls `?stein2` (modified LAPACK function) on each individual process. If insufficient workspace is allocated, the expected orthogonalization may not be done.

---

### NOTE

If the eigenvectors obtained are not orthogonal, increase `lwork` and run the code again.

---

$p = \text{NPROW} * \text{NPCOL}$  is the total number of processes.

## Input Parameters

<code>n</code>	(global) The order of the matrix $T$ ( $n \geq 0$ ).
<code>m</code>	(global) The number of eigenvectors to be returned.
<code>d, e, w</code>	(global) Arrays: <code>d</code> of size $n$ contains the diagonal elements of $T$ . <code>e</code> of size $n-1$ contains the off-diagonal elements of $T$ . <code>w</code> of size $m$ contains all the eigenvalues grouped by split-off block. The eigenvalues are supplied from smallest to largest within the block. (Here the output array <code>w</code> from <code>p?stebz</code> with <code>order = 'B'</code> is expected. The array should be replicated in all processes.)
<code>iblock</code>	(global)

Array of size  $n$ . The submatrix indices associated with the corresponding eigenvalues in  $w$ : 1 for eigenvalues belonging to the first submatrix from the top, 2 for those belonging to the second submatrix, etc. (The output array  $iblock$  from `p?stebz` is expected here).

<code>isplit</code>	(global) Array of size $n$ . The splitting points at which $T$ breaks up into submatrices. The first submatrix consists of rows/columns 1 to <code>isplit[0]</code> , the second of rows/columns <code>isplit[0]+1</code> through <code>isplit[1]</code> , and so on, and the $nsplit$ -th submatrix consists of rows/columns <code>isplit[nsplit-2]+1</code> through <code>isplit[nsplit-1]=n</code> . (The output array <code>isplit</code> from <code>p?stebz</code> is expected here.)
<code>orfac</code>	(global) <code>orfac</code> specifies which eigenvectors should be orthogonalized. Eigenvectors that correspond to eigenvalues within $orfac *   T  $ of each other are to be orthogonalized. However, if the workspace is insufficient (see <code>lwork</code> ), this tolerance may be decreased until all eigenvectors can be stored in one process. No orthogonalization is done if <code>orfac</code> is equal to zero. A default value of 1000 is used if <code>orfac</code> is negative. <code>orfac</code> should be identical on all processes
<code>iz, jz</code>	(global) The row and column indices in the global matrix $Z$ indicating the first row and the first column of the submatrix $Z$ , respectively.
<code>descz</code>	(global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix $Z$ .
<code>work</code>	(local). Workspace array of size <code>lwork</code> .
<code>lwork</code>	(local) <code>lwork</code> controls the extent of orthogonalization which can be done. The number of eigenvectors for which storage is allocated on each process is $nvec = \text{floor}((lwork - \max(5*n, np00*mq00)) / n)$ . Eigenvectors corresponding to eigenvalue clusters of size $(nvec - \text{ceil}(m/p) + 1)$ are guaranteed to be orthogonal (the orthogonality is similar to that obtained from <code>?stein2</code> ).

**NOTE**

`lwork` must be no smaller than  $\max(5*n, np00*mq00) + \text{ceil}(m/p) * n$  and should have the same input value on all processes.

It is the minimum value of `lwork` input on different processes that is significant.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

<code>iwork</code>	(local)
--------------------	---------

Workspace array of size  $3n+p+1$ .

*liwork*

(local) The size of the array *iwork*. It must be greater than  $3*n+p+1$ .

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

## Output Parameters

*z*

(local)

Array of size *descz*[*dlen* - 1],  $n/\text{NPCOL} + \text{NB}$ ). *z* contains the computed eigenvectors associated with the specified eigenvalues. Any vector which fails to converge is set to its current iterate after MAXIT iterations (See [?stein2](#)). On output, *z* is distributed across the *p* processes in block cyclic format.

*work*

On exit, *work*[0] gives a lower bound on the workspace (*lwork*) that guarantees the user desired orthogonalization (see *orfac*). Note that this may overestimate the minimum workspace needed.

*iwork*

On exit, *iwork*[0] contains the amount of integer workspace required.

On exit, the *iwork*[1] through *iwork*[*p*+1] indicate the eigenvectors computed by each process. Process *i* computes eigenvectors indexed *iwork*[*i*+1]+1 through *iwork*[*i*+2].

*ifail*

(global) Array of size *m*. On normal exit, all elements of *ifail* are zero. If one or more eigenvectors fail to converge after MAXIT iterations (as in [?stein](#)), then *info* > 0 is returned. If  $\text{mod}(\text{info}, m+1) > 0$ , then for  $i=1$  to  $\text{mod}(\text{info}, m+1)$ , the eigenvector corresponding to the eigenvalue  $w[\text{ifail}[i-1]-1]$  failed to converge (*w* refers to the array of eigenvalues on output).

---

### NOTE

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

---

*iclustr*

(global) Array of size  $2*p$ .

This output array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be orthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*( $2*I-1$ ) to *iclustr*( $2*I$ ),  $i = 1$  to  $\text{info}/(m+1)$ , could not be orthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr* is a zero terminated array: *iclustr*[ $2*k-1$ ] ≠ 0 and *iclustr*[ $2*k$ ] = 0 if and only if *k* is the number of clusters.

*gap*

(global)

This output array contains the gap between eigenvalues whose eigenvectors could not be orthogonalized. The *info*/*m* output values in this array correspond to the  $\text{info}/(m+1)$  clusters indicated by the

array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*-th cluster may be as high as  $(O(n) * macheps) / gap[i-1]$ .

*info*

(global)

If *info* = 0, the execution is successful.

If *info* < 0: If the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value, then *info* =  $-(i*100+j)$ ,

If the *i*-th argument is a scalar and had an illegal value, then *info* =  $-i$ .

If *info* < 0: if *info* =  $-i$ , the *i*-th argument had an illegal value.

If *info* > 0: if  $\text{mod}(info, m+1) = i$ , then *i* eigenvectors failed to converge in MAXIT iterations. Their indices are stored in the array *ifail*. If  $info / (m + 1) = i$ , then eigenvectors corresponding to *i* clusters of eigenvalues could not be orthogonalized due to insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

## Nonsymmetric Eigenvalue Problems: ScaLAPACK Computational Routines

This section describes ScaLAPACK routines for solving nonsymmetric eigenvalue problems, computing the Schur factorization of general matrices, as well as performing a number of related computational tasks.

To solve a nonsymmetric eigenvalue problem with ScaLAPACK, you usually need to reduce the matrix to the upper Hessenberg form and then solve the eigenvalue problem with the Hessenberg matrix obtained.

Table "Computational Routines for Solving Nonsymmetric Eigenproblems" lists ScaLAPACK routines for reducing the matrix to the upper Hessenberg form by an orthogonal (or unitary) similarity transformation  $A = QHQ^H$ , as well as routines for solving eigenproblems with Hessenberg matrices, and multiplying the matrix after reduction.

### Computational Routines for Solving Nonsymmetric Eigenproblems

Operation performed	General matrix	Orthogonal/Unitary matrix	Hessenberg matrix
Reduce to Hessenberg form $A = QHQ^H$	<a href="#">p?gehrd</a>		
Multiply the matrix after reduction		<a href="#">p?ormhr</a> / <a href="#">p?unmhr</a>	
Find eigenvalues and Schur factorization			<a href="#">p?lahqr</a>

*lwork , MKL_INT *info );
```

## Include Files

- mkl\_scalapack.h

## Description

The `pzgehrd` function reduces a real/complex general distributed matrix  $\text{sub}(A)$  to upper Hessenberg form  $H$  by an orthogonal or unitary similarity transformation

$$Q' \cdot \text{sub}(A) \cdot Q = H,$$

where  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ .

## Input Parameters

<code>n</code>	(global). The order of the distributed matrix $\text{sub}(A)$ ( $n \geq 0$ ).
<code>ilo, ihi</code>	(global). It is assumed that $\text{sub}(A)$ is already upper triangular in rows $\text{ia}:\text{ia}+\text{ilo}-2$ and $\text{ia}+\text{ihi}:\text{ia}+n-1$ and columns $\text{ja}:\text{ja}+\text{ilo}-2$ and $\text{ja}+\text{ihi}:\text{ja}+n-1$ . (See <i>Application Notes</i> below). If $n > 0$ , $1 \leq \text{ilo} \leq \text{ihi} \leq n$ ; otherwise set $\text{ilo} = 1$ , $\text{ihi} = n$ .
<code>a</code>	(local) Pointer into the local memory to an array of size $\text{lld}_a * \text{LOCc}(\text{ja}+n-1)$ . On entry, this array contains the local pieces of the $n$ -by- $n$ general distributed matrix $\text{sub}(A)$ to be reduced.
<code>ia, ja</code>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
<code>desca</code>	(global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $A$ .
<code>work</code>	(local) Workspace array of size $lwork$ .
<code>lwork</code>	(local or global) size of the array <code>work</code> . <code>lwork</code> is local input and must be at least $lwork \geq \text{NB} * \text{NB} + \text{NB} * \max(\text{ihip}+1, \text{ihlp}+\text{inlq})$ where $\text{NB} = \text{mb}_a = \text{nb}_a$ , $\text{iroffa} = \text{mod}(\text{ia}-1, \text{NB})$ , $\text{icoffa} = \text{mod}(\text{ja}-1, \text{NB})$ , $\text{ioff} = \text{mod}(\text{ia}+\text{ilo}-2, \text{NB})$ , $\text{iarow} = \text{indxg2p}(\text{ia}, \text{NB}, \text{MYROW}, \text{rsrc}_a, \text{NPROW})$ , $\text{ihip} = \text{numroc}(\text{ihi}+\text{iroffa}, \text{NB}, \text{MYROW}, \text{iarow}, \text{NPROW})$ , $\text{ilrow} = \text{indxg2p}(\text{ia}+\text{ilo}-1, \text{NB}, \text{MYROW}, \text{rsrc}_a, \text{NPROW})$ , $\text{ihlp} = \text{numroc}(\text{ihi}-\text{ilo}+\text{ioff}+1, \text{NB}, \text{MYROW}, \text{ilrow}, \text{NPROW})$ ,

```

ilcol = indxg2p(ja+ilo-1, NB, MYCOL, csrc_a, NPCOL),
inlq = numroc(n-ilo+ioff+1, NB, MYCOL, ilcol, NPCOL),

```

**NOTE**

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

**Output Parameters**

<code>a</code>	On exit, the upper triangle and the first subdiagonal of $\text{sub}(A)$ are overwritten with the upper Hessenberg matrix $H$ , and the elements below the first subdiagonal, with the array <code>tau</code> , represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors (see <i>Application Notes</i> below).
<code>tau</code>	(local). Array of size at least $\max(ja+n-2)$ .  The scalar factors of the elementary reflectors (see <i>Application Notes</i> below). Elements <code>ja:ja+ilo-2</code> and <code>ja+ihi:ja+n-2</code> of the global vector <code>tau</code> are set to zero. <code>tau</code> is tied to the distributed matrix $A$ .
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful.  < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then <code>info = -(i*100+j)</code> ; if the $i$ -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

**Application Notes**

The matrix  $Q$  is represented as a product of  $(ihi-ilo)$  elementary reflectors

$$Q = H(ilo)*H(ilo+1)*...*H(ihi-1).$$

Each  $H(i)$  has the form

$$H(i) = I - \tau * v * v'$$

where  $\tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(1:i) = 0$ ,  $v(i+1) = 1$  and  $v(ihi+1:n) = 0$ ;  $v(i+2:ihi)$  is stored on exit in  $A(ia+ilo+i:ia+ihi-1, ja+ilo+i-2)$ , and  $\tau$  in  $\text{tau}[ja+ilo+i-3]$ . The contents of  $A$

$(ia:ia+n-1, ja:ja+n-1)$  are illustrated by the following example, with  $n = 7$ ,  $ilo = 2$  and  $ihi = 6$ :

on entry

$$\begin{bmatrix} a & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & & a & a & a & a & a \\ & & & a & a & a & a \\ & & & & a & a & a \\ & & & & & a & a \\ & & & & & & a \end{bmatrix}$$

on exit

$$\begin{bmatrix} a & a & a & h & h & h & a \\ & a & h & h & h & h & a \\ & & h & h & h & h & h \\ v2 & h & h & h & h & h & \\ v2 & v3 & h & h & h & h & \\ v2 & v3 & v4 & h & h & h & \\ & & & & & & a \end{bmatrix}$$

where  $a$  denotes an element of the original matrix  $\text{sub}(A)$ ,  $H$  denotes a modified element of the upper Hessenberg matrix  $H$ , and  $v_i$  denotes an element of the vector defining  $H(j_a+i_l o+i-2)$ .

## Description

The `p?ormhr` function overwrites the general real distributed  $m$ -by- $n$  matrix  $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$  with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where  $Q$  is a real orthogonal distributed matrix of order  $nq$ , with  $nq = m$  if  $side = 'L'$  and  $nq = n$  if  $side = 'R'$ .

$Q$  is defined as the product of  $ihi-ilo$  elementary reflectors, as returned by `p?gehrd`.

$Q = H(ilo) H(ilo+1) \dots H(ihi-1)$ .

## Input Parameters

$side$	(global) = $'L'$ : $Q$ or $Q^T$ is applied from the left. = $'R'$ : $Q$ or $Q^T$ is applied from the right.
$trans$	(global) = $'N'$ , no transpose, $Q$ is applied. = $'T'$ , transpose, $Q^T$ is applied.
$m$	(global) The number of rows in the distributed matrix $\text{sub}(C)$ ( $m \geq 0$ ).
$n$	(global) The number of columns in the distributed matrix $\text{sub}(C)$ ( $n \geq 0$ ).
$ilo, ihi$	(global) $ilo$ and $ihi$ must have the same values as in the previous call of <code>p?gehrd</code> . $Q$ is equal to the unit matrix except for the distributed submatrix $Q(ia+ilo:ia+ihi-1, ja+ilo:ja+ihi-1)$ . If $side = 'L'$ , $1 \leq ilo \leq ihi \leq \max(1, m)$ ; If $side = 'R'$ , $1 \leq ilo \leq ihi \leq \max(1, n)$ ; $ilo$ and $ihi$ are relative indexes.
$a$	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+m-1)$ if $side = 'L'$ , and $lld\_a * LOCC(ja+n-1)$ if $side = 'R'$ . Contains the vectors which define the elementary reflectors, as returned by <code>p?gehrd</code> .
$ia, ja$	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
$desca$	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
$tau$	(local)

Array of size  $LOCc(ja+m-2)$  if  $side = 'L'$ , and  $LOCc(ja+n-2)$  if  $side = 'R'$ .

$\tau[j]$  contains the scalar factor of the elementary reflector  $H(j+1)$  as returned by `p?gehrd` ( $0 \leq j < \text{size}(\tau)$ ).  $\tau$  is tied to the distributed matrix  $A$ .

$c$

(local)

Pointer into the local memory to an array of size  $lld\_c * LOCc(jc+n-1)$ .

Contains the local pieces of the distributed matrix sub( $C$ ).

$ic, jc$

(global) The row and column indices in the global matrix  $C$  indicating the first row and the first column of the submatrix  $C$ , respectively.

$desc$

(global and local) array of size  $dlen\_$ . The array descriptor for the distributed matrix  $C$ .

$work$

(local)

Workspace array with size  $lwork$ .

$lwork$

(local or global)

The size of the array  $work$ .

$lwork$  must be at least  $iaa = ia + ilo; jaa = ja + ilo - 1;$

If  $side = 'L'$ ,

$mi = ihi - ilo; ni = n; icc = ic + ilo; jcc = jc; lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + mpc0) * nb\_a) + nb\_a * nb\_a$

else if  $side = 'R'$ ,

$mi = m; ni = ihi - ilo; icc = ic; jcc = jc + ilo; lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + \max(npa0 + \text{numroc}(\text{numroc}(ni + icoffc, nb\_a, 0, 0, NPCOL), nb\_a, 0, 0, lcmq), mpc0)) * nb\_a) + nb\_a * nb\_a$

end if

where  $lcmq = lcm / NPCOL$  with  $lcm = ilcm(NPROW, NPCOL)$ ,

$iroffa = \text{mod}(iaa - 1, mb\_a)$ ,

$icoffa = \text{mod}(jaa - 1, nb\_a)$ ,

$iarow = \text{indxg2p}(iaa, mb\_a, MYROW, rsrc\_a, NPROW)$ ,

$npa0 = \text{numroc}(ni + iroffa, mb\_a, MYROW, iarow, NPROW)$ ,

$iroffc = \text{mod}(icc - 1, mb\_c)$ ,  $icoffc = \text{mod}(jcc - 1, nb\_c)$ ,

$icrow = \text{indxg2p}(icc, mb\_c, MYROW, rsrc\_c, NPROW)$ ,

$iccol = \text{indxg2p}(jcc, nb\_c, MYCOL, csrc\_c, NPCOL)$ ,

$mpc0 = \text{numroc}(mi + iroffc, mb\_c, MYROW, icrow, NPROW)$ ,

$nqc0 = \text{numroc}(ni + icoffc, nb\_c, MYCOL, iccol, NPCOL)$ ,

**NOTE**

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

`ilcm`, `indxcg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

**Output Parameters**

<code>c</code>	<code>sub(C)</code> is overwritten by $Q*\text{sub}(C)$ , or $Q'*\text{sub}(C)$ , or $\text{sub}(C)*Q'$ , or $\text{sub}(C)*Q$ .
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then $\text{info} = -(i*100+j)$ ; if the $i$ -th argument is a scalar and had an illegal value, then $\text{info} = -i$ .

**Description**

This function overwrites the general complex distributed  $m$ -by- $n$  matrix  $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$  with

	<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
<i>trans</i> = 'H':	$Q^H * \text{sub}(C)$	$\text{sub}(C) * Q^H$

where  $Q$  is a complex unitary distributed matrix of order  $nq$ , with  $nq = m$  if *side* = 'L' and  $nq = n$  if *side* = 'R'.

$Q$  is defined as the product of *ihi-ilo* elementary reflectors, as returned by `p?gehrd`.

$Q = H(ilo) H(ilo+1) \dots H(ihi-1)$ .

## Input Parameters

<i>side</i>	(global) ='L': $Q$ or $Q^H$ is applied from the left. ='R': $Q$ or $Q^H$ is applied from the right.
<i>trans</i>	(global) ='N', no transpose, $Q$ is applied. ='C', conjugate transpose, $Q^H$ is applied.
<i>m</i>	(global) The number of rows in the distributed matrix sub ( $C$ ) ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the distributed matrix sub ( $C$ ) ( $n \geq 0$ ).
<i>ilo, ihi</i>	(global) These must be the same parameters <i>ilo</i> and <i>ihi</i> , respectively, as supplied to <code>p?gehrd</code> . $Q$ is equal to the unit matrix except in the distributed submatrix $Q(ia+ilo:ia+ihi-1, ja+ilo:ja+ihi-1)$ . If <i>side</i> = 'L', then $1 \leq ilo \leq ihi \leq \max(1, m)$ . If <i>side</i> = 'R', then $1 \leq ilo \leq ihi \leq \max(1, n)$ <i>ilo</i> and <i>ihi</i> are relative indexes.
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(ja+m-1)$ if <i>side</i> = 'L', and $lld\_a * LOCc(ja+n-1)$ if <i>side</i> = 'R'. Contains the vectors which define the elementary reflectors, as returned by <code>p?gehrd</code> .
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .
<i>tau</i>	(local) Array of size $LOCc(ja+m-2)$ , if <i>side</i> = 'L', and $LOCc(ja+n-2)$ if <i>side</i> = 'R'. $tau[j]$ contains the scalar factor of the elementary reflector $H(j+1)$ as returned by <code>p?gehrd</code> ( $0 \leq j < \text{size}(tau)$ ). <i>tau</i> is tied to the distributed matrix $A$ .

<i>c</i>	(local) Pointer into the local memory to an array of size $lld\_c * LOCC(jc+n-1)$ . Contains the local pieces of the distributed matrix sub( <i>C</i> ).
<i>ic, jc</i>	(global) The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>desc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) Workspace array with size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the array <i>work</i> .  $lwork$ must be at least $iaa = ia + ilo; jaa = ja + ilo - 1;$ If <i>side</i> = 'L', $mi = ihi - ilo; ni = n; icc = ic + ilo; jcc = jc;$ $lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + mpc0) * nb\_a) + nb\_a * nb\_a$ else if <i>side</i> = 'R', $mi = m; ni = ihi - ilo; icc = ic; jcc = jc + ilo; lwork \geq$ $\max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + \max(np\_a0 + \text{numroc}(\text{numroc}(ni$ $+$ <i>icoffc</i> , <i>nb_</i> <i>a</i> , 0, 0, NPCOL), <i>nb_</i> <i>a</i> , 0, 0, <i>lcmq</i> ), $mpc0)) * nb\_a) + nb\_a * nb\_a$ end if where $lcmq = lcm / NPCOL$ with $lcm = ilcm(NPROW, NPCOL),$ $irow = \text{mod}(iaa - 1, mb\_a),$ $icrow = \text{mod}(jcc - 1, nb\_c),$ $iarow = \text{indxg2p}(iaa, mb\_a, MYROW, rsrc\_a, NPROW),$ $npa0 = \text{numroc}(ni + irow, mb\_a, MYROW, iarow, NPROW),$ $icrow = \text{mod}(icc - 1, mb\_c),$ $icrow = \text{mod}(jcc - 1, nb\_c),$ $icrow = \text{indxg2p}(icc, mb\_c, MYROW, rsrc\_c, NPROW),$ $iccol = \text{indxg2p}(jcc, nb\_c, MYCOL, csrc\_c, NPCOL),$ $mpc0 = \text{numroc}(mi + icrow, mb\_c, MYROW, icrow, NPROW),$ $nqc0 = \text{numroc}(ni + icrow, nb\_c, MYCOL, iccol, NPCOL),$

**NOTE**

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

*ilcm*, *indxg2p* and *numroc* are ScaLAPACK tool functions; *MYROW*, *MYCOL*, *NPROW* and *NPCOL* can be determined by calling the function *blacs\_gridinfo*.

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

<code>c</code>	$C$ is overwritten by $Q * \text{sub}(C)$ or $Q' * \text{sub}(C)$ or $\text{sub}(C) * Q'$ or $\text{sub}(C) * Q$ .
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of $lwork$ required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j - 1$ , had an illegal value, then $info = -(i * 100 + j)$ ; if the $i$ -th argument is a scalar and had an illegal value, then $info = -i$ .

## Description

This is an auxiliary function used to find the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form from columns  $ilo$  and  $ihi$ .

**NOTE**

These restrictions apply to the use of `p?lahqr`:

- The code requires the distributed block size to be square and at least 6.
- The code requires A and Z to be distributed identically and have identical contexts.
- The matrix A must be in upper Hessenberg form. If elements below the subdiagonal are non-zero, the resulting transformations can be nonsimilar.
- All eigenvalues are distributed to all the nodes.

**Input Parameters**

<code>wantt</code>	(global) If <code>wantt ≠ 0</code> , the full Schur form $T$ is required; If <code>wantt = 0</code> , only eigenvalues are required.
<code>wantz</code>	(global) If <code>wantz ≠ 0</code> , the matrix of Schur vectors $Z$ is required; If <code>wantz = 0</code> , Schur vectors are not required.
<code>n</code>	(global) The order of the Hessenberg matrix $A$ (and $z$ if <code>wantz</code> is non-zero). $n ≥ 0$ .
<code>ilo, ihi</code>	(global) It is assumed that $A$ is already upper quasi-triangular in rows and columns $ihi+1:n$ , and that $A(ilo, ilo-1) = 0$ (unless $ilo = 1$ ). <code>p?lahqr</code> works primarily with the Hessenberg submatrix in rows and columns $ilo$ to $ihi$ , but applies transformations to all of $H$ if <code>wantt</code> is non-zero. $1 ≤ ilo ≤ \max(1, ihi)$ ; $ihi ≤ n$ .
<code>a</code>	(global) Array, of size $lld\_a * LOCc(n)$ . On entry, the upper Hessenberg matrix $A$ .
<code>desca</code>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
<code>iloz, ihiz</code>	(global) Specify the rows of the matrix $Z$ to which transformations must be applied if <code>wantz</code> is non-zero. $1 ≤ iloz ≤ ilo$ ; $ihi ≤ ihiz ≤ n$ .
<code>z</code>	(global ) Array. If <code>wantz</code> is non-zero, on entry $z$ must contain the current matrix $Z$ of transformations accumulated by <code>pdhseqr</code> . If <code>wantz</code> is zero, $z$ is not referenced.
<code>descz</code>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $Z$ .
<code>work</code>	(local) Workspace array with size $lwork$ .
<code>lwork</code>	(local) The size of <code>work</code> . $lwork$ is assumed big enough so that $lwork ≥ 3*n + \max(2*\max(lld\_z, lld\_a) + 2*LOCq(n), 7*\text{ceil}(n/hbl) / \text{lcm}(\text{NPROW}, \text{NPCOL}))$ .

If  $lwork = -1$ , then  $work[0]$  gets set to the above number and the code returns immediately.

$iwork$	(global and local) array of size $ilwork$ . Not referenced and can be NULL pointer.
$ilwork$	(local) This holds some of the $iblk$ integer arrays. Not referenced and can be NULL pointer.

## Output Parameters

$a$	On exit, if $wantt$ is non-zero, $A$ is upper quasi-triangular in rows and columns $ilo:ihi$ , with any 2-by-2 or larger diagonal blocks not yet in standard form. If $wantt$ is zero, the contents of $A$ are unspecified on exit.
$work[0]$	On exit $work[0]$ contains the minimum value of $lwork$ required for optimum performance.
$wr, wi$	(global replicated output) Arrays of size $n$ each. The real and imaginary parts, respectively, of the computed eigenvalues $ilo$ to $ihi$ are stored in the corresponding elements of $wr$ and $wi$ . If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of $wr$ and $wi$ , say the $i$ -th and $(i+1)$ -th, with $wi[i-1] > 0$ and $wi[i] < 0$ . If $wantt$ is zero, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in $A$ . $A$ may be returned with larger diagonal blocks until the next release.
$w$	(global replicated output) Array of size $n$ . The computed eigenvalues $ilo$ to $ihi$ are stored in the corresponding elements of $w$ . If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of $w$ , say the $i$ -th and $(i+1)$ -th, with $w[i-1] > 0$ and $w[i] < 0$ . If $wantt$ is zero, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in $A$ . $A$ may be returned with larger diagonal blocks until the next release.
$z$	On exit $z$ has been updated; transformations are applied only to the submatrix $Z(ilo:ihiz, ilo:ihi)$ .
$info$	(global) = 0: the execution is successful. < 0: the parameter number - $info$ is incorrect or inconsistent > 0: $p?lahqr$ failed to compute all the eigenvalues $ilo$ to $ihi$ in a total of $30 * (ihi - ilo + 1)$ iterations; if $info = i$ , elements $i+1: ihiz$ of $wr$ and $wi$ contain the eigenvalues that have been successfully computed.

```

## Include Files

- mkl\_scalapack.h

## Description

`p?trvec` computes some or all of the right and/or left eigenvectors of a complex upper triangular matrix  $T$  in parallel.

The right eigenvector  $x$  and the left eigenvector  $y$  of  $T$  corresponding to an eigenvalue  $w$  are defined by:

$$T*x = w*x,$$

$$y'*T = w*y'$$

where  $y'$  denotes the conjugate transpose of the vector  $y$ .

If all eigenvectors are requested, the routine may either return the matrices  $X$  and/or  $Y$  of right or left eigenvectors of  $T$ , or the products  $Q*X$  and/or  $Q*Y$ , where  $Q$  is an input unitary matrix. If  $T$  was obtained from the Schur factorization of an original matrix  $A = Q*T*Q'$ , then  $Q*X$  and  $Q*Y$  are the matrices of right or left eigenvectors of  $A$ .

## Input Parameters

<i>side</i>	(global) = 'R': compute right eigenvectors only; = 'L': compute left eigenvectors only; = 'B': compute both right and left eigenvectors.
<i>howmny</i>	(global) = 'A': compute all right and/or left eigenvectors; = 'B': compute all right and/or left eigenvectors, and backtransform them using the input matrices supplied in <i>vr</i> and/or <i>vl</i> ; = 'S': compute selected right and/or left eigenvectors, specified by the logical array <i>select</i> .
<i>select</i>	(global)

	Array, size ( $n$ )
	If $howmny = 'S'$ , $select$ specifies the eigenvectors to be computed.
	If $howmny = 'A'$ or $'B'$ , $select$ is not referenced. To select the eigenvector corresponding to the $j$ -th eigenvalue, $select[j - 1]$ must be set to non-zero.
$n$	(global) The order of the matrix $T$ . $n \geq 0$ .
$t$	(local) Array, size $lld\_t * LOCC(n)$ . The upper triangular matrix $T$ . $T$ is modified, but restored on exit.
$desct$	(global and local) Array of size $dlen\_$ . The array descriptor for the distributed matrix $T$ .
$vl$	(local) Array, size $(descvl(lld\_), mm)$ On entry, if $side = 'L'$ or $'B'$ and $howmny = 'B'$ , $vl$ must contain an $n$ -by- $n$ matrix $Q$ (usually the unitary matrix $Q$ of Schur vectors returned by <code>?hseqr</code> ).
$descvl$	(global and local) Array of size $dlen\_$ . The array descriptor for the distributed matrix $VL$ .
$vr$	(local) Array, size $descvr(lld\_)*mm$ . On entry, if $side = 'R'$ or $'B'$ and $howmny = 'B'$ , $vr$ must contain an $n$ -by- $n$ matrix $Q$ (usually the unitary matrix $Q$ of Schur vectors returned by <code>?hseqr</code> ).
$descvr$	(global and local) Array of size $dlen\_$ . The array descriptor for the distributed matrix $VR$ .
$mm$	(global) The number of columns in the arrays $vl$ and/or $vr$ . $mm \geq m$ .
$work$	(local) Array, size $(2 * desct(lld\_))$ Additional workspace may be required if <code>p?lattr</code> s is updated to use $work$ .
$rwork$	Array, size $(desct(lld\_))$

## Output Parameters

<i>t</i>	The upper triangular matrix $T$ . $T$ is modified, but restored on exit.
<i>vl</i>	On exit, if <i>side</i> = 'L' or 'B', <i>vl</i> contains: if <i>howmny</i> = 'A', the matrix $Y$ of left eigenvectors of $T$ ; if <i>howmny</i> = 'B', the matrix $Q*Y$ ; if <i>howmny</i> = 'S', the left eigenvectors of $T$ specified by <i>select</i> , stored consecutively in the columns of <i>vl</i> , in the same order as their eigenvalues. If <i>side</i> = 'R', <i>vl</i> is not referenced.
<i>vr</i>	On exit, if <i>side</i> = 'R' or 'B', <i>vr</i> contains: if <i>howmny</i> = 'A', the matrix $X$ of right eigenvectors of $T$ ; if <i>howmny</i> = 'B', the matrix $Q*X$ ; if <i>howmny</i> = 'S', the right eigenvectors of $T$ specified by <i>select</i> , stored consecutively in the columns of <i>vr</i> , in the same order as their eigenvalues. If <i>side</i> = 'L', <i>vr</i> is not referenced.
<i>m</i>	(global) The number of columns in the arrays <i>vl</i> and/or <i>vr</i> actually used to store the eigenvectors. If <i>howmny</i> = 'A' or 'B', <i>m</i> is set to <i>n</i> . Each selected eigenvector occupies one column.
<i>info</i>	(global) = 0: successful exit < 0: if <i>info</i> = -i, the i-th argument had an illegal value

## Application Notes

The algorithm used in this program is basically backward (forward) substitution. Scaling should be used to make the code robust against possible overflow. But scaling has not yet been implemented in `p?lattr`s which is called by this routine to solve the triangular systems. `p?lattr`s just calls `p?trsv`.

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be  $|x| + |y|$ .

## Singular Value Decomposition: ScaLAPACK Driver Routines

This section describes ScaLAPACK routines for computing the singular value decomposition (SVD) of a general  $m$ -by- $n$  matrix  $A$  (see LAPACK "Singular Value Decomposition").

To find the SVD of a general matrix  $A$ , this matrix is first reduced to a bidiagonal matrix  $B$  by a unitary (orthogonal) transformation, and then SVD of the bidiagonal matrix is computed. Note that the SVD of  $B$  is computed using the LAPACK routine `?bdsqr`.

Table "Computational Routines for Singular Value Decomposition (SVD)" lists ScaLAPACK computational routines for performing this decomposition.

### Computational Routines for Singular Value Decomposition (SVD)

Operation	General matrix	Orthogonal/unitary matrix
Reduce $A$ to a bidiagonal matrix	<code>p?gebrd</code>	
Multiply matrix after reduction		<code>p?ormbr/p?unmbr</code>

## p?gebrd

Reduces a general matrix to bidiagonal form.

### Syntax

```
void psgebrd (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *d , float *e , float *tauq , float *taup , float *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pdgebrd (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , double *d , double *e , double *tauq , double *taup , double *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pcgebrd (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,

MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

### Include Files

- mkl\_scalapack.h

### Description

The p?gebrd function reduces a real/complex general  $m$ -by- $n$  distributed matrix  $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$  to upper or lower bidiagonal form  $B$  by an orthogonal/unitary transformation:

$$Q^* \text{sub}(A) P = B.$$

If  $m \geq n$ ,  $B$  is upper bidiagonal; if  $m < n$ ,  $B$  is lower bidiagonal.

### Input Parameters

$m$	(global) The number of rows in the distributed matrix $\text{sub}(A)$ ( $m \geq 0$ ).
$n$	(global) The number of columns in the distributed matrix $\text{sub}(A)$ ( $n \geq 0$ ).
$a$	(local) Real pointer into the local memory to an array of size $lld\_a * LOCC(\text{ja}+n-1)$ . On entry, this array contains the distributed matrix $\text{sub}(A)$ .
$ia, ja$	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
$desca$	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
$work$	(local) Workspace array of size $lwork$ .
$lwork$	(local or global) size of $work$ , must be at least: $lwork \geq nb * (mpa0 + nqa0 + 1) + nqa0$ where $nb = mb\_a = nb\_a$ , $iroffa = \text{mod}(ia-1, nb)$ , $icoffa = \text{mod}(ja-1, nb)$ ,

```

iarow = indxg2p(ia, nb, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb, MYCOL, csrc_a, NPCOL),
mpa0 = numroc(m + iroffa, nb, MYROW, iarow, NPROW),
nqa0 = numroc(n + icoffa, nb, MYCOL, iacol, NPCOL),

```

**NOTE**

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

**Output Parameters***a*

On exit, if  $m \geq n$ , the diagonal and the first superdiagonal of  $\text{sub}(A)$  are overwritten with the upper bidiagonal matrix  $B$ ; the elements below the diagonal, with the array `tauq`, represent the orthogonal/unitary matrix  $Q$  as a product of elementary reflectors, and the elements above the first superdiagonal, with the array `taup`, represent the orthogonal matrix  $P$  as a product of elementary reflectors. If  $m < n$ , the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix  $B$ ; the elements below the first subdiagonal, with the array `tauq`, represent the orthogonal/unitary matrix  $Q$  as a product of elementary reflectors, and the elements above the diagonal, with the array `taup`, represent the orthogonal matrix  $P$  as a product of elementary reflectors. See *Application Notes* below.

*d*

(local)

Array of size `LOCc(ja+min(m,n)-1)` if  $m \geq n$  and `LOCr(ia+min(m,n)-1)` otherwise. The distributed diagonal elements of the bidiagonal matrix  $B$ :  $d[i] = A(i+1, i+1)$ ,  $0 \leq i < \text{size}(d)$ .

*d* is tied to the distributed matrix  $A$ .

*e*

(local)

Array of size `LOCr(ia+min(m,n)-1)` if  $m \geq n$ ; `LOCc(ja+min(m,n)-2)` otherwise. The distributed off-diagonal elements of the bidiagonal distributed matrix  $B$ :

If  $m \geq n$ ,  $e[i] = A(i+1, i+2)$  for  $i = 0, 1, \dots, n-2$ ; if  $m < n$ ,  $e[i] = A(i+2, i+1)$  for  $i = 0, 1, \dots, m-2$ . *e* is tied to the distributed matrix  $A$ .

*tauq, taup*

(local)

Arrays of size `LOCc(ja+min(m,n)-1)` for `tauq` and `LOCr(ia+min(m,n)-1)` for `taup`. Contain the scalar factors of the elementary reflectors that represent the orthogonal/unitary matrices  $Q$  and  $P$ , respectively. `tauq` and `taup` are tied to the distributed matrix  $A$ . See *Application Notes* below.

*work*[0] On exit *work*[0] contains the minimum value of *lwork* required for optimum performance.

*info* (global)  
 = 0: the execution is successful.  
 < 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then *info* = -(*i*\*100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

## Application Notes

The matrices *Q* and *P* are represented as products of elementary reflectors:

If  $m \geq n$ ,

$Q = H(1)*H(2)*...*H(n)$ , and  $P = G(1)*G(2)*...*G(n-1)$ .

Each *H*(*i*) and *G*(*i*) has the form:

$H(i) = I - \tau uq * v * v'$  and  $G(i) = I - \tau up * u * u'$

where *tauq* and *taup* are real/complex scalars, and *v* and *u* are real/complex vectors;

$v(1:i-1) = 0$ ,  $v(i) = 1$ , and  $v(i+1:m)$  is stored on exit in  $A(ia+i:ia+m-1, ja+i-1)$ ;

$u(1:i) = 0$ ,  $u(i+1) = 1$ , and  $u(i+2:n)$  is stored on exit in  $A(ia+i-1, ja+i+1:ja+n-1)$ ;

*tauq* is stored in *tauq*[*ja+i-2*] and *taup* in *taup*[*ia+i-2*].

If  $m < n$ ,

$Q = H(1)*H(2)*...*H(m-1)$ , and  $P = G(1)*G(2)*...*G(m)$

Each *H*(*i*) and *G*(*i*) has the form:

$H(i) = I - \tau uq * v * v'$  and  $G(i) = I - \tau up * u * u'$

here *tauq* and *taup* are real/complex scalars, and *v* and *u* are real/complex vectors;

$v(1:i) = 0$ ,  $v(i+1) = 1$ , and  $v(i+2:m)$  is stored on exit in  $A(ia+i:ia+m-1, ja+i-1)$ ;  $u(1:i-1) = 0$ ,  $u(i) = 1$ , and  $u(i+1:n)$  is stored on exit in  $A(ia+i-1, ja+i+1:ja+n-1)$ ;

*tauq* is stored in *tauq*[*ja+i-2*] and *taup* in *taup*[*ia+i-2*].

The contents of sub(*A*) on exit are illustrated by the following examples:

$m = 6$  and  $n = 5$  ( $m > n$ ):

$$\begin{bmatrix} d & e & u1 & u1 & u1 \\ v1 & d & e & u2 & u2 \\ v1 & v2 & d & e & u3 \\ v1 & v2 & v3 & d & e \\ v1 & v2 & v3 & v4 & d \\ v1 & v2 & v3 & v4 & v5 \end{bmatrix}$$

$m = 5$  and  $n = 6$  ( $m < n$ ):

$$\begin{bmatrix} d & u1 & & & & \\ e & d & u2 & & & \\ v1 & e & d & u3 & & \\ v1 & v2 & e & d & u4 & \\ v1 & v2 & v3 & e & d & u5 \end{bmatrix}$$

where  $d$  and  $e$  denote diagonal and off-diagonal elements of  $B$ ,  $v_i$  denotes an element of the vector defining  $H(i)$ , and  $u_i$  an element of the vector defining  $G(i)$ .

*info );
```

## Include Files

- mkl\_scalapack.h

## Description

If  $vect = 'Q'$ , the `p?ormbr` function overwrites the general real distributed  $m$ -by- $n$  matrix  $sub(C) = C(ic:ic+m-1, jc:jc+n-1)$  with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q \ sub(C)$	$sub(C) \ Q$
$trans = 'T':$	$Q^T \ sub(C)$	$sub(C) \ Q^T$

If  $vect = 'P'$ , the function overwrites  $sub(C)$  with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$P \ sub(C)$	$sub(C) \ P$
$trans = 'T':$	$P^T \ sub(C)$	$sub(C) \ P^T$

Here  $Q$  and  $P^T$  are the orthogonal distributed matrices determined by `p?gebrd` when reducing a real distributed matrix  $A(ia:*, ja:*)$  to bidiagonal form:  $A(ia:*, ja:*) = Q*B*P^T$ .  $Q$  and  $P^T$  are defined as products of elementary reflectors  $H(i)$  and  $G(i)$  respectively.

Let  $nq = m$  if  $side = 'L'$  and  $nq = n$  if  $side = 'R'$ . Therefore  $nq$  is the order of the orthogonal matrix  $Q$  or  $P^T$  that is applied.

If  $vect = 'Q'$ ,  $A(ia:*, ja:*)$  is assumed to have been an  $nq$ -by- $k$  matrix:

If  $nq \geq k$ ,  $Q = H(1) H(2) \dots H(k)$ ;

If  $nq < k$ ,  $Q = H(1) H(2) \dots H(nq-1)$ .

If  $vect = 'P'$ ,  $A(ia:*, ja:*)$  is assumed to have been a  $k$ -by- $nq$  matrix:

If  $k < nq$ ,  $P = G(1) G(2) \dots G(k)$ ;

If  $k \geq nq$ ,  $P = G(1) G(2) \dots G(nq-1)$ .

## Input Parameters

<i>vect</i>	(global) If <i>vect</i> = 'Q', then $Q$ or $Q^T$ is applied. If <i>vect</i> = 'P', then $P$ or $P^T$ is applied.
<i>side</i>	(global) If <i>side</i> = 'L', then $Q$ or $Q^T$ , $P$ or $P^T$ is applied from the left. If <i>side</i> = 'R', then $Q$ or $Q^T$ , $P$ or $P^T$ is applied from the right.
<i>trans</i>	(global) If <i>trans</i> = 'N', no transpose, $Q$ or $P$ is applied. If <i>trans</i> = 'T', then $Q^T$ or $P^T$ is applied.
<i>m</i>	(global) The number of rows in the distributed matrix sub ( $C$ ).
<i>n</i>	(global) The number of columns in the distributed matrix sub ( $C$ ).
<i>k</i>	(global) If <i>vect</i> = 'Q', the number of columns in the original distributed matrix reduced by <code>p?gebrd</code> ; If <i>vect</i> = 'P', the number of rows in the original distributed matrix reduced by <code>p?gebrd</code> . Constraints: $k \geq 0$ .
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja + \min(nq, k) - 1)$ if <i>vect</i> = 'Q', and $lld\_a * LOCC(ja + nq - 1)$ if <i>vect</i> = 'P'. $nq = m$ if <i>side</i> = 'L', and $nq = n$ otherwise. The vectors that define the elementary reflectors $H(i)$ and $G(i)$ , whose products determine the matrices $Q$ and $P$ , as returned by <code>p?gebrd</code> . If <i>vect</i> = 'Q', $lld\_a \geq \max(1, LOCr(ia + nq - 1))$ ; If <i>vect</i> = 'P', $lld\_a \geq \max(1, LOCr(ia + \min(nq, k) - 1))$ .
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.

<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) Array of size $LOCc(ja+\min(nq, k)-1)$ , if <i>vect</i> = 'Q', and $LOCr(ia+\min(nq, k)-1)$ , if <i>vect</i> = 'P'. <i>tau</i> [ <i>i</i> ] must contain the scalar factor of the elementary reflector $H(i+1)$ or $G(i+1)$ which determines <i>Q</i> or <i>P</i> , as returned by <i>pdgebrd</i> in its array argument <i>tauq</i> or <i>taup</i> . <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) Pointer into the local memory to an array of size $lld\_c*LOCc(jc+n-1)$ . Contains the local pieces of the distributed matrix sub ( <i>C</i> ).
<i>ic, jc</i>	(global) The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>desc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least: If <i>side</i> = 'L' $nq = m$ ; if (( <i>vect</i> = 'Q' and $nq \geq k$ ) or ( <i>vect</i> is not equal to 'Q' and $nq > k$ )), $iaa=ia; jaa=ja; mi=m; ni=n; icc=ic; jcc=jc$ ; else $iaa= ia+1; jaa=ja; mi=m-1; ni=n; icc=ic+1; jcc= jc$ ; end if else If <i>side</i> = 'R', $nq = n$ ; if (( <i>vect</i> = 'Q' and $nq \geq k$ ) or ( <i>vect</i> is not equal to 'Q' and $nq > k$ )), $iaa=ia; jaa=ja; mi=m; ni=n; icc=ic; jcc=jc$ ; else $iaa= ia; jaa= ja+1; mi= m; ni= n-1; icc= ic; jcc= jc+1$ ; end if end if If <i>vect</i> = 'Q', If <i>side</i> = 'L', $lwork \geq \max((nb\_a*(nb\_a-1))/2, (nqc0 + mpc0)*nb\_a) + nb\_a * nb\_a$

```

else if side = 'R',

### p?unmbr

*Multiplies a general matrix by one of the unitary transformation matrices from a reduction to bidiagonal form determined by p?gebrd.*

## Syntax

```
void pcunmbr (char *vect , char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pzunmbr (char *vect , char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

If `vect = 'Q'`, the `p?unmbr` function overwrites the general complex distributed *m*-by-*n* matrix `sub(C) = C(ic:ic+m-1,jc:jc+n-1)` with

	<code>side = 'L'</code>	<code>side = 'R'</code>
<code>trans = 'N':</code>	$Q*\text{sub}(C)$	$\text{sub}(C)*Q$
<code>trans = 'C':</code>	$Q^H*\text{sub}(C)$	$\text{sub}(C)*Q^H$

If `vect = 'P'`, the function overwrites `sub(C)` with

	<code>side = 'L'</code>	<code>side = 'R'</code>
<code>trans = 'N':</code>	$P*\text{sub}(C)$	$\text{sub}(C)*P$
<code>trans = 'C':</code>	$P^H*\text{sub}(C)$	$\text{sub}(C)*P^H$

Here  $Q$  and  $P^H$  are the unitary distributed matrices determined by `p?gebrd` when reducing a complex distributed matrix  $A(ia:*, ja:*)$  to bidiagonal form:  $A(ia:*, ja:*) = Q*B*P^H$ .

$Q$  and  $P^H$  are defined as products of elementary reflectors  $H(i)$  and  $G(i)$  respectively.

Let  $nq = m$  if  $side = 'L'$  and  $nq = n$  if  $side = 'R'$ . Therefore  $nq$  is the order of the unitary matrix  $Q$  or  $P^H$  that is applied.

If  $vect = 'Q'$ ,  $A(ia:*, ja:*)$  is assumed to have been an  $nq$ -by- $k$  matrix:

If  $nq \geq k$ ,  $Q = H(1) H(2) \dots H(k)$ ;

If  $nq < k$ ,  $Q = H(1) H(2) \dots H(nq-1)$ .

If  $vect = 'P'$ ,  $A(ia:*, ja:*)$  is assumed to have been a  $k$ -by- $nq$  matrix:

If  $k < nq$ ,  $P = G(1) G(2) \dots G(k)$ ;

If  $k \geq nq$ ,  $P = G(1) G(2) \dots G(nq-1)$ .

## Input Parameters

<i>vect</i>	(global) If <i>vect</i> = 'Q', then $Q$ or $Q^H$ is applied. If <i>vect</i> = 'P', then $P$ or $P^H$ is applied.
<i>side</i>	(global) If <i>side</i> = 'L', then $Q$ or $Q^H$ , $P$ or $P^H$ is applied from the left. If <i>side</i> = 'R', then $Q$ or $Q^H$ , $P$ or $P^H$ is applied from the right.
<i>trans</i>	(global) If <i>trans</i> = 'N', no transpose, $Q$ or $P$ is applied. If <i>trans</i> = 'C', conjugate transpose, $Q^H$ or $P^H$ is applied.
<i>m</i>	(global) The number of rows in the distributed matrix sub (C) $m \geq 0$ .
<i>n</i>	(global) The number of columns in the distributed matrix sub (C) $n \geq 0$ .
<i>k</i>	(global) If <i>vect</i> = 'Q', the number of columns in the original distributed matrix reduced by <code>p?gebrd</code> ; If <i>vect</i> = 'P', the number of rows in the original distributed matrix reduced by <code>p?gebrd</code> . Constraints: $k \geq 0$ .
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja + \min(nq, k) - 1)$ if <i>vect</i> = 'Q', and $lld\_a * LOCC(ja + nq - 1)$ if <i>vect</i> = 'P'. $nq = m$ if <i>side</i> = 'L', and $nq = n$ otherwise. The vectors that define the elementary reflectors $H(i)$ and $G(i)$ , whose products determine the matrices $Q$ and $P$ , as returned by <code>p?gebrd</code> . If <i>vect</i> = 'Q', $lld\_a \geq \max(1, LOCr(ia + nq - 1))$ ; If <i>vect</i> = 'P', $lld\_a \geq \max(1, LOCr(ia + \min(nq, k) - 1))$ .
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.

<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) Array of size $LOCc(ja+\min(nq, k)-1)$ , if <i>vect</i> = 'Q', and $LOCr(ia+\min(nq, k)-1)$ , if <i>vect</i> = 'P'. <i>tau</i> [ <i>i</i> ] must contain the scalar factor of the elementary reflector $H(i+1)$ or $G(i+1)$ , which determines <i>Q</i> or <i>P</i> , as returned by <code>p?gebrd</code> in its array argument <i>tauq</i> or <i>taup</i> . <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) Pointer into the local memory to an array of size $lld\_c*LOCc(jc+n-1)$ . Contains the local pieces of the distributed matrix sub ( <i>C</i> ).
<i>ic, jc</i>	(global) The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>desc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least: If <i>side</i> = 'L' $nq = m;$ if (( <i>vect</i> = 'Q' and $nq \geq k$ ) or ( <i>vect</i> is not equal to 'Q' and $nq > k$ )), $iaa = ia; jaa = ja; mi = m; ni = n; icc = ic; jcc = jc;$ else $iaa = ia + 1; jaa = ja; mi = m - 1; ni = n; icc = ic + 1; jcc = jc;$ end if else If <i>side</i> = 'R', $nq = n;$ if (( <i>vect</i> = 'Q' and $nq \geq k$ ) or ( <i>vect</i> is not equal to 'Q' and $nq \geq k$ )), $iaa = ia; jaa = ja; mi = m; ni = n; icc = ic; jcc = jc;$ else $iaa = ia; jaa = ja + 1; mi = m; ni = n - 1; icc = ic; jcc = jc + 1;$ end if end if If <i>vect</i> = 'Q', If <i>side</i> = 'L', $lwork \geq \max((nb\_a*(nb\_a-1))/2, (nqc0+mpc0)*nb\_a) + nb\_a*nb\_a$ else if <i>side</i> = 'R',

```

## Generalized Symmetric-Definite Eigenvalue Problems: ScaLAPACK Computational Routines

This section describes ScaLAPACK routines that allow you to reduce the *generalized symmetric-definite eigenvalue problems* (see LAPACK [Generalized Symmetric-Definite Eigenvalue Problems](#) ) to standard symmetric eigenvalue problem  $Cy = \lambda y$ , which you can solve by calling ScaLAPACK routines (see [Symmetric Eigenproblems](#)).

Table "Computational Routines for Reducing Generalized Eigenproblems to Standard Problems" lists these routines.

### Computational Routines for Reducing Generalized Eigenproblems to Standard Problems

Operation	Real symmetric matrices	Complex Hermitian matrices
Reduce to standard problems	<code>p?sygst</code>	<code>p?hegst</code>

### `p?sygst`

*Reduces a real symmetric-definite generalized eigenvalue problem to the standard form.*

### Syntax

```
void pssygst (MKL_INT *ibtype , char *uplo , MKL_INT *n , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb ,
float *scale , MKL_INT *info );
```

```
void pdsygst (MKL_INT *ibtype , char *uplo , MKL_INT *n , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb ,
double *scale , MKL_INT *info );
```

### Description

The `p?sygst` function reduces real symmetric-definite generalized eigenproblems to the standard form.

In the following `sub(A)` denotes  $A(ia:ia+n-1, ja:ja+n-1)$  and `sub(B)` denotes  $B(ib:ib+n-1, jb:jb+n-1)$ .

If `ibtype = 1`, the problem is

$$\text{sub}(A)*x = \lambda*\text{sub}(B)*x,$$

and  $\text{sub}(A)$  is overwritten by  $\text{inv}(U^T)*\text{sub}(A)*\text{inv}(U)$ , or  $\text{inv}(L)*\text{sub}(A)*\text{inv}(L^T)$ .

If  $\text{ibtype} = 2$  or  $3$ , the problem is

$\text{sub}(A)*\text{sub}(B)*x = \lambda*x$ , or  $\text{sub}(B)*\text{sub}(A)*x = \lambda*x$ ,

and  $\text{sub}(A)$  is overwritten by  $U*\text{sub}(A)*U^T$ , or  $L^T*\text{sub}(A)*L$ .

$\text{sub}(B)$  must have been previously factorized as  $U^T*U$  or  $L*L^T$  by `p?potrf`.

## Input Parameters

<i>ibtype</i>	(global) Must be 1 or 2 or 3. If <i>itype</i> = 1, compute $\text{inv}(U^T)*\text{sub}(A)*\text{inv}(U)$ , or $\text{inv}(L)*\text{sub}(A)*\text{inv}(L^T)$ ; If <i>itype</i> = 2 or 3, compute $U*\text{sub}(A)*U^T$ , or $L^T*\text{sub}(A)*L$ .
<i>uplo</i>	(global) Must be 'U' or 'L'. If <i>uplo</i> = 'U', the upper triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as $U^T*U$ . If <i>uplo</i> = 'L', the lower triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as $L*L^T$ .
<i>n</i>	(global) The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$ ( $n \geq 0$ ).
<i>a</i>	(local) Pointer into the local memory to an array of size $\text{lld}_a*\text{LOCc}(j_a+n-1)$ . On entry, the array contains the local pieces of the $n$ -by- $n$ symmetric distributed matrix $\text{sub}(A)$ . If <i>uplo</i> = 'U', the leading $n$ -by- $n$ upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = 'L', the leading $n$ -by- $n$ lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .
<i>b</i>	(local) Pointer into the local memory to an array of size $\text{lld}_b*\text{LOCc}(j_b+n-1)$ . On entry, the array contains the local pieces of the triangular factor from the Cholesky factorization of $\text{sub}(B)$ as returned by <code>p?potrf</code> .
<i>ib, jb</i>	(global) The row and column indices in the global matrix $B$ indicating the first row and the first column of the submatrix $B$ , respectively.
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $B$ .

## Output Parameters

<i>a</i>	On exit, if <i>info</i> = 0, the transformed matrix, stored in the same format as sub( <i>A</i> ).
<i>scale</i>	(global) Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this function. At present, <i>scale</i> is always returned as 1.0, it is returned here to allow for future enhancement.
<i>info</i>	(global) If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -( <i>i</i> *100+ <i>j</i> ); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

## p?hegst

*Reduces a Hermitian positive-definite generalized eigenvalue problem to the standard form.*

## Syntax

```
void pchegst (MKL_INT *ibtype , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , float *scale , MKL_INT *info );
```

```
void pzhegst (MKL_INT *ibtype , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , double *scale , MKL_INT *info );
```

## Include Files

- mkl\_scalapack.h

## Description

The p?hegst function reduces complex Hermitian positive-definite generalized eigenproblems to the standard form.

In the following sub(*A*) denotes  $A(ia:ia+n-1, ja:ja+n-1)$  and sub(*B*) denotes  $B(ib:ib+n-1, jb:jb+n-1)$ .

If *ibtype* = 1, the problem is

$$\text{sub}(A)*x = \lambda*\text{sub}(B)*x,$$

and sub(*A*) is overwritten by  $\text{inv}(U^H)*\text{sub}(A)*\text{inv}(U)$ , or  $\text{inv}(L)*\text{sub}(A)*\text{inv}(L^H)$ .

If *ibtype* = 2 or 3, the problem is

$$\text{sub}(A)*\text{sub}(B)*x = \lambda*x, \text{ or } \text{sub}(B)*\text{sub}(A)*x = \lambda*x,$$

and sub(*A*) is overwritten by  $U*\text{sub}(A)*U^H$ , or  $L^H*\text{sub}(A)*L$ .

sub(*B*) must have been previously factorized as  $U^H*U$  or  $L*L^H$  by p?potrf.

## Input Parameters

<i>ibtype</i>	(global) Must be 1 or 2 or 3. If <i>itype</i> = 1, compute $\text{inv}(U^H) \cdot \text{sub}(A) \cdot \text{inv}(U)$ , or $\text{inv}(L) \cdot \text{sub}(A) \cdot \text{inv}(L^H)$ ; If <i>itype</i> = 2 or 3, compute $U \cdot \text{sub}(A) \cdot U^H$ , or $L^H \cdot \text{sub}(A) \cdot L$ .
<i>uplo</i>	(global) Must be 'U' or 'L'. If <i>uplo</i> = 'U', the upper triangle of sub(A) is stored and sub (B) is factored as $U^H \cdot U$ . If <i>uplo</i> = 'L', the lower triangle of sub(A) is stored and sub (B) is factored as $L \cdot L^H$ .
<i>n</i>	(global) The order of the matrices sub (A) and sub (B) ( $n \geq 0$ ).
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a \cdot LOCC(ja+n-1)$ . On entry, the array contains the local pieces of the $n$ -by- $n$ Hermitian distributed matrix sub(A). If <i>uplo</i> = 'U', the leading $n$ -by- $n$ upper triangular part of sub(A) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = 'L', the leading $n$ -by- $n$ lower triangular part of sub(A) contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A, respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A.
<i>b</i>	(local) Pointer into the local memory to an array of size $lld\_b \cdot LOCC(jb+n-1)$ . On entry, the array contains the local pieces of the triangular factor from the Cholesky factorization of sub (B) as returned by <code>p?potrf</code> .
<i>ib, jb</i>	(global) The row and column indices in the global matrix B indicating the first row and the first column of the submatrix B, respectively.
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix B.

## Output Parameters

<i>a</i>	On exit, if <i>info</i> = 0, the transformed matrix, stored in the same format as sub(A).
<i>scale</i>	(global) Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this function. At present, <i>scale</i> is always returned as 1.0, it is returned here to allow for future enhancement.
<i>info</i>	(global)

If  $info = 0$ , the execution is successful. If  $info < 0$ , if the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j - 1$ , had an illegal value, then  $info = -(j*100+j)$ ; if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

```

## Include Files

- mkl\_scalapack.h

## Description

The `p?geevx` function computes for an  $n$ -by- $n$  real/complex non-symmetric matrix  $A$ , the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors ( $ilo$ ,  $ihi$ ,  $scale$ , and  $abnrm$ ), reciprocal condition numbers for the eigenvalues ( $rconde$ ).

The right eigenvector  $v$  of  $A$  satisfies

$$A \cdot v = \lambda \cdot v$$

where  $\lambda$  is its eigenvalue.

The left eigenvector  $u$  of  $A$  satisfies.

$$u^H A = \lambda u^H$$

where  $u^H$  denotes the conjugate transpose of  $u$ . The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation  $D \cdot A \cdot \text{inv}(D)$ , where  $D$  is a diagonal matrix, to make its rows and columns closer in norm and the condition number of its eigenvalues smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers in exact arithmetic, but diagonal scaling will.

---

### NOTE

The current version doesn't support computation of the reciprocal condition numbers for the right eigenvectors.

---

## Current Notes and Restrictions

All the `p?geevx` interfaces call `p?lahqr` for computing eigenvalues and eigenvectors of the Hessenberg matrices. There are several restrictions for the usage of `p?lahqr`, which include:

- The current implementation of `p?lahqr` requires the distributed block size to be square and at least six (6); unlike simpler codes like LU, this algorithm is extremely sensitive to block size.

- The current implementation of `p?lahqr` requires that input matrix  $A$ , the left and right eigenvector matrices  $VR$  and/or  $VL$  to be distributed identically and have identical context.

## Parameters

<i>balanc</i>	<p>(global). Must be 'N', 'P', 'S', or 'B'. Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues.</p> <p>If <i>balanc</i> = 'N', do not diagonally scale or permute;</p> <p>If <i>balanc</i> = 'P', perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale;</p> <p>If <i>balanc</i> = 'S', diagonally scale the matrix, that is, replace <math>A</math> by <math>D*A*inv(D)</math>, where <math>D</math> is a diagonal matrix chosen to make the rows and columns of <math>A</math> more equal in norm. Do not permute;</p> <p>If <i>balanc</i> = 'B', both diagonally scale and permute <math>A</math>.</p> <p>Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.</p>
<i>jobvl</i>	<p>(global). Must be 'N' or 'V'.</p> <p>If <i>jobvl</i> = 'N', left eigenvectors of <math>A</math> are not computed;</p> <p>If <i>jobvl</i> = 'V', left eigenvectors of <math>A</math> are computed.</p> <p>If <i>sense</i> = 'E', then <i>jobvl</i> must be 'V'.</p>
<i>jobvr</i>	<p>(global). Must be 'N' or 'V'.</p> <p>If <i>jobvr</i> = 'N', right eigenvectors of <math>A</math> are not computed;</p> <p>If <i>jobvr</i> = 'V', right eigenvectors of <math>A</math> are computed.</p> <p>If <i>sense</i> = 'E', then <i>jobvr</i> must be 'V'.</p>
<i>sense</i>	<p>(global). Must be 'N' or 'E'. Determines which reciprocal condition numbers are computed.</p> <p>If <i>sense</i> = 'N', none are computed.</p> <p>If <i>sense</i> = 'E', computed for eigenvalues only.</p>
<i>n</i>	(global) The order of the distributed matrix $A$ ( $n \geq 0$ ).
<i>a</i>	<p>(local)</p> <p>Pointer into the local memory to an array of size <math>lld\_a*LOCc(n)</math>. On entry, this array contains the local pieces of the <math>n</math>-by-<math>n</math> general distributed matrix <math>A</math> to be reduced.</p>
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .
<i>wr, wi</i>	(global output) Arrays, size at least $\max(1, n)$ each. Contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

<i>w</i>	(global output) Array, size at least $\max(1, n)$ . Contains the computed eigenvalues.
<i>vl</i>	(local output) Pointer into the local memory to an array of size $(DESCVL(LLD\_),LOCc(n))$ . If <i>jobvl</i> = 'N', <i>vl</i> is not referenced. If <i>jobvl</i> = 'V', the <i>vl</i> parameter contains the local pieces of the left eigenvectors of the matrix <i>A</i> .
<i>descvl</i>	(global and local input) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>vl</i> .
<i>vr</i>	(local output) Pointer into the local memory to an array of size $(DESCVR(LLD\_),LOCc(n))$ . If <i>jobvr</i> = 'N', <i>vr</i> is not referenced. If <i>jobvr</i> = 'V', the <i>vr</i> parameter contains the local pieces of the right eigenvectors of the matrix <i>A</i> .
<i>descvr</i>	(global and local input) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>vr</i> .
<i>ilo, ihi</i>	(global output) <i>ilo</i> and <i>ihi</i> are integer values determined when <i>A</i> was balanced. The balanced $A(i,j) = 0$ if $i > j$ and $j = 1, \dots, ilo-1$ or $i = ihi+1, \dots, n$ . If <i>balanc</i> = 'N' or 'S', <i>ilo</i> = 1 and <i>ihi</i> = <i>n</i> .
<i>scale</i>	(global output) Array, size at least $\max(1, n)$ . Details of the permutations and scaling factors applied when balancing <i>A</i> . If $P[j - 1]$ is the index of the row and column interchanged with row and column <i>j</i> , and $D[j - 1]$ is the scaling factor applied to row and column <i>j</i> , then $scale[j - 1] = P[j - 1]$ , for $j = 1, \dots, ilo-1$ $= D[j - 1]$ , for $j = ilo, \dots, ihi$ $= P[j - 1]$ for $j = ihi+1, \dots, n$ . The order in which the interchanges are made is <i>n</i> to <i>ihi+1</i> , then 1 to <i>ilo-1</i> .
<i>abnrm</i>	The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).
<i>rconde</i>	Array, size at least $\max(1, n)$ . <i>rconde</i> [ <i>j</i> - 1] is the reciprocal condition number of the <i>j</i> -th eigenvalue.
<i>rcondv</i>	Not supported in the current version. It could be null pointer.
<i>work</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) size of the array <i>work</i> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum size for the work array. These values are returned in the first entry of the <i>work</i> array, and no error message is issued by <a href="#">pxerbla</a> .

*info* (global)

= 0: the execution is successful.

< 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j*- 1, had an illegal value, then *info* =  $-(i*100+j)$ ; if the *i*-th argument is a scalar and had an illegal value, then *info* =  $-i$ .

## p?gesv

*Computes the solution to the system of linear equations with a square distributed matrix and multiple right-hand sides.*

### Syntax

```
void psgesv (MKL_INT *n , MKL_INT *nrhs , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT

### Description

The p?gesv function computes the solution to a real or complex system of linear equations  $\text{sub}(A) * X = \text{sub}(B)$ , where  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$  is an  $n$ -by- $n$  distributed matrix and  $X$  and  $\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1)$  are  $n$ -by- $nrhs$  distributed matrices.

The  $LU$  decomposition with partial pivoting and row interchanges is used to factor  $\text{sub}(A)$  as  $\text{sub}(A) = P * L * U$ , where  $P$  is a permutation matrix,  $L$  is unit lower triangular, and  $U$  is upper triangular.  $L$  and  $U$  are stored in  $\text{sub}(A)$ . The factored form of  $\text{sub}(A)$  is then used to solve the system of equations  $\text{sub}(A) * X = \text{sub}(B)$ .

### Input Parameters

*n* (global) The number of rows and columns to be operated on, that is, the order of the distributed submatrix  $\text{sub}(A)$  ( $n \geq 0$ ).

*nrhs* (global) The number of right hand sides, that is, the number of columns of the distributed submatrices  $B$  and  $X$  ( $nrhs \geq 0$ ).

*a, b* (local)

Pointers into the local memory to arrays of local size *a*:  $\text{lld}_a * \text{LOCc}(\text{ja} + n - 1)$  and *b*:  $\text{lld}_b * \text{LOCc}(\text{jb} + nrhs - 1)$ , respectively.

On entry, the array *a* contains the local pieces of the *n*-by-*n* distributed matrix sub(*A*) to be factored.

On entry, the array *b* contains the right hand side distributed matrix sub(*B*).

<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of sub( <i>A</i> ), respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>ib, jb</i>	(global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of sub( <i>B</i> ), respectively.
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .

## Output Parameters

<i>a</i>	Overwritten by the factors <i>L</i> and <i>U</i> from the factorization $\text{sub}(A) = P * L * U$ ; the unit diagonal elements of <i>L</i> are not stored .
<i>b</i>	Overwritten by the solution distributed matrix <i>X</i> .
<i>ipiv</i>	(local) Array of size $LOCr(m\_a) + mb\_a$ . This array contains the pivoting information. The (local) row <i>i</i> of the matrix was interchanged with the (global) row <i>ipiv</i> [ <i>i</i> - 1].  This array is tied to the distributed matrix <i>A</i> .
<i>info</i>	(global) If <i>info</i> =0, the execution is successful.  <i>info</i> < 0:  If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then $info = -(i * 100 + j)$ ; if the <i>i</i> -th argument is a scalar and had an illegal value, then $info = -i$ .  <i>info</i> > 0:  If $info = k$ , $U(ia+k-1, ja+k-1)$ is exactly zero. The factorization has been completed, but the factor <i>U</i> is exactly singular, so the solution could not be computed.

## Description

The `p?gesvx` function uses the *LU* factorization to compute the solution to a real or complex system of linear equations  $AX = B$ , where  $A$  denotes the  $n$ -by- $n$  submatrix  $A(ia:ia+n-1, ja:ja+n-1)$ ,  $B$  denotes the  $n$ -by- $nrhs$  submatrix  $B(ib:ib+n-1, jb:jb+nrhs-1)$  and  $X$  denotes the  $n$ -by- $nrhs$  submatrix  $X(ix:ix+n-1, jx:jx+nrhs-1)$ .

Error bounds on the solution and a condition estimate are also provided.

In the following description, *af* stands for the subarray of *af* from row *iaf* and column *jaf* to row *iaf+n-1* and column *jaf+n-1*.

The function `p?gesvx` performs the following steps:

1. If *fact* = 'E', real scaling factors  $R$  and  $C$  are computed to equilibrate the system:

$$trans = 'N': \text{diag}(R) * A * \text{diag}(C) * \text{diag}(C)^{-1} * X = \text{diag}(R) * B$$

$$trans = 'T': (\text{diag}(R) * A * \text{diag}(C))^T * \text{diag}(R)^{-1} * X = \text{diag}(C) * B$$

$$trans = 'C': (\text{diag}(R) * A * \text{diag}(C))^H * \text{diag}(R)^{-1} * X = \text{diag}(C) * B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix  $A$ , but if equilibration is used,  $A$  is overwritten by  $\text{diag}(R) * A * \text{diag}(C)$  and  $B$  by  $\text{diag}(R) * B$  (if *trans*='N') or  $\text{diag}(C) * B$  (if *trans* = 'T' or 'C').

2. If *fact* = 'N' or 'E', the *LU* decomposition is used to factor the matrix  $A$  (after equilibration if *fact* = 'E') as  $A = PLU$ , where  $P$  is a permutation matrix,  $L$  is a unit lower triangular matrix, and  $U$  is upper triangular.
3. The factored form of  $A$  is used to estimate the condition number of the matrix  $A$ . If the reciprocal of the condition number is less than relative machine precision, steps 4 - 6 are skipped.

4. The system of equations is solved for  $X$  using the factored form of  $A$ .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix  $X$  is premultiplied by  $\text{diag}(C)$  (if  $\text{trans} = 'N'$ ) or  $\text{diag}(R)$  (if  $\text{trans} = 'T'$  or  $'C'$ ) so that it solves the original system before equilibration.

## Input Parameters

<i>fact</i>	<p>(global) Must be 'F', 'N', or 'E'.</p> <p>Specifies whether or not the factored form of the matrix <math>A</math> is supplied on entry, and if not, whether the matrix <math>A</math> should be equilibrated before it is factored.</p> <p>If <math>\text{fact} = 'F'</math> then, on entry, <math>\text{af}</math> and <math>\text{ipiv}</math> contain the factored form of <math>A</math>. If <math>\text{equed}</math> is not 'N', the matrix <math>A</math> has been equilibrated with scaling factors given by <math>r</math> and <math>c</math>. Arrays <math>a</math>, <math>\text{af}</math>, and <math>\text{ipiv}</math> are not modified.</p> <p>If <math>\text{fact} = 'N'</math>, the matrix <math>A</math> is copied to <math>\text{af}</math> and factored.</p> <p>If <math>\text{fact} = 'E'</math>, the matrix <math>A</math> is equilibrated if necessary, then copied to <math>\text{af}</math> and factored.</p>
<i>trans</i>	<p>(global) Must be 'N', 'T', or 'C'.</p> <p>Specifies the form of the system of equations:</p> <p>If <math>\text{trans} = 'N'</math>, the system has the form <math>A*X = B</math> (No transpose);</p> <p>If <math>\text{trans} = 'T'</math>, the system has the form <math>A^T*X = B</math> (Transpose);</p> <p>If <math>\text{trans} = 'C'</math>, the system has the form <math>A^H*X = B</math> (Conjugate transpose);</p>
<i>n</i>	<p>(global) The number of linear equations; the order of the submatrix <math>A</math> (<math>n \geq 0</math>).</p>
<i>nrhs</i>	<p>(global) The number of right hand sides; the number of columns of the distributed submatrices <math>B</math> and <math>X</math> (<math>\text{nrhs} \geq 0</math>).</p>
<i>a, af, b, work</i>	<p>(local)</p> <p>Pointers into the local memory to arrays of local size <math>a</math>: <math>\text{lld\_a} * \text{LOCC}(ja + n - 1)</math>, <math>\text{af}</math>: <math>\text{lld\_af} * \text{LOCC}(ja + n - 1)</math>, <math>b</math>: <math>\text{lld\_b} * \text{LOCC}(jb + \text{nrhs} - 1)</math>, <math>\text{work}</math>: <math>\text{lwork}</math>.</p> <p>The array <math>a</math> contains the matrix <math>A</math>. If <math>\text{fact} = 'F'</math> and <math>\text{equed}</math> is not 'N', then <math>A</math> must have been equilibrated by the scaling factors in <math>r</math> and/or <math>c</math>.</p> <p>The array <math>\text{af}</math> is an input argument if <math>\text{fact} = 'F'</math>. In this case it contains on entry the factored form of the matrix <math>A</math>, that is, the factors <math>L</math> and <math>U</math> from the factorization <math>A = P * L * U</math> as computed by <code>p?getrf</code>. If <math>\text{equed}</math> is not 'N', then <math>\text{af}</math> is the factored form of the equilibrated matrix <math>A</math>.</p> <p>The array <math>b</math> contains on entry the matrix <math>B</math> whose columns are the right-hand sides for the systems of equations.</p> <p><math>\text{work}</math> is a workspace array. The size of <math>\text{work}</math> is (<math>\text{lwork}</math>).</p>
<i>ia, ja</i>	<p>(global) The row and column indices in the global matrix <math>A</math> indicating the first row and the first column of the submatrix <math>A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)</math>, respectively.</p>

<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>iaf, jaf</i>	(global) The row and column indices in the global matrix <i>AF</i> indicating the first row and the first column of the subarray <i>af</i> , respectively.
<i>descaf</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>AF</i> .
<i>ib, jb</i>	(global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the submatrix $B(ib:ib+n-1, jb:jb+nrhs-1)$ , respectively.
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .
<i>ipiv</i>	<p>(local) Array of size <math>LOCr(m_a)+mb_a</math>.</p> <p>The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F' .</p> <p>On entry, it contains the pivot indices from the factorization <math>A = P^*L^*U</math> as computed by <i>p?getrf</i>; (local) row <i>i</i> of the matrix was interchanged with the (global) row <i>ipiv</i>[<i>i</i> - 1].</p> <p>This array must be aligned with <math>A(ia:ia+n-1, *)</math>.</p>
<i>equed</i>	<p>(global) Must be 'N', 'R', 'C', or 'B'. <i>equed</i> is an input argument if <i>fact</i> = 'F' . It specifies the form of equilibration that was done:</p> <p>If <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N');</p> <p>If <i>equed</i> = 'R', row equilibration was done, that is, <i>A</i> has been premultiplied by <math>diag(r)</math>;</p> <p>If <i>equed</i> = 'C', column equilibration was done, that is, <i>A</i> has been postmultiplied by <math>diag(c)</math>;</p> <p>If <i>equed</i> = 'B', both row and column equilibration was done; <i>A</i> has been replaced by <math>diag(r) * A * diag(c)</math>.</p>
<i>r, c</i>	<p>(local)</p> <p>Arrays of size <math>LOCr(m_a)</math> and <math>LOCc(n_a)</math>, respectively.</p> <p>The array <i>r</i> contains the row scale factors for <i>A</i>, and the array <i>c</i> contains the column scale factors for <i>A</i>. These arrays are input arguments if <i>fact</i> = 'F' only; otherwise they are output arguments. If <i>equed</i> = 'R' or 'B', <i>A</i> is multiplied on the left by <math>diag(r)</math>; if <i>equed</i> = 'N' or 'C', <i>r</i> is not accessed.</p> <p>If <i>fact</i> = 'F' and <i>equed</i> = 'R' or 'B', each element of <i>r</i> must be positive.</p> <p>If <i>equed</i> = 'C' or 'B', <i>A</i> is multiplied on the right by <math>diag(c)</math>; if <i>equed</i> = 'N' or 'R', <i>c</i> is not accessed.</p> <p>If <i>fact</i> = 'F' and <i>equed</i> = 'C' or 'B', each element of <i>c</i> must be positive. Array <i>r</i> is replicated in every process column, and is aligned with the distributed matrix <i>A</i>. Array <i>c</i> is replicated in every process row, and is aligned with the distributed matrix <i>A</i>.</p>

<i>ix, jx</i>	(global) The row and column indices in the global matrix $X$ indicating the first row and the first column of the submatrix $X(ix:ix+n-1, jx:jx+nrhs-1)$ , respectively.
<i>descx</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $X$ .
<i>lwork</i>	(local or global) The size of the array <i>work</i> ; must be at least $\max(p?gecon(lwork), p?gerfs(lwork))+LOCr(n\_a)$ .
<i>iwork</i>	(local, <i>psgesvx</i> / <i>pdgesvx</i> only). Workspace array. The size of <i>iwork</i> is ( <i>liwork</i> ).
<i>liwork</i>	(local, <i>psgesvx</i> / <i>pdgesvx</i> only). The size of the array <i>iwork</i> , must be at least $LOCr(n\_a)$ .
<i>rwork</i>	(local) Workspace array, used in complex flavors only. The size of <i>rwork</i> is ( <i>lrwork</i> ).
<i>lrwork</i>	(local or global, <i>pcgesvx</i> / <i>pzgesvx</i> only). The size of the array <i>rwork</i> ; must be at least $2*LOCc(n\_a)$ .

## Output Parameters

<i>x</i>	(local) Pointer into the local memory to an array of local size $lld\_x*LOCc(jx+nrhs-1)$ .  If <i>info</i> = 0, the array <i>x</i> contains the solution matrix $X$ to the <i>original</i> system of equations. Note that $A$ and $B$ are modified on exit if <i>equed</i> ≠'N', and the solution to the <i>equilibrated</i> system is:  $diag(C)^{-1}*X$ , if <i>trans</i> = 'N' and <i>equed</i> = 'C' or 'B'; and $diag(R)^{-1}*X$ , if <i>trans</i> = 'T' or 'C' and <i>equed</i> = 'R' or 'B'.
<i>a</i>	Array <i>a</i> is not modified on exit if <i>fact</i> = 'F' or 'N', or if <i>fact</i> = 'E' and <i>equed</i> = 'N'.  If <i>equed</i> ≠'N', $A$ is scaled on exit as follows:  <i>equed</i> = 'R': $A = diag(R)*A$ <i>equed</i> = 'C': $A = A*diag(c)$ <i>equed</i> = 'B': $A = diag(R)*A*diag(c)$
<i>af</i>	If <i>fact</i> = 'N' or 'E', then <i>af</i> is an output argument and on exit returns the factors $L$ and $U$ from the factorization $A = P*L*U$ of the original matrix $A$ (if <i>fact</i> = 'N') or of the equilibrated matrix $A$ (if <i>fact</i> = 'E'). See the description of <i>a</i> for the form of the equilibrated matrix.
<i>b</i>	Overwritten by $diag(R)*B$ if <i>trans</i> = 'N' and <i>equed</i> = 'R' or 'B'; overwritten by $diag(c)*B$ if <i>trans</i> = 'T' and <i>equed</i> = 'C' or 'B'; not changed if <i>equed</i> = 'N'.
<i>r, c</i>	These arrays are output arguments if <i>fact</i> ≠'F'.

	See the description of $r$ , $c$ in <i>Input Arguments</i> section.
<code>rcond</code>	(global) An estimate of the reciprocal condition number of the matrix $A$ after equilibration (if done). The function sets <code>rcond = 0</code> if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <code>rcond</code> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
<code>ferr, berr</code>	(local) Arrays of size <code>LOCc(n_b)</code> each. Contain the component-wise forward and relative backward errors, respectively, for each solution vector. Arrays <code>ferr</code> and <code>berr</code> are both replicated in every process row, and are aligned with the matrices $B$ and $X$ .
<code>ipiv</code>	If <code>fact = 'N'</code> or <code>'E'</code> , then <code>ipiv</code> is an output argument and on exit contains the pivot indices from the factorization $A = P*L*U$ of the original matrix $A$ (if <code>fact = 'N'</code> ) or of the equilibrated matrix $A$ (if <code>fact = 'E'</code> ).
<code>equed</code>	If <code>fact ≠ 'F'</code> , then <code>equed</code> is an output argument. It specifies the form of equilibration that was done (see the description of <code>equed</code> in <i>Input Arguments</i> section).
<code>work[0]</code>	If <code>info=0</code> , on exit <code>work[0]</code> returns the minimum value of <code>lwork</code> required for optimum performance.
<code>iwork[0]</code>	If <code>info=0</code> , on exit <code>iwork[0]</code> returns the minimum value of <code>liwork</code> required for optimum performance.
<code>rwork[0]</code>	If <code>info=0</code> , on exit <code>rwork[0]</code> returns the minimum value of <code>lrwork</code> required for optimum performance.
<code>info</code>	If <code>info=0</code> , the execution is successful.  <code>info &lt; 0</code> : if the $i$ th argument is an array and the $j$ th entry had an illegal value, then <code>info = -(i*100+j)</code> ; if the $i$ th argument is a scalar and had an illegal value, then <code>info = -i</code> . If <code>info = i</code> , and $i \leq n$ , then $U(i,i)$ is exactly zero. The factorization has been completed, but the factor $U$ is exactly singular, so the solution and error bounds could not be computed. If <code>info = i</code> , and $i = n + 1$ , then $U$ is nonsingular, but <code>rcond</code> is less than machine precision. The factorization has been completed, but the matrix is singular to working precision and the solution and error bounds have not been computed.

## Description

The `p?gbsv` function computes the solution to a real or complex system of linear equations

$$\text{sub}(A) * X = \text{sub}(B),$$

where  $\text{sub}(A) = A(1:n, ja:ja+n-1)$  is an  $n$ -by- $n$  real/complex general banded distributed matrix with  $bwl$  subdiagonals and  $bwu$  superdiagonals, and  $X$  and  $\text{sub}(B) = B(ib:ib+n-1, 1:rhs)$  are  $n$ -by- $nrhs$  distributed matrices.

The  $LU$  decomposition with partial pivoting and row interchanges is used to factor  $\text{sub}(A)$  as  $\text{sub}(A) = P * L * U * Q$ , where  $P$  and  $Q$  are permutation matrices, and  $L$  and  $U$  are banded lower and upper triangular matrices, respectively. The matrix  $Q$  represents reordering of columns for the sake of parallelism, while  $P$  represents reordering of rows for numerical stability using classic partial pivoting.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

$n$	(global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$ ( $n \geq 0$ ).
$bwl$	(global) The number of subdiagonals within the band of $A$ ( $0 \leq bwl \leq n-1$ ).
$bwu$	(global) The number of superdiagonals within the band of $A$ ( $0 \leq bwu \leq n-1$ ).
$nrhs$	(global) The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ( $nrhs \geq 0$ ).
$a, b$	(local) Pointers into the local memory to arrays of local size $a$ : $lld\_a * LOCC(ja + n - 1)$ and $b$ : $lld\_b * LOCC(nrhs)$ .

On entry, the array *a* contains the local pieces of the global array *A*.

On entry, the array *b* contains the right hand side distributed matrix sub(*B*).

<i>ja</i>	(global) The index in the global matrix <i>A</i> indicating the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i> ).
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .  If <i>desca</i> [ <i>dtype_</i> - 1] = 501, then <i>dlen_</i> ≥ 7; else if <i>desca</i> [ <i>dtype_</i> - 1] = 1, then <i>dlen_</i> ≥ 9.
<i>ib</i>	(global) The row index in the global matrix <i>B</i> indicating the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i> ).
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .  If <i>descb</i> [ <i>dtype_-</i> 1] = 502, then <i>dlen_</i> ≥ 7; else if <i>descb</i> [ <i>dtype_-</i> 1] = 1, then <i>dlen_</i> ≥ 9.
<i>work</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the array <i>work</i> , must be at least $lwork \geq (NB + bwu) * (bwl + bwu) + 6 * (bwl + bwu) * (bwl + 2 * bwu) + \max(nrhs * (NB + 2 * bwl + 4 * bwu), 1)$ .

## Output Parameters

<i>a</i>	On exit, contains details of the factorization. Note that the resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.
<i>b</i>	On exit, this array contains the local pieces of the solution distributed matrix <i>X</i> .
<i>ipiv</i>	(local) array.  The size of <i>ipiv</i> must be at least <i>desca</i> [ <i>NB</i> - 1]. This array contains pivot indices for local factorizations. You should not alter the contents between factorization and solve.
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	If <i>info</i> =0, the execution is successful. <i>info</i> < 0:  If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = -( <i>i</i> *100+ <i>j</i> ); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .  <i>info</i> > 0:

If  $info = k \leq NPROCS$ , the submatrix stored on processor  $info$  and factored locally was not nonsingular, and the factorization was not completed. If  $info = k > NPROCS$ , the submatrix stored on processor  $info - NPROCS$  representing interactions with other processors was not nonsingular, and the factorization was not completed.

## Description

The p?dbsv function solves the following system of linear equations:

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where  $A(1:n, ja:ja+n-1)$  is an  $n$ -by- $n$  real/complex banded diagonally dominant-like distributed matrix with bandwidth  $bwl$ ,  $bwu$ .

Gaussian elimination without pivoting is used to factor a reordering of the matrix into  $LU$ .

Notice revision #20201201

## Input Parameters

$n$	(global) The order of the distributed submatrix $A$ , ( $n \geq 0$ ).
$bwl$	(global) Number of subdiagonals. $0 \leq bwl \leq n-1$ .
$bwu$	(global) Number of subdiagonals. $0 \leq bwu \leq n-1$ .

<i>nrhs</i>	(global) The number of right-hand sides; the number of columns of the distributed submatrix <i>B</i> , ( <i>nrhs</i> ≥ 0).
<i>a</i>	(local). Pointer into the local memory to an array with leading size $lld\_a \geq (bwl + bwu + 1)$ (stored in <i>desca</i> ). On entry, this array contains the local pieces of the distributed matrix.
<i>ja</i>	(global) The index in the global matrix <i>A</i> indicating the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i> ).
<i>desca</i>	(global and local) array of size <i>dlen</i> . If 1d type ( <i>dtype_a</i> =501 or 502), <i>dlen</i> ≥ 7; If 2d type ( <i>dtype_a</i> =1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>A</i> . Contains information of mapping of <i>A</i> to memory.
<i>b</i>	(local) Pointer into the local memory to an array of local lead size $lld\_b \geq nb$ . On entry, this array contains the local pieces of the right hand sides <i>B</i> ( <i>ib</i> : <i>ib</i> + <i>n</i> - 1, 1: <i>nrhs</i> ).
<i>ib</i>	(global) The row index in the global matrix <i>B</i> indicating the first row of the matrix to be operated on (which may be either all of <i>b</i> or a submatrix of <i>B</i> ).
<i>descb</i>	(global and local) array of size <i>dlen</i> . If 1d type ( <i>dtype_b</i> =502), <i>dlen</i> ≥ 7; If 2d type ( <i>dtype_b</i> =1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>B</i> . Contains information of mapping of <i>B</i> to memory.
<i>work</i>	(local). Temporary workspace. This space may be overwritten in between calls to functions. <i>work</i> must be the size given in <i>lwork</i> .
<i>lwork</i>	(local or global) Size of user-input workspace <i>work</i> . If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i> [0] and an error code is returned. $lwork \geq nb(bwl + bwu) + 6 \max(bwl, bwu) * \max(bwl, bwu) + \max(\max(bwl, bwu) nrhs, \max(bwl, bwu) * \max(bwl, bwu))$

## Output Parameters

<i>a</i>	On exit, this array contains information containing details of the factorization.  Note that permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.
<i>b</i>	On exit, this contains the local piece of the solutions distributed matrix <i>X</i> .

*work* On exit, *work*[0] contains the minimal *lwork*.

*info* (local) If *info*=0, the execution is successful.

< 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i*\*100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

> 0: If *info* = *k* < NPROCS, the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed.

If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.

**Input Parameters**

<i>n</i>	(global) The order of the distributed submatrix $A$ ( $n \geq 0$ ).
<i>nrhs</i>	The number of right hand sides; the number of columns of the distributed matrix $B$ ( $nrhs \geq 0$ ).
<i>dl</i>	(local). Pointer to local part of global vector storing the lower diagonal of the matrix. Globally, $dl[0]$ is not referenced, and $dl$ must be aligned with $d$ . Must be of size $> desca[nb\_ - 1]$ .
<i>d</i>	(local). Pointer to local part of global vector storing the main diagonal of the matrix.
<i>du</i>	(local). Pointer to local part of global vector storing the upper diagonal of the matrix. Globally, $du[n - 1]$ is not referenced, and $du$ must be aligned with $d$ .
<i>ja</i>	(global) The index in the global matrix $A$ indicating the start of the matrix to be operated on (which may be either all of $A$ or a submatrix of $A$ ).
<i>desca</i>	(global and local) array of size $dlen$ . If 1d type ( $dtype\_a=501$ or $502$ ), $dlen \geq 7$ ; If 2d type ( $dtype\_a=1$ ), $dlen \geq 9$ . The array descriptor for the distributed matrix $A$ . Contains information of mapping of $A$ to memory.
<i>b</i>	(local) Pointer into the local memory to an array of local lead size $lld\_b > nb$ . On entry, this array contains the local pieces of the right hand sides $B(ib:ib + n - 1, 1:nrhs)$ .
<i>ib</i>	(global) The row index in the global matrix $B$ indicating the first row of the matrix to be operated on (which may be either all of $b$ or a submatrix of $B$ ).
<i>descb</i>	(global and local) array of size $dlen$ . If 1d type ( $dtype\_b = 502$ ), $dlen \geq 7$ ; If 2d type ( $dtype\_b = 1$ ), $dlen \geq 9$ . The array descriptor for the distributed matrix $B$ . Contains information of mapping of $B$ to memory.
<i>work</i>	(local).

*lwork* (local or global) Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work[0]* and an error code is returned.  $lwork > (12 * NPCOL + 3 * nb) + \max((10 + 2 * \min(100, nrhs)) * NPCOL + 4 * nrhs, 8 * NPCOL)$

## Output Parameters

*d1* On exit, this array contains information containing the \* factors of the matrix.

*d* On exit, this array contains information containing the \* factors of the matrix. Must be of size  $> desca[nb\_ - 1]$ .

*du* On exit, this array contains information containing the \* factors of the matrix. Must be of size  $> desca[nb\_ - 1]$ .

*b* On exit, this contains the local piece of the solutions distributed matrix X.

*work* On exit, *work[0]* contains the minimal *lwork*.

*info* (local) If *info*=0, the execution is successful.

< 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then  $info = -(i * 100 + j)$ , if the *i*-th argument is a scalar and had an illegal value, then  $info = -i$ .

> 0: If  $info = k < NPROCS$ , the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed.

If  $info = k > NPROCS$ , the submatrix stored on processor  $info - NPROCS$  representing interactions with other processors was not positive definite, and the factorization was not completed.

## Description

The `p?posv` function computes the solution to a real/complex system of linear equations

$$\text{sub}(A) * X = \text{sub}(B),$$

where  $\text{sub}(A)$  denotes  $A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$  and is an  $n$ -by- $n$  symmetric/Hermitian distributed positive definite matrix and  $X$  and  $\text{sub}(B)$  denoting  $B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1)$  are  $n$ -by- $nrhs$  distributed matrices. The Cholesky decomposition is used to factor  $\text{sub}(A)$  as

$$\text{sub}(A) = U^T * U, \text{ if } \text{uplo} = 'U', \text{ or}$$

$$\text{sub}(A) = L * L^T, \text{ if } \text{uplo} = 'L',$$

where  $U$  is an upper triangular matrix and  $L$  is a lower triangular matrix. The factored form of  $\text{sub}(A)$  is then used to solve the system of equations.

## Input Parameters

<code>uplo</code>	(global) Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of $\text{sub}(A)$ is stored.
<code>n</code>	(global) The order of the distributed matrix $\text{sub}(A)$ ( $n \geq 0$ ).
<code>nrhs</code>	The number of right-hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ( $nrhs \geq 0$ ).
<code>a</code>	(local) Pointer into the local memory to an array of size $\text{lld}_a * \text{LOCc}(\text{ja}+n-1)$ . On entry, this array contains the local pieces of the $n$ -by- $n$ symmetric distributed matrix $\text{sub}(A)$ to be factored.  If <code>uplo = 'U'</code> , the leading $n$ -by- $n$ upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.  If <code>uplo = 'L'</code> , the leading $n$ -by- $n$ lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced.
<code>ia, ja</code>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
<code>desca</code>	(global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $A$ .
<code>b</code>	(local) Pointer into the local memory to an array of size $\text{lld}_b * \text{LOCc}(\text{jb}+nrhs-1)$ . On entry, the local pieces of the right hand sides distributed matrix $\text{sub}(B)$ .
<code>ib, jb</code>	(global) The row and column indices in the global matrix $B$ indicating the first row and the first column of the submatrix $B$ , respectively.
<code>descb</code>	(global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $B$ .

## Output Parameters

<i>a</i>	On exit, if <i>info</i> = 0, this array contains the local pieces of the factor <i>U</i> or <i>L</i> from the Cholesky factorization $\text{sub}(A) = U^H * U$ , or $L * L^H$ .
<i>b</i>	On exit, if <i>info</i> = 0, $\text{sub}(B)$ is overwritten by the solution distributed matrix <i>X</i> .
<i>info</i>	(global) If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> -1, had an illegal value, then <i>info</i> = $-(i*100+j)$ , if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$ . If <i>info</i> > 0: If <i>info</i> = <i>k</i> , the leading minor of order <i>k</i> , $A(ia:ia+k-1, ja:ja+k-1)$ is not positive definite, and the factorization could not be completed, and the solution has not been computed.

## Description

The `p?posvx` function uses the Cholesky factorization  $A=U^T*U$  or  $A=L*L^T$  to compute the solution to a real or complex system of linear equations

$$A(ia:ia+n-1, ja:ja+n-1)*X = B(ib:ib+n-1, jb:jb+nrhs-1),$$

where  $A(ia:ia+n-1, ja:ja+n-1)$  is a  $n$ -by- $n$  matrix and  $X$  and  $B(ib:ib+n-1, jb:jb+nrhs-1)$  are  $n$ -by- $nrhs$  matrices.

Error bounds on the solution and a condition estimate are also provided.

In the following comments  $y$  denotes  $Y(iy:iy+m-1, jy:jy+k-1)$ , an  $m$ -by- $k$  matrix where  $y$  can be  $a$ ,  $af$ ,  $b$  and  $x$ .

The function `p?posvx` performs the following steps:

1. If `fact = 'E'`, real scaling factors  $s$  are computed to equilibrate the system:

$$\text{diag}(sr)*A*\text{diag}(sc)*\text{inv}(\text{diag}(sc))*X = \text{diag}(sr)*B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix  $A$ , but if equilibration is used,  $A$  is overwritten by  $\text{diag}(sr)*A*\text{diag}(sc)$  and  $B$  by  $\text{diag}(sr)*B$ .

2. If `fact = 'N'` or `'E'`, the Cholesky decomposition is used to factor the matrix  $A$  (after equilibration if `fact = 'E'`) as

$$A = U^T*U, \text{ if } uplo = 'U', \text{ or}$$

$$A = L*L^T, \text{ if } uplo = 'L',$$

where  $U$  is an upper triangular matrix and  $L$  is a lower triangular matrix.

3. The factored form of  $A$  is used to estimate the condition number of the matrix  $A$ . If the reciprocal of the condition number is less than machine precision, steps 4-6 are skipped
4. The system of equations is solved for  $X$  using the factored form of  $A$ .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix  $X$  is premultiplied by  $\text{diag}(sr)$  so that it solves the original system before equilibration.

## Input Parameters

<code>fact</code>	(global) Must be 'F', 'N', or 'E'.  Specifies whether or not the factored form of the matrix $A$ is supplied on entry, and if not, whether the matrix $A$ should be equilibrated before it is factored.  If <code>fact = 'F'</code> : on entry, <code>af</code> contains the factored form of $A$ . If <code>equed = 'Y'</code> , the matrix $A$ has been equilibrated with scaling factors given by $s$ . $a$ and <code>af</code> will not be modified.  If <code>fact = 'N'</code> , the matrix $A$ will be copied to <code>af</code> and factored.  If <code>fact = 'E'</code> , the matrix $A$ will be equilibrated if necessary, then copied to <code>af</code> and factored.
<code>uplo</code>	(global) Must be 'U' or 'L'.  Indicates whether the upper or lower triangular part of $A$ is stored.

<i>n</i>	(global) The order of the distributed matrix $\text{sub}(A)$ ( $n \geq 0$ ).
<i>nrhs</i>	(global) The number of right-hand sides; the number of columns of the distributed submatrices $B$ and $X$ . ( $nrhs \geq 0$ ).
<i>a</i>	(local) Pointer into the local memory to an array of local size $lld\_a * LOCC(ja + n - 1)$ . On entry, the symmetric/Hermitian matrix $A$ , except if $fact = 'F'$ and $equed = 'Y'$ , then $A$ must contain the equilibrated matrix $\text{diag}(sr) * A * \text{diag}(sc)$ . If $uplo = 'U'$ , the leading $n$ -by- $n$ upper triangular part of $A$ contains the upper triangular part of the matrix $A$ , and the strictly lower triangular part of $A$ is not referenced. If $uplo = 'L'$ , the leading $n$ -by- $n$ lower triangular part of $A$ contains the lower triangular part of the matrix $A$ , and the strictly upper triangular part of $A$ is not referenced. $A$ is not modified if $fact = 'F'$ or $'N'$ , or if $fact = 'E'$ and $equed = 'N'$ on exit.
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
<i>desca</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
<i>af</i>	(local) Pointer into the local memory to an array of local size $lld\_af * LOCC(ja + n - 1)$ . If $fact = 'F'$ , then $af$ is an input argument and on entry contains the triangular factor $U$ or $L$ from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ , in the same storage format as $A$ . If $equed \neq 'N'$ , then $af$ is the factored form of the equilibrated matrix $\text{diag}(sr) * A * \text{diag}(sc)$ .
<i>iaf, jaf</i>	(global) The row and column indices in the global matrix $AF$ indicating the first row and the first column of the submatrix $AF$ , respectively.
<i>descaf</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $AF$ .
<i>equed</i>	(global) Must be $'N'$ or $'Y'$ . <i>equed</i> is an input argument if $fact = 'F'$ . It specifies the form of equilibration that was done: If $equed = 'N'$ , no equilibration was done (always true if $fact = 'N'$ ); If $equed = 'Y'$ , equilibration was done and $A$ has been replaced by $\text{diag}(sr) * A * \text{diag}(sc)$ .
<i>sr</i>	(local) Array of size $lld\_a$ . The array $s$ contains the scale factors for $A$ . This array is an input argument if $fact = 'F'$ only; otherwise it is an output argument. If $equed = 'N'$ , $s$ is not accessed.

	If <i>fact</i> = 'F' and <i>equed</i> = 'Y', each element of <i>s</i> must be positive.
<i>b</i>	(local) Pointer into the local memory to an array of local size $l1d\_b * LOCc(jb + nrhs - 1)$ . On entry, the <i>n</i> -by- <i>nrhs</i> right-hand side matrix <i>B</i> .
<i>ib, jb</i>	(global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>descb</i>	(global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .
<i>x</i>	(local) Pointer into the local memory to an array of local size $l1d\_x * LOCc(jx + nrhs - 1)$ .
<i>ix, jx</i>	(global) The row and column indices in the global matrix <i>X</i> indicating the first row and the first column of the submatrix <i>X</i> , respectively.
<i>descx</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>X</i> .
<i>work</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork = \max(p?pocon(lwork), p?porfs(lwork)) + LOCr(n\_a)$ . $lwork = 3 * desca[l1d\_ - 1]$ . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i> .
<i>iwork</i>	(local) Workspace array of size <i>liwork</i> .
<i>liwork</i>	(local or global) The size of the array <i>iwork</i> . <i>liwork</i> is local input and must be at least $liwork = desca[l1d\_ - 1]$ $liwork = LOCr(n\_a)$ . If <i>liwork</i> = -1, then <i>liwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i> .

## Output Parameters

<i>a</i>	On exit, if <i>fact</i> = 'E' and <i>equed</i> = 'Y', <i>a</i> is overwritten by $diag(sr) * a * diag(sc)$ .
<i>af</i>	If <i>fact</i> = 'N', then <i>af</i> is an output argument and on exit returns the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ of the original matrix <i>A</i> .

	<p>If <math>fact = 'E'</math>, then <math>af</math> is an output argument and on exit returns the triangular factor <math>U</math> or <math>L</math> from the Cholesky factorization <math>A = U^T * U</math> or <math>A = L * L^T</math> of the equilibrated matrix <math>A</math> (see the description of <math>A</math> for the form of the equilibrated matrix).</p>
<code>equed</code>	<p>If <math>fact \neq 'F'</math>, then <code>equed</code> is an output argument. It specifies the form of equilibration that was done (see the description of <code>equed</code> in <i>Input Arguments</i> section).</p>
<code>sr</code>	<p>This array is an output argument if <math>fact \neq 'F'</math>.</p> <p>See the description of <code>sr</code> in <i>Input Arguments</i> section.</p>
<code>sc</code>	<p>This array is an output argument if <math>fact \neq 'F'</math>.</p> <p>See the description of <code>sc</code> in <i>Input Arguments</i> section.</p>
<code>b</code>	<p>On exit, if <code>equed = 'N'</code>, <code>b</code> is not modified; if <code>trans = 'N'</code> and <code>equed = 'R'</code> or <code>'B'</code>, <code>b</code> is overwritten by <math>\text{diag}(r) * b</math>; if <code>trans = 'T'</code> or <code>'C'</code> and <code>equed = 'C'</code> or <code>'B'</code>, <code>b</code> is overwritten by <math>\text{diag}(c) * b</math>.</p>
<code>x</code>	<p>(local)</p> <p>If <code>info = 0</code> the <math>n</math>-by-<math>nrhs</math> solution matrix <math>X</math> to the original system of equations.</p> <p>Note that <math>A</math> and <math>B</math> are modified on exit if <code>equed</code> <math>\neq</math> <code>'N'</code>, and the solution to the equilibrated system is</p> <p><math>\text{inv}(\text{diag}(sc)) * X</math> if <code>trans = 'N'</code> and <code>equed = 'C'</code> or <code>'B'</code>, or</p> <p><math>\text{inv}(\text{diag}(sr)) * X</math> if <code>trans = 'T'</code> or <code>'C'</code> and <code>equed = 'R'</code> or <code>'B'</code>.</p>
<code>rcond</code>	<p>(global)</p> <p>An estimate of the reciprocal condition number of the matrix <math>A</math> after equilibration (if done). If <code>rcond</code> is less than the machine precision (in particular, if <code>rcond=0</code>), the matrix is singular to working precision. This condition is indicated by a return code of <code>info &gt; 0</code>.</p>
<code>ferr</code>	<p>Arrays of size at least <math>\max(LOC, n\_b)</math>. The estimated forward error bounds for each solution vector <math>X(j)</math> (the <math>j</math>-th column of the solution matrix <math>X</math>). If <code>xtrue</code> is the true solution, <code>ferr[j - 1]</code> bounds the magnitude of the largest entry in <math>(X(j) - xtrue)</math> divided by the magnitude of the largest entry in <math>X(j)</math>. The quality of the error bound depends on the quality of the estimate of <math>\text{norm}(\text{inv}(A))</math> computed in the code; if the estimate of <math>\text{norm}(\text{inv}(A))</math> is accurate, the error bound is guaranteed.</p>
<code>berr</code>	<p>(local)</p> <p>Arrays of size at least <math>\max(LOC, n\_b)</math>. The componentwise relative backward error of each solution vector <math>X(j)</math> (the smallest relative change in any entry of <math>A</math> or <math>B</math> that makes <math>X(j)</math> an exact solution).</p>
<code>work[0]</code>	<p>(local) On exit, <code>work[0]</code> returns the minimal and optimal <code>liwork</code>.</p>
<code>info</code>	<p>(global)</p> <p>If <code>info=0</code>, the execution is successful.</p> <p><math>&lt; 0</math>: if <code>info = -i</code>, the <math>i</math>-th argument had an illegal value</p>

> 0: if *info* = *i*, and *i* is ≤ *n*: if *info* = *i*, the leading minor of order *i* of *a* is not positive definite, so the factorization could not be completed, and the solution and error bounds could not be computed.

= *n*+1: *rcond* is less than machine precision. The factorization has been completed, but the matrix is singular to working precision, and the solution and error bounds have not been computed.

```

## Include Files

- mkl\_scalapack.h

## Description

The p?pbsv function solves a system of linear equations

$$A(1:n, ja:ja+n-1)X = B(ib:ib+n-1, 1:nrhs),$$

where  $A(1:n, ja:ja+n-1)$  is an  $n$ -by- $n$  real/complex banded symmetric positive definite distributed matrix with bandwidth  $bw$ .

Cholesky factorization is used to factor a reordering of the matrix into  $L*L'$ .

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

*uplo*

(global) Must be 'U' or 'L'.

Indicates whether the upper or lower triangular of *A* is stored.

	If <i>uplo</i> = 'U', the upper triangular <i>A</i> is stored
	If <i>uplo</i> = 'L', the lower triangular of <i>A</i> is stored.
<i>n</i>	(global) The order of the distributed matrix <i>A</i> ( $n \geq 0$ ).
<i>bw</i>	(global) The number of subdiagonals in <i>L</i> or <i>U</i> . $0 \leq bw \leq n-1$ .
<i>nrhs</i>	(global) The number of right-hand sides; the number of columns in <i>B</i> ( $nrhs \geq 0$ ).
<i>a</i>	(local). Pointer into the local memory to an array with leading size $lld\_a \geq (bw + 1)$ (stored in <i>desca</i> ). On entry, this array contains the local pieces of the distributed matrix $sub(A)$ to be factored.
<i>ja</i>	(global) The index in the global matrix <i>A</i> indicating the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i> ).
<i>desca</i>	(global and local) array of size <i>dlen</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local) Pointer into the local memory to an array of local lead size $lld\_b \geq nb$ . On entry, this array contains the local pieces of the right hand sides $B(ib:ib + n - 1, 1:nrhs)$ .
<i>ib</i>	(global) The row index in the global matrix <i>B</i> indicating the first row of the matrix to be operated on (which may be either all of <i>b</i> or a submatrix of <i>B</i> ).
<i>descb</i>	(global and local) array of size <i>dlen</i> . If 1D type ( <i>dtype_b</i> = 502), $dlen \geq 7$ ; If 2D type ( <i>dtype_b</i> = 1), $dlen \geq 9$ . The array descriptor for the distributed matrix <i>B</i> . Contains information of mapping of <i>B</i> to memory.
<i>work</i>	(local). Temporary workspace. This space may be overwritten in between calls to functions. <i>work</i> must be the size given in <i>lwork</i> .
<i>lwork</i>	(local or global) Size of user-input workspace <i>work</i> . If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i> [0] and an error code is returned. $lwork \geq (nb + 2 * bw) * bw + \max((bw * nrhs), bw * bw)$

## Output Parameters

<i>a</i>	On exit, this array contains information containing details of the factorization. Note that permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.
<i>b</i>	On exit, contains the local piece of the solutions distributed matrix <i>X</i> .
<i>work</i>	On exit, <i>work</i> [0] contains the minimal <i>lwork</i> .
<i>info</i>	(global) If <i>info</i> =0, the execution is successful.

< 0: If the  $i$ -th argument is an array and the  $j$ -entry had an illegal value, then  $info = -(i*100+j)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

> 0: If  $info = k \leq NPROCS$ , the submatrix stored on processor  $info$  and factored locally was not positive definite, and the factorization was not completed.

If  $info = k > NPROCS$ , the submatrix stored on processor  $info-NPROCS$  representing interactions with other processors was not positive definite, and the factorization was not completed.

```

## Include Files

- mkl\_scalapack.h

## Description

The *p?gels* function solves overdetermined or underdetermined real/ complex linear systems involving an *m*-by-*n* matrix  $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$ , or its transpose/ conjugate-transpose, using a *QTQ* or *LQ* factorization of  $\text{sub}(A)$ . It is assumed that  $\text{sub}(A)$  has full rank.

The following options are provided:

1. If *trans* = 'N' and  $m \geq n$ : find the least squares solution of an overdetermined system, that is, solve the least squares problem

minimize  $||\text{sub}(B) - \text{sub}(A) * X||$

2. If  $\text{trans} = 'N'$  and  $m < n$ : find the minimum norm solution of an underdetermined system  $\text{sub}(A) * X = \text{sub}(B)$ .
3. If  $\text{trans} = 'T'$  and  $m \geq n$ : find the minimum norm solution of an undetermined system  $\text{sub}(A)^T * X = \text{sub}(B)$ .
4. If  $\text{trans} = 'T'$  and  $m < n$ : find the least squares solution of an overdetermined system, that is, solve the least squares problem

minimize  $||\text{sub}(B) - \text{sub}(A)^T * X||$ ,

where  $\text{sub}(B)$  denotes  $B(\text{ib}:\text{ib}+m-1, \text{jb}:\text{jb}+nrhs-1)$  when  $\text{trans} = 'N'$  and  $B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1)$  otherwise. Several right hand side vectors  $b$  and solution vectors  $x$  can be handled in a single call; when  $\text{trans} = 'N'$ , the solution vectors are stored as the columns of the  $n$ -by- $nrhs$  right hand side matrix  $\text{sub}(B)$  and the  $m$ -by- $nrhs$  right hand side matrix  $\text{sub}(B)$  otherwise.

## Input Parameters

<i>trans</i>	(global) Must be 'N', or 'T'.  If $\text{trans} = 'N'$ , the linear system involves matrix $\text{sub}(A)$ ;  If $\text{trans} = 'T'$ , the linear system involves the transposed matrix $A^T$ (for real flavors only).
<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(A)$ ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(A)$ ( $n \geq 0$ ).
<i>nrhs</i>	(global) The number of right-hand sides; the number of columns in the distributed submatrices $\text{sub}(B)$ and $X$ . ( $nrhs \geq 0$ ).
<i>a</i>	(local)  Pointer into the local memory to an array of size $lld\_a * LOCC(\text{ja}+n-1)$ . On entry, contains the $m$ -by- $n$ matrix $A$ .
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
<i>desca</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
<i>b</i>	(local)  Pointer into the local memory to an array of local size $lld\_b * LOCC(\text{jb} + nrhs - 1)$ . On entry, this array contains the local pieces of the distributed matrix $B$ of right-hand side vectors, stored columnwise; $\text{sub}(B)$ is $m$ -by- $nrhs$ if $\text{trans} = 'N'$ , and $n$ -by- $nrhs$ otherwise.
<i>ib, jb</i>	(global) The row and column indices in the global matrix $B$ indicating the first row and the first column of the submatrix $B$ , respectively.
<i>descb</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $B$ .
<i>work</i>	(local)  Workspace array with size $lwork$ .
<i>lwork</i>	(local or global) .

The size of the array *work/work* is local input and must be at least  $lwork \geq ltau + \max(lwf, lws)$ , where if  $m > n$ , then

```
ltau = numroc(ja+min(m,n)-1, nb_a, MYCOL, csrc_a, NPCOL),
```

```
lwf = nb_a*(mpa0 + nqa0 + nb_a)
```

```
lws = max((nb_a*(nb_a-1))/2, (nrhsqb0 + mpb0)*nb_a) +
nb_a*nb_a
```

else

```
ltau = numroc(ia+min(m,n)-1, mb_a, MYROW, rsrc_a, NPROW),
```

```
lwf = mb_a * (mpa0 + nqa0 + mb_a)
```

```
lws = max((mb_a*(mb_a-1))/2, (npb0 + max(nqa0 +
numroc(numroc(n+iroffb, mb_a, 0, 0, NPROW), mb_a, 0, 0,
lcmp), nrhsqb0))*mb_a) + mb_a*mb_a
```

end if,

where  $lcmp = lcm/NPROW$  with  $lcm = ilcm(NPROW, NPCOL)$ ,

```
iroffa = mod(ia-1, mb_a),
```

```
icoffa = mod(ja-1, nb_a),
```

```
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
```

```
iacol= indxg2p(ja, nb_a, MYROW, rsrc_a, NPROW)
```

```
mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow, NPROW),
```

```
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol, NPCOL),
```

```
iroffb = mod(ib-1, mb_b),
```

```
icoffb = mod(jb-1, nb_b),
```

```
ibrow = indxg2p(ib, mb_b, MYROW, rsrc_b, NPROW),
```

```
ibcol = indxg2p(jb, nb_b, MYCOL, csrc_b, NPCOL),
```

```
mpb0 = numroc(m+iroffb, mb_b, MYROW, icrow, NPROW),
```

```
nqb0 = numroc(n+icoffb, nb_b, MYCOL, ibcol, NPCOL),
```

---

#### NOTE

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

---

*ilcm*, *indxg2p* and *numroc* are ScaLAPACK tool functions; *MYROW*, *MYCOL*, *NPROW*, and *NPCOL* can be determined by calling the function *blacs\_gridinfo*.

If  $lwork = -1$ , then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

## Output Parameters

<i>a</i>	On exit, If $m \geq n$ , $\text{sub}(A)$ is overwritten by the details of its <i>QR</i> factorization as returned by <code>p?geqrf</code> ; if $m < n$ , $\text{sub}(A)$ is overwritten by details of its <i>LQ</i> factorization as returned by <code>p?gelqf</code> .
<i>b</i>	On exit, $\text{sub}(B)$ is overwritten by the solution vectors, stored columnwise: if $\text{trans} = \text{'N'}$ and $m \geq n$ , rows 1 to $n$ of $\text{sub}(B)$ contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements $n+1$ to $m$ in that column;  If $\text{trans} = \text{'N'}$ and $m < n$ , rows 1 to $n$ of $\text{sub}(B)$ contain the minimum norm solution vectors;  If $\text{trans} = \text{'T'}$ and $m \geq n$ , rows 1 to $m$ of $\text{sub}(B)$ contain the minimum norm solution vectors; if $\text{trans} = \text{'T'}$ and $m < n$ , rows 1 to $m$ of $\text{sub}(B)$ contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements $m+1$ to $n$ in that column.
<i>work[0]</i>	On exit, <i>work[0]</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global)  = 0: the execution is successful.  < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then $\text{info} = -(i * 100 + j)$ , if the <i>i</i> -th argument is a scalar and had an illegal value, then $\text{info} = -i$ .

## p?syev

*Computes selected eigenvalues and eigenvectors of a symmetric matrix.*

## Syntax

```
void pssyev (char *jobz , char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *w , float *z , MKL_INT *iz , MKL_INT *jz , MKL_INT *descz , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdsyev (char *jobz , char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *w , double *z , MKL_INT *iz , MKL_INT *jz , MKL_INT *descz , double *work , MKL_INT *lwork , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?syev` function computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix *A* by calling the recommended sequence of ScaLAPACK functions.

In its present form, the function assumes a homogeneous system and makes no checks for consistency of the eigenvalues or eigenvectors across the different processes. Because of this, it is possible that a heterogeneous system may return incorrect results without any error messages.

## Input Parameters

$np$  = the number of rows local to a given process.

$nq$  = the number of columns local to a given process.

<i>jobz</i>	(global) Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	(global) Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric matrix <i>A</i> is stored: If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	(global) The number of rows and columns of the matrix <i>A</i> ( $n \geq 0$ ).
<i>a</i>	(local) Block cyclic array of global size $n*n$ and local size $lld\_a*LOCc(ja+n-1)$ . On entry, the symmetric matrix <i>A</i> . If <i>uplo</i> = 'U', only the upper triangular part of <i>A</i> is used to define the elements of the symmetric matrix. If <i>uplo</i> = 'L', only the lower triangular part of <i>A</i> is used to define the elements of the symmetric matrix.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>iz, jz</i>	(global) The row and column indices in the global matrix <i>Z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively.
<i>descz</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> .
<i>work</i>	(local) Array of size <i>lwork</i> .
<i>lwork</i>	(local) See below for definitions of variables used to define <i>lwork</i> . If no eigenvectors are requested ( <i>jobz</i> = 'N'), then $lwork \geq 5*n + sizesytrd + 1$ , where <i>sizesytrd</i> is the workspace for <code>p?sytrd</code> and is $\max(NB*(np + 1), 3*NB)$ . If eigenvectors are requested ( <i>jobz</i> = 'V') then the amount of workspace required to guarantee that all eigenvectors are computed is: $qrmem = 2*n-2$

```
lwork = 5*n + n*ldc + max(sizemqrleft, qrmem) + 1
```

Variable definitions:

```
nb = desca[mb_ - 1] = desca[nb_ - 1] = descz[mb_ - 1] =
descz[nb_ - 1];
```

```
nn = max(n, nb, 2);
```

```
desca[rsrc_ - 1] = desca[rsrc_ - 1] = descz[rsrc_ - 1] =
descz[csrc_ - 1] = 0
```

```
np = numroc(nn, nb, 0, 0, NPROW)
```

```
nq = numroc(max(n, nb, 2), nb, 0, 0, NPCOL)
```

```
nrc = numroc(n, nb, myprowc, 0, NPROCS)
```

```
ldc = max(1, nrc)
```

*sizemqrleft* is the workspace for `p?ormtr` when its *side* argument is 'L'.

*myprowc* is defined when a new context is created as follows:

```
call blacs_get(desca[ctxt_ - 1], 0, contextc)
```

```
call blacs_gridinit(contextc, 'R', NPROCS, 1)
```

```
call blacs_gridinfo(contextc, nprowc, npcold, myprowc,
mypcolc)
```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> ='L') or the upper triangle (if <i>uplo</i> ='U') of <i>A</i> , including the diagonal, is destroyed.
<i>w</i>	(global). Array of size <i>n</i> . On normal exit, the first <i>m</i> entries contain the selected eigenvalues in ascending order.
<i>z</i>	(local). Array, global size $n*n$ , local size $lld\_z*LOCc(jz+n-1)$ . If <i>jobz</i> = 'V', then on normal exit the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If <i>jobz</i> = 'N', then <i>z</i> is not referenced.
<i>work</i> [0]	On output, <i>work</i> [0] returns the workspace needed to guarantee completion. If the input parameters are incorrect, <i>work</i> [0] may also be incorrect. If <i>jobz</i> = 'N' <i>work</i> [0] = minimal (optimal) amount of workspace If <i>jobz</i> = 'V' <i>work</i> [0] = minimal workspace required to generate all the eigenvectors.

*info* (global)

If *info* = 0, the execution is successful.

If *info* < 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* =  $-(i*100+j)$ , if the *i*-th argument is a scalar and had an illegal value, then *info* =  $-i$ .

If *info* > 0:

If *info* = 1 through *n*, the *i*-th eigenvalue did not converge in `?steqr2` after a total of  $30n$  iterations.

If *info* = *n*+1, then `p?syev` has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from `p?syev` cannot be guaranteed.

## Include Files

- `mkl_scalapack.h`

## Description

The `p?syevd` function computes all eigenvalues and eigenvectors of a real symmetric matrix *A* by using a divide and conquer algorithm.

## Input Parameters

*np* = the number of rows local to a given process.

*nq* = the number of columns local to a given process.

*jobz* (global) Must be 'N' or 'V'.  
Specifies if it is necessary to compute the eigenvectors:  
If *jobz* = 'N', then only eigenvalues are computed.  
If *jobz* = 'V', then eigenvalues and eigenvectors are computed.

*uplo* (global) Must be 'U' or 'L'.

	Specifies whether the upper or lower triangular part of the Hermitian matrix $A$ is stored:
	If $uplo = 'U'$ , $a$ stores the upper triangular part of $A$ .
	If $uplo = 'L'$ , $a$ stores the lower triangular part of $A$ .
$n$	(global) The number of rows and columns of the matrix $A$ ( $n \geq 0$ ).
$a$	(local). Block cyclic array of global size $n*n$ and local size $lld\_a*LOCc(ja+n-1)$ . On entry, the symmetric matrix $A$ . If $uplo = 'U'$ , only the upper triangular part of $A$ is used to define the elements of the symmetric matrix. If $uplo = 'L'$ , only the lower triangular part of $A$ is used to define the elements of the symmetric matrix.
$ia, ja$	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
$desca$	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ . If $desca[ctxt\_ - 1]$ is incorrect, $p?syevd$ cannot guarantee correct error reporting.
$iz, jz$	(global) The row and column indices in the global matrix $Z$ indicating the first row and the first column of the submatrix $Z$ , respectively.
$descz$	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $Z$ . $descz[ctxt\_ - 1]$ must equal $desca[ctxt\_ - 1]$ .
$work$	(local). Array of size $lwork$ .
$lwork$	(local) The size of the array $work$ . If eigenvalues are requested: $lwork \geq \max(1+6*n + 2*np*nq, trilwmin) + 2*n$ with $trilwmin = 3*n + \max(nb*(np + 1), 3*nb)$ $np = \text{numroc}(n, nb, myrow, iarow, NPROW)$ $nq = \text{numroc}(n, nb, mycol, iacol, NPCOL)$ If $lwork = -1$ , then $lwork$ is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by $p\text{xerbla}$ .
$iwork$	(local) Workspace array of size $liwork$ .
$liwork$	(local), size of $iwork$ . $liwork = 7*n + 8*npcol + 2$ .

## Output Parameters

<code>a</code>	On exit, the lower triangle (if <code>uplo = 'L'</code> ), or the upper triangle (if <code>uplo = 'U'</code> ) of $A$ , including the diagonal, is overwritten.
<code>w</code>	(global). Array of size $n$ . If <code>info = 0</code> , $w$ contains the eigenvalues in the ascending order.
<code>z</code>	(local). Array, global size $(n, n)$ , local size <code>lld_z*LOCc(jz+n-1)</code> . The $z$ parameter contains the orthonormal eigenvectors of the matrix $A$ .
<code>work[0]</code>	On exit, returns adequate workspace to allow optimal performance.
<code>iwork[0]</code>	(local). On exit, if <code>liwork &gt; 0</code> , <code>iwork[0]</code> returns the optimal <code>liwork</code> .
<code>info</code>	(global) If <code>info = 0</code> , the execution is successful. If <code>info &lt; 0</code> : If the $i$ -th argument is an array and the $j$ -entry had an illegal value, then <code>info = -(i*100+j)</code> . If the $i$ -th argument is a scalar and had an illegal value, then <code>info = -i</code> . If <code>info &gt; 0</code> : The algorithm failed to compute the <code>info/(n+1)</code> -th eigenvalue while working on the submatrix lying in global rows and columns <code>mod(info, n+1)</code> .

---

### NOTE

`mod(x, y)` is the integer remainder of  $x/y$ .

## Description

`p?syevr` computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix  $A$  distributed in 2D blockcyclic format by calling the recommended sequence of ScaLAPACK functions.

First, the matrix  $A$  is reduced to real symmetric tridiagonal form. Then, the eigenproblem is solved using the parallel MRRR algorithm. Last, if eigenvectors have been computed, a backtransformation is done.

Upon successful completion, each processor stores a copy of all computed eigenvalues in  $w$ . The eigenvector matrix  $z$  is stored in 2D block-cyclic format distributed over all processors.

Note that subsets of eigenvalues/vectors can be selected by specifying a range of values or a range of indices for the desired eigenvalues.

Notice revision #20201201

## Input Parameters

<code>jobz</code>	(global) Specifies whether or not to compute the eigenvectors: = 'N': Compute eigenvalues only. = 'V': Compute eigenvalues and eigenvectors.
<code>range</code>	(global) = 'A': all eigenvalues will be found. = 'V': all eigenvalues in the interval $[vl, vu]$ will be found. = 'I': the $il$ -th through $iu$ -th eigenvalues will be found.
<code>uplo</code>	(global) Specifies whether the upper or lower triangular part of the symmetric matrix $A$ is stored: = 'U': Upper triangular = 'L': Lower triangular
<code>n</code>	(global ) The number of rows and columns of the matrix $a$ . $n \geq 0$
<code>a</code>	Block cyclic array of global size $n * n$ , local size $lld\_a * LOC_c(ja+n-1)$ .  This array contains the local pieces of the symmetric distributed matrix $A$ . If <code>uplo = 'U'</code> , only the upper triangular part of $a$ is used to define the elements of the symmetric matrix. If <code>uplo = 'L'</code> , only the lower triangular part of $a$ is used to define the elements of the symmetric matrix.  On exit, the lower triangle (if <code>uplo='L'</code> ) or the upper triangle (if <code>uplo='U'</code> ) of $a$ , including the diagonal, is destroyed.

<i>ia</i>	(global ) Global row index in the global matrix <i>A</i> that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.
<i>ja</i>	(global ) Global column index in the global matrix <i>A</i> that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.
<i>desca</i>	(global and local) array of size <i>dlen_</i> =9. The array descriptor for the distributed matrix <i>a</i> .
<i>vl</i>	(global ) If <i>range</i> ='V', the lower bound of the interval to be searched for eigenvalues. Not referenced if <i>range</i> = 'A' or 'I'.
<i>vu</i>	(global ) If <i>range</i> ='V', the upper bound of the interval to be searched for eigenvalues. Not referenced if <i>range</i> = 'A' or 'I'.
<i>il</i>	(global ) If <i>range</i> ='I', the index (from smallest to largest) of the smallest eigenvalue to be returned. $il \geq 1$ . Not referenced if <i>range</i> = 'A'.
<i>iu</i>	(global ) If <i>range</i> ='I', the index (from smallest to largest) of the largest eigenvalue to be returned. $\min(il, n) \leq iu \leq n$ . Not referenced if <i>range</i> = 'A'.
<i>iz</i>	(global ) Global row index in the global matrix <i>Z</i> that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.
<i>jz</i>	(global ) Global column index in the global matrix <i>Z</i> that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.
<i>descz</i>	array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>z</i> . The context <i>descz</i> [ <i>ctxt_</i> - 1] must equal <i>desca</i> [ <i>ctxt_</i> - 1]. Also note the array alignment requirements specified below.
<i>work</i>	(local workspace) array of size <i>lwork</i>
<i>lwork</i>	(local ) Size of <i>work</i> , must be at least 3.

See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N') then

$$lwork \geq 2 + 5*n + \max( 12 * nn, neig * ( np0 + 1 ) )$$

If eigenvectors are requested (*jobz* = 'V' ) then the amount of workspace required is:

$$lwork \geq 2 + 5*n + \max( 18*nn, np0 * mq0 + 2 * neig * neig ) + ( 2 + \text{iceil}( neig, nprow*npcol) ) * nn$$

Variable definitions:

*neig* = number of eigenvectors requested

$$nb = \text{desca}[ mb_ - 1 ] = \text{desca}( nb_ ) = \text{descz}[ mb_ - 1 ] = \text{descz}( nb_ )$$

$$nn = \max( n, neig, 2 )$$

$$\text{desca}[ rsrc_ - 1 ] = \text{desca}[ csrc\_nb_ - 1 ] = \text{descz}[ rsrc_ - 1 ] = \text{descz}[ csrc_ - 1 ] = 0$$

$$np0 = \text{numroc}( nn, neig, 0, 0, nprow )$$

$$mq0 = \text{numroc}( \max( neig, neig, 2 ), neig, 0, 0, npc0 )$$

*iceil*( *x*, *y* ) is a ScaLAPACK function returning  $\text{ceiling}(x/y)$ , and *nprow* and *npcol* can be determined by calling the function *blacs\_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by [pxerbla](#).

*liwork*

(local )

size of *iwork*

Let  $nnp = \max( n, nprow*npcol + 1, 4 )$ . Then:

$$liwork \geq 12*nnp + 2*n \text{ when the eigenvectors are desired}$$

$$liwork \geq 10*nnp + 2*n \text{ when only the eigenvalues have to be computed}$$

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

## OUTPUT Parameters

*m*

(global )

Total number of eigenvalues found.  $0 \leq m \leq n$ .

*nz*

(global )

Total number of eigenvectors computed.  $0 \leq nz \leq m$ .

The number of columns of *z* that are filled.

If *jobz* ≠ 'V', *nz* is not referenced.

	If $jobz = 'V'$ , $nz = m$
$w$	(global ) array of size $n$ Upon successful exit, the first $m$ entries contain the selected eigenvalues in ascending order.
$z$	Block-cyclic array, global size $n*n$ , local size $lld_z*LOC_c(jz+n-1)$ . On exit, contains local pieces of distributed matrix $Z$ .
$work$	On return, $work[0]$ contains the optimal amount of workspace required for efficient execution. If $jobz='N'$ $work[0]$ = optimal amount of workspace required to compute the eigenvalues. If $jobz='V'$ $work[0]$ = optimal amount of workspace required to compute eigenvalues and eigenvectors.
$iwork$	(local workspace) array On return, $iwork[0]$ contains the amount of integer workspace required.
$info$	(global ) = 0: successful exit < 0: If the $i$ -th argument is an array and the $j$ th-entry had an illegal value, then $info = -(i*100+j)$ , if the $i$ -th argument is a scalar and had an illegal value, then $info = -i$ .

## Application Notes

The distributed submatrices  $a(ia:*, ja:*)$  and  $z(iz:iz+m-1, jz:jz+n-1)$  must satisfy the following alignment properties:

1. Identical (quadratic) dimension:  $desca[m_ - 1] = descz[m_ - 1] = desca[n_ - 1] = descz[n_ - 1]$
2. Quadratic conformal blocking:  $desca[mb_ - 1] = desca[nb_ - 1] = descz[mb_ - 1] = descz[nb_ - 1]$ ,  
 $desca[rsrc_ - 1] = descz[rsrc_ - 1]$
3.  $\text{mod}( ia-1, mb_a ) = \text{mod}( iz-1, mb_z ) = 0$

---

### NOTE

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

---

## Description

The `p?syevx` function computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix  $A$  by calling the recommended sequence of ScaLAPACK functions. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

$np$  = the number of rows local to a given process.

$nq$  = the number of columns local to a given process.

<i>jobz</i>	(global) Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	(global) Must be 'A', 'V', or 'I'. If <i>range</i> = 'A', all eigenvalues will be found. If <i>range</i> = 'V', all eigenvalues in the half-open interval $[vl, vu]$ will be found. If <i>range</i> = 'I', the eigenvalues with indices <i>il</i> through <i>iu</i> will be found.
<i>uplo</i>	(global) Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric matrix $A$ is stored: If <i>uplo</i> = 'U', $a$ stores the upper triangular part of $A$ . If <i>uplo</i> = 'L', $a$ stores the lower triangular part of $A$ .
<i>n</i>	(global) The number of rows and columns of the matrix $A$ ( $n \geq 0$ ).
<i>a</i>	(local). Block cyclic array of global size $n*n$ and local size $lld\_a*LOCc(ja+n-1)$ . On entry, the symmetric matrix $A$ . If <i>uplo</i> = 'U', only the upper triangular part of $A$ is used to define the elements of the symmetric matrix.

If  $uplo = 'L'$ , only the lower triangular part of  $A$  is used to define the elements of the symmetric matrix.

$ia, ja$

(global) The row and column indices in the global matrix  $A$  indicating the first row and the first column of the submatrix  $A$ , respectively.

$desca$

(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $A$ .

$vl, vu$

(global)

If  $range = 'V'$ , the lower and upper bounds of the interval to be searched for eigenvalues;  $vl \leq vu$ . Not referenced if  $range = 'A'$  or  $'I'$ .

$il, iu$

(global)

If  $range = 'I'$ , the indices of the smallest and largest eigenvalues to be returned.

Constraints:  $il \geq 1$

$\min(il, n) \leq iu \leq n$

Not referenced if  $range = 'A'$  or  $'V'$ .

$abstol$

(global).

If  $jobz = 'V'$ , setting  $abstol$  to  $p?lamch(context, 'U')$  yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval  $[a, b]$  of width less than or equal to

$abstol + eps * \max(|a|, |b|)$ ,

where  $eps$  is the machine precision. If  $abstol$  is less than or equal to zero, then  $eps * \text{norm}(T)$  will be used in its place, where  $\text{norm}(T)$  is the 1-norm of the tridiagonal matrix obtained by reducing  $A$  to tridiagonal form.

Eigenvalues will be computed most accurately when  $abstol$  is set to twice the underflow threshold  $2 * p?lamch('S')$  not zero. If this function returns with  $(\text{mod}(info, 2) \neq 0)$  or  $(\text{mod}(info/8, 2) \neq 0)$ , indicating that some eigenvalues or eigenvectors did not converge, try setting  $abstol$  to  $2 * p?lamch('S')$ .

$orfac$

(global).

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within  $tol = orfac * \text{norm}(A)$  of each other are to be reorthogonalized. However, if the workspace is insufficient (see  $lwork$ ),  $tol$  may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if  $orfac$  equals zero. A default value of  $1.0e-3$  is used if  $orfac$  is negative.  $orfac$  should be identical on all processes.

$iz, jz$

(global) The row and column indices in the global matrix  $Z$  indicating the first row and the first column of the submatrix  $Z$ , respectively.

$descz$

(global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $Z$ .  $descz[ctxt_ - 1]$  must equal  $desca[ctxt_ - 1]$ .

*work* (local)  
Array of size *lwork*.

*lwork* (local) The size of the array *work*.  
See below for definitions of variables used to define *lwork*.  
If no eigenvectors are requested (*jobz* = 'N'), then  $lwork \geq 5*n + \max(5*nn, NB*(np0 + 1))$ .  
If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:  
 $lwork \geq 5*n + \max(5*nn, np0*mq0 + 2*NB*NB) + \text{iceil}(neig, NPROW*NPCOL)*nn$

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following to *lwork*:

$(clustersize-1)*n$ ,

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

$\{w[k-1], \dots, w[k+clustersize-2] | w[j] \leq w[j-1]\} + orfac*2*norm(A)$ ,

where

*neig* = number of eigenvectors requested

$nb = desca[mb_ - 1] = desca[nb_ - 1] = descz[mb_ - 1] = descz[nb_ - 1]$ ;

$nn = \max(n, nb, 2)$ ;

$desca[rsrc_ - 1] = desca[nb_ - 1] = descz[rsrc_ - 1] = descz[csrc_ - 1] = 0$ ;

$np0 = \text{numroc}(nn, nb, 0, 0, NPROW)$ ;

$mq0 = \text{numroc}(\max(neig, nb, 2), nb, 0, 0, NPCOL)$

*iceil*(*x*, *y*) is a ScaLAPACK function returning ceiling(*x*/*y*)

If *lwork* is too small to guarantee orthogonality, *p?syevx* attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned.

Note that when *range*='V', number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if *lwork* is large enough to compute the eigenvalues, *p?sygvx* computes the eigenvalues and as many eigenvectors as possible.

Relationship between workspace, orthogonality & performance:

Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

$lwork \geq \max(lwork, 5*n + nsytrd\_lwopt),$

where  $lwork$ , as defined previously, depends upon the number of eigenvectors requested, and

$nsytrd\_lwopt = n + 2*(anb+1)*(4*nps+2) + (nps + 3)*nps;$

$anb = pjl aenv(desca[ctxt_ - 1], 3, 'p?sytrd', 'L', 0, 0, 0, 0);$

$sqnpc = \text{int}(\text{sqrt}(\text{dble}(NPROW * NPCOL)));$

$nps = \max(\text{numroc}(n, 1, 0, 0, sqnpc), 2*anb);$

$\text{numroc}$  is a ScaLAPACK tool functions;

$pjl aenv$  is a ScaLAPACK environmental inquiry function

$MYROW, MYCOL, NPROW$  and  $NPCOL$  can be determined by calling the function  $\text{blacs\_gridinfo}$ .

For large  $n$ , no extra workspace is needed, however the biggest boost in performance comes for small  $n$ , so it is wise to provide the extra workspace (typically less than a megabyte per process).

If  $clustersize > n/\text{sqrt}(NPROW*NPCOL)$ , then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is,  $clustersize = n-1$ )  $p?stein$  will perform no better than  $?stein$  on single processor.

For  $clustersize = n/\text{sqrt}(NPROW*NPCOL)$  reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For  $clustersize > n/\text{sqrt}(NPROW*NPCOL)$  execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by  $pxerbla$ .

$iwork$

(local) Workspace array.

$liwork$

(local) , size of  $iwork$ .  $liwork \geq 6*nnp$

Where:  $nnp = \max(n, NPROW*NPCOL + 1, 4)$

If  $liwork = -1$ , then  $liwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by  $pxerbla$ .

## Output Parameters

$a$

On exit, the lower triangle (if  $uplo = 'L'$ ) or the upper triangle (if  $uplo = 'U'$ ) of  $A$ , including the diagonal, is overwritten.

$m$

(global) The total number of eigenvalues found;  $0 \leq m \leq n$ .

<i>nz</i>	<p>(global) Total number of eigenvectors computed. <math>0 \leq nz \leq m</math>.</p> <p>The number of columns of <i>z</i> that are filled.</p> <p>If <i>jobz</i> ≠ 'V', <i>nz</i> is not referenced.</p> <p>If <i>jobz</i> = 'V', <i>nz</i> = <i>m</i> unless the user supplies insufficient space and <i>p?syevx</i> is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in <i>z</i> (<math>m \leq descz[n_ - 1]</math>) and sufficient workspace to compute them. (See <i>lwork</i>). <i>p?syevx</i> is always able to detect insufficient space without computation unless <i>range</i> = 'V'.</p>
<i>w</i>	<p>(global).</p> <p>Array of size <i>n</i>. The first <i>m</i> elements contain the selected eigenvalues in ascending order.</p>
<i>z</i>	<p>(local).</p> <p>Array, global size <math>n*n</math>, local size <math>lld\_z*LOCc(jz+n-1)</math>.</p> <p>If <i>jobz</i> = 'V', then on normal exit the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of <i>z</i> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i>.</p> <p>If <i>jobz</i> = 'N', then <i>z</i> is not referenced.</p>
<i>work</i> [0]	<p>On exit, returns workspace adequate workspace to allow optimal performance.</p>
<i>iwork</i> [0]	<p>On return, <i>iwork</i>[0] contains the amount of integer workspace required.</p>
<i>ifail</i>	<p>(global).</p> <p>Array of size <i>n</i>.</p> <p>If <i>jobz</i> = 'V', then on normal exit, the first <i>m</i> elements of <i>ifail</i> are zero. If <math>(\text{mod}(\text{info}, 2) \neq 0)</math> on exit, then <i>ifail</i> contains the indices of the eigenvectors that failed to converge.</p> <p>If <i>jobz</i> = 'N', then <i>ifail</i> is not referenced.</p>
<i>iclustr</i>	<p>(global) Array of size <math>(2*NPROW*NPCOL)</math></p> <p>This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see <i>lwork</i>, <i>orfac</i> and <i>info</i>). Eigenvectors corresponding to clusters of eigenvalues indexed <i>iclustr</i>(2*i-1) to <i>iclustr</i>(2*i), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. <i>iclustr</i> is a zero terminated array. <math>iclustr[2*k - 1] \neq 0</math> and <math>iclustr[2*k] = 0</math> if and only if <i>k</i> is the number of clusters.</p> <p><i>iclustr</i> is not referenced if <i>jobz</i> = 'N'.</p>
<i>gap</i>	<p>(global)</p> <p>Array of size <math>NPROW*NPCOL</math></p>

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*th cluster may be as high as  $(C*n) / gap[i - 1]$  where *C* is a small constant.

*info*

(global)

If *info* = 0, the execution is successful.

If *info* < 0:

If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* =  $-(i*100+j)$ , if the *i*-th argument is a scalar and had an illegal value, then *info* =  $-i$ .

If *info* > 0: if  $(\text{mod}(\text{info}, 2) \neq 0)$ , then one or more eigenvectors failed to converge. Their indices are stored in *ifail*. Ensure  $abstol=2.0*p?lamch('U')$ .

If  $(\text{mod}(\text{info}/2, 2) \neq 0)$ , then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If  $(\text{mod}(\text{info}/4, 2) \neq 0)$ , then space limit prevented *p?syevxf* from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If  $(\text{mod}(\text{info}/8, 2) \neq 0)$ , then *p?stebz* failed to compute eigenvalues. Ensure  $abstol=2.0*p?lamch('U')$ .

---

#### NOTE

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

- `mkl_scalapack.h`

## Description

The `p?heev` function computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix  $A$  by calling the recommended sequence of ScaLAPACK functions. The function assumes a homogeneous system and makes spot checks of the consistency of the eigenvalues across the different processes. A heterogeneous system may return incorrect results without any error messages.

## Input Parameters

$np$  = the number of rows local to a given process.

$nq$  = the number of columns local to a given process.

$jobz$	(global) Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If $jobz = 'N'$ , then only eigenvalues are computed. If $jobz = 'V'$ , then eigenvalues and eigenvectors are computed.
$uplo$	(global) Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the Hermitian matrix $A$ is stored: If $uplo = 'U'$ , $a$ stores the upper triangular part of $A$ . If $uplo = 'L'$ , $a$ stores the lower triangular part of $A$ .
$n$	(global) The number of rows and columns of the matrix $A$ ( $n \geq 0$ ).
$a$	(local). Block cyclic array of global size $n*n$ and local size $lld\_a*LOCc(ja+n-1)$ . On entry, the Hermitian matrix $A$ . If $uplo = 'U'$ , only the upper triangular part of $A$ is used to define the elements of the Hermitian matrix. If $uplo = 'L'$ , only the lower triangular part of $A$ is used to define the elements of the Hermitian matrix.
$ia, ja$	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
$desca$	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ . If $desca[ctxt\_ - 1]$ is incorrect, <code>p?heev</code> cannot guarantee correct error reporting.
$iz, jz$	(global) The row and column indices in the global matrix $Z$ indicating the first row and the first column of the submatrix $Z$ , respectively.
$descz$	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $Z$ . $descz[ctxt\_ - 1]$ must equal $desca[ctxt\_ - 1]$ .
$work$	(local). Array of size $lwork$ .
$lwork$	(local) The size of the array $work$ . If only eigenvalues are requested ( $jobz = 'N'$ ): $lwork \geq \max(nb*(np0 + 1), 3) + 3*n$

If eigenvectors are requested ( $jobz = 'V'$ ), then the amount of workspace required:

$$lwork \geq (np0+nq0+nb)*nb + 3*n + n^2$$

with  $nb = desca[mb_ - 1] = desca[ nb_ - 1] = nb = descz[mb_ - 1] = descz[ nb_ - 1]$

$np0 = numroc(nn, nb, 0, 0, NPROW)$ .

$nq0 = numroc( max( n, nb, 2 ), nb, 0, 0, NPCOL)$ .

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by `pxerbla`.

$rwork$

(local).

Workspace array of size  $lwork$ .

$lrwork$

(local) The size of the array  $rwork$ .

See below for definitions of variables used to define  $lrwork$ .

If no eigenvectors are requested ( $jobz = 'N'$ ), then  $lrwork \geq 2*n$ .

If eigenvectors are requested ( $jobz = 'V'$ ), then  $lrwork \geq 2*n + 2*n-2$ .

If  $lrwork = -1$ , then  $lrwork$  is global input and a workspace query is assumed; the function only calculates the minimum size required for the  $rwork$  array. The required workspace is returned as the first element of  $rwork$ , and no error message is issued by `pxerbla`.

## Output Parameters

$a$

On exit, the lower triangle (if  $uplo = 'L'$ ), or the upper triangle (if  $uplo = 'U'$ ) of  $A$ , including the diagonal, is overwritten.

$w$

(global).

Array of size  $n$ . The first  $m$  elements contain the selected eigenvalues in ascending order.

$z$

(local).

Array, global size  $n*n$ , local size  $lld\_z*LOCc(jz+n-1)$ .

If  $jobz = 'V'$ , then on normal exit the first  $m$  columns of  $z$  contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of  $z$  contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If  $jobz = 'N'$ , then  $z$  is not referenced.

$work[0]$

On exit, returns adequate workspace to allow optimal performance.

If  $jobz = 'N'$ , then  $work[0] =$  minimal workspace only for eigenvalues.

If  $jobz = 'V'$ , then  $work[0] =$  minimal workspace required to generate all the eigenvectors.

`rwork[0]` (local)  
 On output, `rwork[0]` returns workspace required to guarantee completion.

`info` (global)  
 If `info = 0`, the execution is successful.  
 If `info < 0`:  
 If the *i*-th argument is an array and the *j*-entry had an illegal value, then `info = -(i*100+j)`. If the *i*-th argument is a scalar and had an illegal value, then `info = -i`.  
 If `info > 0`:  
 If `info = 1` through *n*, the *i*-th eigenvalue did not converge in `?steqr2` after a total of `30*n` iterations.  
 If `info = n+1`, then `p?heevd` detected heterogeneity, and the accuracy of the results cannot be guaranteed.

## Description

The `p?heevd` function computes all eigenvalues and eigenvectors of a complex Hermitian matrix *A* by using a divide and conquer algorithm.

## Input Parameters

*np* = the number of rows local to a given process.

*nq* = the number of columns local to a given process.

`jobz` (global) Must be 'N' or 'V'.

Specifies if it is necessary to compute the eigenvectors:

If `jobz = 'N'`, then only eigenvalues are computed.

	If $jobz = 'V'$ , then eigenvalues and eigenvectors are computed.
<i>uplo</i>	(global) Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is stored: If $uplo = 'U'$ , <i>a</i> stores the upper triangular part of <i>A</i> . If $uplo = 'L'$ , <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	(global) The number of rows and columns of the matrix <i>A</i> ( $n \geq 0$ ).
<i>a</i>	(local). Block cyclic array of global size $n*n$ and local size $lld\_a*LOCc(ja+n-1)$ . On entry, the Hermitian matrix <i>A</i> . If $uplo = 'U'$ , only the upper triangular part of <i>A</i> is used to define the elements of the Hermitian matrix. If $uplo = 'L'$ , only the lower triangular part of <i>A</i> is used to define the elements of the Hermitian matrix.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If $desca[ctxt\_ - 1]$ is incorrect, <code>p?heevd</code> cannot guarantee correct error reporting.
<i>iz, jz</i>	(global) The row and column indices in the global matrix <i>Z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively.
<i>descz</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> . $descz[ctxt\_ - 1]$ must equal $desca[ctxt\_ - 1]$ .
<i>work</i>	(local). Array of size <i>lwork</i> .
<i>lwork</i>	(local) The size of the array <i>work</i> . If eigenvalues are requested: $lwork = n + (nb0 + mq0 + nb)*nb$ with $np0 = \text{numroc}(\max(n, nb, 2), nb, 0, 0, \text{NPROW})$ $mq0 = \text{numroc}(\max(n, nb, 2), nb, 0, 0, \text{NPCOL})$ If $lwork = -1$ , then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by <code>pxerbla</code> .
<i>rwork</i>	(local). Workspace array of size <i>lrwork</i> .
<i>lrwork</i>	(local) The size of the array <i>rwork</i> . $lrwork \geq 1 + 9*n + 3*np*nq,$

```
with np = numroc( n, nb, myrow, iarow, NPROW)
```

```
nq = numroc( n, nb, mycol, iacol, NPCOL)
```

*iwork*

(local) Workspace array of size *liwork*.

*liwork*

(local) , size of *iwork*.

```
liwork = 7*n + 8*npcol + 2.
```

## Output Parameters

*a*

On exit, the lower triangle (if *uplo* = 'L'), or the upper triangle (if *uplo* = 'U') of *A*, including the diagonal, is overwritten.

*w*

(global).

Array of size *n*. If *info* = 0, *w* contains the eigenvalues in the ascending order.

*z*

(local).

Array, global size  $n*n$ , local size  $l1d\_z*LOCc(jz+n-1)$ .

The *z* parameter contains the orthonormal eigenvectors of the matrix *A*.

*work*[0]

On exit, returns adequate workspace to allow optimal performance.

*rwork*[0]

(local)

On output, *rwork*[0] returns workspace required to guarantee completion.

*iwork*[0]

(local).

On return, *iwork*[0] contains the amount of integer workspace required.

*info*

(global)

If *info* = 0, the execution is successful.

If *info* < 0:

If the *i*-th argument is an array and the *j*-entry had an illegal value, then  $info = -(i*100+j)$ . If the *i*-th argument is a scalar and had an illegal value, then  $info = -i$ .

If *info* > 0:

If *info* = 1 through *n*, the *i*-th eigenvalue did not converge.

## Description

p?heevr computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix  $A$  distributed in 2D blockcyclic format by calling the recommended sequence of ScaLAPACK functions.

First, the matrix  $A$  is reduced to complex Hermitian tridiagonal form. Then, the eigenproblem is solved using the parallel MRRR algorithm. Last, if eigenvectors have been computed, a backtransformation is done.

Upon successful completion, each processor stores a copy of all computed eigenvalues in  $w$ . The eigenvector matrix  $Z$  is stored in 2D block-cyclic format distributed over all processors.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.intel.com/PerformanceIndex](http://www.intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

<i>jobz</i>	(global) Specifies whether or not to compute the eigenvectors: = 'N': Compute eigenvalues only. = 'V': Compute eigenvalues and eigenvectors.
<i>range</i>	(global) = 'A': all eigenvalues will be found. = 'V': all eigenvalues in the interval $[vl, vu]$ will be found. = 'I': the $il$ -th through $iu$ -th eigenvalues will be found.
<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the Hermitian matrix $A$ is stored: = 'U': Upper triangular = 'L': Lower triangular
<i>n</i>	(global)

	The number of rows and columns of the matrix $A$ . $n \geq 0$
$a$	Block-cyclic array, global size $n * n$ , local size $lld\_a * LOC_c(ja+n-1)$ Contains the local pieces of the Hermitian distributed matrix $A$ . If $uplo = 'U'$ , only the upper triangular part of $a$ is used to define the elements of the Hermitian matrix. If $uplo = 'L'$ , only the lower triangular part of $a$ is used to define the elements of the Hermitian matrix.
$ia$	(global ) Global row index in the global matrix $A$ that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.
$ja$	(global ) Global column index in the global matrix $A$ that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.
$desca$	(global and local) array of size $dlen\_$ . (The ScaLAPACK descriptor length is $dlen_ = 9$ .) The array descriptor for the distributed matrix $a$ . The descriptor stores details about the 2D block-cyclic storage, see the notes below. If $desca$ is incorrect, <code>p?heevr</code> cannot work correctly. Also note the array alignment requirements specified below
$vl$	(global) If $range='V'$ , the lower bound of the interval to be searched for eigenvalues. Not referenced if $range = 'A'$ or $'I'$ .
$vu$	(global) If $range='V'$ , the upper bound of the interval to be searched for eigenvalues. Not referenced if $range = 'A'$ or $'I'$ .
$il$	(global ) If $range='I'$ , the index (from smallest to largest) of the smallest eigenvalue to be returned. $il \geq 1$ . Not referenced if $range = 'A'$ .
$iu$	(global ) If $range='I'$ , the index (from smallest to largest) of the largest eigenvalue to be returned. $\min(il, n) \leq iu \leq n$ . Not referenced if $range = 'A'$ .
$iz$	(global ) Global row index in the global matrix $Z$ that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.
$jz$	(global )

Global column index in the global matrix  $Z$  that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

*descz*

(global and local) array of size *dlen\_*.

The array descriptor for the distributed matrix  $z$ . *descz*[*ctxt\_* - 1] must equal *desca*[*ctxt\_* - 1]

*work*

(local workspace) array of size *lwork*

*lwork*

(local )

Size of *work* array, must be at least 3.

If only eigenvalues are requested:

$$lwork \geq n + \max( nb * ( np00 + 1 ), nb * 3 )$$

If eigenvectors are requested:

$$lwork \geq n + ( np00 + mq00 + nb ) * nb$$

For definitions of *np00* and *mq00*, see *lwork*.

For optimal performance, greater workspace is needed, i.e.

$$lwork \geq \max( lwork, nhetrd\_lwork )$$

Where *lwork* is as defined above, and

$$nhetrd\_lwork = n + 2 * ( anb + 1 ) * ( 4 * nps + 2 ) + ( nps + 1 ) * nps$$

$$ictxt = desca[ctxt_ - 1]$$

$$anb = pjlaenv( ictxt, 3, 'PCHETTRD', 'L', 0, 0, 0, 0 )$$

$$sqnpc = \text{sqrt}( \text{real}( nprow * npc0l ) )$$

$$nps = \max( \text{numroc}( n, 1, 0, 0, sqnpc ), 2 * anb )$$

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

*rwork*

(local workspace) array of size *lrwork*

*lrwork*

(local )

Size of *rwork*, must be at least 3.

See below for definitions of variables used to define *lrwork*.

If no eigenvectors are requested (*jobz* = 'N') then

$$lrwork \geq 2 + 5 * n + \max( 12 * n, nb * ( np00 + 1 ) )$$

If eigenvectors are requested (*jobz* = 'V') then the amount of workspace required is:

$$lrwork \geq 2 + 5 * n + \max( 18 * n, np00 * mq00 + 2 * nb * nb ) +$$

$$( 2 + \text{iceil}( neig, nprow * npc0l ) ) * n$$

**NOTE**

`iceil(x, y)` is the ceiling of  $x/y$ .

Variable definitions:

$neig$  = number of eigenvectors requested

$nb = desca[mb_ - 1] = desca[nb_ - 1] = descz[mb_ - 1] = descz[nb_ - 1]$

$nn = \max(n, nb, 2)$

$desca[rsrc_ - 1] = desca[csrc_ - 1] = descz[rsrc_ - 1] = descz[csrc_ - 1] = 0$

$np00 = \text{numroc}(nn, nb, 0, 0, nprow)$

$mq00 = \text{numroc}(\max(neig, nb, 2), nb, 0, 0, npc0l)$

`iceil(x, y)` is a ScaLAPACK function returning  $\text{ceiling}(x/y)$ , and  $nprow$  and  $npcol$  can be determined by calling the function `blacs_gridinfo`.

If  $lrwork = -1$ , then  $lrwork$  is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pxerbla`

$iwork$

(local workspace) array of size  $liwork$

$liwork$

(local )

size of  $iwork$

Let  $nnp = \max(n, nprow*npcol + 1, 4)$ . Then:

$liwork \geq 12*nnp + 2*n$  when the eigenvectors are desired

$liwork \geq 10*nnp + 2*n$  when only the eigenvalues have to be computed

If  $liwork = -1$ , then  $liwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`

**OUTPUT Parameters**

$a$

The lower triangle (if  $uplo='L'$ ) or the upper triangle (if  $uplo='U'$ ) of  $a$ , including the diagonal, is destroyed.

$m$

(global )

Total number of eigenvalues found.  $0 \leq m \leq n$ .

$nz$

(global )

Total number of eigenvectors computed.  $0 \leq nz \leq m$ .

The number of columns of  $z$  that are filled.

If  $jobz \neq 'V'$ ,  $nz$  is not referenced.

	If $jobz = 'V'$ , $nz = m$
$w$	(global ) array of size $n$ On normal exit, the first $m$ entries contain the selected eigenvalues in ascending order.
$z$	(local ) array, global size $n * n$ , local size $lld_z * LOC_c(jz+n-1)$ If $jobz = 'V'$ , then on normal exit the first $m$ columns of $z$ contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If $jobz = 'N'$ , then $z$ is not referenced.
$work$	$work[0]$ returns workspace adequate workspace to allow optimal performance.
$rwork$	On return, $rwork[0]$ contains the optimal amount of workspace required for efficient execution. if $jobz='N'$ $rwork[0]$ = optimal amount of workspace required to compute the eigenvalues. if $jobz='V'$ $rwork[0]$ = optimal amount of workspace required to compute eigenvalues and eigenvectors.
$iwork$	On return, $iwork[0]$ contains the amount of integer workspace required.
$info$	(global ) = 0: successful exit < 0: If the $i$ -th argument is an array and the $j$ -th entry had an illegal value, then $info = -(j*100+j)$ , if the $i$ -th argument is a scalar and had an illegal value, then $info = -i$ .

## Application Notes

The distributed submatrices  $a(ia:*, ja:*)$  and  $z(iz:iz+m-1, jz:jz+n-1)$  must satisfy the following alignment properties:

1. Identical (quadratic) dimension:  $desca[m_ - 1] = descz[m_ - 1] = desca[n_ - 1] = descz[n_ - 1]$
2. Quadratic conformal blocking:  $desca[mb_ - 1] = desca[nb_ - 1] = descz[mb_ - 1] = descz[nb_ - 1]$ ,  
 $desca[rsrc_ - 1] = descz[rsrc_ - 1]$
3.  $\text{mod}( ia-1, mb_a ) = \text{mod}( iz-1, mb_z ) = 0$

---

### NOTE

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

## Description

The `p?heevx` function computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix  $A$  by calling the recommended sequence of ScaLAPACK functions. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

$np$  = the number of rows local to a given process.

$nq$  = the number of columns local to a given process.

*jobz* (global) Must be 'N' or 'V'.

Specifies if it is necessary to compute the eigenvectors:

If *jobz* = 'N', then only eigenvalues are computed.

If *jobz* = 'V', then eigenvalues and eigenvectors are computed.

*range* (global) Must be 'A', 'V', or 'I'.

If *range* = 'A', all eigenvalues will be found.

If *range* = 'V', all eigenvalues in the half-open interval  $[vl, vu]$  will be found.

If *range* = 'I', the eigenvalues with indices *il* through *iu* will be found.

*uplo* (global) Must be 'U' or 'L'.

Specifies whether the upper or lower triangular part of the Hermitian matrix  $A$  is stored:

If *uplo* = 'U',  $a$  stores the upper triangular part of  $A$ .

	If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	(global) The number of rows and columns of the matrix <i>A</i> ( $n \geq 0$ ).
<i>a</i>	(local). Block cyclic array of global size $n*n$ and local size $lld\_a*LOCc(ja+n-1)$ . On entry, the Hermitian matrix <i>A</i> . If <i>uplo</i> = 'U', only the upper triangular part of <i>A</i> is used to define the elements of the Hermitian matrix. If <i>uplo</i> = 'L', only the lower triangular part of <i>A</i> is used to define the elements of the Hermitian matrix.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>desca</i> [ <i>ctxt_</i> - 1] is incorrect, <i>p?heevx</i> cannot guarantee correct error reporting.
<i>vl, vu</i>	(global) If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; not referenced if <i>range</i> = 'A' or 'I'.
<i>il, iu</i>	(global) If <i>range</i> = 'I', the indices of the smallest and largest eigenvalues to be returned. Constraints: $il \geq 1; \min(il, n) \leq iu \leq n$ . Not referenced if <i>range</i> = 'A' or 'V'.
<i>abstol</i>	(global). If <i>jobz</i> ='V', setting <i>abstol</i> to <i>p?lamch(context, 'U')</i> yields the most orthogonal eigenvectors. The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol+eps*\max( a ,  b )$ , where <i>eps</i> is the machine precision. If <i>abstol</i> is less than or equal to zero, then $eps*\text{norm}(T)$ will be used in its place, where $\text{norm}(T)$ is the 1-norm of the tridiagonal matrix obtained by reducing <i>A</i> to tridiagonal form. Eigenvalues are computed most accurately when <i>abstol</i> is set to twice the underflow threshold $2*p?lamch('S')$ , not zero. If this function returns with $((\text{mod}(\text{info}, 2) \neq 0) .or. (\text{mod}(\text{info}/8, 2) \neq 0))$ , indicating that some eigenvalues or eigenvectors did not converge, try setting <i>abstol</i> to $2*p?lamch('S')$ .

**NOTE**

---

$\text{mod}(x, y)$  is the integer remainder of  $x/y$ .

---

*orfac* (global).

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within  $tol = orfac * \text{norm}(A)$  of each other are to be reorthogonalized. However, if the workspace is insufficient (see *lwork*), *tol* may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of  $1.0e-3$  is used if *orfac* is negative.

*orfac* should be identical on all processes.

*iz, jz*

(global) The row and column indices in the global matrix *Z* indicating the first row and the first column of the submatrix *Z*, respectively.

*descz*

(global and local) array of size *dlen\_*. The array descriptor for the distributed matrix *Z*. *descz[ctxt\_ - 1]* must equal *desca[ctxt\_ - 1]*.

*work*

(local).

Array of size *lwork*.

*lwork*

(local) The size of the array *work*.

If only eigenvalues are requested:

$$lwork \geq n + \max(nb * (np0 + 1), 3)$$

If eigenvectors are requested:

$$lwork \geq n + (np0 + mq0 + nb) * nb$$

with  $nq0 = \text{numroc}(nn, nb, 0, 0, \text{NPCOL})$ .

$$lwork \geq 5 * n + \max(5 * nn, np0 * mq0 + 2 * nb * nb) + \text{iceil}(neig, \text{NPROW} * \text{NPCOL}) * nn$$

For optimal performance, greater workspace is needed, that is

$$lwork \geq \max(lwork, nhetrd\_lwork)$$

where *lwork* is as defined above, and  $nhetrd\_lwork = n + 2 * (anb + 1) * (4 * nps + 2) + (nps + 1) * nps$

$$ictxt = desca[ctxt_ - 1]$$

$$anb = \text{pjlaenv}(ictxt, 3, 'pchettrd', 'L', 0, 0, 0, 0)$$

$$sqnpc = \text{sqrt}(\text{dble}(\text{NPROW} * \text{NPCOL}))$$

$$nps = \max(\text{numroc}(n, 1, 0, 0, sqnpc), 2 * anb)$$

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by *pxerbla*.

*rwork*

(local)

Workspace array of size *lwork*.

*lrwork*

(local) The size of the array *work*.

See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N'), then  $lrwork \geq 5 * nn + 4 * n$ .

If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

$$lwork \geq 4*n + \max(5*nn, np0*mq0+2*nb*nb) + \text{iceil}(neig, \text{NPROW}*NPCOL)*nn$$

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following values to *lwork*:

$$(clustersize-1)*n,$$

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

$$\{w[k-1], \dots, w[k+clustersize-2] | w[j] \leq w[j-1] + orfac*2*norm(A)\}.$$

Variable definitions:

*neig* = number of eigenvectors requested;

*nb* = *desca*[*mb\_* - 1] = *desca*[*nb\_* - 1] = *descz*[*mb\_* - 1] = *descz*[*nb\_* - 1];

*nn* = max(*n*, *NB*, 2);

*desca*[*rsrc\_* - 1] = *desca*[*nb\_* - 1] = *descz*[*rsrc\_* - 1] = *descz*[*csrc\_* - 1] = 0;

*np0* = numroc(*nn*, *nb*, 0, 0, *NPROW*);

*mq0* = numroc(max(*neig*, *nb*, 2), *nb*, 0, 0, *NPCOL*);

*iceil*(*x*, *y*) is a ScaLAPACK function returning ceiling(*x*/*y*)

When *lwork* is too small:

If *lwork* is too small to guarantee orthogonality, *p?heevx* attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues. If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned. Note that when *range*='V', *p?heevx* does not know how many eigenvectors are requested until the eigenvalues are computed. Therefore, when *range*='V' and as long as *lwork* is large enough to allow *p?heevx* to compute the eigenvalues, *p?heevx* will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality and performance:

If  $clustersize \geq n/\sqrt{NPROW*NPCOL}$ , then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is,  $clustersize = n-1$ ) *p?stein* will perform no better than *?stein* on 1 processor.

For  $clustersize = n/\sqrt{NPROW*NPCOL}$  reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For  $clustersize > n/\sqrt{NPROW*NPCOL}$  execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pxerbla`.

$iwork$  (local) Workspace array.

$liwork$  (local), size of  $iwork$ .

$liwork \geq 6 * nnp$

Where:  $nnp = \max(n, NPROW * NPCOL + 1, 4)$

If  $liwork = -1$ , then  $liwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

$a$  On exit, the lower triangle (if  $uplo = 'L'$ ), or the upper triangle (if  $uplo = 'U'$ ) of  $A$ , including the diagonal, is overwritten.

$m$  (global) The total number of eigenvalues found;  $0 \leq m \leq n$ .

$nz$  (global) Total number of eigenvectors computed.  $0 \leq nz \leq m$ .

The number of columns of  $z$  that are filled.

If  $jobz \neq 'V'$ ,  $nz$  is not referenced.

If  $jobz = 'V'$ ,  $nz = m$  unless the user supplies insufficient space and `p?heevx` is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in  $z$  ( $m \leq descz[n_ - 1]$ ) and sufficient workspace to compute them. (See  $lwork$ ). `p?heevx` is always able to detect insufficient space without computation unless  $range = 'V'$ .

$w$  (global).

Array of size  $n$ . The first  $m$  elements contain the selected eigenvalues in ascending order.

$z$  (local).

Array, global size  $n * n$ , local size  $lld\_z * LOCC(jz + n - 1)$ .

If  $jobz = 'V'$ , then on normal exit the first  $m$  columns of  $z$  contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of  $z$  contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in  $ifail$ .

If  $jobz = 'N'$ , then  $z$  is not referenced.

$work[0]$  On exit, returns adequate workspace to allow optimal performance.

$rwork$  (local).

Array of size *lwork*. On return, *rwork*[0] contains the optimal amount of workspace required for efficient execution.

If *jobz*='N' *rwork*[0] = optimal amount of workspace required to compute eigenvalues efficiently.

If *jobz*='V' *rwork*[0] = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.

If *range*='V', it is assumed that all eigenvectors may be required.

*iwork*[0]

(local)

On return, *iwork*[0] contains the amount of integer workspace required.

*ifail*

(global)

Array of size *n*.

If *jobz* = 'V', then on normal exit, the first *m* elements of *ifail* are zero. If  $(\text{mod}(\text{info}, 2) \neq 0)$  on exit, then *ifail* contains the indices of the eigenvectors that failed to converge.

If *jobz* = 'N', then *ifail* is not referenced.

*iclustr*

(global)

Array of size  $2 * \text{NPROW} * \text{NPCOL}$ .

This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*[2\**i* - 2] to *iclustr*[2\**i* - 1], could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal.

*iclustr* is a zero terminated array. (*iclustr*[2\**k* - 1] ≠ 0 and *iclustr*[2\**k*] = 0) if and only if *k* is the number of clusters. *iclustr* is not referenced if *jobz* = 'N'.

*gap*

(global)

Array of size  $(\text{NPROW} * \text{NPCOL})$

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*-th cluster may be as high as  $(C * n) / \text{gap}(i)$  where *C* is a small constant.

*info*

(global)

If *info* = 0, the execution is successful.

If *info* < 0:

If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* =  $-(i * 100 + j)$ . If the *i*-th argument is a scalar and had an illegal value, then *info* =  $-i$ .

If *info* > 0:

If  $(\text{mod}(\text{info}, 2) \neq 0)$ , then one or more eigenvectors failed to converge. Their indices are stored in *ifail*. Ensure *abstol* =  $2.0 * \text{p2lamch}('U')$

If  $(\text{mod}(\text{info}/2, 2) \neq 0)$ , then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If  $(\text{mod}(\text{info}/4, 2) \neq 0)$ , then space limit prevented `p?syevx` from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If  $(\text{mod}(\text{info}/8, 2) \neq 0)$ , then `p?stebz` failed to compute eigenvalues. Ensure  $\text{abstol} = 2.0 * \text{p?lamch}('U')$ .

### Description

The `p?gesvd` function computes the singular value decomposition (SVD) of an  $m$ -by- $n$  matrix  $A$ , optionally computing the left and/or right singular vectors. The SVD is written

$$A = U \Sigma V^T,$$

where  $\Sigma$  is an  $m$ -by- $n$  matrix that is zero except for its  $\min(m, n)$  diagonal elements,  $U$  is an  $m$ -by- $m$  orthogonal matrix, and  $V$  is an  $n$ -by- $n$  orthogonal matrix. The diagonal elements of  $\Sigma$  are the singular values of  $A$  and the columns of  $U$  and  $V$  are the corresponding right and left singular vectors, respectively. The singular values are returned in array *s* in decreasing order and only the first  $\min(m, n)$  columns of  $U$  and rows of  $vt = V^T$  are computed.

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

**NOTE**

The distributed submatrix  $\text{sub}(A)$  must verify certain alignment properties. These expressions must be true:

- $mb\_a = nb\_a = nb$
- $iroffa = icoffa$

where:

- $iroffa = \text{mod}(ia-1, nb)$
- $icoffa = \text{mod}(ja-1, nb)$

**Input Parameters**

$mp$  = number of local rows in  $A$  and  $U$

$nq$  = number of local columns in  $A$  and  $V^T$

$size = \min(m, n)$

$sizeq$  = number of local columns in  $U$

$sizep$  = number of local rows in  $V^T$

$jobu$	(global) Specifies options for computing all or part of the matrix $U$ . If $jobu = 'V'$ , the first $size$ columns of $U$ (the left singular vectors) are returned in the array $u$ ; If $jobu = 'N'$ , no columns of $U$ (no left singular vectors) are computed.
$jobvt$	(global) Specifies options for computing all or part of the matrix $V^T$ . If $jobvt = 'V'$ , the first $size$ rows of $V^T$ (the right singular vectors) are returned in the array $vt$ ; If $jobvt = 'N'$ , no rows of $V^T$ (no right singular vectors) are computed.
$m$	(global) The number of rows of the matrix $A$ ( $m \geq 0$ ).
$n$	(global) The number of columns in $A$ ( $n \geq 0$ ).
$a$	(local). Block cyclic array, global size $(m, n)$ , local size $(mp, nq)$ .
$ia, ja$	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
$desca$	(global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $A$ .

<i>iu, ju</i>	(global) The row and column indices in the global matrix <i>U</i> indicating the first row and the first column of the submatrix <i>U</i> , respectively.
<i>descu</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>U</i> .
<i>ivt, jvt</i>	(global) The row and column indices in the global matrix <i>VT</i> indicating the first row and the first column of the submatrix <i>VT</i> , respectively.
<i>descvt</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>VT</i> .
<i>work</i>	(local). Workspace array of size <i>lwork</i>
<i>lwork</i>	(local) The size of the array <i>work</i> ; $lwork > 2 + 6 * sizeb + \max(watobd, wbdtosvd),$ where $sizeb = \max(m, n)$ , and <i>watobd</i> and <i>wbdtosvd</i> refer, respectively, to the workspace required to bidiagonalize the matrix <i>A</i> and to go from the bidiagonal matrix to the singular value decomposition <i>USVT</i> . For <i>watobd</i> , the following holds: $watobd = \max(\max(wp?lange, wp?gebrd), \max(wp?lared2d, wp?lared1d)),$ where <i>wp?lange</i> , <i>wp?lared1d</i> , <i>wp?lared2d</i> , <i>wp?gebrd</i> are the workspaces required respectively for the subprograms <i>p?lange</i> , <i>p?lared1d</i> , <i>p?lared2d</i> , <i>p?gebrd</i> . Using the standard notation $mp = \text{numroc}(m, mb, MYROW, desca[ctxt_ - 1], NPROW),$ $nq = \text{numroc}(n, nb, MYCOL, desca[lld_ - 1], NPCOL),$ the workspaces required for the above subprograms are $wp?lange = mp,$ $wp?lared1d = nq0,$ $wp?lared2d = mp0,$ $wp?gebrd = nb * (mp + nq + 1) + nq,$ where <i>nq0</i> and <i>mp0</i> refer, respectively, to the values obtained at <i>MYCOL</i> = 0 and <i>MYROW</i> = 0. In general, the upper limit for the workspace is given by a workspace required on processor (0,0): $watobd \leq nb * (mp0 + nq0 + 1) + nq0.$ In case of a homogeneous process grid this upper limit can be used as an estimate of the minimum workspace for every processor. For <i>wbdtosvd</i> , the following holds: $wbdtosvd = size * (wantu * nru + wantvt * ncvt) + \max(w?bdsqr, \max(wantu * wp?ormbrqln, wantvt * wp?ormbrprt)),$ where

$wantu(wantvt) = 1$ , if left/right singular vectors are wanted, and  $wantu(wantvt) = 0$ , otherwise.  $w?bdsqr$ ,  $wp?ormbrqln$ , and  $wp?ormbrprt$  refer respectively to the workspace required for the subprograms  $?bdsqr$ ,  $p?ormbr(qln)$ , and  $p?ormbr(prt)$ , where  $qln$  and  $prt$  are the values of the arguments *vect*, *side*, and *trans* in the call to  $p?ormbr$ .  $nru$  is equal to the local number of rows of the matrix  $U$  when distributed 1-dimensional "column" of processes. Analogously,  $ncvt$  is equal to the local number of columns of the matrix  $VT$  when distributed across 1-dimensional "row" of processes. Calling the LAPACK procedure  $?bdsqr$  requires

$$w?bdsqr = \max(1, 2*size + (2*size - 4) * \max(wantu, wantvt))$$

on every processor. Finally,

$$wp?ormbrqln = \max((nb*(nb-1))/2, (sizeq+mp)*nb)+nb*nb,$$

$$wp?ormbrprt = \max((mb*(mb-1))/2, (sizep+nq)*mb)+mb*mb,$$

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the minimum size for the work array. The required workspace is returned as the first element of  $work$  and no error message is issued by  $pxerbla$ .

*rwork*

Workspace array of size  $1 + 4*sizeb$ . Not used for  $psgesvd$  and  $pdgesvd$ .

## Output Parameters

*a*

On exit, the contents of *a* are destroyed.

*s*

(global).

Array of size *size*.

Contains the singular values of  $A$  sorted so that  $s(i) \geq s(i+1)$ .

*u*

(local).

local size  $mp*sizeq$ , global size  $m*size$ )

If  $jobu = 'V'$ , *u* contains the first  $\min(m, n)$  columns of  $U$ .

If  $jobu = 'N'$  or  $'O'$ , *u* is not referenced.

*vt*

(local).

local size (*sizep*, *nq*), global size (*size*, *n*)

If  $jobvt = 'V'$ , *vt* contains the first *size* rows of  $V^T$  if  $jobu = 'N'$ , *vt* is not referenced.

*work*

On exit, if  $info = 0$ , then  $work[0]$  returns the required minimal size of *lwork*.

*rwork*

On exit, if  $info = 0$ , then  $rwork[0]$  returns the required size of *rwork*.

*info*

(global)

If  $info = 0$ , the execution is successful.

If  $info < 0$ , If  $info = -i$ , the *i*th parameter had an illegal value.

If  $info > 0$  *i*, then if  $?bdsqr$  did not converge,

If  $info = \min(m, n) + 1$ , then `p?gesvd` has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from `p?gesvd` cannot be guaranteed.

## Description

The `p?sygvx` function computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x, \text{sub}(A) \text{ sub}(B) * x = \lambda * x, \text{ or } \text{sub}(B) * \text{sub}(A) * x = \lambda * x.$$

Here  $x$  denotes eigen vectors,  $\lambda$  (*lambda*) denotes eigenvalues,  $\text{sub}(A)$  denoting  $A(ia:ia+n-1, ja:ja+n-1)$  is assumed to symmetric, and  $\text{sub}(B)$  denoting  $B(ib:ib+n-1, jb:jb+n-1)$  is also positive definite.

Notice revision #20201201

## Input Parameters

*ibtype*

(global) Must be 1 or 2 or 3.

Specifies the problem type to be solved:

If *ibtype* = 1, the problem type is  $\text{sub}(A) * x = \text{lambda} * \text{sub}(B) * x$ ;

If *ibtype* = 2, the problem type is  $\text{sub}(A) * \text{sub}(B) * x = \text{lambda} * x$ ;

	If $ibtype = 3$ , the problem type is $\text{sub}(B) * \text{sub}(A) * x = \text{lambda} * x$ .
<i>jobz</i>	(global) Must be 'N' or 'V'. If $jobz = 'N'$ , then compute eigenvalues only. If $jobz = 'V'$ , then compute eigenvalues and eigenvectors.
<i>range</i>	(global) Must be 'A' or 'V' or 'I'. If $range = 'A'$ , the function computes all eigenvalues. If $range = 'V'$ , the function computes eigenvalues in the interval: $[vl, vu]$ If $range = 'I'$ , the function computes eigenvalues with indices $il$ through $iu$ .
<i>uplo</i>	(global) Must be 'U' or 'L'. If $uplo = 'U'$ , arrays $a$ and $b$ store the upper triangles of $\text{sub}(A)$ and $\text{sub}(B)$ ; If $uplo = 'L'$ , arrays $a$ and $b$ store the lower triangles of $\text{sub}(A)$ and $\text{sub}(B)$ .
<i>n</i>	(global) The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$ , $n \geq 0$ .
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ . On entry, this array contains the local pieces of the $n$ -by- $n$ symmetric distributed matrix $\text{sub}(A)$ . If $uplo = 'U'$ , the leading $n$ -by- $n$ upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix. If $uplo = 'L'$ , the leading $n$ -by- $n$ lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix.
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
<i>desca</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ . If $desca[ctxt\_ - 1]$ is incorrect, $p?sygvx$ cannot guarantee correct error reporting.
<i>b</i>	(local). Pointer into the local memory to an array of size $lld\_b * LOCC(jb+n-1)$ . On entry, this array contains the local pieces of the $n$ -by- $n$ symmetric distributed matrix $\text{sub}(B)$ . If $uplo = 'U'$ , the leading $n$ -by- $n$ upper triangular part of $\text{sub}(B)$ contains the upper triangular part of the matrix. If $uplo = 'L'$ , the leading $n$ -by- $n$ lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix.
<i>ib, jb</i>	(global) The row and column indices in the global matrix $B$ indicating the first row and the first column of the submatrix $B$ , respectively.

<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> . <i>descb</i> [ <i>ctxt_</i> - 1] must be equal to <i>desca</i> [ <i>ctxt_</i> - 1].
<i>vl, vu</i>	(global) If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	(global) If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $il \geq 1, \min(il, n) \leq iu \leq n$ If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>abstol</i>	(global) If <i>jobz</i> ='V', setting <i>abstol</i> to <code>p?lamch(context, 'U')</code> yields the most orthogonal eigenvectors. The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + eps * \max( a ,  b )$ , where <i>eps</i> is the machine precision. If <i>abstol</i> is less than or equal to zero, then $eps * \text{norm}(T)$ will be used in its place, where $\text{norm}(T)$ is the 1-norm of the tridiagonal matrix obtained by reducing <i>A</i> to tridiagonal form. Eigenvalues will be computed most accurately when <i>abstol</i> is set to twice the underflow threshold <code>2*p?lamch('S')</code> not zero. If this function returns with $(\text{mod}(\text{info}, 2) \neq 0)$ or $(\text{mod}(\text{info}/8, 2) \neq 0)$ , indicating that some eigenvalues or eigenvectors did not converge, try setting <i>abstol</i> to <code>2*p?lamch('S')</code> .
<hr/> <b>NOTE</b> <i>mod</i> ( <i>x</i> , <i>y</i> ) is the integer remainder of <i>x</i> / <i>y</i> . <hr/>	
<i>orfac</i>	(global). Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol = orfac * \text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see <i>lwork</i> ), <i>tol</i> may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if <i>orfac</i> equals zero. A default value of 1.0e-3 is used if <i>orfac</i> is negative. <i>orfac</i> should be identical on all processes.
<i>iz, jz</i>	(global) The row and column indices in the global matrix <i>Z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively.
<i>descz</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> . <i>descz</i> [ <i>ctxt_</i> - 1] must equal <i>desca</i> [ <i>ctxt_</i> - 1].
<i>work</i>	(local)

*lwork*Workspace array of size *lwork*

(local)

Size of the array *work*. See below for definitions of variables used to define *lwork*.If no eigenvectors are requested (*jobz* = 'N'), then  $lwork \geq 5*n + \max(5*nn, NB*(np0 + 1))$ .If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is: $lwork \geq 5*n + \max(5*nn, np0*mq0 + 2*nb*nb) + \text{iceil}(neig, NPROW*NPCOL)*nn$ .The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality at the cost of potentially poor performance you should add the following to *lwork*: $(clustersize-1)*n$ ,where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues: $\{w[k-1], \dots, w[k+clustersize-2] \mid w[j] \leq w[j-1] + orfac*2*norm(A)\}$ 

Variable definitions:

*neig* = number of eigenvectors requested, $nb = desca[mb_ - 1] = desca[nb_ - 1] = descz[mb_ - 1] = descz[nb_ - 1]$ , $nn = \max(n, nb, 2)$ , $desca[rsrc_ - 1] = desca[nb_ - 1] = descz[rsrc_ - 1] = descz[csrc_ - 1] = 0$ , $np0 = \text{numroc}(nn, nb, 0, 0, NPROW)$ , $mq0 = \text{numroc}(\max(neig, nb, 2), nb, 0, 0, NPCOL)$ *iceil*(*x*, *y*) is a ScaLAPACK function returning  $\text{ceiling}(x/y)$ If *lwork* is too small to guarantee orthogonality, *p?syevx* attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned.Note that when *range*='V', number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if *lwork* is large enough to compute the eigenvalues, *p?sygvx* computes the eigenvalues and as many eigenvectors as possible.

Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

 $lwork \geq \max(lwork, 5*n + nsytrd\_lwopt, nsygst\_lwopt)$ , where

*lwork*, as defined previously, depends upon the number of eigenvectors requested, and

```
nsytrd_lwopt = n + 2*(anb+1)*(4*nps+2) + (nps+3)*nps
```

```
nsygst_lwopt = 2*np0*nb + nq0*nb + nb*nb
```

```
anb = pjslaenv(desca[ctxt_ - 1], 3, p?sytrd ', 'L', 0, 0, 0, 0)
```

```
sqnpc = int(sqrt(dble(NPROW * NPCOL)))
```

```
nps = max(numroc(n, 1, 0, 0, sqnpc), 2*anb)
```

```
NB = desca[mb_ - 1]
```

```
np0 = numroc(n, nb, 0, 0, NPROW)
```

```
nq0 = numroc(n, nb, 0, 0, NPCOL)
```

numroc is a ScaLAPACK tool functions;

pjslaenv is a ScaLAPACK environmental inquiry function

MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs\_gridinfo.

For large  $n$ , no extra workspace is needed, however the biggest boost in performance comes for small  $n$ , so it is wise to provide the extra workspace (typically less than a Megabyte per process).

If  $clustersize \geq n/\sqrt{NPROW*NPCOL}$ , then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is,  $clustersize = n-1$ ) p?stein will perform no better than ?stein on a single processor.

For  $clustersize = n/\sqrt{NPROW*NPCOL}$  reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For  $clustersize > n/\sqrt{NPROW*NPCOL}$  execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If  $lwork = -1$ , then *lwork* is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by p\_xerbla.

*iwork*

(local) Workspace array.

*liwork*

(local) , size of *iwork*.

```
liwork  $\geq$  6*nnp
```

Where:

```
nnp = max(n, NPROW*NPCOL + 1, 4)
```

If  $liwork = -1$ , then *liwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by p\_xerbla.

## Output Parameters

<code>a</code>	<p>On exit,</p> <p>If <code>jobz = 'V'</code>, and if <code>info = 0</code>, <code>sub(A)</code> contains the distributed matrix <math>Z</math> of eigenvectors. The eigenvectors are normalized as follows:</p> <p>for <code>ibtype = 1</code> or <code>2</code>, <math>Z^T * \text{sub}(B) * Z = I</math>;</p> <p>for <code>ibtype = 3</code>, <math>Z^T * \text{inv}(\text{sub}(B)) * Z = I</math>.</p> <p>If <code>jobz = 'N'</code>, then on exit the upper triangle (if <code>uplo='U'</code>) or the lower triangle (if <code>uplo='L'</code>) of <code>sub(A)</code>, including the diagonal, is destroyed.</p>
<code>b</code>	<p>On exit, if <code>info ≤ n</code>, the part of <code>sub(B)</code> containing the matrix is overwritten by the triangular factor <math>U</math> or <math>L</math> from the Cholesky factorization <math>\text{sub}(B) = U^T * U</math> or <math>\text{sub}(B) = L * L^T</math>.</p>
<code>m</code>	(global) The total number of eigenvalues found, $0 ≤ m ≤ n$ .
<code>nz</code>	<p>(global)</p> <p>Total number of eigenvectors computed. <math>0 ≤ nz ≤ m</math>. The number of columns of <math>z</math> that are filled.</p> <p>If <code>jobz ≠ 'V'</code>, <code>nz</code> is not referenced.</p> <p>If <code>jobz = 'V'</code>, <code>nz = m</code> unless the user supplies insufficient space and <code>p?sygvx</code> is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in <math>z</math> (<code>m ≤ descz(n_)</code>) and sufficient workspace to compute them. (See <code>lwork</code> below.) <code>p?sygvx</code> is always able to detect insufficient space without computation unless <code>range='V'</code>.</p>
<code>w</code>	<p>(global)</p> <p>Array of size <math>n</math>. On normal exit, the first <math>m</math> entries contain the selected eigenvalues in ascending order.</p>
<code>z</code>	<p>(local).</p> <p>global size <math>n * n</math>, local size <code>lld_z * LOcc(jz+n-1)</code>.</p> <p>If <code>jobz = 'V'</code>, then on normal exit the first <math>m</math> columns of <math>z</math> contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of <math>z</math> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <code>ifail</code>.</p> <p>If <code>jobz = 'N'</code>, then <math>z</math> is not referenced.</p>
<code>work</code>	<p>If <code>jobz='N'</code> <code>work[0]</code> = optimal amount of workspace required to compute eigenvalues efficiently</p> <p>If <code>jobz = 'V'</code> <code>work[0]</code> = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.</p> <p>If <code>range='V'</code>, it is assumed that all eigenvectors may be required.</p>
<code>ifail</code>	<p>(global)</p> <p>Array of size <math>n</math>.</p>

*ifail* provides additional information when  $info \neq 0$

If  $(\text{mod}(info/16, 2) \neq 0)$  then  $ifail[0]$  indicates the order of the smallest minor which is not positive definite. If  $(\text{mod}(info, 2) \neq 0)$  on exit, then *ifail* contains the indices of the eigenvectors that failed to converge.

If neither of the above error conditions hold and  $jobz = 'V'$ , then the first  $m$  elements of *ifail* are set to zero.

*iclustr*

(global)

Array of size  $(2 * NPROW * NPCOL)$ . This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed  $iclustr[2*i - 2]$  to  $iclustr[2*i - 1]$ , could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr* is a zero terminated array.

$(iclustr[2*k - 1] \neq 0 \text{ and } iclustr[2*k] = 0)$  if and only if  $k$  is the number of clusters *iclustr* is not referenced if  $jobz = 'N'$ .

*gap*

(global)

Array of size  $NPROW * NPCOL$ . This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the  $i$ -th cluster may be as high as  $(C * n) / gap[i - 1]$ , where  $C$  is a small constant.

*info*

(global)

If  $info = 0$ , the execution is successful.

If  $info < 0$ : the  $i$ -th argument is an array and the  $j$ -entry had an illegal value, then  $info = -(i * 100 + j)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

If  $info > 0$ :

If  $(\text{mod}(info, 2) \neq 0)$ , then one or more eigenvectors failed to converge. Their indices are stored in *ifail*.

If  $(\text{mod}(info, 2, 2) \neq 0)$ , then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If  $(\text{mod}(info/4, 2) \neq 0)$ , then space limit prevented  $p?sygvx$  from computing all of the eigenvectors between  $vl$  and  $vu$ . The number of eigenvectors computed is returned in  $nz$ .

If  $(\text{mod}(info/8, 2) \neq 0)$ , then  $p?stebz$  failed to compute eigenvalues.

If  $(\text{mod}(info/16, 2) \neq 0)$ , then  $B$  was not positive definite.  $ifail(1)$  indicates the order of the smallest minor which is not positive definite.

### Input Parameters

*ibtype* (global) Must be 1 or 2 or 3.  
Specifies the problem type to be solved:

If *ibtype* = 1, the problem type is

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x;$$

If *ibtype* = 2, the problem type is

$$\text{sub}(A) * \text{sub}(B) * x = \lambda * x;$$

If *ibtype* = 3, the problem type is

$$\text{sub}(B) * \text{sub}(A) * x = \lambda * x.$$

<code>jobz</code>	<p>(global) Must be 'N' or 'V'.</p> <p>If <code>jobz = 'N'</code>, then compute eigenvalues only.</p> <p>If <code>jobz = 'V'</code>, then compute eigenvalues and eigenvectors.</p>
<code>range</code>	<p>(global) Must be 'A' or 'V' or 'I'.</p> <p>If <code>range = 'A'</code>, the function computes all eigenvalues.</p> <p>If <code>range = 'V'</code>, the function computes eigenvalues in the interval: [<code>vl</code>, <code>vu</code>]</p> <p>If <code>range = 'I'</code>, the function computes eigenvalues with indices <code>il</code> through <code>iu</code>.</p>
<code>uplo</code>	<p>(global) Must be 'U' or 'L'.</p> <p>If <code>uplo = 'U'</code>, arrays <code>a</code> and <code>b</code> store the upper triangles of sub(<code>A</code>) and sub(<code>B</code>);</p> <p>If <code>uplo = 'L'</code>, arrays <code>a</code> and <code>b</code> store the lower triangles of sub(<code>A</code>) and sub(<code>B</code>).</p>
<code>n</code>	<p>(global)</p> <p>The order of the matrices sub(<code>A</code>) and sub(<code>B</code>) (<math>n \geq 0</math>).</p>
<code>a</code>	<p>(local)</p> <p>Pointer into the local memory to an array of size <code>lld_a*LOCc(ja+n-1)</code>. On entry, this array contains the local pieces of the <math>n</math>-by-<math>n</math> Hermitian distributed matrix sub(<code>A</code>). If <code>uplo = 'U'</code>, the leading <math>n</math>-by-<math>n</math> upper triangular part of sub(<code>A</code>) contains the upper triangular part of the matrix. If <code>uplo = 'L'</code>, the leading <math>n</math>-by-<math>n</math> lower triangular part of sub(<code>A</code>) contains the lower triangular part of the matrix.</p>
<code>ia, ja</code>	<p>(global)</p> <p>The row and column indices in the global matrix <code>A</code> indicating the first row and the first column of the submatrix <code>A</code>, respectively.</p>
<code>desca</code>	<p>(global and local) array of size <code>dlen_</code>.</p> <p>The array descriptor for the distributed matrix <code>A</code>. If <code>desca[ctxt_ - 1]</code> is incorrect, <code>p?hegvx</code> cannot guarantee correct error reporting.</p>
<code>b</code>	<p>(local).</p> <p>Pointer into the local memory to an array of size <code>lld_b*LOCc(jb+n-1)</code>. On entry, this array contains the local pieces of the <math>n</math>-by-<math>n</math> Hermitian distributed matrix sub(<code>B</code>).</p> <p>If <code>uplo = 'U'</code>, the leading <math>n</math>-by-<math>n</math> upper triangular part of sub(<code>B</code>) contains the upper triangular part of the matrix.</p> <p>If <code>uplo = 'L'</code>, the leading <math>n</math>-by-<math>n</math> lower triangular part of sub(<code>B</code>) contains the lower triangular part of the matrix.</p>
<code>ib, jb</code>	<p>(global)</p> <p>The row and column indices in the global matrix <code>B</code> indicating the first row and the first column of the submatrix <code>B</code>, respectively.</p>

<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B.descb[ctxt_ - 1]</i> must be equal to <i>desca[ctxt_ - 1]</i> .
<i>vl, vu</i>	(global) If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	(global) If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $il \geq 1, \min(il, n) \leq iu \leq n$ If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>abstol</i>	(global) If <i>jobz</i> ='V', setting <i>abstol</i> to <code>p?lamch(context, 'U')</code> yields the most orthogonal eigenvectors. The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + eps * \max( a ,  b )$ , where <i>eps</i> is the machine precision. If <i>abstol</i> is less than or equal to zero, then $eps * \text{norm}(\mathbb{T})$ will be used in its place, where $\text{norm}(\mathbb{T})$ is the 1-norm of the tridiagonal matrix obtained by reducing <i>A</i> to tridiagonal form. Eigenvalues will be computed most accurately when <i>abstol</i> is set to twice the underflow threshold $2 * p?lamch('S')$ not zero. If this function returns with $((\text{mod}(\text{info}, 2) \neq 0) .or. * (\text{mod}(\text{info}/8, 2) \neq 0))$ , indicating that some eigenvalues or eigenvectors did not converge, try setting <i>abstol</i> to $2 * p?lamch('S')$ .
<hr/>	
<b>NOTE</b> <i>mod(x, y)</i> is the integer remainder of <i>x/y</i> .	
<i>orfac</i>	(global). Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol = orfac * \text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see <i>lwork</i> ), <i>tol</i> may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if <i>orfac</i> equals zero. A default value of 1.0E-3 is used if <i>orfac</i> is negative. <i>orfac</i> should be identical on all processes.
<i>iz, jz</i>	(global) The row and column indices in the global matrix <i>Z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively.
<i>descz</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z.descz[ctxt_ - 1]</i> must equal <i>desca[ctxt_ - 1]</i> .

*work* (local)  
Workspace array of size *lwork*

*lwork* (local).  
The size of the array *work*.  
If only eigenvalues are requested:  
 $lwork \geq n + \max(NB * (np0 + 1), 3)$   
If eigenvectors are requested:  
 $lwork \geq n + (np0 + mq0 + NB) * NB$   
with  $nq0 = \text{numroc}(nn, NB, 0, 0, NPCOL)$ .  
For optimal performance, greater workspace is needed, that is  
 $lwork \geq \max(lwork, n, nhetrd\_lwopt, nhegst\_lwopt)$   
where *lwork* is as defined above, and  
 $nhetrd\_lwork = 2 * (anb + 1) * (4 * nps + 2) + (nps + 1) * nps$ ;  
 $nhegst\_lwopt = 2 * np0 * nb + nq0 * nb + nb * nb$   
 $nb = \text{desca}[mb\_ - 1]$   
 $np0 = \text{numroc}(n, nb, 0, 0, NPROW)$   
 $nq0 = \text{numroc}(n, nb, 0, 0, NPCOL)$   
 $ictxt = \text{desca}[ctxt\_ - 1]$   
 $anb = \text{pjlaenv}(ictxt, 3, 'p?hettrd', 'L', 0, 0, 0, 0)$   
 $sqnpc = \text{sqrt}(\text{dble}(NPROW * NPCOL))$   
 $nps = \max(\text{numroc}(n, 1, 0, 0, sqnpc), 2 * anb)$   
*numroc* is a ScaLAPACK tool functions;  
*pjlaenv* is a ScaLAPACK environmental inquiry function *MYROW*, *MYCOL*, *NPROW* and *NPCOL* can be determined by calling the function *blacs\_gridinfo*.  
If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by *pxerbla*.

*rwork* (local)  
Workspace array of size *lrwork*.

*lrwork* (local) The size of the array *rwork*.  
See below for definitions of variables used to define *lrwork*.  
If no eigenvectors are requested (*jobz* = 'N'), then  $lrwork \geq 5 * nn + 4 * n$   
If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:  
 $lrwork \geq 4 * n + \max(5 * nn, np0 * mq0) + \text{iceil}(neig, NPROW * NPCOL) * nn$

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following value to *lwork*:

$$(clustersize-1)*n,$$

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

$$\{w[k-1], \dots, w[k+clustersize-2] | w[j] \leq w[j-1] + orfac*2*norm(A)\}$$

Variable definitions:

*neig* = number of eigenvectors requested;

*nb* = *desca*[*mb\_* - 1] = *desca*[*nb\_* - 1] = *descz*[*mb\_* - 1] = *descz*[*nb\_* - 1];

*nn* = max(*n*, *nb*, 2);

*desca*[*rsrc\_* - 1] = *desca*[*nb\_* - 1] = *descz*[*rsrc\_* - 1] = *descz*[*csrc\_* - 1] = 0;

*np0* = numroc(*nn*, *nb*, 0, 0, NPROW);

*mq0* = numroc(max(*neig*, *nb*, 2), *nb*, 0, 0, NPCOL);

*iceil*(*x*, *y*) is a ScaLAPACK function returning ceiling(*x/y*).

When *lwork* is too small:

If *lwork* is too small to guarantee orthogonality, *p?hegvx* attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -25 is returned. Note that when *range*='V', *p?hegvx* does not know how many eigenvectors are requested until the eigenvalues are computed. Therefore, when *range*='V' and as long as *lwork* is large enough to allow *p?hegvx* to compute the eigenvalues, *p?hegvx* will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality & performance:

If  $clustersize > n/\sqrt{NPROW*NPCOL}$ , then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is,  $clustersize = n-1$ ) *p?stein* will perform no better than *?stein* on 1 processor.

For  $clustersize = n/\sqrt{NPROW*NPCOL}$  reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For  $clustersize > n/\sqrt{NPROW*NPCOL}$  execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `p?xerbla`.

$iwork$  (local) Workspace array.

$liwork$  (local) , size of  $iwork$ .

$liwork \geq 6 * nnp$

Where:  $nnp = \max(n, NPROW * NPCOL + 1, 4)$

If  $liwork = -1$ , then  $liwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?xerbla`.

## Output Parameters

$a$  On exit, if  $jobz = 'V'$ , then if  $info = 0$ ,  $sub(A)$  contains the distributed matrix  $Z$  of eigenvectors.

The eigenvectors are normalized as follows:

If  $ibtype = 1$  or  $2$ , then  $Z^H * sub(B) * Z = i$ ;

If  $ibtype = 3$ , then  $Z^H * inv(sub(B)) * Z = i$ .

If  $jobz = 'N'$ , then on exit the upper triangle (if  $uplo='U'$ ) or the lower triangle (if  $uplo='L'$ ) of  $sub(A)$ , including the diagonal, is destroyed.

$b$  On exit, if  $info \leq n$ , the part of  $sub(B)$  containing the matrix is overwritten by the triangular factor  $U$  or  $L$  from the Cholesky factorization  $sub(B) = U^H * U$ , or  $sub(B) = L * L^H$ .

$m$  (global) The total number of eigenvalues found,  $0 \leq m \leq n$ .

$nz$  (global) Total number of eigenvectors computed.  $0 < nz < m$ . The number of columns of  $z$  that are filled.

If  $jobz \neq 'V'$ ,  $nz$  is not referenced.

If  $jobz = 'V'$ ,  $nz = m$  unless the user supplies insufficient space and `p?hegvx` is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in  $z$  ( $m \leq descz[n_ - 1]$ ) and sufficient workspace to compute them. (See  $lwork$  below.) The function `p?hegvx` is always able to detect insufficient space without computation unless  $range = 'V'$ .

$w$  (global)

Array of size  $n$ . On normal exit, the first  $m$  entries contain the selected eigenvalues in ascending order.

$z$  (local).

global size  $n * n$ , local size  $lld\_z * LOCC(jz+n-1)$ .

If  $jobz = 'V'$ , then on normal exit the first  $m$  columns of  $z$  contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of  $z$  contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in  $ifail$ .

If  $jobz = 'N'$ , then  $z$  is not referenced.

*work*

On exit,  $work[0]$  returns the optimal amount of workspace.

*rwork*

On exit,  $rwork[0]$  contains the amount of workspace required for optimal efficiency

If  $jobz='N'$   $rwork[0]$  = optimal amount of workspace required to compute eigenvalues efficiently

If  $jobz='V'$   $rwork[0]$  = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.

If  $range='V'$ , it is assumed that all eigenvectors may be required when computing optimal workspace.

*ifail*

(global)

Array of size  $n$ .

*ifail* provides additional information when  $info \neq 0$

If  $(\text{mod}(\text{info}/16, 2) \neq 0)$ , then  $ifail[0]$  indicates the order of the smallest minor which is not positive definite.

If  $(\text{mod}(\text{info}, 2) \neq 0)$  on exit, then  $ifail[0]$  contains the indices of the eigenvectors that failed to converge.

If neither of the above error conditions are held, and  $jobz = 'V'$ , then the first  $m$  elements of *ifail* are set to zero.

*iclustr*

(global)

Array of size  $(2 * NPROW * NPCOL)$ . This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed  $iclustr(2 * i - 1)$  to  $iclustr(2 * i)$ , could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal.

*iclustr()* is a zero terminated array. ( $iclustr(2 * k) \neq 0$  and  $iclustr(2 * k + 1) = 0$ ) if and only if  $k$  is the number of clusters.

*iclustr* is not referenced if  $jobz = 'N'$ .

*gap*

(global)

Array of size  $NPROW * NPCOL$ .

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the  $i$ -th cluster may be as high as  $(C * n) / gap(i)$ , where  $C$  is a small constant.

*info* (global)

If  $info = 0$ , the execution is successful.

If  $info < 0$ : the  $i$ -th argument is an array and the  $j$ -entry had an illegal value, then  $info = -(i*100+j)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

If  $info > 0$ :

If  $(\text{mod}(info, 2) \neq 0)$ , then one or more eigenvectors failed to converge. Their indices are stored in *ifail*.

If  $(\text{mod}(info, 2, 2) \neq 0)$ , then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If  $(\text{mod}(info/4, 2) \neq 0)$ , then space limit prevented `p?sygvx` from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If  $(\text{mod}(info/8, 2) \neq 0)$ , then `p?stebz` failed to compute eigenvalues.

If  $(\text{mod}(info/16, 2) \neq 0)$ , then *B* was not positive definite. *ifail(1)* indicates the order of the smallest minor which is not positive definite.

## ScaLAPACK Auxiliary Routines

### ScaLAPACK Auxiliary Routines

Routine Name	Data Types	Description
<code>p?lacgv</code>	<i>c, z</i>	Conjugates a complex vector.
<code>p?max1</code>	<i>c, z</i>	Finds the index of the element whose real part has maximum absolute value (similar to the Level 1 PBLAS <code>p?amax</code> , but using the absolute value to the real part).
<code>pmpcol</code>	<i>s, d</i>	<i>Finds the collaborators of a process.</i>
<code>pmpim2</code>	<i>s, d</i>	Computes the eigenpair range assignments for all processes.
<code>?combamax1</code>	<i>c, z</i>	Finds the element with maximum real part absolute value and its corresponding global index.
<code>p?sum1</code>	<i>sc, dz</i>	Forms the 1-norm of a complex vector similar to Level 1 PBLAS <code>p?asum</code> , but using the true absolute value.
<code>p?dbtrsv</code>	<i>s, d, c, z</i>	Computes an <i>LU</i> factorization of a general tridiagonal matrix with no pivoting. The routine is called by <code>p?dbtrs</code> .
<code>p?dttrsv</code>	<i>s, d, c, z</i>	Computes an <i>LU</i> factorization of a general band matrix, using partial pivoting with row interchanges. The routine is called by <code>p?dttrs</code> .
<code>p?gebal</code>	<i>s, d</i>	Balances a general real/complex matrix.

Routine Name	Data Types	Description
<a href="#">p?gebd2</a>	<i>s, d, c, z</i>	Reduces a general rectangular matrix to real bidiagonal form by an orthogonal/unitary transformation (unblocked algorithm).
<a href="#">p?gehd2</a>	<i>s, d, c, z</i>	Reduces a general matrix to upper Hessenberg form by an orthogonal/unitary similarity transformation (unblocked algorithm).
<a href="#">p?gelq2</a>	<i>s, d, c, z</i>	Computes an <i>LQ</i> factorization of a general rectangular matrix (unblocked algorithm).
<a href="#">p?geql2</a>	<i>s, d, c, z</i>	Computes a <i>QL</i> factorization of a general rectangular matrix (unblocked algorithm).
<a href="#">p?geqr2</a>	<i>s, d, c, z</i>	Computes a <i>QR</i> factorization of a general rectangular matrix (unblocked algorithm).
<a href="#">p?gerq2</a>	<i>s, d, c, z</i>	Computes an <i>RQ</i> factorization of a general rectangular matrix (unblocked algorithm).
<a href="#">p?getf2</a>	<i>s, d, c, z</i>	Computes an <i>LU</i> factorization of a general matrix, using partial pivoting with row interchanges (local blocked algorithm).
<a href="#">p?labrd</a>	<i>s, d, c, z</i>	Reduces the first <i>nb</i> rows and columns of a general rectangular matrix <i>A</i> to real bidiagonal form by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of <i>A</i> .
<a href="#">p?lacon</a>	<i>s, d, c, z</i>	Estimates the 1-norm of a square matrix, using the reverse communication for evaluating matrix-vector products.
<a href="#">p?laconsb</a>	<i>s, d</i>	Looks for two consecutive small subdiagonal elements.
<a href="#">p?lACP2</a>	<i>s, d, c, z</i>	Copies all or part of a distributed matrix to another distributed matrix.
<a href="#">p?lACP3</a>	<i>s, d</i>	Copies from a global parallel array into a local replicated array or vice versa.
<a href="#">p?lACPY</a>	<i>s, d, c, z</i>	Copies all or part of one two-dimensional array to another.
<a href="#">p?laevswp</a>	<i>s, d, c, z</i>	Moves the eigenvectors from where they are computed to ScaLAPACK standard block cyclic array.
<a href="#">p?lahrd</a>	<i>s, d, c, z</i>	Reduces the first <i>nb</i> columns of a general rectangular matrix <i>A</i> so that elements below the $k^{th}$ subdiagonal are zero, by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of <i>A</i> .
<a href="#">p?laiect</a>	<i>s, d, c, z</i>	Exploits IEEE arithmetic to accelerate the computations of eigenvalues.
<a href="#">p?lamve</a>	<i>s, d</i>	Copies all or part of one two-dimensional distributed array to another.
<a href="#">p?lange</a>	<i>s, d, c, z</i>	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a general rectangular matrix.
<a href="#">p?lanhs</a>	<i>s, d, c, z</i>	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of an upper Hessenberg matrix.

Routine Name	Data Types	Description
<code>p?lansy, p?lanhe</code>	<code>s, d, c, z/c, z</code>	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a real symmetric or complex Hermitian matrix.
<code>p?lantr</code>	<code>s, d, c, z</code>	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a triangular matrix.
<code>p?lapiv</code>	<code>s, d, c, z</code>	Applies a permutation matrix to a general distributed matrix, resulting in row or column pivoting.
<code>p?laqge</code>	<code>s, d, c, z</code>	Scales a general rectangular matrix, using row and column scaling factors computed by <code>p?geequ</code> .
<code>p?laqr0</code>	<code>s, d</code>	Computes the eigenvalues of a Hessenberg matrix and optionally returns the matrices from the Schur decomposition.
<code>p?laqr1</code>	<code>s, d</code>	Sets a scalar multiple of the first column of the product of a 2-by-2 or 3-by-3 matrix and specified shifts.
<code>p?laqr2</code>	<code>s, d</code>	Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).
<code>p?laqr3</code>	<code>s, d</code>	Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).
<code>p?laqr5</code>	<code>s, d</code>	Performs a single small-bulge multi-shift QR sweep.
<code>p?laqsy</code>	<code>s, d, c, z</code>	Scales a symmetric/Hermitian matrix, using scaling factors computed by <code>p?poequ</code> .
<code>p?lared1d</code>	<code>s, d</code>	Redistributes an array assuming that the input array <i>bycol</i> is distributed across rows and that all process columns contain the same copy of <i>bycol</i> .
<code>p?lared2d</code>	<code>s, d</code>	Redistributes an array assuming that the input array <i>byrow</i> is distributed across columns and that all process rows contain the same copy of <i>byrow</i> .
<code>p?larf</code>	<code>s, d, c, z</code>	Applies an elementary reflector to a general rectangular matrix.
<code>p?larfb</code>	<code>s, d, c, z</code>	Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.
<code>p?larfc</code>	<code>c, z</code>	Applies the conjugate transpose of an elementary reflector to a general matrix.
<code>p?larfg</code>	<code>s, d, c, z</code>	Generates an elementary reflector (Householder matrix).
<code>p?larft</code>	<code>s, d, c, z</code>	Forms the triangular vector <i>T</i> of a block reflector $H=I-VTV^H$
<code>p?larz</code>	<code>s, d, c, z</code>	Applies an elementary reflector as returned by <code>p?tzrzf</code> to a general matrix.
<code>p?larzb</code>	<code>s, d, c, z</code>	Applies a block reflector or its transpose/conjugate-transpose as returned by <code>p?tzrzf</code> to a general matrix.

Routine Name	Data Types	Description
<a href="#">p?larzc</a>	<i>c, z</i>	Applies (multiplies by) the conjugate transpose of an elementary reflector as returned by <a href="#">p?tzrzf</a> to a general matrix.
<a href="#">p?larzt</a>	<i>s, d, c, z</i>	Forms the triangular factor $T$ of a block reflector $H=I-VTV^H$ as returned by <a href="#">p?tzrzf</a> .
<a href="#">p?lascl</a>	<i>s, d, c, z</i>	Multiplies a general rectangular matrix by a real scalar defined as $C_{to}/C_{from}$ .
<a href="#">p?laset</a>	<i>s, d, c, z</i>	Initializes the off-diagonal elements of a matrix to $\alpha$ and the diagonal elements to $\beta$ .
<a href="#">p?lasmsub</a>	<i>s, d</i>	Looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero.
<a href="#">p?lassq</a>	<i>s, d, c, z</i>	Updates a sum of squares represented in scaled form.
<a href="#">p?laswp</a>	<i>s, d, c, z</i>	Performs a series of row interchanges on a general rectangular matrix.
<a href="#">p?latra</a>	<i>s, d, c, z</i>	Computes the trace of a general square distributed matrix.
<a href="#">p?latrd</a>	<i>s, d, c, z</i>	Reduces the first $nb$ rows and columns of a symmetric/Hermitian matrix $A$ to real tridiagonal form by an orthogonal/unitary similarity transformation.
<a href="#">p?latrz</a>	<i>s, d, c, z</i>	Reduces an upper trapezoidal matrix to upper triangular form by means of orthogonal/unitary transformations.
<a href="#">p?lauu2</a>	<i>s, d, c, z</i>	Computes the product $UU^H$ or $L^HL$ , where $U$ and $L$ are upper or lower triangular matrices (local unblocked algorithm).
<a href="#">p?lauum</a>	<i>s, d, c, z</i>	Computes the product $UU^H$ or $L^HL$ , where $U$ and $L$ are upper or lower triangular matrices.
<a href="#">p?lawil</a>	<i>s, d</i>	Forms the Wilkinson transform.
<a href="#">p?org21/p?ung21</a>	<i>s, d, c, z</i>	Generates all or part of the orthogonal/unitary matrix $Q$ from a $QL$ factorization determined by <a href="#">p?geqlf</a> (unblocked algorithm).
<a href="#">p?org2r/p?ung2r</a>	<i>s, d, c, z</i>	Generates all or part of the orthogonal/unitary matrix $Q$ from a $QR$ factorization determined by <a href="#">p?geqrf</a> (unblocked algorithm).
<a href="#">p?orgl2/p?ungl2</a>	<i>s, d, c, z</i>	Generates all or part of the orthogonal/unitary matrix $Q$ from an $LQ$ factorization determined by <a href="#">p?gelqf</a> (unblocked algorithm).
<a href="#">p?orgr2/p?ungr2</a>	<i>s, d, c, z</i>	Generates all or part of the orthogonal/unitary matrix $Q$ from an $RQ$ factorization determined by <a href="#">p?gerqf</a> (unblocked algorithm).
<a href="#">p?orm21/p?unm21</a>	<i>s, d, c, z</i>	Multiplies a general matrix by the orthogonal/unitary matrix from a $QL$ factorization determined by <a href="#">p?geqlf</a> (unblocked algorithm).
<a href="#">p?orm2r/p?unm2r</a>	<i>s, d, c, z</i>	Multiplies a general matrix by the orthogonal/unitary matrix from a $QR$ factorization determined by <a href="#">p?geqrf</a> (unblocked algorithm).
<a href="#">p?orml2/p?unml2</a>	<i>s, d, c, z</i>	Multiplies a general matrix by the orthogonal/unitary matrix from an $LQ$ factorization determined by <a href="#">p?gelqf</a> (unblocked algorithm).
<a href="#">p?ormr2/p?unmr2</a>	<i>s, d, c, z</i>	Multiplies a general matrix by the orthogonal/unitary matrix from an $RQ$ factorization determined by <a href="#">p?gerqf</a> (unblocked algorithm).

Routine Name	Data Types	Description
<code>p?pbtrsv</code>	<code>s, d, c, z</code>	Solves a single triangular linear system via <code>frontsolve</code> or <code>backsolve</code> where the triangular matrix is a factor of a banded matrix computed by <code>p?pbtrf</code> .
<code>p?pttrsv</code>	<code>s, d, c, z</code>	Solves a single triangular linear system via <code>frontsolve</code> or <code>backsolve</code> where the triangular matrix is a factor of a tridiagonal matrix computed by <code>p?pttrf</code> .
<code>p?potf2</code>	<code>s, d, c, z</code>	Computes the Cholesky factorization of a symmetric/Hermitian positive definite matrix (local unblocked algorithm).
<code>p?rot</code>	<code>s, d</code>	Applies a planar rotation to two distributed vectors.
<code>p?rscl</code>	<code>s, d, cs, zd</code>	Multiplies a vector by the reciprocal of a real scalar.
<code>p?sygs2/p?hegs2</code>	<code>s, d, c, z</code>	Reduces a symmetric/Hermitian positive-definite generalized eigenproblem to standard form, using the factorization results obtained from <code>p?potrf</code> (local unblocked algorithm).
<code>p?sytd2/p?hetd2</code>	<code>s, d, c, z</code>	Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (local unblocked algorithm).
<code>p?trord</code>	<code>s, d</code>	Reorders the Schur factorization of a general matrix.
<code>p?trsen</code>	<code>s, d</code>	Reorders the Schur factorization of a matrix and (optionally) computes the reciprocal condition numbers and invariant subspace for the selected cluster of eigenvalues.
<code>p?trti2</code>	<code>s, d, c, z</code>	Computes the inverse of a triangular matrix (local unblocked algorithm).
<code>?lamsh</code>	<code>s, d</code>	Sends multiple shifts through a small (single node) matrix to maximize the number of bulges that can be sent through.
<code>?laqr6</code>	<code>s, d</code>	Performs a single small-bulge multi-shift QR sweep collecting the transformations.
<code>?lar1va</code>	<code>s, d</code>	<i>Computes scaled eigenvector corresponding to given eigenvalue.</i>
<code>?laref</code>	<code>s, d</code>	Applies Householder reflectors to matrices on either their rows or columns.
<code>?larrb2</code>	<code>s, d</code>	Provides limited bisection to locate eigenvalues for more accuracy.
<code>?larrd2</code>	<code>s, d</code>	Computes the eigenvalues of a symmetric tridiagonal matrix to suitable accuracy.
<code>?larre2</code>	<code>s, d</code>	Given a tridiagonal matrix, sets small off-diagonal elements to zero and for each unreduced block, finds base representations and eigenvalues.
<code>?larre2a</code>	<code>s, d</code>	<i>Given a tridiagonal matrix, sets small off-diagonal elements to zero and for each unreduced block, finds base representations and eigenvalues.</i>
<code>?larrf2</code>	<code>s, d</code>	Finds a new relatively robust representation such that at least one of the eigenvalues is relatively isolated.
<code>?larrv2</code>	<code>s, d</code>	Computes the eigenvectors of the tridiagonal matrix $T = L*D*L^T$ given $L$ , $D$ and the eigenvalues of $L*D*L^T$ .

Routine Name	Data Types	Description
<code>?lasorte</code>	<code>s, d</code>	Sorts eigenpairs by real and complex data types.
<code>?lasrt2</code>	<code>s, d</code>	Sorts numbers in increasing or decreasing order.
<code>?stegr2</code>	<code>s, d</code>	Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.
<code>?stegr2a</code>	<code>s, d</code>	Computes selected eigenvalues and initial representations needed for eigenvector computations.
<code>?stegr2b</code>	<code>s, d</code>	From eigenvalues and initial representations computes the selected eigenvalues and eigenvectors of the real symmetric tridiagonal matrix in parallel on multiple processors.
<code>?stein2</code>	<code>s, d</code>	Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix, using inverse iteration.
<code>?dbtff2</code>	<code>s, d, c, z</code>	Computes an <i>LU</i> factorization of a general band matrix with no pivoting (local unblocked algorithm).
<code>?dbtrf</code>	<code>s, d, c, z</code>	Computes an <i>LU</i> factorization of a general band matrix with no pivoting (local blocked algorithm).
<code>?dttrf</code>	<code>s, d, c, z</code>	Computes an <i>LU</i> factorization of a general tridiagonal matrix with no pivoting (local blocked algorithm).
<code>?dttrsv</code>	<code>s, d, c, z</code>	Solves a general tridiagonal system of linear equations using the <i>LU</i> factorization computed by <code>?dttrf</code> .
<code>?pttrsv</code>	<code>s, d, c, z</code>	Solves a symmetric (Hermitian) positive-definite tridiagonal system of linear equations, using the $LDL^H$ factorization computed by <code>?pttrf</code> .
<code>?stegr2</code>	<code>s, d</code>	Computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit <i>QL</i> or <i>QR</i> method.
<code>?trmvt</code>	<code>s, d, c, z</code>	Performs matrix-vector operations.
<code>pilaenv</code>	NA	Returns the positive integer value of the logical blocking size.
<code>pilaenvx</code>	NA	Called from the ScaLAPACK routines to choose problem-dependent parameters for the local environment.
<code>pjlaenv</code>	NA	Called from the ScaLAPACK symmetric and Hermitian tailored eigen-routines to choose problem-dependent parameters for the local environment.

Notice revision #20201201

### `p?lacgv`

*Conjugates a complex vector.*

## Syntax

```
void p?lacgv (MKL_INT *n , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
```

```
void pzlacgv (MKL_INT *n , MKL_Complex16 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?lacgv` function conjugates a complex vector  $\text{sub}(X)$  of length  $n$ , where  $\text{sub}(X)$  denotes  $X(ix, jx:jx+n-1)$  if  $incx = m_x$ , and  $X(ix:ix+n-1, jx)$  if  $incx = 1$ .

## Input Parameters

$n$	(global) The length of the distributed vector $\text{sub}(X)$ .
$x$	(local). Pointer into the local memory to an array of size $lld_x * LOCc(n_x)$ . On entry the vector to be conjugated $x[i] = X(ix+(jx-1)*m_x+i*incx)$ , $0 \leq i < n$ .
$ix$	(global) The row index in the global matrix $X$ indicating the first row of $\text{sub}(X)$ .
$jx$	(global) The column index in the global matrix $X$ indicating the first column of $\text{sub}(X)$ .
$descx$	(global and local) Array of size $dlen_ = 9$ . The array descriptor for the distributed matrix $X$ .
$incx$	(global) The global increment for the elements of $X$ . Only two values of $incx$ are supported in this version, namely 1 and $m_x$ . $incx$ must not be zero.

## Output Parameters

$x$	(local). On exit, the local pieces of conjugated distributed vector $\text{sub}(X)$ .
-----	--

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## p?max1

*Finds the index of the element whose real part has maximum absolute value (similar to the Level 1 PBLAS `p?amax`, but using the absolute value to the real part).*

## Syntax

```
void p?max1 (MKL_INT *n , MKL_Complex8 *amax , MKL_INT *indx , MKL_Complex8 *x ,
MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx );
```

```
void pzmax1 (MKL_INT *n , MKL_Complex16 *amax , MKL_INT *indx , MKL_Complex16 *x ,
MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?max1` function computes the global index of the maximum element in absolute value of a distributed vector  $\text{sub}(X)$ . The global index is returned in `indx` and the value is returned in `amax`, where  $\text{sub}(X)$  denotes  $X(ix:ix+n-1, jx)$  if `incx = 1`,  $X(ix, jx:jx+n-1)$  if `incx = m_x`.

## Input Parameters

<code>n</code>	(global). The number of components of the distributed vector $\text{sub}(X)$ . $n \geq 0$ .
<code>x</code>	(local) Pointer into the local memory to an array of size <code>lld_x * LOCc(jx+n-1)</code> . On entry this array contains the local pieces of the distributed vector $\text{sub}(X)$ .
<code>ix</code>	(global) The row index in the global matrix $X$ indicating the first row of $\text{sub}(X)$ .
<code>jx</code>	(global) The column index in the global matrix $X$ indicating the first column of $\text{sub}(X)$ .
<code>descx</code>	(global and local) Array of size <code>dlen_</code> . The array descriptor for the distributed matrix $X$ .
<code>incx</code>	(global). The global increment for the elements of $X$ . Only two values of <code>incx</code> are supported in this version, namely 1 and <code>m_x</code> . <code>incx</code> must not be zero.

## Output Parameters

<code>amax</code>	(global output). The absolute value of the largest entry of the distributed vector $\text{sub}(X)$ only in the scope of $\text{sub}(X)$ .
<code>indx</code>	(global output). The global index of the element of the distributed vector $\text{sub}(X)$ whose real part has maximum absolute value.

## `pilaver`

*Returns the ScaLAPACK version.*

## Syntax

```
void pilaver (MKL_INT* vers_major, MKL_INT* vers_minor, MKL_INT* vers_patch);
```

## Include Files

- `mkl_scalapack.h`

## Description

This function returns the ScaLAPACK version.

## Output Parameters

<code>vers_major</code>	Return the ScaLAPACK major version.
-------------------------	-------------------------------------

*vers\_minor* Return the ScaLAPACK minor version from the major version.

*vers\_patch* Return the ScaLAPACK patch version from the minor version.

## pmpcol

*Finds the collaborators of a process.*

### Syntax

```
void pmpcol(MKL_INT* myproc, MKL_INT* nprocs, MKL_INT* iil, MKL_INT* needil, MKL_INT*
neediu, MKL_INT* pmyils, MKL_INT* pmyius, MKL_INT* colbrt, MKL_INT* frstcl, MKL_INT*
lastcl);
```

### Include Files

- mkl\_scalapack.h

### Description

Using the output from [pmpim2](#) and given the information on eigenvalue clusters, `pmpcol` finds the collaborators of *myproc*.

#### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

### Input Parameters

*myproc* The processor number,  $0 \leq myproc < nprocs$ .

*nprocs* The total number of processors available.

*iil* The index of the leftmost eigenvalue in the eigenvalue cluster.

*needil* The leftmost position in the eigenvalue cluster needed by *myproc*.

*neediu* The rightmost position in the eigenvalue cluster needed by *myproc*.

*pmyils* array  
For each processor  $p$ ,  $0 < p \leq nprocs$ , *pmyils*[ $p-1$ ] is the index of the first eigenvalue in the eigenvalue cluster to be computed.  
*pmyils*[ $p-1$ ] equals zero if  $p$  stays idle.

*pmyius* array  
For each processor  $p$ , *pmyius*[ $p-1$ ] is the index of the last eigenvalue in the eigenvalue cluster to be computed.  
*pmyius*[ $p-1$ ] equals zero if  $p$  stays idle.

### OUTPUT Parameters

*colbrt* Non-zero if *myproc* collaborates.

*frstcl, lastcl* First and last collaborator of *myproc*.

## ?combamax1

*Finds the element with maximum real part absolute value and its corresponding global index.*

### Syntax

```
void ccombamax1 (MKL_Complex8 *v1 , MKL_Complex8 *v2 );
void zcombamax1 (MKL_Complex16 *v1 , MKL_Complex16 *v2 );
```

### Include Files

- mkl\_scalapack.h

### Description

The ?combamax1 function finds the element having maximum real part absolute value as well as its corresponding global index.

### Input Parameters

v1	(local) Array of size 2. The first maximum absolute value element and its global index. v1[0]=amax, v1[1]=indx.
v2	(local) Array of size 2. The second maximum absolute value element and its global index. v2[0]=amax, v2[1]=indx.

### Output Parameters

v1	(local). The first maximum absolute value element and its global index. v1[0]=amax, v1[1]=indx.
----	---

### See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## p?sum1

*Forms the 1-norm of a complex vector similar to Level 1 PBLAS p?asum, but using the true absolute value.*

### Syntax

```
void pscsum1 (MKL_INT *n , float *asum , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
void pdzsum1 (MKL_INT *n , double *asum , MKL_Complex16 *x , MKL_INT *ix , MKL_INT
*jx , MKL_INT *descx , MKL_INT *incx );
```

### Include Files

- mkl\_scalapack.h

### Description

The p?sum1 function returns the sum of absolute values of a complex distributed vector sub(x) in *asum*, where sub(x) denotes  $X(ix:ix+n-1, jx:jx)$ , if  $incx = 1$ ,  $X(ix:ix, jx:jx+n-1)$ , if  $incx = m_x$ .

Based on `p?asum` from the Level 1 PBLAS. The change is to use the 'genuine' absolute value.

## Input Parameters

<code>n</code>	(global). The number of components of the distributed vector <code>sub(x)</code> . $n \geq 0$ .
<code>x</code>	(local ) Pointer into the local memory to an array of size <code>lld_x * LOCC(jx+n-1)</code> . This array contains the local pieces of the distributed vector <code>sub(X)</code> .
<code>ix</code>	(global) The row index in the global matrix <code>X</code> indicating the first row of <code>sub(X)</code> .
<code>jx</code>	(global) The column index in the global matrix <code>X</code> indicating the first column of <code>sub(X)</code>
<code>descx</code>	(local) Array of size <code>dlen_=9</code> . The array descriptor for the distributed matrix <code>X</code> .
<code>incx</code>	(global) The global increment for the elements of <code>X</code> . Only two values of <code>incx</code> are supported in this version, namely 1 and <code>m_x</code> .

## Output Parameters

<code>asum</code>	(local) The sum of absolute values of the distributed vector <code>sub(X)</code> only in its scope.
-------------------	--

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## `p?dbtrsv`

*Computes an LU factorization of a general triangular matrix with no pivoting. The function is called by `p?dbtrs`.*

## Syntax

```
void psdbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , float *a , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib ,
MKL_INT *descb , float *af , MKL_INT *laf , float *work , MKL_INT *lwork , MKL_INT
*info );

void pddbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , double *a , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib ,
MKL_INT *descb , double *af , MKL_INT *laf , double *work , MKL_INT *lwork , MKL_INT
*info );

void pcdbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , MKL_Complex8 *a , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b ,
MKL_INT *ib , MKL_INT *descb , MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8 *work ,
MKL_INT *lwork , MKL_INT *info );

void pzdbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , MKL_Complex16 *a , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b ,
MKL_INT *ib , MKL_INT *descb , MKL_Complex16 *af , MKL_INT *laf , MKL_Complex16 *work ,
MKL_INT *lwork , MKL_INT *info );
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?dbtrsv` function solves a banded triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs) \text{ or}$$

$$A(1:n, ja:ja+n-1)^T * X = B(ib:ib+n-1, 1:nrhs) \text{ (for real flavors); } A(1:n, ja:ja+n-1)^H * X = B(ib:ib+n-1, 1:nrhs) \text{ (for complex flavors),}$$

where  $A(1:n, ja:ja+n-1)$  is a banded triangular matrix factor produced by the Gaussian elimination code of `p?dbtrf` and is stored in  $A(1:n, ja:ja+n-1)$  and  $af$ . The matrix stored in  $A(1:n, ja:ja+n-1)$  is either upper or lower triangular according to `uplo`, and the choice of solving  $A(1:n, ja:ja+n-1)$  or  $A(1:n, ja:ja+n-1)^T$  is dictated by the user by the parameter `trans`.

The function `p?dbtrf` must be called first.

## Input Parameters

<code>uplo</code>	(global) If <code>uplo = 'U'</code> , the upper triangle of $A(1:n, ja:ja+n-1)$ is stored, if <code>uplo = 'L'</code> , the lower triangle of $A(1:n, ja:ja+n-1)$ is stored.
<code>trans</code>	(global) If <code>trans = 'N'</code> , solve with $A(1:n, ja:ja+n-1)$ , if <code>trans = 'C'</code> , solve with conjugate transpose $A(1:n, ja:ja+n-1)$ .
<code>n</code>	(global) The order of the distributed submatrix $A$ ; ( $n \geq 0$ ).
<code>bwl</code>	(global) Number of subdiagonals. $0 \leq bwl \leq n-1$ .
<code>bwu</code>	(global) Number of subdiagonals. $0 \leq bwu \leq n-1$ .
<code>nrhs</code>	(global) The number of right-hand sides; the number of columns of the distributed submatrix $B$ ( $nrhs \geq 0$ ).
<code>a</code>	(local). Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ , where $lld\_a \geq (bwl+bwu+1)$ . On entry, this array contains the local pieces of the $n$ -by- $n$ unsymmetric banded distributed Cholesky factor $L$ or $L^T$ , represented in global $A$ as $A(1:n, ja:ja+n-1)$ . This local portion is stored in the packed banded format used in LAPACK. See the <i>Application Notes</i> below and the ScaLAPACK manual for more detail on the format of distributed matrices.
<code>ja</code>	(global) The index in the global matrix $A$ that points to the start of the matrix to be operated on (which may be either all of $A$ or a submatrix of $A$ ).
<code>desca</code>	(global and local) array of size $dlen\_$ . if 1d type ( $dtype\_a = 501$ or $502$ ), $dlen \geq 7$ ; if 2d type ( $dtype\_a = 1$ ), $dlen \geq 9$ . The array descriptor for the distributed matrix $A$ . Contains information of mapping of $A$ to memory.

<i>b</i>	(local) Pointer into the local memory to an array of local lead dimension $lld\_b \geq nb$ . On entry, this array contains the local pieces of the right-hand sides $B(ib:ib+n-1, 1:nrhs)$ .
<i>ib</i>	(global) The row index in the global matrix $B$ that points to the first row of the matrix to be operated on (which may be either all of $B$ or a submatrix of $B$ ).
<i>descb</i>	(global and local) array of size <i>dlen_</i> . if 1d type ( <i>dtype_b</i> = 502), <i>dlen</i> ≥ 7; if 2d type ( <i>dtype_b</i> = 1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix $B$ . Contains information of mapping $B$ to memory.
<i>laf</i>	(local) Size of user-input auxiliary fill-in space <i>af</i> . $laf \geq nb * (bwl + bwu) + 6 * \max(bwl, bwu) * \max(bwl, bwu)$ . If <i>laf</i> is not large enough, an error code is returned and the minimum acceptable size will be returned in <i>af</i> [0].
<i>work</i>	(local). Temporary workspace. This space may be overwritten in between function calls. <i>work</i> must be the size given in <i>lwork</i> .
<i>lwork</i>	(local or global) Size of user-input workspace <i>work</i> . If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i> [0] and an error code is returned. $lwork \geq \max(bwl, bwu) * nrhs$ .

## Output Parameters

<i>a</i>	(local). This local portion is stored in the packed banded format used in LAPACK. Please see the ScaLAPACK manual for more detail on the format of distributed matrices.
<i>b</i>	On exit, this contains the local piece of the solutions distributed matrix $X$ .
<i>af</i>	(local). auxiliary fill-in space. The fill-in space is created in a call to the factorization function <code>p?dbtrf</code> and is stored in <i>af</i> . If a linear system is to be solved using <code>p?dbtrf</code> after the factorization function, <i>af</i> must not be altered after the factorization.
<i>work</i>	On exit, <i>work</i> [0] contains the minimal <i>lwork</i> .
<i>info</i>	(local). If <i>info</i> = 0, the execution is successful.

< 0: If the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j-1$ , had an illegal value, then  $info = -(i*100+j)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

## p?dttrs

Computes an LU factorization of a general band matrix, using partial pivoting with row interchanges.

The function is called by p?dttrs.

## Syntax

```
void psdttrs (char *uplo, char *trans, MKL_INT *n, MKL_INT *nrhs, float *dl, float *d, float *du, MKL_INT *ja, MKL_INT *desca, float *b, MKL_INT *ib, MKL_INT *descb, float *af, MKL_INT *laf, float *work, MKL_INT *lwork, MKL_INT *info);
void pddttrs (char *uplo, char *trans, MKL_INT *n, MKL_INT *nrhs, double *dl, double *d, double *du, MKL_INT *ja, MKL_INT *desca, double *b, MKL_INT *ib, MKL_INT *descb, double *af, MKL_INT *laf, double *work, MKL_INT *lwork, MKL_INT *info);
void pcdttrs (char *uplo, char *trans, MKL_INT *n, MKL_INT *nrhs, MKL_Complex8 *dl, MKL_Complex8 *d, MKL_Complex8 *du, MKL_INT *ja, MKL_INT *desca, MKL_Complex8 *b, MKL_INT *ib, MKL_INT *descb, MKL_Complex8 *af, MKL_INT *laf, MKL_Complex8 *work, MKL_INT *lwork, MKL_INT *info);
void pzdtttrs (char *uplo, char *trans, MKL_INT *n, MKL_INT *nrhs, MKL_Complex16 *dl, MKL_Complex16 *d, MKL_Complex16 *du, MKL_INT *ja, MKL_INT *desca, MKL_Complex16 *b, MKL_INT *ib, MKL_INT *descb, MKL_Complex16 *af, MKL_INT *laf, MKL_Complex16 *work, MKL_INT *lwork, MKL_INT *info);
```

## Include Files

- mkl\_scalapack.h

## Description

The p?dttrs function solves a tridiagonal triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs) \text{ or}$$

$$A(1:n, ja:ja+n-1)^T * X = B(ib:ib+n-1, 1:nrhs) \text{ for real flavors; } A(1:n, ja:ja+n-1)^H * X = B(ib:ib+n-1, 1:nrhs) \text{ for complex flavors,}$$

where  $A(1:n, ja:ja+n-1)$  is a tridiagonal matrix factor produced by the Gaussian elimination code of p?dttrf and is stored in  $A(1:n, ja:ja+n-1)$  and  $af$ .

The matrix stored in  $A(1:n, ja:ja+n-1)$  is either upper or lower triangular according to  $uplo$ , and the choice of solving  $A(1:n, ja:ja+n-1)$  or  $A(1:n, ja:ja+n-1)^T$  is dictated by the user by the parameter  $trans$ .

The function p?dttrf must be called first.

## Input Parameters

$uplo$  (global)  
If  $uplo='U'$ , the upper triangle of  $A(1:n, ja:ja+n-1)$  is stored,

	if <i>uplo</i> = 'L', the lower triangle of $A(1:n, ja:ja+n-1)$ is stored.
<i>trans</i>	(global) If <i>trans</i> = 'N', solve with $A(1:n, ja:ja+n-1)$ , if <i>trans</i> = 'C', solve with conjugate transpose $A(1:n, ja:ja+n-1)$ .
<i>n</i>	(global) The order of the distributed submatrix $A$ ; ( $n \geq 0$ ).
<i>nrhs</i>	(global) The number of right-hand sides; the number of columns of the distributed submatrix $B(ib:ib+n-1, 1:nrhs)$ . ( $nrhs \geq 0$ ).
<i>dl</i>	(local). Pointer to local part of global vector storing the lower diagonal of the matrix. Globally, <i>dl</i> [0] is not referenced, and <i>dl</i> must be aligned with <i>d</i> . Must be of size $\geq nb\_a$ .
<i>d</i>	(local). Pointer to local part of global vector storing the main diagonal of the matrix.
<i>du</i>	(local). Pointer to local part of global vector storing the upper diagonal of the matrix. Globally, <i>du</i> [ <i>n</i> -1] is not referenced, and <i>du</i> must be aligned with <i>d</i> .
<i>ja</i>	(global) The index in the global matrix $A$ that points to the start of the matrix to be operated on (which may be either all of $A$ or a submatrix of $A$ ).
<i>desca</i>	(global and local) array of size <i>dlen_</i> . if 1 <i>d</i> type ( <i>dtype_a</i> = 501 or 502), <i>dlen</i> $\geq$ 7; if 2 <i>d</i> type ( <i>dtype_a</i> = 1), <i>dlen</i> $\geq$ 9. The array descriptor for the distributed matrix $A$ . Contains information of mapping of $A$ to memory.
<i>b</i>	(local) Pointer into the local memory to an array of local lead dimension $lld\_b \geq nb$ . On entry, this array contains the local pieces of the right-hand sides $B(ib:ib+n-1, 1:nrhs)$ .
<i>ib</i>	(global) The row index in the global matrix $B$ that points to the first row of the matrix to be operated on (which may be either all of $B$ or a submatrix of $B$ ).
<i>descb</i>	(global and local) array of size <i>dlen_</i> . if 1 <i>d</i> type ( <i>dtype_b</i> = 502), <i>dlen</i> $\geq$ 7; if 2 <i>d</i> type ( <i>dtype_b</i> = 1), <i>dlen</i> $\geq$ 9. The array descriptor for the distributed matrix $B$ . Contains information of mapping $B$ to memory.
<i>laf</i>	(local).

Size of user-input auxiliary fill-in space *af*.

$laf \geq 2 * (nb+2)$ . If *laf* is not large enough, an error code is returned and the minimum acceptable size will be returned in *af*[0].

*work*

(local).

Temporary workspace. This space may be overwritten in between function calls.

*work* must be the size given in *lwork*.

*lwork*

(local or global)

Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*[0] and an error code is returned.

$lwork \geq 10 * npcol + 4 * nrhs$ .

## Output Parameters

*dl*

(local).

On exit, this array contains information containing the factors of the matrix.

*d*

On exit, this array contains information containing the factors of the matrix. Must be of size  $\geq nb\_a$ .

*b*

On exit, this contains the local piece of the solutions distributed matrix X.

*af*

(local).

Auxiliary fill-in space. The fill-in space is created in a call to the factorization function `p?dttrf` and is stored in *af*. If a linear system is to be solved using `p?dttrs` after the factorization function, *af* must not be altered after the factorization.

*work*

On exit, *work*[0] contains the minimal *lwork*.

*info*

(local).

If *info*=0, the execution is successful.

if *info*< 0: If the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value, then *info* = - (*i*\*100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

## `p?gebal`

Balances a general real/complex matrix.

## Syntax

```
void psgebal(char* job, MKL_INT* n, float* a, MKL_INT* desca, MKL_INT* ilo, MKL_INT*
ihi, float* scale, MKL_INT* info);
```

```
void pdgebal(char* job, MKL_INT* n, double* a, MKL_INT* desca, MKL_INT* ilo, MKL_INT*
ihi, double* scale, MKL_INT* info);
```

```
void pcgebal(char* job, MKL_INT* n, complex float* a, MKL_INT* desca, MKL_INT* ilo,
MKL_INT* ihi, float* scale, MKL_INT* info);
```

```
void pzgebal(char* job, MKL_INT* n, complex double* a, MKL_INT* desca, MKL_INT* ilo,
MKL_INT* ihi, double* scale, MKL_INT* info);
```

## Include Files

- mkl\_scalapack.h

## Description

`pzgebal` balances a general real/complex matrix  $A$ . This involves, first, permuting  $A$  by a similarity transformation to isolate eigenvalues in the first 1 to  $ilo-1$  and last  $ihi+1$  to  $n$  elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns  $ilo$  to  $ihi$  to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

## Input Parameters

<code>job</code>	(global ) Specifies the operations to be performed on $a$ : = 'N': none: simply set $ilo = 1$ , $ihi = n$ , $scale[i] = 1.0$ for $i = 0, \dots, n-1$ ; = 'P': permute only; = 'S': scale only; = 'B': both permute and scale.
<code>n</code>	(global ) The order of the matrix $A$ ( $n \geq 0$ ).
<code>a</code>	(local ) Pointer into the local memory to an array of size $lld_a * LOC_c(n)$ This array contains the local pieces of global input matrix $A$ .
<code>desca</code>	(global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $A$ .

## OUTPUT Parameters

<code>a</code>	On exit, $a$ is overwritten by the balanced matrix $A$ . If $job = 'N'$ , $a$ is not referenced. See Notes for further details.
<code>ilo, ihi</code>	(global ) $ilo$ and $ihi$ are set to integers such that on exit matrix elements $A(i,j)$ are zero if $i > j$ and $j = 1, \dots, ilo-1$ or $i = ihi+1, \dots, n$ . If $job = 'N'$ or 'S', $ilo = 1$ and $ihi = n$ .
<code>scale</code>	(global ) array of size $n$ . Details of the permutations and scaling factors applied to $a$ . If $p_j$ is the index of the row and column interchanged with row and column $j$ and $d_j$ is the scaling factor applied to row and column $j$ , then $scale[j-1] = p_j$ for $j = 1, \dots, ilo-1, ihi+1, \dots, n$

$scale[j-1] = dj$  for  $j = ilo, \dots, ihi$

The order in which the interchanges are made is  $n$  to  $ihi+1$ , then 1 to  $ilo-1$ .

*info*

(global )

= 0: successful exit.

< 0: if  $info = -i$ , the  $i$ -th argument had an illegal value.

## Application Notes

The permutations consist of row and column interchanges which put the matrix in the form

$$PAP = \begin{pmatrix} T_1 & X & Y \\ 0 & B & Z \\ 0 & 0 & T_2 \end{pmatrix}$$

where  $T_1$  and  $T_2$  are upper triangular matrices whose eigenvalues lie along the diagonal. The column indices  $ilo$  and  $ihi$  mark the starting and ending columns of the submatrix  $B$ . Balancing consists of applying a diagonal similarity transformation  $D^{-1}BD$  to make the 1-norms of each row of  $B$  and its corresponding column nearly equal. The output matrix is

$$\begin{pmatrix} T_1 & XD & Y \\ 0 & D^{-1}BD & D^{-1}Z \\ 0 & 0 & T_2 \end{pmatrix}$$

Information about the permutations  $P$  and the diagonal matrix  $D$  is returned in the vector *scale*.

void pzgebd2 (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *d , double *e , MKL_Complex16 *tauq , MKL_Complex16 *taup ,
MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

### Include Files

- mkl\_scalapack.h

### Description

The p?gebd2 function reduces a real/complex general  $m$ -by- $n$  distributed matrix  $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$  to upper or lower bidiagonal form  $B$  by an orthogonal/unitary transformation:

$$Q' \text{sub}(A) P = B.$$

If  $m \geq n$ ,  $B$  is the upper bidiagonal; if  $m < n$ ,  $B$  is the lower bidiagonal.

## Input Parameters

<i>m</i>	(global) The number of rows of the distributed matrix sub( <i>A</i> ). ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the distributed matrix sub( <i>A</i> ). ( $n \geq 0$ ).
<i>a</i>	(local). Pointer into the local memory to an array of size $lld\_a * LOC_c(ja+n-1)$ . On entry, this array contains the local pieces of the general distributed matrix sub( <i>A</i> ).
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix sub( <i>A</i> ), respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local). This is a workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork \geq \max(mpa0, nqa0)$ , where $nb = mb\_a = nb\_a$ , $irow = \text{mod}(ia-1, nb)$ , $iarow = \text{indxg2p}(ia, nb, myrow, rsrc\_a, nprow)$ , $iacol = \text{indxg2p}(ja, nb, mycol, csrc\_a, npcpl)$ , $mpa0 = \text{numroc}(m+irow, nb, myrow, iarow, nprow)$ , $nqa0 = \text{numroc}(n+icoffa, nb, mycol, iacol, npcpl)$ . <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; <i>myrow</i> , <i>mycol</i> , <i>nprow</i> , and <i>npcpl</i> can be determined by calling the function <i>blacs_gridinfo</i> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i> .

## Output Parameters

<i>a</i>	(local). On exit, if $m \geq n$ , the diagonal and the first superdiagonal of sub( <i>A</i> ) are overwritten with the upper bidiagonal matrix <i>B</i> ; the elements below the diagonal, with the array <i>tauq</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors, and the elements above the first superdiagonal, with the array <i>taup</i> , represent the orthogonal matrix <i>P</i> as a product of elementary reflectors. If $m < n$ , the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix <i>B</i> ; the elements below the first subdiagonal, with the array <i>tauq</i> , represent the
----------	--

orthogonal/unitary matrix  $Q$  as a product of elementary reflectors, and the elements above the diagonal, with the array  $taup$ , represent the orthogonal matrix  $P$  as a product of elementary reflectors. See *Applications Notes* below.

$d$	(local) Array of size $LOCc(ja+\min(m,n)-1)$ if $m \geq n$ ; $LOCr(ia+\min(m,n)-1)$ otherwise. The distributed diagonal elements of the bidiagonal matrix $B$ : $d[i] = A(i+1,i+1)$ , $i=0, 1, \dots, \text{size}(d) - 1$ . $d$ is tied to the distributed matrix $A$ .
$e$	(local) Array of size $LOCc(ja+\min(m,n)-1)$ if $m \geq n$ ; $LOCr(ia+\min(m,n)-2)$ otherwise. The distributed diagonal elements of the bidiagonal matrix $B$ : if $m \geq n$ , $e[i] = A(i+1,i+2)$ for $i = 0, 1, \dots, n-2$ ; if $m < n$ , $e[i] = A(i+2,i+1)$ for $i = 0, 1, \dots, m-2$ . $e$ is tied to the distributed matrix $A$ .
$tauq$	(local). Array of size $LOCc(ja+\min(m,n)-1)$ . The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix $Q$ . $tauq$ is tied to the distributed matrix $A$ .
$taup$	(local). Array of size $LOCr(ia+\min(m,n)-1)$ . The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix $P$ . $taup$ is tied to the distributed matrix $A$ .
$work$	On exit, $work[0]$ returns the minimal and optimal $lwork$ .
$info$	(local) If $info = 0$ , the execution is successful. if $info < 0$ : If the $i$ -th argument is an array and the $j$ -th entry, indexed $j-1$ , had an illegal value, then $info = -(i*100+j)$ , if the $i$ -th argument is a scalar and had an illegal value, then $info = -i$ .

## Application Notes

The matrices  $Q$  and  $P$  are represented as products of elementary reflectors:

If  $m \geq n$ ,

$$Q = H(1) * H(2) * \dots * H(n), \text{ and } P = G(1) * G(2) * \dots * G(n-1)$$

Each  $H(i)$  and  $G(i)$  has the form:

$$H(i) = I - tauq * v * v', \text{ and } G(i) = I - taup * u * u',$$

where  $tauq$  and  $taup$  are real/complex scalars, and  $v$  and  $u$  are real/complex vectors.  $v(1:i-1) = 0$ ,  $v(i) = 1$ , and  $v(i+1:m)$  is stored on exit in

$$A(ia+i-ia+m-1, ja+i-1);$$

$$u(1:i) = 0, u(i+1) = 1, \text{ and } u(i+2:n) \text{ is stored on exit in } A(ia+i-1, ja+i+1:ja+n-1);$$

*tauq* is stored in *tauq[ja+i-2]* and *taup* in *taup[ia+i-2]*.

If  $m < n$ ,

$v(1:i) = 0$ ,  $v(i+1) = 1$ , and  $v(i+2:m)$  is stored on exit in  $A(ia+i+1: ia+m-1, ja+i-1)$ ;

$u(1:i-1) = 0$ ,  $u(i) = 1$ , and  $u(i+1:n)$  is stored on exit in  $A(ia+i-1, ja+i:ja+n-1)$ ;

*tauq* is stored in *tauq[ja+i-2]* and *taup* in *taup[ia+i-2]*.

The contents of sub(A) on exit are illustrated by the following examples:

$m = 6$  and  $n = 5 (m > n)$  :

$$\begin{bmatrix} d & e & u1 & u1 & u1 \\ v1 & d & e & u2 & u2 \\ v1 & v2 & d & e & u3 \\ v1 & v2 & v3 & d & e \\ v1 & v2 & v3 & v4 & d \\ v1 & v2 & v3 & v4 & v5 \end{bmatrix}$$

$m = 5$  and  $n = 6 (m < n)$  :

$$\begin{bmatrix} d & u1 & u1 & u1 & u1 & u1 \\ e & d & u2 & u2 & u2 & u2 \\ v1 & e & d & u3 & u3 & u3 \\ v1 & v2 & e & d & u4 & u4 \\ v1 & v2 & v3 & e & d & u5 \end{bmatrix}$$

where *d* and *e* denote diagonal and off-diagonal elements of *B*, *vi* denotes an element of the vector defining  $H(i)$ , and *ui* an element of the vector defining  $G(i)$ .

*lwork , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?gehd2` function reduces a real/complex general distributed matrix  $\text{sub}(A)$  to upper Hessenberg form  $H$  by an orthogonal/unitary similarity transformation:  $Q^* \text{sub}(A) Q = H$ , where  $\text{sub}(A) = A(\text{ia}+n-1 : \text{ia}+n-1, \text{ja}+n-1 : \text{ja}+n-1)$ .

## Input Parameters

<code>n</code>	(global) The order of the distributed submatrix $A$ . ( $n \geq 0$ ).
<code>ilo, ihi</code>	(global) It is assumed that the matrix $\text{sub}(A)$ is already upper triangular in rows $\text{ia}:\text{ia}+\text{ilo}-2$ and $\text{ia}+\text{ihi}:\text{ia}+n-1$ and columns $\text{ja}:\text{ja}+\text{jlo}-2$ and $\text{ja}+\text{jhi}:\text{ja}+n-1$ . See <i>Application Notes</i> for further information. If $n \geq 0, 1 \leq \text{ilo} \leq \text{ihi} \leq n$ ; otherwise set $\text{ilo} = 1, \text{ihi} = n$ .
<code>a</code>	(local). Pointer into the local memory to an array of size $\text{lld}_a * \text{LOC}_c(\text{ja}+n-1)$ . On entry, this array contains the local pieces of the $n$ -by- $n$ general distributed matrix $\text{sub}(A)$ to be reduced.
<code>ia, ja</code>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of $\text{sub}(A)$ , respectively.
<code>desca</code>	(global and local) array of size $\text{dlen}_$ . The array descriptor for the distributed matrix $A$ .
<code>work</code>	(local). This is a workspace array of size $\text{lwork}$ .
<code>lwork</code>	(local or global) The size of the array $\text{work}$ . $\text{lwork}$ is local input and must be at least $\text{lwork} \geq \text{nb} + \max(\text{npa0}, \text{nb})$ , where $\text{nb} = \text{mb}_a = \text{nb}_a$ , $\text{irow} = \text{mod}(\text{ia}-1, \text{nb})$ , $\text{iarow} = \text{indxg2p}(\text{ia}, \text{nb}, \text{myrow}, \text{rsrc}_a, \text{nprow})$ , $\text{npa0} = \text{numroc}(\text{ihi} + \text{irow}, \text{nb}, \text{myrow}, \text{iarow}, \text{nprow})$ . $\text{indxg2p}$ and $\text{numroc}$ are ScaLAPACK tool functions; $\text{myrow}$ , $\text{mycol}$ , $\text{nprow}$ , and $\text{npcol}$ can be determined by calling the function <code>blacs_gridinfo</code> . If $\text{lwork} = -1$ , then $\text{lwork}$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> .

## Output Parameters

<code>a</code>	(local). On exit, the upper triangle and the first subdiagonal of $\text{sub}(A)$ are overwritten with the upper Hessenberg matrix $H$ , and the elements below the first subdiagonal, with the array $\text{tau}$ , represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors. (see <i>Application Notes</i> below).
<code>tau</code>	(local).

Array of size  $LOCc(ja+n-2)$  The scalar factors of the elementary reflectors (see *Application Notes* below). Elements  $ja:ja+ilo-2$  and  $ja+ihi:ja+n-2$  of the global vector  $\tau$  are set to zero.  $\tau$  is tied to the distributed matrix  $A$ .

*work*

On exit,  $work[0]$  returns the minimal and optimal  $lwork$ .

*info*

(local)

If  $info = 0$ , the execution is successful.

if  $info < 0$ : If the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j-1$ , had an illegal value, then  $info = -(i*100+j)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

## Application Notes

The matrix  $Q$  is represented as a product of  $(ihi-ilo)$  elementary reflectors

$$Q = H(ilo) * H(ilo+1) * \dots * H(ihi-1).$$

Each  $H(i)$  has the form

$$H(i) = I - \tau v v',$$

where  $\tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(1:i)=0$ ,  $v(i+1)=1$  and  $v(ihi+1:n)=0$ ;  $v(i+2:ihi)$  is stored on exit in  $A(ia+ilo+i:ia+ihi-1, ia+ilo+i-2)$ , and  $\tau$  in  $\tau[ja+ilo+i-3]$ .

The contents of  $A(ia:ia+n-1, ja:ja+n-1)$  are illustrated by the following example, with  $n = 7$ ,  $ilo = 2$  and  $ihi = 6$ :

on entry	on exit
$\begin{bmatrix} a & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & & a & a & a & a & a \\ & & & a & a & a & a \\ & & & & a & a & a \\ & & & & & a & a \\ & & & & & & a \end{bmatrix}$	$\begin{bmatrix} a & a & h & h & h & h & a \\ & a & h & h & h & h & a \\ & & h & h & h & h & h \\ & & v2 & h & h & h & h \\ & & v2 & v3 & h & h & h \\ & & v2 & v3 & v4 & h & h \\ & & & & & & a \end{bmatrix}$

where  $a$  denotes an element of the original matrix  $\text{sub}(A)$ ,  $h$  denotes a modified element of the upper Hessenberg matrix  $H$ , and  $v_i$  denotes an element of the vector defining  $H(ja+ilo+i-2)$ .

## Include Files

- mkl\_scalapack.h

## Description

The `p?gelq2` function computes an  $LQ$  factorization of a real/complex distributed  $m$ -by- $n$  matrix  $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1) = L*Q$ .

## Input Parameters

<code>m</code>	(global) The number of rows of the distributed matrix $\text{sub}(A)$ . ( $m \geq 0$ ).
<code>n</code>	(global) The number of columns of the distributed matrix $\text{sub}(A)$ . ( $n \geq 0$ ).
<code>a</code>	(local). Pointer into the local memory to an array of size <code>lld_a * LOCC(ja+n-1)</code> . On entry, this array contains the local pieces of the $m$ -by- $n$ distributed matrix $\text{sub}(A)$ which is to be factored.
<code>ia, ja</code>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of $\text{sub}(A)$ , respectively.
<code>desca</code>	(global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix $A$ .
<code>work</code>	(local). This is a workspace array of size <code>lwork</code> .
<code>lwork</code>	(local or global) The size of the array <code>work</code> . <code>lwork</code> is local input and must be at least <code>lwork ≥ nq0 + max( 1, mp0 )</code> , where <code>irow = indxcg2p(ia, mb_a, myrow, rsrc_a, nrow)</code> , <code>iacol = indxcg2p(ja, nb_a, mycol, csrc_a, ncol)</code> , <code>mp0 = numroc(m+irow, mb_a, myrow, irow, nrow)</code> ,

$nq0 = \text{numroc}(n+icoff, nb\_a, mycol, iacol, npc0l),$   
 $\text{indxg2p}$  and  $\text{numroc}$  are ScaLAPACK tool functions;  $myrow, mycol, nprow,$   
and  $npc0l$  can be determined by calling the function `blacs_gridinfo`.

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

$a$	(local).  On exit, the elements on and below the diagonal of $\text{sub}(A)$ contain the $m$ by $\min(m,n)$ lower trapezoidal matrix $L$ ( $L$ is lower triangular if $m \leq n$ ); the elements above the diagonal, with the array $\tau$ , represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors (see <i>Application Notes</i> below).
$\tau$	(local).  Array of size $LOCr(ia+\min(m, n)-1)$ . This array contains the scalar factors of the elementary reflectors. $\tau$ is tied to the distributed matrix $A$ .
$work$	On exit, $work[0]$ returns the minimal and optimal $lwork$ .
$info$	(local) If $info = 0$ , the execution is successful. if $info < 0$ : If the $i$ -th argument is an array and the $j$ -th entry, indexed $j-1$ , had an illegal value, then $info = -(i*100+j)$ , if the $i$ -th argument is a scalar and had an illegal value, then $info = -i$ .

## Application Notes

The matrix  $Q$  is represented as a product of elementary reflectors

$Q = H(ia+k-1) * H(ia+k-2) * \dots * H(ia)$  for real flavors,  $Q = (H(ia+k-1))^{H*} (H(ia+k-2))^{H*} \dots (H(ia))^{H*}$  for complex flavors,

where  $k = \min(m,n)$ .

Each  $H(i)$  has the form

$$H(i) = I - \tau * v * v'$$

where  $\tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(1: i-1) = 0$  and  $v(i) = 1$ ;  $v(i+1: n)$  (for real flavors) or  $\text{conjg}(v(i+1: n))$  (for complex flavors) is stored on exit in  $A(ia+i-1, ja+i: ja+n-1)$ , and  $\tau$  in  $\tau[ia+i-2]$ .

## Description

The `p?geql2` function computes a *QL* factorization of a real/complex distributed *m*-by-*n* matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q * L$ .

## Input Parameters

<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(A)$ . ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(A)$ . ( $n \geq 0$ ).
<i>a</i>	(local). Pointer into the local memory to an array of size $lld\_a * LOC_c(ja+n-1)$ . On entry, this array contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix $\text{sub}(A)$ which is to be factored.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local). This is a workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork \geq mp0 + \max(1, nq0)$ , where $iroff = \text{mod}(ia-1, mb\_a)$ , $icoff = \text{mod}(ja-1, nb\_a)$ , $iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprw)$ , $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npccl)$ , $mp0 = \text{numroc}(m+iroff, mb\_a, myrow, iarow, nprw)$ , $nq0 = \text{numroc}(n+icoff, nb\_a, mycol, iacol, npccl)$ , <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; <i>myrow</i> , <i>mycol</i> , <i>nprw</i> , and <i>npccl</i> can be determined by calling the function <code>blacs_gridinfo</code> .

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

$a$	(local). On exit, if $m \geq n$ , the lower triangle of the distributed submatrix $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the $n$ -by- $n$ lower triangular matrix $L$ ; if $m \leq n$ , the elements on and below the $(n-m)$ -th superdiagonal contain the $m$ -by- $n$ lower trapezoidal matrix $L$ ; the remaining elements, with the array $tau$ , represent the orthogonal/ unitary matrix $Q$ as a product of elementary reflectors (see <i>Application Notes</i> below).
$tau$	(local). Array of size $LOCc(ja+n-1)$ . This array contains the scalar factors of the elementary reflectors. $tau$ is tied to the distributed matrix $A$ .
$work$	On exit, $work[0]$ returns the minimal and optimal $lwork$ .
$info$	(local). If $info = 0$ , the execution is successful. if $info < 0$ : If the $i$ -th argument is an array and the $j$ -th entry, indexed $j-1$ , had an illegal value, then $info = -(i*100+j)$ , if the $i$ -th argument is a scalar and had an illegal value, then $info = -i$ .

## Application Notes

The matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(ja+k-1) * \dots * H(ja+1) * H(ja), \text{ where } k = \min(m, n).$$

Each  $H(i)$  has the form

$$H(i) = I - tau * v * v'$$

where  $tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(m-k+i+1:m) = 0$  and  $v(m-k+i) = 1$ ;  $v(1:m-k+i-1)$  is stored on exit in  $A(ia:ia+m-k+i-2, ja+n-k+i-1)$ , and  $tau$  in  $tau[ja+n-k+i-2]$ .

## Description

The `p?geqr2` function computes a  $QR$  factorization of a real/complex distributed  $m$ -by- $n$  matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q^*R$ .

## Input Parameters

<code>m</code>	(global) The number of rows in the distributed matrix $\text{sub}(A)$ . ( $m \geq 0$ ).
<code>n</code>	(global) The number of columns in the distributed matrix $\text{sub}(A)$ . ( $n \geq 0$ ).
<code>a</code>	(local). Pointer into the local memory to an array of size $lld\_a * LOC_c(ja+n-1)$ . On entry, this array contains the local pieces of the $m$ -by- $n$ distributed matrix $\text{sub}(A)$ which is to be factored.
<code>ia, ja</code>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of $\text{sub}(A)$ , respectively.
<code>desca</code>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
<code>work</code>	(local). This is a workspace array of size $lwork$ .
<code>lwork</code>	(local or global) The size of the array <code>work</code> . <code>lwork</code> is local input and must be at least $lwork \geq mp0 + \max(1, nq0)$ , where $irow = \text{mod}(ia-1, mb\_a)$ , $icoff = \text{mod}(ja-1, nb\_a)$ , $iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow)$ , $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcot)$ , $mp0 = \text{numroc}(m+irow, mb\_a, myrow, iarow, nprow)$ , $nq0 = \text{numroc}(n+icoff, nb\_a, mycol, iacol, npcot)$ . <code>indxg2p</code> and <code>numroc</code> are ScaLAPACK tool functions; <code>myrow</code> , <code>mycol</code> , <code>nprow</code> , and <code>npcol</code> can be determined by calling the function <code>blacs_gridinfo</code> .

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

<code>a</code>	(local).  On exit, the elements on and above the diagonal of $\text{sub}(A)$ contain the $\min(m,n)$ by $n$ upper trapezoidal matrix $R$ ( $R$ is upper triangular if $m \geq n$ ); the elements below the diagonal, with the array <code>tau</code> , represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors (see <i>Application Notes</i> below).
<code>tau</code>	(local).  Array of size $LOCc(ja + \min(m,n) - 1)$ . This array contains the scalar factors of the elementary reflectors. <code>tau</code> is tied to the distributed matrix $A$ .
<code>work</code>	On exit, <code>work[0]</code> returns the minimal and optimal $lwork$ .
<code>info</code>	(local)  If <code>info = 0</code> , the execution is successful. if <code>info &lt; 0</code> :  If the $i$ -th argument is an array and the $j$ -th entry, indexed $j-1$ , had an illegal value, then <code>info = - (i*100+j)</code> ,  if the $i$ -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

## Application Notes

The matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(ja) * H(ja+1) * \dots * H(ja+k-1), \text{ where } k = \min(m,n).$$

Each  $H(i)$  has the form

$$H(j) = I - \tau * v * v',$$

where  $\tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(1:i-1) = 0$  and  $v(i) = 1$ ;  $v(i+1:m)$  is stored on exit in  $A(ia+i:ia+m-1, ja+i-1)$ , and  $\tau$  in  $\text{tau}[ja+i-2]$ .

## Description

The `pzgerq2` function computes an  $RQ$  factorization of a real/complex distributed  $m$ -by- $n$  matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = R*Q$ .

## Input Parameters

<code>m</code>	(global) The number of rows in the distributed matrix $\text{sub}(A)$ . ( $m \geq 0$ ).
<code>n</code>	(global) The number of columns in the distributed matrix $\text{sub}(A)$ . ( $n \geq 0$ ).
<code>a</code>	(local). Pointer into the local memory to an array of size $lld\_a * LOC_c(ja+n-1)$ . On entry, this array contains the local pieces of the $m$ -by- $n$ distributed matrix $\text{sub}(A)$ which is to be factored.
<code>ia, ja</code>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of $\text{sub}(A)$ , respectively.
<code>desca</code>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
<code>work</code>	(local). This is a workspace array of size $lwork$ .
<code>lwork</code>	(local or global) The size of the array $work$ . $lwork$ is local input and must be at least $lwork \geq nq0 + \max(1, mp0)$ , where $iroff = \text{mod}(ia-1, mb\_a), \quad icoff = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow),$ $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcot), \quad mp0 = \text{numroc}(m+iroff, mb\_a, myrow, iarow, nprow),$ $nq0 = \text{numroc}(n+icoff, nb\_a, mycol, iacol, npcot),$ $\text{indxg2p}$ and $\text{numroc}$ are ScaLAPACK tool functions; $myrow$ , $mycol$ , $nprow$ , and $npcol$ can be determined by calling the function <code>blacs_gridinfo</code> . If $lwork = -1$ , then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> .

## Output Parameters

`a` (local).

On exit,

if  $m \leq n$ , the upper triangle of  $A(ia+m-n:ia+m-1, ja:ja+n-1)$  contains the  $m$ -by- $m$  upper triangular matrix  $R$ ;

if  $m \geq n$ , the elements on and above the  $(m-n)$ -th subdiagonal contain the  $m$ -by- $n$  upper trapezoidal matrix  $R$ ; the remaining elements, with the array  $\tau$ , represent the orthogonal/ unitary matrix  $Q$  as a product of elementary reflectors (see *Application Notes* below).

$\tau$

(local).

Array of size  $LOCr(ia+m-1)$ . This array contains the scalar factors of the elementary reflectors.  $\tau$  is tied to the distributed matrix  $A$ .

$work$

On exit,  $work[0]$  returns the minimal and optimal  $lwork$ .

$info$

(local)

If  $info = 0$ , the execution is successful.

if  $info < 0$ : If the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j-1$ , had an illegal value, then  $info = -(i*100+j)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

## Application Notes

The matrix  $Q$  is represented as a product of elementary reflectors

$Q = H(ia) * H(ia+1) * \dots * H(ia+k-1)$  for real flavors,

$Q = (H(ia))^H * (H(ia+1))^H \dots (H(ia+k-1))^H$  for complex flavors,

where  $k = \min(m, n)$ .

Each  $H(i)$  has the form

$H(i) = I - \tau * v * v'$ ,

where  $\tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(n-k+i+1:n) = 0$  and  $v(n-k+i) = 1$ ;  $v(1:n-k+i-1)$  for real flavors or  $\text{conjg}(v(1:n-k+i-1))$  for complex flavors is stored on exit in  $A(ia+m-k+i-1, ja:ja+n-k+i-2)$ , and  $\tau$  in  $\tau[ia+m-k+i-2]$ .

## p?getf2

*Computes an LU factorization of a general matrix, using partial pivoting with row interchanges (local blocked algorithm).*

## Syntax

```
void psgetf2 (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
```

```
void pdgetf2 (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
```

```
void pcgetf2 (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
```

```
void pzgetf2 (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `pzgetf2` function computes an  $LU$  factorization of a general  $m$ -by- $n$  distributed matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$  using partial pivoting with row interchanges.

The factorization has the form  $\text{sub}(A) = P * L * U$ , where  $P$  is a permutation matrix,  $L$  is lower triangular with unit diagonal elements (lower trapezoidal if  $m > n$ ), and  $U$  is upper triangular (upper trapezoidal if  $m < n$ ). This is the right-looking Parallel Level 2 BLAS version of the algorithm.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

<code>m</code>	(global) The number of rows in the distributed matrix $\text{sub}(A)$ . ( $m \geq 0$ ).
<code>n</code>	(global) The number of columns in the distributed matrix $\text{sub}(A)$ . ( $nb\_a - \text{mod}(ja-1, nb\_a) \geq n \geq 0$ ).
<code>a</code>	(local). Pointer into the local memory to an array of size $lld\_a * LOC_c(ja+n-1)$ . On entry, this array contains the local pieces of the $m$ -by- $n$ distributed matrix $\text{sub}(A)$ .
<code>ia, ja</code>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix $\text{sub}(A)$ , respectively.
<code>desca</code>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .

## Output Parameters

<code>ipiv</code>	(local) Array of size $(LOC_r(m\_a) + mb\_a)$ . This array contains the pivoting information. <code>ipiv[i]</code> -> The global row that local row $(i + 1)$ was swapped with, $i = 0, 1, \dots, LOC_r(m\_a) + mb\_a - 1$ . This array is tied to the distributed matrix $A$ .
<code>info</code>	(local). If <code>info = 0</code> : successful exit. If <code>info &lt; 0</code> :

- if the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j-1$ , had an illegal value, then  $info = -(i*100+j)$ ,
- if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

If  $info > 0$ : If  $info = k$ , the matrix element  $U_{(ia+k-1, ja+k-1)}$  is exactly zero. The factorization has been completed, but the factor  $U$  is exactly singular, and division by zero will occur if it is used to solve a system of equations.

```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?labrd` function reduces the first  $nb$  rows and columns of a real/complex general  $m$ -by- $n$  distributed matrix  $\text{sub}(A) = A_{(ia:ia+m-1, ja:ja+n-1)}$  to upper or lower bidiagonal form by an orthogonal/unitary transformation  $Q^* A P$ , and returns the matrices  $X$  and  $Y$  necessary to apply the transformation to the unreduced part of  $\text{sub}(A)$ .

If  $m \geq n$ ,  $\text{sub}(A)$  is reduced to upper bidiagonal form; if  $m < n$ ,  $\text{sub}(A)$  is reduced to lower bidiagonal form.

This is an auxiliary function called by `p?gebrd`.

## Input Parameters

<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(A)$ . ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(A)$ . ( $n \geq 0$ ).
<i>nb</i>	(global) The number of leading rows and columns of $\text{sub}(A)$ to be reduced.
<i>a</i>	(local). Pointer into the local memory to an array of size $lld\_a * LOC_c(ja+n-1)$ . On entry, this array contains the local pieces of the general distributed matrix $\text{sub}(A)$ .
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
<i>ix, jx</i>	(global) The row and column indices in the global matrix $X$ indicating the first row and the first column of the matrix $\text{sub}(X)$ , respectively.
<i>descx</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $X$ .
<i>iy, jy</i>	(global) The row and column indices in the global matrix $Y$ indicating the first row and the first column of the matrix $\text{sub}(Y)$ , respectively.
<i>descy</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $Y$ .
<i>work</i>	(local). Workspace array of size $lwork$ . $lwork \geq nb\_a + nq$ , with $nq = \text{numroc}(n + \text{mod}(ia-1, nb\_y), nb\_y, mycol, iacol, npcot)$ $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcot)$ $\text{indxg2p}$ and $\text{numroc}$ are ScaLAPACK tool functions; $myrow$ , $mycol$ , $nprow$ , and $npcol$ can be determined by calling the function <code>blacs_gridinfo</code> .

## Output Parameters

<i>a</i>	(local) On exit, the first $nb$ rows and columns of the matrix are overwritten; the rest of the distributed matrix $\text{sub}(A)$ is unchanged. If $m \geq n$ , elements on and below the diagonal in the first $nb$ columns, with the array $\text{tauq}$ , represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors; and elements above the diagonal in the first $nb$ rows, with the array $\text{taup}$ , represent the orthogonal/unitary matrix $P$ as a product of elementary reflectors.
----------	--

If  $m < n$ , elements below the diagonal in the first  $nb$  columns, with the array  $tauq$ , represent the orthogonal/unitary matrix  $Q$  as a product of elementary reflectors, and elements on and above the diagonal in the first  $nb$  rows, with the array  $taup$ , represent the orthogonal/unitary matrix  $P$  as a product of elementary reflectors. See *Application Notes* below.

 $d$ 

(local).

Array of size  $LOCr(ia+\min(m,n)-1)$  if  $m \geq n$ ;  $LOCc(ja+\min(m,n)-1)$  otherwise. The distributed diagonal elements of the bidiagonal distributed matrix  $B$ :

$$d[i] = A(ia+i, ja+i), i = 0, 1, \dots, \text{size}(d)-1$$

$d$  is tied to the distributed matrix  $A$ .

 $e$ 

(local).

Array of size  $LOCr(ia+\min(m,n)-1)$  if  $m \geq n$ ;  $LOCc(ja+\min(m,n)-2)$  otherwise. The distributed off-diagonal elements of the bidiagonal distributed matrix  $B$ :

$$\text{if } m \geq n, e[i] = A(ia+i, ja+i+1) \text{ for } i = 0, 1, \dots, n-2;$$

$$\text{if } m < n, e[i] = A(ia+i+1, ja+i) \text{ for } i = 0, 1, \dots, m-2.$$

$e$  is tied to the distributed matrix  $A$ .

 $tauq, taup$ 

(local).

Array size  $LOCc(ja+\min(m,n)-1)$  for  $tauq$ , size  $LOCr(ia+\min(m,n)-1)$  for  $taup$ . The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix  $Q$  for  $tauq$ ,  $P$  for  $taup$ .  $tauq$  and  $taup$  are tied to the distributed matrix  $A$ . See *Application Notes* below.

 $x$ 

(local)

Pointer into the local memory to an array of size  $lld\_x * nb$ . On exit, the local pieces of the distributed  $m$ -by- $nb$  matrix  $X(ix:ix+m-1, jx:jx+nb-1)$  required to update the unreduced part of  $\text{sub}(A)$ .

 $y$ 

(local).

Pointer into the local memory to an array of size  $lld\_y * nb$ . On exit, the local pieces of the distributed  $n$ -by- $nb$  matrix  $Y(iy:iy+n-1, jy:jy+nb-1)$  required to update the unreduced part of  $\text{sub}(A)$ .

## Application Notes

The matrices  $Q$  and  $P$  are represented as products of elementary reflectors:

$$Q = H(1) * H(2) * \dots * H(nb), \text{ and } P = G(1) * G(2) * \dots * G(nb)$$

Each  $H(i)$  and  $G(i)$  has the form:

$$H(i) = I - tauq * v * v', \text{ and } G(i) = I - taup * u * u',$$

where  $tauq$  and  $taup$  are real/complex scalars, and  $v$  and  $u$  are real/complex vectors.

If  $m \geq n$ ,  $v(1:i-1) = 0$ ,  $v(i) = 1$ , and  $v(i:m)$  is stored on exit in

$A(ia+i-1:ia+m-1, ja+i-1)$ ;  $u(1:i) = 0$ ,  $u(i+1) = 1$ , and  $u(i+1:n)$  is stored on exit in  $A(ia+i-1, ja+i:ja+n-1)$ ;  $tauq$  is stored in  $tauq[ja+i-2]$  and  $taup$  in  $taup[ia+i-2]$ .

If  $m < n$ ,  $v(1:i) = 0$ ,  $v(i+1) = 1$ , and  $v(i+1:m)$  is stored on exit in

$A(ia+i+1:ia+m-1, ja+i-1)$ ;  $u(1:i-1) = 0$ ,  $u(i) = 1$ , and  $u(i:n)$  is stored on exit in  $A(ia+i-1, ja+i:ja+n-1)$ ;  $\tau uq$  is stored in  $\tau uq[ja+i-2]$  and  $\tau up$  in  $\tau up[ia+i-2]$ . The elements of the vectors  $v$  and  $u$  together form the  $m$ -by- $nb$  matrix  $V$  and the  $nb$ -by- $n$  matrix  $U'$  which are necessary, with  $X$  and  $Y$ , to apply the transformation to the unreduced part of the matrix, using a block update of the form:  $\text{sub}(A) := \text{sub}(A) - V*Y' - X*U'$ . The contents of  $\text{sub}(A)$  on exit are illustrated by the following examples with  $nb = 2$ :

$m = 6$  and  $n = 5 (m > n)$ :

$$\begin{bmatrix} 1 & 1 & u1 & u1 & u1 \\ v1 & 1 & 1 & u2 & u2 \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \end{bmatrix}$$

$m = 5$  and  $n = 6 (m < n)$ :

$$\begin{bmatrix} 1 & u1 & u1 & u1 & u1 & u1 \\ 1 & 1 & u2 & u2 & u2 & u2 \\ v1 & 1 & a & a & a & a \\ v1 & v2 & a & a & a & a \\ v1 & v2 & a & a & a & a \end{bmatrix}$$

where  $a$  denotes an element of the original matrix which is unchanged,  $v_i$  denotes an element of the vector defining  $H(i)$ , and  $u_i$  an element of the vector defining  $G(i)$ .

## p?lacon

*Estimates the 1-norm of a square matrix, using the reverse communication for evaluating matrix-vector products.*

## Syntax

```
void pslacon (MKL_INT *n , float *v , MKL_INT *iv , MKL_INT *jv , MKL_INT *descv , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *isgn , float *est , MKL_INT *kase );
```

```
void pdlacon (MKL_INT *n , double *v , MKL_INT *iv , MKL_INT *jv , MKL_INT *descv , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *isgn , double *est , MKL_INT *kase );
```

```
void pclacon (MKL_INT *n , MKL_Complex8 *v , MKL_INT *iv , MKL_INT *jv , MKL_INT *descv , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , float *est , MKL_INT *kase );
```

```
void pzlacon (MKL_INT *n , MKL_Complex16 *v , MKL_INT *iv , MKL_INT *jv , MKL_INT *descv , MKL_Complex16 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , double *est , MKL_INT *kase );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?lacon` function estimates the 1-norm of a square, real/unitary distributed matrix  $A$ . Reverse communication is used for evaluating matrix-vector products.  $x$  and  $v$  are aligned with the distributed matrix  $A$ , this information is implicitly contained within  $iv$ ,  $ix$ ,  $descv$ , and  $descx$ .

## Input Parameters

$n$	(global) The length of the distributed vectors $v$ and $x$ . $n \geq 0$ .
$v$	(local). Pointer into the local memory to an array of size $LOCr(n+\text{mod}(iv-1, mb_v))$ . On the final return, $v = a*w$ , where $est = \text{norm}(v)/\text{norm}(w)$ ( $w$ is not returned).
$iv, jv$	(global) The row and column indices in the global matrix $V$ indicating the first row and the first column of the submatrix $V$ , respectively.
$descv$	(global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $V$ .
$x$	(local). Pointer into the local memory to an array of size $LOCr(n+\text{mod}(ix-1, mb_x))$ .
$ix, jx$	(global) The row and column indices in the global matrix $X$ indicating the first row and the first column of the submatrix $X$ , respectively.
$descx$	(global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $X$ .
$isgn$	(local). Array of size $LOCr(n+\text{mod}(ix-1, mb_x))$ . $isgn$ is aligned with $x$ and $v$ .
$kase$	(local). On the initial call to <code>p?lacon</code> , $kase$ should be 0.

## Output Parameters

$x$	(local). On an intermediate return, $X$ should be overwritten by $A*X$ , if $kase=1$ , $A'*X$ , if $kase=2$ , <code>p?lacon</code> must be re-called with all the other parameters unchanged.
$est$	(global).
$kase$	(local) On an intermediate return, $kase$ is 1 or 2, indicating whether $X$ should be overwritten by $A*X$ , or $A'*X$ . On the final return from <code>p?lacon</code> , $kase$ is again 0.

## p?laconsb

Looks for two consecutive small subdiagonal elements.

### Syntax

```
void pslaconsb (const float *a, const MKL_INT *desca, const MKL_INT *i, const MKL_INT
 *l, MKL_INT *m, const float *h44, const float *h33, const float *h43h34, float *buf,
 const MKL_INT *lwork );
```

```
void pdlaconsb (const double *a, const MKL_INT *desca, const MKL_INT *i, const MKL_INT
 *l, MKL_INT *m, const double *h44, const double *h33, const double *h43h34, double *buf,
 const MKL_INT *lwork );
```

```
void pclaconsb (const MKL_Complex8 *a , const MKL_INT *desca , const MKL_INT *i , const
 MKL_INT *l , MKL_INT *m , const MKL_Complex8 *h44 , const MKL_Complex8 *h33 , const
 MKL_Complex8 *h43h34 , MKL_Complex8 *buf , const MKL_INT *lwork );
```

```
void pzlaconsb (const MKL_Complex16 *a , const MKL_INT *desca , const MKL_INT *i ,
 const MKL_INT *l , MKL_INT *m , const MKL_Complex16 *h44 , const MKL_Complex16 *h33 ,
 const MKL_Complex16 *h43h34 , MKL_Complex16 *buf , const MKL_INT *lwork );
```

### Include Files

- mkl\_scalapack.h

### Description

The p?laconsb function looks for two consecutive small subdiagonal elements by analyzing the effect of starting a double shift QR iteration given by *h44*, *h33*, and *h43h34* to see if this process makes a subdiagonal negligible.

### Input Parameters

<i>a</i>	(local) Array of size $lld\_a * LOCc(n\_a)$ . On entry, the Hessenberg matrix whose tridiagonal part is being scanned. Unchanged on exit.
<i>desca</i>	(global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>i</i>	(global) The global location of the bottom of the unreduced submatrix of <i>A</i> . Unchanged on exit.
<i>l</i>	(global) The global location of the top of the unreduced submatrix of <i>A</i> . Unchanged on exit.
<i>h44, h33, h43h34</i>	(global). These three values are for the double shift QR iteration.
<i>lwork</i>	(local) This must be at least $7 * \text{ceil}(\text{ceil}((i-1)/mb\_a) / \text{lcm}(n\text{prow}, n\text{pcol}))$ . Here <i>lcm</i> is the least common multiple and <i>npro w</i> * <i>npcol</i> is the logical grid size.

## Output Parameters

<i>m</i>	(global). On exit, this yields the starting location of the QR double shift. This will satisfy: $l \leq m \leq i-2$ .
<i>buf</i>	(local). Array of size <i>lwork</i> .

## p?lacp2

*Copies all or part of a distributed matrix to another distributed matrix.*

## Syntax

```
void pslacp2 (char *uplo , MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
void pdlacp2 (char *uplo , MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
void pclacp2 (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
void pzlacp2 (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
```

## Include Files

- mkl\_scalapack.h

## Description

The p?lacp2 function copies all or part of a distributed matrix *A* to another distributed matrix *B*. No communication is performed, p?lacp2 performs a local copy  $\text{sub}(A) := \text{sub}(B)$ , where  $\text{sub}(A)$  denotes  $A(ia:ia+m-1, a:ja+n-1)$  and  $\text{sub}(B)$  denotes  $B(ib:ib+m-1, jb:jb+n-1)$ .

p?lacp2 requires that only dimension of the matrix operands is distributed.

## Input Parameters

<i>uplo</i>	(global) Specifies the part of the distributed matrix $\text{sub}(A)$ to be copied: = 'U': Upper triangular part is copied; the strictly lower triangular part of $\text{sub}(A)$ is not referenced; = 'L': Lower triangular part is copied; the strictly upper triangular part of $\text{sub}(A)$ is not referenced. Otherwise: all of the matrix $\text{sub}(A)$ is copied.
<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(A)$ . ( $m \geq 0$ ).

$n$	(global) The number of columns in the distributed matrix $\text{sub}(A)$ . ( $n \geq 0$ ).
$a$	(local). Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ . On entry, this array contains the local pieces of the $m$ -by- $n$ distributed matrix $\text{sub}(A)$ .
$ia, ja$	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of $\text{sub}(A)$ , respectively.
$desca$	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
$ib, jb$	(global) The row and column indices in the global matrix $B$ indicating the first row and the first column of $\text{sub}(B)$ , respectively.
$descb$	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $B$ .

## Output Parameters

$b$	(local). Pointer into the local memory to an array of size $lld\_b * LOCC(jb+n-1)$ . This array contains on exit the local pieces of the distributed matrix $\text{sub}(B)$ set as follows: if $uplo = 'U'$ , $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$ , $1 \leq i \leq j$ , $1 \leq j \leq n$ ; if $uplo = 'L'$ , $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$ , $j \leq i \leq m$ , $1 \leq j \leq n$ ; otherwise, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$ , $1 \leq i \leq m$ , $1 \leq j \leq n$ .
-----	--

## p?lacp3

*Copies from a global parallel array into a local replicated array or vice versa.*

## Syntax

```
void pslacp3 (const MKL_INT *m, const MKL_INT *i, float *a, const MKL_INT *desca, float
*b, const MKL_INT *ldb, const MKL_INT *ii, const MKL_INT *jj, const MKL_INT *rev );
void pdlacp3 (const MKL_INT *m, const MKL_INT *i, double *a, const MKL_INT *desca,
double *b, const MKL_INT *ldb, const MKL_INT *ii, const MKL_INT *jj, const MKL_INT
*rev );
void pclacp3 (const MKL_INT *m, const MKL_INT *i, MKL_Complex8 *a, const MKL_INT
*desca, MKL_Complex8 *b, const MKL_INT *ldb, const MKL_INT *ii, const MKL_INT *jj,
const MKL_INT *rev);
void pzlacp3 (const MKL_INT *m, const MKL_INT *i, MKL_Complex16 *a, const MKL_INT
*desca, MKL_Complex16 *b, const MKL_INT *ldb, const MKL_INT *ii, const MKL_INT *jj,
const MKL_INT *rev);
```

## Include Files

- `mkl_scalapack.h`

## Description

This is an auxiliary function that copies from a global parallel array into a local replicated array or vice versa. Note that the entire submatrix that is copied gets placed on one node or more. The receiving node can be specified precisely, or all nodes can receive, or just one row or column of nodes.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

<i>m</i>	(global) <i>m</i> is the order of the square submatrix that is copied. <i>m</i> ≥ 0. Unchanged on exit.
<i>i</i>	(global) The matrix element $A(i, i)$ is the global location that the copying starts from. Unchanged on exit.
<i>a</i>	(local) Array of size $lld\_a * LOCc(n\_a)$ . On entry, the parallel matrix to be copied into or from.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local) Array of size $ldb * LOCc(m)$ . If <i>rev</i> = 0, this is the global portion of the matrix $A(i:i+m-1, i:i+m-1)$ . If <i>rev</i> = 1, this is unchanged on exit.
<i>ldb</i>	(local) The leading dimension of <i>B</i> .
<i>ii, jj</i>	(global) By using <i>rev</i> 0 and 1, data can be sent out and returned again. If <i>rev</i> = 0, then <i>ii</i> is destination row index and <i>jj</i> is destination column index for the node(s) receiving the replicated matrix <i>B</i> . If <i>ii</i> ≥ 0, <i>jj</i> ≥ 0, then node ( <i>ii, jj</i> ) receives the data. If <i>ii</i> = -1, <i>jj</i> ≥ 0, then all rows in column <i>jj</i> receive the data. If <i>ii</i> ≥ 0, <i>jj</i> = -1, then all cols in row <i>ii</i> receive the data. If <i>ii</i> = -1, <i>jj</i> = -1, then all nodes receive the data. If <i>rev</i> != 0, then <i>ii</i> is the source row index for the node(s) sending the replicated <i>B</i> .
<i>rev</i>	(global) Use <i>rev</i> = 0 to send global matrix <i>A</i> into locally replicated matrix <i>B</i> (on node ( <i>ii, jj</i> )). Use <i>rev</i> != 0 to send locally replicated <i>B</i> from node ( <i>ii, jj</i> ) to its owner (which changes depending on its location in <i>A</i> ) into the global <i>A</i> .

## Output Parameters

<i>a</i>	On exit, if <i>rev</i> = 1, the copied data. Unchanged on exit if <i>rev</i> = 0.
<i>b</i>	If <i>rev</i> = 1, this is unchanged on exit.

## p?lacpy

*Copies all or part of one two-dimensional array to another.*

## Syntax

```
void pslacpy (char *uplo , MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
void pdlacpy (char *uplo , MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
void pclacpy (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
void pzlacpy (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
```

## Include Files

- mkl\_scalapack.h

## Description

The p?lacpy function copies all or part of a distributed matrix *A* to another distributed matrix *B*. No communication is performed, p?lacpy performs a local copy  $\text{sub}(B) := \text{sub}(A)$ , where  $\text{sub}(A)$  denotes  $A(ia:ia+m-1, ja:ja+n-1)$  and  $\text{sub}(B)$  denotes  $B(ib:ib+m-1, jb:jb+n-1)$ .

## Input Parameters

<i>uplo</i>	(global) Specifies the part of the distributed matrix $\text{sub}(A)$ to be copied: = 'U': Upper triangular part; the strictly lower triangular part of $\text{sub}(A)$ is not referenced; = 'L': Lower triangular part; the strictly upper triangular part of $\text{sub}(A)$ is not referenced. Otherwise: all of the matrix $\text{sub}(A)$ is copied.
<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(A)$ . ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(A)$ . ( $n \geq 0$ ).
<i>a</i>	(local). Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ .

On entry, this array contains the local pieces of the distributed matrix  $\text{sub}(A)$ .

<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .
<i>ib, jb</i>	(global) The row and column indices in the global matrix $B$ indicating the first row and the first column of $\text{sub}(B)$ respectively.
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .

## Output Parameters

<i>b</i>	(local). Pointer into the local memory to an array of size $lld\_b * LOCC(jb+n-1)$ . This array contains on exit the local pieces of the distributed matrix $\text{sub}(B)$ set as follows: if <i>uplo</i> = 'U', $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$ , $1 \leq i \leq j$ , $1 \leq j \leq n$ ; if <i>uplo</i> = 'L', $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$ , $j \leq i \leq m$ , $1 \leq j \leq n$ ; otherwise, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$ , $1 \leq i \leq m$ , $1 \leq j \leq n$ .

*lwork );
```

```
void pclaevswp (MKL_INT *n , float *zin , MKL_INT *ldzi , MKL_Complex8 *z , MKL_INT
*iz , MKL_INT *jz , MKL_INT *descz , MKL_INT *nvs , MKL_INT *key , float *rwork ,
MKL_INT *lrwork );
```

```
void pzlaevswp (MKL_INT *n , double *zin , MKL_INT *ldzi , MKL_Complex16 *z , MKL_INT
*iz , MKL_INT *jz , MKL_INT *descz , MKL_INT *nvs , MKL_INT *key , double *rwork ,
MKL_INT *lrwork );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?laevswp` function moves the eigenvectors (potentially unsorted) from where they are computed, to a ScaLAPACK standard block cyclic array, sorted so that the corresponding eigenvalues are sorted.

## Input Parameters

$np$  = the number of rows local to a given process.

$nq$  = the number of columns local to a given process.

$n$	(global) The order of the matrix $A$ . $n \geq 0$ .
$zin$	(local). Array of size $ldzi * nvs[iam+1]$ . The eigenvectors on input. $iam$ is a process rank from $[0, nprocs)$ interval. Each eigenvector resides entirely in one process. Each process holds a contiguous set of $nvs[iam+1]$ eigenvectors. The global number of the first eigenvector that the process holds is: ((sum for $i=[0, iam]$ of $nvs[i]$ )+1).
$ldzi$	(local) The leading dimension of the $zin$ array.
$iz, jz$	(global) The row and column indices in the global matrix $Z$ indicating the first row and the first column of the submatrix $Z$ , respectively.
$descz$	(global and local) Array of size $dlen_$ . The array descriptor for the distributed matrix $Z$ .
$nvs$	(global) Array of size $nprocs+1$ $nvs[i]$ = number of eigenvectors held by processes $[0, i)$ $nvs[0]$ = number of eigenvectors held by processes $[0, 0) = 0$ $nvs[nprocs]$ = number of eigenvectors held by $[0, nprocs)$ = total number of eigenvectors.
$key$	(global) Array of size $n$ . Indicates the actual index (after sorting) for each of the eigenvectors.
$rwork$	(local). Array of size $lrwork$ .
$lrwork$	(local) Size of $work$ .

## Output Parameters

$z$	(local). Array of global size $n * n$ and of local size $lld_z * nq$ . The eigenvectors on output. The eigenvectors are distributed in a block cyclic manner in both dimensions, with a block size of $nb$ .

## p?lahrd

*Reduces the first  $nb$  columns of a general rectangular matrix  $A$  so that elements below the  $k$ -th subdiagonal are zero, by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of  $A$ .*

## Syntax

```
void pslahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *t , float *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , float *work );
```

```
void pdlahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *t , double *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , double *work );
```

```
void pclahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *t , MKL_Complex8 *y ,
MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_Complex8 *work );
```

```
void pzlahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *t , MKL_Complex16
*y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_Complex16 *work );
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?lahrd` function reduces the first  $nb$  columns of a real general  $n$ -by- $(n-k+1)$  distributed matrix  $A$  ( $ia:ia+n-1$  ,  $ja:ja+n-k$ ) so that elements below the  $k$ -th subdiagonal are zero. The reduction is performed by an orthogonal/unitary similarity transformation  $Q^*A^*Q$ . The function returns the matrices  $V$  and  $T$  which determine  $Q$  as a block reflector  $I-V^*T^*V'$ , and also the matrix  $Y = A^*V^*T$ .

This is an auxiliary function called by `p?gehrd`. In the following comments  $sub(A)$  denotes  $A(ia:ia+n-1, ja:ja+n-1)$ .

## Input Parameters

$n$	(global) The order of the distributed matrix $sub(A)$ . $n \geq 0$ .
$k$	(global) The offset for the reduction. Elements below the $k$ -th subdiagonal in the first $nb$ columns are reduced to zero.
$nb$	(global) The number of columns to be reduced.
$a$	(local).

Pointer into the local memory to an array of size  $lld\_a * LOCc(ja+n-k)$ . On entry, this array contains the local pieces of the  $n$ -by- $(n-k+1)$  general distributed matrix  $A(ia:ia+n-1, ja:ja+n-k)$ .

<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix sub( $A$ ), respectively.
<i>desca</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
<i>iy, jy</i>	(global) The row and column indices in the global matrix $Y$ indicating the first row and the first column of the matrix sub( $Y$ ), respectively.
<i>descy</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $Y$ .
<i>work</i>	(local). Array of size $nb$ .

## Output Parameters

<i>a</i>	(local). On exit, the elements on and above the $k$ -th subdiagonal in the first $nb$ columns are overwritten with the corresponding elements of the reduced distributed matrix; the elements below the $k$ -th subdiagonal, with the array $tau$ , represent the matrix $Q$ as a product of elementary reflectors. The other columns of the matrix $A(ia:ia+n-1, ja:ja+n-k)$ are unchanged. (See <i>Application Notes</i> below.)
<i>tau</i>	(local) Array of size $LOCc(ja+n-2)$ . The scalar factors of the elementary reflectors (see <i>Application Notes</i> below). $tau$ is tied to the distributed matrix $A$ .
<i>t</i>	(local) Array of size $nb\_a * nb\_a$ . The upper triangular matrix $T$ .
<i>y</i>	(local). Pointer into the local memory to an array of size $lld\_y * nb\_a$ . On exit, this array contains the local pieces of the $n$ -by- $nb$ distributed matrix $Y$ . $lld\_y \geq LOCr(ia+n-1)$ .

## Application Notes

The matrix  $Q$  is represented as a product of  $nb$  elementary reflectors

$$Q = H(1) * H(2) * \dots * H(nb).$$

Each  $H(i)$  has the form

$$H(i) = I - \tau * v * v',$$

where  $\tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(1:i+k-1) = 0$ ,  $v(i+k) = 1$ ;  $v(i+k+1:n)$  is stored on exit in  $A(ia+i+k:ia+n-1, ja+i-1)$ , and  $\tau$  in  $tau[ja+i-2]$ .

$n$  The order of the tridiagonal matrix  $T$ .  $n \geq 1$ .

$d$  Array of size  $2n-1$ .  
On entry, this array contains the diagonals and the squares of the off-diagonal elements of the tridiagonal matrix  $T$ . These elements are assumed to be interleaved in memory for better cache performance. The diagonal entries of  $T$  are in the entries  $d[0]$ ,  $d[2]$ , ...,  $d[2n-2]$ , while the squares of the off-diagonal entries are  $d[1]$ ,  $d[3]$ , ...,  $d[2n-3]$ . To avoid overflow, the matrix must be scaled so that its largest entry is no greater than  $overflow^{(1/2)} * underflow^{(1/4)}$  in absolute value, and for greatest accuracy, it should not be much smaller than that.

## Output Parameters

$n$  The count of the number of eigenvalues of  $T$  less than or equal to  $sigma$ .

## p?lamve

*Copies all or part of one two-dimensional distributed array to another.*

## Syntax

```
void pslamve(char* uplo, MKL_INT* m, MKL_INT* n, float* a, MKL_INT* ia, MKL_INT* ja,
MKL_INT* desca, float* b, MKL_INT* ib, MKL_INT* jb, MKL_INT* descb, float* dwork);
void pdlamve(char* uplo, MKL_INT* m, MKL_INT* n, double* a, MKL_INT* ia, MKL_INT* ja,
MKL_INT* desca, double* b, MKL_INT* ib, MKL_INT* jb, MKL_INT* descb, double* dwork);
```

## Include Files

- `mkl_scalapack.h`

## Description

`p?lamve` copies all or part of a distributed matrix  $A$  to another distributed matrix  $B$ . There is no alignment assumptions at all except that  $A$  and  $B$  are of the same size.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

$uplo$  (global )  
Specifies the part of the distributed matrix  $sub(A)$  to be copied:  
= 'U': Upper triangular part is copied; the strictly lower triangular part of  $sub(A)$  is not referenced;  
= 'L': Lower triangular part is copied; the strictly upper triangular part of  $sub(A)$  is not referenced;

	Otherwise: All of the matrix $\text{sub}(A)$ is copied.
$m$	(global ) The number of rows to be operated on, which is the number of rows of the distributed matrix $\text{sub}(A)$ . $m \geq 0$ .
$n$	(global ) The number of columns to be operated on, which is the number of columns of the distributed matrix $\text{sub}(A)$ . $n \geq 0$ .
$a$	(local ) pointer into the local memory to an array of size $lld_a * LOC_c(ja + n - 1)$ . This array contains the local pieces of the distributed matrix $\text{sub}(A)$ to be copied from.
$ia$	(global ) The row index in the global matrix $A$ indicating the first row of $\text{sub}(A)$ .
$ja$	(global ) The column index in the global matrix $A$ indicating the first column of $\text{sub}(A)$ .
$desca$	(global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $A$ .
$ib$	(global ) The row index in the global matrix $B$ indicating the first row of $\text{sub}(B)$ .
$jb$	(global ) The column index in the global matrix $B$ indicating the first column of $\text{sub}(B)$ .
$descb$	(global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $B$ .
$dwork$	(local workspace) array If $uplo = 'U'$ or $uplo = 'L'$ and number of processors $> 1$ , the length of $dwork$ is at least as large as the length of $b$ . Otherwise, $dwork$ is not referenced.

## OUTPUT Parameters

$b$	(local ) pointer into the local memory to an array of size $lld_b * LOC_c(jb + n - 1)$ . This array contains on exit the local pieces of the distributed matrix $\text{sub}(B)$ .

## **p?lange**

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a general rectangular matrix.

## Syntax

```
float pslange (char *norm , MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *work );
```

```
double pdlange (char *norm , MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *work );
```

```
float pclange (char *norm , MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *work );
```

```
double pzlange (char *norm , MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *work );
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?lange` function returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ .

## Input Parameters

<i>norm</i>	(global) Specifies what value is returned by the function: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$ , largest absolute value of the matrix $A$ , it s not a matrix norm. = '1' or 'O' or 'o': $val = \text{norm1}(A)$ , 1-norm of the matrix $A$ (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$ , infinity norm of the matrix $A$ (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$ , Frobenius norm of the matrix $A$ (square root of sum of squares).
<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(A)$ . When $m = 0$ , <code>p?lange</code> is set to zero. $m \geq 0$ .
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(A)$ . When $n = 0$ , <code>p?lange</code> is set to zero. $n \geq 0$ .
<i>a</i>	(local). Pointer into the local memory to an array of size $lld\_a * LOCc(ja+n-1)$ containing the local pieces of the distributed matrix $\text{sub}(A)$ .
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
<i>work</i>	(local). Array size $lwork$ .

$lwork \geq 0$  if  $norm = 'M'$  or  $'m'$  (not referenced),  
 $nq0$  if  $norm = '1', 'O'$  or  $'o'$ ,  
 $mp0$  if  $norm = 'I'$  or  $'i'$ ,  
 $0$  if  $norm = 'F', 'f', 'E'$  or  $'e'$  (not referenced),  
 where  
 $iroffa = \text{mod}(ia-1, mb\_a)$ ,  $icoffa = \text{mod}(ja-1, nb\_a)$ ,  
 $iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow)$ ,  
 $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcot)$ ,  
 $mp0 = \text{numroc}(m+iroffa, mb\_a, myrow, iarow, nprow)$ ,  
 $nq0 = \text{numroc}(n+icoffa, nb\_a, mycol, iacol, npcot)$ ,  
 $\text{indxg2p}$  and  $\text{numroc}$  are ScaLAPACK tool functions;  $myrow$ ,  $mycol$ ,  $nprow$ ,  
 and  $npcot$  can be determined by calling the function `blacs_gridinfo`.

## Output Parameters

*val* The value returned by the function.

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## p?lanhs

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of an upper Hessenberg matrix.

## Syntax

```
float pslanhs (char *norm , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *work );
```

```
double pdlanhs (char *norm , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *work );
```

```
float pclanhs (char *norm , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *work );
```

```
double pzlanhs (char *norm , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *work );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?lanhs` function returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an upper Hessenberg distributed matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ .

## Input Parameters

*norm* Specifies the value to be returned by the function:

	<p>= 'M' or 'm': <math>val = \max(\text{abs}(A_{ij}))</math>, largest absolute value of the matrix <math>A</math>.</p> <p>= '1' or 'O' or 'o': <math>val = \text{norm1}(A)</math>, 1-norm of the matrix <math>A</math> (maximum column sum),</p> <p>= 'I' or 'i': <math>val = \text{normI}(A)</math>, infinity norm of the matrix <math>A</math> (maximum row sum),</p> <p>= 'F', 'f', 'E' or 'e': <math>val = \text{normF}(A)</math>, Frobenius norm of the matrix <math>A</math> (square root of sum of squares).</p>
$n$	<p>(global)</p> <p>The number of columns in the distributed matrix <math>\text{sub}(A)</math>. When <math>n = 0</math>, <code>p?lanhs</code> is set to zero. <math>n \geq 0</math>.</p>
$a$	<p>(local).</p> <p>Pointer into the local memory to an array of size <math>lld\_a * LOCC(ja+n-1)</math> containing the local pieces of the distributed matrix <math>\text{sub}(A)</math>.</p>

## p?lansy, p?lanhe

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a real symmetric or a complex Hermitian matrix.

### Syntax

```
float pslansy (char *norm , char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *work );

double pdlansy (char *norm , char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *work );

float pclansy (char *norm , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *work );

double pzlansy (char *norm , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *work );

float pplanhe (char *norm , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *work );

double pzlanhe (char *norm , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *work );
```

### Include Files

- mkl\_scalapack.h

### Description

The p?lansy and p?lanhe functions return the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix  $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$ .

### Input Parameters

<i>norm</i>	(global) Specifies what value is returned by the function: = 'M' or 'm': $\text{val} = \max(\text{abs}(A_{ij}))$ , largest absolute value of the matrix <i>A</i> , it s not a matrix norm. = '1' or 'O' or 'o': $\text{val} = \text{norm1}(A)$ , 1-norm of the matrix <i>A</i> (maximum column sum), = 'I' or 'i': $\text{val} = \text{normI}(A)$ , infinity norm of the matrix <i>A</i> (maximum row sum), = 'F', 'f', 'E' or 'e': $\text{val} = \text{normF}(A)$ , Frobenius norm of the matrix <i>A</i> (square root of sum of squares).
<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the symmetric matrix $\text{sub}(A)$ is to be referenced. = 'U': Upper triangular part of $\text{sub}(A)$ is referenced, = 'L': Lower triangular part of $\text{sub}(A)$ is referenced.
<i>n</i>	(global)

The number of columns in the distributed matrix  $\text{sub}(A)$ . When  $n = 0$ ,  $\text{p?lansy}$  is set to zero.  $n \geq 0$ .

<i>a</i>	<p>(local).</p> <p>Pointer into the local memory to an array of size <math>\text{lld}_a * \text{LOCc}(ja+n-1)</math> containing the local pieces of the distributed matrix <math>\text{sub}(A)</math>.</p> <p>If <math>\text{uplo} = 'U'</math>, the leading <math>n</math>-by-<math>n</math> upper triangular part of <math>\text{sub}(A)</math> contains the upper triangular matrix whose norm is to be computed, and the strictly lower triangular part of this matrix is not referenced. If <math>\text{uplo} = 'L'</math>, the leading <math>n</math>-by-<math>n</math> lower triangular part of <math>\text{sub}(A)</math> contains the lower triangular matrix whose norm is to be computed, and the strictly upper triangular part of <math>\text{sub}(A)</math> is not referenced.</p>
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of size $\text{dlen}_$ . The array descriptor for the distributed matrix $A$ .
<i>work</i>	<p>(local).</p> <p>Array of size <math>\text{lwork}</math>.</p> <p><math>\text{lwork} \geq 0</math> if <math>\text{norm} = 'M'</math> or <math>'m'</math> (not referenced),</p> <p><math>2 * \text{nq0} + \text{mp0} + \text{ldw}</math> if <math>\text{norm} = '1', 'O'</math> or <math>'o', 'I'</math> or <math>'i'</math>,</p> <p>where <math>\text{ldw}</math> is given by:</p> <pre> if( nprow≠npcol ) then   ldw = mb_a*iceil(iceil(np0,mb_a), (lcm/nprow)) else   ldw = 0 end if </pre> <p>0 if <math>\text{norm} = 'F', 'f', 'E'</math> or <math>'e'</math> (not referenced),</p> <p>where <math>\text{lcm}</math> is the least common multiple of <math>\text{nprow}</math> and <math>\text{npcol}</math>, <math>\text{lcm} = \text{ilcm}(\text{nprow}, \text{npcol})</math> and <math>\text{iceil}(x,y)</math> is a ScaLAPACK function that returns ceiling <math>(x/y)</math>.</p> <p><math>\text{iroffa} = \text{mod}(\text{ia}-1, \text{mb}_a)</math>, <math>\text{icoffa} = \text{mod}(\text{ja}-1, \text{nb}_a)</math>,</p> <p><math>\text{iarow} = \text{indxg2p}(\text{ia}, \text{mb}_a, \text{myrow}, \text{rsrc}_a, \text{nprow})</math>,</p> <p><math>\text{iacol} = \text{indxg2p}(\text{ja}, \text{nb}_a, \text{mycol}, \text{csrc}_a, \text{npcol})</math>,</p> <p><math>\text{mp0} = \text{numroc}(m + \text{iroffa}, \text{mb}_a, \text{myrow}, \text{iarow}, \text{nprow})</math>,</p> <p><math>\text{nq0} = \text{numroc}(n + \text{icoffa}, \text{nb}_a, \text{mycol}, \text{iacol}, \text{npcol})</math>,</p> <p><math>\text{ilcm}</math>, <math>\text{iceil}</math>, <math>\text{indxg2p}</math>, and <math>\text{numroc}</math> are ScaLAPACK tool functions; <math>\text{myrow}</math>, <math>\text{mycol}</math>, <math>\text{nprow}</math>, and <math>\text{npcol}</math> can be determined by calling the function <math>\text{blacs\_gridinfo}</math>.</p>

## Output Parameters

*val* The value returned by the function.

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## p?lantr

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a triangular matrix.

## Syntax

```
float pslantr (char *norm , char *uplo , char *diag , MKL_INT *m , MKL_INT *n , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *work );
```

```
double pdlantr (char *norm , char *uplo , char *diag , MKL_INT *m , MKL_INT *n , double
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *work );
```

```
float pclantr (char *norm , char *uplo , char *diag , MKL_INT *m , MKL_INT *n ,

## Description

The `p?lantr` function returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular distributed matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ .

## Input Parameters

<code>norm</code>	(global) Specifies what value is returned by the function: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$ , largest absolute value of the matrix $A$ , it is not a matrix norm. = '1' or 'O' or 'o': $val = \text{norm1}(A)$ , 1-norm of the matrix $A$ (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$ , infinity norm of the matrix $A$ (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$ , Frobenius norm of the matrix $A$ (square root of sum of squares).
<code>uplo</code>	(global) Specifies whether the upper or lower triangular part of the symmetric matrix $\text{sub}(A)$ is to be referenced. = 'U': Upper trapezoidal, = 'L': Lower trapezoidal. Note that $\text{sub}(A)$ is triangular instead of trapezoidal if $m = n$ .
<code>diag</code>	(global) Specifies whether the distributed matrix $\text{sub}(A)$ has unit diagonal.

	= 'N': Non-unit diagonal.
	= 'U': Unit diagonal.
<i>m</i>	(global) The number of rows in the distributed matrix sub(A). When $m = 0$ , <code>p?lantr</code> is set to zero. $m \geq 0$ .
<i>n</i>	(global) The number of columns in the distributed matrix sub(A). When $n = 0$ , <code>p?lantr</code> is set to zero. $n \geq 0$ .
<i>a</i>	(local). Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ containing the local pieces of the distributed matrix sub(A).
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix sub(A), respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A.
<i>work</i>	(local). Array size <i>lwork</i> . $lwork \geq 0$ if <i>norm</i> = 'M' or 'm' (not referenced), $nq0$ if <i>norm</i> = '1', 'O' or 'o', $mp0$ if <i>norm</i> = 'I' or 'i', 0 if <i>norm</i> = 'F', 'f', 'E' or 'e' (not referenced), $irow = \text{mod}(ia-1, mb\_a)$ , $icol = \text{mod}(ja-1, nb\_a)$ , $irow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow)$ , $icol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcol)$ , $mp0 = \text{numroc}(m+irow, mb\_a, myrow, irow, nprow)$ , $nq0 = \text{numroc}(n+icol, nb\_a, mycol, icol, npcol)$ , <code>indxg2p</code> and <code>numroc</code> are ScaLAPACK tool functions; <i>myrow</i> , <i>mycol</i> , <i>nprow</i> , and <i>npcol</i> can be determined by calling the function <code>blacs_gridinfo</code> .

## Output Parameters

*val* The value returned by the function.

*ip , MKL_INT *jp , MKL_INT *descip , MKL_INT *iwork );
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?lapiv` function applies either  $P$  (permutation matrix indicated by `ipiv`) or  $\text{inv}(P)$  to a general  $m$ -by- $n$  distributed matrix  $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ , resulting in row or column pivoting. The pivot vector may be distributed across a process row or a column. The pivot vector should be aligned with the distributed matrix  $A$ . This function will transpose the pivot vector, if necessary.

For example, if the row pivots should be applied to the columns of  $\text{sub}(A)$ , pass `rowcol='C'` and `pivroc='C'`.

## Input Parameters

<code>direc</code>	(global)
	Specifies in which order the permutation is applied:
	= 'F' (Forward): Applies pivots forward from top of matrix. Computes $P * \text{sub}(A)$ .
	= 'B' (Backward): Applies pivots backward from bottom of matrix. Computes $\text{inv}(P) * \text{sub}(A)$ .
<code>rowcol</code>	(global)
	Specifies if the rows or columns are to be permuted:
	= 'R': Rows will be permuted,
	= 'C': Columns will be permuted.
<code>pivroc</code>	(global)
	Specifies whether <code>ipiv</code> is distributed over a process row or column:
	= 'R': <code>ipiv</code> is distributed over a process row,
	= 'C': <code>ipiv</code> is distributed over a process column.
<code>m</code>	(global)

	The number of rows in the distributed matrix sub(A). When $m = 0$ , <code>p?lapiv</code> is set to zero. $m \geq 0$ .
<code>n</code>	(global) The number of columns in the distributed matrix sub(A). When $n = 0$ , <code>p?lapiv</code> is set to zero. $n \geq 0$ .
<code>a</code>	(local). Pointer into the local memory to an array of size <code>lld_a * LOcc(ja+n-1)</code> containing the local pieces of the distributed matrix sub(A).
<code>ia, ja</code>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix sub(A), respectively.
<code>desca</code>	(global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix A.
<code>ipiv</code>	(local) Array of size <code>lipiv</code> ; when <code>rowcol='R' or 'r'</code> : <code>lipiv ≥ LOCr(ia+m-1) + mb_a</code> if <code>pivroc='C' or 'c'</code> , <code>lipiv ≥ LOcc(m + mod(jp-1, nb_p))</code> if <code>pivroc='R' or 'r'</code> , and, when <code>rowcol='C' or 'c'</code> : <code>lipiv ≥ LOCr(n + mod(ip-1, mb_p))</code> if <code>pivroc='C' or 'c'</code> , <code>lipiv ≥ LOcc(ja+n-1) + nb_a</code> if <code>pivroc='R' or 'r'</code> . This array contains the pivoting information. <code>ipiv(i)</code> is the global row (column), local row (column) <i>i</i> was swapped with. When <code>rowcol='R' or 'r'</code> and <code>pivroc='C' or 'c'</code> , or <code>rowcol='C' or 'c'</code> and <code>pivroc='R' or 'r'</code> , the last piece of this array of size <code>mb_a</code> (resp. <code>nb_a</code> ) is used as workspace. In those cases, this array is tied to the distributed matrix A.
<code>ip, jp</code>	(global) The row and column indices in the global matrix P indicating the first row and the first column of the matrix sub(P), respectively.
<code>descip</code>	(global and local) array of size <code>dlen_</code> . The array descriptor for the distributed vector <code>ipiv</code> .
<code>iwork</code>	(local). Array of size <code>ldw</code> , where <code>ldw</code> is equal to the workspace necessary for transposition, and the storage of the transposed <code>ipiv</code> : Let <code>lcm</code> be the least common multiple of <code>nprow</code> and <code>npcol</code> .

```

if( *rowcol == 'r' && *pivroc == 'r') {
    if( nprow == npcol) {
        ldw = LOCr( n_p + (*jp-1)%nb_p ) + nb_p;
    } else {
        ldw = LOCr( n_p + (*jp-1)%nb_p ) +
            nb_p * ceil( ceil(LOcc(n_p)/nb_p) / (lcm/npcol) );
    }
}

```

```

} else if( *rowcol == 'c' && *pivroc == 'c') {
    if( nrow == ncol ) {
        ldw = LOcc( m_p + (*ip-1)%mb_p ) + mb_p;
    } else {
        ldw = LOcc( m_p + (*ip-1)%mb_p ) +
            mb_p *ceil(ceil(LOCr(m_p)/mb_p) / (lcm/nrow) );
    }
} else {
    // iwork is not referenced.

```

## Output Parameters

*a* (local).  
On exit, the local pieces of the permuted distributed submatrix.

## See Also

MKL_INT* ipiv, const MKL_INT* ip, const MKL_INT* jp, const MKL_INT* descip);
```

## Include Files

- mkl\_scalapack.h

## Description

p?lapv2 applies either  $P$  (permutation matrix indicated by *ipiv*) or  $\text{inv}(P)$  to an  $m$ -by- $n$  distributed matrix  $\text{sub}(A)$  denoting  $A(ia:ia+m-1, ja:ja+n-1)$ , resulting in row or column pivoting. The pivot vector should be aligned with the distributed matrix  $A$ . For pivoting the rows of  $\text{sub}(A)$ , *ipiv* should be distributed along a process column and replicated over all process rows. Similarly, *ipiv* should be distributed along a process row and replicated over all process columns for column pivoting.

## Input Parameters

*direc* (global)  
Specifies in which order the permutation is applied:

= 'F' (Forward) Applies pivots Forward from top of matrix. Computes  $P * \text{sub}(A)$ ;  
 = 'B' (Backward) Applies pivots Backward from bottom of matrix. Computes  $\text{inv}(P) * \text{sub}(A)$ .

*rowcol*

(global)

Specifies if the rows or columns are to be permuted:

= 'R' Rows will be permuted,

= 'C' Columns will be permuted.

*m*

(global)

The number of rows to be operated on, i.e. the number of rows of the distributed submatrix  $\text{sub}(A)$ .  $m \geq 0$ .*n*

(global)

The number of columns to be operated on, i.e. the number of columns of the distributed submatrix  $\text{sub}(A)$ .  $n \geq 0$ .*a*Pointer into local memory to an array of size  $lld\_a * LOcc(j\_a + n - 1)$ .On entry, this local array contains the local pieces of the distributed matrix  $\text{sub}(A)$  to which the row or columns interchanges will be applied.*ia*

(global)

The row index in the global array *a* indicating the first row of  $\text{sub}(A)$ .*ja*

(global)

The column index in the global array *a* indicating the first column of  $\text{sub}(A)$ .*desca*

(global and local)

Array of size *dlen\_*.The array descriptor for the distributed matrix *A*.*ipiv*Array, size  $\geq LOCr(m\_a) + mb\_a$  if *rowcol* = 'R',  $LOcc(n\_a) + nb\_a$  otherwise.It contains the pivoting information. *ipiv*[*i* - 1] is the global row (column), local row (column) *i* was swapped with. The last piece of the array of size *mb\_a* or *nb\_a* is used as workspace. *ipiv* is tied to the distributed matrix *A*.*ip*

(global)

The global row index of *ipiv*, which points to the beginning of the submatrix on which to operate.*jp*

(global)

The global column index of *ipiv*, which points to the beginning of the submatrix on which to operate.*descip*

(global and local)

Array of size 8.

The array descriptor for the distributed matrix *ipiv*.

## Output Parameters

*a* On exit, this array contains the local pieces of the permuted distributed matrix.

## p?laqge

*Scales a general rectangular matrix, using row and column scaling factors computed by p?geequ.*

## Syntax

```
void pslaqge (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *r , float *c , float *rowcnd , float *colcnd , float *amax , char
*equed );
```

```
void pdlaqge (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT

char *equed );
```

```
void pzlaqge (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *r , double *c , double *rowcnd , double *colcnd , double
*amax , char *equed );
```

## Include Files

- mkl\_scalapack.h

## Description

The p?laqge function equilibrates a general  $m$ -by- $n$  distributed matrix  $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$  using the row and scaling factors in the vectors  $r$  and  $c$  computed by p?geequ.

## Input Parameters

<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(A)$ . ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(A)$ . ( $n \geq 0$ ).
<i>a</i>	(local). Pointer into the local memory to an array of size $lld\_a * LOCC(\text{ja}+n-1)$ . On entry, this array contains the distributed matrix $\text{sub}(A)$ .
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the matrix $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .

<i>r</i>	(local). Array of size $LOCr(m\_a)$ . The row scale factors for sub(A). <i>r</i> is aligned with the distributed matrix <i>A</i> , and replicated across every process column. <i>r</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local). Array of size $LOCc(n\_a)$ . The row scale factors for sub(A). <i>c</i> is aligned with the distributed matrix <i>A</i> , and replicated across every process column. <i>c</i> is tied to the distributed matrix <i>A</i> .
<i>rowcnd</i>	(local). The global ratio of the smallest $r[i]$ to the largest $r[i]$ , $ia-1 \leq i \leq ia+m-2$ .
<i>colcnd</i>	(local). The global ratio of the smallest $c[i]$ to the largest $c[i]$ , $ia-1 \leq i \leq ia+n-2$ .
<i>amax</i>	(global). Absolute value of largest distributed submatrix entry.

## Output Parameters

<i>a</i>	(local). On exit, the equilibrated distributed matrix. See <i>equed</i> for the form of the equilibrated distributed submatrix.
<i>equed</i>	(global) Specifies the form of equilibration that was done. = 'N': No equilibration = 'R': Row equilibration, that is, sub(A) has been pre-multiplied by $\text{diag}(r[ia-1:ia+m-2])$ , = 'C': column equilibration, that is, sub(A) has been post-multiplied by $\text{diag}(c[ja-1:ja+n-2])$ , = 'B': Both row and column equilibration, that is, sub(A) has been replaced by $\text{diag}(r[ia-1:ia+m-2]) * \text{sub}(A) * \text{diag}(c[ja-1:ja+n-2])$ .

## p?laqr0

*Computes the eigenvalues of a Hessenberg matrix and optionally returns the matrices from the Schur decomposition.*

## Syntax

```
void pslaqr0(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* n, MKL_INT* ilo, MKL_INT* ihi,
float* h, MKL_INT* desch, float* wr, float* wi, MKL_INT* iloz, MKL_INT* ihiz, float* z,
MKL_INT* descz, float* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT*
info, MKL_INT* recllevel);
```

```
void pdlaqr0(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* n, MKL_INT* ilo, MKL_INT* ihi,
double* h, MKL_INT* desch, double* wr, double* wi, MKL_INT* iloz, MKL_INT* ihiz, double*
z, MKL_INT* descz, double* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork,
MKL_INT* info, MKL_INT* recllevel);
```

## Include Files

- mkl\_scalapack.h

## Description

`p?laqr0` computes the eigenvalues of a Hessenberg matrix  $H$  and, optionally, the matrices  $T$  and  $Z$  from the Schur decomposition  $H = Z^*T^*Z^T$ , where  $T$  is an upper quasi-triangular matrix (the Schur form), and  $Z$  is the orthogonal matrix of Schur vectors.

Optionally  $Z$  may be postmultiplied into an input orthogonal matrix  $Q$  so that this function can give the Schur factorization of a matrix  $A$  which has been reduced to the Hessenberg form  $H$  by the orthogonal matrix  $Q$ :  $A = Q * H * Q^T = (QZ) * T * (QZ)^T$ .

## Input Parameters

<code>wantt</code>	(global ) Non-zero : the full Schur form $T$ is required; Zero : only eigenvalues are required.
<code>wantz</code>	(global ) Non-zero : the matrix of Schur vectors $Z$ is required; Zero: Schur vectors are not required.
<code>n</code>	(global ) The order of the Hessenberg matrix $H$ (and $Z$ if <code>wantz</code> is non-zero). $n \geq 0$ .
<code>ilo, ihi</code>	(global ) It is assumed that the matrix $H$ is already upper triangular in rows and columns $1:ilo-1$ and $ihiz+1:n$ . <code>ilo</code> and <code>ihiz</code> are normally set by a previous call to <code>p?gebal</code> , and then passed to <code>p?gehrd</code> when the matrix output by <code>ihiz</code> is reduced to Hessenberg form. Otherwise <code>ilo</code> and <code>ihiz</code> should be set to 1 and <code>n</code> , respectively. If $n > 0$ , then $1 \leq ilo \leq ihiz \leq n$ . If $n = 0$ , then <code>ilo</code> = 1 and <code>ihiz</code> = 0.
<code>h</code>	(global ) array of size $lld_h * LOC_c(n)$ The upper Hessenberg matrix $H$ .
<code>desch</code>	(global and local ) Array of size <code>dlen_</code> . The array descriptor for the distributed matrix $H$ .
<code>iloz, ihiz</code>	Specify the rows of the matrix $Z$ to which transformations must be applied if <code>wantz</code> is non-zero, $1 \leq iloz \leq ilo$ ; $ihiz \leq ihiz \leq n$ .
<code>z</code>	Array of size $lld_z * LOC_c(n)$ . If <code>wantz</code> is non-zero, contains the matrix $Z$ .

	If <i>wantzequals</i> zero, <i>z</i> is not referenced.
<i>descz</i>	(global and local ) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> .
<i>work</i>	(local workspace) array of size <i>lwork</i>
<i>lwork</i>	(local ) The length of the workspace array <i>work</i> .
<i>iwork</i>	(local workspace) array of size <i>liwork</i>
<i>liwork</i>	(local ) The length of the workspace array <i>iwork</i> .
<i>recllevel</i>	(local ) Level of recursion. <i>recllevel</i> = 0 must hold on entry.

## OUTPUT Parameters

<i>h</i>	On exit, if <i>wantt</i> is non-zero, the matrix <i>H</i> is upper quasi-triangular in rows and columns <i>ilo:ihi</i> , with 1-by-1 and 2-by-2 blocks on the main diagonal. The 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with $H(i,i) = H(i+1,i+1)$ and $H(i+1,i)*H(i,i+1) < 0$ . If <i>info</i> = 0 and <i>wanttequals</i> zero, the contents of <i>h</i> are unspecified on exit.
<i>wr, wi</i>	The real and imaginary parts, respectively, of the computed eigenvalues <i>ilo</i> to <i>ihi</i> are stored in the corresponding elements of <i>wr</i> and <i>wi</i> . If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of <i>wr</i> and <i>wi</i> , say the <i>i</i> -th and ( <i>i</i> +1)th, with $wi[i-1] > 0$ and $wi[i] < 0$ . If <i>wantt</i> is non-zero, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in <i>h</i> .
<i>z</i>	Updated matrix with transformations applied only to the submatrix $Z(ilo:ihi,ilo:ihi)$ . If <i>COMPZ</i> = 'I', on exit, if <i>info</i> = 0, <i>z</i> contains the orthogonal matrix <i>Z</i> of the Schur vectors of <i>H</i> . If <i>wantz</i> is non-zero, then $Z(ilo:ihi,iloz:ihiz)$ is replaced by $Z(ilo:ihi,iloz:ihiz)*U$ , when <i>U</i> is the orthogonal/unitary Schur factor of $H(ilo:ihi,ilo:ihi)$ . If <i>wantzequals</i> zero, then <i>z</i> is not defined.
<i>work</i> [0]	On exit, if <i>info</i> = 0, <i>work</i> [0] returns the optimal <i>lwork</i> .
<i>iwork</i> [0]	On exit, if <i>info</i> = 0, <i>iwork</i> [0] returns the optimal <i>liwork</i> .
<i>info</i>	> 0: if <i>info</i> = <i>i</i> , then the function failed to compute all the eigenvalues. Elements 0: <i>ilo</i> -2 and <i>i</i> : <i>n</i> -1 of <i>wr</i> and <i>wi</i> contain those eigenvalues which have been successfully computed.

> 0: if *wantt* equals zero, then the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns *ilo* through *ihi* of the final output value of *H*.

> 0: if *wantt* is non-zero, then (initial value of *H*)\**U* = *U*\*(final value of *H*), where *U* is an orthogonal/unitary matrix. The final value of *H* is upper Hessenberg and quasi-triangular/triangular in rows and columns *info+1* through *ihi*.

> 0: if *wantz* is non-zero, then (final value of  $Z(ilo:ihi, iloz:ihiz)$ )=(initial value of  $Z(ilo:ihi, iloz:ihiz)$ )\**U*, where *U* is the orthogonal/unitary matrix in the previous expression (regardless of the value of *wantt*).

> 0: if *wantz* equals zero, then *z* is not accessed.

## Include Files

- mkl\_scalapack.h

## Description

p?laqr1 is an auxiliary function used to find the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form from columns *ilo* to *ihi*.

This is a modified version of p?lahqr from ScaLAPACK version 1.7.3. The following modifications were made:

- Workspace query functionality was added.
- Aggressive early deflation is implemented.
- Aggressive deflation (looking for two consecutive small subdiagonal elements by PSLACONS) is abandoned.
- The returned Schur form is now in canonical form, i.e., the returned 2-by-2 blocks really correspond to complex conjugate pairs of eigenvalues.
- For some reason, the original version of p?lahqr sometimes did not read out the converged eigenvalues correctly. This is now fixed.

Notice revision #20201201

**Input Parameters**

<i>wantt</i>	(global ) Non-zero : the full Schur form $T$ is required; Zero: only eigenvalues are required.
<i>wantz</i>	Non-zero : the matrix of Schur vectors $Z$ is required; Zero: Schur vectors are not required.
<i>n</i>	(global ) The order of the Hessenberg matrix $A$ (and $Z$ if <i>wantz</i> is non-zero). $n \geq 0$ .
<i>ilo, ihi</i>	(global ) It is assumed that the matrix $A$ is already upper quasi-triangular in rows and columns $ihi+1:n$ , and that $A(ilo,ilo-1) = 0$ (unless $ilo = 1$ ). <i>p?laqr1</i> works primarily with the Hessenberg submatrix in rows and columns $ilo$ to $ihi$ , but applies transformations to all of $H$ if <i>wantt</i> is non-zero. $1 \leq ilo \leq \max(1, ihi); ihi \leq n$ .
<i>a</i>	(global ) array of size $lld\_a * LOC_c(n)$ On entry, the upper Hessenberg matrix $A$ .
<i>desca</i>	(global and local ) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
<i>iloz, ihiz</i>	(global ) Specify the rows of the matrix $Z$ to which transformations must be applied if <i>wantz</i> is non-zero. $1 \leq iloz \leq ilo; ihi \leq ihiz \leq n$ .
<i>z</i>	(global ) array of size $lld\_z * LOC_c(n)$ . If <i>wantz</i> is non-zero, on entry <i>z</i> must contain the current matrix $Z$ of transformations accumulated by <i>p?hseqr</i> . If <i>wantz</i> is zero, <i>z</i> is not referenced.
<i>descz</i>	(global and local ) array of size $dlen\_$ . The array descriptor for the distributed matrix $Z$ .
<i>work</i>	(local output) array of size <i>lwork</i>
<i>lwork</i>	(local ) The size of the work array ( $lwork \geq 1$ ).

	If $lwork=-1$ , then a workspace query is assumed.
$iwork$	(global and local ) array of size $ilwork$ This holds the some of the IBLK integer arrays.
$ilwork$	(local ) The size of the $iwork$ array ( $ilwork \geq 3$ ).

## OUTPUT Parameters

$a$	If $wantt$ is non-zero, the matrix $A$ is upper quasi-triangular in rows and columns $ilo:ihi$ , with any 2-by-2 or larger diagonal blocks not yet in standard form. If $wantt$ equals zero, the contents of $a$ are unspecified on exit.
$wr, wi$	(global replicated ) array of size $n$ The real and imaginary parts, respectively, of the computed eigenvalues $ilo$ to $ihi$ are stored in the corresponding elements of $wr$ and $wi$ . If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of $wr$ and $wi$ , say the $i$ -th and $(i+1)$ th, with $wi[i-1] > 0$ and $wi[i] < 0$ . If $wantt$ is non-zero, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in $a$ . $a$ may be returned with larger diagonal blocks until the next release.
$z$	On exit $z$ is updated; transformations are applied only to the submatrix $Z(ilo:ihiz,ilo:ihi)$ . If $wantz$ equals zero, $z$ is not referenced.
$work[0]$	On exit, if $info = 0$ , $work[0]$ returns the optimal $lwork$ .
$info$	(global ) < 0: parameter number $-info$ incorrect or inconsistent = 0: successful exit > 0: $p?laqr1$ failed to compute all the eigenvalues $ilo$ to $ihi$ in a total of $30*(ihi-ilo+1)$ iterations; if $info = i$ , elements $i:ihi-1$ of $wr$ and $wi$ contain those eigenvalues which have been successfully computed.

## Application Notes

This algorithm is very similar to [p?ahqr](#). Unlike [p?lahqr](#), instead of sending one double shift through the largest unreduced submatrix, this algorithm sends multiple double shifts and spaces them apart so that there can be parallelism across several processor row/columns. Another critical difference is that this algorithm aggregates multiple transforms together in order to apply them in a block fashion.

Current Notes and/or Restrictions:

- This code requires the distributed block size to be square and at least six (6); unlike simpler codes like LU, this algorithm is extremely sensitive to block size. Unwise choices of too small a block size can lead to bad performance.
- This code requires  $a$  and  $z$  to be distributed identically and have identical contexts.
- This release currently does not have a function for resolving the Schur blocks into regular 2x2 form after this code is completed. Because of this, a significant performance impact is required while the deflation is done by sometimes a single column of processors.

- This code does not currently block the initial transforms so that none of the rows or columns for any bulge are completed until all are started. To offset pipeline start-up it is recommended that at least  $2 * \text{LCM}(\text{NPROW}, \text{NPCOL})$  bulges are used (if possible)
- The maximum number of bulges currently supported is fixed at 32. In future versions this will be limited only by the incoming *work* array.
- The matrix *A* must be in upper Hessenberg form. If elements below the subdiagonal are nonzero, the resulting transforms may be nonsimilar. This is also true with the LAPACK function.
- For this release, it is assumed *rsrc\_*=*csrc\_*=0
- Currently, all the eigenvalues are distributed to all the nodes. Future releases will probably distribute the eigenvalues by the column partitioning.
- The internals of this function are subject to change.

## Description

`p?laqr2` accepts as input an upper Hessenberg matrix *A* and performs an orthogonal similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output *A* is overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal similarity transformation of *A*. It is to be hoped that the final version of *A* has many zero subdiagonal entries.

This function handles small deflation windows which is affordable by one processor. Normally, it is called by `p?laqr1`. All the inputs are assumed to be valid without checking.

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

*wantt* (global )

If *wantt* is non-zero, then the Hessenberg matrix *A* is fully updated so that the quasi-triangular Schur factor may be computed (in cooperation with the calling function).

If *wantt* equals zero, then only enough of *A* is updated to preserve the eigenvalues.

*wantz*

(global )

If *wantz* is non-zero, then the orthogonal matrix *Z* is updated so that the orthogonal Schur factor may be computed (in cooperation with the calling function).

If *wantz* equals zero, then *z* is not referenced.

*n*

(global )

The order of the matrix *A* and (if *wantz* is non-zero) the order of the orthogonal matrix *Z*.

*ktop, kbot*

(global )

It is assumed without a check that either  $kbot = n$  or  $A(kbot+1, kbot) = 0$ . *kbot* and *ktop* together determine an isolated block along the diagonal of the Hessenberg matrix. However,  $A(ktop, ktop-1) = 0$  is not essentially necessary if *wantt* is non-zero .

*nw*

(global )

Deflation window size.  $1 \leq nw \leq (kbot - ktop + 1)$ . Normally  $nw \geq 3$  if `p?laqr2` is called by `p?laqr1`.

*a*

(local ) array of size  $lld\_a * LOC_c(n)$

The initial *n*-by-*n* section of *a* stores the Hessenberg matrix undergoing aggressive early deflation.

*desca*

(global and local) array of size *dlen\_*.

The array descriptor for the distributed matrix *A*.

*iloz, ihiz*

(global )

Specify the rows of the matrix *Z* to which transformations must be applied if *wantz* is non-zero.  $1 \leq iloz \leq ihiz \leq n$ .

*z*

Array of size  $lld\_z * LOC_c(n)$

If *wantz* is non-zero, then on output, the orthogonal similarity transformation mentioned above has been accumulated into the matrix  $Z(iloz:ihiz,$

$kbot:ktop)$ , stored in *z*, from the right.

If *wantz* is zero, then *z* is unreferenced.

*descz*

(global and local) array of size *dlen\_*.

The array descriptor for the distributed matrix *Z*.

*t*

(local workspace) array of size  $ldt * nw$ .

*ldt*

(local )

	The leading dimension of the array $t$ . $ldt \geq nw$ .
$v$	(local workspace) array of size $ldv * nw$ .
$ldv$	(local ) The leading dimension of the array $v$ . $ldv \geq nw$ .
$wr, wi$	(local workspace) array of size $kbot$ .
$work$	(local workspace) array of size $lwork$ .
$lwork$	(local ) $work(lwork)$ is a local array and $lwork$ is assumed big enough so that $lwork \geq nw * nw$ .

## OUTPUT Parameters

$a$	On output $a$ has been transformed by an orthogonal similarity transformation, perturbed, and returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.
$z$	
$ns$	(global ) The number of unconverged (that is, approximate) eigenvalues returned in $sr$ and $si$ that may be used as shifts by the calling function.
$nd$	(global ) The number of converged eigenvalues uncovered by this function.
$sr, si$	(global ) array of size $kbot$ On output, the real and imaginary parts of approximate eigenvalues that may be used for shifts are stored in $sr[kbot-nd-ns]$ through $sr[kbot-nd-1]$ and $si[kbot-nd-ns]$ through $si[kbot-nd-1]$ , respectively. On processor #0, the real and imaginary parts of converged eigenvalues are stored in $sr[kbot-nd]$ through $sr[kbot-1]$ and $si[kbot-nd]$ through $si[kbot-1]$ , respectively. On other processors, these entries are set to zero.

## Description

This function accepts as input an upper Hessenberg matrix  $H$  and performs an orthogonal similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output  $H$  is overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal similarity transformation of  $H$ . It is to be hoped that the final version of  $H$  has many zero subdiagonal entries.

## Input Parameters

<i>wantt</i>	(global )	If <i>wantt</i> is non-zero, then the Hessenberg matrix $H$ is fully updated so that the quasi-triangular Schur factor may be computed (in cooperation with the calling function). If <i>wantt</i> equals zero, then only enough of $H$ is updated to preserve the eigenvalues.
<i>wantz</i>	(global )	If <i>wantz</i> is non-zero, then the orthogonal matrix $Z$ is updated so that the orthogonal Schur factor may be computed (in cooperation with the calling function). If <i>wantz</i> equals zero, then $z$ is not referenced.
<i>n</i>	(global )	The order of the matrix $H$ and (if <i>wantz</i> is non-zero), the order of the orthogonal matrix $Z$ .
<i>ktop</i>	(global )	It is assumed that either $ktop = 1$ or $H(ktop,ktop-1)=0$ . <i>kbot</i> and <i>ktop</i> together determine an isolated block along the diagonal of the Hessenberg matrix.
<i>kbot</i>	(global )	It is assumed without a check that either $kbot = n$ or $H(kbot+1,kbot)=0$ . <i>kbot</i> and <i>ktop</i> together determine an isolated block along the diagonal of the Hessenberg matrix.
<i>nw</i>	(global )	Deflation window size. $1 \leq nw \leq (kbot-ktop+1)$ .
<i>h</i>	(local ) array of size $lld_h * LOC_c(n)$	The initial $n$ -by- $n$ section of $H$ stores the Hessenberg matrix undergoing aggressive early deflation.

<i>desch</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>H</i> .
<i>iloz, ihiz</i>	(global ) Specify the rows of the matrix <i>Z</i> to which transformations must be applied if <i>wantz</i> is non-zero. $1 \leq iloz \leq ihiz \leq n$ .
<i>z</i>	Array of size $lld\_z * LOC_c(n)$ If <i>wantz</i> is non-zero, then on output, the orthogonal similarity transformation mentioned above has been accumulated into the matrix $Z(iloz:ihiz, kbot:ktop)$ from the right. If <i>wantz</i> is zero, then <i>z</i> is unreferenced.
<i>descz</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> .
<i>v</i>	(global workspace) array of size $lld\_v * LOC_c(nw)$ An <i>nw</i> -by- <i>nw</i> distributed work array.
<i>descv</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>V</i> .
<i>nh</i>	The number of columns of <i>t</i> . $nh \geq nw$ .
<i>t</i>	(global workspace) array of size $lld\_t * LOC_c(nh)$
<i>desct</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>T</i> .
<i>nv</i>	(global ) The number of rows of work array <i>wv</i> available for workspace. $nv \geq nw$ .
<i>wv</i>	(global workspace) array of size $lld\_w * LOC_c(nw)$
<i>descw</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>wv</i> .
<i>work</i>	(local workspace) array of size <i>lwork</i> .
<i>lwork</i>	(local ) The size of the work array <i>work</i> ( $lwork \geq 1$ ). $lwork = 2 * nw$ suffices, but greater efficiency may result from larger values of <i>lwork</i> . If $lwork = -1$ , then a workspace query is assumed; p?laqr3 only estimates the optimal workspace size for the given values of <i>n</i> , <i>nw</i> , <i>ktop</i> and <i>kbot</i> . The estimate is returned in <i>work</i> [0]. No error message related to <i>lwork</i> is issued by <i>xerbla</i> . Neither <i>h</i> nor <i>z</i> are accessed.
<i>iwork</i>	(local workspace) array of size <i>liwork</i>
<i>liwork</i>	(local ) The length of the workspace array <i>iwork</i> ( $liwork \geq 1$ ).

If *liwork*=-1, then a workspace query is assumed.

## OUTPUT Parameters

<i>h</i>	On output <i>h</i> has been transformed by an orthogonal similarity transformation, perturbed, and the returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.
<i>z</i>	IF <i>wantz</i> is non-zero, then on output, the orthogonal similarity transformation mentioned above has been accumulated into the matrix $Z(i_{loz}:i_{hiz}, k_{bot}:k_{top})$ from the right. If <i>wantz</i> is zero, then <i>z</i> is unreferenced.
<i>ns</i>	(global ) The number of unconverged (that is, approximate) eigenvalues returned in <i>sr</i> and <i>si</i> that may be used as shifts by the calling function.
<i>nd</i>	(global ) The number of converged eigenvalues uncovered by this function.
<i>sr, si</i>	(global ) array of size <i>kbot</i> . The real and imaginary parts of approximate eigenvalues that may be used for shifts are stored in <i>sr</i> [ <i>kbot-nd-ns</i> ] through <i>sr</i> [ <i>kbot-nd-1</i> ] and <i>si</i> [ <i>kbot-nd-ns</i> ] through <i>si</i> [ <i>kbot-nd-1</i> ], respectively. The real and imaginary parts of converged eigenvalues are stored in <i>sr</i> [ <i>kbot-nd</i> ] through <i>sr</i> [ <i>kbot-1</i> ] and <i>si</i> [ <i>kbot-nd</i> ] through <i>si</i> [ <i>kbot-1</i> ], respectively.
<i>work</i> [0]	On exit, if <i>info</i> = 0, <i>work</i> [0] returns the optimal <i>lwork</i>
<i>iwork</i> [0]	On exit, if <i>info</i> = 0, <i>iwork</i> [0] returns the optimal <i>liwork</i>

## Include Files

- mkl\_scalapack.h

## Description

This auxiliary function called by `p?laqr0` performs a single small-bulge multi-shift QR sweep by chasing separated groups of bulges along the main block diagonal of a Hessenberg matrix  $H$ .

## Input Parameters

<code>wantt</code>	(global) scalar <code>wantt</code> is non-zero if the quasi-triangular Schur factor is being computed. <code>wantt</code> is set to zero otherwise.
<code>wantz</code>	(global) scalar <code>wantz</code> is non-zero if the orthogonal Schur factor is being computed. <code>wantz</code> is set to zero otherwise.
<code>kacc22</code>	(global) Value 0, 1, or 2. Specifies the computation mode of far-from-diagonal orthogonal updates. = 0: <code>p?laqr5</code> does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries. = 1: <code>p?laqr5</code> accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries. = 2: <code>p?laqr5</code> accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies.
<code>n</code>	(global) scalar The order of the Hessenberg matrix $H$ and, if <code>wantz</code> is non-zero, the order of the orthogonal matrix $Z$ .
<code>ktop, kbot</code>	(global) scalar These are the first and last rows and columns of an isolated diagonal block upon which the QR sweep is to be applied. It is assumed without a check that either <code>ktop = 1</code> or $H(ktop, ktop-1) = 0$ and either <code>kbot = n</code> or $H(kbot+1, kbot) = 0$ .
<code>nshfts</code>	(global) scalar <code>nshfts</code> gives the number of simultaneous shifts. <code>nshfts</code> must be positive and even.
<code>sr, si</code>	(global) Array of size <code>nshfts</code> <code>sr</code> contains the real parts and <code>si</code> contains the imaginary parts of the <code>nshfts</code> shifts of origin that define the multi-shift QR sweep.
<code>h</code>	(local) Array of size <code>lld_h * LOC_c(n)</code> On input <code>h</code> contains a Hessenberg matrix $H$ .
<code>desch</code>	(global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix $H$ .

<i>iloz, ihiz</i>	(global) Specify the rows of the matrix <i>Z</i> to which transformations must be applied if <i>wantzis</i> non-zero. $1 \leq iloz \leq ihiz \leq n$
<i>z</i>	(local) array of size $lld\_z * LOC_c(n)$ If <i>wantzis</i> non-zero, then the QR Sweep orthogonal similarity transformation is accumulated into the matrix $Z(iloz:ihiz, kbot:ktop)$ from the right. If <i>wantzequals</i> zero, then <i>z</i> is unreferenced.
<i>descz</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> .
<i>work</i>	(local workspace) array of size <i>lwork</i>
<i>lwork</i>	(local) The size of the <i>work</i> array ( $lwork \geq 1$ ). If <i>lwork</i> =-1, then a workspace query is assumed.
<i>iwork</i>	(local workspace) array of size <i>liwork</i>
<i>liwork</i>	(local) The size of the <i>iwork</i> array ( $liwork \geq 1$ ). If <i>liwork</i> =-1, then a workspace query is assumed.

## Output Parameters

<i>h</i>	A multi-shift QR sweep with shifts $sr(j)+i*si(j)$ is applied to the isolated diagonal block in rows and columns <i>ktop</i> through <i>kbot</i> of the matrix <i>H</i> .
<i>z</i>	If <i>wantzis</i> non-zero, <i>z</i> is updated with transformations applied only to the submatrix $Z(iloz:ihiz, kbot:ktop)$ .
<i>work</i> [0]	On exit, if <i>info</i> = 0, <i>work</i> [0] returns the optimal <i>lwork</i> .
<i>iwork</i> [0]	On exit, if <i>info</i> = 0, <i>iwork</i> [0] returns the optimal <i>liwork</i> .

## p?laqsy

*Scales a symmetric/Hermitian matrix, using scaling factors computed by p?poequ.*

## Syntax

```
void pslaqsy (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *sr , float *sc , float *scond , float *amax , char *equet );
void pdlaqsy (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *sr , double *sc , double *scond , double *amax , char *equet );
void pclaqsy (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *sr , float *sc , float *scond , float *amax , char *equet );
```

```
void pzlaqsy (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *sr , double *sc , double *scond , double *amax , char *equed );
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?laqsy` function equilibrates a symmetric distributed matrix  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$  using the scaling factors in the vectors `sr` and `sc`. The scaling factors are computed by `p?poequ`.

## Input Parameters

<code>uplo</code>	(global) Specifies the upper or lower triangular part of the symmetric distributed matrix <code>sub(A)</code> is to be referenced: = 'U': Upper triangular part; = 'L': Lower triangular part.
<code>n</code>	(global) The order of the distributed matrix <code>sub(A)</code> . $n \geq 0$ .
<code>a</code>	(local). Pointer into the local memory to an array of size <code>lld_a * LOCc(ja+n-1)</code> . On entry, this array contains the local pieces of the distributed matrix <code>sub(A)</code> . On entry, the local pieces of the distributed symmetric matrix <code>sub(A)</code> . If <code>uplo = 'U'</code> , the leading $n$ -by- $n$ upper triangular part of <code>sub(A)</code> contains the upper triangular part of the matrix, and the strictly lower triangular part of <code>sub(A)</code> is not referenced. If <code>uplo = 'L'</code> , the leading $n$ -by- $n$ lower triangular part of <code>sub(A)</code> contains the lower triangular part of the matrix, and the strictly upper triangular part of <code>sub(A)</code> is not referenced.
<code>ia, ja</code>	(global) The row and column indices in the global matrix <code>A</code> indicating the first row and the first column of the matrix <code>sub(A)</code> , respectively.
<code>desca</code>	(global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix <code>A</code> .
<code>sr</code>	(local) Array of size <code>LOCr(m_a)</code> . The scale factors for the matrix <code>A(ia:ia+m-1, ja:ja+n-1)</code> . <code>sr</code> is aligned with the distributed matrix <code>A</code> , and replicated across every process column. <code>sr</code> is tied to the distributed matrix <code>A</code> .
<code>sc</code>	(local) Array of size <code>LOCc(m_a)</code> . The scale factors for the matrix <code>A(ia:ia+m-1, ja:ja+n-1)</code> . <code>sc</code> is aligned with the distributed matrix <code>A</code> , and replicated across every process column. <code>sc</code> is tied to the distributed matrix <code>A</code> .
<code>scond</code>	(global).

Ratio of the smallest  $sr[i]$  (respectively  $sc[j]$ ) to the largest  $sr[i]$  (respectively  $sc[j]$ ), with  $ia - 1 \leq i < ia + n - 1$  and  $ja - 1 \leq j < ja + n - 1$ .

*amax*

(global).

Absolute value of largest distributed submatrix entry.

## Output Parameters

*a*

On exit,

if *equed* = 'Y', the equilibrated matrix:

$\text{diag}(sr_{ia}, \dots, sr_{ia+n-1}) * \text{sub}(A) * \text{diag}(sc_{ja}, \dots, sc_{ja+n-1})$ .

*equed*

(global).

Specifies whether or not equilibration was done.

= 'N': No equilibration.

= 'Y': Equilibration was done, that is, sub(A) has been replaced by:

$\text{diag}(sr_{ia}, \dots, sr_{ia+n-1}) * \text{sub}(A) * \text{diag}(sc_{ja}, \dots, sc_{ja+n-1})$ .

## p?lared1d

*Redistributes an array assuming that the input array, bycol, is distributed across rows and that all process columns contain the same copy of bycol.*

## Syntax

```
void pslared1d (MKL_INT *n , MKL_INT *ia , MKL_INT *ja , MKL_INT *desc , float *bycol ,
float *byall , float *work , MKL_INT *lwork );
```

```
void pdlared1d (MKL_INT *n , MKL_INT *ia , MKL_INT *ja , MKL_INT *desc , double
*bycol , double *byall , double *work , MKL_INT *lwork );
```

## Include Files

- mkl\_scalapack.h

## Description

The p?lared1d function redistributes a 1D array. It assumes that the input array *bycol* is distributed across rows and that all process column contain the same copy of *bycol*. The output array *byall* is identical on all processes and contains the entire array.

## Input Parameters

*np* = Number of local rows in *bycol*()

*n*

(global)

The number of elements to be redistributed.  $n \geq 0$ .

*ia, ja*

(global) *ia, ja* must be equal to 1.

*desc*

(local) array of size 9. A 2D array descriptor, which describes *bycol*.

<i>bycol</i>	(local). Distributed block cyclic array of global size $n$ and of local size $np$ . <i>bycol</i> is distributed across the process rows. All process columns are assumed to contain the same value.
<i>work</i>	(local). size <i>lwork</i> . Used to hold the buffers sent from one process to another.
<i>lwork</i>	(local) The size of the <i>work</i> array. $lwork \geq \text{numroc}(n, \text{desc}[\text{nb}_], 0, 0, \text{npcol})$ .

## Output Parameters

<i>byall</i>	(global). Global size $n$ , local size $n$ . <i>byall</i> is exactly duplicated on all processes. It contains the same values as <i>bycol</i> , but it is replicated across all processes rather than being distributed.

## p?lared2d

*Redistributes an array assuming that the input array *byrow* is distributed across columns and that all process rows contain the same copy of *byrow*.*

## Syntax

```
void pslared2d (MKL_INT *n , MKL_INT *ia , MKL_INT *ja , MKL_INT *desc , float *byrow ,
float *byall , float *work , MKL_INT *lwork );
```

```
void pdlared2d (MKL_INT *n , MKL_INT *ia , MKL_INT *ja , MKL_INT *desc , double
*byrow , double *byall , double *work , MKL_INT *lwork );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?lared2d` function redistributes a 1D array. It assumes that the input array *byrow* is distributed across columns and that all process rows contain the same copy of *byrow*. The output array *byall* will be identical on all processes and will contain the entire array.

## Input Parameters

$np$  = Number of local rows in *byrow*()

$n$	(global) The number of elements to be redistributed. $n \geq 0$ .
$ia, ja$	(global) $ia, ja$ must be equal to 1.
<i>desc</i>	(local) array of size $dlen_$ . A 2D array descriptor, which describes <i>byrow</i> .

<i>byrow</i>	(local). Distributed block cyclic array of global size $n$ and of local size $np$ . <i>byrow</i> is distributed across the process columns. All process rows are assumed to contain the same value.
<i>work</i>	(local). size <i>lwork</i> . Used to hold the buffers sent from one process to another.
<i>lwork</i>	(local) The size of the <i>work</i> array. $lwork \geq \text{numroc}(n, \text{desc}[nb\_], 0, 0, npcol)$ .

## Output Parameters

<i>byall</i>	(global). Global size $n$ , local size $n$ . <i>byall</i> is exactly duplicated on all processes. It contains the same values as <i>byrow</i> , but it is replicated across all processes rather than being distributed.

```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?larf` function applies a real/complex elementary reflector  $Q$  (or  $Q^T$ ) to a real/complex  $m$ -by- $n$  distributed matrix  $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ , from either the left or the right.  $Q$  is represented in the form

$$Q = I - \tau * v * v',$$

where  $\tau$  is a real/complex scalar and  $v$  is a real/complex vector.

If  $\tau = 0$ , then  $Q$  is taken to be the unit matrix.

## Input Parameters

<i>side</i>	(global). = 'L': form $Q^* \text{sub}(C)$ , = 'R': form $\text{sub}(C) * Q$ , $Q=Q^T$ .
<i>m</i>	(global) The number of rows in the distributed submatrix $\text{sub}(A)$ . ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the distributed submatrix $\text{sub}(A)$ . ( $n \geq 0$ ).
<i>v</i>	(local). Pointer into the local memory to an array of size $lld\_v * LOCC(n\_v)$ , containing the local pieces of the global distributed matrix $V$ representing the Householder transformation $Q$ , $V(iv:iv+m-1, jv)$ if $side = 'L'$ and $incv = 1$ , $V(iv, jv:jv+m-1)$ if $side = 'L'$ and $incv = m\_v$ , $V(iv:iv+n-1, jv)$ if $side = 'R'$ and $incv = 1$ , $V(iv, jv:jv+n-1)$ if $side = 'R'$ and $incv = m\_v$ . The array $v$ is the representation of $Q$ . $v$ is not used if $tau = 0$ .
<i>iv, jv</i>	(global) The row and column indices in the global matrix $V$ indicating the first row and the first column of the matrix $\text{sub}(V)$ , respectively.
<i>descv</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $V$ .
<i>incv</i>	(global) The global increment for the elements of $V$ . Only two values of $incv$ are supported in this version, namely 1 and $m\_v$ . $incv$ must not be zero.
<i>tau</i>	(local). Array of size $LOCC(jv)$ if $incv = 1$ , and $LOCr(iv)$ otherwise. This array contains the Householder scalars related to the Householder vectors. $tau$ is tied to the distributed matrix $V$ .
<i>c</i>	(local). Pointer into the local memory to an array of size $lld\_c * LOCC(jc+n-1)$ , containing the local pieces of $\text{sub}(C)$ .
<i>ic, jc</i>	(global) The row and column indices in the global matrix $C$ indicating the first row and the first column of the matrix $\text{sub}(C)$ , respectively.
<i>desc</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $C$ .
<i>work</i>	(local).

Array of size *lwork*.

```

## Description

The `p?larfb` function applies a real/complex block reflector  $Q$  or its transpose  $Q^T$ /conjugate transpose  $Q^H$  to a real/complex distributed  $m$ -by- $n$  matrix  $\text{sub}(C) = C(\text{ic}:\text{ic}+m-1, \text{jc}:\text{jc}+n-1)$  from the left or the right.

## Input Parameters

<code>side</code>	(global) if $\text{side} = 'L'$ : apply $Q$ or $Q^T$ for real flavors ( $Q^H$ for complex flavors) from the Left; if $\text{side} = 'R'$ : apply $Q$ or $Q^T$ for real flavors ( $Q^H$ for complex flavors) from the Right.
<code>trans</code>	(global) if $\text{trans} = 'N'$ : no transpose, apply $Q$ ; for real flavors, if $\text{trans} = 'T'$ : transpose, apply $Q^T$ for complex flavors, if $\text{trans} = 'C'$ : conjugate transpose, apply $Q^H$ ;
<code>direct</code>	(global) Indicates how $Q$ is formed from a product of elementary reflectors. if $\text{direct} = 'F'$ : $Q = H(1) * H(2) * \dots * H(k)$ (Forward) if $\text{direct} = 'B'$ : $Q = H(k) * \dots * H(2) * H(1)$ (Backward)

<i>storev</i>	(global) Indicates how the vectors that define the elementary reflectors are stored: if <i>storev</i> = 'C': Columnwise if <i>storev</i> = 'R': Rowwise.
<i>m</i>	(global) The number of rows in the distributed matrix sub(C). ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the distributed matrix sub(C). ( $n \geq 0$ ).
<i>k</i>	(global) The order of the matrix T.
<i>v</i>	(local). Pointer into the local memory to an array of size <i>lld_v</i> * <i>LOCc</i> ( <i>qv</i> + <i>k</i> -1) if <i>storev</i> = 'C', <i>lld_v</i> * <i>LOCc</i> ( <i>qv</i> + <i>m</i> -1) if <i>storev</i> = 'R' and <i>side</i> = 'L', <i>lld_v</i> * <i>LOCc</i> ( <i>qv</i> + <i>n</i> -1) if <i>storev</i> = 'R' and <i>side</i> = 'R'. It contains the local pieces of the distributed vectors <i>V</i> representing the Householder transformation. if <i>storev</i> = 'C' and <i>side</i> = 'L', $lld\_v \geq \max(1, LOCr(iv+m-1))$ ; if <i>storev</i> = 'C' and <i>side</i> = 'R', $lld\_v \geq \max(1, LOCr(iv+n-1))$ ; if <i>storev</i> = 'R', $lld\_v \geq LOCr(qv+k-1)$ .
<i>iv, qv</i>	(global) The row and column indices in the global matrix <i>V</i> indicating the first row and the first column of the matrix sub( <i>V</i> ), respectively.
<i>descv</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>V</i> .
<i>c</i>	(local). Pointer into the local memory to an array of size <i>lld_c</i> * <i>LOCc</i> ( <i>qc</i> + <i>n</i> -1), containing the local pieces of sub(C).
<i>ic, qc</i>	(global) The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the matrix sub(C), respectively.
<i>descC</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local). Workspace array of size <i>lwork</i> . If <i>storev</i> = 'C', if <i>side</i> = 'L', $lwork \geq (nqc0 + mpc0) * k$

```

else if side = 'R',
  lwork ≥ ( nqc0 + max( npv0 + numroc( numroc( n +
    icoffc, nb_v, 0, 0, npcol ), nb_v, 0, 0, lcmq ),
    mpc0 ) ) * k
end if
else if storev = 'R' ,
  if side = 'L' ,
    lwork ≥ ( mpc0 + max( mqv0 + numroc( numroc( m +
      iroffc, mb_v, 0, 0, nproW ), mb_v, 0, 0, lcmp ),
      nqc0 ) ) * k
  else if side = 'R',

## Description

The `p?larfg` function generates a real/complex elementary reflector  $H$  of order  $n$ , such that

$$H * \text{sub}(X) = H * \begin{pmatrix} x(\text{iax}, \text{jax}) \\ x \end{pmatrix} = \begin{pmatrix} \text{alpha} \\ 0 \end{pmatrix}, \quad H^* H = I,$$

where  $\text{alpha}$  is a scalar (a real scalar - for complex flavors), and  $\text{sub}(X)$  is an  $(n-1)$ -element real/complex distributed vector  $X(\text{ix}:\text{ix}+n-2, \text{jx})$  if  $\text{incx} = 1$  and  $X(\text{ix}, \text{jx}:\text{jx}+n-2)$  if  $\text{incx} = m_x$ .  $H$  is represented in the form

$$H = I - \text{tau} * \begin{pmatrix} 1 \\ v \end{pmatrix} * (1 \ v')$$

where  $\text{tau}$  is a real/complex scalar and  $v$  is a real/complex  $(n-1)$ -element vector. Note that  $H$  is not Hermitian.

If the elements of  $\text{sub}(X)$  are all zero (and  $X(\text{iax}, \text{jax})$  is real for complex flavors), then  $\text{tau} = 0$  and  $H$  is taken to be the unit matrix.

Otherwise  $1 \leq \text{real}(\text{tau}) \leq 2$  and  $\text{abs}(\text{tau}-1) \leq 1$ .

## Input Parameters

$n$	(global) The global order of the elementary reflector. $n \geq 0$ .
$\text{iax}, \text{jax}$	(global) The global row and column indices of $X(\text{iax}, \text{jax})$ in the global matrix $X$ .
$x$	(local). Pointer into the local memory to an array of size $\text{lld}_x * \text{LOCc}(n_x)$ . This array contains the local pieces of the distributed vector $\text{sub}(X)$ . Before entry, the incremented array $\text{sub}(X)$ must contain vector $x$ .
$\text{ix}, \text{jx}$	(global) The row and column indices in the global matrix $X$ indicating the first row and the first column of $\text{sub}(X)$ , respectively.
$\text{descx}$	(global and local) Array of size $\text{dlen}_x$ . The array descriptor for the distributed matrix $X$ .

*incx* (global)  
The global increment for the elements of  $x$ . Only two values of *incx* are supported in this version, namely 1 and  $m_x$ . *incx* must not be zero.

## Output Parameters

*alpha* (local)  
On exit, *alpha* is computed in the process scope having the vector sub( $X$ ).

*x* (local).  
On exit, it is overwritten with the vector  $v$ .

*tau* (local).  
Array of size  $LOCc(jx)$  if  $incx = 1$ , and  $LOCr(ix)$  otherwise. This array contains the Householder scalars related to the Householder vectors.  
*tau* is tied to the distributed matrix  $X$ .

## p?larft

Forms the triangular vector  $T$  of a block reflector  $H=I-V^*T^*V^H$ .

## Syntax

```
void pslarft (char *direct , char *storev , MKL_INT *n , MKL_INT *k , float *v , MKL_INT
*iv , MKL_INT *jv , MKL_INT *descv , float *tau , float *t , float *work );

void pdlarft (char *direct , char *storev , MKL_INT *n , MKL_INT *k , double *v ,
MKL_INT *iv , MKL_INT *jv , MKL_INT *descv , double *tau , double *t , double *work );

void pclarft (char *direct , char *storev , MKL_INT *n , MKL_INT *k , MKL_Complex8 *v ,
MKL_INT *iv , MKL_INT *jv , MKL_INT *descv , MKL_Complex8 *tau , MKL_Complex8 *t ,
MKL_Complex8 *work );

void pzlarft (char *direct , char *storev , MKL_INT *n , MKL_INT *k , MKL_Complex16
*v , MKL_INT *iv , MKL_INT *jv , MKL_INT *descv , MKL_Complex16 *tau , MKL_Complex16
*t , MKL_Complex16 *work );
```

## Include Files

- mkl\_scalapack.h

## Description

The p?larft function forms the triangular factor  $T$  of a real/complex block reflector  $H$  of order  $n$ , which is defined as a product of  $k$  elementary reflectors.

If *direct* = 'F',  $H = H(1)*H(2) \dots *H(k)$ , and  $T$  is upper triangular;

If *direct* = 'B',  $H = H(k)* \dots *H(2)*H(1)$ , and  $T$  is lower triangular.

If *storev* = 'C', the vector which defines the elementary reflector  $H(i)$  is stored in the  $i$ -th column of the distributed matrix  $V$ , and

$$H = I - V^*T^*V'$$

If  $storev = 'R'$ , the vector which defines the elementary reflector  $H(i)$  is stored in the  $i$ -th row of the distributed matrix  $V$ , and

$$H = I - V' * T * V.$$

## Input Parameters

<i>direct</i>	(global) Specifies the order in which the elementary reflectors are multiplied to form the block reflector: if $direct = 'F'$ : $H = H(1) * H(2) * \dots * H(k)$ (forward) if $direct = 'B'$ : $H = H(k) * \dots * H(2) * H(1)$ (backward).
<i>storev</i>	(global) Specifies how the vectors that define the elementary reflectors are stored (See <i>Application Notes</i> below): if $storev = 'C'$ : columnwise; if $storev = 'R'$ : rowwise.
<i>n</i>	(global) The order of the block reflector $H$ . $n \geq 0$ .
<i>k</i>	(global) The order of the triangular factor $T$ , is equal to the number of elementary reflectors. $1 \leq k \leq mb\_v (= nb\_v)$ .
<i>v</i>	Pointer into the local memory to an array of local size $LOCr(iv+n-1) * LOCc(jv+k-1)$ if $storev = 'C'$ , and $LOCr(iv+k-1) * LOCc(jv+n-1)$ if $storev = 'R'$ . The distributed matrix $V$ contains the Householder vectors. (See <i>Application Notes</i> below).
<i>iv, jv</i>	(global) The row and column indices in the global matrix $V$ indicating the first row and the first column of the matrix $sub(V)$ , respectively.
<i>descv</i>	(local) array of size $dlen\_$ . The array descriptor for the distributed matrix $V$ .
<i>tau</i>	(local) Array of size $LOCr(iv+k-1)$ if $incv = m\_v$ , and $LOCc(jv+k-1)$ otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix $V$ .
<i>work</i>	(local). Workspace array of size $k*(k-1)/2$ .

## Output Parameters

$v$

$t$

(local)

Array of size  $nb_v * nb_v$  if  $storev = 'C'$ , and  $mb_v * mb_v$  otherwise. It contains the  $k$ -by- $k$  triangular factor of the block reflector associated with  $v$ . If  $direct = 'F'$ ,  $t$  is upper triangular;

if  $direct = 'B'$ ,  $t$  is lower triangular.

## Application Notes

The shape of the matrix  $V$  and the storage of the vectors that define the  $H(i)$  is best illustrated by the following example with  $n = 5$  and  $k = 3$ . The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

$direct = 'F'$  and  $storev = 'C'$  :

$$V(iv : iv + n - 1, \\ jv : jv + k - 1) = \begin{bmatrix} 1 & & & & \\ v1 & 1 & & & \\ v1 & v2 & 1 & & \\ v1 & v2 & v3 & & \\ v1 & v2 & v3 & & \end{bmatrix}$$

$direct = 'F'$  and  $storev = 'R'$

$$V(iv : iv + k - 1, \\ jv : jv + n - 1) = \begin{bmatrix} 1 & v1 & v1 & v1 & \\ & 1 & v2 & v2 & \\ & & 1 & v3 & \\ & & & 1 & \\ & & & & 1 \end{bmatrix}$$

$direct = 'B'$  and  $storev = 'C'$

$$V(iv : iv + n - 1, \\ jv : jv + k - 1) = \begin{bmatrix} v1 & v2 & v3 & & \\ v1 & v2 & v3 & & \\ 1 & v2 & v3 & & \\ & 1 & v3 & & \\ & & & 1 & \end{bmatrix}$$

$direct = 'B'$  and  $storev = 'R'$

$$V(iv : iv + k - 1, \\ jv : jv + n - 1) = \begin{bmatrix} v1 & v1 & 1 & & \\ v2 & v2 & v2 & 1 & \\ v3 & v3 & v3 & v3 & 1 \end{bmatrix}$$

## Description

The `p?larz` function applies a real/complex elementary reflector  $Q$  (or  $Q^T$ ) to a real/complex  $m$ -by- $n$  distributed matrix  $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ , from either the left or the right.  $Q$  is represented in the form

$$Q = I - \tau * v * v',$$

where  $\tau$  is a real/complex scalar and  $v$  is a real/complex vector.

If  $\tau = 0$ , then  $Q$  is taken to be the unit matrix.

$Q$  is a product of  $k$  elementary reflectors as returned by `p?tzzrf`.

## Input Parameters

<code>side</code>	(global) if <code>side = 'L'</code> : form $Q * \text{sub}(C)$ , if <code>side = 'R'</code> : form $\text{sub}(C) * Q$ , $Q = Q^T$ (for real flavors).
<code>m</code>	(global) The number of rows in the distributed matrix $\text{sub}(C)$ . ( $m \geq 0$ ).
<code>n</code>	(global) The number of columns in the distributed matrix $\text{sub}(C)$ . ( $n \geq 0$ ).
<code>l</code>	(global) The columns of the distributed matrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. If <code>side = 'L'</code> , $m \geq l \geq 0$ , if <code>side = 'R'</code> , $n \geq l \geq 0$ .
<code>v</code>	(local). Pointer into the local memory to an array of size $lld_v * LOCc(n_v)$ containing the local pieces of the global distributed matrix $V$ representing the Householder transformation $Q$ , $V(iv:iv+l-1, jv)$ if <code>side = 'L'</code> and <code>incv = 1</code> , $V(iv, jv:jv+l-1)$ if <code>side = 'L'</code> and <code>incv = m_v</code> , $V(iv:iv+l-1, jv)$ if <code>side = 'R'</code> and <code>incv = 1</code> , $V(iv, jv:jv+l-1)$ if <code>side = 'R'</code> and <code>incv = m_v</code> . The vector $v$ in the representation of $Q$ . $v$ is not used if $\tau = 0$ .

<i>iv, jv</i>	(global) The row and column indices in the global distributed matrix <i>V</i> indicating the first row and the first column of the matrix sub( <i>V</i> ), respectively.
<i>descv</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>V</i> .
<i>incv</i>	(global) The global increment for the elements of <i>V</i> . Only two values of <i>incv</i> are supported in this version, namely 1 and <i>m_v</i> . <i>incv</i> must not be zero.
<i>tau</i>	(local) Array of size <i>LOCc(jv)</i> if <i>incv</i> = 1, and <i>LOCr(iv)</i> otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix <i>V</i> .
<i>c</i>	(local). Pointer into the local memory to an array of size <i>lld_c</i> * <i>LOCc(jc+n-1)</i> , containing the local pieces of sub( <i>C</i> ).
<i>ic, jc</i>	(global) The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the matrix sub( <i>C</i> ), respectively.
<i>desc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local). Array of size <i>lwork</i> If <i>incv</i> = 1, if <i>side</i> = 'L' , if <i>ivcol</i> = <i>iccol</i> , <i>lwork</i> ≥ <i>NqC0</i> else <i>lwork</i> ≥ <i>MpC0</i> + max(1, <i>NqC0</i> ) end if else if <i>side</i> = 'R' , <i>lwork</i> ≥ <i>NqC0</i> + max(max(1, <i>MpC0</i> ), numroc(numroc( <i>n</i> + <i>icoffc</i> , <i>nb_v</i> , 0, 0, <i>npcol</i> ), <i>nb_v</i> , 0, 0, <i>lcmq</i> )) end if else if <i>incv</i> = <i>m_v</i> , if <i>side</i> = 'L' , <i>lwork</i> ≥ <i>MpC0</i> + max(max(1, <i>NqC0</i> ), numroc(numroc( <i>m</i> + <i>iroffc</i> , <i>mb_v</i> , 0, 0, <i>nprow</i> ), <i>mb_v</i> , 0, 0, <i>lcmp</i> )) else if <i>side</i> = 'R' ,

```

        if ivrow = icrow,
            lwork ≥ MpC0
        else
            lwork ≥ NqC0 + max(1, MpC0)
        end if
    end if
end if.

```

Here *lcm* is the least common multiple of *nproW* and *npcol* and

```
lcm = ilcm( nproW, npcol ), lcmp = lcm / nproW,
```

```
lcmq = lcm / npcol,
```

```
iroffc = mod( ic-1, mb_c ), icoffc = mod( jc-1, nb_c ),
```

```
icrow = indxg2p( ic, mb_c, myrow, rsrc_c, nproW ),
```

```
iccol = indxg2p( jc, nb_c, mycol, csrc_c, npcol ),
```

```
mpc0 = numroc( m+iroffc, mb_c, myrow, icrow, nproW ),
```

```
nqc0 = numroc( n+icoffc, nb_c, mycol, iccol, npcol ),
```

*ilcm*, *indxg2p*, and *numroc* are ScaLAPACK tool functions; *myrow*, *mycol*, *nproW*, and *npcol* can be determined by calling the function `blacs_gridinfo`.

## Output Parameters

*c*

(local).

On exit, *sub(C)* is overwritten by the  $Q \cdot \text{sub}(C)$  if *side* = 'L', or  $\text{sub}(C) \cdot Q$  if *side* = 'R'.

## Description

The `p?larzbf` function applies a real/complex block reflector  $Q$  or its transpose  $Q^T$  (conjugate transpose  $Q^H$  for complex flavors) to a real/complex distributed  $m$ -by- $n$  matrix  $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$  from the left or the right.

$Q$  is a product of  $k$  elementary reflectors as returned by `p?tzrzf`.

Currently, only `storev = 'R'` and `direct = 'B'` are supported.

## Input Parameters

<code>side</code>	(global) if <code>side = 'L'</code> : apply $Q$ or $Q^T$ ( $Q^H$ for complex flavors) from the Left; if <code>side = 'R'</code> : apply $Q$ or $Q^T$ ( $Q^H$ for complex flavors) from the Right.
<code>trans</code>	(global) if <code>trans = 'N'</code> : No transpose, apply $Q$ ; If <code>trans='T'</code> : Transpose, apply $Q^T$ (real flavors); If <code>trans='C'</code> : Conjugate transpose, apply $Q^H$ (complex flavors).
<code>direct</code>	(global) Indicates how $H$ is formed from a product of elementary reflectors. if <code>direct = 'F'</code> : $H = H(1)*H(2)*\dots*H(k)$ - forward (not supported) ; if <code>direct = 'B'</code> : $H = H(k)*\dots*H(2)*H(1)$ - backward.
<code>storev</code>	(global) Indicates how the vectors that define the elementary reflectors are stored: if <code>storev = 'C'</code> : columnwise (not supported) . if <code>storev = 'R'</code> : rowwise.
<code>m</code>	(global) The number of rows in the distributed submatrix $\text{sub}(C)$ . ( $m \geq 0$ ).
<code>n</code>	(global) The number of columns in the distributed submatrix $\text{sub}(C)$ . ( $n \geq 0$ ).
<code>k</code>	(global)

	The order of the matrix $T$ . (= the number of elementary reflectors whose product defines the block reflector).
$l$	(global) The columns of the distributed submatrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. If $side = 'L', m \geq l \geq 0$ , if $side = 'R', n \geq l \geq 0$ .
$v$	(local). Pointer into the local memory to an array of size $lld_v * LOCC(jv+m-1)$ if $side = 'L', lld_v * LOCC(jv+m-1)$ if $side = 'R'$ . It contains the local pieces of the distributed vectors $V$ representing the Householder transformation as returned by <code>p?tzrzf</code> . $lld_v \geq LOCr(iv+k-1)$ .
$iv, jv$	(global) The row and column indices in the global matrix $V$ indicating the first row and the first column of the submatrix $\text{sub}(V)$ , respectively.
$descv$	(global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $V$ .
$t$	(local) Array of size $mb_v * mb_v$ . The lower triangular matrix $T$ in the representation of the block reflector.
$c$	(local). Pointer into the local memory to an array of size $lld_c * LOCC(jc+n-1)$ . On entry, the $m$ -by- $n$ distributed matrix $\text{sub}(C)$ .
$ic, jc$	(global) The row and column indices in the global matrix $C$ indicating the first row and the first column of the submatrix $\text{sub}(C)$ , respectively.
$descC$	(global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $C$ .
$work$	(local).

Array of size *lwork*.

```

If storev = 'C' ,
  if side = 'L' ,
    lwork ≥ (nqc0 + mpc0) * k
  else if side = 'R' ,
    lwork ≥ (nqc0 + max(npv0 + numroc(numroc(n+icoffc, nb_v, 0, 0,
npcol),
    nb_v, 0, 0, lcmq), mpc0)) * k
  end if
else if storev = 'R' ,
  if side = 'L' ,
    lwork ≥ (mpc0 + max(mqv0 + numroc(numroc(m+iroffc, mb_v, 0, 0,
nprow),
    mb_v, 0, 0, lcmp), nqc0)) * k
  else if side = 'R' ,
    lwork ≥ (mpc0 + nqc0) * k
  end if
end if.

```

Here  $lcmq = lcm/npcol$  with  $lcm = iclm(nprow, npcol)$ ,  
 $iroffv = \text{mod}(iv-1, mb_v)$ ,  $icoffv = \text{mod}(jv-1, nb_v)$ ,  
 $ivrow = \text{indxg2p}(iv, mb_v, myrow, rsrc_v, nprow)$ ,  
 $ivcol = \text{indxg2p}(jv, nb_v, mycol, csrc_v, npcol)$ ,  
 $mqv0 = \text{numroc}(m+icoffv, nb_v, mycol, ivcol, npcol)$ ,  
 $npv0 = \text{numroc}(n+iroffv, mb_v, myrow, ivrow, nprow)$ ,  
 $iroffc = \text{mod}(ic-1, mb_c)$ ,  $icoffc = \text{mod}(jc-1, nb_c)$ ,  
 $icrow = \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprow)$ ,  
 $iccol = \text{indxg2p}(jc, nb_c, mycol, csrc_c, npcol)$ ,  
 $mpc0 = \text{numroc}(m+iroffc, mb_c, myrow, icrow, nprow)$ ,  
 $npc0 = \text{numroc}(n+icoffc, mb_c, myrow, icrow, nprow)$ ,  
 $nqc0 = \text{numroc}(n+icoffc, nb_c, mycol, iccol, npcol)$ ,  
 $iclm$ ,  $\text{indxg2p}$ , and  $\text{numroc}$  are ScaLAPACK tool functions;  $myrow$ ,  $mycol$ ,  
 $nprow$ , and  $npcol$  can be determined by calling the function  
 $\text{blacs\_gridinfo}$ .

## Output Parameters

*c*

(local).

On exit,  $\text{sub}(C)$  is overwritten by the  $Q^* \text{sub}(C)$ , or  $Q' * \text{sub}(C)$ , or  $\text{sub}(C) * Q$ , or  $\text{sub}(C) * Q'$ , where  $Q'$  is the transpose (conjugate transpose) of  $Q$ .

## Description

The `p?larzc` function applies a complex elementary reflector  $Q^H$  to a complex  $m$ -by- $n$  distributed matrix  $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ , from either the left or the right.  $Q$  is represented in the form

$$Q = I - \tau * v * v',$$

where  $\tau$  is a complex scalar and  $v$  is a complex vector.

If  $\tau = 0$ , then  $Q$  is taken to be the unit matrix.

$Q$  is a product of  $k$  elementary reflectors as returned by `p?tzrzf`.

## Input Parameters

<code>side</code>	(global) if <code>side = 'L'</code> : form $Q^H * \text{sub}(C)$ ; if <code>side = 'R'</code> : form $\text{sub}(C) * Q^H$ .
<code>m</code>	(global) The number of rows in the distributed matrix $\text{sub}(C)$ . ( $m \geq 0$ ).
<code>n</code>	(global) The number of columns in the distributed matrix $\text{sub}(C)$ . ( $n \geq 0$ ).
<code>l</code>	(global) The columns of the distributed matrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. If <code>side = 'L'</code> , $m \geq l \geq 0$ ,

	if $side = 'R', n \geq l \geq 0$ .
$v$	(local).  Pointer into the local memory to an array of size $lld_v * LOCC(n_v)$ containing the local pieces of the global distributed matrix $V$ representing the Householder transformation $Q$ , $V(iv:iv+l-1, jv)$ if $side = 'L'$ and $incv = 1$ , $V(iv, jv:jv+l-1)$ if $side = 'L'$ and $incv = m_v$ , $V(iv:iv+l-1, jv)$ if $side = 'R'$ and $incv = 1$ , $V(iv, jv:jv+l-1)$ if $side = 'R'$ and $incv = m_v$ .  The vector $v$ in the representation of $Q$ . $v$ is not used if $tau = 0$ .
$iv, jv$	(global)  The row and column indices in the global matrix $V$ indicating the first row and the first column of the matrix $sub(V)$ , respectively.
$descv$	(global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $V$ .
$incv$	(global)  The global increment for the elements of $V$ . Only two values of $incv$ are supported in this version, namely 1 and $m_v$ .  $incv$ must not be zero.
$tau$	(local)  Array of size $LOCC(jv)$ if $incv = 1$ , and $LOCr(iv)$ otherwise. This array contains the Householder scalars related to the Householder vectors.  $tau$ is tied to the distributed matrix $V$ .
$c$	(local).  Pointer into the local memory to an array of size $lld_c * LOCC(jc+n-1)$ , containing the local pieces of $sub(C)$ .
$ic, jc$	(global)  The row and column indices in the global matrix $C$ indicating the first row and the first column of the matrix $sub(C)$ , respectively.
$descC$	(global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $C$ .
$work$	(local).  If $incv = 1$ , if $side = 'L'$ , if $ivcol = iccol$ , $lwork \geq nqc0$ else $lwork \geq mpc0 + \max(1, nqc0)$ end if else if $side = 'R'$ , $lwork \geq nqc0 + \max(\max(1, mpc0), \text{numroc}(\text{numroc}(n+icoffc, nb_v,$

```

0, 0, npcol),
    nb_v, 0, 0, lcmq) end if
else if incv = m_v,
    if side = 'L' ,
        lwork ≥ mpc0 + max(max(1, nqc0), numroc(numroc(m+iroffc, mb_v,
0, 0, nrow),
            mb_v, 0, 0, lcmp))
    else if side = 'R',
        if ivrow = icrow,
            lwork ≥ mpc0
        else
            lwork ≥ nqc0 + max(1, mpc0)
        end if
    end if
end if
end if

```

Here *lcm* is the least common multiple of *nrow* and *ncol*;

```
lcm = ilcm(nrow, ncol), lcmp = lcm/nrow, lcmq= lcm/ncol,
```

```
iroffc = mod(ic-1, mb_c), icoffc= mod(jc-1, nb_c),
```

```
icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nrow),
```

```
iccol = indxg2p(jc, nb_c, mycol, csrc_c, ncol),
```

```
mpc0 = numroc(m+iroffc, mb_c, myrow, icrow, nrow),
```

```
nqc0 = numroc(n+icoffc, nb_c, mycol, iccol, ncol),
```

*ilcm*, *indxg2p*, and *numroc* are ScaLAPACK tool functions;

*myrow*, *mycol*, *nrow*, and *ncol* can be determined by calling the function `blacs_gridinfo`.

## Output Parameters

*c* (local).

On exit, *sub(C)* is overwritten by the  $Q^H \cdot \text{sub}(C)$  if *side* = 'L', or  $\text{sub}(C) \cdot Q^H$  if *side* = 'R'.

*t , MKL_Complex16 *work );
```

## Include Files

- mkl\_scalapack.h

## Description

The `pzlarzt` function forms the triangular factor  $T$  of a real/complex block reflector  $H$  of order greater than  $n$ , which is defined as a product of  $k$  elementary reflectors as returned by `pztzrzf`.

If  $direct = 'F'$ ,  $H = H(1)*H(2)*\dots*H(k)$ , and  $T$  is upper triangular;

If  $direct = 'B'$ ,  $H = H(k)*\dots*H(2)*H(1)$ , and  $T$  is lower triangular.

If  $storev = 'C'$ , the vector which defines the elementary reflector  $H(i)$ , is stored in the  $i$ -th column of the array  $v$ , and

$$H = I - v * t * v'$$

If  $storev = 'R'$ , the vector, which defines the elementary reflector  $H(i)$ , is stored in the  $i$ -th row of the array  $v$ , and

$$H = I - v' * t * v$$

Currently, only  $storev = 'R'$  and  $direct = 'B'$  are supported.

## Input Parameters

<code>direct</code>	(global) Specifies the order in which the elementary reflectors are multiplied to form the block reflector: if $direct = 'F'$ : $H = H(1)*H(2)*\dots*H(k)$ (Forward, not supported) if $direct = 'B'$ : $H = H(k)*\dots*H(2)*H(1)$ (Backward).
<code>storev</code>	(global) Specifies how the vectors which defines the elementary reflectors are stored: if $storev = 'C'$ : columnwise (not supported); if $storev = 'R'$ : rowwise.
<code>n</code>	(global) The order of the block reflector $H$ . $n \geq 0$ .
<code>k</code>	(global) The order of the triangular factor $T$ (= the number of elementary reflectors). $1 \leq k \leq mb\_v (= nb\_v)$ .
<code>v</code>	Pointer into the local memory to an array of local size $LOCr(iv+k-1) * IOCC(jv+n-1)$ . The distributed matrix $V$ contains the Householder vectors. See <i>Application Notes</i> below.

<i>iv, jv</i>	(global) The row and column indices in the global matrix $V$ indicating the first row and the first column of the matrix $\text{sub}(V)$ , respectively.
<i>descv</i>	(local) array of size $dlen\_$ . The array descriptor for the distributed matrix $V$ .
<i>tau</i>	(local) Array of size $LOCr(iv+k-1)$ if $incv = m\_v$ , and $LOCc(jv+k-1)$ otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix $V$ .
<i>work</i>	(local). Workspace array of size $(k*(k-1)/2)$ .

## Output Parameters

<i>v</i>	
<i>t</i>	(local) Array of size $mb\_v * mb\_v$ . It contains the $k$ -by- $k$ triangular factor of the block reflector associated with $v$ . $t$ is lower triangular.

## Application Notes

The shape of the matrix  $V$  and the storage of the vectors which define the  $H(i)$  is best illustrated by the following example with  $n = 5$  and  $k = 3$ . The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

*direct='F' and storev='C'*

$$V = \begin{bmatrix} v1 & v2 & v3 \\ v1 & v2 & v3 \end{bmatrix}$$

$$V = \begin{bmatrix} . & . & . \\ . & . & . \\ 1 & . & . \\ & 1 & . \\ & & 1 \end{bmatrix}$$

*direct='F' and storev='R':*

$$\begin{bmatrix} \overbrace{v1 \ v1 \ v1 \ v1 \ v1} & . & . & . & 1 \\ v2 \ v2 \ v2 \ v2 \ v2 & . & . & . & 1 \\ v3 \ v3 \ v3 \ v3 \ v3 & . & . & . & 1 \end{bmatrix}$$

*direct='B' and storev='C':*

$$v = \begin{bmatrix} 1 \\ . \ 1 \\ . \ . \ 1 \\ . \ . \ . \\ . \ . \ . \end{bmatrix}$$

$$\begin{bmatrix} v1 \ v2 \ v3 \\ v1 \ v2 \ v3 \end{bmatrix}$$

*direct='B' and storev='R':*

$$\begin{bmatrix} 1 \ . \ . \ . \ . \ \overbrace{v1 \ v1 \ v1 \ v1 \ v1} \\ . \ 1 \ . \ . \ . \ v2 \ v2 \ v2 \ v2 \ v2 \\ . \ . \ 1 \ . \ . \ v3 \ v3 \ v3 \ v3 \ v3 \end{bmatrix}$$

### p?lascl

*Multiplies a general rectangular matrix by a real scalar defined as  $C_{to}/C_{from}$ .*

## Syntax

```
void pslascl (char *type , float *cfrom , float *cto , MKL_INT *m , MKL_INT *n , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pdlascl (char *type , double *cfrom , double *cto , MKL_INT *m , MKL_INT *n ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pclascl (char *type , float *cfrom , float *cto , MKL_INT *m , MKL_INT *n ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pzlascl (char *type , double *cfrom , double *cto , MKL_INT *m , MKL_INT *n ,
MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?lascl` function multiplies the  $m$ -by- $n$  real/complex distributed matrix sub( $A$ ) denoting  $A(ia:ia+m-1, ja:ja+n-1)$  by the real/complex scalar  $cto/cfrom$ . This is done without over/underflow as long as the final result  $cto*A(i,j)/cfrom$  does not over/underflow. *type* specifies that sub( $A$ ) may be full, upper triangular, lower triangular or upper Hessenberg.

## Input Parameters

<i>type</i>	(global) <i>type</i> indicates the storage type of the input distributed matrix. if <i>type</i> = 'G': sub( $A$ ) is a full matrix, if <i>type</i> = 'L': sub( $A$ ) is a lower triangular matrix, if <i>type</i> = 'U': sub( $A$ ) is an upper triangular matrix, if <i>type</i> = 'H': sub( $A$ ) is an upper Hessenberg matrix.
<i>cfrom, cto</i>	(global) The distributed matrix sub( $A$ ) is multiplied by $cto/cfrom$ . $A(i,j)$ is computed without over/underflow if the final result $cto*A(i,j)/cfrom$ can be represented without over/underflow. <i>cfrom</i> must be nonzero.
<i>m</i>	(global) The number of rows in the distributed matrix sub( $A$ ). ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the distributed matrix sub( $A$ ). ( $n \geq 0$ ).
<i>a</i>	(local input/local output) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ . This array contains the local pieces of the distributed matrix sub( $A$ ).
<i>ia, ja</i>	(global) The column and row indices in the global matrix $A$ indicating the first row and column of the matrix sub( $A$ ), respectively.
<i>desca</i>	(global and local)

Array of size *dlen\_*. The array descriptor for the distributed matrix *A*.

## Output Parameters

<i>a</i>	(local). On exit, this array contains the local pieces of the distributed matrix multiplied by <i>cto/cfrom</i> .
<i>info</i>	(local) if <i>info</i> = 0: the execution is successful. if <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j-1</i> , had an illegal value, then <i>info</i> = $-(i*100+j)$ , if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$ .

## See Also

## p?lase2

*Initializes an m-by-n distributed matrix.*

## Syntax

```
void pslase2 (const char* uplo, const MKL_INT* m, const MKL_INT* n, const float* alpha,
const float* beta, float* a, const MKL_INT* ia, const MKL_INT* ja, const MKL_INT*
desca);
```

```
void pdlase2 (const char* uplo, const MKL_INT* m, const MKL_INT* n, const double*
alpha, const double* beta, double* a, const MKL_INT* ia, const MKL_INT* ja, const
MKL_INT* desca);
```

```
void pclase2 (const char* uplo, const MKL_INT* m, const MKL_INT* n, const MKL_Complex8*
alpha, const MKL_Complex8* beta, MKL_Complex8* a, const MKL_INT* ia, const MKL_INT* ja,
const MKL_INT* desca);
```

```
void pzlase2 (const char* uplo, const MKL_INT* m, const MKL_INT* n, const
MKL_Complex16* alpha, const MKL_Complex16* beta, MKL_Complex16* a, const MKL_INT* ia,
const MKL_INT* ja, const MKL_INT* desca);
```

## Include Files

- mkl\_scalapack.h

## Description

p?lase2 initializes an *m*-by-*n* distributed matrix sub( *A* ) denoting  $A(ia:ia+m-1, ja:ja+n-1)$  to *beta* on the diagonal and *alpha* on the off-diagonals. p?lase2 requires that only the dimension of the matrix operand is distributed.

## Input Parameters

<i>uplo</i>	(global) Specifies the part of the distributed matrix sub( <i>A</i> ) to be set: = 'U': Upper triangular part is set; the strictly lower triangular part of sub( <i>A</i> ) is not changed;
-------------	---

= 'L': Lower triangular part is set; the strictly upper triangular part of  $\text{sub}(A)$  is not changed;

Otherwise: All of the matrix  $\text{sub}(A)$  is set.

<i>m</i>	(global) The number of rows to be operated on i.e the number of rows of the distributed submatrix $\text{sub}(A)$ . $m \geq 0$ .
<i>n</i>	(global) The number of columns to be operated on i.e the number of columns of the distributed submatrix $\text{sub}(A)$ . $n \geq 0$ .
<i>alpha</i>	(global) The constant to which the off-diagonal elements are to be set.
<i>beta</i>	(global) The constant to which the diagonal elements are to be set.
<i>ia</i>	(global) The row index in the global array <i>a</i> indicating the first row of $\text{sub}(A)$ .
<i>ja</i>	(global) The column index in the global array <i>a</i> indicating the first column of $\text{sub}(A)$ .
<i>desca</i>	(global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .

## Output Parameters

<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(ja+n-1)$ . This array contains the local pieces of the distributed matrix $\text{sub}(A)$ to be set. On exit, the leading <i>m</i> -by- <i>n</i> submatrix $\text{sub}(A)$ is set as follows: if <i>uplo</i> = 'U', $A(ia+i-1, ja+j-1) = alpha, 1 \leq i \leq j-1, 1 \leq j \leq n$ , if <i>uplo</i> = 'L', $A(ia+i-1, ja+j-1) = alpha, j+1 \leq i \leq m, 1 \leq j \leq n$ , otherwise, $A(ia+i-1, ja+j-1) = alpha, 1 \leq i \leq m, 1 \leq j \leq n, ia+i \neq ja+j$ , and, for all <i>uplo</i> , $A(ia+i-1, ja+i-1) = beta, 1 \leq i \leq \min(m, n)$ .
----------	--

## **p?laset**

*Initializes the offdiagonal elements of a matrix to alpha and the diagonal elements to beta.*

## Syntax

```
void pslaset (char *uplo , MKL_INT *m , MKL_INT *n , float *alpha , float *beta , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

```
void pdlaset (char *uplo , MKL_INT *m , MKL_INT *n , double *alpha , double *beta ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

```
void pclaset (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex8 *alpha , MKL_Complex8
*beta , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

```
void pzlaset (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex16 *alpha ,
MKL_Complex16 *beta , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

## Include Files

- mkl\_scalapack.h

## Description

The `p?laset` function initializes an  $m$ -by- $n$  distributed matrix  $\text{sub}(A)$  denoting  $A(ia:ia+m-1, ja:ja+n-1)$  to  $\beta$  on the diagonal and  $\alpha$  on the offdiagonals.

## Input Parameters

<i>uplo</i>	(global) Specifies the part of the distributed matrix $\text{sub}(A)$ to be set: if <i>uplo</i> = 'U': upper triangular part; the strictly lower triangular part of $\text{sub}(A)$ is not changed; if <i>uplo</i> = 'L': lower triangular part; the strictly upper triangular part of $\text{sub}(A)$ is not changed. Otherwise: all of the matrix $\text{sub}(A)$ is set.
<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(A)$ . ( $m \geq 0$ ).
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(A)$ . ( $n \geq 0$ ).
<i>alpha</i>	(global). The constant to which the offdiagonal elements are to be set.
<i>beta</i>	(global). The constant to which the diagonal elements are to be set.

## Output Parameters

<i>a</i>	(local). Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ . This array contains the local pieces of the distributed matrix $\text{sub}(A)$ to be set. On exit, the leading $m$ -by- $n$ matrix $\text{sub}(A)$ is set as follows: if <i>uplo</i> = 'U', $A(ia+i-1, ja+j-1) = \alpha, 1 \leq i \leq j-1, 1 \leq j \leq n$ , if <i>uplo</i> = 'L', $A(ia+i-1, ja+j-1) = \alpha, j+1 \leq i \leq m, 1 \leq j \leq n$ ,
----------	--

otherwise,  $A(ia+i-1, ja+j-1) = \alpha$ ,  $1 \leq i \leq m$ ,  $1 \leq j \leq n$ ,  $ia+i \neq ja+j$ , and, for all *uplo*,  $A(ia+i-1, ja+i-1) = \beta$ ,  $1 \leq i \leq \min(m, n)$ .

*ia, ja*

(global)

The column and row indices in the distributed matrix *A* indicating the first row and column of the matrix sub(*A*), respectively.

*desca*

(global and local)

Array of size *dlen\_*. The array descriptor for the distributed matrix *A*.

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## p?lasmsub

Looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero.

## Syntax

```
void pslasmsub (const float *a, const MKL_INT *desca, const MKL_INT *i, const MKL_INT *l, MKL_INT *k, const float *smlnum, float *buf, const MKL_INT *lwork );
void pdlasmsub (const double *a, const MKL_INT *desca, const MKL_INT *i, const MKL_INT *l, MKL_INT *k, const double *smlnum, double *buf, const MKL_INT *lwork );
void pclasmsub (const MKL_Complex8 *a , const MKL_INT *desca , const MKL_INT *i , const MKL_INT *l , MKL_INT *k , const float *smlnum , MKL_Complex8 *buf , const MKL_INT *lwork );
void pzlasmsub (const MKL_Complex16 *a , const MKL_INT *desca , const MKL_INT *i , const MKL_INT *l , MKL_INT *k , const double *smlnum , MKL_Complex16 *buf , const MKL_INT *lwork );
```

## Include Files

- mkl\_scalapack.h

## Description

The p?lasmsub function looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero. This function performs a global maximum and must be called by all processes.

## Input Parameters

*a*

(local)

Array of size *lld\_a\*LOCc(n\_a)*.

On entry, the Hessenberg matrix whose tridiagonal part is being scanned. Unchanged on exit.

*desca*

(global and local)

Array of size *dlen\_*. The array descriptor for the distributed matrix *A*.

*i*

(global)

The global location of the bottom of the unreduced submatrix of *A*. Unchanged on exit.

<i>l</i>	(global) The global location of the top of the unreduced submatrix of <i>A</i> . Unchanged on exit.
<i>smlnum</i>	(global) On entry, a "small number" for the given matrix. Unchanged on exit. The machine-dependent constants for the stopping criterion.
<i>lwork</i>	(local) This must be at least $2 * \text{ceil}(\text{ceil}((i-1)/mb\_a) / \text{lcm}(nprow, npcol))$ . Here <i>lcm</i> is least common multiple and <i>nprow</i> $\times$ <i>npcol</i> is the logical grid size.

## Output Parameters

<i>k</i>	(global) On exit, this yields the bottom portion of the unreduced submatrix. This will satisfy: $l \leq k \leq i-1$ .
<i>buf</i>	(local). Array of size <i>lwork</i> .

## Application Notes

This routine parallelizes the code from `?lahqr` that looks for a single small subdiagonal element.

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## p?lasrt

*Sorts the numbers in an array and the corresponding vectors in increasing order.*

## Syntax

```
void pslasrt (const char* id, const MKL_INT* n, float* d, const float* q, const
MKL_INT* iq, const MKL_INT* jq, const MKL_INT* descq, float* work, const MKL_INT*
lwork, MKL_INT* iwork, const MKL_INT* liwork, MKL_INT* info);

void pdlasrt (const char* id, const MKL_INT* n, double* d, const double* q, const
MKL_INT* iq, const MKL_INT* jq, const MKL_INT* descq, double* work, const MKL_INT*
lwork, MKL_INT* iwork, const MKL_INT* liwork, MKL_INT* info);
```

## Include Files

- `mkl_scalapack.h`

## Description

`p?lasrt` sorts the numbers in *d* and the corresponding vectors in *q* in increasing order.

## Input Parameters

<i>id</i>	(global) = 'I': sort <i>d</i> in increasing order;
-----------	---

	= 'D': sort $d$ in decreasing order. (NOT IMPLEMENTED YET)
$n$	(global) The number of columns to be operated on i.e the number of columns of the distributed submatrix sub( $Q$ ). $n \geq 0$ .
$d$	(global) Array, size ( $n$ )
$q$	(local) Pointer into the local memory to an array of size $lld\_q * LOCC(jq+n-1)$ . This array contains the local pieces of the distributed matrix sub( $A$ ) to be copied from.
$iq$	(global) The row index in the global array $A$ indicating the first row of sub( $Q$ ).
$jq$	(global) The column index in the global array $A$ indicating the first column of sub( $Q$ ).
$descq$	(global and local) Array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
$work$	(local) Array, size ( $lwork$ )
$lwork$	(local) The size of the array $work$ . $lwork = \text{MAX}( n, NP * ( NB + NQ ) )$ , where $NP = \text{numroc}( n, NB, MYROW, IAROW, NPROW )$ , $NQ = \text{numroc}( n, NB, MYCOL, DESCQ( csrc\_ ), NPCOL )$ . $\text{numroc}$ is a ScaLAPACK tool function.
$iwork$	(local) Array, size ( $liwork$ )
$liwork$	(local) The size of the array $iwork$ . $liwork = n + 2 * NB + 2 * NPCOL$

## Output Parameters

$d$	On exit, the numbers in $d$ are sorted in increasing order.
$info$	(global) = 0: successful exit

< 0: If the  $i$ -th argument is an array and the  $j$ -th entry had an illegal value, then  $info = -(i*100+j)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

## p?lassq

Updates a sum of squares represented in scaled form.

### Syntax

```
void pslasq (MKL_INT *n , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , float *scale , float *sumsq );
```

```
void pdlasq (MKL_INT *n , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , double *scale , double *sumsq );
```

```
void pclassq (MKL_INT *n , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , float *scale , float *sumsq );
```

```
void pzlassq (MKL_INT *n , MKL_Complex16 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , double *scale , double *sumsq );
```

### Include Files

- mkl\_scalapack.h

### Description

The p?lassq function returns the values  $scl$  and  $ssq$  such that

$$scl^2 * ssq = x_1^2 + \dots + x_n^2 + scale^2 * sumsq,$$

where

$x_i = \text{sub}(X) = X(ix + (jx-1)*m_x + (i-1)*incx)$  for pslasq/pdlasq ,

$x_i = \text{sub}(X) = \text{abs}(X(ix + (jx-1)*m_x + (i-1)*incx))$  for pclassq/pzlassq.

For real functions pslasq/pdlasq the value of  $sumsq$  is assumed to be non-negative and  $scl$  returns the value

$$scl = \max(scale, \text{abs}(x_i)).$$

For complex functions pclassq/pzlassq the value of  $sumsq$  is assumed to be at least unity and the value of  $ssq$  will then satisfy

$$1.0 \leq ssq \leq sumsq + 2n$$

Value  $scale$  is assumed to be non-negative and  $scl$  returns the value

$$scl = \max_i \left( scale, \text{abs}(\text{real}(x_i)), \text{abs}(\text{aimag}(x_i)) \right)$$

For all functions p?lassq values  $scale$  and  $sumsq$  must be supplied in  $scale$  and  $sumsq$  respectively, and  $scale$  and  $sumsq$  are overwritten by  $scl$  and  $ssq$  respectively.

All functions p?lassq make only one pass through the vector  $\text{sub}(X)$ .

### Input Parameters

$n$  (global)  
The length of the distributed vector  $\text{sub}(x)$ .

<code>x</code>	The array that stores the vector for which a scaled sum of squares is computed: $x[ix + (jx-1)*m_x + i*incx], 0 \leq i < n.$
<code>ix</code>	(global) The row index in the global matrix $X$ indicating the first row of $\text{sub}(X)$ .
<code>jx</code>	(global) The column index in the global matrix $X$ indicating the first column of $\text{sub}(X)$ .
<code>descx</code>	(global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix $X$ .
<code>incx</code>	(global) The global increment for the elements of $X$ . Only two values of <code>incx</code> are supported in this version, namely 1 and <code>m_x</code> . The argument <code>incx</code> must not equal zero.
<code>scale</code>	(local). On entry, the value <code>scale</code> in the equation above.
<code>sumsq</code>	(local) On entry, the value <code>sumsq</code> in the equation above.

## Output Parameters

<code>scale</code>	(local). On exit, <code>scale</code> is overwritten with <code>scl</code> , the scaling factor for the sum of squares.
<code>sumsq</code>	(local). On exit, <code>sumsq</code> is overwritten with the value <code>smsq</code> , the basic sum of squares from which <code>scl</code> has been factored out.

## p?laswp

*Performs a series of row interchanges on a general rectangular matrix.*

### Syntax

```
void pslaswp (char *direc , char *rowcol , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *k1 , MKL_INT *k2 , MKL_INT *ipiv );
void pdlaswp (char *direc , char *rowcol , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *k1 , MKL_INT *k2 , MKL_INT *ipiv );
void pclaswp (char *direc , char *rowcol , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *k1 , MKL_INT *k2 , MKL_INT *ipiv );
void pzlaswp (char *direc , char *rowcol , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *k1 , MKL_INT *k2 , MKL_INT *ipiv );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?laswp` function performs a series of row or column interchanges on the distributed matrix  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ . One interchange is initiated for each of rows or columns  $k1$  through  $k2$  of  $\text{sub}(A)$ . This function assumes that the pivoting information has already been broadcast along the process row or column. Also note that this function will only work for  $k1$ - $k2$  being in the same  $mb$  (or  $nb$ ) block. If you want to pivot a full matrix, use `p?lapiv`.

## Input Parameters

<code>direc</code>	(global) Specifies in which order the permutation is applied: = 'F' - forward, = 'B' - backward.
<code>rowcol</code>	(global) Specifies if the rows or columns are permuted: = 'R' - rows, = 'C' - columns.
<code>n</code>	(global) If <code>rowcol='R'</code> , the length of the rows of the distributed matrix $A(*, \text{ja}:\text{ja}+n-1)$ to be permuted; If <code>rowcol='C'</code> , the length of the columns of the distributed matrix $A(\text{ia}:\text{ia}+n-1, *)$ to be permuted;
<code>a</code>	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(n\_a)$ . On entry, this array contains the local pieces of the distributed matrix to which the row/columns interchanges will be applied.
<code>ia</code>	(global) The row index in the global matrix $A$ indicating the first row of $\text{sub}(A)$ .
<code>ja</code>	(global) The column index in the global matrix $A$ indicating the first column of $\text{sub}(A)$ .
<code>desca</code>	(global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix $A$ .
<code>k1</code>	(global) The first element of <code>ipiv</code> for which a row or column interchange will be done.
<code>k2</code>	(global) The last element of <code>ipiv</code> for which a row or column interchange will be done.

*ipiv* (local)  
 Array of size  $LOCr(m_a)+mb_a$  for row pivoting and  $LOCr(n_a)+nb_a$  for column pivoting. This array is tied to the matrix  $A$ ,  $ipiv[k]=l$  implies rows (or columns)  $k+1$  and  $l$  are to be interchanged,  $k = 0, 1, \dots, \text{size}(ipiv) - 1$ .

## Output Parameters

$A$  (local)  
 On exit, the permuted distributed matrix.

## p?latra

*Computes the trace of a general square distributed matrix.*

## Syntax

```
float pslatra (MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
double pdlatra (MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
void pclatra (MKL_Complex8 * , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
void pzlatra (MKL_Complex16 * , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

## Include Files

- mkl\_scalapack.h

## Description

This function computes the trace of an  $n$ -by- $n$  distributed matrix  $\text{sub}(A)$  denoting  $A(ia:ia+n-1, ja:ja+n-1)$ . The result is left on every process of the grid.

## Input Parameters

$n$  (global)  
 The number of rows and columns to be operated on, that is, the order of the distributed matrix  $\text{sub}(A)$ .  $n \geq 0$ .

$a$  (local).  
 Pointer into the local memory to an array of size  $lld_a * LOCc(ja+n-1)$  containing the local pieces of the distributed matrix, the trace of which is to be computed.

$ia, ja$  (global) The row and column indices respectively in the global matrix  $A$  indicating the first row and the first column of the matrix  $\text{sub}(A)$ , respectively.

$desca$  (global and local) array of size  $dlen_$ . The array descriptor for the distributed matrix  $A$ .

## Output Parameters

*val* The value returned by the function.

## p?latrd

*Reduces the first  $nb$  rows and columns of a symmetric/Hermitian matrix  $A$  to real tridiagonal form by an orthogonal/unitary similarity transformation.*

## Syntax

```
void pslatrd (char *uplo , MKL_INT *n , MKL_INT *nb , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *d , float *e , float *tau , float *w , MKL_INT *iw , MKL_INT *jw , MKL_INT *descw , float *work );
```

```
void pdlatrd (char *uplo , MKL_INT *n , MKL_INT *nb , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *d , double *e , double *tau , double *w , MKL_INT *iw , MKL_INT *jw , MKL_INT *descw , double *work );
```

```
void pclatrd (char *uplo , MKL_INT *n , MKL_INT *nb , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *d , float *e , MKL_Complex8 *tau , MKL_Complex8 *w , MKL_INT *iw , MKL_INT *jw , MKL_INT *descw , MKL_Complex8 *work );
```

```
void pzlatrd (char *uplo , MKL_INT *n , MKL_INT *nb , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *d , double *e , MKL_Complex16 *tau , MKL_Complex16 *w , MKL_INT *iw , MKL_INT *jw , MKL_INT *descw , MKL_Complex16 *work );
```

## Include Files

- mkl\_scalapack.h

## Description

The p?latrd function reduces  $nb$  rows and columns of a real symmetric or complex Hermitian matrix  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$  to symmetric/complex tridiagonal form by an orthogonal/unitary similarity transformation  $Q' * \text{sub}(A) * Q$ , and returns the matrices  $V$  and  $W$ , which are needed to apply the transformation to the unreduced part of  $\text{sub}(A)$ .

If  $uplo = U$ , p?latrd reduces the last  $nb$  rows and columns of a matrix, of which the upper triangle is supplied;

if  $uplo = L$ , p?latrd reduces the first  $nb$  rows and columns of a matrix, of which the lower triangle is supplied.

This is an auxiliary function called by p?sytrd/p?hetrd.

## Input Parameters

*uplo* (global)  
Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix  $\text{sub}(A)$  is stored:  
= 'U': Upper triangular  
= L: Lower triangular.

<i>n</i>	(global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$ . $n \geq 0$ .
<i>nb</i>	(global) The number of rows and columns to be reduced.
<i>a</i>	Pointer into the local memory to an array of size $ld_a * LOC(j_a+n-1)$ . On entry, this array contains the local pieces of the symmetric/Hermitian distributed matrix $\text{sub}(A)$ . If $uplo = U$ , the leading $n$ -by- $n$ upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If $uplo = L$ , the leading $n$ -by- $n$ lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.
<i>ia</i>	(global) The row index in the global matrix $A$ indicating the first row of $\text{sub}(A)$ .
<i>ja</i>	(global) The column index in the global matrix $A$ indicating the first column of $\text{sub}(A)$ .
<i>desca</i>	(global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $A$ .
<i>iw</i>	(global) The row index in the global matrix $W$ indicating the first row of $\text{sub}(W)$ .
<i>iw</i>	(global) The column index in the global matrix $W$ indicating the first column of $\text{sub}(W)$ .
<i>descw</i>	(global and local) array of size $dlen_$ . The array descriptor for the distributed matrix $W$ .
<i>work</i>	(local) Workspace array of size $nb_a$ .

## Output Parameters

<i>a</i>	(local) On exit, if $uplo = 'U'$ , the last $nb$ columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of $\text{sub}(A)$ ; the elements above the diagonal with the array $\tau$ represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors;
----------	---

if  $uplo = 'L'$ , the first  $nb$  columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of  $sub(A)$ ; the elements below the diagonal with the array  $tau$  represent the orthogonal/unitary matrix  $Q$  as a product of elementary reflectors.

$d$	(local) Array of size $LOCc(ja+n-1)$ . The diagonal elements of the tridiagonal matrix $T$ : $d[i] = A(i+1,i+1)$ , $i = 0, 1, \dots, LOCc(ja+n-1)-1$ . $d$ is tied to the distributed matrix $A$ .
$e$	(local) Array of size $LOCc(ja+n-1)$ if $uplo = 'U'$ , $LOCc(ja+n-2)$ otherwise. The off-diagonal elements of the tridiagonal matrix $T$ : $e[i] = A(i+1, i+2)$ if $uplo = 'U'$ , $e[i] = A(i+2, i+1)$ if $uplo = 'L'$ , $i = 0, 1, \dots, LOCc(ja+n-1)-1$ . $e$ is tied to the distributed matrix $A$ .
$tau$	(local) Array of size $LOCc(ja+n-1)$ . This array contains the scalar factors of the elementary reflectors. $tau$ is tied to the distributed matrix $A$ .
$w$	(local) Pointer into the local memory to an array of size $lld_w * nb_w$ . This array contains the local pieces of the $n$ -by- $nb_w$ matrix $w$ required to update the unreduced part of $sub(A)$ .

## Application Notes

If  $uplo = 'U'$ , the matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(n) * H(n-1) * \dots * H(n-nb+1)$$

Each  $H(i)$  has the form

$$H(i) = I - tau * v * v'$$

where  $tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(i:n) = 0$  and  $v(i-1) = 1$ ;  $v(1:i-1)$  is stored on exit in  $A(ia:ia+i-1, ja+i)$ , and  $tau$  in  $tau[ja+i-2]$ .

If  $uplo = 'L'$ , the matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(nb)$$

Each  $H(i)$  has the form

$$H(i) = I - tau * v * v'$$

where  $tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(1:i) = 0$  and  $v(i+1) = 1$ ;  $v(i+2:n)$  is stored on exit in  $A(ia+i+1:ia+n-1, ja+i-1)$ , and  $tau$  in  $tau[ja+i-2]$ .

The elements of the vectors  $v$  together form the  $n$ -by- $nb$  matrix  $V$  which is needed, with  $W$ , to apply the transformation to the unreduced part of the matrix, using a symmetric/Hermitian rank- $2k$  update of the form:

$$sub(A) := sub(A) - v * w' - w * v'$$

The contents of  $a$  on exit are illustrated by the following examples with

$n = 5$  and  $nb = 2$ :

$$\begin{array}{l} \text{if } \text{uplo}=\text{'U'}: \\ \left[ \begin{array}{ccccc} a & a & a & v_4 & v_5 \\ & a & a & v_4 & v_5 \\ & & a & 1 & v_5 \\ & & & d & 1 \\ & & & & d \end{array} \right] \end{array} \qquad \begin{array}{l} \text{if } \text{uplo}=\text{'L'}: \\ \left[ \begin{array}{ccccc} d & & & & \\ 1 & d & & & \\ v_1 & 1 & a & & \\ v_1 & v_2 & a & a & \\ v_1 & v_2 & a & a & a \end{array} \right] \end{array}$$

where  $d$  denotes a diagonal element of the reduced matrix,  $a$  denotes an element of the original matrix that is unchanged, and  $v_i$  denotes an element of the vector defining  $H(i)$ .

MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , double *scale , double *cnorm ,
MKL_Complex16 *work );
```

## Include Files

- mkl\_scalapack.h

## Description

The p?latrs function solves a triangular system of equations  $Ax = sb$ ,  $A^T x = sb$  or  $A^H x = sb$ , where  $s$  is a scale factor set to prevent overflow. The description of the function will be extended in the future releases.

## Input Parameters

<i>uplo</i>	Specifies whether the matrix $A$ is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular
<i>trans</i>	Specifies the operation applied to $Ax$ . = 'N': Solve $Ax = s*b$ (no transpose) = 'T': Solve $A^T x = s*b$ (transpose) = 'C': Solve $A^H x = s*b$ (conjugate transpose), where $s$ - is a scale factor
<i>diag</i>	Specifies whether or not the matrix $A$ is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular
<i>normin</i>	Specifies whether <i>cnorm</i> has been set or not. = 'Y': <i>cnorm</i> contains the column norms on entry; = 'N': <i>cnorm</i> is not set on entry. On exit, the norms will be computed and stored in <i>cnorm</i> .
<i>n</i>	The order of the matrix $A$ . $n \geq 0$
<i>a</i>	Array of size $lda * n$ . Contains the triangular matrix $A$ . If <i>uplo</i> = 'U', the leading $n$ -by- $n$ upper triangular part of the array $a$ contains the upper triangular matrix, and the strictly lower triangular part of $a$ is not referenced. If <i>uplo</i> = 'L', the leading $n$ -by- $n$ lower triangular part of the array $a$ contains the lower triangular matrix, and the strictly upper triangular part of $a$ is not referenced. If <i>diag</i> = 'U', the diagonal elements of $a$ are also not referenced and are assumed to be 1.
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the submatrix $A$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .
<i>x</i>	Array of size $n$ . On entry, the right hand side $b$ of the triangular system.
<i>ix</i>	(global).The row index in the global matrix $X$ indicating the first row of sub( $x$ ).
<i>jx</i>	(global) The column index in the global matrix $X$ indicating the first column of sub( $X$ ).

<i>descx</i>	(global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>X</i> .
<i>cnorm</i>	Array of size <i>n</i> . If <i>normin</i> = 'Y', <i>cnorm</i> is an input argument and <i>cnorm</i> [ <i>j</i> ] contains the norm of the off-diagonal part of the ( <i>j</i> +1)-th column of the matrix <i>A</i> , <i>j</i> =0, 1, ..., <i>n</i> -1. If <i>trans</i> = 'N', <i>cnorm</i> [ <i>j</i> ] must be greater than or equal to the infinity-norm, and if <i>trans</i> = 'T' or 'C', <i>cnorm</i> [ <i>j</i> ] must be greater than or equal to the 1-norm.
<i>work</i>	(local). Temporary workspace.

## Output Parameters

<i>x</i>	On exit, <i>x</i> is overwritten by the solution vector <i>x</i> .
<i>scale</i>	Array of size <i>lda</i> * <i>n</i> . The scaling factor <i>s</i> for the triangular system as described above.  If <i>scale</i> = 0, the matrix <i>A</i> is singular or badly scaled, and the vector <i>x</i> is an exact or approximate solution to $Ax = 0$ .
<i>cnorm</i>	If <i>normin</i> = 'N', <i>cnorm</i> is an output argument and <i>cnorm</i> [ <i>j</i> ] returns the 1-norm of the off-diagonal part of the ( <i>j</i> +1)-th column of <i>A</i> , <i>j</i> =0, 1, ..., <i>n</i> -1.

void pclatz (MKL_INT *m , MKL_INT *n , MKL_INT *l , MKL_Complex8 *a , MKL_INT *ia ,
 MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work );
void pzlatrz (MKL_INT *m , MKL_INT *n , MKL_INT *l , MKL_Complex16 *a , MKL_INT *ia ,
 MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work );
```

## Include Files

- mkl\_scalapack.h

## Description

The p?latrz function reduces the *m*-by-*n* ( $m \leq n$ ) real/complex upper trapezoidal matrix  $\text{sub}(A) = [A(ia:ia+m-1, ja:ja+m-1)A(ia:ia+m-1, ja+n-l:ja+n-1)]$  to upper triangular form by means of orthogonal/unitary transformations.

The upper trapezoidal matrix  $\text{sub}(A)$  is factored as

$\text{sub}(A) = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$

where  $Z$  is an  $n$ -by- $n$  orthogonal/unitary matrix and  $R$  is an  $m$ -by- $m$  upper triangular matrix.

## Input Parameters

$m$	(global) The number of rows in the distributed matrix $\text{sub}(A)$ . $m \geq 0$ .
$n$	(global) The number of columns in the distributed matrix $\text{sub}(A)$ . $n \geq 0$ .
$l$	(global) The number of columns of the distributed matrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. $l > 0$ .
$a$	(local) Pointer into the local memory to an array of size $l \cdot d_{len\_a} * LOC_c(j_a+n-1)$ . On entry, the local pieces of the $m$ -by- $n$ distributed matrix $\text{sub}(A)$ , which is to be factored.
$ia$	(global) The row index in the global matrix $A$ indicating the first row of $\text{sub}(A)$ .
$ja$	(global) The column index in the global matrix $A$ indicating the first column of $\text{sub}(A)$ .
$desca$	(global and local) array of size $d_{len\_}$ . The array descriptor for the distributed matrix $A$ .
$work$	(local) Workspace array of size $lwork$ . $lwork \geq nq0 + \max(1, mp0)$ , where $iroff = \text{mod}(ia-1, mb\_a),$ $icoff = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow),$ $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcot),$ $mp0 = \text{numroc}(m+iroff, mb\_a, myrow, iarow, nprow),$ $nq0 = \text{numroc}(n+icoff, nb\_a, mycol, iacol, npcot),$ $\text{numroc}, \text{indxg2p},$ and $\text{numroc}$ are ScaLAPACK tool functions; $myrow,$ $mycol,$ $nprow,$ and $npcot$ can be determined by calling the function <code>blacs_gridinfo</code> .

## Output Parameters

<i>a</i>	On exit, the leading $m$ -by- $m$ upper triangular part of $\text{sub}(A)$ contains the upper triangular matrix $R$ , and elements $n-l+1$ to $n$ of the first $m$ rows of $\text{sub}(A)$ , with the array <i>tau</i> , represent the orthogonal/unitary matrix $Z$ as a product of $m$ elementary reflectors.
<i>tau</i>	(local) Array of size $\text{LOCr}(ja+m-1)$ . This array contains the scalar factors of the elementary reflectors. <i>tau</i> is tied to the distributed matrix $A$ .

## Application Notes

The factorization is obtained by Householder's method. The  $k$ -th transformation matrix,  $Z(k)$ , which is used (or, in case of complex functions, whose conjugate transpose is used) to introduce zeros into the  $(m - k + 1)$ -th row of  $\text{sub}(A)$ , is given in the form

$$Z(k) = \begin{bmatrix} I & 0 \\ 0 & T(k) \end{bmatrix},$$

where

$$T(k) = I - \tau * u(k) * u(k)', \quad u(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}$$

$\tau$  is a scalar and  $z(k)$  is an  $(n-m)$ -element vector.  $\tau$  and  $z(k)$  are chosen to annihilate the elements of the  $k$ -th row of  $\text{sub}(A)$ . The scalar  $\tau$  is returned in the  $k$ -th element of *tau*, indexed  $k-1$ , and the vector  $u(k)$  in the  $k$ -th row of  $\text{sub}(A)$ , such that the elements of  $z(k)$  are in  $A(k, m+1), \dots, A(k, n)$ . The elements of  $R$  are returned in the upper triangular part of  $\text{sub}(A)$ .

$Z$  is given by

$$Z = Z(1)Z(2)\dots Z(m).$$

## p?lauu2

*Computes the product  $U*U'$  or  $L'*L$ , where  $U$  and  $L$  are upper or lower triangular matrices (local unblocked algorithm).*

## Syntax

```
void pslauu2 (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

```
void pdlauu2 (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

```
void pclauu2 (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

```
void pzlaau2 (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca );
```

## Include Files

- mkl\_scalapack.h

## Description

The `pzlaau2` function computes the product  $U*U'$  or  $L'*L$ , where the triangular factor  $U$  or  $L$  is stored in the upper or lower triangular part of the distributed matrix

$sub(A) = A(ia:ia+n-1, ja:ja+n-1)$ .

If `uplo = 'U'` or `'u'`, then the upper triangle of the result is stored, overwriting the factor  $U$  in  $sub(A)$ .

If `uplo = 'L'` or `'l'`, then the lower triangle of the result is stored, overwriting the factor  $L$  in  $sub(A)$ .

This is the unblocked form of the algorithm, calling [BLAS Level 2 Routines](#). No communication is performed by this function, the matrix to operate on should be strictly local to one process.

## Input Parameters

<code>uplo</code>	(global) Specifies whether the triangular factor stored in the <i>matrix</i> $sub(A)$ is upper or lower triangular: = U: upper triangular = L: lower triangular.
<code>n</code>	(global) The number of rows and columns to be operated on, that is, the order of the triangular factor $U$ or $L$ . $n \geq 0$ .
<code>a</code>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ . On entry, the local pieces of the triangular factor $U$ or $L$ .
<code>ia</code>	(global) The row index in the global matrix $A$ indicating the first row of $sub(A)$ .
<code>ja</code>	(global) The column index in the global matrix $A$ indicating the first column of $sub(A)$ .
<code>desca</code>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .

## Output Parameters

<code>a</code>	(local) On exit, if <code>uplo = 'U'</code> , the upper triangle of the distributed matrix $sub(A)$ is overwritten with the upper triangle of the product $U*U'$ ; if <code>uplo = 'L'</code> , the lower triangle of $sub(A)$ is overwritten with the lower triangle of the product $L'*L$ .

## p?lauum

Computes the product  $U*U'$  or  $L'*L$ , where  $U$  and  $L$  are upper or lower triangular matrices.

## Syntax

```
void pslauum (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

```
void pdlauum (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

```
void pclauum (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

```
void pzlauum (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

## Include Files

- mkl\_scalapack.h

## Description

The p?lauum function computes the product  $U*U'$  or  $L'*L$ , where the triangular factor  $U$  or  $L$  is stored in the upper or lower triangular part of the matrix  $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ .

If  $uplo = 'U'$  or  $'u'$ , then the upper triangle of the result is stored, overwriting the factor  $U$  in  $\text{sub}(A)$ . If  $uplo = 'L'$  or  $'l'$ , then the lower triangle of the result is stored, overwriting the factor  $L$  in  $\text{sub}(A)$ .

This is the blocked form of the algorithm, calling Level 3 PBLAS.

## Input Parameters

$uplo$	(global)	Specifies whether the triangular factor stored in the matrix $\text{sub}(A)$ is upper or lower triangular: = 'U': upper triangular = 'L': lower triangular.
$n$	(global)	The number of rows and columns to be operated on, that is, the order of the triangular factor $U$ or $L$ . $n \geq 0$ .
$a$	(local)	Pointer into the local memory to an array of size $lld_a * LOCC(ja+n-1)$ . On entry, the local pieces of the triangular factor $U$ or $L$ .
$ia$	(global)	The row index in the global matrix $A$ indicating the first row of $\text{sub}(A)$ .
$ja$	(global)	

The column index in the global matrix  $A$  indicating the first column of  $\text{sub}(A)$ .

*desca*

(global and local) array of size  $dlen\_$ . The array descriptor for the distributed matrix  $A$ .

## Output Parameters

*a*

(local)

On exit, if  $uplo = 'U'$ , the upper triangle of the distributed matrix  $\text{sub}(A)$  is overwritten with the upper triangle of the product  $U*U'$ ; if  $uplo = 'L'$ , the lower triangle of  $\text{sub}(A)$  is overwritten with the lower triangle of the product  $L'*L$ .

## p?lawil

*Forms the Wilkinson transform.*

## Syntax

```
void pslawil (const MKL_INT *ii, const MKL_INT *jj, const MKL_INT *m, const float *a,
const MKL_INT *desca, const float *h44, const float *h33, const float *h43h34, float
*v );
```

```
void pdlawil (const MKL_INT *ii, const MKL_INT *jj, const MKL_INT *m, const double *a,
const MKL_INT *desca, const double *h44, const double *h33, const double *h43h34,
double *v );
```

```
void pclawil (const MKL_INT *ii , const MKL_INT *jj , const MKL_INT *m , const
MKL_Complex8 *a , const MKL_INT *desca , const MKL_Complex8 *h44 , const MKL_Complex8
*h33 , const MKL_Complex8 *h43h34 , MKL_Complex8 *v );
```

```
void pzlawil (const MKL_INT *ii , const MKL_INT *jj , const MKL_INT *m , const
MKL_Complex16 *a , const MKL_INT *desca , const MKL_Complex16 *h44 , const
MKL_Complex16 *h33 , const MKL_Complex16 *h43h34 , MKL_Complex16 *v );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?lawil` function gets the transform given by  $h44$ ,  $h33$ , and  $h43h34$  into  $v$  starting at row  $m$ .

## Input Parameters

*ii*

(global)

Number of the process row which owns the matrix element  $A(m+2, m+2)$ .

*jj*

(global)

Number of the process column which owns the matrix element  $A(m+2, m+2)$ .

*m*

(global)

	On entry, the location from where the transform starts (row $m$ ). Unchanged on exit.
<code>a</code>	(local) Array of size $lld\_a * LOCC(n\_a)$ . On entry, the Hessenberg matrix. Unchanged on exit.
<code>desca</code>	(global and local) Array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ . Unchanged on exit.
<code>h43h34</code>	(global) These three values are for the double shift $QR$ iteration. Unchanged on exit.

## Output Parameters

<code>v</code>	(global) Array of size 3 that contains the transform on output.
----------------	--

## `p?org2l/p?ung2l`

*Generates all or part of the orthogonal/unitary matrix  $Q$  from a  $QL$  factorization determined by `p?geqlf` (unblocked algorithm).*

## Syntax

```
void psorg2l (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );

void pdorg2l (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );

void pcung2l (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );

void pzung2l (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT
*lwork , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?org2l/p?ung2l` function generates an  $m$ -by- $n$  real/complex distributed matrix  $Q$  denoting  $A(ia:ia+m-1, ja:ja+n-1)$  with orthonormal columns, which is defined as the last  $n$  columns of a product of  $k$  elementary reflectors of order  $m$ :

$Q = H(k) * \dots * H(2) * H(1)$  as returned by `p?geqlf`.

## Input Parameters

<i>m</i>	(global) The number of rows in the distributed submatrix <i>Q</i> . $m \geq 0$ .
<i>n</i>	(global) The number of columns in the distributed submatrix <i>Q</i> . $m \geq n \geq 0$ .
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix <i>Q</i> . $n \geq k \geq 0$ .
<i>a</i>	Pointer into the local memory to an array of size $lld\_a * LOCc(ja+n-1)$ . On entry, the <i>j</i> -th column of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(j)$ , $ja+n-k \leq j \leq ja+n-1$ , as returned by <code>p?geqlf</code> in the <i>k</i> columns of its <i>distributed matrix</i> argument $A(ia:*, ja+n-k: ja+n-1)$ .
<i>ia</i>	(global) The row index in the global matrix <i>A</i> indicating the first row of sub( <i>A</i> ).
<i>ja</i>	(global) The column index in the global matrix <i>A</i> indicating the first column of sub( <i>A</i> ).
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) Array of size $LOCc(ja+n-1)$ . <i>tau</i> [ <i>j</i> ] contains the scalar factor of the elementary reflector $H(j+1)$ , $j = 0, 1, \dots, LOCc(ja+n-1)-1$ , as returned by <code>p?geqlf</code> .
<i>work</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork \geq mpa0 + \max(1, nqa0)$ , where $iroffa = \text{mod}(ia-1, mb\_a),$ $icoffa = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow),$ $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcot),$ $mpa0 = \text{numroc}(m+iroffa, mb\_a, myrow, iarow, nprow),$ $nqa0 = \text{numroc}(n+icoffa, nb\_a, mycol, iacol, npcot).$ <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; <i>myrow</i> , <i>mycol</i> , <i>nprow</i> , and <i>npcol</i> can be determined by calling the function <code>blacs_gridinfo</code> .

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

<code>a</code>	On exit, this array contains the local pieces of the $m$ -by- $n$ distributed matrix $Q$ .
<code>work</code>	On exit, <code>work[0]</code> returns the minimal and optimal $lwork$ .
<code>info</code>	(local). = 0: successful exit < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j-1$ , had an illegal value, then $info = -(i*100 + j)$ , if the $i$ -th argument is a scalar and had an illegal value, then $info = -i$ .

*lwork , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?org2r/p?ung2r` function generates an  $m$ -by- $n$  real/complex matrix  $Q$  denoting  $A(ia:ia+m-1, ja:ja+n-1)$  with orthonormal columns, which is defined as the first  $n$  columns of a product of  $k$  elementary reflectors of order  $m$ :

$$Q = H(1)*H(2)*...*H(k)$$

as returned by `p?geqrf`.

## Input Parameters

<i>m</i>	(global) The number of rows in the distributed submatrix $Q$ . $m \geq 0$ .
<i>n</i>	(global) The number of columns in the distributed submatrix $Q$ . $m \geq n \geq 0$ .
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix $Q$ . $n \geq k \geq 0$ .
<i>a</i>	Pointer into the local memory to an array of size $ld_a * LOCC(ja+n-1)$ On entry, the $j$ -th column of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(j)$ , $ja \leq j \leq ja+k-1$ , as returned by <code>p?geqrf</code> in the $k$ columns of its <i>distributed matrix</i> argument $A(ia:*, ja:ja+k-1)$ .
<i>ia</i>	(global) The row index in the global matrix $A$ indicating the first row of sub( $A$ ).
<i>ja</i>	(global) The column index in the global matrix $A$ indicating the first column of sub( $A$ ).
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .
<i>tau</i>	(local) Array of size $LOCC(ja+k-1)$ . <i>tau</i> [ $j$ ] contains the scalar factor of the elementary reflector $H(j+1)$ , $j = 0, 1, \dots, LOCC(ja+k-1)-1$ , as returned by <code>p?geqrf</code> . This array is tied to the distributed matrix $A$ .
<i>work</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork \geq mpa0 + \max(1, nqa0)$ , where $iroffa = \text{mod}(ia-1, mb_a)$ , $icoffa = \text{mod}(ja-1, nb_a)$ , $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$ , $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcot)$ , $mpa0 = \text{numroc}(m+iroffa, mb_a, myrow, iarow, nprow)$ , $nqa0 = \text{numroc}(n+icoffa, nb_a, mycol, iacol, npcot)$ .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nprow`, and `npcol` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

*lwork , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?orgl2/p?ungl2` function generates a  $m$ -by- $n$  real/complex matrix  $Q$  denoting  $A$  ( $ia:ia+m-1$ ,  $ja:ja+n-1$ ) with orthonormal rows, which is defined as the first  $m$  rows of a product of  $k$  elementary reflectors of order  $n$

$Q = H(k) * \dots * H(2) * H(1)$  (for real flavors),

$Q = (H(k))^H * \dots * (H(2))^H * (H(1))^H$  (for complex flavors) as returned by `p?gelqf`.

## Input Parameters

<i>m</i>	(global) The number of rows in the distributed submatrix <i>Q</i> . $m \geq 0$ .
<i>n</i>	(global) The number of columns in the distributed submatrix <i>Q</i> . $n \geq m \geq 0$ .
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix <i>Q</i> . $m \geq k \geq 0$ .
<i>a</i>	Pointer into the local memory to an array of size $lld\_a * LOCr(ja+n-1)$ . On entry, the <i>i</i> -th row of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(i)$ , $ia \leq i \leq ia+k-1$ , as returned by <code>p?gelqf</code> in the <i>k</i> rows of its <i>distributed matrix</i> argument <i>A</i> ( <i>ia:ia+k-1</i> , <i>ja:*</i> ).
<i>ia</i>	(global) The row index in the global matrix <i>A</i> indicating the first row of sub( <i>A</i> ).
<i>ja</i>	(global) The column index in the global matrix <i>A</i> indicating the first column of sub( <i>A</i> ).
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) Array of size $LOCr(ja+k-1)$ . <i>tau</i> [ <i>j</i> ] contains the scalar factor of the elementary reflectors $H(j+1)$ , $j = 0, 1, \dots, LOCr(ja+k-1)-1$ , as returned by <code>p?gelqf</code> . This array is tied to the distributed matrix <i>A</i> .
<i>WORK</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork \geq nqa0 + \max(1, mpa0)$ , where $iroffa = \text{mod}(ia-1, mb\_a),$ $icoffa = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nrow),$ $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, ncol),$ $mpa0 = \text{numroc}(m+iroffa, mb\_a, myrow, iarow, nrow),$ $nqa0 = \text{numroc}(n+icoffa, nb\_a, mycol, iacol, ncol).$

`indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nrow`, and `ncol` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

<code>a</code>	On exit, this array contains the local pieces of the $m$ -by- $n$ distributed matrix $Q$ .
<code>work</code>	On exit, <code>work[0]</code> returns the minimal and optimal <code>lwork</code> .
<code>info</code>	(local) = 0: successful exit < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j-1$ , had an illegal value, then <code>info = -(i*100 + j)</code> , if the $i$ -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

*lwork , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?orgr2/p?ungr2` function generates an  $m$ -by- $n$  real/complex matrix  $Q$  denoting  $A(ia:ia+m-1, ja:ja+n-1)$  with orthonormal rows, which is defined as the last  $m$  rows of a product of  $k$  elementary reflectors of order  $n$

$Q = H(1)*H(2)*...*H(k)$  (for real flavors);

$Q = (H(1))^H*(H(2))^H*...*(H(k))^H$  (for complex flavors) as returned by `p?gerqf`.

## Input Parameters

<i>m</i>	(global) The number of rows in the distributed submatrix <i>Q</i> . $m \geq 0$ .
<i>n</i>	(global) The number of columns in the distributed submatrix <i>Q</i> . $n \geq m \geq 0$ .
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix <i>Q</i> . $m \geq k \geq 0$ .
<i>a</i>	Pointer into the local memory to an array of size $lld\_a * LOCr(ja+n-1)$ . On entry, the <i>i</i> -th row of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(i)$ , $ia+m-k \leq i \leq ia+m-1$ , as returned by <code>p?gerqf</code> in the <i>k</i> rows of its <i>distributed matrix</i> argument <i>A</i> ( $ia+m-k:ia+m-1, ja:*$ ).
<i>ia</i>	(global) The row index in the global matrix <i>A</i> indicating the first row of sub( <i>A</i> ).
<i>ja</i>	(global) The column index in the global matrix <i>A</i> indicating the first column of sub( <i>A</i> ).
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) Array of size $LOCr(ja+m-1)$ . <i>tau</i> [ <i>j</i> ] contains the scalar factor of the elementary reflectors $H(j+1)$ , $j = 0, 1, \dots, LOCr(ja+m-1)-1$ , as returned by <code>p?gerqf</code> . This array is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the array <i>work</i> .  <i>lwork</i> is local input and must be at least $lwork \geq nqa0 + \max(1, mpa0)$ , where $irow = \text{mod}(ia-1, mb\_a)$ , $icol = \text{mod}(ja-1, nb\_a)$ , $irow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow)$ , $icol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcil)$ , $mpa0 = \text{numroc}(m+irow, mb\_a, myrow, irow, nprow)$ , $nqa0 = \text{numroc}(n+icol, nb\_a, mycol, icol, npcil)$ .  <code>indxg2p</code> and <code>numroc</code> are ScaLAPACK tool functions; <i>myrow</i> , <i>mycol</i> , <i>nprow</i> , and <i>npcil</i> can be determined by calling the function <code>blacs_gridinfo</code> .

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

<code>a</code>	On exit, this array contains the local pieces of the $m$ -by- $n$ distributed matrix $Q$ .
<code>work</code>	On exit, <code>work[0]</code> returns the minimal and optimal $lwork$ .
<code>info</code>	(local) = 0: successful exit < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j-1$ , had an illegal value, then $info = -(i*100 + j)$ , if the $i$ -th argument is a scalar and had an illegal value, then $info = -i$ .

## Description

The `p?orm2l/p?unm2l` function overwrites the general real/complex  $m$ -by- $n$  distributed matrix sub  $(C)=C(ic:ic+m-1,jc:jc+n-1)$  with

$Q \cdot \text{sub}(C)$  if  $side = 'L'$  and  $trans = 'N'$ , or

$Q^T \cdot \text{sub}(C) / Q^H \cdot \text{sub}(C)$  if  $side = 'L'$  and  $trans = 'T'$  (for real flavors) or  $trans = 'C'$  (for complex flavors), or

$\text{sub}(C) \cdot Q$  if  $side = 'R'$  and  $trans = 'N'$ , or

$\text{sub}(C) \cdot Q^T / \text{sub}(C) \cdot Q^H$  if  $side = 'R'$  and  $trans = 'T'$  (for real flavors) or  $trans = 'C'$  (for complex flavors).

where  $Q$  is a real orthogonal or complex unitary distributed matrix defined as the product of  $k$  elementary reflectors

$Q = H(k) \cdot \dots \cdot H(2) \cdot H(1)$  as returned by `p?geqlf`.  $Q$  is of order  $m$  if  $side = 'L'$  and of order  $n$  if  $side = 'R'$ .

## Input Parameters

<i>side</i>	(global) = 'L': apply $Q$ or $Q^T$ for real flavors ( $Q^H$ for complex flavors) from the left, = 'R': apply $Q$ or $Q^T$ for real flavors ( $Q^H$ for complex flavors) from the right.
<i>trans</i>	(global) = 'N': apply $Q$ (no transpose) = 'T': apply $Q^T$ (transpose, for real flavors) = 'C': apply $Q^H$ (conjugate transpose, for complex flavors)
<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(C)$ . $m \geq 0$ .
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(C)$ . $n \geq 0$ .
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix $Q$ . If $side = 'L'$ , $m \geq k \geq 0$ ; if $side = 'R'$ , $n \geq k \geq 0$ .
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(ja+k-1)$ . On entry, the $j$ -th row of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(j)$ , $ja \leq j \leq ja+k-1$ , as returned by <code>p?geqlf</code> in the $k$ columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$ . The argument $A(ia:*, ja:ja+k-1)$ is modified by the function but restored on exit. If $side = 'L'$ , $lld\_a \geq \max(1, LOCr(ia+m-1))$ , if $side = 'R'$ , $lld\_a \geq \max(1, LOCr(ia+n-1))$ .
<i>ia</i>	(global) The row index in the global matrix $A$ indicating the first row of $\text{sub}(A)$ .

<i>ja</i>	(global) The column index in the global matrix <i>A</i> indicating the first column of <i>sub(A)</i> .
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) Array of size $LOCc(ja+n-1)$ . <i>tau[j]</i> contains the scalar factor of the elementary reflector $H(j+1)$ , $j = 0, 1, \dots, LOCc(ja+n-1)-1$ , as returned by <a href="#">p?geqlf</a> . This array is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) Pointer into the local memory to an array of size $lld\_c * LOCc(jc+n-1)$ . On entry, the local pieces of the distributed matrix <i>sub(C)</i> .
<i>ic</i>	(global) The row index in the global matrix <i>C</i> indicating the first row of <i>sub(C)</i> .
<i>jc</i>	(global) The column index in the global matrix <i>C</i> indicating the first column of <i>sub(C)</i> .
<i>descc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) Workspace array of size <i>lwork</i> . On exit, <i>work(1)</i> returns the minimal and optimal <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least if <i>side</i> = 'L', $lwork \geq mpc0 + \max(1, nqc0)$ , if <i>side</i> = 'R', $lwork \geq nqc0 + \max(\max(1, mpc0), \text{numroc}(\text{numroc}(n + icoffc, nb\_a, 0, 0, npc0l), nb\_a, 0, 0, lcmq))$ , where $lcmq = lcm/npc0l$ , $lcm = iclm(nprow, npc0l)$ , $iroffc = \text{mod}(ic-1, mb\_c)$ , $icoffc = \text{mod}(jc-1, nb\_c)$ , $icrow = \text{indxg2p}(ic, mb\_c, myrow, rsrc\_c, nprow)$ , $iccol = \text{indxg2p}(jc, nb\_c, mycol, csrc\_c, npc0l)$ , $Mqc0 = \text{numroc}(m+icoffc, nb\_c, mycol, icrow, nprow)$ , $Npc0 = \text{numroc}(n+iroffc, mb\_c, myrow, iccol, npc0l)$ ,

`ilcm`, `indxg2p`, and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `npro`, and `npcol` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

<code>c</code>	On exit, <code>c</code> is overwritten by $Q \cdot \text{sub}(C)$ , or $Q^T \cdot \text{sub}(C) / Q^H \cdot \text{sub}(C)$ , or $\text{sub}(C) \cdot Q$ , or $\text{sub}(C) \cdot Q^T / \text{sub}(C) \cdot Q^H$
<code>work</code>	On exit, <code>work[0]</code> returns the minimal and optimal <code>lwork</code> .
<code>info</code>	(local) = 0: successful exit < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> -1, had an illegal value, then <code>info = - (i*100 + j)</code> , if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

---

### NOTE

The distributed submatrices  $A(ia:*, ja:*)$  and  $C(ic:ic+m-1, jc:jc+n-1)$  must verify some alignment properties, namely the following expressions should be true:

If `side = 'L'`, ( `mb_a == mb_c` && `iroffa == iroffc` && `iarow == icrow` )

If `side = 'R'`, ( `mb_a == nb_c` && `iroffa == iroffc` ).

## Description

The `p?orm2r/p?unm2r` function overwrites the general real/complex  $m$ -by- $n$  distributed matrix sub( $C$ )= $C(ic:ic+m-1, jc:jc+n-1)$  with

$Q*\text{sub}(C)$  if `side = 'L'` and `trans = 'N'`, or

$Q^T*\text{sub}(C) / Q^H*\text{sub}(C)$  if `side = 'L'` and `trans = 'T'` (for real flavors) or `trans = 'C'` (for complex flavors), or

$\text{sub}(C)*Q$  if `side = 'R'` and `trans = 'N'`, or

$\text{sub}(C)*Q^T / \text{sub}(C)*Q^H$  if `side = 'R'` and `trans = 'T'` (for real flavors) or `trans = 'C'` (for complex flavors).

where  $Q$  is a real orthogonal or complex unitary matrix defined as the product of  $k$  elementary reflectors

$Q = H(k)*\dots*H(2)*H(1)$  as returned by `p?geqrf`.  $Q$  is of order  $m$  if `side = 'L'` and of order  $n$  if `side = 'R'`.

## Input Parameters

<code>side</code>	(global) = 'L': apply $Q$ or $Q^T$ for real flavors ( $Q^H$ for complex flavors) from the left, = 'R': apply $Q$ or $Q^T$ for real flavors ( $Q^H$ for complex flavors) from the right.
<code>trans</code>	(global) = 'N': apply $Q$ (no transpose) = 'T': apply $Q^T$ (transpose, for real flavors) = 'C': apply $Q^H$ (conjugate transpose, for complex flavors)
<code>m</code>	(global) The number of rows in the distributed matrix sub( $C$ ). $m \geq 0$ .
<code>n</code>	(global) The number of columns in the distributed matrix sub( $C$ ). $n \geq 0$ .
<code>k</code>	(global) The number of elementary reflectors whose product defines the matrix $Q$ . If <code>side = 'L'</code> , $m \geq k \geq 0$ ;

	if $side = 'R', n \geq k \geq 0$ .
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+k-1)$ . On entry, the $j$ -th column of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(j)$ , $ja \leq j \leq ja+k-1$ , as returned by <code>p?geqrf</code> in the $k$ columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$ . The argument $A(ia:*, ja:ja+k-1)$ is modified by the function but restored on exit. If $side = 'L', lld\_a \geq \max(1, LOCr(ia+m-1))$ , if $side = 'R', lld\_a \geq \max(1, LOCr(ia+n-1))$ .
<i>ia</i>	(global) The row index in the global matrix $A$ indicating the first row of sub( $A$ ).
<i>ja</i>	(global) The column index in the global matrix $A$ indicating the first column of sub( $A$ ).
<i>desca</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
<i>tau</i>	(local) Array of size $LOCC(ja+k-1)$ . $tau[j]$ contains the scalar factor of the elementary reflector $H(j+1)$ , $j = 0, 1, \dots, LOCC(ja+k-1)-1$ , as returned by <code>p?geqrf</code> . This array is tied to the distributed matrix $A$ .
<i>c</i>	(local) Pointer into the local memory to an array of size $lld\_c * LOCC(jc+n-1)$ . On entry, the local pieces of the distributed matrix sub ( $C$ ).
<i>ic</i>	(global) The row index in the global matrix $C$ indicating the first row of sub( $C$ ).
<i>jc</i>	(global) The column index in the global matrix $C$ indicating the first column of sub( $C$ ).
<i>descc</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $C$ .
<i>work</i>	(local) Workspace array of size $lwork$ .
<i>lwork</i>	(local or global) The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least if $side = 'L', lwork \geq mpc0 + \max(1, nqc0)$ ,

if  $side = 'R', lwork \geq nqc0 + \max(\max(1, mpc0), \text{numroc}(\text{numroc}(n + icoffc, nb\_a, 0, 0, npc0l), nb\_a, 0, 0, lcmq)),$

where

```
lcmq = lcm/npcol,
lcm = iclm(nprow, npc0l),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nprow),
iccol = indxg2p(jc, nb_c, mycol, csrc_c, npc0l),
Mqc0 = numroc(m+icoffc, nb_c, mycol, icrow, nprow),
Npc0 = numroc(n+iroffc, mb_c, myrow, iccol, npc0l),
iclm, indxg2p and numroc are ScaLAPACK tool functions; myrow, mycol,
nprow, and npc0l can be determined by calling the function
blacs_gridinfo.
```

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

<i>c</i>	On exit, <i>c</i> is overwritten by $Q \cdot \text{sub}(C)$ , or $Q^T \cdot \text{sub}(C) / Q^H \cdot \text{sub}(C)$ , or $\text{sub}(C) \cdot Q$ , or $\text{sub}(C) \cdot Q^T / \text{sub}(C) \cdot Q^H$
<i>work</i>	On exit, <i>work</i> [0] returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local) = 0: successful exit < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> -1, had an illegal value, then <i>info</i> = - ( <i>i</i> *100 + <i>j</i> ), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

---

### NOTE

The distributed submatrices  $A(ia:*, ja:*)$  and  $C(ic:ic+m-1, jc:jc+n-1)$  must verify some alignment properties, namely the following expressions should be true:

If  $side = 'L', (mb\_a == mb\_c) \ \&\& \ (iroffa == iroffc) \ \&\& \ (iarow == icrow).$

If  $side = 'R', (mb\_a == nb\_c) \ \&\& \ (iroffa == iroffc).$

### Description

The p?orml2/p?unml2 function overwrites the general real/complex  $m$ -by- $n$  distributed matrix sub  $(C) = C(ic:ic+m-1, jc:jc+n-1)$  with

$Q * \text{sub}(C)$  if  $side = 'L'$  and  $trans = 'N'$ , or

$Q^T * \text{sub}(C) / Q^H * \text{sub}(C)$  if  $side = 'L'$  and  $trans = 'T'$  (for real flavors) or  $trans = 'C'$  (for complex flavors), or

$\text{sub}(C) * Q$  if  $side = 'R'$  and  $trans = 'N'$ , or

$\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$  if  $side = 'R'$  and  $trans = 'T'$  (for real flavors) or  $trans = 'C'$  (for complex flavors).

where  $Q$  is a real orthogonal or complex unitary distributed matrix defined as the product of  $k$  elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$  (for real flavors)

$Q = (H(k))^H * \dots * (H(2))^H * (H(1))^H$  (for complex flavors)

as returned by p?gelqf .  $Q$  is of order  $m$  if  $side = 'L'$  and of order  $n$  if  $side = 'R'$ .

### Input Parameters

*side* (global)  
 = 'L': apply  $Q$  or  $Q^T$  for real flavors ( $Q^H$  for complex flavors) from the left,  
 = 'R': apply  $Q$  or  $Q^T$  for real flavors ( $Q^H$  for complex flavors) from the right.

<i>trans</i>	(global) = 'N': apply $Q$ (no transpose) = 'T': apply $Q^T$ (transpose, for real flavors) = 'C': apply $Q^H$ (conjugate transpose, for complex flavors)
<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(C)$ . $m \geq 0$ .
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(C)$ . $n \geq 0$ .
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix $Q$ . If $side = 'L', m \geq k \geq 0$ ; if $side = 'R', n \geq k \geq 0$ .
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(ja+m-1)$ if $side='L'$ , $lld\_a * LOCc(ja+n-1)$ if $side='R'$ , where $lld\_a \geq \max(1, LOCr(ia+k-1))$ . On entry, the $i$ -th row of the matrix stored in $a$ must contain the vector that defines the elementary reflector $H(i)$ , $ia \leq i \leq ia+k-1$ , as returned by <a href="#">p?gelqf</a> in the $k$ rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$ . The argument $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit.
<i>ia</i>	(global) The row index in the global matrix $A$ indicating the first row of $\text{sub}(A)$ .
<i>ja</i>	(global) The column index in the global matrix $A$ indicating the first column of $\text{sub}(A)$ .
<i>desca</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
<i>tau</i>	(local) Array of size $LOCc(ia+k-1)$ . $tau[i]$ contains the scalar factor of the elementary reflector $H(i+1)$ , $i = 0, 1, \dots, LOCc(ja+k-1) - 1$ , as returned by <a href="#">p?gelqf</a> . This array is tied to the distributed matrix $A$ .
<i>c</i>	(local) Pointer into the local memory to an array of size $lld\_c * LOCc(jc+n-1)$ . On entry, the local pieces of the distributed matrix $\text{sub}(C)$ .
<i>ic</i>	(global) The row index in the global matrix $C$ indicating the first row of $\text{sub}(C)$ .

<i>jc</i>	(global) The column index in the global matrix <i>C</i> indicating the first column of <i>sub(C)</i> .
<i>desc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least if <i>side</i> = 'L', $lwork \geq mqc0 + \max(\max(1, npc0), \text{numroc}(\text{numroc}(m + icoffc, mb\_a, 0, 0, nprow), mb\_a, 0, 0, lcm)),$ if <i>side</i> = 'R', $lwork \geq npc0 + \max(1, mqc0),$ where $lcmp = lcm / nprow,$ $lcm = iclm(nprow, npc0),$ $irow = mod(ic-1, mb\_c),$ $icrow = mod(jc-1, nb\_c),$ $icrow = \text{indxg2p}(ic, mb\_c, myrow, rsrc\_c, nprow),$ $iccol = \text{indxg2p}(jc, nb\_c, mycol, csrc\_c, npc0),$ $Mpc0 = \text{numroc}(m+icoffc, mb\_c, mycol, icrow, nprow),$ $Nqc0 = \text{numroc}(n+irow, nb\_c, myrow, iccol, npc0),$ <i>iclm</i> , <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; <i>myrow</i> , <i>mycol</i> , <i>nprow</i> , and <i>npc0</i> can be determined by calling the function <i>blacs_gridinfo</i> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <a href="#">pxerbla</a> .

## Output Parameters

<i>c</i>	On exit, <i>c</i> is overwritten by $Q*\text{sub}(C)$ , or $Q^T*\text{sub}(C)/Q^H*\text{sub}(C)$ , or $\text{sub}(C)*Q$ , or $\text{sub}(C)*Q^T / \text{sub}(C)*Q^H$
<i>work</i>	On exit, <i>work</i> [0] returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local) = 0: successful exit < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> -1, had an illegal value, then $info = -(i*100 + j),$

if the  $i$ -th argument is a scalar and had an illegal value,  
then  $info = -i$ .

**NOTE**

The distributed submatrices  $A(ia:*, ja:*)$  and  $C(ic:ic+m-1, jc:jc+n-1)$  must verify some alignment properties, namely the following expressions should be true:

If  $side = 'L'$ ,  $(nb\_a == mb\_c \ \&\& \ icoffa == iroffc)$

If  $side = 'R'$ ,  $(nb\_a == nb\_c \ \&\& \ icoffa == icoffc \ \&\& \ iacol == iccol)$ .

**Description**

The p?ormr2/p?unmr2 function overwrites the general real/complex  $m$ -by- $n$  distributed matrix sub  $(C)=C(ic:ic+m-1, jc:jc+n-1)$  with

$Q$ \*sub( $C$ ) if  $side = 'L'$  and  $trans = 'N'$ , or

$Q^T$ \*sub( $C$ ) /  $Q^H$ \*sub( $C$ ) if  $side = 'L'$  and  $trans = 'T'$  (for real flavors) or  $trans = 'C'$  (for complex flavors), or

sub( $C$ )\* $Q$  if  $side = 'R'$  and  $trans = 'N'$ , or

sub( $C$ )\* $Q^T$  / sub( $C$ )\* $Q^H$  if  $side = 'R'$  and  $trans = 'T'$  (for real flavors) or  $trans = 'C'$  (for complex flavors).

where  $Q$  is a real orthogonal or complex unitary distributed matrix defined as the product of  $k$  elementary reflectors

$Q = H(1)*H(2)*...*H(k)$  (for real flavors)

$Q = (H(1))^H*(H(2))^H*...*(H(k))^H$  (for complex flavors)

as returned by `p?gerqf`.  $Q$  is of order  $m$  if  $side = 'L'$  and of order  $n$  if  $side = 'R'$ .

## Input Parameters

<i>side</i>	(global) = 'L': apply $Q$ or $Q^T$ for real flavors ( $Q^H$ for complex flavors) from the left, = 'R': apply $Q$ or $Q^T$ for real flavors ( $Q^H$ for complex flavors) from the right.
<i>trans</i>	(global) = 'N': apply $Q$ (no transpose) = 'T': apply $Q^T$ (transpose, for real flavors) = 'C': apply $Q^H$ (conjugate transpose, for complex flavors)
<i>m</i>	(global) The number of rows in the distributed matrix $sub(C)$ . $m \geq 0$ .
<i>n</i>	(global) The number of columns in the distributed matrix $sub(C)$ . $n \geq 0$ .
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix $Q$ . If $side = 'L'$ , $m \geq k \geq 0$ ; if $side = 'R'$ , $n \geq k \geq 0$ .
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(ja+m-1)$ if $side='L'$ , $lld\_a * LOCc(ja+n-1)$ if $side='R'$ , where $lld\_a \geq \max(1, LOCr(ia+k-1))$ . On entry, the $i$ -th row of the matrix stored in $a$ must contain the vector that defines the elementary reflector $H(i)$ , $ia \leq i \leq ia+k-1$ , as returned by <code>p?gerqf</code> in the $k$ rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$ . The argument $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit.
<i>ia</i>	(global) The row index in the global matrix $A$ indicating the first row of $sub(A)$ .
<i>ja</i>	(global)

	The column index in the global matrix $A$ indicating the first column of $\text{sub}(A)$ .
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .
<i>tau</i>	(local) Array of size $LOCc(ia+k-1)$ . <i>tau</i> [ <i>j</i> ] contains the scalar factor of the elementary reflector $H(j+1)$ , $j = 0, 1, \dots, LOCc(ja+k-1)-1$ , as returned by <a href="#">p?gerqf</a> . This array is tied to the distributed matrix $A$ .
<i>c</i>	(local) Pointer into the local memory to an array of size $lld\_c * LOCc(jc+n-1)$ . On entry, the local pieces of the distributed matrix $\text{sub}(C)$ .
<i>ic</i>	(global) The row index in the global matrix $C$ indicating the first row of $\text{sub}(C)$ .
<i>jc</i>	(global) The column index in the global matrix $C$ indicating the first column of $\text{sub}(C)$ .
<i>desc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $C$ .
<i>work</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least if <i>side</i> = 'L', $lwork \geq mpc0 + \max(\max(1, nqc0), \text{numroc}(\text{numroc}(m + iroffc, mb\_a, 0, 0, nprow), mb\_a, 0, 0, lcmp))$ , if <i>side</i> = 'R', $lwork \geq nqc0 + \max(1, mpc0)$ , where $lcmp = lcm/nprow$ , $lcm = iclm(nprow, npc0l)$ , $iroffc = \text{mod}(ic-1, mb\_c)$ , $icoffc = \text{mod}(jc-1, nb\_c)$ , $icrow = \text{indxg2p}(ic, mb\_c, myrow, rsrc\_c, nprow)$ , $iccol = \text{indxg2p}(jc, nb\_c, mycol, csrc\_c, npc0l)$ , $Mpc0 = \text{numroc}(m + iroffc, mb\_c, myrow, icrow, nprow)$ , $Nqc0 = \text{numroc}(n + icoffc, nb\_c, mycol, iccol, npc0l)$ , <i>iclm</i> , <i>indxg2p</i> and <i>numroc</i> are <b>ScalLAPACK</b> tool functions; <i>myrow</i> , <i>mycol</i> , <i>nprow</i> , and <i>npc0l</i> can be determined by calling the function <i>blacs_gridinfo</i> .

If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

## Output Parameters

<code>c</code>	On exit, <code>c</code> is overwritten by $Q \cdot \text{sub}(C)$ , or $Q^T \cdot \text{sub}(C) / Q^H \cdot \text{sub}(C)$ , or $\text{sub}(C) \cdot Q$ , or $\text{sub}(C) \cdot Q^T / \text{sub}(C) \cdot Q^H$
<code>work</code>	On exit, <code>work[0]</code> returns the minimal and optimal $lwork$ .
<code>info</code>	(local) = 0: successful exit < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j-1$ , had an illegal value, then $info = -(i \cdot 100 + j)$ , if the $i$ -th argument is a scalar and had an illegal value, then $info = -i$ .

---

### NOTE

The distributed submatrices  $A(ia:*, ja:*)$  and  $C(ic:ic+m-1, jc:jc+n-1)$  must verify some alignment properties, namely the following expressions should be true:

If  $side = 'L'$ ,  $(nb\_a == mb\_c) \ \&\& \ (icoffa == iroffc)$ .

If  $side = 'R'$ ,  $(nb\_a == nb\_c) \ \&\& \ (icoffa == icoffc) \ \&\& \ (iacol == iccol)$ .

## Description

The pzpbtrsv function solves a banded triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(jb:jb+n-1, 1:nrhs)$$

or

$$A(1:n, ja:ja+n-1)^T * X = B(jb:jb+n-1, 1:nrhs) \text{ for real flavors,}$$

$$A(1:n, ja:ja+n-1)^H * X = B(jb:jb+n-1, 1:nrhs) \text{ for complex flavors,}$$

where  $A(1:n, ja:ja+n-1)$  is a banded triangular matrix factor produced by the Cholesky factorization code pzpbtrf and is stored in  $A(1:n, ja:ja+n-1)$  and  $af$ . The matrix stored in  $A(1:n, ja:ja+n-1)$  is either upper or lower triangular according to  $uplo$ .

The function pzpbtrf must be called first.

### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.intel.com/PerformanceIndex](http://www.intel.com/PerformanceIndex).

Notice revision #20201201

## Input Parameters

<i>uplo</i>	(global) Must be 'U' or 'L'. If <i>uplo</i> = 'U', upper triangle of $A(1:n, ja:ja+n-1)$ is stored; If <i>uplo</i> = 'L', lower triangle of $A(1:n, ja:ja+n-1)$ is stored.
<i>trans</i>	(global) Must be 'N' or 'T' or 'C'. If <i>trans</i> = 'N', solve with $A(1:n, ja:ja+n-1)$ ; If <i>trans</i> = 'T' or 'C' for real flavors, solve with $A(1:n, ja:ja+n-1)^T$ . If <i>trans</i> = 'C' for complex flavors, solve with conjugate transpose $(A(1:n, ja:ja+n-1))^H$ .
<i>n</i>	(global) The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$ . $n \geq 0$ .
<i>bw</i>	(global) The number of subdiagonals in 'L' or 'U', $0 \leq bw \leq n-1$ .
<i>nrhs</i>	(global) The number of right hand sides; the number of columns of the distributed submatrix $B(jb:jb+n-1, 1:nrhs)$ ; $nrhs \geq 0$ .

<i>a</i>	<p>(local)</p> <p>Pointer into the local memory to an array with the first size <math>lld\_a \geq (bw + 1)</math>, stored in <i>desca</i>.</p> <p>On entry, this array contains the local pieces of the <math>n</math>-by-<math>n</math> symmetric banded distributed Cholesky factor <math>L</math> or <math>L^T * A(1:n, ja:ja+n-1)</math>.</p> <p>This local portion is stored in the packed banded format used in LAPACK. See the <i>Application Notes</i> below and the ScaLAPACK manual for more detail on the format of distributed matrices.</p>
<i>ja</i>	<p>(global) The index in the global in the global matrix <math>A</math> that points to the start of the matrix to be operated on (which may be either all of <math>A</math> or a submatrix of <math>A</math>).</p>
<i>desca</i>	<p>(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix <math>A</math>.</p> <p>If 1D type (<i>dtype_a</i> = 501), then <math>dlen \geq 7</math>;</p> <p>If 2D type (<i>dtype_a</i> = 1), then <math>dlen \geq 9</math>.</p> <p>Contains information on mapping of <math>A</math> to memory. (See ScaLAPACK manual for full description and options.)</p>
<i>b</i>	<p>(local)</p> <p>Pointer into the local memory to an array of local lead size <math>lld\_b \geq nb</math>.</p> <p>On entry, this array contains the local pieces of the right hand sides <math>B(jb:jb+n-1, 1:nrhs)</math>.</p>
<i>ib</i>	<p>(global) The row index in the global matrix <math>B</math> that points to the first row of the matrix to be operated on (which may be either all of <math>B</math> or a submatrix of <math>B</math>).</p>
<i>descb</i>	<p>(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix <math>B</math>.</p> <p>If 1D type (<i>dtype_b</i> = 502), then <math>dlen \geq 7</math>;</p> <p>If 2D type (<i>dtype_b</i> = 1), then <math>dlen \geq 9</math>.</p> <p>Contains information on mapping of <math>B</math> to memory. Please, see ScaLAPACK manual for full description and options.</p>
<i>laf</i>	<p>(local)</p> <p>The size of user-input auxiliary fill-in space <i>af</i>. Must be <math>laf \geq (nb + 2 * bw) * bw</math>. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i>[0].</p>
<i>work</i>	<p>(local)</p> <p>The array <i>work</i> is a temporary workspace array of size <i>lwork</i>. This space may be overwritten in between function calls.</p>
<i>lwork</i>	<p>(local or global) The size of the user-input workspace <i>work</i>, must be at least <math>lwork \geq bw * nrhs</math>. If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i>[0] and an error code is returned.</p>

## Output Parameters

<i>af</i>	(local) The array <i>af</i> is of size <i>laf</i> . It contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function <code>p?pbtrf</code> and is stored in <i>af</i> . If a linear system is to be solved using <code>p?pbtrs</code> after the factorization function, <i>af</i> must not be altered after the factorization.
<i>b</i>	On exit, this array contains the local piece of the solutions distributed matrix <i>X</i> .
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> .
<i>info</i>	(local) = 0: successful exit < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> -1, had an illegal value, then <i>info</i> = - ( <i>i</i> *100 + <i>j</i> ), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

## Application Notes

If the factorization function and the solve function are to be called separately to solve various sets of right-hand sides using the same coefficient matrix, the auxiliary space *af* must not be altered between calls to the factorization function and the solve function.

The best algorithm for solving banded and tridiagonal linear systems depends on a variety of parameters, especially the bandwidth. Currently, only algorithms designed for the case  $N/P \gg bw$  are implemented. These algorithms go by many names, including Divide and Conquer, Partitioning, domain decomposition-type, etc.

The Divide and Conquer algorithm assumes the matrix is narrowly banded compared with the number of equations. In this situation, it is best to distribute the input matrix *A* one-dimensionally, with columns atomic and rows divided amongst the processes. The basic algorithm divides the banded matrix up into *P* pieces with one stored on each processor, and then proceeds in 2 phases for the factorization or 3 for the solution of a linear system.

- 1. Local Phase:** The individual pieces are factored independently and in parallel. These factors are applied to the matrix creating fill-in, which is stored in a non-inspectable way in auxiliary space *af*. Mathematically, this is equivalent to reordering the matrix *A* as  $PAP^T$  and then factoring the principal leading submatrix of size equal to the sum of the sizes of the matrices factored on each processor. The factors of these submatrices overwrite the corresponding parts of *A* in memory.
- 2. Reduced System Phase:** A small ( $bw*(P-1)$ ) system is formed representing interaction of the larger blocks and is stored (as are its factors) in the space *af*. A parallel Block Cyclic Reduction algorithm is used. For a linear system, a parallel front solve followed by an analogous backsolve, both using the structure of the factored matrix, are performed.
- 3. Back Substitution Phase:** For a linear system, a local backsubstitution is performed on each processor in parallel.

### Description

The `p?pttrsv` function solves a tridiagonal triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(jb:jb+n-1, 1:nrhs)$$

or

$$A(1:n, ja:ja+n-1)^T * X = B(jb:jb+n-1, 1:nrhs) \text{ for real flavors,}$$

$$A(1:n, ja:ja+n-1)^H * X = B(jb:jb+n-1, 1:nrhs) \text{ for complex flavors,}$$

where  $A(1:n, ja:ja+n-1)$  is a tridiagonal triangular matrix factor produced by the Cholesky factorization code `p?pttrf` and is stored in  $A(1:n, ja:ja+n-1)$  and `af`. The matrix stored in  $A(1:n, ja:ja+n-1)$  is either upper or lower triangular according to `uplo`.

The function `p?pttrf` must be called first.

### Input Parameters

`uplo` (global) Must be 'U' or 'L'.  
 If `uplo` = 'U', upper triangle of  $A(1:n, ja:ja+n-1)$  is stored;  
 If `uplo` = 'L', lower triangle of  $A(1:n, ja:ja+n-1)$  is stored.

`trans` (global) Must be 'N' or 'C'.  
 If `trans` = 'N', solve with  $A(1:n, ja:ja+n-1)$ ;  
 If `trans` = 'C' (for complex flavors), solve with conjugate transpose  $(A(1:n, ja:ja+n-1))^H$ .

<i>n</i>	(global) The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$ . $n \geq 0$ .
<i>nrhs</i>	(global) The number of right hand sides; the number of columns of the distributed submatrix $B(jb:jb+n-1, 1:nrhs)$ ; $nrhs \geq 0$ .
<i>d</i>	(local) Pointer to the local part of the global vector storing the main diagonal of the matrix; must be of size $\geq nb\_a$ .
<i>e</i>	(local) Pointer to the local part of the global vector $du$ storing the upper diagonal of the matrix; must be of size $\geq nb\_a$ . Globally, $du(n)$ is not referenced, and $du$ must be aligned with $d$ .
<i>ja</i>	(global) The index in the global matrix $A$ that points to the start of the matrix to be operated on (which may be either all of $A$ or a submatrix of $A$ ).
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ . If 1D type ( $dtype\_a = 501$ or $502$ ), then $dlen \geq 7$ ; If 2D type ( $dtype\_a = 1$ ), then $dlen \geq 9$ . Contains information on mapping of $A$ to memory. See ScaLAPACK manual for full description and options.
<i>b</i>	(local) Pointer into the local memory to an array of local lead size $lld\_b \geq nb$ . On entry, this array contains the local pieces of the right hand sides $B(jb:jb+n-1, 1:nrhs)$ .
<i>ib</i>	(global) The row index in the global matrix $B$ that points to the first row of the matrix to be operated on (which may be either all of $B$ or a submatrix of $B$ ).
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $B$ . If 1D type ( $dtype\_b = 502$ ), then $dlen \geq 7$ ; If 2D type ( $dtype\_b = 1$ ), then $dlen \geq 9$ . Contains information on mapping of $B$ to memory. See ScaLAPACK manual for full description and options.
<i>laf</i>	(local) The size of user-input auxiliary fill-in space $af$ . Must be $laf \geq (nb + 2 * bw) * bw$ . If $laf$ is not large enough, an error code will be returned and the minimum acceptable size will be returned in $af[0]$ .
<i>work</i>	(local)

The array *work* is a temporary workspace array of size *lwork*. This space may be overwritten in between function calls.

*lwork*

(local or global) The size of the user-input workspace *work*, must be at least  $lwork \geq (10 + 2 * \min(100, nrhs)) * npcol + 4 * nrhs$ . If *lwork* is too small, the minimal acceptable size will be returned in *work*[0] and an error code is returned.

## Output Parameters

*d, e*

(local).

On exit, these arrays contain information on the factors of the matrix.

*af*

(local)

The array *af* is of size *laf*. It contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function `p?pbtrf` and is stored in *af*. If a linear system is to be solved using `p?pttrs` after the factorization function, *af* must not be altered after the factorization.

*b*

On exit, this array contains the local piece of the solutions distributed matrix *X*.

*work*[0]

On exit, *work*[0] contains the minimum value of *lwork*.

*info*

(local)

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value,

then  $info = -(i * 100 + j)$ ,

if the *i*-th argument is a scalar and had an illegal value,

then  $info = -i$ .

## p?potf2

*Computes the Cholesky factorization of a symmetric/Hermitian positive definite matrix (local unblocked algorithm).*

### Syntax

```
void pspotf2 (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pdpotf2 (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pcpotf2 (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pzpotf2 (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

## Include Files

- `mk1_scalapack.h`

## Description

The `p?potf2` function computes the Cholesky factorization of a real symmetric or complex Hermitian positive definite distributed matrix  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ .

The factorization has the form

$\text{sub}(A) = U^*U$ , if `uplo = 'U'`, or  $\text{sub}(A) = L^*L'$ , if `uplo = 'L'`,

where  $U$  is an upper triangular matrix,  $L$  is lower triangular.  $X'$  denotes transpose (conjugate transpose) of  $X$ .

## Input Parameters

<code>uplo</code>	(global) Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $A$ is stored. = 'U': upper triangle of $\text{sub}(A)$ is stored; = 'L': lower triangle of $\text{sub}(A)$ is stored.
<code>n</code>	(global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$ . $n \geq 0$ .
<code>a</code>	(local) Pointer into the local memory to an array of size <code>lld_a * LOCc(ja+n-1)</code> containing the local pieces of the $n$ -by- $n$ symmetric distributed matrix $\text{sub}(A)$ to be factored.  If <code>uplo = 'U'</code> , the leading $n$ -by- $n$ upper triangular part of $\text{sub}(A)$ contains the upper triangular matrix and the strictly lower triangular part of this matrix is not referenced.  If <code>uplo = 'L'</code> , the leading $n$ -by- $n$ lower triangular part of $\text{sub}(A)$ contains the lower triangular matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
<code>ia, ja</code>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the $\text{sub}(A)$ , respectively.
<code>desca</code>	(global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix $A$ .

## Output Parameters

<code>a</code>	(local) On exit, if <code>uplo = 'U'</code> , the upper triangular part of the distributed matrix contains the Cholesky factor $U$ ; if <code>uplo = 'L'</code> , the lower triangular part of the distributed matrix contains the Cholesky factor $L$ .
----------------	---

*info* (local)

- = 0: successful exit
- < 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value, then  $info = -(i*100 + j)$ ,
- if the *i*-th argument is a scalar and had an illegal value, then  $info = -i$ .
- > 0: if  $info = k$ , the leading minor of order *k* is not positive definite, and the factorization could not be completed.

## p?rot

Applies a planar rotation to two distributed vectors.

## Syntax

```
void psrot(MKL_INT* n, float* x, MKL_INT* ix, MKL_INT* jx, MKL_INT* descx, MKL_INT* incx, float* y, MKL_INT* iy, MKL_INT* jy, MKL_INT* descy, MKL_INT* incy, float* cs, float* sn, float* work, MKL_INT* lwork, MKL_INT* info);
```

```
void pdrot(MKL_INT* n, double* x, MKL_INT* ix, MKL_INT* jx, MKL_INT* descx, MKL_INT* incx, double* y, MKL_INT* iy, MKL_INT* jy, MKL_INT* descy, MKL_INT* incy, double* cs, double* sn, double* work, MKL_INT* lwork, MKL_INT* info);
```

## Include Files

- `mkl_scalapack.h`

## Description

`p?rot` applies a planar rotation defined by *cs* and *sn* to the two distributed vectors `sub(x)` and `sub(y)`.

## Input Parameters

<i>n</i>	(global ) The number of elements to operate on when applying the planar rotation to <i>x</i> and <i>y</i> ( $n \geq 0$ ).
<i>x</i>	(local) array of size $((j_x - 1) * m_x + ix + (n - 1) * \text{abs}(inc_x))$ This array contains the entries of the distributed vector <code>sub(x)</code> .
<i>ix</i>	(global ) The global row index of the submatrix of the distributed matrix <i>x</i> to operate on. If $inc_x = 1$ , then it is required that $ix = iy$ . $1 \leq ix \leq m_x$ .
<i>jx</i>	(global ) The global column index of the submatrix of the distributed matrix <i>x</i> to operate on. If $inc_x = m_x$ , then it is required that $jx = jy$ . $1 \leq ix \leq n_x$ .
<i>descx</i>	(global and local) array of size 9

	The array descriptor of the distributed matrix $x$ .
<i>incx</i>	(global ) The global increment for the elements of $x$ . Only two values of <i>incx</i> are supported in this version, namely 1 and $m_x$ . Moreover, it must hold that $incx = m_x$ if $incy = m_y$ and that $incx = 1$ if $incy = 1$ .
<i>y</i>	(local) array of size $((jy-1)*m_y + iy + (n-1)*abs(incy))$ This array contains the entries of the distributed vector $sub(y)$ .
<i>iy</i>	(global ) The global row index of the submatrix of the distributed matrix $y$ to operate on. If $incy = 1$ , then it is required that $iy = ix$ . $1 \leq iy \leq m_y$ .
<i>jy</i>	(global ) The global column index of the submatrix of the distributed matrix $y$ to operate on. If $incy = m_x$ , then it is required that $jy = jx$ . $1 \leq jy \leq m_y$ .
<i>descy</i>	(global and local) array of size 9 The array descriptor of the distributed matrix $y$ .
<i>incy</i>	(global ) The global increment for the elements of $y$ . Only two values of <i>incy</i> are supported in this version, namely 1 and $m_y$ . Moreover, it must hold that $incy = m_y$ if $incx = m_x$ and that $incy = 1$ if $incx = 1$ .
<i>cs, sn</i>	(global) The parameters defining the properties of the planar rotation. It must hold that $0 \leq cs, sn \leq 1$ and that $sn^2 + cs^2 = 1$ . The latter is hardly checked in finite precision arithmetics.
<i>work</i>	(local workspace) array of size <i>lwork</i>
<i>lwork</i>	(local ) The length of the workspace array <i>work</i> . If $incx = 1$ and $incy = 1$ , then $lwork = 2*m_x$ If $lwork = -1$ , then a workspace query is assumed; the function only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by <a href="#">pxerbla</a> .

## OUTPUT Parameters

<i>x</i>	
<i>y</i>	
<i>work[0]</i>	On exit, if $info = 0$ , <i>work[0]</i> returns the optimal <i>lwork</i>
<i>info</i>	(global ) = 0: successful exit < 0: if $info = -i$ , the $i$ -th argument had an illegal value.

If the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j-1$ , had an illegal value, then  $info = -(i*100+j)$ , if the  $i$ -th argument is a scalar and had an illegal value, then  $info = -i$ .

## p?rscl

*Multiplies a vector by the reciprocal of a real scalar.*

## Syntax

```
void p?rscl (MKL_INT *n , float *sa , float *sx , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );

void pdrsc1 (MKL_INT *n , double *sa , double *sx , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );

void pc?rscl (MKL_INT *n , float *sa , MKL_Complex8 *sx , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );

void pzdrsc1 (MKL_INT *n , double *sa , MKL_Complex16 *sx , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?rscl` function multiplies an  $n$ -element real/complex vector  $\text{sub}(X)$  by the real scalar  $1/a$ . This is done without overflow or underflow as long as the final result  $\text{sub}(X)/a$  does not overflow or underflow.

$\text{sub}(X)$  denotes  $X(ix:ix+n-1, jx:jx)$ , if  $incx = 1$ ,

and  $X(ix:ix, jx:jx+n-1)$ , if  $incx = m_x$ .

## Input Parameters

$n$	(global) The number of components of the distributed vector $\text{sub}(X)$ . $n \geq 0$ .
$sa$	The scalar $a$ that is used to divide each component of the vector $\text{sub}(X)$ . This parameter must be $\geq 0$ .
$sx$	Array containing the local pieces of a distributed matrix of size of at least $((jx-1)*m_x + ix + (n-1)*abs(incx))$ . This array contains the entries of the distributed vector $\text{sub}(X)$ .
$ix$	(global) The row index of the submatrix of the distributed matrix $X$ to operate on.
$jx$	(global) The column index of the submatrix of the distributed matrix $X$ to operate on.
$descx$	(global and local) Array of size 9. The array descriptor for the distributed matrix $X$ .

`incx` (global)  
The increment for the elements of  $X$ . This version supports only two values of `incx`, namely 1 and  $m_x$ .

## Output Parameters

`sx` On exit, the result  $x/a$ .

MKL_INT *info );
```

```
void pchegs2 (MKL_INT *ibtype , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , MKL_INT *info );
```

```
void pzhegs2 (MKL_INT *ibtype , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

The p?sygs2/p?hegs2 function reduces a real symmetric-definite or a complex Hermitian positive-definite generalized eigenproblem to standard form.

Here  $\text{sub}(A)$  denotes  $A(ia:ia+n-1, ja:ja+n-1)$ , and  $\text{sub}(B)$  denotes  $B(ib:ib+n-1, jb:jb+n-1)$ .

If `ibtype = 1`, the problem is

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x$$

and `sub(A)` is overwritten by

$\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$  or  $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$  - for real flavors, and

$\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$  or  $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$  - for complex flavors.

If `ibtype = 2` or `3`, the problem is

$$\text{sub}(A) * \text{sub}(B) x = \lambda * x \text{ or } \text{sub}(B) * \text{sub}(A) x = \lambda * x$$

and `sub(A)` is overwritten by

$U * \text{sub}(A) * U^T$  or  $L * * T * \text{sub}(A) * L$  for real flavors and

$U * \text{sub}(A) * U^H$  or  $L * * H * \text{sub}(A) * L$  for complex flavors.

The matrix  $\text{sub}(B)$  must have been previously factorized as  $U^T * U$  or  $L * L^T$  (for real flavors), or as  $U^H * U$  or  $L * L^H$  (for complex flavors) by `p?potrf`.

## Input Parameters

<i>ibtype</i>	(global) = 1: compute $\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$ , or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$ for real functions, and $\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$ , or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$ for complex functions; = 2 or 3: compute $U * \text{sub}(A) * U^T$ , or $L^T * \text{sub}(A) * L$ for real functions, and $U * \text{sub}(A) * U^H$ or $L^H * \text{sub}(A) * L$ for complex functions.
<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored, and how $\text{sub}(B)$ is factorized. = 'U': Upper triangular of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factorized as $U^T * U$ (for real functions) or as $U^H * U$ (for complex functions). = 'L': Lower triangular of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factorized as $L * L^T$ (for real functions) or as $L * L^H$ (for complex functions)
<i>n</i>	(global) The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$ . $n \geq 0$ .
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ . On entry, this array contains the local pieces of the $n$ -by- $n$ symmetric/Hermitian distributed matrix $\text{sub}(A)$ . If <i>uplo</i> = 'U', the leading $n$ -by- $n$ upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced. If <i>uplo</i> = 'L', the leading $n$ -by- $n$ lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix $A$ .
<i>B</i>	(local) Pointer into the local memory to an array of size $lld\_b * LOCC(jb+n-1)$ .

On entry, this array contains the local pieces of the triangular factor from the Cholesky factorization of  $\text{sub}(B)$  as returned by `p?potrf`.

`ib, jb` (global)  
The row and column indices in the global matrix  $B$  indicating the first row and the first column of the  $\text{sub}(B)$ , respectively.

`descb` (global and local) array of size `dlen_`. The array descriptor for the distributed matrix  $B$ .

## Output Parameters

`a` (local)  
On exit, if `info = 0`, the transformed matrix is stored in the same format as  $\text{sub}(A)$ .

`info`  
= 0: successful exit.  
< 0: if the  $i$ -th argument is an array and the  $j$ -th entry, indexed  $j-1$ , had an illegal value,  
then `info = -(i*100+ j)`,  
if the  $i$ -th argument is a scalar and had an illegal value,  
then `info = -i`.

## `p?sytd2/p?hetd2`

*Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (local unblocked algorithm).*

## Syntax

```
void pssytd2 (char *uplo, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT
*desca, float *d, float *e, float *tau, float *work, MKL_INT *lwork, MKL_INT *info);

void pdsytd2 (char *uplo, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT
*desca, double *d, double *e, double *tau, double *work, MKL_INT *lwork, MKL_INT *info);

void pchetd2 (char *uplo, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja, MKL_INT
*desca, float *d, float *e, MKL_Complex8 *tau, MKL_Complex8 *work, MKL_INT *lwork,
MKL_INT *info);

void pzheta2 (char *uplo, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja,
MKL_INT *desca, double *d, double *e, MKL_Complex16 *tau, MKL_Complex16 *work, MKL_INT
*lwork, MKL_INT *info);
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?sytd2/p?hetd2` function reduces a real symmetric/complex Hermitian matrix  $\text{sub}(A)$  to symmetric/Hermitian tridiagonal form  $T$  by an orthogonal/unitary similarity transformation:

$Q' * \text{sub}(A) * Q = T$ , where  $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ .

## Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored: = 'U': upper triangular = 'L': lower triangular
<i>n</i>	(global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$ . $n \geq 0$ .
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOC_c(\text{ja}+n-1)$ . On entry, this array contains the local pieces of the $n$ -by- $n$ symmetric/Hermitian distributed matrix $\text{sub}(A)$ . If $uplo = 'U'$ , the leading $n$ -by- $n$ upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced. If $uplo = 'L'$ , the leading $n$ -by- $n$ lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
<i>ia, ja</i>	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the $\text{sub}(A)$ , respectively.
<i>desca</i>	(global and local) array of size $dlen\_$ . The array descriptor for the distributed matrix $A$ .
<i>work</i>	(local) The array <i>work</i> is a temporary workspace array of size <i>lwork</i> .

## Output Parameters

<i>a</i>	On exit, if $uplo = 'U'$ , the diagonal and first superdiagonal of $\text{sub}(A)$ are overwritten by the corresponding elements of the tridiagonal matrix $T$ , and the elements above the first superdiagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors; if $uplo = 'L'$ , the diagonal and first subdiagonal of $A$ are overwritten by the corresponding elements of the tridiagonal matrix $T$ , and the elements below the first subdiagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix $Q$ as a product of elementary reflectors. See the <i>Application Notes</i> below.
<i>d</i>	(local) Array of size $LOC_c(\text{ja}+n-1)$ . The diagonal elements of the tridiagonal matrix $T$ :

	$d[i] = A(i+1,i+1)$ , where $i=0,1, \dots, LOCC(ja+n-1) - 1$ ; $d$ is tied to the distributed matrix $A$ .
$e$	<p>(local)</p> <p>Array of size <math>LOCC(ja+n-1)</math>,</p> <p>if <math>uplo = 'U'</math>, <math>LOCC(ja+n-2)</math> otherwise.</p> <p>The off-diagonal elements of the tridiagonal matrix <math>T</math>:</p> $e[i] = A(i+1,i+2) \text{ if } uplo = 'U',$ $e[i] = A(i+2,i+1) \text{ if } uplo = 'L',$ <p>where <math>i=0,1, \dots, LOCC(ja+n-1) - 1</math>.</p> <p><math>e</math> is tied to the distributed matrix <math>A</math>.</p>
$tau$	<p>(local)</p> <p>Array of size <math>LOCC(ja+n-1)</math>.</p> <p>The scalar factors of the elementary reflectors. <math>tau</math> is tied to the distributed matrix <math>A</math>.</p>
$work[0]$	On exit, $work[0]$ returns the minimal and optimal value of $lwork$ .
$lwork$	<p>(local or global)</p> <p>The size of the workspace array <math>work</math>.</p> <p><math>lwork</math> is local input and must be at least <math>lwork \geq 3n</math>.</p> <p>If <math>lwork = -1</math>, then <math>lwork</math> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code>.</p>
$info$	<p>(local)</p> <p>= 0: successful exit</p> <p>&lt; 0: if the <math>i</math>-th argument, indexed <math>i-1</math>, is an array and the <math>j</math>-th entry had an illegal value,</p> <p>then <math>info = -(j*100+j)</math>,</p> <p>if the <math>i</math>-th argument is a scalar and had an illegal value,</p> <p>then <math>info = -i</math>.</p>

## Application Notes

If  $uplo = 'U'$ , the matrix  $Q$  is represented as a product of elementary reflectors

$$Q = H(n-1) * \dots * H(2) * H(1)$$

Each  $H(i)$  has the form

$$H(i) = I - tau * v * v'$$

where  $tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(i+1:n) = 0$  and  $v(i) = 1$ ;  $v(1:i-1)$  is stored on exit in  $A(ia:ia+i-2, ja+i)$ , and  $tau$  in  $tau[ja+i-2]$ .

If  $uplo = 'L'$ , the matrix  $Q$  is represented as a product of elementary reflectors

$Q = H(1) * H(2) * \dots * H(n-1)$ .

Each  $H(i)$  has the form

$$H(i) = I - \tau v v^T,$$

where  $\tau$  is a real/complex scalar, and  $v$  is a real/complex vector with  $v(1:i) = 0$  and  $v(i+1) = 1$ ;  $v(i+2:n)$  is stored on exit in  $A(ia+i+1:ia+n-1, ja+i-1)$ , and  $\tau$  in  $\tau[ja+i-2]$ .

The contents of sub (A) on exit are illustrated by the following examples with  $n = 5$ :

<p><b>if uplo='U':</b></p> $\begin{bmatrix} d & e & v_2 & v_3 & v_4 \\ & d & e & v_3 & v_4 \\ & & d & e & v_4 \\ & & & d & e \\ & & & & d \end{bmatrix}$	<p><b>if uplo='L':</b></p> $\begin{bmatrix} d & & & & \\ e & d & & & \\ v_1 & e & d & & \\ v_1 & v_2 & e & d & \\ v_1 & v_2 & v_3 & e & d \end{bmatrix}$
--	--

where  $d$  and  $e$  denotes diagonal and off-diagonal elements of  $T$ , and  $v_i$  denotes an element of the vector defining  $H(i)$ .

---

**NOTE**

The distributed matrix sub(A) must verify some alignment properties, namely the following expression should be true:

$$(mb\_a == nb\_a \ \&\& \ iroffa == icoffa) \text{ where } iroffa = \text{mod}(ia - 1, mb\_a) \text{ and } icoffa = \text{mod}(ja - 1, nb\_a).$$

---

**Description**

p?trord reorders the real Schur factorization of a real matrix  $A = Q * T * Q^T$ , so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix  $T$ , and the leading columns of  $Q$  form an orthonormal basis of the corresponding right invariant subspace.

$T$  must be in Schur form (as returned by `p?lahqr`), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks.

This function uses a delay and accumulate procedure for performing the off-diagonal updates.

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

### Input Parameters

<i>compq</i>	(global) = 'V': update the matrix $q$ of Schur vectors; = 'N': do not update $q$ .
<i>select</i>	(global) array of size $n$  <i>select</i> specifies the eigenvalues in the selected cluster. To select a real eigenvalue $w(j)$ , <i>select</i> [ $j-1$ ] must be set to 1. To select a complex conjugate pair of eigenvalues $w(j)$ and $w(j+1)$ , corresponding to a 2-by-2 diagonal block, either <i>select</i> [ $j-1$ ] or <i>select</i> [ $j$ ] or both must be set to 1; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded.
<i>para</i>	(global) Block parameters:
<i>para</i> [0]	maximum number of concurrent computational windows allowed in the algorithm; $0 < para[0] \leq \min(nprow, npcot)$ must hold;
<i>para</i> [1]	number of eigenvalues in each window; $0 < para[1] < para[2]$ must hold;
<i>para</i> [2]	window size; $para[1] < para[2] < mb\_t$ must hold;
<i>para</i> [3]	minimal percentage of FLOPS required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations; $0 \leq para[3] \leq 100$ must hold;
<i>para</i> [4]	width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form; $0 < para[4] \leq mb\_t$ must hold.
<i>para</i> [5]	the maximum number of eigenvalues moved together over a process border; in practice, this will be approximately half of the cross border window size; $0 < para[5] \leq para[1]$ must hold.
$n$	(global)

	The order of the globally distributed matrix $t$ . $n \geq 0$ .
$t$	(local) array of size $lld\_t * LOC_c(n)$ . The local pieces of the global distributed upper quasi-triangular matrix $T$ , in Schur form.
$it, jt$	(global) The row and column index in the global matrix $T$ indicating the first column of $T$ . $it = jt = 1$ must hold (see Application Notes).
$desc_t$	(global and local) array of size $dlen\_$ . The array descriptor for the global distributed matrix $T$ .
$q$	(local) array of size $lld\_q * LOC_c(n)$ . On entry, if $compq = 'V'$ , the local pieces of the global distributed matrix $Q$ of Schur vectors. If $compq = 'N'$ , $q$ is not referenced.
$iq, jq$	(global) The column index in the global matrix $Q$ indicating the first column of $Q$ . $iq = jq = 1$ must hold (see Application Notes).
$desc_q$	(global and local) array of size $dlen\_$ . The array descriptor for the global distributed matrix $Q$ .
$work$	(local workspace) array of size $lwork$
$lwork$	(local) The size of the array $work$ . If $lwork = -1$ , then a workspace query is assumed; the function only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by <a href="#">pxerbla</a> .
$iwork$	(local workspace) array of size $liwork$
$liwork$	(local) The size of the array $iwork$ . If $liwork = -1$ , then a workspace query is assumed; the function only calculates the optimal size of the $iwork$ array, returns this value as the first entry of the $iwork$ array, and no error message related to $liwork$ is issued by <a href="#">pxerbla</a> .

## OUTPUT Parameters

$select$	(global) array of size $n$ The (partial) reordering is displayed.
$t$	On exit, $t$ is overwritten by the local pieces of the reordered matrix $T$ , again in Schur form, with the selected eigenvalues in the globally leading diagonal blocks.

$q$	<p>On exit, if <math>compq = 'V'</math>, <math>q</math> has been postmultiplied by the global orthogonal transformation matrix which reorders <math>t</math>; the leading <math>m</math> columns of <math>q</math> form an orthonormal basis for the specified invariant subspace.</p> <p>If <math>compq = 'N'</math>, <math>q</math> is not referenced.</p>
$wr, wi$	<p>(global ) array of size <math>n</math></p> <p>The real and imaginary parts, respectively, of the reordered eigenvalues of the matrix <math>T</math>. $info$	<p>(global)</p> <p>= 0: successful exit</p> <p>&lt; 0: if <math>info = -i</math>, the <math>i</math>-th argument had an illegal value. If the <math>i</math>-th argument is an array and the <math>j</math>-th entry, indexed <math>j-1</math>, had an illegal value, then <math>info = -(i*1000+j)</math>, if the <math>i</math>-th argument is a scalar and had an illegal value, then <math>info = -i</math>.</p> <p>&gt; 0: here we have several possibilities</p> <ul style="list-style-type: none"> <li>Reordering of <math>t</math> failed because some eigenvalues are too close to separate (the problem is very ill-conditioned);</li> </ul> <p><math>t</math> may have been partially reordered, and <math>wr</math> and <math>wi</math> contain the eigenvalues in the same order as in <math>t</math>.</p> <p>On exit, <math>info = \{\text{the index of } t \text{ where the swap failed (indexing starts at 1)}\}</math>. <ul style="list-style-type: none"> <li>A 2-by-2 block to be reordered split into two 1-by-1 blocks and the second block failed to swap with an adjacent block.</li> </ul> <p>On exit, <math>info = \{\text{the index of } t \text{ where the swap failed}\}</math>. <ul style="list-style-type: none"> <li>If <math>info = n+1</math>, there is no valid BLACS context (see the BLACS documentation for details).</li> </ul> </p></p>

## Application Notes

The following alignment requirements must hold:

- $mb_t = nb_t = mb_q = nb_q$
- $rsrc_t = rsrc_q$
- $csrc_t = csrc_q$

All matrices must be blocked by a block factor larger than or equal to two (3). This is to simplify reordering across processor borders in the presence of 2-by-2 blocks.

This algorithm cannot work on submatrices of  $t$  and  $q$ , i.e.,  $it = jt = iq = jq = 1$  must hold. This is however no limitation since `p?lahqr` does not compute Schur forms of submatrices anyway.

Parallel execution recommendations:

- Use a square grid, if possible, for maximum performance. The block parameters in `para` should be kept well below the data distribution block size.
- In general, the parallel algorithm strives to perform as much work as possible without crossing the block borders on the main block diagonal.

Notice revision #20201201

## Input Parameters

`job` (global )

Specifies whether condition numbers are required for the cluster of eigenvalues ( $s$ ) or the invariant subspace ( $sep$ ):

= 'N': no condition numbers are required;

= 'E': only the condition number for the cluster of eigenvalues is computed ( $s$ );

= 'V': only the condition number for the invariant subspace is computed ( $sep$ );

= 'B': condition numbers for both the cluster and the invariant subspace are computed ( $s$  and  $sep$ ).

*compq*

(global )

= 'V': update the matrix  $q$  of Schur vectors;

= 'N': do not update  $q$ .

*select*

(global ) array of size  $n$

*select* specifies the eigenvalues in the selected cluster. To select a real eigenvalue  $w(j)$ ,  $select[j-1]$  must be set to a non-zero number. To select a complex conjugate pair of eigenvalues  $w(j)$  and  $w(j+1)$ , corresponding to a 2-by-2 diagonal block, either  $select[j-1]$  or  $select[j]$  or both must be set to a non-zero number; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded.

*para*

(global )

Block parameters:

*para*[0] maximum number of concurrent computational windows allowed in the algorithm;  $0 < para[0] \leq \min(NPROW, NPCOL)$  must hold;

*para*[1] number of eigenvalues in each window;  $0 < para[1] < para[2]$  must hold;

*para*[2] window size;  $para[1] < para[2] < mb\_t$  must hold;

*para*[3] minimal percentage of flops required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations;  $0 \leq para[3] \leq 100$  must hold;

*para*[4] width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form;  $0 < para[4] \leq mb\_t$  must hold.

*para*[5] the maximum number of eigenvalues moved together over a process border; in practice, this will be approximately half of the cross border window size  $0 < para[5] \leq para[1]$  must hold;

*n*

(global )

The order of the globally distributed matrix  $t$ .  $n \geq 0$ .

<i>t</i>	(local ) array of size $lld\_t * LOC_c(n)$ . The local pieces of the global distributed upper quasi-triangular matrix $T$ , in Schur form.
<i>it, jt</i>	(global ) The row and column index in the global matrix $T$ indicating the first column of $T$ . $it = jt = 1$ must hold (see Application Notes).
<i>desc_t</i>	(global and local) array of size $dlen\_$ . The array descriptor for the global distributed matrix $T$ .
<i>q</i>	(local ) array of size $lld\_q * LOC_c(n)$ . On entry, if $compq = 'V'$ , the local pieces of the global distributed matrix $Q$ of Schur vectors. If $compq = 'N'$ , $q$ is not referenced.
<i>iq, jq</i>	(global ) The column index in the global matrix $Q$ indicating the first column of $Q$ . $iq = jq = 1$ must hold (see Application Notes).
<i>desc_q</i>	(global and local) array of size $dlen\_$ . The array descriptor for the global distributed matrix $Q$ .
<i>work</i>	(local workspace) array of size $lwork$
<i>lwork</i>	(local ) The size of the array $work$ . If $lwork = -1$ , then a workspace query is assumed; the function only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by <a href="#">pxerbla</a> .
<i>iwork</i>	(local workspace) array of size $liwork$
<i>liwork</i>	(local ) The size of the array $iwork$ . If $liwork = -1$ , then a workspace query is assumed; the function only calculates the optimal size of the $iwork$ array, returns this value as the first entry of the $iwork$ array, and no error message related to $liwork$ is issued by <a href="#">pxerbla</a> .

## OUTPUT Parameters

<i>t</i>	$t$ is overwritten by the local pieces of the reordered matrix $T$ , again in Schur form, with the selected eigenvalues in the globally leading diagonal blocks.
<i>q</i>	On exit, if $compq = 'V'$ , $q$ has been postmultiplied by the global orthogonal transformation matrix which reorders $t$ ; the leading $m$ columns of $q$ form an orthonormal basis for the specified invariant subspace.

	If <i>compq</i> = 'N', <i>q</i> is not referenced.
<i>wr, wi</i>	(global ) array of size <i>n</i> The real and imaginary parts, respectively, of the reordered eigenvalues of the matrix <i>T</i> . The eigenvalues are in principle stored in the same order as on the diagonal of <i>T</i> , with <i>wr</i> [ <i>i</i> ] = <i>T</i> ( <i>i</i> +1, <i>i</i> +1) and, if <i>T</i> ( <i>i</i> : <i>i</i> +1, <i>i</i> : <i>i</i> +1) is a 2-by-2 diagonal block, <i>wi</i> [ <i>i</i> -1] > 0 and <i>wi</i> [ <i>i</i> ] = - <i>wi</i> [ <i>i</i> -1]. Note also that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.
<i>m</i>	(global ) The size of the specified invariant subspace. $0 \leq m \leq n$ .
<i>s</i>	(global ) If <i>job</i> = 'E' or 'B', <i>s</i> is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues. <i>s</i> cannot underestimate the true reciprocal condition number by more than a factor of sqrt( <i>n</i> ). If <i>m</i> = 0 or <i>n</i> , <i>s</i> = 1. If <i>job</i> = 'N' or 'V', <i>s</i> is not referenced.
<i>sep</i>	(global ) If <i>job</i> = 'V' or 'B', <i>sep</i> is the estimated reciprocal condition number of the specified invariant subspace. If <i>m</i> = 0 or <i>n</i> , <i>sep</i> = norm( <i>t</i> ). If <i>job</i> = 'N' or 'E', <i>sep</i> is not referenced.
<i>work</i> [0]	On exit, if <i>info</i> = 0, <i>work</i> [0] returns the optimal <i>lwork</i> .
<i>iwork</i> [0]	On exit, if <i>info</i> = 0, <i>iwork</i> [0] returns the optimal <i>liwork</i> .
<i>info</i>	(global ) = 0: successful exit < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value. If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> -1, had an illegal value, then <i>info</i> = -( <i>i</i> *1000+ <i>j</i> ), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . > 0: here we have several possibilities <ul style="list-style-type: none"> <li>• Reordering of <i>t</i> failed because some eigenvalues are too close to separate (the problem is very ill-conditioned); <i>t</i> may have been partially reordered, and <i>wr</i> and <i>wi</i> contain the eigenvalues in the same order as in <i>t</i>. On exit, <i>info</i> = {the index of <i>t</i> where the swap failed (indexing starts at 1)}.</li> <li>• A 2-by-2 block to be reordered split into two 1-by-1 blocks and the second block failed to swap with an adjacent block. On exit, <i>info</i> = {the index of <i>t</i> where the swap failed}.</li> <li>• If <i>info</i> = <i>n</i>+1, there is no valid BLACS context (see the BLACS documentation for details).</li> </ul>

## Application Notes

The following alignment requirements must hold:

- $mb\_t = nb\_t = mb\_q = nb\_q$
- $rsrc\_t = rsrc\_q$
- $csrc\_t = csrc\_q$

All matrices must be blocked by a block factor larger than or equal to two (3). This to simplify reordering across processor borders in the presence of 2-by-2 blocks.

This algorithm cannot work on submatrices of  $t$  and  $q$ , i.e.,  $it = jt = iq = jq = 1$  must hold. This is however no limitation since `p?lahqr` does not compute Schur forms of submatrices anyway.

For parallel execution, use a square grid, if possible, for maximum performance. The block parameters in `para` should be kept well below the data distribution block size.

In general, the parallel algorithm strives to perform as much work as possible without crossing the block borders on the main block diagonal.

## p?trti2

*Computes the inverse of a triangular matrix (local unblocked algorithm).*

---

## Syntax

```
void pstrti2 (char *uplo , char *diag , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , MKL_INT *info );
void pdtrti2 (char *uplo , char *diag , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , MKL_INT *info );
void pctrti2 (char *uplo , char *diag , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
void pztrti2 (char *uplo , char *diag , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

## Include Files

- `mkl_scalapack.h`

## Description

The `p?trti2` function computes the inverse of a real/complex upper or lower triangular block matrix sub ( $A$ ) =  $A(ia:ia+n-1, ja:ja+n-1)$ .

This matrix should be contained in one and only one process memory space (local operation).

## Input Parameters

<code>uplo</code>	(global)
	Specifies whether the matrix sub ( $A$ ) is upper or lower triangular.
	= 'U': sub ( $A$ ) is upper triangular
	= 'L': sub ( $A$ ) is lower triangular.
<code>diag</code>	(global)

Specifies whether or not the matrix  $A$  is unit triangular.

= 'N': sub ( $A$ ) is non-unit triangular

= 'U': sub ( $A$ ) is unit triangular.

$n$	(global) The number of rows and columns to be operated on, i.e., the order of the distributed submatrix $\text{sub}(A)$ . $n \geq 0$ .
$a$	(local) Pointer into the local memory to an array, size $\text{lld}_a * \text{LOCc}(j_a+n-1)$ . On entry, this array contains the local pieces of the triangular matrix $\text{sub}(A)$ . If $\text{uplo} = 'U'$ , the leading $n$ -by- $n$ upper triangular part of the matrix $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced. If $\text{uplo} = 'L'$ , the leading $n$ -by- $n$ lower triangular part of the matrix $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced. If $\text{diag} = 'U'$ , the diagonal elements of $\text{sub}(A)$ are not referenced either and are assumed to be 1.
$ia, ja$	(global) The row and column indices in the global matrix $A$ indicating the first row and the first column of the $\text{sub}(A)$ , respectively.
$\text{desca}$	(global and local) array of size $\text{dlen}_$ . The array descriptor for the distributed matrix $A$ .

## Output Parameters

$a$	On exit, the (triangular) inverse of the original matrix, in the same storage format.
$\text{info}$	= 0: successful exit < 0: if the $i$ -th argument is an array and the $j$ -th entry, indexed $j-1$ , had an illegal value, then $\text{info} = -(i*100+j)$ , if the $i$ -th argument is a scalar and had an illegal value, then $\text{info} = -i$ .

## ?lahqr2

Updates the eigenvalues and Schur decomposition.

## Syntax

```
void clahqr2 (const MKL_INT* wantt, const MKL_INT* wantz, const MKL_INT* n, const
MKL_INT* ilo, const MKL_INT* ihi, MKL_Complex8* h, const MKL_INT* ldh, MKL_Complex8* w,
const MKL_INT* iloz, const MKL_INT* ihiz, MKL_Complex8* z, const MKL_INT* ldz, MKL_INT*
info);
```

```
void zlahqr2 (const MKL_INT* wantt, const MKL_INT* wantz, const MKL_INT* n, const
MKL_INT* ilo, const MKL_INT* ihi, MKL_Complex16* h, const MKL_INT* ldh, MKL_Complex16*
w, const MKL_INT* iloz, const MKL_INT* ihiz, MKL_Complex16* z, const MKL_INT* ldz,
MKL_INT* info);
```

## Include Files

- `mkl_scalapack.h`

## Description

`?lahqr2` is an auxiliary routine called by `?hseqr` to update the eigenvalues and Schur decomposition already computed by `?hseqr`, by dealing with the Hessenberg submatrix in rows and columns `ilo` to `ihi`. This version of `?lahqr` (not the standard LAPACK version) uses a double-shift algorithm (like LAPACK's `?lahqr`). Unlike the standard LAPACK convention, this does not assume the subdiagonal is real, nor does it work to preserve this quality if given.

## Input Parameters

<code>wantt</code>	$\neq 0$ : the full Schur form $T$ is required; $= 0$ : only eigenvalues are required.
<code>wantz</code>	$\neq 0$ : the matrix of Schur vectors $Z$ is required; $= 0$ : Schur vectors are not required.
<code>n</code>	The order of the matrix $H$ . $n \geq 0$ .
<code>ilo, ihi</code>	It is assumed that the matrix $H$ is upper triangular in rows and columns $ihi + 1 : n$ , and that matrix element $H(ilo, ilo - 1) = 0$ (unless $ilo = 1$ ). <code>?lahqr</code> works primarily with the Hessenberg submatrix in rows and columns <code>ilo</code> to <code>ihi</code> , but applies transformations to all of $h$ if <code>wantt</code> is nonzero. $1 \leq ilo \leq \max(1, ihi)$ ; $ihiz \leq n$ .
<code>h</code>	Array, size $ldh * n$ . On entry, the upper Hessenberg matrix $H$ .
<code>ldh</code>	The leading dimension of the array $h$ . $ldh \geq \max(1, n)$ .
<code>iloz, ihiz</code>	Specify the rows of $Z$ to which transformations must be applied if <code>wantz</code> $\neq 0$ . $1 \leq iloz \leq ilo$ ; $ihiz \leq ihi \leq n$ .
<code>z</code>	Array, size $ldz * n$ . If <code>wantz</code> $\neq 0$ , on entry $z$ must contain the current matrix $Z$ of transformations. If <code>wantz</code> $= 0$ , $z$ is not referenced.

*ldz* The leading dimension of the array *z*.  $ldz \geq \max(1, n)$ .

## Output Parameters

<i>h</i>	On exit, if <i>wantt</i> ≠ 0, <i>h</i> is upper triangular in rows and columns <i>ilo:ihi</i> . If <i>wantt</i> = 0, the contents of <i>h</i> are unspecified on exit.
<i>w</i>	Array, size ( <i>n</i> ) The computed eigenvalues <i>ilo</i> to <i>ihi</i> are stored in the corresponding elements of <i>w</i> . If <i>wantt</i> ≠ 0, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in <i>h</i> , with $w[i] = H(i, i)$ .
<i>z</i>	If <i>wantz</i> ≠ 0, on exit <i>z</i> has been updated; transformations are applied only to the submatrix $Z(i_{loz}:i_{hiz}, i_{lo}:i_{hi})$ . If <i>wantz</i> = 0, <i>z</i> is not referenced.
<i>info</i>	= 0: successful exit > 0: if <i>info</i> = <i>i</i> , ?lahqr failed to compute all the eigenvalues <i>ilo</i> to <i>ihi</i> in a total of $30 \cdot (ihi - ilo + 1)$ iterations; elements $w[i:ihi - 1]$ contain those eigenvalues which have been successfully computed.

## ?lamsh

*Sends multiple shifts through a small (single node) matrix to maximize the number of bulges that can be sent through.*

### Syntax

```
void slamsh (float *s, const MKL_INT *lds, MKL_INT *nbulge, const MKL_INT *jblk, float *h, const MKL_INT *ldh, const MKL_INT *n, const float *ulp );
```

```
void dlamsh (double *s, const MKL_INT *lds, MKL_INT *nbulge, const MKL_INT *jblk, double *h, const MKL_INT *ldh, const MKL_INT *n, const double *ulp );
```

```
void clamsh (MKL_Complex8 *s , const MKL_INT *lds , MKL_INT *nbulge , const MKL_INT *jblk , MKL_Complex8 *h , const MKL_INT *ldh , const MKL_INT *n , const float *ulp );
```

```
void zlamsh (MKL_Complex16 *s , const MKL_INT *lds , MKL_INT *nbulge , const MKL_INT *jblk , MKL_Complex16 *h , const MKL_INT *ldh , const MKL_INT *n , const double *ulp );
```

### Include Files

- mkl\_scalapack.h

### Description

The ?lamsh function sends multiple shifts through a small (single node) matrix to see how small consecutive subdiagonal elements are modified by subsequent shifts in an effort to maximize the number of bulges that can be sent through. The function should only be called when there are multiple shifts/bulges (*nbulge* > 1) and the first shift is starting in the middle of an unreduced Hessenberg matrix because of two or more small consecutive subdiagonal elements.

## Input Parameters

<i>s</i>	(local) Array of size $lds*2*jblk$ . On entry, the matrix of shifts. Only the 2x2 diagonal of <i>s</i> is referenced. It is assumed that <i>s</i> has <i>jblk</i> double shifts (size 2).
<i>lds</i>	(local) On entry, the leading dimension of <i>S</i> ; unchanged on exit. $1 < nbulge \leq jblk \leq lds/2$ .
<i>nbulge</i>	(local) On entry, the number of bulges to send through <i>h</i> ( $>1$ ). <i>nbulge</i> should be less than the maximum determined ( <i>jblk</i> ). $1 < nbulge \leq jblk \leq lds/2$ .
<i>jblk</i>	(local) On entry, the number of double shifts determined for <i>S</i> ; unchanged on exit.
<i>h</i>	(local) Array of size $ldh*n$ . On entry, the local matrix to apply the shifts on. <i>h</i> should be aligned so that the starting row is 2.
<i>ldh</i>	(local) On entry, the leading dimension of <i>H</i> ; unchanged on exit.
<i>n</i>	(local) On entry, the size of <i>H</i> . If all the bulges are expected to go through, <i>n</i> should be at least $4nbulge+2$ . Otherwise, <i>nbulge</i> may be reduced by this function.
<i>ulp</i>	(local) On entry, machine precision. Unchanged on exit.

## Output Parameters

<i>s</i>	On exit, the data is rearranged in the best order for applying.
<i>nbulge</i>	On exit, the maximum number of bulges that can be sent through.
<i>h</i>	On exit, the data is destroyed.

## ?lapst

Sorts the numbers in increasing or decreasing order.

## Syntax

```
void slapst (const char* id, const MKL_INT* n, const float* d, MKL_INT* indx, MKL_INT* info);
```

```
void dlapst (const char* id, const MKL_INT* n, const double* d, MKL_INT* indx, MKL_INT* info);
```

## Include Files

- mkl\_scalapack.h

## Description

?lapst is a modified version of the LAPACK routine ?lasrt.

Define a permutation *indx* that sorts the numbers in *d* in increasing order (if *id* = 'I') or in decreasing order (if *id* = 'D').

Use Quick Sort, reverting to Insertion sort on arrays of size  $\leq 20$ . Dimension of STACK limits *n* to about  $2^{32}$ .

## Input Parameters

<i>id</i>	= 'I': sort <i>d</i> in increasing order; = 'D': sort <i>d</i> in decreasing order.
<i>n</i>	The length of the array <i>d</i> .
<i>d</i>	Array, size ( <i>n</i> ) The array to be sorted.

## Output Parameters

<i>indx</i>	Array, size ( <i>n</i> ). The permutation which sorts the array <i>d</i> .
<i>info</i>	= 0: successful exit < 0: if <i>info</i> = -i, the i-th argument had an illegal value

## ?laqr6

*Performs a single small-bulge multi-shift QR sweep collecting the transformations.*

## Syntax

```
void slaqr6(char* job, MKL_INT* wantt, MKL_INT* wantz, MKL_INT* kacc22, MKL_INT* n, MKL_INT* ktop, MKL_INT* kbot, MKL_INT* nshfts, float* sr, float* si, float* h, MKL_INT* ldh, MKL_INT* iloz, MKL_INT* ihiz, float* z, MKL_INT* ldz, float* v, MKL_INT* ldv, float* u, MKL_INT* ldu, MKL_INT* nv, float* wv, MKL_INT* ldwv, MKL_INT* nh, float* wh, MKL_INT* ldwh);
```

```
void dlaqr6(char* job, MKL_INT* wantt, MKL_INT* wantz, MKL_INT* kacc22, MKL_INT* n, MKL_INT* ktop, MKL_INT* kbot, MKL_INT* nshfts, double* sr, double* si, double* h, MKL_INT* ldh, MKL_INT* iloz, MKL_INT* ihiz, double* z, MKL_INT* ldz, double* v, MKL_INT* ldv, double* u, MKL_INT* ldu, MKL_INT* nv, double* wv, MKL_INT* ldwv, MKL_INT* nh, double* wh, MKL_INT* ldwh);
```

## Include Files

- `mkl_scalapack.h`

## Description

This auxiliary function performs a single small-bulge multi-shift QR sweep, moving the chain of bulges from top to bottom in the submatrix  $H(k_{top}:k_{bot}, k_{top}:k_{bot})$ , collecting the transformations in the matrix  $V$  or accumulating the transformations in the matrix  $Z$  (see below).

This is a modified version of `?laqr5` from LAPACK 3.1.

## Input Parameters

<i>job</i>	Set the kind of job to do in <code>?laqr6</code> , as follows: <i>job</i> = 'I': Introduce and chase bulges in submatrix <i>job</i> = 'C': Chase bulges from top to bottom of submatrix <i>job</i> = 'O': Chase bulges off submatrix
<i>wantt</i>	<i>wantt</i> is non-zero if the quasi-triangular Schur factor is being computed. <i>wantt</i> is set to zero otherwise.
<i>wantz</i>	<i>wantz</i> is non-zero if the orthogonal Schur factor is being computed. <i>wantz</i> is set to zero otherwise.
<i>kacc22</i>	Specifies the computation mode of far-from-diagonal orthogonal updates. = 0: <code>?laqr6</code> does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries. = 1: <code>?laqr6</code> accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries. = 2: <code>?laqr6</code> accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies.
<i>n</i>	<i>n</i> is the order of the Hessenberg matrix $H$ upon which this function operates.
<i>k<sub>top</sub>, k<sub>bot</sub></i>	These are the first and last rows and columns of an isolated diagonal block upon which the QR sweep is to be applied. It is assumed without a check that either $k_{top} = 1$ or $H(k_{top}, k_{top}-1) = 0$ and either $k_{bot} = n$ or $H(k_{bot} + 1, k_{bot}) = 0$ .
<i>nshfts</i>	<i>nshfts</i> gives the number of simultaneous shifts. <i>nshfts</i> must be positive and even.
<i>sr, si</i>	Array of size <i>nshfts</i> <i>sr</i> contains the real parts and <i>si</i> contains the imaginary parts of the <i>nshfts</i> shifts of origin that define the multi-shift QR sweep.
<i>h</i>	Array of size $ldh * n$ On input <i>h</i> contains a Hessenberg matrix $H$ .
<i>ldh</i>	<i>ldh</i> is the leading dimension of $H$ just as declared in the calling function. $ldh \geq \max(1, n)$ .

<i>iloz, ihiz</i>	Specify the rows of the matrix <i>Z</i> to which transformations must be applied if <i>wantzis</i> is non-zero. $1 \leq iloz \leq ihiz \leq n$
<i>z</i>	Array of size $ldz * ktop$ If <i>wantzis</i> is non-zero, then the QR sweep orthogonal similarity transformation is accumulated into the matrix $Z(iloz:ihiz, kbot:ktop)$ , stored in the array <i>z</i> , from the right. If <i>wantzequals</i> zero, then <i>z</i> is unreferenced.
<i>ldz</i>	<i>ldz</i> is the leading dimension of <i>z</i> just as declared in the calling function. $ldz \geq n$ .
<i>v</i>	(workspace) array of size $ldv * nshfts/2$
<i>ldv</i>	<i>ldv</i> is the leading dimension of <i>v</i> as declared in the calling function. $ldv \geq 3$ .
<i>u</i>	(workspace) array of size $ldu * (3*nshfts-3)$
<i>ldu</i>	<i>ldu</i> is the leading dimension of <i>u</i> just as declared in the calling function. $ldu \geq 3*nshfts-3$ .
<i>nh</i>	<i>nh</i> is the number of columns in array <i>wh</i> available for workspace. $nh \geq 1$ is required for usage of this workspace, otherwise the updates of the far-from-diagonal elements will be updated without level 3 BLAS.
<i>wh</i>	(workspace) array of size $ldwh * nh$
<i>ldwh</i>	Leading dimension of <i>wh</i> just as declared in the calling function. $ldwh \geq 3*nshfts-3$ .
<i>nv</i>	<i>nv</i> is the number of rows in <i>wv</i> available for workspace. $nv \geq 1$ is required for usage of this workspace, otherwise the updates of the far-from-diagonal elements will be updated without level 3 BLAS.
<i>wv</i>	(workspace) array of size $ldwv * 3*nshfts$
<i>ldwv</i>	scalar <i>ldwv</i> is the leading dimension of <i>wv</i> as declared in the in the calling function. $ldwv \geq nv$ .

## OUTPUT Parameters

<i>h</i>	A multi-shift QR sweep with shifts $sr[j]+i*si[j]$ is applied to the isolated diagonal block in matrix rows and columns <i>ktop</i> through <i>kbot</i> .
<i>z</i>	If <i>wantzis</i> is non-zero, then the QR sweep orthogonal/unitary similarity transformation is accumulated into the matrix $Z(iloz:ihiz, kbot:ktop)$ from the right. If <i>wantzequals</i> zero, then <i>z</i> is unreferenced.

## ?lar1va

*Computes scaled eigenvector corresponding to given eigenvalue.*

## Syntax

```
void slar1va(MKL_INT* n, MKL_INT* b1, MKL_INT* bn, float* lambda, float* d, float* l,
float* ld, float* lld, float* pivmin, float* gaptol, float* z, MKL_INT* wantnc, MKL_INT*
negcnt, float* ztz, float* mingma, MKL_INT* r, MKL_INT* isuppz, float* nrminv, float*
resid, float* rqcorr, float* work);
```

```
void dlar1va(MKL_INT* n, MKL_INT* b1, MKL_INT* bn, double* lambda, double* d, double* l,
double* ld, double* lld, double* pivmin, double* gaptol, double* z, MKL_INT* wantnc,
MKL_INT* negcnt, double* ztz, double* mingma, MKL_INT* r, MKL_INT* isuppz, double*
nrminv, double* resid, double* rqcorr, double* work);
```

## Include Files

- mkl\_scalapack.h

## Description

?slar1va computes the (scaled)  $r$ -th column of the inverse of the submatrix in rows  $b1$  through  $bn$  of the tridiagonal matrix  $LDL^T - \lambda I$ . When  $\lambda$  is close to an eigenvalue, the computed vector is an accurate eigenvector. Usually,  $r$  corresponds to the index where the eigenvector is largest in magnitude. The following steps accomplish this computation :

1. Stationary qd transform,  $LDL^T - \lambda I = L_+ D_+ L_+^T$ ,
2. Progressive qd transform,  $LDL^T - \lambda I = U_+ D_+ U_+^T$ ,
3. Computation of the diagonal elements of the inverse of  $LDL^T - \lambda I$  by combining the above transforms, and choosing  $r$  as the index where the diagonal of the inverse is (one of the) largest in magnitude.
4. Computation of the (scaled)  $r$ -th column of the inverse using the twisted factorization obtained by combining the top part of the stationary and the bottom part of the progressive transform.

## Input Parameters

$n$	The order of the matrix $LDL^T$ .
$b1$	First index of the submatrix of $LDL^T$ .
$bn$	Last index of the submatrix of $LDL^T$ .
$lambda$	The shift $\lambda$ . In order to compute an accurate eigenvector, $lambda$ should be a good approximation to an eigenvalue of $LDL^T$ .
$l$	Array of size $n-1$ The $(n-1)$ subdiagonal elements of the unit bidiagonal matrix $L$ , in elements 0 to $n-2$ .
$d$	Array of size $n$ The $n$ diagonal elements of the diagonal matrix $D$ .
$ld$	Array of size $n-1$ The $n-1$ elements $l[i]*d[i]$ , $i=0, \dots, n-2$ .

<i>lld</i>	Array of size $n-1$ The $n-1$ elements $l[j]*l[j]*d[i], i=0,\dots,n-2$ .
<i>pivmin</i>	The minimum pivot in the Sturm sequence.
<i>gaptol</i>	Tolerance that indicates when eigenvector entries are negligible with respect to their contribution to the residual.
<i>z</i>	Array of size $n$ On input, all entries of $z$ must be set to 0.
<i>wantnc</i>	Specifies whether <i>negcnt</i> has to be computed.
<i>r</i>	The twist index for the twisted factorization used to compute $z$ . On input, $0 \leq r \leq n$ . If $r$ is input as 0, $r$ is set to the index where $(LDL^T - \sigma I)^{-1}$ is largest in magnitude. If $1 \leq r \leq n$ , $r$ is unchanged. Ideally, $r$ designates the position of the maximum entry in the eigenvector.
<i>work</i>	(Workspace) array of size $4*n$

## OUTPUT Parameters

<i>z</i>	On output, $z$ contains the (scaled) $r$ -th column of the inverse. The scaling is such that $z[r-1]$ equals 1.
<i>negcnt</i>	If <i>wantnc</i> is non-zero then <i>negcnt</i> = the number of pivots $< pivmin$ in the matrix factorization $LDL^T$ , and <i>negcnt</i> = -1 otherwise.
<i>ztz</i>	The square of the 2-norm of $z$ .
<i>mingma</i>	The reciprocal of the largest (in magnitude) diagonal element of the inverse of $LDL^T - \sigma I$ .
<i>r</i>	On output, $r$ contains the twist index used to compute $z$ .
<i>isuppz</i>	array of size 2 The support of the vector in $z$ , i.e., the vector $z$ is non-zero only in elements <i>isuppz</i> [0] and <i>isuppz</i> [1].
<i>nrminv</i>	$nrminv = 1/\text{SQRT}( ztz )$
<i>resid</i>	The residual of the FP vector. $resid = \text{ABS}( mingma )/\text{SQRT}( ztz )$
<i>rqcorr</i>	The Rayleigh Quotient correction to <i>lambda</i> .

## Include Files

- mkl\_scalapack.h

## Description

?larref applies one or several Householder reflectors of size 3 to one or two matrices (if column is specified) on either their rows or columns.

## Input Parameters

<i>type</i>	(local)  If 'R': Apply reflectors to the rows of the matrix (apply from left) Otherwise: Apply reflectors to the columns of the matrix Unchanged on exit.
<i>a</i>	(local) Array, $lld\_a * LOCc(ja+n-1)$ On entry, the matrix to receive the reflections.
<i>lda</i>	(local)  On entry, the leading dimension of <i>a</i> . Unchanged on exit.
<i>wantz</i>	(local)

	<p>If <math>wantz \neq 0</math>, then apply any column reflections to <math>z</math> as well.</p> <p>If <math>wantz = 0</math>, then do no additional work on <math>z</math>.</p>
$z$	<p>(local)</p> <p>Array, <math>ldz * ncols</math>, where the value <math>ncols</math> depends on other arguments. If <math>wantz \neq 0</math> and <math>type \neq 'R'</math> then <math>ncols = icoll + 3 * (lihiz - liloz + 1)</math>. Otherwise, <math>ncols</math> is unused.</p> <p>On entry, the second matrix to receive column reflections.</p> <p>This is changed only if <math>wantz</math> is set.</p>
$ldz$	<p>(local)</p> <p>On entry, the leading dimension of <math>z</math>.</p> <p>Unchanged on exit.</p>
$block$	<p>(local)</p> <p>If nonzero, then apply several reflectors at once and read their data from the <math>vecs</math> array.</p> <p>If zero, apply the single reflector given by <math>v2, v3, t1, t2</math>, and <math>t3</math>.</p>
$irow1$	<p>(local)</p> <p>On entry, the local row element of <math>a</math>.</p>
$icoll$	<p>(local)</p> <p>On entry, the local column element of <math>a</math>.</p>
$istart$	<p>(local)</p> <p>Specifies the "number" of the first reflector. This is used as an index into <math>vecs</math> if <math>block</math> is set. <math>istart</math> is ignored if <math>block</math> is zero.</p>
$istop$	<p>(local)</p> <p>Specifies the "number" of the last reflector. This is used as an index into <math>vecs</math> if <math>block</math> is set. <math>istop</math> is ignored if <math>block</math> is zero.</p>
$itmp1$	<p>(local)</p> <p>Starting range into <math>a</math>. For rows, this is the local first column. For columns, this is the local first row.</p>
$itmp2$	<p>(local)</p> <p>Ending range into <math>a</math>. For rows, this is the local last column. For columns, this is the local last row.</p>
$liloz, lihiz$	<p>(local)</p> <p>These serve the same purpose as <math>itmp1, itmp2</math> but for <math>z</math> when <math>wantz</math> is set.</p>
$vecs$	<p>(local)</p>

Array of size 3\*N (matrix size)

This holds the size 3 reflectors one after another and this is only accessed when *block* is nonzero

*v2, v3, t1, t2, t3*

(local)

This holds information on a single size 3 Householder reflector and is read when *block* is zero, and overwritten when *block* is nonzero

## Output Parameters

<i>a</i>	The updated matrix on exit.
<i>z</i>	This is changed only if <i>wantz</i> is set.
<i>irow1</i>	Undefined on output.
<i>icol1</i>	Undefined on output.
<i>v2, v3, t1, t2, t3</i>	Overwritten when <i>block</i> is nonzero.

## ?larrb2

*Provides limited bisection to locate eigenvalues for more accuracy.*

## Syntax

```
void slarrb2(MKL_INT* n, float* d, float* lld, MKL_INT* ifirst, MKL_INT* ilast, float*
rtol1, float* rtol2, MKL_INT* offset, float* w, float* wgap, float* werr, float* work,
MKL_INT* iwork, float* pivmin, float* lgpvmn, float* lgspdm, MKL_INT* twist, MKL_INT*
info);
```

```

double* rtol1, double* rtol2, MKL_INT* offset, double* w, double* wgap, double* werr,
double* work, MKL_INT* iwork, double* pivmin, double* lgpvmn, double* lgspdm, MKL_INT*
twist, MKL_INT* info);
```

## Include Files

- `mkl_scalapack.h`

## Description

Given the relatively robust representation (RRR)  $LDL^T$ , ?larrb2 does "limited" bisection to refine the eigenvalues of  $LDL^T$  with indices in a given range to more accuracy. Initial guesses for these eigenvalues are input in *w*, the corresponding estimate of the error in these guesses and their gaps are input in *werr* and *wgap*, respectively. During bisection, intervals [*left*, *right*] are maintained by storing their mid-points and semi-widths in the arrays *w* and *werr* respectively. The range of indices is specified by the *ifirst*, *ilast*, and *offset* parameters, as explained in [Input Parameters](#).

**NOTE**

There are very few minor differences between `larrb` from LAPACK and this current function `?larrb2`. The most important reason for creating this nearly identical copy is profiling: in the ScaLAPACK MRRR algorithm, eigenvalue computation using `?larrb2` is used for refinement in the construction of the representation tree, as opposed to the initial computation of the eigenvalues for the root RRR which uses `?larrb`. When profiling, this allows an easy quantification of refinement work vs. computing eigenvalues of the root.

**Input Parameters**

<code>n</code>	The order of the matrix.
<code>d</code>	Array of size $n$ . The $n$ diagonal elements of the diagonal matrix $D$ .
<code>lld</code>	Array of size $n-1$ . The $(n-1)$ elements $l_{i+1} * l_{i+1} * d[i]$ , $i=0, \dots, n-2$ .
<code>ifirst</code>	The index of the first eigenvalue to be computed.
<code>ilast</code>	The index of the last eigenvalue to be computed.
<code>rtol1, rtol2</code>	Tolerance for the convergence of the bisection intervals. An interval $[left, right]$ has converged if $right - left < \max (rtol1 * gap, rtol2 * \max( left ,  right ))$ where $gap$ is the (estimated) distance to the nearest eigenvalue.
<code>offset</code>	Offset for the arrays $w$ , $wgap$ and $werr$ , i.e., the elements indexed $ifirst - offset - 1$ through $ilast - offset - 1$ of these arrays are to be used.
<code>w</code>	Array of size $n$ On input, $w[ifirst - offset - 1]$ through $w[ilast - offset - 1]$ are estimates of the eigenvalues of $LDL^T$ indexed $ifirst$ through $ilast$ .
<code>wgap</code>	Array of size $n-1$ . On input, the (estimated) gaps between consecutive eigenvalues of $LDL^T$ , i.e., $wgap[I - offset - 1]$ is the gap between eigenvalues $I$ and $I + 1$ . Note that if $ifirst = ilast$ then $wgap[ifirst - offset - 1]$ must be set to zero.
<code>werr</code>	Array of size $n$ . On input, $werr[ifirst - offset - 1]$ through $werr[ilast - offset - 1]$ are the errors in the estimates of the corresponding elements in $w$ .
<code>work</code>	(workspace) array of size $4*n$ . Workspace.
<code>iwork</code>	(workspace) array of size $2*n$ . Workspace.
<code>pivmin</code>	The minimum pivot in the Sturm sequence.

<code>lgpvmn</code>	Logarithm of <code>pivmin</code> , precomputed.
<code>lgspdm</code>	Logarithm of the spectral diameter, precomputed.
<code>twist</code>	The twist index for the twisted factorization that is used for the <code>negcount</code> . $twist = n$ : Compute <code>negcount</code> from $LDL^T - \lambda I = L_+ D_+ L_+^T$ $twist = 1$ : Compute <code>negcount</code> from $LDL^T - \lambda I = U \cdot D \cdot U^T$ $twist = r, 1 < r < n$ : Compute <code>negcount</code> from $LDL^T - \lambda I = N_r \Delta_r N_r^T$

## OUTPUT Parameters

<code>w</code>	On output, the eigenvalue estimates in <code>w</code> are refined.
<code>wgap</code>	On output, the eigenvalue gaps in <code>wgap</code> are refined.
<code>werr</code>	On output, the errors in <code>werr</code> are refined.
<code>info</code>	Error flag.

## Include Files

- `mkl_scalapack.h`

## Description

`?larrd2` computes the eigenvalues of a symmetric tridiagonal matrix  $T$  to limited initial accuracy. This is an auxiliary code to be called from [larre2a](#).

`?larrd2` has been created using the LAPACK code `larrd` which itself stems from [stebz](#). The motivation for creating `?larrd2` is efficiency: When computing eigenvalues in parallel and the input tridiagonal matrix splits into blocks, `?larrd2` can skip over blocks which contain none of the eigenvalues from DOL to DOU for which the processor responsible. In extreme cases (such as large matrices consisting of many blocks of small size like 2x2), the gain can be substantial.

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

**Input Parameters**

<i>range</i>	<p>= 'A': ("All") all eigenvalues will be found.</p> <p>= 'V': ("Value") all eigenvalues in the half-open interval (<math>v_l, v_u]</math> will be found.</p> <p>= 'I': ("Index") eigenvalues of the entire matrix with the indices in a given range will be found.</p>
<i>order</i>	<p>= 'B': ("By Block") the eigenvalues will be grouped by split-off block (see <i>iblock</i>, <i>isplit</i>) and ordered from smallest to largest within the block.</p> <p>= 'E': ("Entire matrix") the eigenvalues for the entire matrix will be ordered from smallest to largest.</p>
<i>n</i>	The order of the tridiagonal matrix $T$ . $n \geq 0$ .
<i>v_l, v_u</i>	<p>If <i>range</i>='V', the lower and upper bounds of the interval to be searched for eigenvalues. Eigenvalues less than or equal to <math>v_l</math>, or greater than <math>v_u</math>, will not be returned. <math>v_l &lt; v_u</math>.</p> <p>Not referenced if <i>range</i> = 'A' or 'I'.</p>
<i>il, iu</i>	<p>If <i>range</i>='I', the indices (in ascending order) of the smallest eigenvalue, to be returned in <math>w[il-1]</math>, and largest eigenvalue, to be returned in <math>w[iu-1]</math>.</p> <p><math>1 \leq il \leq iu \leq n</math>, if <math>n &gt; 0</math>; <math>il = 1</math> and <math>iu = 0</math> if <math>n = 0</math>.</p> <p>Not referenced if <i>range</i> = 'A' or 'V'.</p>
<i>gers</i>	<p>Array of size <math>2*n</math></p> <p>The <math>n</math> Gerschgorin intervals (the <math>i</math>-th Gerschgorin interval is (<math>gers[2*i-2]</math>, <math>gers[2*i-1]</math>)).</p>
<i>reltol</i>	The minimum relative width of an interval. When an interval is narrower than <i>reltol</i> times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. Note: this should always be at least $\text{radix} * \text{machine epsilon}$ .
<i>d</i>	<p>Array of size <math>n</math></p> <p>The <math>n</math> diagonal elements of the tridiagonal matrix <math>T</math>.</p>
<i>e</i>	<p>Array of size <math>n-1</math></p> <p>The <math>(n-1)</math> off-diagonal elements of the tridiagonal matrix <math>T</math>.</p>
<i>e2</i>	<p>Array of size <math>n-1</math></p> <p>The <math>(n-1)</math> squared off-diagonal elements of the tridiagonal matrix <math>T</math>.</p>
<i>pivmin</i>	The minimum pivot allowed in the sturm sequence for $T$ .

<i>nsplit</i>	The number of diagonal blocks in the matrix $T$ . $1 \leq nsplit \leq n$ .
<i>isplit</i>	Array of size $n$ The splitting points, at which $T$ breaks up into submatrices. The first submatrix consists of rows/columns 1 to <i>isplit</i> [0], the second of rows/columns <i>isplit</i> [0]+1 through <i>isplit</i> [1], etc., and the <i>nsplit</i> -th submatrix consists of rows/columns <i>isplit</i> [ <i>nsplit</i> -2]+1 through <i>isplit</i> [ <i>nsplit</i> -1]= $n$ . (Only the first <i>nsplit</i> elements will actually be used, but since the user cannot know a priori what value <i>nsplit</i> will have, $n$ words must be reserved for <i>isplit</i> .)
<i>work</i>	(workspace) Array of size $4*n$
<i>iwork</i>	(workspace) Array of size $3*n$
<i>dol, dou</i>	Specifying an index range <i>dol</i> : <i>dou</i> allows the user to work on only a selected part of the representation tree. Otherwise, the setting <i>dol</i> =1, <i>dou</i> = $n$ should be applied. Note that <i>dol</i> and <i>dou</i> refer to the order in which the eigenvalues are stored in $W$ .

## OUTPUT Parameters

<i>m</i>	The actual number of eigenvalues found. $0 \leq m \leq n$ . (See also the description of <i>info</i> =2,3.)
<i>w</i>	Array of size $n$ On exit, the first $m$ elements of <i>w</i> will contain the eigenvalue approximations. ? <i>larrrd2</i> computes an interval $I_j = (a_j, b_j]$ that includes eigenvalue $j$ . The eigenvalue approximation is given as the interval midpoint $w[j-1] = (a_j + b_j)/2$ . The corresponding error is bounded by $werr[j-1] = \text{abs}(a_j - b_j)/2$ .
<i>werr</i>	Array of size $n$ The error bound on the corresponding eigenvalue approximation in <i>w</i> .
<i>wl, wu</i>	The interval ( <i>wl</i> , <i>wu</i> ] contains all the wanted eigenvalues. If <i>range</i> ='V', then <i>wl</i> = <i>vl</i> and <i>wu</i> = <i>vu</i> . If <i>range</i> ='A', then <i>wl</i> and <i>wu</i> are the global Gerschgorin bounds on the spectrum. If <i>range</i> ='I', then <i>wl</i> and <i>wu</i> are computed by SLAEBZ from the index range specified.
<i>iblock</i>	Array of size $n$

At each row/column  $j$  where  $e[j-1]$  is zero or small, the matrix  $T$  is considered to split into a block diagonal matrix. On exit, if  $info = 0$ ,  $iblock[i]$  specifies to which block (from 0 to the number of blocks minus one) the eigenvalue  $w[i]$  belongs. (`?larre2` may use the remaining  $n-m$  elements as workspace.)

*indexw*Array of size  $n$ 

The indices of the eigenvalues within each block (submatrix); for example,  $indexw[i]=j$  and  $iblock[i]=k$  imply that the  $(i+1)$ -th eigenvalue  $w[i]$  is the  $j$ -th eigenvalue in block  $k$ .

*info*

= 0: successful exit

< 0: if  $info = -i$ , the  $i$ -th argument had an illegal value

&gt; 0: some or all of the eigenvalues failed to converge or were not computed:

- =1 or 3: Bisection failed to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances.
- =2 or 3:  $range='I'$  only: Not all of the eigenvalues  $il:iu$  were found.
- = 4:  $range='I'$ , and the Gershgorin interval initially used was too small. No eigenvalues were computed.

## Description

To find the desired eigenvalues of a given real symmetric tridiagonal matrix  $T$ , `?larre2` sets, via `?larra`, "small" off-diagonal elements to zero. For each block  $T_i$ , it finds

- a suitable shift at one end of the block's spectrum,

- the root RRR,  $T_i - \sigma_i I = L_i D_i L_i^T$ , and
- eigenvalues of each  $L_i D_i L_i^T$ .

The representations and eigenvalues found are then returned to `?stegr2` to compute the eigenvectors  $T$ .

`?larre2` is more suitable for parallel computation than the original LAPACK code for computing the root RRR and its eigenvalues. When computing eigenvalues in parallel and the input tridiagonal matrix splits into blocks, `?larre2` can skip over blocks which contain none of the eigenvalues from `dol` to `dou` for which the processor is responsible. In extreme cases (such as large matrices consisting of many blocks of small size, e.g. 2x2), the gain can be substantial.

### Input Parameters

<code>range</code>	<p>= 'A': ("All") all eigenvalues will be found.</p> <p>= 'V': ("Value") all eigenvalues in the half-open interval <math>(vl, vu]</math> will be found.</p> <p>= 'I': ("Index") eigenvalues of the entire matrix with the indices in a given range will be found.</p>
<code>n</code>	The order of the matrix. $n > 0$ .
<code>vl, vu</code>	<p>If <code>range='V'</code>, the lower and upper bounds for the eigenvalues.</p> <p>Eigenvalues less than or equal to <code>vl</code>, or greater than <code>vu</code>, will not be returned. <math>vl &lt; vu</math>.</p>
<code>il, iu</code>	<p>If <code>range='I'</code>, the indices (in ascending order) of the smallest eigenvalue, to be returned in <code>w[il-1]</code>, and largest eigenvalue, to be returned in <code>w[iu-1]</code>.</p> <p><math>1 \leq il \leq iu \leq n</math>.</p>
<code>d</code>	<p>Array of size <math>n</math></p> <p>The <math>n</math> diagonal elements of the tridiagonal matrix <math>T</math>.</p>
<code>e</code>	<p>Array of size <math>n</math></p> <p>The first <math>(n-1)</math> entries contain the subdiagonal elements of the tridiagonal matrix <math>T</math>; <code>e[n-1]</code> need not be set.</p>
<code>e2</code>	<p>Array of size <math>n</math></p> <p>The first <math>(n-1)</math> entries contain the squares of the subdiagonal elements of the tridiagonal matrix <math>T</math>; <code>e2[n-1]</code> need not be set.</p>
<code>rtol1, rtol2</code>	<p>Parameters for bisection.</p> <p>An interval <math>[left, right]</math> has converged if <math>right-left &lt; \max( rtol1*gap, rtol2*\max( left ,  right ) )</math></p>
<code>spltol</code>	The threshold for splitting.

*dol, dou* Specifying an index range *dol:dou* allows the user to work on only a selected part of the representation tree. Otherwise, the setting *dol=1, dou=n* should be applied.

Note that *dol* and *dou* refer to the order in which the eigenvalues are stored in *w*.

*work* Workspace array of size  $6*n$

*iwork* Workspace array of size  $5*n$

## OUTPUT Parameters

*vl, vu* If *range='I'* or *'A'*, *?larre2* contains bounds on the desired part of the spectrum.

*d* The  $n$  diagonal elements of the diagonal matrices  $D_i$ .

*e* *e* contains the subdiagonal elements of the unit bidiagonal matrices  $L_i$ . The entries  $e[isplit[i]]$ ,  $0 \leq i < nsplit$ , contain the base points  $\sigma_{i+1}$  on output.

*e2* The entries  $e2[isplit[i]]$ ,  $0 \leq i < nsplit$ , are set to zero.

*nsplit* The number of blocks *T* splits into.  $1 \leq nsplit \leq n$ .

*isplit* Array of size  $n$

The splitting points, at which *T* breaks up into blocks.

The first block consists of rows/columns 1 to  $isplit[0]$ , the second of rows/columns  $isplit[0]+1$  through  $isplit[1]$ , etc., and the *nsplit*-th block consists of rows/columns  $isplit[nsplit-2]+1$  through  $isplit[nsplit-1]=n$ .

*m* The total number of eigenvalues (of all  $L_i D_i L_i^T$ ) found.

*w* Array of size  $n$

The first  $m$  elements contain the eigenvalues. The eigenvalues of each of the blocks,  $L_i D_i L_i^T$ , are sorted in ascending order (*?larre2* may use the remaining  $n-m$  elements as workspace).

Note that immediately after exiting this function, only the eigenvalues in *w* with indices in range *dol-1:dou-1* might rely on this processor when the eigenvalue computation is done in parallel.

*werr* Array of size  $n$

The error bound on the corresponding eigenvalue in *w*.

Note that immediately after exiting this function, only the uncertainties in *werr* with indices in range *dol-1:dou-1* might rely on this processor when the eigenvalue computation is done in parallel.

*wgap* Array of size  $n$

The separation from the right neighbor eigenvalue in *w*.

The gap is only with respect to the eigenvalues of the same block as each block has its own representation tree.

Exception: at the right end of a block we store the left gap

Note that immediately after exiting this function, only the gaps in *wgap* with indices in range *dol-1:dou-1* might rely on this processor when the eigenvalue computation is done in parallel.

*iblock*

Array of size *n*

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in *w*; *iblock*[*i*]=1 if eigenvalue *w*[*i*] belongs to the first block from the top, *iblock*[*i*]=2 if *w*[*i*] belongs to the second block, and so on.

*indexw*

Array of size *n*

The indices of the eigenvalues within each block (submatrix); for example, *indexw*[*i*]= 10 and *iblock*[*i*]=2 imply that the (*i*+1)-th eigenvalue *w*[*i*] is the 10th eigenvalue in block 2.

*gers*

Array of size  $2*n$

The *n* Gerschgorin intervals (the *i*-th Gerschgorin interval is (*gers*[ $2*i-2$ ], *gers*[ $2*i-1$ ])).

*pivmin*

The minimum pivot in the sturm sequence for *T*.

*info*

= 0: successful exit

> 0: A problem occurred in ?larre2.

< 0: One of the called functions signaled an internal problem.

Needs inspection of the corresponding parameter *info* for further information.

=-1: Problem in ?larrd.

=-2: Not enough internal iterations to find the base representation.

=-3: Problem in ?larrb when computing the refined root representation for ?lasq2.

=-4: Problem in ?larrb when performing bisection on the desired part of the spectrum.

=-5: Problem in ?lasq2

=-6: Problem in ?lasq2

## Include Files

- mkl\_scalapack.h

## Description

To find the desired eigenvalues of a given real symmetric tridiagonal matrix  $T$ , `?larre2a` sets any "small" off-diagonal elements to zero, and for each unreduced block  $T_i$ , it finds

- a suitable shift at one end of the block's spectrum,
- the base representation,  $T_i - \sigma_i I = L_i D_i L_i^T$ , and
- eigenvalues of each  $L_i D_i L_i^T$ .

### NOTE

The algorithm obtains a crude picture of all the wanted eigenvalues (as selected by `range`). However, to reduce work and improve scalability, only the eigenvalues `dol` to `dou` are refined. Furthermore, if the matrix splits into blocks, RRRs for blocks that do not contain eigenvalues from `dol` to `dou` are skipped. The DQDS algorithm (function `?lasq2`) is not used, unlike in the sequential case. Instead, eigenvalues are computed in parallel to some figures using bisection.

Notice revision #20201201

## Input Parameters

<code>range</code>	<p>= 'A': ("All") all eigenvalues will be found.</p> <p>= 'V': ("Value") all eigenvalues in the half-open interval <math>(vl, vu]</math> will be found.</p> <p>= 'I': ("Index") eigenvalues of the entire matrix with the indices in a given range will be found.</p>
<code>n</code>	The order of the matrix. $n > 0$ .
<code>vl, vu</code>	<p>If <code>range='V'</code>, the lower and upper bounds for the eigenvalues. Eigenvalues less than or equal to <code>vl</code>, or greater than <code>vu</code>, will not be returned. <math>vl &lt; vu</math>.</p> <p>If <code>range='I'</code> or <code>'A'</code>, <code>?larre2a</code> computes bounds on the desired part of the spectrum.</p>

<i>il, iu</i>	If <i>range</i> ='I', the indices (in ascending order) of the smallest eigenvalue, to be returned in <i>w</i> [ <i>il</i> -1], and largest eigenvalue, to be returned in <i>w</i> [ <i>iu</i> -1]. $1 \leq il \leq iu \leq n$ .
<i>d</i>	Array of size <i>n</i> On entry, the <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i> .
<i>e</i>	Array of size <i>n</i> The first ( <i>n</i> -1) entries contain the subdiagonal elements of the tridiagonal matrix <i>T</i> ; <i>e</i> [ <i>n</i> -1] need not be set.
<i>e2</i>	Array of size <i>n</i> The first ( <i>n</i> -1) entries contain the squares of the subdiagonal elements of the tridiagonal matrix <i>T</i> ; <i>e2</i> [ <i>n</i> -1] need not be set.
<i>rtol1, rtol2</i>	Parameters for bisection. An interval [ <i>left</i> , <i>right</i> ] has converged if $right - left < \max( rtol1*gap, rtol2*\max( left , right ) )$
<i>spltol</i>	The threshold for splitting.
<i>dol, dou</i>	If the user wants to work on only a selected part of the representation tree, he can specify an index range <i>dol</i> : <i>dou</i> . Otherwise, the setting <i>dol</i> =1, <i>dou</i> = <i>n</i> should be applied. Note that <i>dol</i> and <i>dou</i> refer to the order in which the eigenvalues are stored in <i>w</i> .
<i>work</i>	Workspace array of size $6*n$
<i>iwork</i>	Workspace array of size $5*n$
<i>minrgp</i>	The minimum relative gap threshold to decide whether an eigenvalue or a cluster boundary is reached.

## OUTPUT Parameters

<i>vl, vu</i>	If <i>range</i> ='V', the lower and upper bounds for the eigenvalues. Eigenvalues less than or equal to <i>vl</i> , or greater than <i>vu</i> , are not returned. $vl < vu$ . If <i>range</i> ='I' or <i>range</i> ='A', ?larre2a computes bounds on the desired part of the spectrum.
<i>d</i>	The <i>n</i> diagonal elements of the diagonal matrices <i>D<sub>i</sub></i> .
<i>e</i>	<i>e</i> contains the subdiagonal elements of the unit bidiagonal matrices <i>L<sub>i</sub></i> . The entries <i>e</i> [ <i>isplit</i> [ <i>i</i> ]], $0 \leq i < nsplit$ , contain the base points $\sigma_{i+1}$ on output.
<i>e2</i>	The entries <i>e2</i> [ <i>isplit</i> [ <i>i</i> ]], $0 \leq i < nsplit$ have been set to zero.
<i>nsplit</i>	The number of blocks <i>T</i> splits into. $1 \leq nsplit \leq n$ .
<i>isplit</i>	Array of size <i>n</i> The splitting points, at which <i>T</i> breaks up into blocks.

The first block consists of rows/columns 1 to  $isplit[0]$ , the second of rows/columns  $isplit[0]+1$  through  $isplit[1]$ , etc., and the  $nsplit$ -th block consists of rows/columns  $isplit[nsplit-2]+1$  through  $isplit[nsplit-1]=n$ .

$m$	The total number of eigenvalues (of all $L_i D_i L_i^T$ ) found.
$needil, neediu$	The indices of the leftmost and rightmost eigenvalues of the root node RRR which are needed to accurately compute the relevant part of the representation tree.
$w$	<p>Array of size <math>n</math></p> <p>The first <math>m</math> elements contain the eigenvalues. ## Description

Given the initial representation  $LDL^T$  and its cluster of close eigenvalues (in a relative measure), defined by the indices of the first and last eigenvalues in the cluster, ?larrf2 finds a new relatively robust representation  $LDL^T - \sigma I = L_+D_+L_+^T$  such that at least one of the eigenvalues of  $L_+D_+L_+^T$  is relatively isolated.

This is an enhanced version of ?larrf that also tries shifts in the middle of the cluster, should there be a large gap, in order to break large clusters into at least two pieces.

## Input Parameters

- |          |   |
|----------|---|
| <i>n</i> | The order of the matrix (subblock, if the matrix was split).  |
| <i>d</i> | Array of size <i>n</i><br>The <i>n</i> diagonal elements of the diagonal matrix <i>D</i> .                    |
| <i>l</i> | Array of size <i>n</i> -1<br>The ( <i>n</i> -1) subdiagonal elements of the unit bidiagonal matrix <i>L</i> . |

<i>ld</i>	Array of size $n-1$ The $(n-1)$ elements $l[i]*d[i]$ .
<i>clstrt</i>	The index of the first eigenvalue in the cluster.
<i>clend</i>	The index of the last eigenvalue in the cluster.
<i>clmid1, clmid2</i>	The index of a middle eigenvalue pair with large gap.
<i>w</i>	Array of size $\geq (clend-clstrt+1)$ The eigenvalue approximations of $LDL^T$ in ascending order. $w[clstrt - 1]$ through $w[clend - 1]$ form the cluster of relatively close eigenvalues.
<i>wgap</i>	Array of size $\geq (clend-clstrt+1)$ The separation from the right neighbor eigenvalue in $w$ .
<i>werr</i>	Array of size $\geq (clend-clstrt+1)$ <i>werr</i> contains the semiwidth of the uncertainty interval of the corresponding eigenvalue approximation in $w$ .
<i>spdiam</i>	Estimate of the spectral diameter obtained from the Gerschgorin intervals
<i>clgapl, clgapr</i>	Absolute gap on each end of the cluster. Set by the calling function to protect against shifts too close to eigenvalues outside the cluster.
<i>pivmin</i>	The minimum pivot allowed in the Sturm sequence.
<i>work</i>	Workspace array of size $2*n$

## OUTPUT Parameters

<i>wgap</i>	Contains refined values of its input approximations. Very small gaps are unchanged.
<i>sigma</i>	The shift ( $\sigma$ ) used to form $L_+D_+L_+^T$ .
<i>dplus</i>	Array of size $n$ The $n$ diagonal elements of the diagonal matrix $D_+$ .
<i>lplus</i>	Array of size $n-1$ The first $(n-1)$ elements of <i>lplus</i> contain the subdiagonal elements of the unit bidiagonal matrix $L_+$ .

## Description

?larrv2 computes the eigenvectors of the tridiagonal matrix  $T = LDL^T$  given  $L$ ,  $D$  and approximations to the eigenvalues of  $LDL^T$ . The input eigenvalues should have been computed by [larre2a](#) or by previous calls to ?larrv2.

The major difference between the parallel and the sequential construction of the representation tree is that in the parallel case, not all eigenvalues of a given cluster might be computed locally. Other processors might "own" and refine part of an eigenvalue cluster. This is crucial for scalability. Thus there might be communication necessary before the current level of the representation tree can be parsed.

Please note:

- The calling sequence has two additional integer parameters, *dol* and *dou*, that should satisfy  $m \geq dou \geq dol \geq 1$ . These parameters are only relevant when both eigenvalues and eigenvectors are computed (*stegr2b* parameter *jobz* = 'V'). ?larrv2 only computes the eigenvectors corresponding to eigenvalues *dol* through *dou* in *w*. (That is, instead of computing the eigenvectors belonging to  $w[0]$  through  $w[m-1]$ , only the eigenvectors belonging to eigenvalues  $w[dol - 1]$  through  $w[dou - 1]$  are computed. In this case, only the eigenvalues *dol:dou* are guaranteed to be accurately refined to all figures by Rayleigh-Quotient iteration.
- The additional arguments *vstart*, *finish*, *ndepth*, *parity*, *zoffset* are included as a thread-safe implementation equivalent to save variables. These variables store details about the local representation tree which is computed layerwise. For scalability reasons, eigenvalues belonging to the locally relevant representation tree might be computed on other processors. These need to be communicated before the inspection of the RRRs can proceed on any given layer. Note that only when the variable *finish* is non-zero, the computation has ended. All eigenpairs between *dol* and *dou* have been computed. *m* is set to  $dou - dol + 1$ .
- ?larrv2 needs more workspace in *z* than the sequential *slarrv*. It is used to store the conformal embedding of the local representation tree.

Notice revision #20201201

## Input Parameters

<i>n</i>	The order of the matrix. $n \geq 0$ .
<i>vl, vu</i>	Lower and upper bounds of the interval that contains the desired eigenvalues. $vl < vu$ . Needed to compute gaps on the left or right end of the extremal eigenvalues in the desired range. <i>vu</i> is currently not used but kept as parameter in case needed.
<i>d</i>	Array of size <i>n</i> The <i>n</i> diagonal elements of the diagonal matrix <i>d</i> . On exit, <i>d</i> is overwritten.
<i>l</i>	Array of size <i>n</i> The ( <i>n</i> -1) subdiagonal elements of the unit bidiagonal matrix <i>L</i> are in elements 0 to <i>n</i> -2 of <i>l</i> (if the matrix is not split.) At the end of each block is stored the corresponding shift as given by <i>larre</i> . On exit, <i>l</i> is overwritten.
<i>pivmin</i>	The minimum pivot allowed in the sturm sequence.
<i>isplit</i>	Array of size <i>n</i> The splitting points, at which the matrix <i>T</i> breaks up into blocks. The first block consists of rows/columns 1 to <i>isplit</i> [ 0 ], the second of rows/columns <i>isplit</i> [ 0 ] + 1 through <i>isplit</i> [ 1 ], etc.
<i>m</i>	The total number of input eigenvalues. $0 \leq m \leq n$ .
<i>dol, dou</i>	If you want to compute only selected eigenvectors from all the eigenvalues supplied, you can specify an index range <i>dol:dou</i> . Or else the setting <i>dol</i> =1, <i>dou</i> = <i>m</i> should be applied. Note that <i>dol</i> and <i>dou</i> refer to the order in which the eigenvalues are stored in <i>w</i> . If you want to compute only selected eigenpairs, the columns <i>dol</i> -1 to <i>dou</i> +1 of the eigenvector space <i>Z</i> contain the computed eigenvectors. All other columns of <i>Z</i> are set to zero. If <i>dol</i> > 1, then $Z(:, dol-1-zoffset)$ is used. If <i>dou</i> < <i>m</i> , then $Z(:, dou+1-zoffset)$ is used.
<i>needil, neediu</i>	Describe which are the left and right outermost eigenvalues that still need to be included in the computation. These indices indicate whether eigenvalues from other processors are needed to correctly compute the conformally embedded representation tree. When $dol \leq needil \leq neediu \leq dou$ , all required eigenvalues are local to the processor and no communication is required to compute its part of the representation tree.
<i>minrgp</i>	The minimum relative gap threshold to decide whether an eigenvalue or a cluster boundary is reached.
<i>rtol1, rtol2</i>	Parameters for bisection. An interval [ <i>left</i> , <i>right</i> ] has converged if $right-left < \max( rtol1*gap, rtol2*\max( left , right ) )$
<i>w</i>	Array of size <i>n</i>

The first  $m$  elements of  $w$  contain the approximate eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array  $w$  from `?stegr2a` is expected here.) Furthermore, they are with respect to the shift of the corresponding root representation for their block.

<code>werr</code>	Array of size $n$  The first $m$ elements contain the semiwidth of the uncertainty interval of the corresponding eigenvalue in $w$ .
<code>wgap</code>	Array of size $n$  The separation from the right neighbor eigenvalue in $w$ .
<code>iblock</code>	Array of size $n$  The indices of the blocks (submatrices) associated with the corresponding eigenvalues in $w$ ; <code>iblock[i]=1</code> if eigenvalue $w[i]$ belongs to the first block from the top, <code>iblock[i]=2</code> if $w[i]$ belongs to the second block, and so on.
<code>indexw</code>	Array of size $n$  The indices of the eigenvalues within each block (submatrix). For example: <code>indexw[i]= 10</code> and <code>iblock[i]=2</code> imply that the $(i+1)$ -th eigenvalue $w[i]$ is the 10th eigenvalue in block 2.
<code>gers</code>	Array of size $2*n$  The $n$ Gerschgorin intervals (the $i$ -th Gerschgorin interval is $(gers[2*i-2], gers[2*i-1])$ ). The Gerschgorin intervals should be computed from the original unshifted matrix.  Not used but kept as parameter for possible future use.
<code>sdiam</code>	Array of size $n$  The spectral diameters for all unreduced blocks.
<code>ldz</code>	The leading dimension of the array $z$ . $ldz \geq 1$ , and if <code>stegr2b</code> parameter <code>jobz = 'V'</code> , $ldz \geq \max(1, n)$ .
<code>work</code>	(workspace) array of size $12*n$
<code>iwork</code>	(workspace) Array of size $7*n$
<code>vstart</code>	Non-zero on initialization, set to zero afterwards.
<code>finish</code>	A flag that indicates whether all eigenpairs have been computed.
<code>maxcls</code>	The largest cluster worked on by this processor in the representation tree.
<code>ndepth</code>	The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.
<code>parity</code>	An internal parameter needed for the storage of the clusters on the current level of the representation tree.
<code>zoffset</code>	Offset for storing the eigenpairs when $z$ is distributed in 1D-cyclic fashion.

## OUTPUT Parameters

*needil, neediu*

*w* Unshifted eigenvalues for which eigenvectors have already been computed.

*werr* Contains refined values of its input approximations.

*wgap* Contains refined values of its input approximations. Very small gaps are changed.

*z* Array of size  $ldz * \max(1,m)$   
 If *info* = 0, the first *m* columns of the matrix *Z*, stored in the array *z*, contain the orthonormal eigenvectors of the matrix *T* corresponding to the input eigenvalues, with the *i*-th column of *Z* holding the eigenvector associated with *w*[*i* - 1].  
 In the distributed version, only a subset of columns is accessed, see *dol*, *dou*, and *zoffset*.

*isuppz* Array of size  $2 * \max(1,m)$   
 The support of the eigenvectors in *z*, i.e., the indices indicating the non-zero elements in *z*. The *i*-th eigenvector is non-zero only in elements *isuppz*[  $2 * i - 2$  ] through *isuppz*[  $2 * i - 1$  ].

*vstart* Non-zero on initialization, set to zero afterwards.

*finish* A flag that indicates whether all eigenpairs have been computed.

*maxcls* The largest cluster worked on by this processor in the representation tree.

*ndepth* The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.

*parity* An internal parameter needed for the storage of the clusters on the current level of the representation tree.

*info*

- = 0: successful exit
- > 0: A problem occurred in ?larrv2.
- < 0: One of the called functions signaled an internal problem. Needs inspection of the corresponding parameter *info* for further information.
- =-1: Problem in ?larrb2 when refining a child's eigenvalues.
- =-2: Problem in ?larrf2 when computing the RRR of a child. When a child is inside a tight cluster, it can be difficult to find an RRR. A partial remedy from the user's point of view is to make the parameter *minrgp* smaller and recompile. However, as the orthogonality of the computed vectors is proportional to  $1/minrgp$ , be aware that decreasing *minrgp* might be reduce precision.
- =-3: Problem in ?larrb2 when refining a single eigenvalue after the Rayleigh correction was rejected.
- = 5: The Rayleigh Quotient Iteration failed to converge to full accuracy.

## ?lasorte

*Sorts eigenpairs by real and complex data types.*

## Syntax

```
void slasorte (float *s , MKL_INT *lds , MKL_INT *j , float *out , MKL_INT *info );
void dlasorte (double *s , MKL_INT *lds , MKL_INT *j , double *out , MKL_INT *info );
```

## Include Files

- mkl\_scalapack.h

## Description

The ?lasortefunction sorts eigenpairs so that real eigenpairs are together and complex eigenpairs are together. This helps to employ 2x2 shifts easily since every second subdiagonal is guaranteed to be zero. This function does no parallel work and makes no calls.

### Product and Performance Information

Notice revision #20201201

## Input Parameters

<i>s</i>	(local) Array of size <i>lds</i> . On entry, a matrix already in Schur form.
<i>lds</i>	(local) On entry, the leading dimension of the array <i>s</i> ; unchanged on exit.
<i>j</i>	(local) On entry, the order of the matrix <i>S</i> ; unchanged on exit.
<i>out</i>	(local) Array of size 2*j. The work buffer required by the function.
<i>info</i>	(local) Set, if the input matrix had an odd number of real eigenvalues and things could not be paired or if the input matrix <i>S</i> was not originally in Schur form. 0 indicates successful completion.

## Output Parameters

<i>s</i>	On exit, the diagonal blocks of <i>S</i> have been rewritten to pair the eigenvalues. The resulting matrix is no longer similar to the input.
<i>out</i>	Work buffer.

## See Also

## ?lasrt2

*Sorts numbers in increasing or decreasing order.*

## Syntax

```
void slasrt2 (char *id , MKL_INT *n , float *d , MKL_INT *key , MKL_INT *info );
void dlasrt2 (char *id , MKL_INT *n , double *d , MKL_INT *key , MKL_INT *info );
```

## Include Files

- mkl\_scalapack.h

## Description

The ?lasrt2 function is modified LAPACK function ?lasrt, which sorts the numbers in  $d$  in increasing order (if  $id = 'I'$ ) or in decreasing order (if  $id = 'D'$ ). It uses Quick Sort, reverting to Insertion Sort on arrays of size  $\leq 20$ . The size of `STACK` limits  $n$  to about  $2^{32}$ .

## Input Parameters

$id$	= 'I': sort $d$ in increasing order; = 'D': sort $d$ in decreasing order.
$n$	The length of the array $d$ .
$d$	Array of size $n$ . On entry, the array to be sorted.
$key$	Array of size $n$ . On entry, $key$ contains a key to each of the entries in $d$ . Typically, $key[i] = i+1$ for all $i = 0, \dots, n-1$ .

## Output Parameters

$d$	On exit, $d$ has been sorted into increasing order ( $d[0] \leq \dots \leq d[n - 1]$ ) or into decreasing order ( $d[0] \geq \dots \geq d[n - 1]$ ), depending on $id$ .
$info$	= 0: successful exit < 0: if $info = -i$ , the $i$ -th argument had an illegal value.
$key$	On exit, $key$ is permuted in exactly the same manner as $d$ was permuted from input to output. Therefore, if $key[i] = i+1$ for all $i = 0, \dots, n-1$ on input, $d[i]$ on output equals $d[key[i]-1]$ on input.

## See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

## ?stegr2

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

### Syntax

```
void sstegr2(char* jobz, char* range, MKL_INT* n, float* d, float* e, float* vl, float*
vu, MKL_INT* il, MKL_INT* iu, MKL_INT* m, float* w, float* z, MKL_INT* ldz, MKL_INT*
nzc, MKL_INT* isuppz, float* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork,
MKL_INT* dol, MKL_INT* dou, MKL_INT* zoffset, MKL_INT* info);
```

```
void dstegr2(char* jobz, char* range, MKL_INT* n, double* d, double* e, double* vl,
double* vu, MKL_INT* il, MKL_INT* iu, MKL_INT* m, double* w, double* z, MKL_INT* ldz,
MKL_INT* nzc, MKL_INT* isuppz, double* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT*
liwork, MKL_INT* dol, MKL_INT* dou, MKL_INT* zoffset, MKL_INT* info);
```

### Include Files

- mkl\_scalapack.h

### Description

?stegr2 computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix  $T$ . It is invoked in the ScaLAPACK MRRR driver p?syevr and the corresponding Hermitian version either when only eigenvalues are to be computed, or when only a single processor is used (the sequential-like case).

?stegr2 has been adapted from LAPACK's ?stegr. Please note the following crucial changes.

1. The calling sequence has two additional integer parameters,  $dol$  and  $dou$ , that should satisfy  $m \geq dou \geq dol \geq 1$ . ?stegr2 only computes the eigenpairs corresponding to eigenvalues  $dol$  through  $dou$  in  $w$ , indexed  $dol-1$  through  $dou-1$ . (That is, instead of computing the eigenpairs belonging to  $w[0]$  through  $w[m-1]$ , only the eigenvectors belonging to eigenvalues  $w[dol-1]$  through  $w[dou-1]$  are computed. In this case, only the eigenvalues  $dol$  through  $dou$  are guaranteed to be fully accurate.
2.  $m$  is not the number of eigenvalues specified by  $range$ , but is  $m = dou - dol + 1$ . This concerns the case where only eigenvalues are computed, but on more than one processor. Thus, in this case  $m$  refers to the number of eigenvalues computed on this processor.
3. The arrays  $w$  and  $z$  might not contain all the wanted eigenpairs locally, instead this information is distributed over other processors.

#### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

### Input Parameters

- $jobz$  = 'N': Compute eigenvalues only;  
= 'V': Compute eigenvalues and eigenvectors.
- $range$  = 'A': all eigenvalues will be found.  
= 'V': all eigenvalues in the half-open interval  $(vl, vu]$  will be found.  
= 'I': eigenvalues of the entire matrix with the indices in a given range will be found.

<i>n</i>	The order of the matrix. $n \geq 0$ .
<i>d</i>	Array of size <i>n</i> On entry, the <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i> . Overwritten on exit.
<i>e</i>	Array of size <i>n</i> On entry, the ( <i>n</i> -1) subdiagonal elements of the tridiagonal matrix <i>T</i> in elements 0 to <i>n</i> -2 of <i>e</i> . <i>e</i> [ <i>n</i> -1] need not be set on input, but is used internally as workspace. Overwritten on exit.
<i>vl</i>	
<i>vu</i>	If <i>range</i> ='V', the lower and upper bounds of the interval to be searched for eigenvalues. $vl < vu$ . Not referenced if <i>range</i> = 'A' or 'I'.
<i>il, iu</i>	If <i>range</i> ='I', the indices (in ascending order) of the smallest eigenvalue, to be returned in <i>w</i> [ <i>il</i> -1], and largest eigenvalue, to be returned in <i>w</i> [ <i>iu</i> -1]. $1 \leq il \leq iu \leq n$ , if $n > 0$ . Not referenced if <i>range</i> = 'A' or 'V'.
<i>ldz</i>	The leading dimension of the array <i>z</i> . $ldz \geq 1$ , and if <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$ .
<i>nzc</i>	The number of eigenvectors to be held in the array <i>z</i> , storing the matrix <i>Z</i> . If <i>range</i> = 'A', then $nzc \geq \max(1, n)$ . If <i>range</i> = 'V', then $nzc \geq$ the number of eigenvalues in ( <i>vl</i> , <i>vu</i> ]. If <i>range</i> = 'I', then $nzc \geq iu - il + 1$ . If <i>nzc</i> = -1, then a workspace query is assumed; the function calculates the number of columns of the matrix <i>Z</i> that are needed to hold the eigenvectors. This value is returned as the first entry of the <i>z</i> array, and no error message related to <i>nzc</i> is issued.
<i>lwork</i>	The size of the array <i>work</i> . $lwork \geq \max(1, 18 * n)$ if <i>jobz</i> = 'V', and $lwork \geq \max(1, 12 * n)$ if <i>jobz</i> = 'N'. If <i>lwork</i> = -1, then a workspace query is assumed; the function only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued.
<i>liwork</i>	The size of the array <i>iwork</i> . $liwork \geq \max(1, 10 * n)$ if the eigenvectors are desired, and $liwork \geq \max(1, 8 * n)$ if only the eigenvalues are to be computed. If <i>liwork</i> = -1, then a workspace query is assumed; the function only calculates the optimal size of the <i>iwork</i> array, returns this value as the first entry of the <i>iwork</i> array, and no error message related to <i>liwork</i> is issued.
<i>dol, dou</i>	From the eigenvalues <i>w</i> [0] through <i>w</i> [ <i>m</i> -1], only eigenvectors <i>Z</i> (:, <i>dol</i> ) to <i>Z</i> (:, <i>dou</i> ) are computed. If <i>dol</i> > 1, then <i>Z</i> (:, <i>dol</i> -1- <i>zoffset</i> ) is used and overwritten.

If  $dou < m$ , then  $Z(:,dou+1-zoffset)$  is used and overwritten.

*zoffset*

Offset for storing the eigenpairs when  $z$  is distributed in 1D-cyclic fashion

## OUTPUT Parameters

*m*

Globally summed over all processors,  $m$  equals the total number of eigenvalues found.  $0 \leq m \leq n$ . If  $range = 'A'$ ,  $m = n$ , and if  $range = 'I'$ ,  $m = iu - il + 1$ . The local output equals  $m = dou - dol + 1$ .

*w*

Array of size  $n$

The first  $m$  elements contain the selected eigenvalues in ascending order. Note that immediately after exiting this function, only the eigenvalues indexed  $dol-1$  through  $dou-1$  are reliable on this processor because the eigenvalue computation is done in parallel. Other processors will hold reliable information on other parts of the  $w$  array. This information is communicated in the ScaLAPACK driver.

*z*

Array of size  $ldz * \max(1,m)$ .

If  $jobz = 'V'$ , and if  $info = 0$ , then the first  $m$  columns of the matrix  $Z$  stored in  $z$  contain some of the orthonormal eigenvectors of the matrix  $T$  corresponding to the selected eigenvalues, with the  $i$ -th column of  $Z$  holding the eigenvector associated with  $w[i-1]$ .

If  $jobz = 'N'$ , then  $z$  is not referenced.

Note: the user must ensure that at least  $\max(1,m)$  columns of the matrix are supplied in the array  $z$ ; if  $range = 'V'$ , the exact value of  $m$  is not known in advance and can be computed with a workspace query by setting  $nzc = -1$ , see below.

*isuppz*

array of size  $2 * \max(1,m)$

The support of the eigenvectors in  $z$ , i.e., the indices indicating the nonzero elements in  $z$ . The  $i$ -th computed eigenvector is nonzero only in elements  $isuppz[2*i-2]$  through  $isuppz[2*i-1]$ . This is relevant in the case when the matrix is split.  $isuppz$  is only set if  $n > 2$ .

*work*

On exit, if  $info = 0$ ,  $work[0]$  returns the optimal (and minimal)  $lwork$ .

*iwork*

On exit, if  $info = 0$ ,  $iwork[0]$  returns the optimal  $liwork$ .

*info*

On exit,  $info$

= 0: successful exit

other: if  $info = -i$ , the  $i$ -th argument had an illegal value

if  $info = 10X$ , internal error in ?larre2,

if  $info = 20X$ , internal error in ?larrv.

Here, the digit  $X = \text{ABS}(iinfo) < 10$ , where  $iinfo$  is the nonzero error code returned by ?larre2 or ?larrv, respectively.

```

```
void dstegr2a(char* jobz, char* range, MKL_INT* n, double* d, double* e, double* vl,
double* vu, MKL_INT* il, MKL_INT* iu, MKL_INT* m, double* w, double* z, MKL_INT* ldz,
MKL_INT* nzc, double* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT*
dol, MKL_INT* dou, MKL_INT* needil, MKL_INT* neediu, MKL_INT* inderr, MKL_INT* nsplit,
double* pivmin, double* scale, double* wl, double* wu, MKL_INT* info);
```

### Include Files

- mkl\_scalapack.h

### Description

?stegr2a computes selected eigenvalues and initial representations needed for eigenvector computations in ?stegr2b. It is invoked in the ScaLAPACK MRRR driver p?syevr and the corresponding Hermitian version when both eigenvalues and eigenvectors are computed in parallel on multiple processors. For this case, ?stegr2a implements the first part of the MRRR algorithm, parallel eigenvalue computation and finding the root RRR. At the end of ?stegr2a, other processors might have a part of the spectrum that is needed to continue the computation locally. Once this eigenvalue information has been received by the processor, the computation can then proceed by calling the second part of the parallel MRRR algorithm, ?stegr2b.

Please note:

- The calling sequence has two additional integer parameters, (compared to LAPACK's *stegr*), these are *dol* and *dou* and should satisfy  $m \geq dou \geq dol \geq 1$ . These parameters are only relevant for the case *jobz* = 'V'.

Globally invoked over all processors, ?stegr2a computes all the eigenvalues specified by *range*.

?stegr2a locally only computes the eigenvalues corresponding to eigenvalues *dol* through *dou* in *w*, indexed *dol*-1 through *dou*-1. (That is, instead of computing the eigenvectors belonging to  $w[0]$  through  $w[m-1]$ , only the eigenvectors belonging to eigenvalues  $w[dol-1]$  through  $w[dou-1]$  are computed. In this case, only the eigenvalues *dol* through *dou* are guaranteed to be fully accurate.

- *m* is not the number of eigenvalues specified by *range*, but it is  $m = dou - dol + 1$ . Instead, *m* refers to the number of eigenvalues computed on this processor.
- While no eigenvectors are computed in ?stegr2a itself (this is done later in ?stegr2b), the interface

If *jobz* = 'V' then, depending on *range* and *dol*, *dou*, ?stegr2a might need more workspace in *z* than the original ?stegr. In particular, the arrays *w* and *z* might not contain all the wanted eigenpairs locally, instead this information is distributed over other processors.

Notice revision #20201201

## Input Parameters

<i>jobz</i>	<p>= 'N': Compute eigenvalues only;</p> <p>= 'V': Compute eigenvalues and eigenvectors.</p>
<i>range</i>	<p>= 'A': all eigenvalues will be found.</p> <p>= 'V': all eigenvalues in the half-open interval <math>(v_l, v_u]</math> will be found.</p> <p>= 'I': eigenvalues of the entire matrix with the indices in a given range will be found.</p>
<i>n</i>	The order of the matrix. $n \geq 0$ .
<i>d</i>	<p>Array of size <math>n</math></p> <p>The <math>n</math> diagonal elements of the tridiagonal matrix <math>T</math>. Overwritten on exit.</p>
<i>e</i>	<p>Array of size <math>n</math></p> <p>On entry, the <math>(n-1)</math> subdiagonal elements of the tridiagonal matrix <math>T</math> in elements 0 to <math>n-2</math> of <math>e</math>. <math>e[n-1]</math> need not be set on input, but is used internally as workspace. Overwritten on exit.</p>
<i>v_l, v_u</i>	<p>If <math>range='V'</math>, the lower and upper bounds of the interval to be searched for eigenvalues. <math>v_l &lt; v_u</math>.</p> <p>Not referenced if <math>range = 'A'</math> or <math>'I'</math>.</p>
